You can monitor RDS Proxy by using Amazon CloudWatch. CloudWatch collects and processes raw data
from the proxies into readable, near-real-time metrics. To find these metrics in the CloudWatch console,
choose Metrics, then choose RDS, and choose Per-Proxy Metrics. For more information, see Using
Amazon CloudWatch metrics in the Amazon CloudWatch User Guide.

Note
RDS publishes these metrics for each underlying Amazon EC2 instance associated with a proxy.
A single proxy might be served by more than one EC2 instance. Use CloudWatch statistics to
aggregate the values for a proxy across all the associated instances.
Some of these metrics might not be visible until after the first successful connection by a proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name
can be the name you specified for a user-defined endpoint, or the special name default for read/write
requests using the default endpoint of a proxy.

All RDS Proxy metrics are in the group proxy.

Each proxy endpoint has its own CloudWatch metrics. You can monitor the usage of each proxy endpoint
independently. For more information about proxy endpoints, see Working with Amazon RDS Proxy
endpoints (p. 993).

You can aggregate the values for each metric using one of the following dimension sets. For example,
by using the ProxyName dimension set, you can analyze all the traffic for a particular proxy. By using
the other dimension sets, you can split the metrics in different ways. You can split the metrics based on
the different endpoints or target databases of each proxy, or the read/write and read-only traffic to each
database.

- Dimension set 1: ProxyName
- Dimension set 2: ProxyName, EndpointName
- Dimension set 3: ProxyName, TargetGroup, Target
- Dimension set 4: ProxyName, TargetGroup, TargetRole

</tbody>
</table>

You can find logs of RDS Proxy activity under CloudWatch in the AWS Management Console. Each proxy has an entry in the Log groups page.

**Important**
These logs are intended for human consumption for troubleshooting purposes and not for programmatic access. The format and content of the logs is subject to change. In particular, older logs don't contain any prefixes indicating the endpoint for each request. In newer logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint, or the special name default for requests using the default endpoint of a proxy.
Working with RDS Proxy events

An event indicates a change in an environment. This can be an AWS environment or a service or application from a software as a service (SaaS) partner. Or it can be one of your own custom applications or services. For example, Amazon RDS generates an event when you create or modify an RDS Proxy. Amazon RDS delivers events to CloudWatch Events and Amazon EventBridge in near-real time. Following, you can find a list of RDS Proxy events that you can subscribe to and an example of an RDS Proxy event.

For more information about working with events, see the following:

- For instructions on how to view events by using the AWS Management Console, AWS CLI, or RDS API, see Viewing Amazon RDS events (p. 682).
- To learn how to configure Amazon RDS to send events to EventBridge, see Creating a rule that triggers on an Amazon RDS event (p. 699).

RDS Proxy events

The following table shows the event category and a list of events when an RDS Proxy is the source type.

<table>
<thead>
<tr>
<th>Category</th>
<th>RDS event ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration</td>
<td>RDS-EVENT-0204</td>
<td>RDS modified the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>change</td>
<td>RDS-EVENT-0207</td>
<td>RDS modified the endpoint of the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>configuration</td>
<td>RDS-EVENT-0213</td>
<td>RDS detected the addition of the DB instance and automatically added it to</td>
</tr>
<tr>
<td>change</td>

```

**RDS Proxy command-line examples**

To see how combinations of connection commands and SQL statements interact with RDS Proxy, look at the following examples.

**Examples**
- Preserving Connections to a MySQL Database Across a Failover
- Adjusting the max_connections Setting for an Aurora DB Cluster

**Example: Preserving connections to a MySQL database across a failover**

This MySQL example demonstrates how open connections continue working during a failover. An example is when you reboot a database or it becomes unavailable due to a problem. This example uses a proxy named the-proxy and an Aurora DB cluster with DB instances instance-8898 and instance-9814. When you run the failover-db-cluster command from the Linux command line, the writer instance that the proxy is connected to changes to a different DB instance. You can see that the DB instance associated with the proxy changes while the connection remains open.

```bash
$ mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p
Enter password:
...
mysql> select @aurora_server_id;
+---------------------+
| @aurora_server_id   |
+---------------------+
| instance-9814       |
+---------------------+
```
Example Adjusting the max_connections setting for an Aurora DB cluster

This example demonstrates how you can adjust the max_connections setting for an Aurora MySQL DB cluster. To do so, you create your own DB cluster parameter group based on the default parameter settings for clusters that are compatible with MySQL 5.6 or 5.7. You specify a value for the max_connections setting, overriding the formula that sets the default value. You associate the DB cluster parameter group with your DB cluster.

```
export REGION=us-east-1
export CLUSTER_PARAM_GROUP=rds-proxy-mysql-56-max-connections-demo
export CLUSTER_NAME=rds-proxy-mysql-56

aws rds create-db-parameter-group --region $REGION \
    --db-parameter-group-family aurora5.6 \
    --db-parameter-group-name $CLUSTER_PARAM_GROUP \
    --description "Aurora MySQL 5.6 cluster parameter group for RDS Proxy demo."

aws rds modify-db-cluster --region $REGION \
    --db-cluster-identifier $CLUSTER_NAME \
    --max_connections 1007
```
Troubleshooting for RDS Proxy

Following, you can find troubleshooting ideas for some common RDS Proxy issues and information on CloudWatch logs for RDS Proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint. Or it can be the special name default for read/write requests using the default endpoint of a proxy. For more information about proxy endpoints, see Working with Amazon RDS Proxy endpoints (p. 993).

Topics

• Verifying connectivity for a proxy (p. 1008)
• Common issues and solutions (p. 1009)

Verifying connectivity for a proxy

You can use the following commands to verify that all components of the connection mechanism can communicate with the other components.

Examine the proxy itself using the `describe-db-proxies` command. Also examine the associated target group using the `describe-db-proxy-target-groups` command. Check that the details of the targets match the RDS DB instance or Aurora DB cluster that you intend to associate with the proxy. Use commands such as the following.

```
aws rds describe-db-proxies --db-proxy-name $DB_PROXY_NAME
aws rds describe-db-proxy-target-groups --db-proxy-name $DB_PROXY_NAME
```

To confirm that the proxy can connect to the underlying database, examine the targets specified in the target groups using the `describe-db-proxy-targets` command. Use a command such as the following.

```
aws rds describe-db-proxies --db-proxy-name $DB_PROXY_NAME
```
aws rds describe-db-proxy-targets --db-proxy-name $DB_PROXY_NAME

The output of the `describe-db-proxy-targets` command includes a `TargetHealth` field. You can examine the fields `State`, `Reason`, and `Description` inside `TargetHealth` to check if the proxy can communicate with the underlying DB instance.

- A `State` value of `AVAILABLE` indicates that the proxy can connect to the DB instance.
- A `State` value of `UNAVAILABLE` indicates a temporary or permanent connection problem. In this case, examine the `Reason` and `Description` fields. For example, if `Reason` has a value of `PENDING_PROXY_CAPACITY`, try connecting again after the proxy finishes its scaling operation. If `Reason` has a value of `UNREACHABLE`, `CONNECTION_FAILED`, or `AUTH_FAILURE`, use the explanation from the `Description` field to help you diagnose the issue.
- The `State` field might have a value of `REGISTERING` for a brief time before changing to `AVAILABLE` or `UNAVAILABLE`.

If the following Netcat command (nc) is successful, you can access the proxy endpoint from the EC2 instance or other system where you're logged in. This command reports failure if you're not in the same VPC as the proxy and the associated database. You might be able to log directly in to the database without being in the same VPC. However, you can't log into the proxy unless you're in the same VPC.

```bash
nc -zx MySQL_proxy_endpoint 3306
nc -zx PostgreSQL_proxy_endpoint 5432
```

You can use the following commands to make sure that your EC2 instance has the required properties. In particular, the VPC for the EC2 instance must be the same as the VPC for the RDS DB instance or Aurora DB cluster that the proxy connects to.

```bash
aws ec2 describe-instances --instance-ids your_ec2_instance_id
```

Examine the Secrets Manager secrets used for the proxy.

```bash
aws secretsmanager list-secrets
aws secretsmanager get-secret-value --secret-id your_secret_id
```

Make sure that the `SecretString` field displayed by `get-secret-value` is encoded as a JSON string that includes `username` and `password` fields. The following example shows the format of the `SecretString` field.

```json
{
  "ARN": "some_arn",
  "Name": "some_name",
  "VersionId": "some_version_id",
  "SecretString": '{"username":"some_username","password":"some_password"}',
  "VersionStages": [ "some_stage" ],
  "CreatedDate": some_timestamp
}
```

**Common issues and solutions**

For possible causes and solutions to some common problems that you might encounter using RDS Proxy, see the following.

You might encounter the following issues while creating a new proxy or connecting to a proxy.
### Error 403: The security token included in the request is invalid

Select an existing IAM role instead of choosing to create a new one.

---

You might encounter the following issues while connecting to a MySQL proxy.

### Error 1040 (HY000): Connections rate limit exceeded

The rate of connection requests from the client to the proxy has exceeded the limit.

### Error 1040 (HY000): IAM authentication rate limit exceeded

The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.

### Error 1040 (HY000): Number simultaneous connections exceeded

The number of simultaneous connection requests from the client to the proxy exceeded the limit.

### Error 1045 (28000): Access denied for user 'DB_USER'@'%' (using password: YES)

Some possible reasons include the following:

- The Secrets Manager secret used by the proxy doesn't match the user name and password of an existing database user. Either update the credentials in the Secrets Manager secret, or make sure the database user exists and has the same password as in the secret.

### Error 1105 (HY000): Unknown error

An unknown error occurred.

### Error 1231 (42000): Variable 'character_set_client' can't be set to the value of `value`

The value set for the character_set_client parameter is not valid. For example, the value `ucs2` is not valid because it can crash the MySQL server.

### Error 3159 (HY000): This RDS Proxy requires TLS connections.

You enabled the setting **Require Transport Layer Security** in the proxy but your connection included the parameter `ssl-mode=DISABLED` in the MySQL client. Do either of the following:

- Disable the setting **Require Transport Layer Security** for the proxy.
- Connect to the database using the minimum setting of `ssl-mode=REQUIRED` in the MySQL client.
<table>
<thead>
<tr>
<th>Error</th>
<th>Causes or workarounds</th>
</tr>
</thead>
</table>
| ERROR 2026 (HY000): SSL connection error: Internal Server Error | The TLS handshake to the proxy failed. Some possible reasons include the following:  
  • SSL is required but the server doesn't support it.  
  • An internal server error occurred.  
  • A bad handshake occurred.                                                                                                                                                                                                                                                                 |
| ERROR 9501 (HY000): Timed-out waiting to acquire database connection | The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following:  
  • The proxy is unable to establish a database connection because the maximum connections have been reached  
  • The proxy is unable to establish a database connection because the database is unavailable.                                                                                                                                                                                                 |

You might encounter the following issues while connecting to a PostgreSQL proxy.

<table>
<thead>
<tr>
<th>Error</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>IAM authentication is allowed only with SSL connections.</td>
<td>The user tried to connect to the database using IAM authentication with the setting sslmode=disable in the PostgreSQL client.</td>
<td>The user needs to connect to the database using the minimum setting of sslmode=require in the PostgreSQL client. For more information, see the PostgreSQL SSL support documentation.</td>
</tr>
</tbody>
</table>
| This RDS Proxy requires TLS connections. | The user enabled the option Require Transport Layer Security but tried to connect with sslmode=disable in the PostgreSQL client. | To fix this error, do one of the following:  
  • Disable the proxy's Require Transport Layer Security option.  
  • Connect to the database using the minimum setting of sslmode=allow in the PostgreSQL client. |
| IAM authentication failed for user user_name. Check the IAM token for this user and try again. | This error might be due to the following reasons:  
  • The client supplied the incorrect IAM user name.  
  • The client supplied an incorrect IAM authorization token for the user.  
  • The client is using an IAM policy that does not have the necessary permissions.  
  • The client supplied an expired IAM authorization token for the user. | To fix this error, do the following:  
  1. Confirm that the provided IAM user exists.  
  2. Confirm that the IAM authorization token belongs to the provided IAM user.  
  3. Confirm that the IAM policy has adequate permissions for RDS.  
  4. Check the validity of the IAM authorization token used. |

<tr>
<td>The IAM authentication failed for the role <em>role_name</em>. Check the IAM token for this role and try again.</td>
<td>There is a problem with the IAM token used for IAM authentication.</td>
<td>Generate a new authentication token and use it in a new connection.</td>
</tr>
<tr>
<td>IAM is allowed only with SSL connections.</td>
<td>A client tried to connect using IAM authentication, but SSL wasn't enabled.</td>
<td>Enable SSL in the PostgreSQL client.</td>
</tr>
<tr>
<td>Unknown error.</td>
<td>An unknown error occurred.</td>
<td>Reach out to AWS Support to investigate the issue.</td>
</tr>
<tr>
<td>Timed-out waiting to acquire database connection.</td>
<td>The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following:</td>
<td>Possible solutions are the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Check the target of the RDS DB instance or Aurora DB cluster status to see if it's unavailable.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Check if there are long-running transactions and/or queries being executed. They can use database connections from the connection pool for a long time.</td>
</tr>
<tr>
<td>Request returned an error: <em>database_error</em>.</td>
<td>The database connection established from the proxy returned an error.</td>
<td>The solution depends on the specific database error. One example is: Request returned an error: database &quot;your-database-name&quot; does not exist. This means that the specified database name doesn't exist on the database server. Or it means that the user name used as a database name (if a database name isn't specified) doesn't exist on the server.</td>
</tr>
</tbody>
</table>

### Using RDS Proxy with AWS CloudFormation

You can use RDS Proxy with AWS CloudFormation. Doing so helps you to create groups of related resources. Such a group can include a proxy that can connect to a newly created Amazon RDS DB instance or Aurora DB cluster. RDS Proxy support in AWS CloudFormation involves two new registry types: DBProxy and DBProxyTargetGroup.
The following listing shows a sample AWS CloudFormation template for RDS Proxy.

```yaml
Resources:
  DBProxy:
    Type: AWS::RDS::DBProxy
    Properties:
      DBProxyName: CanaryProxy
      EngineFamily: MYSQL
      RoleArn:
        Fn::ImportValue: SecretReaderRoleArn
      Auth:
        - {AuthScheme: SECRETS, SecretArn: !ImportValue ProxySecret, IAMAuth: DISABLED}
      VpcSubnetIds:
        Fn::Split: [",", "Fn::ImportValue": SubnetIds]

  ProxyTargetGroup:
    Type: AWS::RDS::DBProxyTargetGroup
    Properties:
      DBProxyName: CanaryProxy
      TargetGroupName: default
      DBInstanceIdentifiers:
        - Fn::ImportValue: DBInstanceName
    DependsOn: DBProxy
```

For more information about the Amazon RDS and Aurora resources that you can create using AWS CloudFormation, see [RDS resource type reference](#).
Amazon RDS supports DB instances that run the following versions of MariaDB:

- MariaDB 10.6
- MariaDB 10.5
- MariaDB 10.4
- MariaDB 10.3
- MariaDB 10.2 (end of life scheduled for October 15, 2022)

For more information about minor version support, see MariaDB on Amazon RDS versions (p. 1023).

To create a MariaDB DB instance, use the Amazon RDS management tools or interfaces. You can then use the Amazon RDS tools to perform management actions for the DB instance. These include actions such as the following:

- Reconfiguring or resizing the DB instance
- Authorizing connections to the DB instance
- Creating and restoring from backups or snapshots
- Creating Multi-AZ secondaries
- Creating read replicas
- Monitoring the performance of your DB instance

To store and access the data in your DB instance, use standard MariaDB utilities and applications.

MariaDB is available in all of the AWS Regions. For more information about AWS Regions, see Regions, Availability Zones, and Local Zones (p. 79).

You can use Amazon RDS for MariaDB databases to build HIPAA-compliant applications. You can store healthcare-related information, including protected health information (PHI), under a Business Associate Agreement (BAA) with AWS. For more information, see HIPAA compliance. AWS Services in Scope have been fully assessed by a third-party auditor and result in a certification, attestation of compliance, or Authority to Operate (ATO). For more information, see AWS services in scope by compliance program.

Before creating a DB instance, complete the steps in Setting up for Amazon RDS (p. 153). When you create a DB instance, the RDS master user gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running MariaDB inside a virtual private cloud (VPC) based on Amazon VPC. You can also add features to your MariaDB DB instance by enabling various options. Amazon RDS supports Multi-AZ deployments for MariaDB as a high-availability, failover solution.
Important
To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced privileges. You can access your database using standard SQL clients such as the mysql client. However, you can’t access the host directly by using Telnet or Secure Shell (SSH).

MariaDB feature support on Amazon RDS

RDS for MariaDB supports most of the features and capabilities of MariaDB. Some features might have limited support or restricted privileges.

You can filter new Amazon RDS features on the What’s New with Database? page. For Products, choose Amazon RDS. Then search using keywords such as MariaDB 2022.

Note
The following lists are not exhaustive.

Topics
- MariaDB feature support on Amazon RDS for MariaDB major versions (p. 1016)
- Supported storage engines for MariaDB on Amazon RDS (p. 1020)
- Cache warming for MariaDB on Amazon RDS (p. 1021)
- MariaDB features not supported by Amazon RDS (p. 1022)

MariaDB feature support on Amazon RDS for MariaDB major versions

In the following sections, find information about MariaDB feature support on Amazon RDS for MariaDB major versions:

Topics
- MariaDB 10.6 support on Amazon RDS (p. 1017)
- MariaDB 10.5 support on Amazon RDS (p. 1018)
- MariaDB 10.4 support on Amazon RDS (p. 1018)
- MariaDB 10.3 support on Amazon RDS (p. 1019)
• MariaDB 10.2 support on Amazon RDS (p. 1019)

For information about supported minor versions of Amazon RDS for MariaDB, see MariaDB on Amazon RDS versions (p. 1023).

MariaDB 10.6 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.6 or higher:

• **MyRocks storage engine** – You can use the MyRocks storage engine with RDS for MariaDB to optimize storage consumption of your write-intensive, high-performance web applications. For more information, see Supported storage engines for MariaDB on Amazon RDS (p. 1020) and MyRocks.

• **AWS Identity and Access Management (IAM) DB authentication** – You can use IAM DB authentication for better security and central management of connections to your MariaDB DB instances. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2195).

• **Upgrade options** – You can now upgrade to RDS for MariaDB version 10.6 from any prior major release (10.2, 10.3, 10.4, 10.5). You can also restore a snapshot of an existing MySQL 5.6 or 5.7 DB instance to a MariaDB 10.6 instance. For more information, see Upgrading the MariaDB DB engine (p. 1039).

• **Delayed replication** – You can now set a configurable time period for which a read replica lags behind the source database. In a standard MariaDB replication configuration, there is minimal replication delay between the source and the replica. With delayed replication, you can set an intentional delay as a strategy for disaster recovery. For more information, see Configuring delayed replication with MariaDB (p. 1071).

• **Oracle PL/SQL compatibility** – By using RDS for MariaDB version 10.6, you can more easily migrate your legacy Oracle applications to Amazon RDS. For more information, see SQL_MODE=ORACLE.

• **Atomic DDL** – Your dynamic data language (DDL) statements can be relatively crash-safe with RDS for MariaDB version 10.6. CREATE TABLE, ALTER TABLE, RENAME TABLE, DROP TABLE, DROP DATABASE and related DDL statements are now atomic. Either the statement succeeds, or it's completely reversed. For more information, see Atomic DDL.

• **Other enhancements** – These enhancements include a JSON_TABLE function for transforming JSON data to relational format within SQL, and faster empty table data load with Innodb. They also include new sys_schema for analysis and troubleshooting, optimizer enhancement for ignoring unused indexes, and performance improvements. For more information, see JSON_TABLE.

• **New default values for parameters** – The following parameters have new default values for MariaDB version 10.6 DB instances:
  
  The default value for the following parameters has changed from utf8 to utf8mb3:
  
  • character_set_client
  • character_set_connection
  • character_set_results
  • character_set_system

  Although the default values have changed for these parameters, there is no functional change. For more information, see Supported Character Sets and Collations in the MariaDB documentation.

  • The default value of the collation_connection parameter has changed from utf8_general_ci to utf8mb3_general_ci. Although the default value has changed for this parameter, there is no functional change.

  • The default value of the old_mode parameter has changed from unset to UTF8_IS_UTF8MB3. Although the default value has changed for this parameter, there is no functional change.

For a list of all MariaDB 10.6 features and their documentation, see Changes and improvements in MariaDB 10.6 and Release notes - MariaDB 10.6 series on the MariaDB website.
MariaDB 10.5 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.5 or later:

- **InnoDB enhancements** – MariaDB version 10.5 includes InnoDB enhancements. For more information, see InnoDB: Performance Improvements etc. in the MariaDB documentation.

- **Performance schema updates** – MariaDB version 10.5 includes performance schema updates. For more information, see Performance Schema Updates to Match MySQL 5.7 Instrumentation and Tables in the MariaDB documentation.

- **One file in the InnoDB redo log** – In versions of MariaDB before version 10.5, the value of the innodb_log_files_in_group parameter was set to 2. In MariaDB version 10.5, the value of this parameter is set to 1.

If you are upgrading from a prior version to MariaDB version 10.5, and you don't modify the parameters, the innodb_log_file_size parameter value is unchanged. However, it applies to one log file instead of two. The result is that your upgraded MariaDB version 10.5 DB instance uses half of the redo log size that it was using before the upgrade. This change can have a noticeable performance impact. To address this issue, you can double the value of the innodb_log_file_size parameter. For information about modifying parameters, see Modifying parameters in a DB parameter group (p. 300).

- **SHOW SLAVE STATUS command not supported** – In versions of MariaDB before version 10.5, the SHOW SLAVE STATUS command required the REPLICATION SLAVE privilege. In MariaDB version 10.5, the equivalent SHOW REPLICA STATUS command requires the REPLICATION REPLICA ADMIN privilege. This new privilege isn't granted to the RDS master user.

Instead of using the SHOW REPLICA STATUS command, run the new mysql.rds_replica_status stored procedure to return similar information. For more information, see mysql.rds_replica_status (p. 1090).

- **SHOW RELAYLOG EVENTS command not supported** – In versions of MariaDB before version 10.5, the SHOW RELAYLOG EVENTS command required the REPLICATION SLAVE privilege. In MariaDB version 10.5, this command requires the REPLICATION REPLICA ADMIN privilege. This new privilege isn't granted to the RDS master user.

- **New default values for parameters** – The following parameters have new default values for MariaDB version 10.5 DB instances:
  - The default value of the max_connections parameter has changed to LEAST({DBInstanceClassMemory/25165760},12000). For information about the LEAST parameter function, see DB parameter functions (p. 318).
  - The default value of the innodb_adaptive_hash_index parameter has changed to OFF (0).
  - The default value of the innodb_checksum_algorithm parameter has changed to fullcrc32.
  - The default value of the innodb_log_file_size parameter has changed to 2 GB.

For a list of all MariaDB 10.5 features and their documentation, see Changes and improvements in MariaDB 10.5 and Release notes - MariaDB 10.5 series on the MariaDB website.

For a list of unsupported features, see MariaDB features not supported by Amazon RDS (p. 1022).

MariaDB 10.4 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.4 or later:

- **User account security enhancements** – Password expiration and account locking improvements
• **Optimizer enhancements** – Optimizer trace feature
• **InnoDB enhancements** – Instant DROP COLUMN support and instant VARCHAR extension for ROW_FORMAT=DYNAMIC and ROW_FORMAT=COMPACT
• **New parameters** – Including `tcp_nodelay`, `tls_version`, and `gtid_cleanup_batch_size`

For a list of all MariaDB 10.4 features and their documentation, see [Changes and improvements in MariaDB 10.4](https://mariadb.com/downloads/mariadb-10-4-series) and [Release notes - MariaDB 10.4 series](https://mariadb.com/downloads/mariadb-10-4-series) on the MariaDB website.

For a list of unsupported features, see [MariaDB features not supported by Amazon RDS](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/MariaDB-10-4.0.html#MariaDB-10-4-unsupported-features) (p. 1022).

### MariaDB 10.3 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.3 or later:

• **Oracle compatibility** – PL/SQL compatibility parser, sequences, INTERSECT and EXCEPT to complement UNION, new TYPE OF and ROW TYPE OF declarations, and invisible columns
• **Temporal data processing** – System versioned tables for querying of past and present states of the database
• **Flexibility** – User-defined aggregates, storage-independent column compression, and proxy protocol support to relay the client IP address to the server
• **Manageability** – Instant ADD COLUMN operations and fast-fail data definition language (DDL) operations

For a list of all MariaDB 10.3 features and their documentation, see [Changes & improvements in MariaDB 10.3](https://mariadb.com/downloads/mariadb-10-3-series) and [Release notes - MariaDB 10.3 series](https://mariadb.com/downloads/mariadb-10-3-series) on the MariaDB website.

For a list of unsupported features, see [MariaDB features not supported by Amazon RDS](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/MariaDB-10-3.0.html#MariaDB-10-3-unsupported-features) (p. 1022).

### MariaDB 10.2 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.2 or later:

• ALTER USER
• Common Table Expressions
• Compressing Events to Reduce Size of the Binary Log
• CREATE USER — new options for limiting resource usage and SSL/TLS
• EXECUTE IMMEDIATE
• Flashback
• InnoDB — now the default storage engine instead of XtraDB
• InnoDB — set the buffer pool size dynamically
• JSON Functions
• Window Functions
• WITH

For a list of all MariaDB 10.2 features and their documentation, see [Changes & improvements in MariaDB 10.2](https://mariadb.com/downloads/mariadb-10-2-series) and [Release notes - MariaDB 10.2 series](https://mariadb.com/downloads/mariadb-10-2-series) on the MariaDB website.

For a list of unsupported features, see [MariaDB features not supported by Amazon RDS](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/MariaDB-10-2.0.html#MariaDB-10-2-unsupported-features) (p. 1022).
Supported storage engines for MariaDB on Amazon RDS

RDS for MariaDB supports the following storage engines.

Topics
- The InnoDB storage engine (p. 1020)
- The MyRocks storage engine (p. 1020)

Other storage engines aren't currently supported by RDS for MariaDB.

The InnoDB storage engine

Although MariaDB supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. InnoDB is the recommended storage engine for MariaDB DB instances on Amazon RDS. Amazon RDS features such as point-in-time restore and snapshot restore require a recoverable storage engine and are supported only for the recommended storage engine for the MariaDB version.

For more information, see InnoDB.

The MyRocks storage engine

The MyRocks storage engine is available in RDS for MariaDB version 10.6 and higher. Before using the MyRocks storage engine in a production database, we recommend that you perform thorough benchmarking and testing to verify any potential benefits over InnoDB for your use case.

The default parameter group for MariaDB version 10.6 includes MyRocks parameters. For more information, see Parameters for MariaDB (p. 1084) and Working with parameter groups (p. 295).

To create a table that uses the MyRocks storage engine, specify ENGINE=RocksDB in the CREATE TABLE statement. The following example creates a table that uses the MyRocks storage engine.

```
CREATE TABLE test (a INT NOT NULL, b CHAR(10)) ENGINE=RocksDB;
```

We strongly recommend that you don't run transactions that span both InnoDB and MyRocks tables. MariaDB doesn't guarantee ACID (atomicity, consistency, isolation, durability) for transactions across storage engines. Although it is possible to have both InnoDB and MyRocks tables in a DB instance, we don't recommend this approach except during a migration from one storage engine to the other. When both InnoDB and MyRocks tables exist in a DB instance, each storage engine has its own buffer pool, which might cause performance to degrade.

MyRocks doesn't support SERIALIZABLE isolation or gap locks. So, generally you can't use MyRocks with statement-based replication. For more information, see MyRocks and Replication.

Currently, you can modify only the following MyRocks parameters:
- rocksdb_block_cache_size
- rocksdb_bulk_load
- rocksdb_bulk_load_size
- rocksdb_deadlock_detect
- rocksdb_deadlock_detect_depth
Cache warming

- `rocksdb_max_latest_deadlocks`

The MyRocks storage engine and the InnoDB storage engine can compete for memory based on the settings for the `rocksdb_block_cache_size` and `innodb_buffer_pool_size` parameters. In some cases, you might only intend to use the MyRocks storage engine on a particular DB instance. If so, we recommend setting the `innodb_buffer_pool_size` minimal parameter to a minimal value and setting the `rocksdb_block_cache_size` as high as possible.

You can access MyRocks log files by using the `DescribeDBLogFiles` and `DownloadDBLogFilePortion` operations.

For more information about MyRocks, see MyRocks on the MariaDB website.

**Cache warming for MariaDB on Amazon RDS**

InnoDB cache warming can provide performance gains for your MariaDB DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This approach bypasses the need for the buffer pool to "warm up" from normal database use and instead preloads the buffer pool with the pages for known common queries. For more information on cache warming, see Dumping and restoring the buffer pool in the MariaDB documentation.

Cache warming is enabled by default on MariaDB 10.2 and higher DB instances. To enable it, set the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group affects all MariaDB DB instances that use that parameter group. To enable cache warming for specific MariaDB DB instances, you might need to create a new parameter group for those DB instances. For information on parameter groups, see Working with parameter groups (p. 295).

Cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you don't commonly see a significant performance benefit.

**Important**

If your MariaDB DB instance doesn't shut down normally, such as during a failover, then the buffer pool state isn't saved to disk. In this case, MariaDB loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might not reflect the most recent state of the buffer pool before the restart. To ensure that you have a recent state of the buffer pool available to warm the cache on startup, we recommend that you periodically dump the buffer pool "on demand." You can dump or load the buffer pool on demand.

You can create an event to dump the buffer pool automatically and at a regular interval. For example, the following statement creates an event named `periodic_buffer_pool_dump` that dumps the buffer pool every hour.

```sql
CREATE EVENT periodic_buffer_pool_dump
    ON SCHEDULE EVERY 1 HOUR
    DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information, see Events in the MariaDB documentation.

**Dumping and loading the buffer pool on demand**

You can save and load the cache on demand using the following stored procedures:

- To dump the current state of the buffer pool to disk, call the `mysql.rds_innodb_buffer_pool_dump_now` (p. 1511) stored procedure.
• To load the saved state of the buffer pool from disk, call the `mysql.rds_innodb_buffer_pool_load_now (p. 1511)` stored procedure.
• To cancel a load operation in progress, call the `mysql.rds_innodb_buffer_pool_load_abort (p. 1511)` stored procedure.

**MariaDB features not supported by Amazon RDS**

The following MariaDB features are not supported on Amazon RDS:

• S3 storage engine
• Authentication plugin – GSSAPI
• Authentication plugin – Unix Socket
• AWS Key Management encryption plugin
• Delayed replication for MariaDB versions lower than 10.6
• Native MariaDB encryption at rest for InnoDB and Aria.

You can enable encryption at rest for a MariaDB DB instance by following the instructions in [Encrypting Amazon RDS resources (p. 2147)](#).

• HandlerSocket
• JSON table type for MariaDB versions lower than 10.6
• MariaDB ColumnStore
• MariaDB Galera Cluster
• Multisource replication
• MyRocks storage engine for MariaDB versions lower than 10.6
• Password validation plugin, `simple_password_check` and `cracklib_password_check`
• Spider storage engine
• Sphinx storage engine
• TokuDB storage engine
• Storage engine-specific object attributes, as described in [Engine-defined new Table/Field/Index attributes in the MariaDB documentation](#)
• Table and tablespace encryption

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection.
MariaDB on Amazon RDS versions

For MariaDB, version numbers are organized as version X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes, for example going from version 10.5 to 10.6. A version change is considered minor if only the minor version number changes, for example going from version 10.6.5 to 10.6.7.

</table>

You can specify any currently supported MariaDB version when creating a new DB instance. You can specify the major version (such as MariaDB 10.5), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

For example, to list the supported engine versions for RDS for MariaDB, run the following CLI command:

```bash
```

The default MariaDB version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region using the following AWS CLI command:

```bash
```

Replace `major-engine-version` with the major engine version, and replace `region` with the AWS Region. For example, the following AWS CLI command returns the default MariaDB minor engine version for the 10.5 major version and the US West (Oregon) AWS Region (us-west-2):

```bash
```

**RDS for MariaDB release calendar**

RDS for MariaDB major versions remain available at least until community end of life for the corresponding community version. You can use the following dates to plan your testing and upgrade cycles. If Amazon extends support for an RDS for MariaDB version for longer than originally stated, we plan to update this table to reflect the later date.

**Note**

Dates with only a month and a year are approximate and are updated with an exact date when it's known.
MariaDB 10.3 end of life

On October 23, 2023, Amazon RDS is starting the end-of-life process for MariaDB version 10.3 using the following schedule, which includes upgrade recommendations. The end-of-life process ends standard support for this version. We recommend that you upgrade all MariaDB 10.3 DB instances to MariaDB 10.6 as soon as possible. For more information, see Upgrading the MariaDB DB engine (p. 1039).

**MariaDB 10.2 end of life**

On October 15, 2022, Amazon RDS is starting the end-of-life process for MariaDB version 10.2 using the following schedule, which includes upgrade recommendations. The end-of-life process ends standard support for this version. We recommend that you upgrade all MariaDB 10.2 DB instances to MariaDB 10.3 or higher as soon as possible. For more information, see [Upgrading the MariaDB DB engine](p. 1039).

For more information about Amazon RDS for MariaDB 10.2 end of life, see [Announcement: Amazon Relational Database Service (Amazon RDS) for MariaDB 10.2 End-of-Life date is October 15, 2022](Announcement: Amazon Relational Database Service (Amazon RDS) for MariaDB 10.2 End-of-Life date is October 15, 2022).

**Deprecated versions for Amazon RDS for MariaDB**

Amazon RDS for MariaDB version 10.0, 10.1, and 10.2 are deprecated.

For information about the Amazon RDS deprecation policy for MariaDB, see [Amazon RDS FAQs](Amazon RDS FAQs).
Connecting to a DB instance running the MariaDB database engine

After Amazon RDS provisions your DB instance, you can use any standard MariaDB client application or utility to connect to the instance. In the connection string, you specify the Domain Name System (DNS) address from the DB instance endpoint as the host parameter. You also specify the port number from the DB instance endpoint as the port parameter.

You can connect to an Amazon RDS for MariaDB DB instance by using tools like the MySQL command-line client. For more information on using the MySQL command-line client, see mysql command-line client in the MariaDB documentation. One GUI-based application that you can use to connect is Heidi. For more information, see the Download HeidiSQL page. For information about installing MySQL (including the MySQL command-line client), see Installing and upgrading MySQL.

Most Linux distributions include the MariaDB client instead of the Oracle MySQL client. To install the MySQL command-line client on most RPM-based Linux distributions, including Amazon Linux 2, run the following command.

```
yum install mariadb
```

To install the MySQL command-line client on most DEB-based Linux distributions, run the following command.

```
apt-get install mariadb-client
```

To check the version of your MySQL command-line client, run the following command.

```
mysql --version
```

To read the MySQL documentation for your current client version, run the following command.

```
man mysql
```

To connect to a DB instance from outside of a virtual private cloud (VPC) based on Amazon VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance (p. 2289).

You can use SSL encryption on connections to a MariaDB DB instance. For information, see Using SSL/TLS with a MariaDB DB instance (p. 1033).

**Topics**

- Finding the connection information for a MariaDB DB instance (p. 1027)
- Connecting from the MySQL command-line client (unencrypted) (p. 1030)
- Troubleshooting connections to your MariaDB DB instance (p. 1031)

**Finding the connection information for a MariaDB DB instance**

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is `mydb.123456789012.us-`
Finding the connection information

east-1.rds.amazonaws.com. In this case, the port value is 3306, and the database user is admin. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify mydb.123456789012.us-east-1.rds.amazonaws.com.
- For port, specify 3306.
- For user, specify admin.

To connect to a DB instance, use any client for the MariaDB DB engine. For example, you might use the MySQL command-line client or MySQL Workbench.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS Command Line Interface (AWS CLI) describe-db-instances command, or the Amazon RDS API DescribeDBInstances operation to list its details.

**Console**

**To find the connection information for a DB instance in the AWS Management Console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases to display a list of your DB instances.
3. Choose the name of the MariaDB DB instance to display its details.
4. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
5. If you need to find the master user name, choose the **Configuration** tab and view the **Master username** value.

**AWS CLI**

To find the connection information for a MariaDB DB instance by using the AWS CLI, call the `describe-db-instances` command. In the call, query for the DB instance ID, endpoint, port, and master user name.
Connecting from the MySQL command-line client (unencrypted)

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
   --filters "Name=engine,Values=mariadb" \
   --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```
aws rds describe-db-instances ^
   --filters "Name=engine,Values=mariadb" ^
   --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```
[ 
    "mydb1", 
    "mydb1.123456789012.us-east-1.rds.amazonaws.com", 3306, 
    "admin"
],
[ 
    "mydb2", 
    "mydb2.123456789012.us-east-1.rds.amazonaws.com", 3306, 
    "admin"
]
```

**RDS API**

To find the connection information for a DB instance by using the Amazon RDS API, call the `DescribeDBInstances` operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

**Connecting from the MySQL command-line client (unencrypted)**

**Important**

Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting from the MySQL command-line client with SSL/TLS (encrypted) (p. 1034).

To connect to a DB instance using the MySQL command-line client, enter the following command at a command prompt on a client computer. Doing this connects you to a database on a MariaDB DB instance. Substitute the DNS name (endpoint) for `<endpoint>` and the master user name that you used for `<mymasteruser>`. Provide the master password that you used when prompted for a password.

```
mysql -h `<endpoint>` -P 3306 -u `<mymasteruser>` -p
```

After you enter the password for the user, you see output similar to the following.

```
Welcome to the MariaDB monitor. Commands end with ; or \g.
Your MariaDB connection id is 31
Server version: 10.5.15-MariaDB-log Source distribution
```
Troubleshooting connections to your MariaDB DB instance

Two common causes of connection failures to a new DB instance are the following:

- The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MariaDB application or utility is running. The DB instance must have a VPC security group that authorizes the connections. For more information, see Amazon VPC VPCs and Amazon RDS (p. 2251).

  You can add or edit an inbound rule in the security group. For **Source**, choose **My IP**. This allows access to the DB instance from the IP address detected in your browser.

- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see Can't connect to Amazon RDS DB instance (p. 2289).
Securing MariaDB DB instance connections

You can manage the security of your MariaDB DB instances.

Topics
- MariaDB security on Amazon RDS (p. 1032)
- Encrypting client connections to MariaDB DB instances with SSL/TLS (p. 1033)
- Using new SSL/TLS certificates for MariaDB DB instances (p. 1035)

MariaDB security on Amazon RDS

Security for MariaDB DB instances is managed at three levels:

- AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management for Amazon RDS (p. 2162).

- When you create a DB instance, you use a VPC security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance. These connections can be made using Secure Socket Layer (SSL) and Transport Layer Security (TLS). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.

- Once a connection has been opened to a MariaDB DB instance, authentication of the login and permissions are applied the same way as in a stand-alone instance of MariaDB. Commands such as CREATE USER, RENAME USER, GRANT, REVOKE, and SET PASSWORD work just as they do in stand-alone databases, as does directly modifying database schema tables.

When you create an Amazon RDS DB instance, the master user has the following default privileges:

- alter
- alter routine
- create
- create routine
- create temporary tables
- create user
- create view
- delete
- drop
- event
- execute
- grant option
- index
- insert
- lock tables
- process
- references
- reload

1032
This privilege is limited on MariaDB DB instances. It doesn't grant access to the FLUSH LOGS or FLUSH TABLES WITH READ LOCK operations.

- replication client
- replication slave
- select
- show databases
- show view
- trigger
- update

For more information about these privileges, see User account management in the MariaDB documentation.

**Note**
Although you can delete the master user on a DB instance, we don't recommend doing so. To recreate the master user, use the ModifyDBInstance API or the modify-db-instance AWS CLI and specify a new master user password with the appropriate parameter. If the master user does not exist in the instance, the master user is created with the specified password.

To provide management services for each DB instance, the rdsadmin user is created when the DB instance is created. Attempting to drop, rename, change the password for, or change privileges for the rdsadmin account results in an error.

To allow management of the DB instance, the standard kill and kill_query commands have been restricted. The Amazon RDS commands mysql.rds_kill, mysql.rds_kill_query, and mysql.rds_kill_query_id are provided for use in MariaDB and also MySQL so that you can end user sessions or queries on DB instances.

### Encrypting client connections to MariaDB DB instances with SSL/TLS

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS). Amazon RDS supports SSL/TLS encryption for MariaDB DB instances. Using SSL/TLS, you can encrypt a connection between your application client and your MariaDB DB instance. SSL/TLS support is available in all AWS Regions.

**Topics**
- Using SSL/TLS with a MariaDB DB instance (p. 1033)
- Connecting from the MySQL command-line client with SSL/TLS (encrypted) (p. 1034)

### Using SSL/TLS with a MariaDB DB instance

Amazon RDS creates an SSL/TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL/TLS certificate includes the DB instance endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

An SSL/TLS certificate created by Amazon RDS is the trusted root entity and should work in most cases but might fail if your application does not accept certificate chains. If your application does not accept certificate chains, you might need to use an intermediate certificate to connect to your AWS Region. For
example, you must use an intermediate certificate to connect to the AWS GovCloud (US) Regions using SSL/TLS.

For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152). For more information about using SSL/TLS with MySQL, see Using new SSL/TLS certificates for MariaDB DB instances (p. 1035).

Amazon RDS for MariaDB supports Transport Layer Security (TLS) versions 1.0, 1.1, 1.2, and 1.3 for all MariaDB versions.

You can require SSL/TLS connections for specific users accounts. For example, you can use one of the following statements, depending on your MariaDB version, to require SSL/TLS connections on the user account encrypted_user.

Use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL/TLS connections with MariaDB, see Securing Connections for Client and Server in the MariaDB documentation.

**Connecting from the MySQL command-line client with SSL/TLS (encrypted)**

The `mysql` client program parameters are slightly different if you are using the MySQL 5.7 version, the MySQL 8.0 version, or the MariaDB version.

To find out which version you have, run the `mysql` command with the `--version` option. In the following example, the output shows that the client program is from MariaDB.

```
$ mysql --version
mysql Ver 15.1 Distrib 10.5.15-MariaDB, for osx10.15 (x86_64) using readline 5.1
```

Most Linux distributions, such as Amazon Linux, CentOS, SUSE, and Debian have replaced MySQL with MariaDB, and the `mysql` version in them is from MariaDB.

To connect to your DB instance using SSL/TLS, follow these steps:

**To connect to a DB instance with SSL/TLS using the MySQL command-line client**

1. Download a root certificate that works for all AWS Regions.
   
   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).

2. Use a MySQL command-line client to connect to a DB instance with SSL/TLS encryption. For the `-h` parameter, substitute the DNS name (endpoint) for your DB instance. For the `--ssl-ca` parameter, substitute the SSL/TLS certificate file name. For the `-P` parameter, substitute the port for your DB instance. For the `-u` parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

   The following example shows how to launch the client using the `--ssl-ca` parameter using the MariaDB client:

   ```
   mysql -h `mysql-instance1.123456789012.us-east-1.rds.amazonaws.com` --ssl-ca=global-bundle.pem --ssl -P 3306 -u myadmin -p
   ```
To require that the SSL/TLS connection verifies the DB instance endpoint against the endpoint in the SSL/TLS certificate, enter the following command:

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-verify-server-cert -P 3306 -u myadmin -p
```

The following example shows how to launch the client using the `--ssl-ca` parameter using the MySQL 5.7 client or later:

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=REQUIRED -P 3306 -u myadmin -p
```

3. Enter the master user password when prompted.

You should see output similar to the following.

```
Welcome to the MariaDB monitor. Commands end with ; or \g.
Your MariaDB connection id is 31
Server version: 10.5.15-MariaDB-log Source distribution
Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.
Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.
MariaDB [(none)]>
```

Using new SSL/TLS certificates for MariaDB DB instances

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether your applications require certificate verification to connect to your DB instances.

**Note**

Some applications are configured to connect to MariaDB only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.

You can specify the following SSL modes: disabled, preferred, and required. When you use the preferred SSL mode and the CA certificate doesn't exist or isn't up to date, the connection falls back to not using SSL and still connects successfully.

We recommend avoiding preferred mode. In preferred mode, if the connection encounters an invalid certificate, it stops using encryption and proceeds unencrypted.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate](p. 2154). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance](p. 2152). For information about using SSL/TLS with MariaDB DB instances, see [Using SSL/TLS with a MariaDB DB instance](p. 1033).

**Topics**
Determining whether a client requires certificate verification in order to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

**JDBC**

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see Configuration properties in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the server CA certificate if your connection properties have `sslMode` set to `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```java
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

*Note*
If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

**MySQL**

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see Client-side configuration for encrypted connections in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the `--ssl-mode` option you specify `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the `--ssl-verify-server-cert` option, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-verify-server-cert
```
Updating your application trust store

For information about updating the trust store for MySQL applications, see Using TLS/SSL with MariaDB Connector/J in the MariaDB documentation.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).

For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 2160).

**Note**
When you update the trust store, you can retain older certificates in addition to adding the new certificates.

If you are using the MariaDB Connector/J JDBC driver in an application, set the following properties in the application.

```
System.setProperty("javax.net.ssl.trustStore", "certs");
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

When you start the application, set the following properties.

```
java -Djavax.net.ssl.trustStore=/path_to_truststore/MyTruststore.jks -Djavax.net.ssl.trustStorePassword=My_truststore_password com.companyName.MyApplication
```

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection using JDBC.

```java
private static final String DB_USER = "admin";
private static final String DB_USER = "user name";
private static final String DB_PASSWORD = "password";
// This key store has only the prod root ca.
private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
private static final String KEY_STORE_PASS = "keystore-password";

public static void main(String[] args) throws Exception {
    Class.forName("org.mariadb.jdbc.Driver");
    System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
    System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);

    Properties properties = new Properties();
    properties.put("user", DB_USER);
    properties.put("password", DB_PASSWORD);

    Connection connection = DriverManager.getConnection("jdbc:mysql://ssl-mariadb-public.cni62e2e7kwh.us-east-1.rds.amazonaws.com:33067/useSSL=true",properties);
```
Statement stmt=connection.createStatement();
ResultSet rs=stmt.executeQuery("SELECT 1 from dual");
return;
}

**Important**
After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance](p. 2154).
Upgrading the MariaDB DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MariaDB DB instances: major version upgrades and minor version upgrades.

**Major version upgrades** can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you follow the instructions in Major version upgrades for MariaDB (p. 1040).

In contrast, **minor version upgrades** include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or you can enable the **Auto minor version upgrade** option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. For information about performing an upgrade, see Upgrading a DB instance engine version (p. 369).

If your MariaDB DB instance is using read replicas, you must upgrade all of the read replicas before upgrading the source instance. If your DB instance is in a Multi-AZ deployment, both the writer and standby replicas are upgraded. Your DB instance might not be available until the upgrade is complete.

For more information about MariaDB supported versions and version management, see MariaDB on Amazon RDS versions (p. 1023).

Database engine upgrades require downtime. The duration of the downtime varies based on the size of your DB instance.

**Tip**
You can minimize the downtime required for DB instance upgrade by using a blue/green deployment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates (p. 438).

Topics
- Overview of upgrading (p. 1039)
- Major version upgrades for MariaDB (p. 1040)
- Upgrading a MariaDB DB instance (p. 1041)
- Automatic minor version upgrades for MariaDB (p. 1041)

**Overview of upgrading**

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
  --engine mariadb \
  --engine-version version-number \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
```
For example, to identify the valid upgrade targets for a MariaDB version 10.5.15 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions
   --engine mariadb
   --engine-version 10.5.15
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:

```
aws rds describe-db-engine-versions
   --engine mariadb
   --engine-version 10.5.15
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. If the upgrade doesn't work for your databases, you can restore this snapshot to create a DB instance running the old version. The second DB snapshot is taken when the upgrade completes.

**Note**
Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see Modifying an Amazon RDS DB instance (p. 333).

After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance is using read replication, you must upgrade all of the Read Replicas before upgrading the source instance.

If your DB instance is in a Multi-AZ deployment, both the primary and standby DB instances are upgraded. The primary and standby DB instances are upgraded at the same time and you will experience an outage until the upgrade is complete. The time for the outage varies based on your database engine, engine version, and the size of your DB instance.

## Major version upgrades for MariaDB

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically. You must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.

Amazon RDS supports the following in-place upgrades for major versions of the MariaDB database engine:
• Any MariaDB version to MariaDB 10.6
• MariaDB 10.4 to MariaDB 10.5
• MariaDB 10.3 to MariaDB 10.4
• MariaDB 10.2 to MariaDB 10.3

To perform a major version upgrade to MariaDB version 10.6, you can upgrade directly from any MariaDB version to version 10.6.

To perform a major version upgrade to a MariaDB version lower than 10.6, upgrade to each major version in order. For example, to upgrade from version 10.2 to version 10.5, upgrade in the following order: 10.2 to 10.3, 10.3 to 10.4, and then 10.4 to 10.5.

If you are using a custom parameter group, and you perform a major version upgrade, you must specify either a default parameter group for the new DB engine version or create your own custom parameter group for the new DB engine version. Associating the new parameter group with the DB instance requires a customer-initiated database reboot after the upgrade completes. The instance's parameter group status will show pending-reboot if the instance needs to be rebooted to apply the parameter group changes. An instance's parameter group status can be viewed in the AWS console or by using a "describe" call such as describe-db-instances.

Upgrading a MariaDB DB instance

For information about manually or automatically upgrading a MariaDB DB instance, see Upgrading a DB instance engine version (p. 369).

Automatic minor version upgrades for MariaDB

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

• The Auto minor version upgrade setting is enabled.
• The Backup retention period setting is greater than 0.

In the AWS Management Console, these settings are under Additional configuration. The following image shows the Auto minor version upgrade setting.
For more information about these settings, see Settings for DB instances (p. 334).

For some RDS for MariaDB major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the MariaDB community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified MariaDB minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
  --engine mariadb
  --engine-version minor-version
  --region region
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}"
  --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions
  --engine mariadb
  --engine-version minor-version
  --region region
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}"
  --output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MariaDB minor version 10.2.39 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
  --engine mariadb
  --engine-version 10.2.39
  --region us-east-2
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}"
  --output table
```

For Windows:

```bash
aws rds describe-db-engine-versions
  --engine mariadb
  --engine-version 10.2.39
  --region us-east-2
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}"
  --output table
```
Your output is similar to the following.

<table>
<thead>
<tr>
<th>DescribeDBEngineVersions</th>
<th>---------------+-----------------</th>
</tr>
</thead>
<tbody>
<tr>
<td>AutoUpgrade</td>
<td>EngineVersion</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>True</td>
<td>10.2.40</td>
</tr>
<tr>
<td>False</td>
<td>10.2.41</td>
</tr>
<tr>
<td>False</td>
<td>10.2.43</td>
</tr>
<tr>
<td>False</td>
<td>10.2.44</td>
</tr>
<tr>
<td>False</td>
<td>10.3.28</td>
</tr>
<tr>
<td>False</td>
<td>10.3.31</td>
</tr>
<tr>
<td>False</td>
<td>10.3.32</td>
</tr>
<tr>
<td>False</td>
<td>10.3.34</td>
</tr>
<tr>
<td>False</td>
<td>10.3.35</td>
</tr>
<tr>
<td>False</td>
<td>10.6.5</td>
</tr>
<tr>
<td>False</td>
<td>10.6.7</td>
</tr>
<tr>
<td>False</td>
<td>10.6.8</td>
</tr>
</tbody>
</table>

In this example, the AutoUpgrade value is True for MariaDB version 10.2.40. So, the automatic minor upgrade target is MariaDB version 10.2.40, which is highlighted in the output.

A MariaDB DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see Automatically upgrading the minor engine version (p. 371).
### Importing data into a MariaDB DB instance

You can use several different techniques to import data into an RDS for MariaDB DB instance. The best approach depends on the source of the data, the amount of data, and whether the import is done one time or is ongoing. If you are migrating an application along with the data, also consider the amount of downtime that you are willing to experience.

Find techniques to import data into an RDS for MariaDB DB instance in the following table.

<table>
<thead>
<tr>
<th>Source</th>
<th>Amount of data</th>
<th>One time or ongoing</th>
<th>Application downtime</th>
<th>Technique</th>
<th>More information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Existing MariaDB DB instance</td>
<td>Any</td>
<td>One time or ongoing</td>
<td>Minimal</td>
<td>Create a read replica for ongoing replication. Promote the read replica for one-time creation of a new DB instance.</td>
<td>Working with read replicas (p. 382)</td>
</tr>
<tr>
<td>Existing MariaDB or MySQL database</td>
<td>Small</td>
<td>One time</td>
<td>Some</td>
<td>Copy the data directly to your MySQL DB instance using a command-line utility.</td>
<td>Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance (p. 1045)</td>
</tr>
<tr>
<td>Data not stored in an existing database</td>
<td>Medium</td>
<td>One time</td>
<td>Some</td>
<td>Create flat files and import them using the mysqlimport utility.</td>
<td>Importing data from any source to a MariaDB or MySQL DB instance (p. 1060)</td>
</tr>
<tr>
<td>Existing MariaDB or MySQL database on premises or on Amazon EC2</td>
<td>Any</td>
<td>Ongoing</td>
<td>Minimal</td>
<td>Configure replication with an existing MariaDB or MySQL database as the replication source.</td>
<td>Configuring binary log file position replication with an external source instance (p. 1077)</td>
</tr>
</tbody>
</table>

You can configure replication into a MariaDB DB instance using MariaDB global transaction identifiers (GTIDs) when the external instance is MariaDB version 10.0.24 or higher, or using binary log coordinates for MySQL instances or MariaDB instances on earlier versions than 10.0.24. MariaDB GTIDs are implemented differently than MySQL GTIDs, which aren’t supported by Amazon RDS.
Importing data from an external database

<table>
<thead>
<tr>
<th>Source</th>
<th>Amount of data</th>
<th>One time or ongoing</th>
<th>Applicatioi downtime</th>
<th>Technique</th>
<th>More information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any existing database</td>
<td>Any</td>
<td>One time or ongoing</td>
<td>Minimal</td>
<td>Use AWS Database Migration Service to migrate the database with minimal downtime and, for many database DB engines, continue ongoing replication.</td>
<td>What is AWS Database Migration Service and Using a MySQL-compatible database as a target for AWS DMS in the AWS Database Migration Service User Guide</td>
</tr>
</tbody>
</table>

**Note**
The mysql system database contains authentication and authorization information required to log into your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the mysql database in your DB instance can result in errors and might render the DB instance and your data inaccessible. If this occurs, the DB instance can be restored from a snapshot using the AWS CLI `restore-db-instance-from-db-snapshot` or recovered using `restore-db-instance-to-point-in-time` commands.

**Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance**

You can also import data from an existing MariaDB or MySQL database to a MySQL or MariaDB DB instance. You do so by copying the database with `mysqldump` and piping it directly into the MariaDB or MySQL DB instance. The `mysqldump` command line utility is commonly used to make backups and transfer data from one MariaDB or MySQL server to another. It’s included with MySQL and MariaDB client software.

**Note**
If you are using a MySQL DB instance and your scenario supports it, it’s easier to move data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see Restoring a backup into a MySQL DB instance (p. 1408).
A typical `mysqldump` command to move data from an external database to an Amazon RDS DB instance looks similar to the following.

```
mysqldump -u local_user \
    --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary \
    -plocal_password | mysql -u RDS_user \
    --port=port_number \
    --host=host_name \
    -pRDS_password
```

**Important**
Make sure not to leave a space between the `-p` option and the entered password.

Make sure that you're aware of the following recommendations and considerations:

- Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The `mysqldump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the `pt-show-grants` utility.
- To perform the import, make sure the user doing so has access to the DB instance. For more information, see Controlling access with security groups (p. 2232).

The parameters used are as follows:

- `-u local_user` – Use to specify a user name. In the first usage of this parameter, you specify the name of a user account on the local MariaDB or MySQL database identified by the `--databases` parameter.
- `--databases database_name` – Use to specify the name of the database on the local MariaDB or MySQL instance that you want to import into Amazon RDS.
- `--single-transaction` – Use to ensure that all of the data loaded from the local database is consistent with a single point in time. If there are other processes changing the data while `mysqldump` is reading it, using this parameter helps maintain data integrity.
- `--compress` – Use to reduce network bandwidth consumption by compressing the data from the local database before sending it to Amazon RDS.
- `--order-by-primary` – Use to reduce load time by sorting each table's data by its primary key.
- `-plocal_password` – Use to specify a password. In the first usage of this parameter, you specify the password for the user account identified by the first `-u` parameter.
- `-u RDS_user` – Use to specify a user name. In the second usage of this parameter, you specify the name of a user account on the default database for the MariaDB or MySQL DB instance identified by the `--host` parameter.
- `--port port_number` – Use to specify the port for your MariaDB or MySQL DB instance. By default, this is 3306 unless you changed the value when creating the instance.
- `--host host_name` – Use to specify the Domain Name System (DNS) name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.
- `-pRDS_password` – Use to specify a password. In the second usage of this parameter, you specify the password for the user account identified by the second `-u` parameter.

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when...
you run `mysqldump`. To do so, include the following parameters with your `mysqldump` command: `--routines=0 --triggers=0 --events=0`.

The following example copies the `world` sample database on the local host to a MySQL DB instance.

For Linux, macOS, or Unix:

```bash
sudo mysqldump -u localuser
   --databases world
   --single-transaction
   --compress
   --order-by-primary
   --routines=0
   --triggers=0
   --events=0
   -p localpassword | mysql -u rdsuser
   --port=3306
   --host=myinstance.123456789012.us-east-1.rds.amazonaws.com
   -p rdspassword
```

For Windows, run the following command in a command prompt that has been opened by right-clicking Command Prompt on the Windows programs menu and choosing Run as administrator:

```bash
mysqldump -u localuser
   --databases world
   --single-transaction
   --compress
   --order-by-primary
   --routines=0
   --triggers=0
   --events=0
   -p localpassword | mysql -u rdsuser
   --port=3306
   --host=myinstance.123456789012.us-east-1.rds.amazonaws.com
   -p rdspassword
```

### Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime

In some cases, you might need to import data from an external MariaDB or MySQL database that supports a live application to a MariaDB or MySQL DB instance. In these cases, you can use the following procedure to minimize the impact on application availability. This procedure can also help if you are working with a very large database. Here, the procedure helps because you can reduce the cost of the import by reducing the amount of data that is passed across the network to AWS.

In this procedure, you transfer a copy of your database data to an Amazon EC2 instance and import the data into a new Amazon RDS DB instance. You then use replication to bring the Amazon RDS DB instance up-to-date with your live external instance, before redirecting your application to the Amazon RDS DB instance. You configure MariaDB replication based on global transaction identifiers (GTIDs) if the external instance is MariaDB 10.0.24 or higher and the target instance is RDS for MariaDB. Otherwise, you configure replication based on binary log coordinates. We recommend GTID-based replication if your external database supports it due to its enhanced crash-safety features. For more information, see [Global transaction ID](https://mariadb.com/kb/en/gtid/) in the MariaDB documentation.

**Note**

If you want to import data into a MySQL DB instance and your scenario supports it, it is easier to move data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see [Restoring a backup into a MySQL DB instance](p. 1408).
Note
We don’t recommend that you use this procedure with source MySQL databases from MySQL versions earlier than version 5.5, due to potential replication issues. For more information, see Replication compatibility between MySQL versions in the MySQL documentation.

Create a copy of your existing database

The first step in the process of migrating a large amount of data to an Amazon RDS MariaDB or MySQL DB instance with minimal downtime is to create a copy of the source data.
You can use the mysqldump utility to create a database backup in either SQL or delimited-text format. We recommend that you do a test run with each format in a nonproduction environment to see which method minimizes the amount of time that mysqldump runs.

We also recommend that you weigh mysqldump performance against the benefit offered by using the delimited-text format for loading. A backup using delimited-text format creates a tab-separated text file for each table being dumped. To reduce the amount of time required to import your database, you can load these files in parallel using the \texttt{LOAD DATA LOCAL INFILE} command. For more information about choosing a mysqldump format and then loading the data, see Using \texttt{mysqldump} for backups in the MySQL documentation.

Before you start the backup operation, make sure to set the replication options on the MariaDB or MySQL database that you are copying to Amazon RDS. The replication options include turning on binary logging and setting a unique server ID. Setting these options causes your server to start logging database transactions and prepares it to be a source replication instance later in this process.

\textbf{Note}

Use the \texttt{--single-transaction} option with mysqldump because it dumps a consistent state of the database. To ensure a valid dump file, don't run data definition language (DDL) statements while mysqldump is running. You can schedule a maintenance window for these operations.

Exclude the following schemas from the dump file: \texttt{sys}, \texttt{performance_schema}, and \texttt{information_schema}. The mysqldump utility excludes these schemas by default.

To migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the \texttt{pt-show-grants} utility.

\textbf{To set replication options}

1. Edit the \texttt{my.cnf} file (this file is usually under /etc).

\begin{verbatim}
sudo vi /etc/my.cnf
\end{verbatim}

Add the \texttt{log_bin} and \texttt{server_id} options to the [\texttt{mysqld}] section. The \texttt{log_bin} option provides a file name identifier for binary log files. The \texttt{server_id} option provides a unique identifier for the server in source-replica relationships.

The following example shows the updated [\texttt{mysqld}] section of a \texttt{my.cnf} file.

\begin{verbatim}
[mysqld]
log-bin=mysql-bin
server-id=1
\end{verbatim}

For more information, see the MySQL documentation.

2. Restart the mysql service.

\begin{verbatim}
sudo service mysqld restart
\end{verbatim}

\textbf{To create a backup copy of your existing database}

1. Create a backup of your data using the mysqldump utility, specifying either SQL or delimited-text format.

Specify \texttt{--master-data=2} to create a backup file that can be used to start replication between servers. For more information, see the mysqldump documentation.
To improve performance and ensure data integrity, use the `--order-by-primary` and `--single-transaction` options of `mysqldump`.

To avoid including the MySQL system database in the backup, do not use the `--all-databases` option with `mysqldump`. For more information, see Creating a data snapshot using `mysqldump` in the MySQL documentation.

Use `chmod` if necessary to make sure that the directory where the backup file is being created is writeable.

**Important**

- On Windows, run the command window as an administrator.
- To produce SQL output, use the following command.

For Linux, macOS, or Unix:

```
sudo mysqldump
   --databases database_name
   --master-data=2
   --single-transaction
   --order-by-primary
   -r backup.sql
   -u local_user
   -p password
```

For Windows:

```
mysqldump
   --databases database_name
   --master-data=2
   --single-transaction
   --order-by-primary
   -r backup.sql
   -u local_user
   -p password
```

- To produce delimited-text output, use the following command.

For Linux, macOS, or Unix:

```
sudo mysqldump
   --tab=target_directory
   --fields-terminated-by ','
   --fields-enclosed-by '"'
   --lines-terminated-by 0x0d0a
   database_name
   --master-data=2
   --single-transaction
   --order-by-primary
   -p password
```

For Windows:

```
mysqldump
   --tab=target_directory
   --fields-terminated-by "",""^
   --fields-enclosed-by ""^
   --lines-terminated-by 0x0d0a
   database_name^
```
Importing data to a DB instance with reduced downtime

```
--master-data=2
--single-transaction
--order-by-primary
-p password
```

**Note**

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, exclude them when you run mysqldump. To do so, include the following arguments with your mysqldump command: `--routines=0 --triggers=0 --events=0`.

When using the delimited-text format, a `CHANGE MASTER TO` comment is returned when you run mysqldump. This comment contains the master log file name and position. If the external instance is other than MariaDB version 10.0.24 or higher, note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`. You need these values when setting up replication.

```
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```

If you are using SQL format, you can get the master log file name and position in the `CHANGE MASTER TO` comment in the backup file. If the external instance is MariaDB version 10.0.24 or higher, you can get the GTID in the next step.

2. If the external instance you are using is MariaDB version 10.0.24 or higher, you use GTID-based replication. Run `SHOW MASTER STATUS` on the external MariaDB instance to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance.

```
SELECT BINLOG_GTID_POS('binary log file name', binary log file position);
```

Note the GTID returned; you need it to configure replication.

3. Compress the copied data to reduce the amount of network resources needed to copy your data to the Amazon RDS DB instance. Take note of the size of the backup file; you need this information when determining how large an Amazon EC2 instance to create. When you are done, compress the backup file using GZIP or your preferred compression utility.

- To compress SQL output, use the following command.

```
gzip backup.sql
```

- To compress delimited-text output, use the following command.

```
tar -zcvf backup.tar.gz target_directory
```

**Create an Amazon EC2 instance and copy the compressed database**

Copying your compressed database backup file to an Amazon EC2 instance takes fewer network resources than doing a direct copy of uncompressed data between database instances. After your data is in Amazon EC2, you can copy it from there directly to your MariaDB or MySQL DB instance. For you to save on the cost of network resources, your Amazon EC2 instance must be in the same AWS Region as your Amazon RDS DB instance. Having the Amazon EC2 instance in the same AWS Region as your Amazon RDS DB instance also reduces network latency during the import.
To create an Amazon EC2 instance and copy your data

1. In the AWS Region where you plan to create the RDS DB instance to run your MySQL database engine, create a virtual private cloud (VPC), a VPC security group, and a VPC subnet. Ensure that the inbound rules for your VPC security group allow the IP addresses required for your application to connect to AWS. This can be a range of IP addresses (for example, 203.0.113.0/24), or another VPC security group. You can use the Amazon VPC Management Console to create and manage VPCs, subnets, and security groups. For more information, see Getting started with Amazon VPC in the Amazon Virtual Private Cloud Getting Started Guide.

2. Open the Amazon EC2 Management Console and choose the AWS Region to contain both your Amazon EC2 instance and your Amazon RDS DB instance. Launch an Amazon EC2 instance using the VPC, subnet, and security group that you created in Step 1. Ensure that you select an instance type with enough storage for your database backup file when it is uncompressed. For details on Amazon EC2 instances, see Getting started with Amazon EC2 Linux instances in the Amazon Elastic Compute Cloud User Guide for Linux.

3. To connect to your Amazon RDS DB instance from your Amazon EC2 instance, edit your VPC security group. Add an inbound rule specifying the private IP address of your EC2 instance. You can find the private IP address on the Details tab of the Instance pane in the EC2 console window. To edit the VPC security group and add an inbound rule, choose Security Groups in the EC2 console navigation pane, choose your security group, and then add an inbound rule for MySQL or Aurora specifying the private IP address of your EC2 instance. To learn how to add an inbound rule to a VPC security group, see Adding and removing rules in the Amazon VPC User Guide.

4. Copy your compressed database backup file from your local system to your Amazon EC2 instance. Use chmod if necessary to make sure that you have write permission for the target directory of the Amazon EC2 instance. You can use scp or a Secure Shell (SSH) client to copy the file. The following is an example.

```bash
$ scp -i key_pair.pem backup.sql.gz ec2-user@EC2 DNS:/target_directory/backup.sql.gz
```

Important

Be sure to copy sensitive data using a secure network transfer protocol.
5. Connect to your Amazon EC2 instance and install the latest updates and the MySQL client tools using the following commands.

```
sudo yum update -y
sudo yum install mysql -y
```

For more information, see [Connect to your instance](#) in the *Amazon Elastic Compute Cloud User Guide for Linux*.

**Important**

This example installs the MySQL client on an Amazon Machine Image (AMI) for an Amazon Linux distribution. To install the MySQL client on a different distribution, such as Ubuntu or RedHat Enterprise Linux, this example doesn't work. For information about installing MySQL, see [Installing and Upgrading MySQL](#) in the MySQL documentation.

6. While connected to your Amazon EC2 instance, decompress your database backup file. The following are examples.

- To decompress SQL output, use the following command.

```
gzip backup.sql.gz -d
```

- To decompress delimited-text output, use the following command.

```
tar xzvf backup.tar.gz
```

---

**Create a MySQL or MariaDB DB instance and import data from your Amazon EC2 instance**

By creating a MariaDB or MySQL DB instance in the same AWS Region as your Amazon EC2 instance, you can import the database backup file from EC2 faster than over the internet.
To create a MariaDB or MySQL DB instance and import your data

1. Determine which DB instance class and what amount of storage space is required to support the expected workload for this Amazon RDS DB instance. As part of this process, decide what is sufficient space and processing capacity for your data load procedures. Also decide what is required to handle the production workload. You can estimate this based on the size and resources of the source MariaDB or MySQL database. For more information, see DB instance classes (p. 10).

2. Determine if Amazon RDS provisioned I/O operations per second (IOPS) is required to support the workloads. Provisioned IOPS storage delivers fast throughput for online transaction processing (OLTP) workloads, which are I/O intensive. For more information, see Provisioned IOPS SSD storage (p. 73).

3. Open the Amazon RDS console. In the upper-right corner, choose the AWS Region that contains your Amazon EC2 instance.

4. In the navigation pane, choose Databases.

5. Choose Create database, and then go through the steps to choose options for your DB instance:
   a. Make sure that Standard Create is chosen.
   b. In the Engine options section, choose MySQL or MariaDB, as appropriate.
   c. For Version, choose the version that is compatible with your source MySQL instance, as follows:
      • If your source instance is MySQL 5.5.x, the Amazon RDS DB instance must be MySQL.
      • If your source instance is MySQL 5.6.x or 5.7.x, the Amazon RDS DB instance must be MySQL or MariaDB.
      • If your source instance is MySQL 8.0.x, the Amazon RDS DB instance must be MySQL 8.0.x.
      • If your source instance is MariaDB 5.5 or higher, the Amazon RDS DB instance must be MariaDB.
   d. In the Templates section, choose Dev/Test to skip configuring Multi-AZ deployment and provisioned IOPS storage.
   e. In the Settings section, specify the requested DB instance identifier and user information.
   f. In the DB instance class and Storage sections, specify the DB instance class and allocated storage size that you want.
   g. In the Availability & durability section, choose Do not create a standby instance for Multi-AZ deployment.
   h. In the Connectivity section, choose the same virtual private cloud (VPC) and VPC security group as for your Amazon EC2 instance. This approach ensures that your Amazon EC2 instance and your Amazon RDS instance are visible to each other over the network. Set Publicly accessible to Yes. To set up replication with your source database as described later, your DB instance must be publicly accessible.

   Use the default values for the other settings in this section.

   In the Backup section, set the backup retention period to 0 days.

   Use the default values for the other settings in this section.

   i. Open the Additional configuration section, and specify an Initial database name.

   Set the Backup retention period to 0 days

   Use the default values for the other settings in this section.

   j. Choose Create database.

Your new DB instance appears in the Databases list with the status Creating. Wait for the Status of your new DB instance to show as Available.
Don’t configure multiple Availability Zones, backup retention, or read replicas until after you have imported the database backup. When that import is done, you can set Multi-AZ and backup retention the way that you want them for the production instance. For a detailed walkthrough of creating a DB instance, see Creating an Amazon RDS DB instance (p. 236).

6. Review the default configuration options for the Amazon RDS DB instance. In the RDS console navigation pane, choose Parameter groups, and then choose the magnifying glass icon next to the default.mysqlx.x or default.mariadbx.x parameter group. If this parameter group doesn't have the configuration options that you want, find a different one that does or create a new parameter group. For more information on creating a parameter group, see Working with parameter groups (p. 295).

To use a different parameter group than the default, associate it with your Amazon RDS DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 333).

7. Connect to the new Amazon RDS DB instance as the master user. Create the users required to support the administrators, applications, and services that need to access the instance. The host name for the Amazon RDS DB instance is the Endpoint value for this instance without including the port number. An example is mysampledb.claxc2oy9ak1.us-west-2.rds.amazonaws.com. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

8. Connect to your Amazon EC2 instance. For more information, see Connect to your instance in the Amazon Elastic Compute Cloud User Guide for Linux.

9. Connect to your Amazon RDS DB instance as a remote host from your Amazon EC2 instance using the mysql command. The following is an example.

```bash
mysql -h host_name -P 3306 -u db_master_user -p
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

10. At the mysql prompt, run the source command and pass it the name of your database dump file to load the data into the Amazon RDS DB instance:

   • For SQL format, use the following command.

     ```
     mysql> source backup.sql;
     ```

   • For delimited-text format, first create the database, if it isn't the default database you created when setting up the Amazon RDS DB instance.

     ```
     mysql> create database database_name;
     $ mysql> use database_name;
     ```

     Then create the tables.

     ```
     mysql> source table1.sql
     $ mysql> source table2.sql etc...
     ```

     Then import the data.

     ```
     mysql> LOAD DATA LOCAL INFILE 'table1.txt' INTO TABLE table1 FIELDS TERMINATED BY ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
     $ mysql> LOAD DATA LOCAL INFILE 'table2.txt' INTO TABLE table2 FIELDS TERMINATED BY ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
     etc...
     ```
To improve performance, you can perform these operations in parallel from multiple connections so that all of your tables get created and then loaded at the same time.

**Note**

If you used any data-formatting options with mysqldump when you initially dumped the table, make sure to use the same options with mysqlimport or LOAD DATA LOCAL INFILE to ensure proper interpretation of the data file contents.

11. Run a simple SELECT query against one or two of the tables in the imported database to verify that the import was successful.

If you no longer need the Amazon EC2 instance used in this procedure, terminate the EC2 instance to reduce your AWS resource usage. To terminate an EC2 instance, see *Terminating an instance* in the *Amazon EC2 User Guide*.

### Replicate between your external database and new Amazon RDS DB instance

Your source database was likely updated during the time that it took to copy and transfer the data to the MariaDB or MySQL DB instance. That being the case, you can use replication to bring the copied database up-to-date with the source database.

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure to use either the Amazon RDS mysql.rds_set_external_master (p. 1488) command or the mysql.rds_set_external_master_gtid (p. 1091) command to configure replication, and the mysql.rds_start_replication (p. 1504) command to start replication between your live database and your Amazon RDS database.

**To start replication**

Earlier, you turned on binary logging and set a unique server ID for your source database. Now you can set up your Amazon RDS DB instance as a replica with your live database as the source replication instance.
1. In the Amazon RDS Management Console, add the IP address of the server that hosts the source database to the VPC security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance, so that it can communicate with your source instance. To find the IP address of the Amazon RDS DB instance, use the host command.

   host  db_instance_endpoint

The host name is the DNS name from the Amazon RDS DB instance endpoint, for example myinstance.123456789012.us-east-1.rds.amazonaws.com. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

2. Using the client of your choice, connect to the source instance and create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

MySQL 5.5, 5.6, and 5.7

   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';

MySQL 8.0

   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';

3. For the source instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

MySQL 5.5, 5.6, and 5.7

   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';

MySQL 8.0

   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';

4. If you used SQL format to create your backup file and the external instance is not MariaDB 10.0.24 or higher, look at the contents of that file.

   cat backup.sql

The file includes a CHANGE MASTER TO comment that contains the master log file name and position. This comment is included in the backup file when you use the --master-data option with mysqldump. Note the values for MASTER_LOG_FILE and MASTER_LOG_POS.

```
--
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```
If you used delimited text format to create your backup file and the external instance isn't MariaDB 10.0.24 or higher, you should already have binary log coordinates from step 1 of the procedure at "To create a backup copy of your existing database" in this topic.

If the external instance is MariaDB 10.0.24 or higher, you should already have the GTID from which to start replication from step 2 of the procedure at "To create a backup copy of your existing database" in this topic.

5. Make the Amazon RDS DB instance the replica. If the external instance isn't MariaDB 10.0.24 or higher, connect to the Amazon RDS DB instance as the master user and identify the source database as the source replication instance by using the `mysql.rds_set_external_master` (p. 1488) command. Use the master log file name and master log position that you determined in the previous step if you have a SQL format backup file. Or use the name and position that you determined when creating the backup files if you used delimited-text format. The following is an example.

```
CALL mysql.rds_set_external_master ('myserver.mydomain.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

If the external instance is MariaDB 10.0.24 or higher, connect to the Amazon RDS DB instance as the master user and identify the source database as the source replication instance by using the `mysql.rds_set_external_master_gtid` (p. 1091) command. Use the GTID that you determined in step 2 of the procedure at "To create a backup copy of your existing database" in this topic. The following is an example.

```
CALL mysql.rds_set_external_master_gtid ('source_server_ip_address', 3306, 'ReplicationUser', 'password', 'GTID', 0);
```

The `source_server_ip_address` is the IP address of source replication instance. An EC2 private DNS address is currently not supported.

6. On the Amazon RDS DB instance, issue the `mysql.rds_start_replication` (p. 1504) command to start replication.

```
CALL mysql.rds_start_replication;
```

7. On the Amazon RDS DB instance, run the `SHOW REPLICA STATUS` command to determine when the replica is up-to-date with the source replication instance. The results of the `SHOW REPLICA STATUS` command include the `Seconds_Behind_Master` field. When the `Seconds_Behind_Master` field returns 0, then the replica is up-to-date with the source replication instance.

**Note**
Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

For a MariaDB 10.5 or 10.6 DB instance, run the `mysql.rds_replica_status` (p. 1090) procedure instead of the MySQL command.

8. After the Amazon RDS DB instance is up-to-date, turn on automated backups so you can restore that database if needed. You can turn on or modify automated backups for your Amazon RDS DB instance using the Amazon RDS Management Console. For more information, see Working with backups (p. 462).

### Redirect your live application to your Amazon RDS instance

After the MariaDB or MySQL DB instance is up-to-date with the source replication instance, you can now update your live application to use the Amazon RDS instance.
To redirect your live application to your MariaDB or MySQL DB instance and stop replication

1. To add the VPC security group for the Amazon RDS DB instance, add the IP address of the server that hosts the application. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

2. Verify that the Seconds_Behind_Master field in the SHOW REPLICA STATUS command results is 0, which indicates that the replica is up-to-date with the source replication instance.

```
SHOW REPLICA STATUS;
```

**Note**

Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

For a MariaDB 10.5 or 10.6 DB instance, run the `mysql.rds_replica_status` procedure instead of the MySQL command.

3. Close all connections to the source when their transactions complete.

4. Update your application to use the Amazon RDS DB instance. This update typically involves changing the connection settings to identify the host name and port of the Amazon RDS DB instance, the user account and password to connect with, and the database to use.

5. Stop replication for the Amazon RDS instance using the `mysql.rds_stop_replication` command.

```
CALL mysql.rds_stop_replication;
```

6. Run the `mysql.rds_reset_external_master` command on your Amazon RDS DB instance to reset the replication configuration so this instance is no longer identified as a replica.

```
CALL mysql.rds_reset_external_master;
```
7. Turn on additional Amazon RDS features such as Multi-AZ support and read replicas. For more information, see Multi-AZ deployments for high availability (p. 125) and Working with read replicas (p. 382).

**Importing data from any source to a MariaDB or MySQL DB instance**

If you have more than 1 GiB of data to load, or if your data is coming from somewhere other than a MariaDB or MySQL database, we recommend creating flat files and loading them with mysqlimport. The mysqlimport utility is another command line utility bundled with the MySQL and MariaDB client software. Its purpose is to load flat files into MySQL or MariaDB. For information about mysqlimport, see mysqlimport - a data import program in the MySQL documentation.

We also recommend creating DB snapshots of the target Amazon RDS DB instance before and after the data load. Amazon RDS DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. When you initiate a DB snapshot, I/O operations to your DB instance are momentarily suspended while your database is backed up.

Creating a DB snapshot immediately before the load makes it possible for you to restore the database to its state before the load, if you need to. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap and can also be used to seed new database instances.

The following list shows the steps to take. Each step is discussed in more detail following.

1. Create flat files containing the data to be loaded.
2. Stop any applications accessing the target DB instance.
3. Create a DB snapshot.
4. Consider turning off Amazon RDS automated backups.
5. Load the data using mysqlimport.
6. Enable automated backups again.

**Step 1: Create flat files containing the data to be loaded**

Use a common format, such as comma-separated values (CSV), to store the data to be loaded. Each table must have its own file; you can't combine data for multiple tables in the same file. Give each file the same name as the table it corresponds to. The file extension can be anything you like. For example, if the table name is sales, the file name might be sales.csv or sales.txt, but not sales_01.csv.

Whenever possible, order the data by the primary key of the table being loaded. Doing this drastically improves load times and minimizes disk storage requirements.

The speed and efficiency of this procedure depends on keeping the size of the files small. If the uncompressed size of any individual file is larger than 1 GiB, split it into multiple files and load each one separately.

On Unix-like systems (including Linux), use the split command. For example, the following command splits the sales.csv file into multiple files of less than 1 GiB, splitting only at line breaks (-C 1024m). The new files are named sales.part_00, sales.part_01, and so on.

```
split -C 1024m -d sales.csv sales.part_
```

Similar utilities are available for other operating systems.
Importing data from any source

Step 2: Stop any applications accessing the target DB instance

Before starting a large load, stop all application activity accessing the target DB instance that you plan to load to. We recommend this particularly if other sessions will be modifying the tables being loaded or tables that they reference. Doing this reduces the risk of constraint violations occurring during the load and improves load performance. It also makes it possible to restore the DB instance to the point just before the load without losing changes made by processes not involved in the load.

Of course, this might not be possible or practical. If you can't stop applications from accessing the DB instance before the load, take steps to ensure the availability and integrity of your data. The specific steps required vary greatly depending upon specific use cases and site requirements.

Step 3: Create a DB snapshot

If you plan to load data into a new DB instance that contains no data, you can skip this step. Otherwise, creating a DB snapshot of your DB instance makes it possible for you to restore the DB instance to the point just before the load, if it becomes necessary. As previously mentioned, when you initiate a DB snapshot, I/O operations to your DB instance are suspended for a few minutes while the database is backed up.

The example following uses the AWS CLI `create-db-snapshot` command to create a DB snapshot of the AcmeRDS instance and give the DB snapshot the identifier "preload".

For Linux, macOS, or Unix:

```bash
aws rds create-db-snapshot --db-instance-identifier AcmeRDS --db-snapshot-identifier preload
```

For Windows:

```bash
aws rds create-db-snapshot --db-instance-identifier AcmeRDS --db-snapshot-identifier preload
```

You can also use the restore from DB snapshot functionality to create test DB instances for dry runs or to undo changes made during the load.

Keep in mind that restoring a database from a DB snapshot creates a new DB instance that, like all DB instances, has a unique identifier and endpoint. To restore the DB instance without changing the endpoint, first delete the DB instance so that you can reuse the endpoint.

For example, to create a DB instance for dry runs or other testing, you give the DB instance its own identifier. In the example, AcmeRDS-2^ is the identifier. The example connects to the DB instance using the endpoint associated with AcmeRDS-2^.

For Linux, macOS, or Unix:

```bash
aws rds restore-db-instance-from-db-snapshot --db-instance-identifier AcmeRDS-2 --db-snapshot-identifier preload
```

For Windows:

```bash
aws rds restore-db-instance-from-db-snapshot --db-instance-identifier AcmeRDS-2 --db-snapshot-identifier preload
```
To reuse the existing endpoint, first delete the DB instance and then give the restored database the same identifier.

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
  --db-instance-identifier AcmeRDS \
  --final-db-snapshot-identifier AcmeRDS-Final
aws rds restore-db-instance-from-db-snapshot \
  --db-instance-identifier AcmeRDS \
  --db-snapshot-identifier preload
```

For Windows:

```
aws rds delete-db-instance ^
  --db-instance-identifier AcmeRDS ^
  --final-db-snapshot-identifier AcmeRDS-Final
aws rds restore-db-instance-from-db-snapshot ^
  --db-instance-identifier AcmeRDS ^
  --db-snapshot-identifier preload
```

The preceding example takes a final DB snapshot of the DB instance before deleting it. This is optional but recommended.

### Step 4: Consider turning off Amazon RDS automated backups

**Warning**

Do not turn off automated backups if you need to perform point-in-time recovery.

Turning off automated backups erases all existing backups, so point-in-time recovery isn't possible after automated backups have been turned off. Disabling automated backups is a performance optimization and isn't required for data loads. Manual DB snapshots aren't affected by turning off automated backups. All existing manual DB snapshots are still available for restore.

Turning off automated backups reduces load time by about 25 percent and reduces the amount of storage space required during the load. If you plan to load data into a new DB instance that contains no data, turning off backups is an easy way to speed up the load and avoid using the additional storage needed for backups. However, in some cases you might plan to load into a DB instance that already contains data. If so, weigh the benefits of turning off backups against the impact of losing the ability to perform point-in-time-recovery.

DB instances have automated backups turned on by default (with a one day retention period). To turn off automated backups, set the backup retention period to zero. After the load, you can turn backups back on by setting the backup retention period to a nonzero value. To turn on or turn off backups, Amazon RDS shuts the DB instance down and restarts it to turn MariaDB or MySQL logging on or off.

Use the AWS CLI `modify-db-instance` command to set the backup retention to zero and apply the change immediately. Setting the retention period to zero requires a DB instance restart, so wait until the restart has completed before proceeding.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier AcmeRDS \
```

1062
---apply-immediately \ 
--backup-retention-period 0

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier AcmeRDS ^
  --apply-immediately ^
  --backup-retention-period 0
```

You can check the status of your DB instance with the AWS CLI describe-db-instances command. The following example displays the DB instance status of the AcmeRDS DB instance.

```bash
aws rds describe-db-instances --db-instance-identifier AcmeRDS --query "*[].{DBInstanceStatus:DBInstanceStatus}"
```

When the DB instance status is available, you're ready to proceed.

**Step 5: Load the data**

Use the mysqlimport utility to load the flat files into Amazon RDS. The following example tells mysqlimport to load all of the files named "sales" with an extension starting with "part_". This is a convenient way to load all of the files created in the "split" example.

Use the --compress option to minimize network traffic. The --fields-terminated-by=',' option is used for CSV files, and the --local option specifies that the incoming data is located on the client. Without the --local option, the Amazon RDS DB instance looks for the data on the database host, so always specify the --local option. For the --host option, specify the DB instance endpoint of the RDS for MySQL DB instance.

In the following examples, replace `master_user` with the master username for your DB instance.

Replace `hostname` with the endpoint for your DB instance. An example of a DB instance endpoint is `my-db-instance.123456789012.us-west-2.rds.amazonaws.com`.

For RDS for MySQL version 8.0.15 and higher, run the following statement before using the mysqlimport utility.

```
GRANT SESSION_VARIABLES_ADMIN ON *.* TO master_user;
```

For Linux, macOS, or Unix:

```bash
mysqlimport --local \ 
  --compress \ 
  --user=master_user \ 
  --password \ 
  --host=hostname \ 
  --fields-terminated-by=',' Acme sales.part_*
```

For Windows:

```bash
mysqlimport --local ^
  --compress ^
  --user=master_user ^
  --password ^
  --host=hostname ^
  --fields-terminated-by=""," Acme sales.part_*
```
For very large data loads, take additional DB snapshots periodically between loading files and note which files have been loaded. If a problem occurs, you can easily resume from the point of the last DB snapshot, avoiding lengthy reloads.

**Step 6: Turn Amazon RDS automated backups back on**

After the load is finished, turn Amazon RDS automated backups on by setting the backup retention period back to its preload value. As noted earlier, Amazon RDS restarts the DB instance, so be prepared for a brief outage.

The following example uses the AWS CLI modify-db-instance command to turn on automated backups for the AcmeRDS DB instance and set the retention period to one day.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier AcmeRDS \
  --backup-retention-period 1 \
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier AcmeRDS ^
  --backup-retention-period 1 ^
  --apply-immediately
```
Working with MariaDB replication in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with read replicas (p. 382). For specific information about working with read replicas on Amazon RDS for MariaDB, see Working with MariaDB read replicas (p. 1065).

You can also configure replication based on binary log coordinates for a MariaDB DB instance. For MariaDB instances, you can also configure replication based on global transaction IDs (GTIDs), which provides better crash safety. For more information, see Configuring GTID-based replication with an external source instance (p. 1075).

The following are other replication options available with RDS for MariaDB:

- You can set up replication between an RDS for MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS. For information about configuring replication with an external source, see Configuring binary log file position replication with an external source instance (p. 1077).
- You can configure replication to import databases from a MySQL or MariaDB instance that is external to Amazon RDS, or to export databases to such instances. For more information, see Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1047) and Exporting data from a MySQL DB instance by using replication (p. 1459).

For any of these replication options, you can use either row-based replication, statement-based, or mixed replication. Row-based replication only replicates the changed rows that result from a SQL statement. Statement-based replication replicates the entire SQL statement. Mixed replication uses statement-based replication when possible, but switches to row-based replication when SQL statements that are unsafe for statement-based replication are run. In most cases, mixed replication is recommended. The binary log format of the DB instance determines whether replication is row-based, statement-based, or mixed. For information about setting the binary log format, see Binary logging format (p. 728).

Topics
- Working with MariaDB read replicas (p. 1065)
- Configuring GTID-based replication with an external source instance (p. 1075)
- Configuring binary log file position replication with an external source instance (p. 1077)

Working with MariaDB read replicas

Following, you can find specific information about working with read replicas on Amazon RDS for MariaDB. For general information about read replicas and instructions for using them, see Working with read replicas (p. 382).

Topics
- Configuring read replicas with MariaDB (p. 1066)
- Configuring replication filters with MariaDB (p. 1066)
- Configuring delayed replication with MariaDB (p. 1071)
- Updating read replicas with MariaDB (p. 1072)
- Working with Multi-AZ read replica deployments with MariaDB (p. 1072)
- Using cascading read replicas with RDS for MariaDB (p. 1072)
- Monitoring MariaDB read replicas (p. 1073)
- Starting and stopping replication with MariaDB read replicas (p. 1074)
- Troubleshooting a MariaDB read replica problem (p. 1074)
Configuring read replicas with MariaDB

Before a MariaDB DB instance can serve as a replication source, make sure to turn on automatic backups on the source DB instance by setting the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica.

You can create up to 15 read replicas from one DB instance within the same Region. For replication to operate effectively, each read replica should have as the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

RDS for MariaDB supports cascading read replicas. To learn how to configure cascading read replicas, see Using cascading read replicas with RDS for MariaDB (p. 1072).

You can run multiple read replica create and delete actions at the same time that reference the same source DB instance. When you perform these actions, stay within the limit of 15 read replicas for each source instance.

Configuring replication filters with MariaDB

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB instance that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.

Note

You can also use replication filters to specify which databases and tables are replicated with a primary MariaDB DB instance that is configured as a replica in an inbound replication topology. For more information about this configuration, see Configuring binary log file position replication with an external source instance (p. 1455).

Topics

- Setting replication filtering parameters for RDS for MariaDB (p. 1066)
- Replication filtering limitations for RDS for MariaDB (p. 1067)
- Replication filtering examples for RDS for MariaDB (p. 1067)
- Viewing the replication filters for a read replica (p. 1070)

Setting replication filtering parameters for RDS for MariaDB

To configure replication filters, set the following replication filtering parameters on the read replica:

- `replicate-do-db` – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- `replicate-ignore-db` – Don't replicate changes to the specified databases. When the `replicate-do-db` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-do-table` – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the `replicate-do-`
db or replicate-ignore-db parameter is set, the database that includes the specified tables must be included in replication with the read replica.

- replicate-ignore-table – Don't replicate changes to the specified tables. When the replicate-do-table parameter is set for a read replica, this parameter isn't evaluated.
- replicate-wild-do-table – Replicate tables based on the specified database and table name patterns. The % and _ wildcard characters are supported. When the replicate-do-db or replicate-ignore-db parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- replicate-wild-ignore-table – Don't replicate tables based on the specified database and table name patterns. The % and _ wildcard characters are supported. When the replicate-do-table or replicate-wild-do-table parameter is set for a read replica, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MariaDB documentation.

By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the % and _ wildcard characters in the replicate-wild-do-table and replicate-wild-ignore-table parameters. The % wildcard matches any number of characters, and the _ wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the binlog_format parameter determines whether the replication is row-based or statement-based. For more information, see Binary logging format (p. 728).

Note
All data definition language (DDL) statements are replicated as statements, regardless of the binlog_format setting on the source DB instance.

Replication filtering limitations for RDS for MariaDB

The following limitations apply to replication filtering for RDS for MariaDB:

- Each replication filtering parameter has a 2,000-character limit.
- Commas aren't supported in replication filters.
- The MariaDB binlog_do_db and binlog_ignore_db options for binary log filtering aren't supported.
- Replication filtering doesn't support XA transactions.

For more information, see Restrictions on XA Transactions in the MySQL documentation.

Replication filtering isn't supported for RDS for MariaDB version 10.2.

Replication filtering examples for RDS for MariaDB

To configure replication filtering for a read replica, modify the replication filtering parameters in the parameter group associated with the read replica.

Note
You can't modify a default parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB parameter groups, see Working with parameter groups (p. 295).

You can set parameters in a parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see Modifying parameters in a DB parameter group (p. 300).

When you set parameters in a parameter group, all of the DB instances associated with the parameter
group use the parameter settings. If you set the replication filtering parameters in a parameter group, make sure that the parameter group is associated only with read replicas. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set `ApplyMethod` to `pending-reboot`.

The following examples set replication filters:

- Including databases in replication
- Including tables in replication
- Including tables in replication with wildcard characters
- Escaping wildcard characters in names
- Excluding databases from replication
- Excluding tables from replication
- Excluding tables from replication using wildcard characters

**Example Including databases in replication**

The following example includes the `mydb1` and `mydb2` databases in replication. When you set `replicate-do-db` for a read replica, only the databases specified in the parameter are replicated.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group
  --db-parameter-group-name myparametergroup
  --parameters
  
  ["ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2",
  "ApplyMethod": "immediate"]
```

For Windows:

```bash
aws rds modify-db-parameter-group
  --db-parameter-group-name myparametergroup
  --parameters
  
  ["ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2",
  "ApplyMethod": "immediate"]
```

**Example Including tables in replication**

The following example includes the `table1` and `table2` tables in database `mydb1` in replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group
  --db-parameter-group-name myparametergroup
  --parameters
  
  ["ParameterName": "replicate-do-table", "ParameterValue": "mydb1.table1,mydb1.table2",
  "ApplyMethod": "immediate"]
```

For Windows:

```bash
aws rds modify-db-parameter-group
  --db-parameter-group-name myparametergroup
  --parameters
  
  ["ParameterName": "replicate-do-table", "ParameterValue": "mydb1.table1,mydb1.table2",
  "ApplyMethod": "immediate"]
```
Amazon Relational Database Service User Guide
Working with MariaDB read replicas

Example Including tables in replication using wildcard characters
The following example includes tables with names that begin with orders and returns in database
mydb in replication.
For Linux, macOS, or Unix:
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue":
"mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"}]"

For Windows:
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue":
"mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"}]"

Example Escaping wildcard characters in names
The following example shows you how to use the escape character \ to escape a wildcard character that
is part of a name.
Assume that you have several table names in database mydb1 that start with my_table, and you want
to include these tables in replication. The table names include an underscore, which is also a wildcard
character, so the example escapes the underscore in the table names.
For Linux, macOS, or Unix:
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue": "my\_table
%", "ApplyMethod":"immediate"}]"

For Windows:
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue": "my\_table
%", "ApplyMethod":"immediate"}]"

Example Excluding databases from replication
The following example excludes the mydb1 and mydb2 databases from replication.
For Linux, macOS, or Unix:
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-ignore-db", "ParameterValue": "mydb1,mydb2",
"ApplyMethod":"immediate"}]"

For Windows:
aws rds modify-db-parameter-group ^

1069


Example Excluding tables from replication

The following example excludes tables table1 and table2 in database mydb1 from replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \ 
--db-parameter-group-name myparametergroup \ 
--parameters "["ParameterName": "replicate-ignore-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod": "immediate"]"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
   --db-parameter-group-name myparametergroup ^
   --parameters "["ParameterName": "replicate-ignore-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod": "immediate"]"
```

Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with orders and returns in database mydb from replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \ 
--db-parameter-group-name myparametergroup \ 
--parameters "["ParameterName": "replicate-wild-ignore-table", "ParameterValue": "mydb.orders%,mydb.returns%", "ApplyMethod": "immediate"]"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
   --db-parameter-group-name myparametergroup ^
   --parameters "["ParameterName": "replicate-wild-ignore-table", "ParameterValue": "mydb.orders%,mydb.returns%", "ApplyMethod": "immediate"]"
```

Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.

  For instructions, see Viewing parameter values for a DB parameter group (p. 307).

- In a MariaDB client, connect to the read replica and run the `SHOW REPLICA STATUS` statement.

In the output, the following fields show the replication filters for the read replica:

- Replicate_Do_DB
- Replicate_Ignore_DB
- Replicate_Do_Table
- Replicate_Ignore_Table
Configuring delayed replication with MariaDB

You can use delayed replication as a strategy for disaster recovery. With delayed replication, you specify the minimum amount of time, in seconds, to delay replication from the source to the read replica. In the event of a disaster, such as a table deleted unintentionally, you complete the following steps to recover from the disaster quickly:

- Stop replication to the read replica before the change that caused the disaster is sent to it.
- Promote the read replica to be the new source DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 389).

Note

- Delayed replication is supported for MariaDB 10.6 and higher.
- Use stored procedures to configure delayed replication. You can't configure delayed replication with the AWS Management Console, the AWS CLI, or the Amazon RDS API.
- You can use replication based on global transaction identifiers (GTIDs) in a delayed replication configuration.

Topics

- Configuring delayed replication during read replica creation (p. 1071)
- Modifying delayed replication for an existing read replica (p. 1072)
- Promoting a read replica (p. 1072)

Configuring delayed replication during read replica creation

To configure delayed replication for any future read replica created from a DB instance, run the mysql.rds_set_configuration (p. 1511) stored procedure with the target delay parameter.

To configure delayed replication during read replica creation

1. Using a MariaDB client, connect to the MariaDB DB instance to be the source for read replicas as the master user.
2. Run the mysql.rds_set_configuration (p. 1511) stored procedure with the target delay parameter.

For example, run the following stored procedure to specify that replication is delayed by at least one hour (3,600 seconds) for any read replica created from the current DB instance.

```sql
call mysql.rds_set_configuration('target delay', 3600);
```
Modifying delayed replication for an existing read replica

To modify delayed replication for an existing read replica, run the `mysql.rds_set_source_delay` stored procedure.

To modify delayed replication for an existing read replica

1. Using a MariaDB client, connect to the read replica as the master user.
2. Use the `mysql.rds_stop_replication` stored procedure to stop replication.
3. Run the `mysql.rds_set_source_delay` stored procedure.

   For example, run the following stored procedure to specify that replication to the read replica is delayed by at least one hour (3600 seconds).

   ```sql
   call mysql.rds_set_source_delay(3600);
   ```

4. Use the `mysql.rds_start_replication` stored procedure to start replication.

Promoting a read replica

After replication is stopped, in a disaster recovery scenario, you can promote a read replica to be the new source DB instance. For information about promoting a read replica, see Promoting a read replica to be a standalone DB instance (p. 389).

Updating read replicas with MariaDB

Read replicas are designed to support read queries, but you might need occasional updates. For example, you might need to add an index to speed the specific types of queries accessing the replica. You can enable updates by setting the `read_only` parameter to 0 in the DB parameter group for the read replica.

Working with Multi-AZ read replica deployments with MariaDB

You can create a read replica from either single-AZ or Multi-AZ DB instance deployments. You use Multi-AZ deployments to improve the durability and availability of critical data, but you can’t use the Multi-AZ secondary to serve read-only queries. Instead, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. If the source instance of a Multi-AZ deployment fails over to the secondary, any associated read replicas automatically switch to use the secondary (now primary) as their replication source. For more information, see Multi-AZ deployments for high availability (p. 125).

You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

Using cascading read replicas with RDS for MariaDB

RDS for MariaDB supports cascading read replicas. With cascading read replicas, you can scale reads without adding overhead to your source RDS for MariaDB DB instance.

With cascading read replicas, your RDS for MariaDB DB instance sends data to the first read replica in the chain. That read replica then sends data to the second replica in the chain, and so on. The end result is
that all read replicas in the chain have the changes from the RDS for MariaDB DB instance, but without
the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for MariaDB DB instance.
For example, suppose that you have an RDS for MariaDB DB instance, mariadb-main. You can do the
following:

• Starting with mariadb-main, create the first read replica in the chain, read-replica-1.
• Next, from read-replica-1, create the next read replica in the chain, read-replica-2.
• Finally, from read-replica-2, create the third read replica in the chain, read-replica-3.

You can't create another read replica beyond this third cascading read replica in the series for mariadb-
main. A complete series of instances from an RDS for MariaDB source DB instance through to the end of
a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, each source RDS for MariaDB DB instance must have automated
backups turned on. To turn on automatic backups on a read replica, first create the read replica, and
then modify the read replica to turn on automatic backups. For more information, see Creating a read
replica (p. 387).

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read
replica from within a chain of read replicas removes that replica from the chain. For example, suppose
that you want to move some of the workload from your mariadb-main DB instance to a new instance
for use by the accounting department only. Assuming the chain of three read replicas from the example,
you decide to promote read-replica-2. The chain is affected as follows:

• Promoting read-replica-2 removes it from the replication chain.
  • It is now a full read/write DB instance.
  • It continues replicating to read-replica-3, just as it was doing before promotion.
• Your mariadb-main continues replicating to read-replica-1.

For more information about promoting read replicas, see Promoting a read replica to be a standalone DB
instance (p. 389).

Monitoring MariaDB read replicas

For MariaDB read replicas, you can monitor replication lag in Amazon CloudWatch by viewing
the Amazon RDS ReplicaLag metric. The ReplicaLag metric reports the value of the
Seconds_Behind_Master field of the SHOW REPLICA STATUS command.

  Note
  Previous versions of MariaDB used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If
  you are using a MariaDB version before 10.5, then use SHOW SLAVE STATUS.

Common causes for replication lag for MariaDB are the following:

• A network outage.
• Writing to tables with indexes on a read replica. If the read_only parameter is not set to 0 on the
  read replica, it can break replication.
• Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB
  storage engine on MariaDB.

When the ReplicaLag metric reaches 0, the replica has caught up to the source DB instance. If the
ReplicaLag metric returns -1, then replication is currently not active. ReplicaLag = -1 is equivalent to
Seconds_Behind_Master = NULL.
Starting and stopping replication with MariaDB read replicas

You can stop and restart the replication process on an Amazon RDS DB instance by calling the system stored procedures `mysql.rds_stop_replication` (p. 1507) and `mysql.rds_start_replication` (p. 1504). You can do this when replicating between two Amazon RDS instances for long-running operations such as creating large indexes. You also need to stop and start replication when importing or exporting databases. For more information, see Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1418) and Exporting data from a MySQL DB instance by using replication (p. 1459).

If replication is stopped for more than 30 consecutive days, either manually or due to a replication error, Amazon RDS ends replication between the source DB instance and all read replicas. It does so to prevent increased storage requirements on the source DB instance and long failover times. The read replica DB instance is still available. However, replication can't be resumed because the binary logs required by the read replica are deleted from the source DB instance after replication is ended. You can create a new read replica for the source DB instance to reestablish replication.

Troubleshooting a MariaDB read replica problem

The replication technologies for MariaDB are asynchronous. Because they are asynchronous, occasional `BinLogDiskUsage` increases on the source DB instance and `ReplicaLag` on the read replica are to be expected. For example, a high volume of write operations to the source DB instance can occur in parallel. In contrast, write operations to the read replica are serialized using a single I/O thread, which can lead to a lag between the source instance and read replica. For more information about read-only replicas in the MariaDB documentation, go to Replication overview.

You can do several things to reduce the lag between updates to a source DB instance and the subsequent updates to the read replica, such as the following:

- Sizing a read replica to have a storage size and DB instance class comparable to the source DB instance.
- Ensuring that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter later in this section.

Amazon RDS monitors the replication status of your read replicas and updates the Replication State field of the read replica instance to Error if replication stops for any reason. An example might be if DML queries run on your read replica conflict with the updates made on the source DB instance.

You can review the details of the associated error thrown by the MariaDB engine by viewing the Replication Error field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045 (p. 710), RDS-EVENT-0046 (p. 710), and RDS-EVENT-0047 (p. 707). For more information about events and subscribing to events, see Working with Amazon RDS event notification (p. 685). If a MariaDB error message is returned, review the error in the MariaDB error message documentation.

One common issue that can cause replication errors is when the value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance. The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group that is used to specify the maximum size of DML code that can be run on the database. In some cases, the `max_allowed_packet` parameter value in the DB parameter group associated with a source DB instance is smaller than the `max_allowed_packet` parameter value in the DB parameter group associated with the source's read replica. In these cases, the replication process can throw an error (Packet bigger than 'max_allowed_packet' bytes) and stop replication. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.
Other common situations that can cause replication errors include the following:

- Writing to tables on a read replica. If you are creating indexes on a read replica, you need to have the `read_only` parameter set to 0 to create the indexes. If you are writing to tables on the read replica, it might break replication.
- Using a non-transactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the InnoDB storage engine on MariaDB.
- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see Determination of safe and unsafe statements in binary logging.

If you decide that you can safely skip an error, you can follow the steps described in Skipping the current replication error (p. 1475). Otherwise, you can delete the read replica and create an instance using the same DB instance identifier so that the endpoint remains the same as that of your old read replica. If a replication error is fixed, the Replication State changes to replicating.

For MariaDB DB instances, in some cases read replicas can’t be switched to the secondary if some binary log (binlog) events aren’t flushed during the failure. In these cases, manually delete and recreate the read replicas. You can reduce the chance of this happening by setting the following parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`. These settings might reduce performance, so test their impact before implementing the changes in a production environment.

### Configuring GTID-based replication with an external source instance

You can set up replication based on global transaction identifiers (GTIDs) from an external MariaDB instance of version 10.0.24 or higher into an RDS for MariaDB DB instance. Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

- Monitor failover events for the RDS for MariaDB DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification (p. 685).
- Maintain the binary logs (binlogs) on your source instance until you have verified that they have been applied to the replica. This maintenance ensures that you can restore your source instance in the event of a failure.
- Turn on automated backups on your MariaDB DB instance on Amazon RDS. Turning on automated backups ensures that you can restore your replica to a particular point in time if you need to resynchronize your source instance and replica. For information on backups and Point-In-Time Restore, see Backing up and restoring an Amazon RDS DB instance (p. 461).

**Note**

The permissions required to start replication on a MariaDB DB instance are restricted and not available to your Amazon RDS master user. Because of this, you must use the Amazon RDS `mysql.rds_set_external_master_gtid` (p. 1091) and `mysql.rds_start_replication` (p. 1504) commands to set up replication between your live database and your RDS for MariaDB database.

To start replication between an external source instance and a MariaDB DB instance on Amazon RDS, use the following procedure.

**To start replication**

1. Make the source MariaDB instance read-only:

   ```sql
   mysql> FLUSH TABLES WITH READ LOCK;
   ```
2. Get the current GTID of the external MariaDB instance. You can do this by using \texttt{mysql} or the query editor of your choice to run \texttt{SELECT @@gtid_current_pos;}. The GTID is formatted as \texttt{<domain-id>-<server-id>-<sequence-id>}. A typical GTID looks something like \texttt{0-1234510749-1728}. For more information about GTIDs and their component parts, see \texttt{Global transaction ID} in the MariaDB documentation.

3. Copy the database from the external MariaDB instance to the MariaDB DB instance using \texttt{mysqldump}. For very large databases, you might want to use the procedure in Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1418).

   For Linux, macOS, or Unix:
   \begin{verbatim}
   mysqldump  \
   --databases database_name  \
   --single-transaction  \
   --compress  \
   --order-by-primary  \
   -u local_user  \
   -plocal_password | mysql  \
   --host=hostname  \
   --port=3306  \
   -u RDS_user_name  \
   -pRDS_password
   \end{verbatim}

   For Windows:
   \begin{verbatim}
   mysqldump ^  \
   --databases database_name ^  \
   --single-transaction ^  \
   --compress ^  \
   --order-by-primary ^  \
   -u local_user ^  \
   -plocal_password | mysql ^  \
   --host=hostname ^  \
   --port=3306 ^  \
   -u RDS_user_name ^  \
   -pRDS_password
   \end{verbatim}

   \textbf{Note}
   Make sure that there isn't a space between the \texttt{-p} option and the entered password.

   Use the \texttt{--host}, \texttt{--user (-u)}, \texttt{--port} and \texttt{-p} options in the \texttt{mysql} command to specify the host name, user name, port, and password to connect to your MariaDB DB instance. The host name is the DNS name from the MariaDB DB instance endpoint, for example \texttt{myinstance.123456789012.us-east-1.rds.amazonaws.com}. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

4. Make the source MariaDB instance writeable again.

   mysql> SET GLOBAL read_only = OFF;
   mysql> UNLOCK TABLES;

5. In the Amazon RDS Management Console, add the IP address of the server that hosts the external MariaDB database to the VPC security group for the MariaDB DB instance. For more information on modifying a VPC security group, go to Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

   The IP address can change when the following conditions are met:
• You are using a public IP address for communication between the external source instance and the DB instance.
• The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your MariaDB DB instance, so that it can communicate with your external MariaDB instance. To find the IP address of the MariaDB DB instance, use the `host` command.

```
host db_instance_endpoint
```

The host name is the DNS name from the MariaDB DB instance endpoint.

6. Using the client of your choice, connect to the external MariaDB instance and create a MariaDB user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

7. For the external MariaDB instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

8. Make the MariaDB DB instance the replica. Connect to the MariaDB DB instance as the master user and identify the external MariaDB database as the replication source instance by using the `mysql.rds_set_external_master_gtid` (p. 1091) command. Use the GTID that you determined in Step 2. The following is an example.

```
CALL mysql.rds_set_external_master_gtid ('mymasterserver.mydomain.com', 3306, 'repl_user', 'password', 'GTID', 0);
```

9. On the MariaDB DB instance, issue the `mysql.rds_start_replication` (p. 1504) command to start replication.

```
CALL mysql.rds_start_replication;
```

### Configuring binary log file position replication with an external source instance

You can set up replication between an RDS for MySQL or MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS using binary log file replication.

**Topics**

- Before you begin (p. 1078)
- Configuring binary log file position replication with an external source instance (p. 1078)
Before you begin

You can configure replication using the binary log file position of replicated transactions.

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure that you use the Amazon RDS mysql.rds_set_external_master (p. 1488) and mysql.rds_start_replication (p. 1504) commands to set up replication between your live database and your Amazon RDS database.

To set the binary logging format for a MySQL or MariaDB database, update the binlog_format parameter. If your DB instance uses the default DB instance parameter group, create a new DB parameter group to modify binlog_format settings. We recommend that you use the default setting for binlog_format, which is MIXED. However, you can also set binlog_format to ROW or STATEMENT if you need a specific binary log (binlog) format. Reboot your DB instance for the change to take effect.

For information about setting the binlog_format parameter, see Configuring MySQL binary logging (p. 742). For information about the implications of different MySQL replication types, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

Configuring binary log file position replication with an external source instance

Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

- Monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification (p. 685).
- Maintain the binlogs on your source instance until you have verified that they have been applied to the replica. This maintenance makes sure that you can restore your source instance in the event of a failure.
- Turn on automated backups on your Amazon RDS DB instance. Turning on automated backups makes sure that you can restore your replica to a particular point in time if you need to re-synchronize your source instance and replica. For information on backups and point-in-time restore, see Backing up and restoring an Amazon RDS DB instance (p. 461).

To configure binary log file replication with an external source instance

1. Make the source MySQL or MariaDB instance read-only.

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SET GLOBAL read_only = ON;
   ```

2. Run the SHOW MASTER STATUS command on the source MySQL or MariaDB instance to determine the binlog location.

   You receive output similar to the following example.

<table>
<thead>
<tr>
<th>File</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-bin-changelog.000031</td>
<td>107</td>
</tr>
</tbody>
</table>

3. Copy the database from the external instance to the Amazon RDS DB instance using mysqldump.
   For very large databases, you might want to use the procedure in Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1418).
Configuring binary log file position replication with an external source instance

For Linux, macOS, or Unix:

```
mysqldump --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary \
    -u local_user \
    -plocal_password | mysql \
        --host=hostname \
        --port=3306 \
    -u RDS_user_name \
    -pRDS_password
```

For Windows:

```
mysqldump --databases database_name ^
    --single-transaction ^
    --compress ^
    --order-by-primary ^
    -u local_user ^
    -plocal_password | mysql ^
        --host=hostname ^
        --port=3306 ^
    -u RDS_user_name ^
    -pRDS_password
```

**Note**
Make sure that there isn't a space between the `-p` option and the entered password.

To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command. The host name is the Domain Name Service (DNS) name from the Amazon RDS DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see the MySQL documentation.

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the virtual private cloud (VPC) security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your
external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the `host` command.

```
host  
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication and restrict it to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

7. For the external instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `repl_user` user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the source instance by using the `mysql.rds_set_external_master` command. Use the master log file name and master log position that you determined in step 2. The following is an example.

```
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

**Note**

On RDS for MySQL, you can choose to use delayed replication by running the `mysql.rds_set_external_master_with_delay` stored procedure instead. On RDS for MySQL, one reason to use delayed replication is to turn on disaster recovery with the `mysql.rds_start_replication_until` stored procedure. Currently, RDS for MariaDB supports delayed replication but doesn't support the `mysql.rds_start_replication_until` procedure.

9. On the Amazon RDS DB instance, issue the `mysql.rds_start_replication` command to start replication.

```
CALL mysql.rds_start_replication;
```
Options for MariaDB database engine

Following, you can find descriptions for options, or additional features, that are available for Amazon RDS instances running the MariaDB DB engine. To turn on these options, you add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see Working with option groups (p. 279).

Amazon RDS supports the following options for MariaDB:

<table>
<thead>
<tr>
<th>Option ID</th>
<th>Engine versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MARIADB_AUDIT_PLUGIN</td>
<td>MariaDB 10.2 and higher</td>
</tr>
</tbody>
</table>

MariaDB Audit Plugin support

Amazon RDS supports using the MariaDB Audit Plugin on MariaDB database instances. The MariaDB Audit Plugin records database activity such as users logging on to the database, queries run against the database, and more. The record of database activity is stored in a log file.

Audit Plugin option settings

Amazon RDS supports the following settings for the MariaDB Audit Plugin option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERVER_AUDIT_FILE_PATH</td>
<td>/rdsdbdata/log/audit/</td>
<td>/rdsdbdata/log/audit/</td>
<td>The location of the log file. The log file contains the record of the activity specified in SERVER_AUDIT_EVENTS. For more information, see Viewing and listing database log files (p. 716) and MariaDB database log files (p. 723).</td>
</tr>
<tr>
<td>SERVER_AUDIT_FILE_ROTATE_SIZE</td>
<td>1–100000000</td>
<td>1000000</td>
<td>The size in bytes that when reached, causes the file to rotate. For more information, see Log file size (p. 727).</td>
</tr>
<tr>
<td>SERVER_AUDIT_FILE_ROTATIONS</td>
<td>0–100</td>
<td>9</td>
<td>The number of log rotations to save. For more information, see Log file size (p. 727) and Downloading a database log file (p. 717).</td>
</tr>
<tr>
<td>SERVER_AUDIT_EVENTS</td>
<td>CONNECT, QUERY, TABLE, QUERY_DDL, QUERY_DML, QUERY_DML_NO_SELECT, QUERY_DCL</td>
<td>CONNECT, QUERY</td>
<td>The types of activity to record in the log. Installing the MariaDB Audit Plugin is itself logged.</td>
</tr>
</tbody>
</table>

• CONNECT: Log successful and unsuccessful connections to the database, and disconnections from the database.
• QUERY: Log the text of all queries run against the database.
• TABLE: Log tables affected by queries when the queries are run against the database.
• QUERY_DDL: Similar to the QUERY event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on).
Option setting | Valid values | Default value | Description
--- | --- | --- | ---
| **QUERY_DML** | | | • QUERY_DML: Similar to the QUERY event, but returns only data manipulation language (DML) queries (INSERT, UPDATE, and so on, and also SELECT).
• QUERY_DML_NO_SELECT: Similar to the QUERY_DML event, but doesn't log SELECT queries.
• QUERY_DCL: Similar to the QUERY event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on).

| **SERVER_AUDIT_INCL_USERS** | Multiple comma-separated values | None | Include only activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_INCL_USERS, make sure no values are added to SERVER_AUDIT_EXCL_USERS.

| **SERVER_AUDIT_EXCL_USERS** | Multiple comma-separated values | None | Exclude activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_EXCL_USERS, make sure no values are added to SERVER_AUDIT_INCL_USERS.

The rdsadmin user queries the database every second to check the health of the database. Depending on your other settings, this activity can possibly cause the size of your log file to grow very large, very quickly. If you don't need to record this activity, add the rdsadmin user to the SERVER_AUDIT_EXCL_USERS list.

**Note**

CONNECT activity is always recorded for all users, even if the user is specified for this option setting.

| **SERVER_AUDIT_LOGGING** | | ON | Logging is active. The only valid value is ON. Amazon RDS does not support deactivating logging. If you want to deactivate logging, remove the MariaDB Audit Plugin. For more information, see Removing the MariaDB Audit Plugin (p. 1083).

| **SERVER_AUDIT_QUERY_LOG_LIMIT** | | 0–2147483647 | The limit on the length of the query string in a record.

**Adding the MariaDB Audit Plugin**

The general process for adding the MariaDB Audit Plugin to a DB instance is the following:
1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

After you add the MariaDB Audit Plugin, you don't need to restart your DB instance. As soon as the option group is active, auditing begins immediately.

**To add the MariaDB Audit Plugin**

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group. Choose mariadb for **Engine**, and choose 10.2 or higher for **Major engine version**. For more information, see [Creating an option group](p. 280).
2. Add the MARIADB_AUDIT_PLUGIN option to the option group, and configure the option settings. For more information about adding options, see [Adding an option to an option group](p. 283). For more information about each setting, see [Audit Plugin option settings](p. 1081).
3. Apply the option group to a new or existing DB instance.
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](p. 236).
   - For an existing DB instance, you apply the option group by modifying the DB instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](p. 333).

**Viewing and downloading the MariaDB Audit Plugin log**

After you enable the MariaDB Audit Plugin, you access the results in the log files the same way you access any other text-based log files. The audit log files are located at /rdsdbdata/log/audit/. For information about viewing the log file in the console, see [Viewing and listing database log files](p. 716). For information about downloading the log file, see [Downloading a database log file](p. 717).

**Modifying MariaDB Audit Plugin settings**

After you enable the MariaDB Audit Plugin, you can modify settings for the plugin. For more information about how to modify option settings, see [Modifying an option setting](p. 288). For more information about each setting, see [Audit Plugin option settings](p. 1081).

**Removing the MariaDB Audit Plugin**

Amazon RDS doesn't support turning off logging in the MariaDB Audit Plugin. However, you can remove the plugin from a DB instance. When you remove the MariaDB Audit Plugin, the DB instance is restarted automatically to stop auditing.

To remove the MariaDB Audit Plugin from a DB instance, do one of the following:

- Remove the MariaDB Audit Plugin option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](p. 291)
- Modify the DB instance and specify a different option group that doesn't include the plugin. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](p. 333).
Parameters for MariaDB

By default, a MariaDB DB instance uses a DB parameter group that is specific to a MariaDB database. This parameter group contains some but not all of the parameters contained in the Amazon RDS DB parameter groups for the MySQL database engine. It also contains a number of new, MariaDB-specific parameters. For information about working with parameter groups and setting parameters, see Working with parameter groups (p. 295).

Viewing MariaDB parameters

RDS for MariaDB parameters are set to the default values of the storage engine that you have selected. For more information about MariaDB parameters, see the MariaDB documentation. For more information about MariaDB storage engines, see Supported storage engines for MariaDB on Amazon RDS (p. 1020).

You can view the parameters available for a specific RDS for MariaDB version using the RDS console or the AWS CLI. For information about viewing the parameters in a MariaDB parameter group in the RDS console, see Viewing parameter values for a DB parameter group (p. 307).

Using the AWS CLI, you can view the parameters for an RDS for MariaDB version by running the describe-engine-default-parameters command. Specify one of the following values for the --db-parameter-group-family option:

- mariadb10.6
- mariadb10.5
- mariadb10.4
- mariadb10.3
- mariadb10.2

For example, to view the parameters for RDS for MariaDB version 10.6, run the following command.

```plaintext
aws rds describe-engine-default-parameters --db-parameter-group-family mariadb10.6
```

Your output looks similar to the following.

```json
{
  "EngineDefaults": {
    "Parameters": [
      {
        "ParameterName": "alter_algorithm",
        "Description": "Specify the alter table algorithm.",
        "Source": "engine-default",
        "ApplyType": "dynamic",
        "DataType": "string",
        "AllowedValues": "DEFAULT,COPY,INPLACE,NOCOPY,INSTANT",
        "IsModifiable": true
      },
      {
        "ParameterName": "analyze_sample_percentage",
        "Description": "Percentage of rows from the table ANALYZE TABLE will sample to collect table statistics.",
        "Source": "engine-default",
        "ApplyType": "dynamic",
        "DataType": "float",
        "AllowedValues": "0-100",
        "IsModifiable": true
      }
    ]
  }
}
```
MySQL parameters that aren't available

The following MySQL parameters are not available in MariaDB-specific DB parameter groups:

- bind_address
- binlog_error_action
- binlog_gtid_simple_recovery
- binlog_max_flush_queue_time
- binlog_order_commits
- binlog_row_image
- binlog_rows_query_log_events
- binlogging_impossible_mode
- block_encryption_mode
- core_file
- default_tmp_storage_engine
- div_precision_increment
- end_markers_in_json
- enforce_gtid_consistency
- eq_range_index_dive_limit
- explicit_defaults_for_timestamp
- gtid_executed
- gtid-mode
MySQL parameters that aren't available

- gtid_next
- gtid_owned
- gtid_purged
- log_bin_basename
- log_bin_index
- log_bin_use_v1_row_events
- log_slow_admin_statements
- log_slow_slave_statements
- log_throttle_queries_not_using_indexes
- master-info-repository
- optimizer_trace
- optimizer_trace_features
- optimizer_trace_limit
- optimizer_trace_max_mem_size
- optimizer_trace_offset
- relay_log_info_repository
- rpl_stop_slave_timeout
- slave_parallel_workers
- slave_pending_jobs_size_max
- slave_rows_search_algorithms
- storage_engine
- table_open_cache_instances
- timed_mutexes
- transaction_allow_batching
- validate-password
- validate_password_dictionary_file
- validate_password_length
- validate_password_mixed_case_count
- validate_password_number_count
- validate_password_policy
- validate_password_special_char_count

For more information on MySQL parameters, see the MySQL documentation.
Migrating data from a MySQL DB snapshot to a MariaDB DB instance

You can migrate an RDS for MySQL DB snapshot to a new DB instance running MariaDB using the AWS Management Console, the AWS CLI, or Amazon RDS API. You must use a DB snapshot that was created from an Amazon RDS DB instance running MySQL 5.6 or 5.7. To learn how to create an RDS for MySQL DB snapshot, see Creating a DB snapshot (p. 483).

Migrating the snapshot doesn't affect the original DB instance from which the snapshot was taken. You can test and validate the new DB instance before diverting traffic to it as a replacement for the original DB instance.

After you migrate from MySQL to MariaDB, the MariaDB DB instance is associated with the default DB parameter group and option group. After you restore the DB snapshot, you can associate a custom DB parameter group with the new DB instance. However, a MariaDB parameter group has a different set of configurable system variables. For information about the differences between MySQL and MariaDB system variables, see System Variable Differences between MariaDB and MySQL. To learn about DB parameter groups, see Working with parameter groups (p. 295). To learn about option groups, see Working with option groups (p. 279).

Performing the migration

You can migrate an RDS for MySQL DB snapshot to a new MariaDB DB instance using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To migrate a MySQL DB snapshot to a MariaDB DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots, and then select the MySQL DB snapshot you want to migrate.
3. For Actions, choose Migrate snapshot. The Migrate database page appears.
4. For Migrate to DB Engine, choose mariadb.

Amazon RDS selects the DB engine version automatically. You can't change the DB engine version.
5. For the remaining sections, specify your DB instance settings. For information about each setting, see Settings for DB instances (p. 243).

6. Choose Migrate.

AWS CLI

To migrate data from a MySQL DB snapshot to a MariaDB DB instance, use the AWS CLI `restore-db-instance-from-db-snapshot` command with the following parameters:

- `--db-instance-identifier` – Name of the DB instance to create from the DB snapshot.
- `--db-snapshot-identifier` – The identifier for the DB snapshot to restore from.
- `--engine` – The database engine to use for the new instance.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
  --db-instance-identifier newmariadbinstance \
  --db-snapshot-identifier mysqlsnapshot \
  --engine mariadb
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
  --db-instance-identifier newmariadbinstance ^
  --db-snapshot-identifier mysqlsnapshot ^
  --engine mariadb
```
API

To migrate data from a MySQL DB snapshot to a MariaDB DB instance, call the Amazon RDS API operation `RestoreDBInstanceFromDBSnapshot`.

Incompatibilities between MariaDB and MySQL

Incompatibilities between MySQL and MariaDB include the following:

- You can't migrate a DB snapshot created with MySQL 8.0 to MariaDB.
- If the source MySQL database uses a SHA256 password hash, make sure to reset user passwords that are SHA256 hashed before you connect to the MariaDB database. The following code shows how to reset a password that is SHA256 hashed.

```sql
SET old_passwords = 0;
UPDATE mysql.user SET plugin = 'mysql_native_password',
Password = PASSWORD('new_password')
WHERE (User, Host) = ('master_user_name', %);
FLUSH PRIVILEGES;
```

- If your RDS master user account uses the SHA-256 password hash, make sure to reset the password using the AWS Management Console, the `modify-db-instance` AWS CLI command, or the `ModifyDBInstance` RDS API operation. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 333).
- MariaDB doesn't support the Memcached plugin. However, the data used by the Memcached plugin is stored as InnoDB tables. After you migrate a MySQL DB snapshot, you can access the data used by the Memcached plugin using SQL. For more information about the innodb_memcache database, see InnoDB memcached Plugin Internals.
MariaDB on Amazon RDS SQL reference

Following, you can find descriptions of system stored procedures that are available for Amazon RDS instances running the MariaDB DB engine.

You can use the system stored procedures that are available for MySQL DB instances and MariaDB DB instances. These stored procedures are documented at MySQL on Amazon RDS SQL reference (p. 1486). MariaDB DB instances support all of the stored procedures, except for `mysql.rds_start_replication_until` and `mysql.rds_start_replication_until_gtid`.

Additionally, the following system stored procedures are supported only for Amazon RDS DB instances running MariaDB:

- `mysql.rds_replica_status` (p. 1090)
- `mysql.rds_set_external_master_gtid` (p. 1091)
- `mysql.rds_kill_query_id` (p. 1093)

### mysql.rds_replica_status

Shows the replication status of a MariaDB read replica.

Call this procedure on the read replica to show status information on essential parameters of the replica threads.

**Syntax**

```
CALL mysql.rds_replica_status;
```

**Usage notes**

This procedure is only supported for MariaDB DB instances running MariaDB version 10.5 and higher.

This procedure is the equivalent of the `SHOW REPLICA STATUS` command. This command isn't supported for MariaDB version 10.5 and higher DB instances.

In prior versions of MariaDB, the equivalent `SHOW SLAVE STATUS` command required the `REPLICATION SLAVE` privilege. In MariaDB version 10.5 and higher, it requires the `REPLICATION REPLICA_ADMIN` privilege. To protect the RDS management of MariaDB 10.5 and higher DB instances, this new privilege isn't granted to the RDS master user.

**Examples**

The following example shows the status of a MariaDB read replica:

```sql
CALL mysql.rds_replica_status;
```

The response is similar to the following:

```
*************************** 1. row ***************************
Replica_IO_State: Waiting for master to send event
Source_Host: XX.XX.XX.XXX
Source_User: rdsrepladmin
Source_Port: 3306
```
mysql.rds_set_external_master_gtid

Configures GTID-based replication from a MariaDB instance running external to Amazon RDS to a MariaDB DB instance. This stored procedure is supported only where the external MariaDB instance is version 10.0.24 or higher. When setting up replication where one or both instances do not support MariaDB global transaction identifiers (GTIDs), use mysql.rds_set_external_master (p. 1488).

Using GTIDs for replication provides crash-safety features not offered by binary log replication, so we recommend it in cases where the replicating instances support it.
Syntax

```
CALL mysql.rds_set_external_master_gtid(
    host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , gtid
  , ssl_encryption
);
```

Parameters

`host_name`

String. The host name or IP address of the MariaDB instance running external to Amazon RDS that will become the source instance.

`host_port`

Integer. The port used by the MariaDB instance running external to Amazon RDS to be configured as the source instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.

`replication_user_name`

String. The ID of a user with `REPLICATION_SLAVE` permissions in the MariaDB DB instance to be configured as the read replica.

`replication_user_password`

String. The password of the user ID specified in `replication_user_name`.

`gtid`

String. The global transaction ID on the source instance that replication should start from.

You can use `@@gtid_current_pos` to get the current GTID if the source instance has been locked while you are configuring replication, so the binary log doesn't change between the points when you get the GTID and when replication starts.

Otherwise, if you are using `mysqldump` version 10.0.13 or greater to populate the replica instance prior to starting replication, you can get the GTID position in the output by using the `--master-data` or `--dump-slave` options. If you are not using `mysqldump` version 10.0.13 or greater, you can run the `SHOW MASTER STATUS` or use those same `mysqldump` options to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance:

```
SELECT BINLOG_GTID_POS('<binary log file name>', <binary log file position>);
```

For more information about the MariaDB implementation of GTIDs, go to Global transaction ID in the MariaDB documentation.

`ssl_encryption`

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

**Note**

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.
Usage notes

The `mysql.rds_set_external_master_gtid` procedure must be run by the master user. It must be run on the MariaDB DB instance that you are configuring as the replica of a MariaDB instance running external to Amazon RDS. Before running `mysql.rds_set_external_master_gtid`, you must have configured the instance of MariaDB running external to Amazon RDS as a source instance. For more information, see Importing data into a MariaDB DB instance (p. 1044).

**Warning**
Do not use `mysql.rds_set_external_master_gtid` to manage replication between two Amazon RDS DB instances. Use it only when replicating with a MariaDB instance running external to RDS. For information about managing replication between Amazon RDS DB instances, see Working with read replicas (p. 382).

After calling `mysql.rds_set_external_master_gtid` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` (p. 1504) on the replica to start the replication process. You can call `mysql.rds_reset_external_master` (p. 1500) to remove the read replica configuration.

When `mysql.rds_set_external_master_gtid` is called, Amazon RDS records the time, user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

Examples

When run on a MariaDB DB instance, the following example configures it as the replica of an instance of MariaDB running external to Amazon RDS.

```sql
CALL mysql.rds_set_external_master_gtid
('Sourcedb.some.com',3306,'ReplicationUser','SomePassW0rd','0-123-456',0);
```

### `mysql.rds_kill_query_id`

Ends a query running against the MariaDB server.

**Syntax**

```sql
CALL mysql.rds_kill_query_id(queryID);
```

**Parameters**

<table>
<thead>
<tr>
<th>queryID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer. The identity of the query to be ended.</td>
</tr>
</tbody>
</table>

**Usage notes**

To stop a query running against the MariaDB server, use the `mysql.rds_kill_query_id` procedure and pass in the ID of that query. To obtain the query ID, query the MariaDB `Information schema PROCESSLIST` table, as shown following:

```sql
SELECT USER, HOST, COMMAND, TIME, STATE, INFO, QUERY_ID FROM INFORMATION_SCHEMA.PROCESSLIST WHERE USER = '<user name>';
```

The connection to the MariaDB server is retained.
Examples

The following example ends a query with a query ID of 230040:

```
call mysql.rds_kill_query_id(230040);
```
Local time zone for MariaDB DB instances

By default, the time zone for a MariaDB DB instance is Universal Time Coordinated (UTC). You can set the time zone for your DB instance to the local time zone for your application instead.

To set the local time zone for a DB instance, set the `time_zone` parameter in the parameter group for your DB instance to one of the supported values listed later in this section. When you set the `time_zone` parameter for a parameter group, all DB instances and read replicas that are using that parameter group change to use the new local time zone. For information on setting parameters in a parameter group, see Working with parameter groups (p. 295).

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

You can set a different local time zone for a DB instance and one or more of its read replicas. To do this, use a different parameter group for the DB instance and the replica or replicas and set the `time_zone` parameter in each parameter group to a different local time zone.

If you are replicating across AWS Regions, then the source DB instance and the read replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the `time_zone` parameter in the instance's and read replica's parameter groups.

When you restore a DB instance from a DB snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB instance to a point in time, then the local time zone for the restored DB instance is the time zone setting from the parameter group of the restored DB instance.

You can set your local time zone to one of the following values.

<table>
<thead>
<tr>
<th>Africa/Cairo</th>
<th>Asia/Riyadh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Africa/Casablanca</td>
<td>Asia/Seoul</td>
</tr>
<tr>
<td>Africa/Harare</td>
<td>Asia/Shanghai</td>
</tr>

</table>
RDS for MariaDB limitations

Following are important limitations of using RDS for MariaDB.

Note
This list is not exhaustive.

Topics
• MariaDB file size limits in Amazon RDS (p. 1097)
• InnoDB reserved word (p. 1098)

MariaDB file size limits in Amazon RDS

For MariaDB DB instances, the maximum size of a table is 16 TB when using InnoDB file-per-table
tablespaces. This limit also constrains the system tablespace to a maximum size of 16 TB. InnoDB file-
per-table tablespaces (with tables each in their own tablespace) are set by default for MariaDB DB
instances. This limit isn't related to the maximum storage limit for MariaDB DB instances. For more
information about the storage limit, see Amazon RDS DB instance storage (p. 71).

There are advantages and disadvantages to using InnoDB file-per-table tablespaces, depending on your
application. To determine the best approach for your application, see File-per-table tablespaces in the
MySQL documentation.

We don't recommend allowing tables to grow to the maximum file size. In general, a better practice is to
partition data into smaller tables, which can improve performance and recovery times.

One option that you can use for breaking a large table up into smaller tables is partitioning. Partitioning
distributes portions of your large table into separate files based on rules that you specify. For example,
if you store transactions by date, you can create partitioning rules that distribute older transactions into
separate files using partitioning. Then periodically, you can archive the historical transaction data that
doesn't need to be readily available to your application. For more information, see Partitioning in the
MySQL documentation.

To determine the file size of a table

Use the following SQL command to determine if any of your tables are too large and are candidates for
partitioning. To update table statistics, issue an ANALYZE TABLE command on each table. For more
information, see ANALYZE TABLE statement in the MySQL documentation.

```sql
SELECT TABLE_SCHEMA, TABLE_NAME,
    round(((DATA_LENGTH + INDEX_LENGTH) / 1024 / 1024), 2) As "Approximate size (MB)",
    DATA_FREE
FROM information_schema.TABLES
WHERE TABLE_SCHEMA NOT IN ('mysql', 'information_schema', 'performance_schema');
```

To enable InnoDB file-per-table tablespaces

• To enable InnoDB file-per-table tablespaces, set the innodb_file_per_table parameter to 1 in the
  parameter group for the DB instance.

To disable InnoDB file-per-table tablespaces

• To disable InnoDB file-per-table tablespaces, set the innodb_file_per_table parameter to 0 in the
  parameter group for the DB instance.
For information on updating a parameter group, see Working with parameter groups (p. 295).

When you have enabled or disabled InnoDB file-per-table tablespaces, you can issue an ALTER TABLE command. You can use this command to move a table from the global tablespace to its own tablespace. Or you can move a table from its own tablespace to the global tablespace. Following is an example.

```
ALTER TABLE table_name ENGINE=InnoDB, ALGORITHM=COPY;
```

### InnoDB reserved word

InnoDB is a reserved word for RDS for MariaDB. You can't use this name for a MariaDB database.
Amazon RDS for Microsoft SQL Server

Amazon RDS supports several versions and editions of Microsoft SQL Server. The most recent supported version of each major version is listed here. For the full list of supported versions, editions, and RDS engine versions, see Microsoft SQL Server versions on Amazon RDS (p. 1107).

- SQL Server 2019 CU16 15.0.4236.7, released per KB5014353 on June 14, 2022.
- SQL Server 2016 SP3 GDR 13.0.6419.1, released per KB5014355 on June 14, 2022.
- SQL Server 2014 SP3 CU4 12.0.6439.10, released per KB5014164 on June 14, 2022.
- SQL Server 2012: It’s no longer possible to provision new instances in any Region. Amazon RDS is actively migrating existing instances off this version.
- SQL Server 2008: It’s no longer possible to provision new instances in any Region. Amazon RDS is actively migrating existing instances off this version.

For information about licensing for SQL Server, see Licensing Microsoft SQL Server on Amazon RDS (p. 1124). For information about SQL Server builds, see this Microsoft support article about the latest SQL Server builds.

With Amazon RDS, you can create DB instances and DB snapshots, point-in-time restores, and automated or manual backups. DB instances running SQL Server can be used inside a VPC. You can also use Secure Sockets Layer (SSL) to connect to a DB instance running SQL Server, and you can use transparent data encryption (TDE) to encrypt data at rest. Amazon RDS currently supports Multi-AZ deployments for SQL Server using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs) as a high-availability, failover solution.

To deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application such as Microsoft SQL Server Management Studio. Amazon RDS does not allow direct host access to a DB instance via Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection. When you create a DB instance, the master user is assigned to the db_owner role for all user databases on that instance, and has all database-level permissions except for those that are used for backups. Amazon RDS manages backups for you.

Before creating your first DB instance, you should complete the steps in the setting up section of this guide. For more information, see Setting up for Amazon RDS (p. 153).

Topics
- Common management tasks for Microsoft SQL Server on Amazon RDS (p. 1100)
- Limitations for Microsoft SQL Server DB instances (p. 1101)
- DB instance class support for Microsoft SQL Server (p. 1103)

</tr>
<tr>
<td>A production DB instance should use Multi-AZ deployments. Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. Multi-AZ deployments for SQL Server are implemented using SQL Server's native DBM or AGs technology.</td>
<td>Multi-AZ deployments using Microsoft SQL Server Database Mirroring or Always On availability groups (p. 1112)</td>
</tr>
<tr>
<td><strong>Amazon Virtual Private Cloud (VPC)</strong></td>
<td>Working with a DB instance in a VPC (p. 2251)</td>
</tr>
<tr>
<td>If your AWS account has a default VPC, then your DB instance is automatically created inside the default VPC. If your account does not have a default VPC, and you want the DB instance in a VPC, you must create the VPC and subnet groups before you create the DB instance.</td>
<td></td>
</tr>
</tbody>
</table>
Limitations for Microsoft SQL Server DB instances

The Amazon RDS implementation of Microsoft SQL Server on a DB instance has some limitations that you should be aware of:

There are also advanced administrative tasks for working with SQL Server DB instances. For more information, see the following documentation:

- Common DBA tasks for Microsoft SQL Server (p. 1332).
- Using Windows Authentication with a SQL Server DB instance (p. 1184)
- Accessing the tempdb database (p. 1333)
The maximum number of databases supported on a DB instance depends on the instance class type and the availability mode—Single-AZ, Multi-AZ Database Mirroring (DBM), or Multi-AZ Availability Groups (AGs). The Microsoft SQL Server system databases don't count toward this limit.

The following table shows the maximum number of supported databases for each instance class type and availability mode. Use this table to help you decide if you can move from one instance class type to another, or from one availability mode to another. If your source DB instance has more databases than the target instance class type or availability mode can support, modifying the DB instance fails. You can see the status of your request in the **Events** pane.

<table>
<thead>
<tr>
<th>Instance class type</th>
<th>Single-AZ</th>
<th>Multi-AZ with DBM</th>
<th>Multi-AZ with Always On AGs</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.<em>.micro to db.</em>.medium</td>
<td>30</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>db.*.large</td>
<td>30</td>
<td>30</td>
<td>30</td>
</tr>
<tr>
<td>db.<em>.xlarge to db.</em>.16xlarge</td>
<td>100</td>
<td>50</td>
<td>75</td>
</tr>
<tr>
<td>db.*.24xlarge</td>
<td>100</td>
<td>50</td>
<td>100</td>
</tr>
</tbody>
</table>

* Represents the different instance class types.

For example, let’s say that your DB instance runs on a db.*.16xlarge with Single-AZ and that it has 76 databases. You modify the DB instance to upgrade to using Multi-AZ Always On AGs. This upgrade fails, because your DB instance contains more databases than your target configuration can support. If you upgrade your instance class type to db.*.24xlarge instead, the modification succeeds.

If the upgrade fails, you see events and messages similar to the following:

- Unable to modify database instance class. The instance has 76 databases, but after conversion it would only support 75.
- Unable to convert the DB instance to Multi-AZ: The instance has 76 databases, but after conversion it would only support 75.

If the point-in-time restore or snapshot restore fails, you see events and messages similar to the following:

- Database instance put into incompatible-restore. The instance has 76 databases, but after conversion it would only support 75.
- Some ports are reserved for Amazon RDS, and you can't use them when you create a DB instance.
- Client connections from IP addresses within the range 169.254.0.0/16 are not permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.
- SQL Server Standard Edition uses only a subset of the available processors if the DB instance has more processors than the software limits (24 cores, 4 sockets, and 128GB RAM). Examples of this are the db.m5.24xlarge and db.r5.24xlarge instance classes.

For more information, see the table of scale limits under Editions and supported features of SQL Server 2019 (15.x) in the Microsoft documentation.

- Amazon RDS for SQL Server doesn't support importing data into the msdb database.
- You can't rename databases on a DB instance in a SQL Server Multi-AZ deployment.
- Make sure that you use these guidelines when setting the following DB parameters on RDS for SQL Server:
  - `max server memory (mb) >= 256 MB`
DB instance class support for Microsoft SQL Server

The computation and memory capacity of a DB instance is determined by its DB instance class. The DB instance class you need depends on your processing power and memory requirements. For more information, see DB instance classes (p. 10).

The following list of DB instance classes supported for Microsoft SQL Server is provided here for your convenience. For the most current list, see the RDS console: https://console.aws.amazon.com/rds/.

Not all DB instance classes are available on all supported SQL Server minor versions. For example, some newer DB instance classes such as db.r6i aren't available on older minor versions. You can use the describe-orderable-db-instance-options AWS CLI command to find out which DB instance classes are available for your SQL Server edition and version.

</tbody>
</table>
Microsoft SQL Server security

The Microsoft SQL Server database engine uses role-based security. The master user name that you specify when you create a DB instance is a SQL Server Authentication login that is a member of the processadmin, public, and setupadmin fixed server roles.

Any user who creates a database is assigned to the db_owner role for that database and has all database-level permissions except for those that are used for backups. Amazon RDS manages backups for you.

The following server-level roles aren't available in Amazon RDS for SQL Server:

- bulkadmin
- dbcreator
- diskadmin
- securityadmin
- serveradmin
- sysadmin

The following server-level permissions aren't available on RDS for SQL Server DB instances:

- ALTER ANY DATABASE
- ALTER ANY EVENT NOTIFICATION
- ALTER RESOURCES
• ALTER SETTINGS (you can use the DB parameter group API operations to modify parameters; for more information, see Working with parameter groups (p. 295))
• AUTHENTICATE SERVER
• CONTROL_SERVER
• CREATE DDL EVENT NOTIFICATION
• CREATE ENDPOINT
• CREATE SERVER ROLE
• CREATE TRACE EVENT NOTIFICATION
• DROP ANY DATABASE
• EXTERNAL ACCESS ASSEMBLY
• SHUTDOWN (You can use the RDS reboot option instead)
• UNSAFE ASSEMBLY
• ALTER ANY AVAILABILITY GROUP
• CREATE ANY AVAILABILITY GROUP

Compliance program support for Microsoft SQL Server DB instances

AWS Services in scope have been fully assessed by a third-party auditor and result in a certification, attestation of compliance, or Authority to Operate (ATO). For more information, see AWS services in scope by compliance program.

HIPAA support for Microsoft SQL Server DB instances

You can use Amazon RDS for Microsoft SQL Server databases to build HIPAA-compliant applications. You can store healthcare-related information, including protected health information (PHI), under a Business Associate Agreement (BAA) with AWS. For more information, see HIPAA compliance.

Amazon RDS for SQL Server supports HIPAA for the following versions and editions:

• SQL Server 2019 Enterprise, Standard, and Web Editions
• SQL Server 2017 Enterprise, Standard, and Web Editions
• SQL Server 2016 Enterprise, Standard, and Web Editions
• SQL Server 2014 Enterprise, Standard, and Web Editions

To enable HIPAA support on your DB instance, set up the following three components.

<table>
<thead>
<tr>
<th>Component</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auditing</td>
<td>To set up auditing, set the parameter rds.sqlserver_audit to the value fedramp_hipaa. If your DB instance is not already using a custom DB parameter group, you must create a custom parameter group and attach it to your DB instance before you can modify the rds.sqlserver_audit parameter. For more information, see Working with parameter groups (p. 295).</td>
</tr>
<tr>
<td>Transport encryption</td>
<td>To set up transport encryption, force all connections to your DB instance to use Secure Sockets Layer (SSL). For more information, see Forcing connections to your DB instance to use SSL (p. 1176).</td>
</tr>
</tbody>
</table>
SSL support

### Component Details

Encryption at rest

To set up encryption at rest, you have two options:

1. If you’re running SQL Server 2014–2019 Enterprise Edition or 2019 Standard Edition, you can use Transparent Data Encryption (TDE) to achieve encryption at rest. For more information, see Support for Transparent Data Encryption in SQL Server (p. 1258).

2. You can set up encryption at rest by using AWS Key Management Service (AWS KMS) encryption keys. For more information, see Encrypting Amazon RDS resources (p. 2147).

---

### SSL support for Microsoft SQL Server DB instances

You can use SSL to encrypt connections between your applications and your Amazon RDS DB instances running Microsoft SQL Server. You can also force all connections to your DB instance to use SSL. If you force connections to use SSL, it happens transparently to the client, and the client doesn't have to do any work to use SSL.

SSL is supported in all AWS Regions and for all supported SQL Server editions. For more information, see Using SSL with a Microsoft SQL Server DB instance (p. 1176).

---

### Microsoft SQL Server versions on Amazon RDS

You can specify any currently supported Microsoft SQL Server version when creating a new DB instance. You can specify the Microsoft SQL Server major version (such as Microsoft SQL Server 14.00), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified.

The following table shows the supported versions for all editions and all AWS Regions, except where noted. You can also use the describe-db-engine-versions AWS CLI command to see a list of supported versions, as well as defaults for newly created DB instances.

#### SQL Server versions supported in RDS

<table>
<thead>

</tbody>
</table>
Version management in Amazon RDS

Amazon RDS includes flexible version management that enables you to control when and how your DB instance is patched or upgraded. This enables you to do the following for your DB engine:

- Maintain compatibility with database engine patch versions.
- Test new patch versions to verify that they work with your application before you deploy them in production.
- Plan and perform version upgrades to meet your service level agreements and timing requirements.

Microsoft SQL Server engine patching in Amazon RDS

Amazon RDS periodically aggregates official Microsoft SQL Server database patches into a DB instance engine version that's specific to Amazon RDS. For more information about the Microsoft SQL Server patches in each engine version, see Version and feature support on Amazon RDS.

Currently, you manually perform all engine upgrades on your DB instance. For more information, see Upgrading the Microsoft SQL Server DB engine (p. 1135).

Deprecation schedule for major engine versions of Microsoft SQL Server on Amazon RDS

The following table displays the planned schedule of deprecations for major engine versions of Microsoft SQL Server.

<table>
<thead>
<tr>
<th>Date</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>July 12, 2022</td>
<td>Microsoft will stop critical patch updates for SQL Server 2012. For more information, see documentation.</td>
</tr>
<tr>
<td>June 1, 2022</td>
<td>Amazon RDS plans to end support of Microsoft SQL Server 2012 on RDS for SQL Server. A new instance is scheduled to migrate to SQL Server 2014 (latest minor version available). For more information, see Amazon RDS ending support for SQL Server 2012 major versions.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Major version</th>
<th>Minor version</th>
<th>RDS API EngineVersion and CLI engine-version</th>
</tr>
</thead>
<tbody>
<tr>
<td>14.00.3356.20 (CU22)</td>
<td>14.00.3356.20.v1</td>

</table>
Microsoft SQL Server features on Amazon RDS

The supported SQL Server versions on Amazon RDS include the following features. In general, a version also includes features from the previous versions, unless otherwise noted in the Microsoft documentation.

Topics
- Microsoft SQL Server 2019 features (p. 1109)
- Microsoft SQL Server 2017 features (p. 1110)
- Microsoft SQL Server 2016 features (p. 1110)
- Microsoft SQL Server 2014 features (p. 1110)
- Microsoft SQL Server 2012 end of support on Amazon RDS (p. 1111)
- Microsoft SQL Server 2008 R2 end of support on Amazon RDS (p. 1111)

Microsoft SQL Server 2019 features

SQL Server 2019 includes many new features, such as the following:

- Accelerated database recovery (ADR) – Reduces crash recovery time after a restart or a long-running transaction rollback.
- Intelligent Query Processing (IQP):
  - Row mode memory grant feedback – Corrects excessive grants automatically, that would otherwise result in wasted memory and reduced concurrency.
  - Batch mode on rowstore – Enables batch mode execution for analytic workloads without requiring columnstore indexes.
  - Table variable deferred compilation – Improves plan quality and overall performance for queries that reference table variables.
- Intelligent performance:
  - OPTIMIZE_FOR_SEQUENTIAL_KEY index option – Improves throughput for high-concurrency inserts into indexes.
  - Improved indirect checkpoint scalability – Helps databases with heavy DML workloads.
  - Concurrent Page Free Space (PFS) updates – Enables handling as a shared latch rather than an exclusive latch.
Monitoring improvements:
- WAIT_ON_SYNC_STATISTICS_REFRESH wait type – Shows accumulated instance-level time spent on synchronous statistics refresh operations.
- Database-scoped configurations – Include LIGHTWEIGHT_QUERY_PROFILING and LAST_QUERY_PLAN_STATS.
- Dynamic management functions (DMFs) – Include sys.dm_exec_query_plan_stats and sys.dm_db_page_info.
- Verbose truncation warnings – The data truncation error message defaults to include table and column names and the truncated value.
- Resumable online index creation – In SQL Server 2017, only resumable online index rebuild is supported.

For the full list of SQL Server 2019 features, see What's new in SQL Server 2019 (15.x) in the Microsoft documentation.

For a list of unsupported features, see Features not supported and features with limited support (p. 1112).

Microsoft SQL Server 2017 features

SQL Server 2017 includes many new features, such as the following:
- Adaptive query processing
- Automatic plan correction (an automatic tuning feature)
- GraphDB
- Resumable index rebuilds

For the full list of SQL Server 2017 features, see What's new in SQL Server 2017 in the Microsoft documentation.

For a list of unsupported features, see Features not supported and features with limited support (p. 1112).

Microsoft SQL Server 2016 features

Amazon RDS supports the following features of SQL Server 2016:
- Always Encrypted
- JSON Support
- Operational Analytics
- Query Store
- Temporal Tables

For the full list of SQL Server 2016 features, see What's new in SQL Server 2016 in the Microsoft documentation.

Microsoft SQL Server 2014 features

In addition to supported features of SQL Server 2012, Amazon RDS supports the new query optimizer available in SQL Server 2014, and also the delayed durability feature.
For a list of unsupported features, see Features not supported and features with limited support (p. 1112).

SQL Server 2014 supports all the parameters from SQL Server 2012 and uses the same default values. SQL Server 2014 includes one new parameter, backup checksum default. For more information, see How to enable the CHECKSUM option if backup utilities do not expose the option in the Microsoft documentation.

Microsoft SQL Server 2012 end of support on Amazon RDS

SQL Server 2012 has reached its end of support on Amazon RDS.

RDS is upgrading all existing DB instances that are still using SQL Server 2012 to the latest minor version of SQL Server 2014. For more information, see Version management in Amazon RDS (p. 1108).

Microsoft SQL Server 2008 R2 end of support on Amazon RDS

SQL Server 2008 R2 has reached its end of support on Amazon RDS.

RDS is upgrading all existing DB instances that are still using SQL Server 2008 R2 to the latest minor version of SQL Server 2012. For more information, see Version management in Amazon RDS (p. 1108).

Change data capture support for Microsoft SQL Server DB instances

Amazon RDS supports change data capture (CDC) for your DB instances running Microsoft SQL Server. CDC captures changes that are made to the data in your tables, and stores metadata about each change that you can access later. For more information, see Change data capture in the Microsoft documentation.

Amazon RDS supports CDC for the following SQL Server editions and versions:

- Microsoft SQL Server Enterprise Edition (All versions)
- Microsoft SQL Server Standard Edition:
  - 2019
  - ea
  - 2017
  - 2016 version 13.00.4422.0 SP1 CU2 and later

To use CDC with your Amazon RDS DB instances, first enable or disable CDC at the database level by using RDS-provided stored procedures. After that, any user that has the db_owner role for that database can use the native Microsoft stored procedures to control CDC on that database. For more information, see Using change data capture (p. 1344).

You can use CDC and AWS Database Migration Service to enable ongoing replication from SQL Server DB instances.
Features not supported and features with limited support

The following Microsoft SQL Server features aren't supported on Amazon RDS:

- Backing up to Microsoft Azure Blob Storage
- Buffer pool extension
- Custom password policies
- Data Quality Services
- Database Log Shipping
- Database snapshots (Amazon RDS supports only DB instance snapshots)
- Extended stored procedures, including xp_cmdshell
- FILESTREAM support
- File tables
- Machine Learning and R Services (requires OS access to install it)
- Maintenance plans
- Performance Data Collector
- Policy-Based Management
- PolyBase
- Replication
- Resource Governor
- Server-level triggers
- Service Broker endpoints
- Stretch database
- TRUSTWORTHY database property (requires sysadmin role)
- T-SQL endpoints (all operations using CREATE ENDPOINT are unavailable)
- WCF Data Services

The following Microsoft SQL Server features have limited support on Amazon RDS:

- Distributed queries/linked servers. For more information, see [Implement linked servers with Amazon RDS for Microsoft SQL Server](#).
- Common Runtime Language (CLR). On RDS for SQL Server 2016 and lower versions, CLR is supported in SAFE mode and using assembly bits only. CLR isn't supported on RDS for SQL Server 2017 and higher versions. For more information, see [Common Runtime Language Integration](#) in the Microsoft documentation.

Multi-AZ deployments using Microsoft SQL Server Database Mirroring or Always On availability groups

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails
over to the up-to-date secondary replica so database operations can resume quickly without manual intervention. The primary and secondary instances use the same endpoint, whose physical network address transitions to the passive secondary replica as part of the failover process. You don’t have to reconfigure your application when a failover occurs.

Amazon RDS manages failover by actively monitoring your Multi-AZ deployment and initiating a failover when a problem with your primary occurs. Failover doesn’t occur unless the standby and primary are fully in sync. Amazon RDS actively maintains your Multi-AZ deployment by automatically repairing unhealthy DB instances and re-establishing synchronous replication. You don’t have to manage anything. Amazon RDS handles the primary, the witness, and the standby instance for you. When you set up SQL Server Multi-AZ, RDS configures passive secondary instances for all of the databases on the instance.

For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 1170).

Using Transparent Data Encryption to encrypt data at rest

Amazon RDS supports Microsoft SQL Server Transparent Data Encryption (TDE), which transparently encrypts stored data. Amazon RDS uses option groups to enable and configure these features. For more information about the TDE option, see Support for Transparent Data Encryption in SQL Server (p. 1258).

Functions and stored procedures for Amazon RDS for Microsoft SQL Server

Following, you can find a list of the Amazon RDS functions and stored procedures that help automate SQL Server tasks.

<table>
<thead>
<tr>
<th>Task type</th>

</table>
Local time zone for Microsoft SQL Server DB instances

The time zone of an Amazon RDS DB instance running Microsoft SQL Server is set by default. The current default is Coordinated Universal Time (UTC). You can set the time zone of your DB instance to a local time zone instead, to match the time zone of your applications.

You set the time zone when you first create your DB instance. You can create your DB instance by using the AWS Management Console, the Amazon RDS API CreateDBInstance action, or the AWS CLI create-db-instance command.

If your DB instance is part of a Multi-AZ deployment (using SQL Server DBM or AGs), then when you fail over, your time zone remains the local time zone that you set. For more information, see Multi-AZ deployments using Microsoft SQL Server Database Mirroring or Always On availability groups (p. 1112).

When you request a point-in-time restore, you specify the time to restore to. The time is shown in your local time zone. For more information, see Restoring a DB instance to a specified time (p. 534).

The following are limitations to setting the local time zone on your DB instance:
• You can't modify the time zone of an existing SQL Server DB instance.
• You can't restore a snapshot from a DB instance in one time zone to a DB instance in a different time zone.
• We strongly recommend that you don't restore a backup file from one time zone to a different time zone. If you restore a backup file from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change. For more information, see Importing and exporting SQL Server databases using native backup and restore (p. 1140).

Supported time zones

You can set your local time zone to one of the values listed in the following table.

<table>
<thead>
<tr>
<th>Time zone</th>
<th>Standard time offset</th>
<th>Description</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Afghanistan Standard Time</td>

Licensing Microsoft SQL Server on Amazon RDS

When you set up an Amazon RDS DB instance for Microsoft SQL Server, the software license is included. This means that you don't need to purchase SQL Server licenses separately. AWS holds the license for the SQL Server database software. Amazon RDS pricing includes the software license, underlying hardware resources, and Amazon RDS management capabilities.

Amazon RDS supports the following Microsoft SQL Server editions:

- Enterprise
- Standard
- Web
- Express

**Note**
Licensing for SQL Server Web Edition supports only public and internet-accessible webpages, websites, web applications, and web services. This level of support is required for compliance with Microsoft's usage rights. For more information, see [AWS service terms](#).

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). There are no additional licensing requirements for Multi-AZ deployments. For more information, see [Multi-AZ deployments for Amazon RDS for Microsoft SQL Server](p. 1170).

**Restoring license-terminated DB instances**

Amazon RDS takes snapshots of license-terminated DB instances. If your instance is terminated for licensing issues, you can restore it from the snapshot to a new DB instance. New DB instances have a license included.

For more information, see [Restoring license-terminated DB instances](p. 1343).

**Development and test**

Because of licensing requirements, we can't offer SQL Server Developer Edition on Amazon RDS. You can use Express Edition for many development, testing, and other nonproduction needs. However, if you need the full feature capabilities of an enterprise-level installation of SQL Server for development, you can download and install SQL Server Developer Edition (and other MSDN products) on Amazon EC2. Dedicated infrastructure isn't required for Developer Edition. By using your own host, you also gain access to other programmability features that are not accessible on Amazon RDS. For more information on the difference between SQL Server editions, see [Editions and supported features of SQL Server 2017](http) in the Microsoft documentation.
Connecting to a DB instance running the Microsoft SQL Server database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the DB instance. In this topic, you connect to your DB instance by using either Microsoft SQL Server Management Studio (SSMS) or SQL Workbench/J.

For an example that walks you through the process of creating and connecting to a sample DB instance, see Creating a Microsoft SQL Server DB instance and connecting to it (p. 168).

Before you connect

Before you can connect to your DB instance, it has to be available and accessible.

1. Make sure that its status is available. You can check this on the details page for your instance in the AWS Management Console or by using the describe-db-instances AWS CLI command.

2. Make sure that it is publicly accessible. You can check this when you check the availability.

3. Make sure that the inbound rules of your VPC security group allow access to your DB instance. For more information, see Can't connect to Amazon RDS DB instance (p. 2289).

Finding the DB instance endpoint and port number

You need both the endpoint and the port number to connect to the DB instance.

To find the endpoint and port

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region of your DB instance.
3. Find the Domain Name System (DNS) name (endpoint) and port number for your DB instance:
   a. Open the RDS console and choose Databases to display a list of your DB instances.
   b. Choose the SQL Server DB instance name to display its details.
   c. On the Connectivity & security tab, copy the endpoint.
   d. Note the port number.

Connecting to your DB instance with Microsoft SQL Server Management Studio

In this procedure, you connect to your sample DB instance by using Microsoft SQL Server Management Studio (SSMS). To download a standalone version of this utility, see Download SQL Server Management Studio (SSMS) in the Microsoft documentation.

To connect to a DB instance using SSMS

1. Start SQL Server Management Studio.

   The Connect to Server dialog box appears.
2. Provide the information for your DB instance:
   a. For **Server type**, choose **Database Engine**.
   b. For **Server name**, enter the DNS name (endpoint) and port number of your DB instance, separated by a comma.
      
      **Important**
      
      Change the colon between the endpoint and port number to a comma.
      
      Your server name should look like the following example.

     database-2.cg034itsfake.us-east-1.rds.amazonaws.com,1433
   
   c. For **Authentication**, choose **SQL Server Authentication**.
   d. For **Login**, enter the master user name for your DB instance.
   e. For **Password**, enter the password for your DB instance.

3. Choose **Connect**.

   After a few moments, SSMS connects to your DB instance.

   If you can't connect to your DB instance, see Security group considerations (p. 1130) and Troubleshooting connections to your SQL Server DB instance (p. 1130).

4. Your SQL Server DB instance comes with SQL Server's standard built-in system databases (**master**, **model**, **msdb**, and **tempdb**). To explore the system databases, do the following:
   a. In SSMS, on the **View** menu, choose **Object Explorer**.
   b. Expand your DB instance, expand **Databases**, and then expand **System Databases**.
5. Your SQL Server DB instance also comes with a database named rdsadmin. Amazon RDS uses this database to store the objects that it uses to manage your database. The rdsadmin database also includes stored procedures that you can run to perform advanced tasks. For more information, see Common DBA tasks for Microsoft SQL Server (p. 1332).

6. You can now start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your DB instance, do the following:
   
a. In SSMS, on the File menu point to New and then choose Query with Current Connection.
   
b. Enter the following SQL query.

   ```
   select @@VERSION
   ```
   
c. Run the query. SSMS returns the SQL Server version of your Amazon RDS DB instance.

---

**Connecting to your DB instance with SQL Workbench/J**

This example shows how to connect to a DB instance running the Microsoft SQL Server database engine by using the SQL Workbench/J database tool. To download SQL Workbench/J, see [SQL Workbench/J](#).

SQL Workbench/J uses JDBC to connect to your DB instance. You also need the JDBC driver for SQL Server. To download this driver, see [Microsoft JDBC drivers 4.1 (preview) and 4.0 for SQL Server](#).
To connect to a DB instance using SQL Workbench/J

1. Open SQL Workbench/J. The Select Connection Profile dialog box appears, as shown following.

![Select Connection Profile dialog box](image)

2. In the first box at the top of the dialog box, enter a name for the profile.
3. For **Driver**, choose **SQL JDBC 4.0**.
4. For **URL**, enter `jdbc:sqlserver://`, then enter the endpoint of your DB instance. For example, the URL value might be the following.

   ```sql
   ```

5. For **Username**, enter the master user name for the DB instance.
6. For **Password**, enter the password for the master user.
7. Choose the save icon in the dialog toolbar, as shown following.

![Save icon](image)

8. Choose **OK**. After a few moments, SQL Workbench/J connects to your DB instance. If you can't connect to your DB instance, see [Security group considerations](p. 1130) and [Troubleshooting connections to your SQL Server DB instance](p. 1130).
9. In the query pane, enter the following SQL query.

   ```sql
   select @@VERSION
   ```

10. Choose the **Execute** icon in the toolbar, as shown following.

![Execute icon](image)

   The query returns the version information for your DB instance, similar to the following.
Security group considerations

To connect to your DB instance, your DB instance must be associated with a security group. This security group contains the IP addresses and network configuration that you use to access the DB instance. You might have associated your DB instance with an appropriate security group when you created your DB instance. If you assigned a default, no-configured security group when you created your DB instance, your DB instance firewall prevents connections.

In some cases, you might need to create a new security group to make access possible. For instructions on creating a new security group, see Controlling access with security groups (p. 2232). For a topic that walks you through the process of setting up rules for your VPC security group, see Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2268).

After you have created the new security group, modify your DB instance to associate it with the security group. For more information, see Modifying an Amazon RDS DB instance (p. 333).

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see Using SSL with a Microsoft SQL Server DB instance (p. 1176).

Troubleshooting connections to your SQL Server DB instance

The following table shows error messages that you might encounter when you attempt to connect to your SQL Server DB instance. For more information on connection issues, see Can't connect to Amazon RDS DB instance (p. 2289).

<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
</table>
| Could not open a connection to SQL Server – Microsoft SQL Server, Error: 53 | Make sure that you specified the server name correctly. For **Server name**, enter the DNS name and port number of your sample DB instance, separated by a comma.  
**Important**  
If you have a colon between the DNS name and port number, change the colon to a comma.  
Your server name should look like the following example.  
```
sample-instance.cg034itsfake.us-east-1.rds.amazonaws.com,1433
```
| No connection could be made because the target machine actively refused it – Microsoft SQL Server, Error: 10061 | You were able to reach the DB instance but the connection was refused. This issue is usually caused by specifying the user name or password incorrectly. Verify the user name and password, then retry.  
<p>| A network-related or instance-specific error occurred while establishing a connection to SQL Server. The server was not found | The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group. |</p>
<table>
<thead>
<tr>
<th><strong>Issue</strong></th>
<th><strong>Troubleshooting suggestions</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>or was not accessible... The wait operation timed out – Microsoft SQL Server, Error: 258</td>
<td>Your database instance must be publicly accessible. To connect to it from outside of the VPC, the instance must have a public IP address assigned.</td>
</tr>
</tbody>
</table>
Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances. If they do, you can further check whether those applications require certificate verification to connect.

**Note**
Some applications are configured to connect to SQL Server DB instances only if they can successfully verify the certificate on the server.
For such applications, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 2154). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152). For information about using SSL/TLS with Microsoft SQL Server DB instances, see Using SSL with a Microsoft SQL Server DB instance (p. 1176).

**Topics**
- Determining whether any applications are connecting to your Microsoft SQL Server DB instance using SSL (p. 1132)
- Determining whether a client requires certificate verification in order to connect (p. 1133)
- Updating your application trust store (p. 1134)

Determining whether any applications are connecting to your Microsoft SQL Server DB instance using SSL

Check the DB instance configuration for the value of the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). If the `rds.force_ssl` parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see Working with parameter groups (p. 295).

Run the following query to get the current encryption option for all the open connections to a DB instance. The column `ENCRYPT_OPTION` returns TRUE if the connection is encrypted.

```sql
select SESSION_ID, 
      ENCRYPT_OPTION, 
      NET_TRANSPORT, 
      AUTH_SCHEME 
from SYS.DM_EXEC_CONNECTIONS
```

This query shows only the current connections. It doesn't show whether applications that have connected and disconnected in the past have used SSL.
Determining whether a client requires certificate verification in order to connect

You can check whether different types of clients require certificate verification to connect.

**Note**
If you use connectors other than the ones listed, see the specific connector's documentation for information about how it enforces encrypted connections. For more information, see Connection modules for Microsoft SQL databases in the Microsoft SQL Server documentation.

**SQL Server Management Studio**

Check whether encryption is enforced for SQL Server Management Studio connections:

1. Launch SQL Server Management Studio.
2. For **Connect to server**, enter the server information, login user name, and password.
3. Choose **Options**.
4. Check if **Encrypt connection** is selected in the connect page.

For more information about SQL Server Management Studio, see Use SQL Server Management Studio.

**Sqlcmd**

The following example with the sqlcmd client shows how to check a script's SQL Server connection to determine whether successful connections require a valid certificate. For more information, see Connecting with sqlcmd in the Microsoft SQL Server documentation.

When using sqlcmd, an SSL connection requires verification against the server certificate if you use the `-N` command argument to encrypt connections, as in the following example.

```bash
$ sqlcmd -N -S dbinstance.rds.amazon.com -d ExampleDB
```

**Note**
If sqlcmd is invoked with the `-C` option, it trusts the server certificate, even if that doesn't match the client-side trust store.

**ADO.NET**

In the following example, the application connects using SSL, and the server certificate must be verified.

```csharp
using SQLC = Microsoft.Data.SqlClient;
... 
static public void Main()
{
    using (var connection = new SQLC.SqlConnection(
        "Server=tcp:dbinstance.rds.amazon.com;" +
        "Database=ExampleDB;User ID=LOGIN_NAME;" +
        "Password=YOUR_PASSWORD;" +
        "Encrypt=True;TrustServerCertificate=False;"
    ))
```
Java

In the following example, the application connects using SSL, and the server certificate must be verified.

```java
    { connection.Open(); ...
 }
```

To enable SSL encryption for clients that connect using JDBC, you might need to add the Amazon RDS certificate to the Java CA certificate store. For instructions, see Configuring the client for encryption in the Microsoft SQL Server documentation. You can also provide the trusted CA certificate file name directly by appending `trustStore=path-to-certificate-trust-store-file` to the connection string.

**Note**
If you use `TrustServerCertificate=true` (or its equivalent) in the connection string, the connection process skips the trust chain validation. In this case, the application connects even if the certificate can't be verified. Using `TrustServerCertificate=false` enforces certificate validation and is a best practice.

### Updating your application trust store

You can update the trust store for applications that use Microsoft SQL Server. For instructions, see Encrypting specific connections (p. 1177). Also, see Configuring the client for encryption in the Microsoft SQL Server documentation.

If you are using an operating system other than Microsoft Windows, see the software distribution documentation for SSL/TLS implementation for information about adding a new root CA certificate. For example, OpenSSL and GnuTLS are popular options. Use the implementation method to add trust to the RDS root CA certificate. Microsoft provides instructions for configuring certificates on some systems.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).

For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 2160).

**Note**
When you update the trust store, you can retain older certificates in addition to adding the new certificates.
Upgrading the Microsoft SQL Server DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for SQL Server DB instances: major version upgrades and minor version upgrades.

**Major version upgrades** can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you test the upgrade by following the steps described in [Testing an upgrade](p. 1138).

In contrast, **minor version upgrades** include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Alternatively, you can enable the **Auto minor version upgrade** option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. You can confirm whether the minor version upgrade will be automatic by using the `describe-db-engine-versions` AWS CLI command. For example:

```bash
aws rds describe-db-engine-versions --engine sqlserver-se --engine-version 14.00.3049.1.v1
```

In the following example, the CLI command returns a response indicating that upgrades are automatic.

```
...
"ValidUpgradeTarget": [
  {
    "Engine": "sqlserver-se",
    "EngineVersion": "14.00.3192.2.v1",
    "Description": "SQL Server 2017 14.00.3192.2.v1",
    "AutoUpgrade": true,
    "IsMajorVersionUpgrade": false
  }
...`
```

For more information about performing upgrades, see [Upgrading a SQL Server DB instance](p. 1139). For information about what SQL Server versions are available on Amazon RDS, see [Amazon RDS for Microsoft SQL Server](p. 1099).

**Topics**
- Overview of upgrading (p. 1136)
- Major version upgrades (p. 1136)
- Multi-AZ and in-memory optimization considerations (p. 1137)
- Option group considerations (p. 1138)
- Parameter group considerations (p. 1138)
- Testing an upgrade (p. 1138)
- Upgrading a SQL Server DB instance (p. 1139)
- Upgrading deprecated DB instances before support ends (p. 1139)
Overview of upgrading

Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. The second DB snapshot is taken after the upgrade finishes.

**Note**
Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see [Modifying an Amazon RDS DB instance](p. 333).

After an upgrade is completed, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore from the DB snapshot that was taken before the upgrade to create a new DB instance.

During a minor or major version upgrade of SQL Server, the **Free Storage Space** and **Disk Queue Depth** metrics will display -1. After the upgrade is completed, both metrics will return to normal.

Major version upgrades

Amazon RDS currently supports the following major version upgrades to a Microsoft SQL Server DB instance.

You can upgrade your existing DB instance to SQL Server 2017 or 2019 from any version except SQL Server 2008. To upgrade from SQL Server 2008, first upgrade to one of the other versions.

<table>
<thead>
<tr>
<th>Current version</th>
<th>Supported upgrade versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL Server 2017</td>
<td>SQL Server 2019</td>
</tr>
<tr>
<td>SQL Server 2016</td>
<td>SQL Server 2019</td>
</tr>
<tr>
<td>SQL Server 2014</td>
<td>SQL Server 2019</td>
</tr>
<tr>
<td>SQL Server 2014</td>
<td>SQL Server 2017</td>
</tr>
<tr>
<td>SQL Server 2012 (end of support)</td>
<td>SQL Server 2019</td>
</tr>
<tr>
<td>SQL Server 2012 (end of support)</td>
<td>SQL Server 2017</td>
</tr>
<tr>
<td>SQL Server 2012 (end of support)</td>
<td>SQL Server 2016</td>
</tr>
<tr>
<td>SQL Server 2008 R2 (end of support)</td>
<td>SQL Server 2016</td>
</tr>
</tbody>
</table>

You can use an AWS CLI query, such as the following example, to find the available upgrades for a particular database engine version.
Example

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine sqlserver-se \
  --engine-version 14.00.3049.1.v1 \n  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" \
  --output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine sqlserver-se ^
  --engine-version 14.00.3049.1.v1 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" ^
  --output table
```

The output shows that you can upgrade version 14.00.3049.1 to the latest SQL Server 2017 or 2019 versions.

```

Database compatibility level

You can use Microsoft SQL Server database compatibility levels to adjust some database behaviors to mimic previous versions of SQL Server. For more information, see Compatibility level in the Microsoft documentation.

When you upgrade your DB instance, all existing databases remain at their original compatibility level. For example, if you upgrade from SQL Server 2014 to SQL Server 2016, all existing databases have a compatibility level of 120. Any new database created after the upgrade have compatibility level 130.

You can change the compatibility level of a database by using the ALTER DATABASE command. For example, to change a database named customeracct to be compatible with SQL Server 2014, issue the following command:

```
ALTER DATABASE customeracct SET COMPATIBILITY_LEVEL = 120
```

Multi-AZ and in-memory optimization considerations

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 1170).

If your DB instance is in a Multi-AZ deployment, both the primary and standby instances are upgraded. Amazon RDS does rolling upgrades. You have an outage only for the duration of a failover.
Option group considerations

If your DB instance uses a custom DB option group, in some cases Amazon RDS can't automatically assign your DB instance a new option group. For example, when you upgrade to a new major version, you must specify a new option group. We recommend that you create a new option group, and add the same options to it as your existing custom option group.

For more information, see Creating an option group (p. 280) or Copying an option group (p. 282).

Parameter group considerations

If your DB instance uses a custom DB parameter group:

- Amazon RDS automatically reboots the DB instance after an upgrade.
- In some cases, RDS can't automatically assign a new parameter group to your DB instance.

For example, when you upgrade to a new major version, you must specify a new parameter group. We recommend that you create a new parameter group, and configure the parameters as in your existing custom parameter group.

For more information, see Creating a DB parameter group (p. 297) or Copying a DB parameter group (p. 304).

Testing an upgrade

Before you perform a major version upgrade on your DB instance, you should thoroughly test your database, and all applications that access the database, for compatibility with the new version. We recommend that you use the following procedure.

To test a major version upgrade

1. Review Upgrade SQL Server in the Microsoft documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications.
2. If your DB instance uses a custom option group, create a new option group compatible with the new version you are upgrading to. For more information, see Option group considerations (p. 1138).
3. If your DB instance uses a custom parameter group, create a new parameter group compatible with the new version you are upgrading to. For more information, see Parameter group considerations (p. 1138).
4. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot (p. 483).
5. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring from a DB snapshot (p. 487).
6. Modify this new test DB instance to upgrade it to the new version, by using one of the following methods:
   - Console (p. 369)
   - AWS CLI (p. 370)
   - RDS API (p. 370)
7. Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage.
8. Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version. Implement any new tests needed to evaluate the impact of any compatibility issues you identified in step 1. Test all stored procedures and functions. Direct test versions of your applications to the upgraded DB instance.

9. If all tests pass, then perform the upgrade on your production DB instance. We recommend that you do not allow write operations to the DB instance until you confirm that everything is working correctly.

**Upgrading a SQL Server DB instance**

For information about manually or automatically upgrading a SQL Server DB instance, see the following:

- Upgrading a DB instance engine version (p. 369)
- Best practices for upgrading SQL Server 2008 R2 to SQL Server 2016 on Amazon RDS for SQL Server

**Important**

If you have any snapshots that are encrypted using AWS KMS, we recommend that you initiate an upgrade before support ends.

**Upgrading deprecated DB instances before support ends**

After a major version is deprecated, you can't install it on new DB instances. RDS will try to automatically upgrade all existing DB instances.

If you need to restore a deprecated DB instance, you can do point-in-time recovery (PITR) or restore a snapshot. Doing this gives you temporary access a DB instance that uses the version that is being deprecated. However, after a major version is fully deprecated, these DB instances will also be automatically upgraded to a supported version.
Importing and exporting SQL Server databases using native backup and restore

Amazon RDS supports native backup and restore for Microsoft SQL Server databases using full backup files (.bak files). When you use RDS, you access files stored in Amazon S3 rather than using the local file system on the database server.

For example, you can create a full backup from your local server, store it on S3, and then restore it onto an existing Amazon RDS DB instance. You can also make backups from RDS, store them on S3, and then restore them wherever you want.

Native backup and restore is available in all AWS Regions for Single-AZ and Multi-AZ DB instances, including Multi-AZ DB instances with read replicas. Native backup and restore is available for all editions of Microsoft SQL Server supported on Amazon RDS.

The following diagram shows the supported scenarios.

Using native .bak files to back up and restore databases is usually the fastest way to back up and restore databases. There are many additional advantages to using native backup and restore. For example, you can do the following:

- Migrate databases to or from Amazon RDS.
- Move databases between RDS for SQL Server DB instances.
- Migrate data, schemas, stored procedures, triggers, and other database code inside .bak files.
- Backup and restore single databases, instead of entire DB instances.
- Create copies of databases for development, testing, training, and demonstrations.
- Store and transfer backup files with Amazon S3, for an added layer of protection for disaster recovery.
- Create native backups of databases that have Transparent Data Encryption (TDE) turned on, and restore those backups to on-premises databases. For more information, see Support for Transparent Data Encryption in SQL Server (p. 1258).
- Restore native backups of on-premises databases that have TDE turned on to RDS for SQL Server DB instances. For more information, see Support for Transparent Data Encryption in SQL Server (p. 1258).

Contents

- Limitations and recommendations (p. 1141)
- Setting up for native backup and restore (p. 1142)
Limitations and recommendations

The following are some limitations to using native backup and restore:

- You can’t back up to, or restore from, an Amazon S3 bucket in a different AWS Region from your Amazon RDS DB instance.
- You can’t restore a database with the same name as an existing database. Database names are unique.
- We strongly recommend that you don’t restore backups from one time zone to a different time zone. If you restore backups from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change.
- Amazon S3 has a size limit of 5 TB per file. For native backups of larger databases, you can use multfile backup.
• The maximum database size that can be backed up to S3 depends on the available memory, CPU, I/O, and network resources on the DB instance. The larger the database, the more memory the backup agent consumes. Our testing shows that you can make a compressed backup of a 16-TB database on our newest-generation instance types from 2xlarge instance sizes and larger, given sufficient system resources.

• You can't back up to or restore from more than 10 backup files at the same time.

• A differential backup is based on the last full backup. For differential backups to work, you can't take a snapshot between the last full backup and the differential backup. If you want a differential backup, but a manual or automated snapshot exists, then do another full backup before proceeding with the differential backup.

• Differential and log restores aren't supported for databases with files that have their file_guid (unique identifier) set to NULL.

• You can run up to two backup or restore tasks at the same time.

• You can't perform native log backups from SQL Server on Amazon RDS.

• RDS supports native restores of databases up to 16 TB. Native restores of databases on SQL Server Express Edition are limited to 10 GB.

• You can't do a native backup during the maintenance window, or any time Amazon RDS is in the process of taking a snapshot of the database. If a native backup task overlaps with the RDS daily backup window, the native backup task is canceled.

• On Multi-AZ DB instances, you can only natively restore databases that are backed up in the full recovery model.

• Restoring from differential backups on Multi-AZ instances isn't supported.

• Calling the RDS procedures for native backup and restore within a transaction isn't supported.

• Use a symmetric encryption AWS KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the AWS Key Management Service Developer Guide.

• Native backup files are encrypted with the specified KMS key using the "Encryption-Only" crypto mode. When you are restoring encrypted backup files, be aware that they were encrypted with the "Encryption-Only" crypto mode.

• You can't restore a database that contains a FILESTREAM file group.

If your database can be offline while the backup file is created, copied, and restored, we recommend that you use native backup and restore to migrate it to RDS. If your on-premises database can't be offline, we recommend that you use the AWS Database Migration Service to migrate your database to Amazon RDS. For more information, see What is AWS Database Migration Service?

Native backup and restore isn't intended to replace the data recovery capabilities of the cross-region snapshot copy feature. We recommend that you use snapshot copy to copy your database snapshot to another AWS Region for cross-region disaster recovery in Amazon RDS. For more information, see Copying a DB snapshot (p. 493).

Setting up for native backup and restore

To set up for native backup and restore, you need three components:

1. An Amazon S3 bucket to store your backup files.

You must have an S3 bucket to use for your backup files and then upload backups you want to migrate to RDS. If you already have an Amazon S3 bucket, you can use that. If you don't, you can create a bucket. Alternatively, you can choose to have a new bucket created for you when you add the SQLSERVER_BACKUP_RESTORE option by using the AWS Management Console.
For information on using S3, see the *Amazon Simple Storage Service User Guide* for a simple introduction. For more depth, see the *Amazon Simple Storage Service User Guide*.

2. An AWS Identity and Access Management (IAM) role to access the bucket.

   If you already have an IAM role, you can use that. You can choose to have a new IAM role created for you when you add the SQLSERVER_BACKUP_RESTORE option by using the AWS Management Console. Alternatively, you can create a new one manually.

   If you want to create a new IAM role manually, take the approach discussed in the next section. Do the same if you want to attach trust relationships and permissions policies to an existing IAM role.

3. The SQLSERVER_BACKUP_RESTORE option added to an option group on your DB instance.

   To enable native backup and restore on your DB instance, you add the SQLSERVER_BACKUP_RESTORE option to an option group on your DB instance. For more information and instructions, see Support for native backup and restore in SQL Server (p. 1255).

### Manually creating an IAM role for native backup and restore

If you want to manually create a new IAM role to use with native backup and restore, you can do so. In this case, you create a role to delegate permissions from the Amazon RDS service to your Amazon S3 bucket. When you create an IAM role, you attach a trust relationship and a permissions policy. The trust relationship allows RDS to assume this role. The permissions policy defines the actions this role can perform. For more information about creating the role, see Creating a role to delegate permissions to an AWS service.

For the native backup and restore feature, use trust relationships and permissions policies similar to the examples in this section. In the following example, we use the service principal name rds.amazonaws.com as an alias for all service accounts. In the other examples, we specify an Amazon Resource Name (ARN) to identify another account, user, or role that we're granting access to in the trust policy.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full ARN of the resources accessing the role. For native backup and restore, make sure to include both the DB option group and the DB instances, as shown in the following example.

#### Example trust relationship with global condition context key for native backup and restore

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            }
        }
    ]
}
```
The following example uses an ARN to specify a resource. For more information on using ARNs, see Amazon resource names (ARNs).

Example permissions policy for native backup and restore without encryption support

```
{  
  "Version": "2012-10-17",  
  "Statement": [
    {  
      "Effect": "Allow",  
      "Action":  
        [  
          "s3:ListBucket",  
          "s3:GetBucketLocation"
        ],  
      "Resource": "arn:aws:s3:::bucket_name"
    },  
    {  
      "Effect": "Allow",  
      "Action":  
        [  
          "s3:GetObjectAttributes",  
          "s3:GetObject",  
          "s3:PutObject",  
          "s3:ListMultipartUploadParts",  
          "s3:AbortMultipartUpload"
        ],  
      "Resource": "arn:aws:s3:::bucket_name/*"
    }
  ]
}
```

Example permissions policy for native backup and restore with encryption support

If you want to encrypt your backup files, include an encryption key in your permissions policy. For more information about encryption keys, see Getting started in the AWS Key Management Service Developer Guide.

**Note**

You must use a symmetric encryption KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the AWS Key Management Service Developer Guide.

The IAM role must also be a key user and key administrator for the KMS key, that is, it must be specified in the key policy. For more information, see Creating symmetric encryption KMS keys in the AWS Key Management Service Developer Guide.
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Action": [
            "kms:DescribeKey",
            "kms:GenerateDataKey",
            "kms:Encrypt",
            "kms:Decrypt"
        ],
        "Resource": "arn:aws:kms:region:account-id:key/key-id"
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3:ListBucket",
            "s3:GetBucketLocation"
        ],
        "Resource": "arn:aws:s3:::bucket_name"
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3:GetObjectAttributes",
            "s3:GetObject",
            "s3:PutObject",
            "s3:ListMultipartUploadParts",
            "s3:AbortMultipartUpload"
        ],
        "Resource": "arn:aws:s3:::bucket_name/*"
    }
]
Using native backup and restore

After you have enabled and configured native backup and restore, you can start using it. First, you connect to your Microsoft SQL Server database, and then you call an Amazon RDS stored procedure to do the work. For instructions on connecting to your database, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 1125).

Some of the stored procedures require that you provide an Amazon Resource Name (ARN) to your Amazon S3 bucket and file. The format for your ARN is `arn:aws:s3:::bucket_name/file_name.extension`. Amazon S3 doesn't require an account number or AWS Region in ARNs.

If you also provide an optional KMS key, the format for the ARN of the key is `arn:aws:kms:region:account-id:key/key-id`. For more information, see Amazon resource names (ARNs) and AWS service namespaces. You must use a symmetric encryption KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the AWS Key Management Service Developer Guide.

**Note**
Whether or not you use a KMS key, the native backup and restore tasks enable server-side Advanced Encryption Standard (AES) 256-bit encryption by default for files uploaded to S3.

For instructions on how to call each stored procedure, see the following topics:

- Backing up a database (p. 1146)
- Restoring a database (p. 1149)
- Restoring a log (p. 1151)
- Finishing a database restore (p. 1152)
- Working with partially restored databases (p. 1153)
- Canceling a task (p. 1153)
- Tracking the status of tasks (p. 1153)

**Backing up a database**

To back up your database, use the `rds_backup_database` stored procedure.

**Note**
You can't back up a database during the maintenance window, or while Amazon RDS is taking a snapshot.

**Usage**

```sql
exec msdb.dbo.rds_backup_database
@source_db_name='database_name',
@s3_arn_to_backup_to='arn:aws:s3:::bucket_name/file_name.extension',
[@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@overwrite_s3_backup_file=0|1],
[@type='DIFFERENTIAL|FULL'],
[@number_of_files=n];
```

The following parameters are required:

- `@source_db_name` – The name of the database to back up.
- `@s3_arn_to_backup_to` – The ARN indicating the Amazon S3 bucket to use for the backup, plus the name of the backup file.
The file can have any extension, but .bak is usually used.

The following parameters are optional:

- @kms_master_key_arn – The ARN for the symmetric encryption KMS key to use to encrypt the item.
  - You can't use the default encryption key. If you use the default key, the database won't be backed up.
  - If you don't specify a KMS key identifier, the backup file won't be encrypted. For more information, see Encrypting Amazon RDS resources.
  - When you specify a KMS key, client-side encryption is used.
  - Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the AWS Key Management Service Developer Guide.
- @overwrite_s3_backup_file – A value that indicates whether to overwrite an existing backup file.
  - 0 – Doesn't overwrite an existing file. This value is the default.
  - 1 – Overwrites an existing file that has the specified name, even if it isn't a backup file.
- @type – The type of backup.
  - DIFFERENTIAL – Makes a differential backup.
  - FULL – Makes a full backup. This value is the default.

A differential backup is based on the last full backup. For differential backups to work, you can't take a snapshot between the last full backup and the differential backup. If you want a differential backup, but a snapshot exists, then do another full backup before proceeding with the differential backup.

You can look for the last full backup or snapshot using the following example SQL query:

```
select top 1
database_name,
    backup_start_date,
    backup_finish_date
from    msdb.dbo.backupset
where   database_name='mydatabase'
        and type = 'D'
order by backup_start_date desc;
```

- @number_of_files – The number of files into which the backup will be divided (chunked). The maximum number is 10.
  - Multifile backup is supported for both full and differential backups.
  - If you enter a value of 1 or omit the parameter, a single backup file is created.

Provide the prefix that the files have in common, then suffix that with an asterisk (*). The asterisk can be anywhere in the file_name part of the S3 ARN. The asterisk is replaced by a series of alphanumeric strings in the generated files, starting with 1-of-number_of_files.

For example, if the file names in the S3 ARN are backup*.bak and you set @number_of_files=4, the backup files generated are backup1-of-4.bak, backup2-of-4.bak, backup3-of-4.bak, and backup4-of-4.bak.

- If any of the file names already exists, and @overwrite_s3_backup_file is 0, an error is returned.
- Multifile backups can only have one asterisk in the file_name part of the S3 ARN.
- Single-file backups can have any number of asterisks in the file_name part of the S3 ARN. Asterisks aren't removed from the generated file name.
Examples

Example of differential backup

```sql
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup1.bak',
@overwrite_s3_backup_file=1,
@type='DIFFERENTIAL';
```

Example of full backup with encryption

```sql
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup1.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE',
@overwrite_s3_backup_file=1,
@type='FULL';
```

Example of multfile backup

```sql
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@number_of_files=4;
```

Example of multfile differential backup

```sql
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@type='DIFFERENTIAL',
@number_of_files=4;
```

Example of multfile backup with encryption

```sql
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE',
@number_of_files=4;
```

Example of multfile backup with S3 overwrite

```sql
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@overwrite_s3_backup_file=1,
@number_of_files=4;
```

Example of single-file backup with the @number_of_files parameter

This example generates a backup file named backup*.bak.

```sql
exec msdb.dbo.rds_backup_database
```
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@number_of_files=1;

# Restoring a database

To restore your database, call the `rds_restore_database` stored procedure. Amazon RDS creates an initial snapshot of the database after the restore task is complete and the database is open.

**Usage**

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='database_name',
@s3_arn_to_restore_from='arn:aws:s3:::bucket_name/file_name.extension',
@with_norecovery=0|1,
[kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@type='DIFFERENTIAL|FULL'];
```

The following parameters are required:

- `@restore_db_name` – The name of the database to restore. Database names are unique. You can't restore a database with the same name as an existing database.
- `@s3_arn_to_restore_from` – The ARN indicating the Amazon S3 prefix and names of the backup files used to restore the database.
  - For a single-file backup, provide the entire file name.
  - For a multi-file backup, provide the prefix that the files have in common, then suffix that with an asterisk (*).
  - If `@s3_arn_to_restore_from` is empty, the following error message is returned: S3 ARN prefix cannot be empty.

The following parameter is required for differential restores, but optional for full restores:

- `@with_norecovery` – The recovery clause to use for the restore operation.
  - Set it to 0 to restore with RECOVERY. In this case, the database is online after the restore.
  - Set it to 1 to restore with NORECOVERY. In this case, the database remains in the RESTORING state after restore task completion. With this approach, you can do later differential restores.
  - For DIFFERENTIAL restores, specify 0 or 1.
  - For FULL restores, this value defaults to 0.

The following parameters are optional:

- `@kms_master_key_arn` – If you encrypted the backup file, the KMS key to use to decrypt the file.
  - When you specify a KMS key, client-side encryption is used.
- `@type` – The type of restore. Valid types are DIFFERENTIAL and FULL. The default value is FULL.

**Note**

For differential restores, either the database must be in the RESTORING state or a task must already exist that restores with NORECOVERY.
You can't restore later differential backups while the database is online.
You can't submit a restore task for a database that already has a pending restore task with RECOVERY.
Full restores with NORECOVERY and differential restores aren't supported on Multi-AZ instances.
Restoring a database on a Multi-AZ instance with read replicas is similar to restoring a database on a Multi-AZ instance. You don't have to take any additional actions to restore a database on a replica.

**Examples**

**Example of single-file restore**

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak';
```

**Example of multifile restore**

To avoid errors when restoring multiple files, make sure that all the backup files have the same prefix, and that no other files use that prefix.

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup*';
```

**Example of full database restore with RECOVERY**

The following three examples perform the same task, full restore with RECOVERY.

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak';
```

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='DIFFERENTIAL|FULL';
```

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='FULL',
@with_norecovery=0;
```

**Example of full database restore with encryption**

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE';
```

**Example of full database restore with NORECOVERY**

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='FULL',
@with_norecovery=1;
```
Example of differential restore with NORECOVERY

exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='DIFFERENTIAL',
@with_norecovery=1;

Example of differential restore with RECOVERY

exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='DIFFERENTIAL',
@with_norecovery=0;

Restoring a log

To restore your log, call the rds_restore_log stored procedure.

Usage

exec msdb.dbo.rds_restore_log
@restore_db_name='database_name',
@s3_arn_to_restore_from='arn:aws:s3:::bucket_name/log_file_name.extension',
[@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@with_norecovery=0|1],
[@stopat='datetime'];

The following parameters are required:

- @restore_db_name – The name of the database whose log to restore.
- @s3_arn_to_restore_from – The ARN indicating the Amazon S3 prefix and name of the log file used to restore the log. The file can have any extension, but .trn is usually used.

  If @s3_arn_to_restore_from is empty, the following error message is returned: S3 ARN prefix cannot be empty.

The following parameters are optional:

- @kms_master_key_arn – If you encrypted the log, the KMS key to use to decrypt the log.
- @with_norecovery – The recovery clause to use for the restore operation. This value defaults to 1.
  - Set it to 0 to restore with RECOVERY. In this case, the database is online after the restore. You can't restore further log backups while the database is online.
  - Set it to 1 to restore with NORECOVERY. In this case, the database remains in the RESTORING state after restore task completion. With this approach, you can do later log restores.
- @stopat – A value that specifies that the database is restored to its state at the date and time specified (in datetime format). Only transaction log records written before the specified date and time are applied to the database.

  If this parameter isn't specified (it is NULL), the complete log is restored.

Note

For log restores, either the database must be in a state of restoring or a task must already exist that restores with NORECOVERY.
You can't restore log backups while the database is online.
You can't submit a log restore task on a database that already has a pending restore task with RECOVERY.
Log restores aren't supported on Multi-AZ instances.

**Examples**

**Example of log restore**

```sql
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn';
```

**Example of log restore with encryption**

```sql
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE';
```

**Example of log restore with NORECOVERY**

The following two examples perform the same task, log restore with NORECOVERY.

```sql
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=1;
```

```sql
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn';
```

**Example of log restore with RECOVERY**

```sql
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=0;
```

**Example of log restore with STOPAT clause**

```sql
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=0,
@stopat='2019-12-01 03:57:09';
```

**Finishing a database restore**

If the last restore task on the database was performed using @with_norecovery=1, the database is now in the RESTORING state. Open this database for normal operation by using the rds_finish_restore stored procedure.
Usage

exec msdb.dbo.rds_finish_restore @db_name='database_name';

Note
To use this approach, the database must be in the RESTORING state without any pending restore tasks.
The `rds_finish_restore` procedure isn't supported on Multi-AZ instances.
To finish restoring the database, use the master login. Or use the user login that most recently restored the database or log with NORECOVERY.

Working with partially restored databases

Dropping a partially restored database

To drop a partially restored database (left in the RESTORING state), use the `rds_drop_database` stored procedure.

exec msdb.dbo.rds_drop_database @db_name='database_name';

Note
You can't submit a DROP database request for a database that already has a pending restore or finish restore task.
To drop the database, use the master login. Or use the user login that most recently restored the database or log with NORECOVERY.

Snapshot restore and point-in-time recovery behavior for partially restored databases

Partially restored databases in the source instance (left in the RESTORING state) are dropped from the target instance during snapshot restore and point-in-time recovery.

Canceling a task

To cancel a backup or restore task, call the `rds_cancel_task` stored procedure.

Note
You can't cancel a FINISH_RESTORE task.

Usage

exec msdb.dbo.rds_cancel_task @task_id=ID_number;

The following parameter is required:

• @task_id – The ID of the task to cancel. You can get the task ID by calling `rds_task_status`.

Tracking the status of tasks

To track the status of your backup and restore tasks, call the `rds_task_status` stored procedure. If you don't provide any parameters, the stored procedure returns the status of all tasks. The status for tasks is updated approximately every two minutes. Task history is retained for 36 days.

Usage

exec msdb.dbo.rds_task_status
The following parameters are optional:

- \(@\text{db\_name}=\text{database\_name}@\) – The name of the database to show the task status for.
- \(@\text{task\_id}=\text{ID\_number}@\) – The ID of the task to show the task status for.

**Examples**

**Example of listing the status for a specific task**

```
exec msdb.dbo.rds_task_status @task_id=5;
```

**Example of listing the status for a specific database and task**

```
exec msdb.dbo.rds_task_status @db_name='my_database',
@task_id=5;
```

**Example of listing all tasks and their statuses on a specific database**

```
exec msdb.dbo.rds_task_status @db_name='my_database';
```

**Example of listing all tasks and their statuses on the current instance**

```
exec msdb.dbo.rds_task_status;
```

**Response**

The rds_task_status stored procedure returns the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>task_type</td>
<td>Task type depending on the input parameters, as follows:</td>
</tr>
<tr>
<td></td>
<td>• For backup tasks:</td>
</tr>
<tr>
<td></td>
<td>• BACKUP_DB – Full database backup</td>
</tr>
<tr>
<td></td>
<td>• BACKUP_DB_DIFFERENTIAL – Differential database backup</td>
</tr>
<tr>
<td></td>
<td>• For restore tasks:</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB – Full database restore with RECOVERY</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB_NORECOVERY – Full database restore with NORECOVERY</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB_DIFFERENTIAL – Differential database restore with RECOVERY</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB_DIFFERENTIAL_NORECOVERY – Differential database restore with NORECOVERY</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB_LOG – Log restore with RECOVERY</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB_LOG_NORECOVERY – Log restore with NORECOVERY</td>
</tr>
<tr>
<td></td>
<td>• For tasks that finish a restore:</td>
</tr>
<tr>
<td></td>
<td>• FINISH_RESTORE – Finish restore and open database</td>
</tr>
</tbody>
</table>
Amazon RDS creates an initial snapshot of the database after it is open on completion of the following restore tasks:

- RESTORE_DB
- RESTORE_DB_DIFFERENTIAL
- RESTORE_DB_LOG
- FINISH_RESTORE

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>database_name</td>
<td>The name of the database that the task is associated with.</td>
</tr>
<tr>
<td>% complete</td>
<td>The progress of the task as a percent value.</td>
</tr>
<tr>
<td>duration (mins)</td>
<td>The amount of time spent on the task, in minutes.</td>
</tr>
<tr>
<td>lifecycle</td>
<td>The status of the task. The possible statuses are the following:</td>
</tr>
<tr>
<td></td>
<td>• CREATED – As soon as you call rds_backup_database or</td>
</tr>
<tr>
<td></td>
<td>rds_restore_database, a task is created and the status is set to CREATED.</td>
</tr>
<tr>
<td></td>
<td>• IN_PROGRESS – After a backup or restore task starts, the status is set to</td>
</tr>
<tr>
<td></td>
<td>IN_PROGRESS. It can take up to 5 minutes for the status to change from</td>
</tr>
<tr>
<td></td>
<td>CREATED to IN_PROGRESS.</td>
</tr>
<tr>
<td></td>

</tr>
</tbody>
</table>
Compressing backup files

To save space in your Amazon S3 bucket, you can compress your backup files. For more information about compressing backup files, see Backup compression in the Microsoft documentation.

Compressing your backup files is supported for the following database editions:

- Microsoft SQL Server Enterprise Edition
- Microsoft SQL Server Standard Edition

To turn on compression for your backup files, run the following code:

```sql
exec rdsadmin..rds_set_configuration 'S3 backup compression', 'true';
```

To turn off compression for your backup files, run the following code:

```sql
exec rdsadmin..rds_set_configuration 'S3 backup compression', 'false';
```

Troubleshooting

The following are issues you might encounter when you use native backup and restore.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database backup/restore option is not enabled yet or is in the process of being enabled. Please try again later.</td>
<td>Make sure that you have added the SQLSERVER_BACKUP_RESTORE option to the DB option group associated with your DB instance. For more information, see Adding the native backup and restore option (p. 1255).</td>
</tr>
</tbody>
</table>
| Access Denied | The backup or restore process can't access the backup file. This is usually caused by issues like the following:  
- Referencing the incorrect bucket. Referencing the bucket using an incorrect format. Referencing a file name without using the ARN.  
- Incorrect permissions on the bucket file. For example, if it is created by a different account that is trying to access it now, add the correct permissions.  
- An IAM policy that is incorrect or incomplete. Your IAM role must include all the necessary elements, including, for example, the correct version. These are highlighted in Importing and exporting SQL Server databases using native backup and restore (p. 1140). |
<p>| BACKUP DATABASE WITH COMPRESSION isn't supported on &lt;edition_name&gt; Edition | Compressing your backup files is only supported for Microsoft SQL Server Enterprise Edition and Standard Edition. For more information, see Compressing backup files (p. 1156). |
| Key &lt;ARN&gt; does not exist | You attempted to restore an encrypted backup, but didn't provide a valid encryption key. Check your encryption key and retry. For more information, see Restoring a database (p. 1149). |</p>
<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
</table>
| Please reissue task with correct type and overwrite property | If you attempt to back up your database and provide the name of a file that already exists, but set the overwrite property to false, the save operation fails. To fix this error, either provide the name of a file that doesn't already exist, or set the overwrite property to true.  
For more information, see Backing up a database (p. 1146).  
It's also possible that you intended to restore your database, but called the rds_backup_database stored procedure accidentally. In that case, call the rds_restore_database stored procedure instead.  
For more information, see Restoring a database (p. 1149).  
If you intended to restore your database and called the rds_restore_database stored procedure, make sure that you provided the name of a valid backup file.  
For more information, see Using native backup and restore (p. 1146). |
| Please specify a bucket that is in the same region as RDS instance | You can't back up to, or restore from, an Amazon S3 bucket in a different AWS Region from your Amazon RDS DB instance. You can use Amazon S3 replication to copy the backup file to the correct AWS Region.  
For more information, see Cross-Region replication in the Amazon S3 documentation. |
| The specified bucket does not exist | Verify that you have provided the correct ARN for your bucket and file, in the correct format.  
For more information, see Using native backup and restore (p. 1146). |
| User <ARN> is not authorized to perform <kms action> on resource <ARN> | You requested an encrypted operation, but didn't provide correct AWS KMS permissions. Verify that you have the correct permissions, or add them.  
For more information, see Setting up for native backup and restore (p. 1142). |
| The Restore task is unable to restore from more than 10 backup file(s). Please reduce the number of files matched and try again. | Reduce the number of files that you're trying to restore from. You can make each individual file larger if necessary. |
| Database 'database_name' already exists. Two databases that differ only by case or accent are not allowed. Choose a different database name. | You can't restore a database with the same name as an existing database. Database names are unique. |
Importing and exporting SQL Server data using other methods

Following, you can find information about using snapshots to import your Microsoft SQL Server data to Amazon RDS. You can also find information about using snapshots to export your data from an RDS DB instance running SQL Server.

If your scenario supports it, it's easier to move data in and out of Amazon RDS by using the native backup and restore functionality. For more information, see Importing and exporting SQL Server databases using native backup and restore (p. 1140).

Note
Amazon RDS for Microsoft SQL Server doesn't support importing data into the msdb database.

Importing data into RDS for SQL Server by using a snapshot

To import data into a SQL Server DB instance by using a snapshot

1. Create a DB instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
2. Stop applications from accessing the destination DB instance.
   
   If you prevent access to your DB instance while you are importing data, data transfer is faster. Additionally, you don't need to worry about conflicts while data is being loaded if other applications cannot write to the DB instance at the same time. If something goes wrong and you have to roll back to an earlier database snapshot, the only changes that you lose are the imported data. You can import this data again after you resolve the issue.

   For information about controlling access to your DB instance, see Controlling access with security groups (p. 2232).
3. Create a snapshot of the target database.

   If the target database is already populated with data, we recommend that you take a snapshot of the database before you import the data. If something goes wrong with the data import or you want to discard the changes, you can restore the database to its previous state by using the snapshot. For information about database snapshots, see Creating a DB snapshot (p. 483).

   Note
   When you take a database snapshot, I/O operations to the database are suspended for a moment (milliseconds) while the backup is in progress.
4. Disable automated backups on the target database.

   Disabling automated backups on the target DB instance improves performance while you are importing your data because Amazon RDS doesn't log transactions when automatic backups are disabled. However, there are some things to consider. Automated backups are required to perform a point-in-time recovery. Thus, you can't restore the database to a specific point in time while you are importing data. Additionally, any automated backups that were created on the DB instance are erased unless you choose to retain them.

   Choosing to retain the automated backups can help protect you against accidental deletion of data. Amazon RDS also saves the database instance properties along with each automated backup to make it easy to recover. Using this option lets you can restore a deleted database instance to a specified point in time within the backup retention period even after deleting it. Automated backups are automatically deleted at the end of the specified backup window, just as they are for an active database instance.

   You can also use previous snapshots to recover the database, and any snapshots that you have taken remain available. For information about automated backups, see Working with backups (p. 462).
5. Disable foreign key constraints, if applicable.

If you need to disable foreign key constraints, you can do so with the following script.

```
--Disable foreign keys on all tables
DECLARE @table_name SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE table_cursor CURSOR FOR SELECT name FROM sys.tables;
OPEN table_cursor;
FETCH NEXT FROM table_cursor INTO @table_name;
WHILE @@FETCH_STATUS = 0 BEGIN
    SELECT @cmd = 'ALTER TABLE ' + QUOTENAME(@table_name) + ' NOCHECK CONSTRAINT ALL';
    EXEC (@cmd);
    FETCH NEXT FROM table_cursor INTO @table_name;
END
CLOSE table_cursor;
DEALLOCATE table_cursor;
GO
```

6. Drop indexes, if applicable.

7. Disable triggers, if applicable.

If you need to disable triggers, you can do so with the following script.

```
--Disable triggers on all tables
DECLARE @enable BIT = 0;
DECLARE @trigger SYSNAME;
DECLARE @table SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE trigger_cursor CURSOR FOR SELECT trigger_object.name trigger_name,
table_object.name table_name
FROM sysobjects trigger_object
JOIN sysobjects table_object ON trigger_object.parent_obj = table_object.id
WHERE trigger_object.type = 'TR';
OPEN trigger_cursor;
FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
WHILE @@FETCH_STATUS = 0 BEGIN
    IF @enable = 1
        SET @cmd = 'ENABLE ';
    ELSE
        SET @cmd = 'DISABLE ';
    SET @cmd = @cmd + ' TRIGGER dbo.' + QUOTENAME(@trigger) + ' ON
dbo.' + QUOTENAME(@table) + ' ';
    EXEC (@cmd);
    FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
END
CLOSE trigger_cursor;
DEALLOCATE trigger_cursor;
GO
```

8. Query the source SQL Server instance for any logins that you want to import to the destination DB instance.
SQL Server stores logins and passwords in the master database. Because Amazon RDS doesn't grant access to the master database, you cannot directly import logins and passwords into your destination DB instance. Instead, you must query the master database on the source SQL Server instance to generate a data definition language (DDL) file. This file should include all logins and passwords that you want to add to the destination DB instance. This file also should include role memberships and permissions that you want to transfer.

For information about querying the master database, see How to transfer the logins and the passwords between instances of SQL Server 2005 and SQL Server 2008 in the Microsoft Knowledge Base.

The output of the script is another script that you can run on the destination DB instance. The script in the Knowledge Base article has the following code:

```
p.type IN
```

Every place `p.type` appears, use the following code instead:

```
p.type = 'S'
```

9. Import the data using the method in Import the data (p. 1161).

10. Grant applications access to the target DB instance.

When your data import is complete, you can grant access to the DB instance to those applications that you blocked during the import. For information about controlling access to your DB instance, see Controlling access with security groups (p. 2232).

11. Enable automated backups on the target DB instance.

For information about automated backups, see Working with backups (p. 462).

12. Enable foreign key constraints.

If you disabled foreign key constraints earlier, you can now enable them with the following script.

```
--Enable foreign keys on all tables
DECLARE @table_name SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE table_cursor CURSOR FOR SELECT name FROM sys.tables;
OPEN table_cursor;
FETCH NEXT FROM table_cursor INTO @table_name;
WHILE @@FETCH_STATUS = 0 BEGIN
    SELECT @cmd = 'ALTER TABLE '+QUOTENAME(@table_name)+' CHECK CONSTRAINT ALL';
    EXEC (@cmd);
    FETCH NEXT FROM table_cursor INTO @table_name;
END
CLOSE table_cursor;
DEALLOCATE table_cursor;
```

13. Enable indexes, if applicable.

14. Enable triggers, if applicable.

If you disabled triggers earlier, you can now enable them with the following script.

```
--Enable triggers on all tables
DECLARE @enable BIT = 1;
```
DECLARE @trigger SYSNAME;
DECLARE @table SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE trigger_cursor CURSOR FOR SELECT trigger_object.name trigger_name,
table_object.name table_name
FROM sysobjects trigger_object
JOIN sysobjects table_object ON trigger_object.parent_obj = table_object.id
WHERE trigger_object.type = 'TR';

OPEN trigger_cursor;
FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
WHILE @@FETCH_STATUS = 0 BEGIN
IF @enable = 1
SET @cmd = 'ENABLE ';
ELSE
SET @cmd = 'DISABLE ';
SET @cmd = @cmd + ' TRIGGER dbo.'+QUOTENAME(@trigger)+' ON
dbo.'+QUOTENAME(@table)+' ';
EXEC (@cmd);
FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
END
CLOSE trigger_cursor;
DEALLOCATE trigger_cursor;

Import the data

Microsoft SQL Server Management Studio is a graphical SQL Server client that is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio Express is available from Microsoft as a free download. To find this download, see the Microsoft website.

Note
SQL Server Management Studio is available only as a Windows-based application.

SQL Server Management Studio includes the following tools, which are useful in importing data to a SQL Server DB instance:

- Generate and Publish Scripts Wizard
- Import and Export Wizard
- Bulk copy

Generate and Publish Scripts Wizard

The Generate and Publish Scripts Wizard creates a script that contains the schema of a database, the data itself, or both. You can generate a script for a database in your local SQL Server deployment. You can then run the script to transfer the information that it contains to an Amazon RDS DB instance.

Note
For databases of 1 GiB or larger, it's more efficient to script only the database schema. You then use the Import and Export Wizard or the bulk copy feature of SQL Server to transfer the data.

For detailed information about the Generate and Publish Scripts Wizard, see the Microsoft SQL Server documentation.

In the wizard, pay particular attention to the advanced options on the Set Scripting Options page to ensure that everything you want your script to include is selected. For example, by default, database triggers are not included in the script.
When the script is generated and saved, you can use SQL Server Management Studio to connect to your DB instance and then run the script.

Import and Export Wizard

The Import and Export Wizard creates a special Integration Services package, which you can use to copy data from your local SQL Server database to the destination DB instance. The wizard can filter which tables and even which tuples within a table are copied to the destination DB instance.

Note
The Import and Export Wizard works well for large datasets, but it might not be the fastest way to remotely export data from your local deployment. For an even faster way, consider the SQL Server bulk copy feature.

For detailed information about the Import and Export Wizard, see the Microsoft SQL Server documentation.

In the wizard, on the Choose a Destination page, do the following:

- For Server Name, type the name of the endpoint for your DB instance.
- For the server authentication mode, choose Use SQL Server Authentication.
- For User name and Password, type the credentials for the master user that you created for the DB instance.

Bulk copy

The SQL Server bulk copy feature is an efficient means of copying data from a source database to your DB instance. Bulk copy writes the data that you specify to a data file, such as an ASCII file. You can then run bulk copy again to write the contents of the file to the destination DB instance.

This section uses the bcp utility, which is included with all editions of SQL Server. For detailed information about bulk import and export operations, see the Microsoft SQL Server documentation.

Note
Before you use bulk copy, you must first import your database schema to the destination DB instance. The Generate and Publish Scripts Wizard, described earlier in this topic, is an excellent tool for this purpose.

The following command connects to the local SQL Server instance. It generates a tab-delimited file of a specified table in the C:\ root directory of your existing SQL Server deployment. The table is specified by its fully qualified name, and the text file has the same name as the table that is being copied.

```
bcp dbname.schema_name.table_name out C:\table_name.txt -n -S localhost -U username -P password -b 10000
```

The preceding code includes the following options:

- `-n` specifies that the bulk copy uses the native data types of the data to be copied.
- `-S` specifies the SQL Server instance that the bcp utility connects to.
- `-U` specifies the user name of the account to log in to the SQL Server instance.
- `-P` specifies the password for the user specified by `-U`.
- `-b` specifies the number of rows per batch of imported data.

Note
There might be other parameters that are important to your import situation. For example, you might need the `-E` parameter that pertains to identity values. For more information; see
the full description of the command line syntax for the bcp utility in the Microsoft SQL Server documentation.

For example, suppose that a database named store that uses the default schema, dbo, contains a table named customers. The user account admin, with the password insecure, copies 10,000 rows of the customers table to a file named customers.txt.

```
bcp store.dbo.customers out C:\customers.txt -n -S localhost -U admin -P insecure -b 10000
```

After you generate the data file, you can upload the data to your DB instance by using a similar command. Beforehand, create the database and schema on the target DB instance. Then use the in argument to specify an input file instead of out to specify an output file. Instead of using localhost to specify the local SQL Server instance, specify the endpoint of your DB instance. If you use a port other than 1433, specify that too. The user name and password are the master user and password for your DB instance. The syntax is as follows.

```
bcp dbname.schema_name.table_name in C:\table_name.txt -n -S endpoint,port -U master_user_name -P master_user_password -b 10000
```

To continue the previous example, suppose that the master user name is admin, and the password is insecure. The endpoint for the DB instance is rds.ckz2kqd4qsn1.us-east-1.rds.amazonaws.com, and you use port 4080. The command is as follows.

```
bcp store.dbo.customers in C:\customers.txt -n -S rds.ckz2kqd4qsn1.us-east-1.rds.amazonaws.com,4080 -U admin -P insecure -b 10000
```

# Exporting data from RDS for SQL Server

You can choose one of the following options to export data from an RDS for SQL Server DB instance:

- **Native database backup using a full backup file (.bak)** – Using .bak files to backup databases is heavily optimized, and is usually the fastest way to export data. For more information, see Importing and exporting SQL Server databases using native backup and restore (p. 1140).

- **SQL Server Import and Export Wizard** – For more information, see SQL Server Import and Export Wizard (p. 1163).

- **SQL Server Generate and Publish Scripts Wizard and bcp utility** – For more information, see SQL Server Generate and Publish Scripts Wizard and bcp utility (p. 1164).

## SQL Server Import and Export Wizard

You can use the SQL Server Import and Export Wizard to copy one or more tables, views, or queries from your RDS for SQL Server DB instance to another data store. This choice is best if the target data store is not SQL Server. For more information, see SQL Server Import and Export Wizard in the SQL Server documentation.

The SQL Server Import and Export Wizard is available as part of Microsoft SQL Server Management Studio. This graphical SQL Server client is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio is available only as a Windows-based application. SQL Server Management Studio Express is available from Microsoft as a free download. To find this download, see the Microsoft website.

### To use the SQL Server Import and Export Wizard to export data

1. In SQL Server Management Studio, connect to your RDS for SQL Server DB instance. For details on how to do this, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 1125).
2. In **Object Explorer**, expand **Databases**, open the context (right-click) menu for the source database, choose **Tasks**, and then choose **Export Data**. The wizard appears.

3. On the **Choose a Data Source** page, do the following:
   a. For **Data source**, choose **SQL Server Native Client 11.0**.
   b. Verify that the **Server name** box shows the endpoint of your RDS for SQL Server DB instance.
   c. Select **Use SQL Server Authentication**. For **User name** and **Password**, type the master user name and password of your DB instance.
   d. Verify that the **Database** box shows the database from which you want to export data.
   e. Choose **Next**.

4. On the **Choose a Destination** page, do the following:
   a. For **Destination**, choose **SQL Server Native Client 11.0**.
      
      **Note**
      
      Other target data sources are available. These include .NET Framework data providers, OLE DB providers, SQL Server Native Client providers, ADO.NET providers, Microsoft Office Excel, Microsoft Office Access, and the Flat File source. If you choose to target one of these data sources, skip the remainder of step 4. For details on the connection information to provide next, see **Choose a destination** in the SQL Server documentation.
   b. For **Server name**, type the server name of the target SQL Server DB instance.
   c. Choose the appropriate authentication type. Type a user name and password if necessary.
   d. For **Database**, choose the name of the target database, or choose **New** to create a new database to contain the exported data.
      
      If you choose **New**, see **Create database** in the SQL Server documentation for details on the database information to provide.
   e. Choose **Next**.

5. On the **Table Copy or Query** page, choose **Copy data from one or more tables or views** or **Write a query to specify the data to transfer**. Choose **Next**.

6. If you chose **Write a query to specify the data to transfer**, you see the **Provide a Source Query** page. Type or paste in a SQL query, and then choose **Parse** to verify it. Once the query validates, choose **Next**.

7. On the **Select Source Tables and Views** page, do the following:
   a. Select the tables and views that you want to export, or verify that the query you provided is selected.
   b. Choose **Edit Mappings** and specify database and column mapping information. For more information, see **Column mappings** in the SQL Server documentation.
   c. (Optional) To see a preview of data to be exported, select the table, view, or query, and then choose **Preview**.
   d. Choose **Next**.

8. On the **Run Package** page, verify that **Run immediately** is selected. Choose **Next**.

9. On the **Complete the Wizard** page, verify that the data export details are as you expect. Choose **Finish**.

10. On the **The execution was successful** page, choose **Close**.

**SQL Server Generate and Publish Scripts Wizard and bcp utility**

You can use the SQL Server Generate and Publish Scripts Wizard to create scripts for an entire database or just selected objects. You can run these scripts on a target SQL Server DB instance to recreate the
scripted objects. You can then use the bcp utility to bulk export the data for the selected objects to the target DB instance. This choice is best if you want to move a whole database (including objects other than tables) or large quantities of data between two SQL Server DB instances. For a full description of the bcp command-line syntax, see bcp utility in the Microsoft SQL Server documentation.

The SQL Server Generate and Publish Scripts Wizard is available as part of Microsoft SQL Server Management Studio. This graphical SQL Server client is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio is available only as a Windows-based application. SQL Server Management Studio Express is available from Microsoft as a free download.

**To use the SQL Server Generate and Publish Scripts Wizard and the bcp utility to export data**

1. In SQL Server Management Studio, connect to your RDS for SQL Server DB instance. For details on how to do this, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 1125).
2. In Object Explorer, expand the Databases node and select the database you want to script.
3. Follow the instructions in Generate and publish scripts Wizard in the SQL Server documentation to create a script file.
4. In SQL Server Management Studio, connect to your target SQL Server DB instance.
5. With the target SQL Server DB instance selected in Object Explorer, choose Open on the File menu, choose File, and then open the script file.
6. If you have scripted the entire database, review the CREATE DATABASE statement in the script. Make sure that the database is being created in the location and with the parameters that you want. For more information, see CREATE DATABASE in the SQL Server documentation.
7. If you are creating database users in the script, check to see if server logins exist on the target DB instance for those users. If not, create logins for those users; the scripted commands to create the database users fail otherwise. For more information, see Create a login in the SQL Server documentation.
8. Choose ! Execute on the SQL Editor menu to run the script file and create the database objects. When the script finishes, verify that all database objects exist as expected.
9. Use the bcp utility to export data from the RDS for SQL Server DB instance into files. Open a command prompt and type the following command.

```bash
bcp database_name.schema_name.table_name out data_file -n -S aws_rds_sql_endpoint -U username -P password
```

The preceding code includes the following options:

- `table_name` is the name of one of the tables that you’ve recreated in the target database and now want to populate with data.
- `data_file` is the full path and name of the data file to be created.
- `-n` specifies that the bulk copy uses the native data types of the data to be copied.
- `-S` specifies the SQL Server DB instance to export from.
- `-U` specifies the user name to use when connecting to the SQL Server DB instance.
- `-P` specifies the password for the user specified by `-U`.

The following shows an example command.

```bash
bcp world.dbo.city out C:\Users\JohnDoe\city.dat -n -S sql-jdoe.1234abcd.us-west-2.rds.amazonaws.com,1433 -U JohnDoe -P ClearTextPassword
```

Repeat this step until you have data files for all of the tables you want to export.
10. Prepare your target DB instance for bulk import of data by following the instructions at Basic guidelines for bulk importing data in the SQL Server documentation.
11. Decide on a bulk import method to use after considering performance and other concerns discussed in About bulk import and bulk export operations in the SQL Server documentation.
12. Bulk import the data from the data files that you created using the bcp utility. To do so, follow the instructions at either Import and export bulk data by using the bcp utility or Import bulk data by using BULK INSERT or OPENROWSET(BULK...) in the SQL Server documentation, depending on what you decided in step 11.
Working with read replicas for Microsoft SQL Server in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with read replicas (p. 382).

In this section, you can find specific information about working with read replicas on Amazon RDS for SQL Server.

Topics

• Configuring read replicas for SQL Server (p. 1167)
• Read replica limitations with SQL Server (p. 1167)
• Option considerations for RDS for SQL Server replicas (p. 1168)
• Troubleshooting a SQL Server read replica problem (p. 1169)

Configuring read replicas for SQL Server

Before a DB instance can serve as a source instance for replication, you must enable automatic backups on the source DB instance. To do so, you set the backup retention period to a value other than 0. The source DB instance must be a Multi-AZ deployment with Always On Availability Groups (AGs). Setting this type of deployment also enforces that automatic backups are enabled.

Creating a SQL Server read replica doesn't require an outage for the primary DB instance. Amazon RDS sets the necessary parameters and permissions for the source DB instance and the read replica without any service interruption. A snapshot is taken of the source DB instance, and this snapshot becomes the read replica. No outage occurs when you delete a read replica.

You can create up to five read replicas from one source DB instance. For replication to operate effectively, we recommend that you configure each read replica with the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

The SQL Server DB engine version of the source DB instance and all of its read replicas must be the same. Amazon RDS upgrades the primary immediately after upgrading the read replicas, regardless of the maintenance window. For more information about upgrading the DB engine version, see Upgrading the Microsoft SQL Server DB engine (p. 1135).

For a read replica to receive and apply changes from the source, it should have sufficient compute and storage resources. If a read replica reaches compute, network, or storage resource capacity, the read replica stops receiving or applying changes from its source. You can modify the storage and CPU resources of a read replica independently from its source and other read replicas.

Read replica limitations with SQL Server

The following limitations apply to SQL Server read replicas on Amazon RDS:

• Read replicas are only available on the SQL Server Enterprise Edition (EE) engine.
• Read replicas are available for SQL Server versions 2016–2019.
• The source DB instance to be replicated must be a Multi-AZ deployment with Always On AGs.
• Read replicas are only available for DB instances running on DB instance classes with four or more vCPUs.
• The following aren't supported on Amazon RDS for SQL Server:
• Backup retention of read replicas
• Point-in-time recovery from read replicas
• Manual snapshots of read replicas
• Multi-AZ read replicas
• Creating read replicas of read replicas
• Synchronization of user logins to read replicas

Amazon RDS for SQL Server doesn't intervene to mitigate high replica lag between a source DB instance and its read replicas. Make sure that the source DB instance and its read replicas are sized properly, in terms of computing power and storage, to suit their operational load.

Option considerations for RDS for SQL Server replicas

Before you create an RDS for SQL Server replica, consider the following requirements, restrictions, and recommendations:

• If your SQL Server replica is in the same Region as its source DB instance, make sure that it belongs to the same option group as the source DB instance. Modifications to the source option group or source option group membership propagate to replicas. These changes are applied to the replicas immediately after they are applied to the source DB instance, regardless of the replica's maintenance window.

For more information about option groups, see Working with option groups (p. 279).

• When you create a SQL Server cross-Region replica, Amazon RDS creates a dedicated option group for it.

You can't remove an SQL Server cross-Region replica from its dedicated option group. No other DB instances can use the dedicated option group for a SQL Server cross-Region replica.

The following options are replicated options. To add replicated options to a SQL Server cross-Region replica, add it to the source DB instance's option group. The option is also installed on all of the source DB instance's replicas.

• TDE

The following options are non-replicated options. You can add or remove non-replicated options from a dedicated option group.

• MSDTC
• SQLSERVER_AUDIT

To enable the SQLSERVER_AUDIT option on cross-Region read replica, add the SQLSERVER_AUDIT option on the dedicated option group on the cross-region read replica and the source instance's option group. By adding the SQLSERVER_AUDIT option on the source instance of SQL Server cross-Region read replica, you can create Server Level Audit Object and Server Level Audit Specifications on each of the cross-Region read replicas of the source instance. To allow the cross-Region read replicas access to upload the completed audit logs to an Amazon S3 bucket, add the SQLSERVER_AUDIT option to the dedicated option group and configure the option settings. The Amazon S3 bucket that you use as a target for audit files must be in the same Region as the cross-Region read replica. You can modify the option setting of the SQLSERVER_AUDIT option for each cross region read replica independently so each can access an Amazon S3 bucket in their respective Region.

The following options are not supported for cross-Region read replicas.

• SSRS
• SSAS
• SSIS
The following options are partially supported for cross-Region read replicas.

- **SQLSERVER_BACKUP_RESTORE**
- The source DB instance of a SQL Server cross-Region replica can have the SQLSERVER_BACKUP_RESTORE option, but you can not perform native restores on the source DB instance until you delete all its cross-Region replicas. Any existing native restore tasks will be cancelled during the creation of a cross-Region replica. You can't add the SQLSERVER_BACKUP_RESTORE option to a dedicated option group.

For more information on native backup and restore, see Importing and exporting SQL Server databases using native backup and restore (p. 1140)

When you promote a SQL Server cross-Region read replica, the promoted replica behaves the same as other SQL Server DB instances, including the management of its options. For more information about option groups, see Working with option groups (p. 279).

### Troubleshooting a SQL Server read replica problem

You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric. For information about replication lag time, see Monitoring read replication (p. 392).

If replication lag is too long, you can use the following query to get information about the lag.

```sql
SELECT AR.replica_server_name, DB_NAME(ARS.database_id) 'database_name', AR.availability_mode_desc, ARS.synchronization_health_desc, ARS.last_hardened_lsn, ARS.last_redone_lsn, ARS.secondary_lag_seconds
FROM sys.dm_hadr_database_replica_states ARS
INNER JOIN sys.availability_replicas AR ON ARS.replica_id = AR.replica_id
--WHERE DB_NAME(ARS.database_id) = 'database_name'
ORDER BY AR.replica_server_name;
```
Multi-AZ deployments for Amazon RDS for Microsoft SQL Server

Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary DB instance. This functionality lets database operations resume quickly without manual intervention. The primary and standby instances use the same endpoint, whose physical network address transitions to the secondary replica as part of the failover process. You don’t have to reconfigure your application when a failover occurs.

Amazon RDS supports Multi-AZ deployments for Microsoft SQL Server by using either SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). Amazon RDS monitors and maintains the health of your Multi-AZ deployment. If problems occur, RDS automatically repairs unhealthy DB instances, reestablishes synchronization, and initiates failovers. Failover only occurs if the standby and primary are fully in sync. You don’t have to manage anything.

When you set up SQL Server Multi-AZ, RDS automatically configures all databases on the instance to use DBM or AGs. Amazon RDS handles the primary, the witness, and the secondary DB instance for you. Because configuration is automatic, RDS selects DBM or Always On AGs based on the version of SQL Server that you deploy.

Amazon RDS supports Multi-AZ with Always On AGs for the following SQL Server versions and editions:

- SQL Server 2019:
  - Standard Edition 15.00.4073.23 and higher
  - Enterprise Edition
- SQL Server 2017:
  - Standard Edition 14.00.3401.7 and higher
  - Enterprise Edition 14.00.3049.1 and higher
- SQL Server 2016: Enterprise Edition 13.00.5216.0 and higher

Amazon RDS supports Multi-AZ with DBM for the following SQL Server versions and editions, except for the versions noted previously:

- SQL Server 2019: Standard Edition 15.00.4043.16
- SQL Server 2017: Standard and Enterprise Editions
- SQL Server 2016: Standard and Enterprise Editions
- SQL Server 2014: Standard and Enterprise Editions

You can use the following SQL query to determine whether your SQL Server DB instance is Single-AZ, Multi-AZ with DBM, or Multi-AZ with Always On AGs.

```sql
SELECT CASE WHEN dm.mirroring_state_desc IS NOT NULL THEN 'Multi-AZ (Mirroring)'
            WHEN dhdrs.group_database_id IS NOT NULL THEN 'Multi-AZ (AlwaysOn)'
            ELSE 'Single-AZ'
        END 'high_availability'
FROM sys.databases sd
LEFT JOIN sys.database_mirroring dm ON sd.database_id = dm.database_id
LEFT JOIN sys.dm_hadr_database_replica_states dhdrs ON sd.database_id = dhdrs.database_id
  AND dhdrs.is_local = 1
WHERE DB_NAME(sd.database_id) = 'rdsadmin';
```
Adding Multi-AZ to a Microsoft SQL Server DB instance

When you create a new SQL Server DB instance using the AWS Management Console, you can add Multi-AZ with Database Mirroring (DBM) or Always On AGs. You do so by choosing Yes (Mirroring / Always On) from Multi-AZ deployment. For more information, see Creating an Amazon RDS DB instance (p. 236).

When you modify an existing SQL Server DB instance using the console, you can add Multi-AZ with DBM or AGs by choosing Yes (Mirroring / Always On) from Multi-AZ deployment on the Modify DB instance page. For more information, see Modifying an Amazon RDS DB instance (p. 333).

Note
If your DB instance is running Database Mirroring (DBM)—not Always On Availability Groups (AGs)—you might need to disable in-memory optimization before you add Multi-AZ. Disable in-memory optimization with DBM before you add Multi-AZ if your DB instance runs SQL Server 2014, 2016, or 2017 Enterprise Edition and has in-memory optimization enabled. If your DB instance is running AGs, it doesn’t require this step.

Removing Multi-AZ from a Microsoft SQL Server DB instance

When you modify an existing SQL Server DB instance using the AWS Management Console, you can remove Multi-AZ with DBM or AGs. You can do this by choosing No (Mirroring / Always On) from Multi-AZ deployment on the Modify DB instance page. For more information, see Modifying an Amazon RDS DB instance (p. 333).

Microsoft SQL Server Multi-AZ deployment limitations, notes, and recommendations

The following are some limitations when working with Multi-AZ deployments on RDS for SQL Server DB instances:

- Cross-Region Multi-AZ isn’t supported.
- You can’t configure the secondary DB instance to accept database read activity.
- Multi-AZ with Always On Availability Groups (AGs) supports in-memory optimization.
- Multi-AZ with Always On Availability Groups (AGs) doesn’t support Kerberos authentication for the availability group listener. This is because the listener has no Service Principal Name (SPN).
- You can’t rename a database on a SQL Server DB instance that is in a SQL Server Multi-AZ deployment. If you need to rename a database on such an instance, first turn off Multi-AZ for the DB instance, then rename the database. Finally, turn Multi-AZ back on for the DB instance.
- You can only restore Multi-AZ DB instances that are backed up using the full recovery model.
- Multi-AZ deployments have a limit of 100 SQL Server Agent jobs.

If you need a higher limit, request an increase by contacting AWS Support. Open the AWS Support Center page, sign in if necessary, and choose Create case. Choose Service limit increase. Complete and submit the form.
Limitations, notes, and recommendations

The following are some notes about working with Multi-AZ deployments on RDS for SQL Server DB instances:

- Amazon RDS exposes the Always On AGs availability group listener endpoint. The endpoint is visible in the console, and is returned by the DescribeDBInstances API operation as an entry in the endpoints field.

- Amazon RDS supports availability group multisubnet failovers.

- To use SQL Server Multi-AZ with a SQL Server DB instance in a virtual private cloud (VPC), first create a DB subnet group that has subnets in at least two distinct Availability Zones. Then assign the DB subnet group to the primary replica of the SQL Server DB instance.

- When a DB instance is modified to be a Multi-AZ deployment, during the modification it has a status of modifying. Amazon RDS creates the standby, and makes a backup of the primary DB instance. After the process is complete, the status of the primary DB instance becomes available.

- Multi-AZ deployments maintain all databases on the same node. If a database on the primary host fails over, all your SQL Server databases fail over as one atomic unit to your standby host. Amazon RDS provisions a new healthy host, and replaces the unhealthy host.

- Multi-AZ with DBM or AGs supports a single standby replica.

- Users, logins, and permissions are automatically replicated for you on the secondary. You don't need to recreate them. User-defined server roles are only replicated in DB instances that use Always On AGs for Multi-AZ deployments.

- In Multi-AZ deployments, SQL Server Agent jobs are replicated from the primary host to the secondary host when the job replication feature is turned on. For more information, see Turning on SQL Server Agent job replication (p. 1347).

- You might observe elevated latencies compared to a standard DB instance deployment (in a single Availability Zone) because of the synchronous data replication.

- Failover times are affected by the time it takes to complete the recovery process. Large transactions increase the failover time.

- In SQL Server Multi-AZ deployments, reboot with failover reboots only the primary DB instance. After the failover, the primary DB instance becomes the new secondary DB instance. Parameters might not be updated for Multi-AZ instances. For reboot without failover, both the primary and secondary DB instances reboot, and parameters are updated after the reboot. If the DB instance is unresponsive, we recommend reboot without failover.

The following are some recommendations for working with Multi-AZ deployments on RDS for Microsoft SQL Server DB instances:

- For databases used in production or preproduction, we recommend the following options:
  - Multi-AZ deployments for high availability
  - "Provisioned IOPS" for fast, consistent performance
  - "Memory optimized" rather than "General purpose"

- You can't select the Availability Zone (AZ) for the secondary instance, so when you deploy application hosts, take this into account. Your database might fail over to another AZ, and the application hosts might not be in the same AZ as the database. For this reason, we recommend that you balance your application hosts across all AZs in the given AWS Region.

- For best performance, don't enable Database Mirroring or Always On AGs during a large data load operation. If you want your data load to be as fast as possible, finish loading data before you convert your DB instance to a Multi-AZ deployment.

- Applications that access the SQL Server databases should have exception handling that catches connection errors. The following code sample shows a try/catch block that catches a communication error. In this example, the break statement exits the while loop if the connection is successful, but retries up to 10 times if an exception is thrown.
int RetryMaxAttempts = 10;
int RetryIntervalPeriodInSeconds = 1;
int iRetryCount = 0;
while (iRetryCount < RetryMaxAttempts)
{
    using (SqlConnection connection = new SqlConnection(DatabaseConnString))
    {
        using (SqlCommand command = connection.CreateCommand())
        {
            command.CommandText = "INSERT INTO SOME_TABLE VALUES ('SomeValue');";
            try
            {
                connection.Open();
                command.ExecuteNonQuery();
                break;
            }
            catch (Exception ex)
            {
                Logger(ex.Message);
                iRetryCount++;
            }
        }
        finally {
            connection.Close();
        }
    }
    Thread.Sleep(RetryIntervalPeriodInSeconds * 1000);
}

• Don't use the Set Partner Off command when working with Multi-AZ instances. For example, don't do the following.

   --Don't do this
   ALTER DATABASE db1 SET PARTNER off

• Don't set the recovery mode to simple. For example, don't do the following.

   --Don't do this
   ALTER DATABASE db1 SET RECOVERY simple

• Don't use the DEFAULT_DATABASE parameter when creating new logins on Multi-AZ DB instances, because these settings can't be applied to the standby mirror. For example, don't do the following.

   --Don't do this
   CREATE LOGIN [test_dba] WITH PASSWORD=foo, DEFAULT_DATABASE=[db2]

   Also, don't do the following.

   --Don't do this
   ALTER LOGIN [test_dba] SET DEFAULT_DATABASE=[db3]

Determining the location of the secondary

You can determine the location of the secondary replica by using the AWS Management Console. You need to know the location of the secondary if you are setting up your primary DB instance in a VPC.
You can also view the Availability Zone of the secondary using the AWS CLI command `describe-db-instances` or RDS API operation `DescribeDBInstances`. The output shows the secondary AZ where the standby mirror is located.

**Migrating from Database Mirroring to Always On Availability Groups**

In version 14.00.3049.1 of Microsoft SQL Server Enterprise Edition, Always On Availability Groups (AGs) are enabled by default.

To migrate from Database Mirroring (DBM) to AGs, first check your version. If you are using a DB instance with a version prior to Enterprise Edition 13.00.5216.0, modify the instance to patch it to 13.00.5216.0 or later. If you are using a DB instance with a version prior to Enterprise Edition 14.00.3049.1, modify the instance to patch it to 14.00.3049.1 or later.

If you want to upgrade a mirrored DB instance to use AGs, run the upgrade first, modify the instance to remove Multi-AZ, and then modify it again to add Multi-AZ. This converts your instance to use Always On AGs.
Additional features for Microsoft SQL Server on Amazon RDS

In the following sections, you can find information about augmenting Amazon RDS instances running the Microsoft SQL Server DB engine.

Topics
- Using SSL with a Microsoft SQL Server DB instance (p. 1176)
- Configuring security protocols and ciphers (p. 1179)
- Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1184)
- Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 (p. 1194)
- Using Database Mail on Amazon RDS for SQL Server (p. 1208)
- Instance store support for the tempdb database on Amazon RDS for SQL Server (p. 1219)
- Using extended events with Amazon RDS for Microsoft SQL Server (p. 1221)
- Access to transaction log backups with RDS for SQL Server (p. 1224)
Using SSL with a Microsoft SQL Server DB instance

You can use Secure Sockets Layer (SSL) to encrypt connections between your client applications and your Amazon RDS DB instances running Microsoft SQL Server. SSL support is available in all AWS regions for all supported SQL Server editions.

When you create a SQL Server DB instance, Amazon RDS creates an SSL certificate for it. The SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

There are 2 ways to use SSL to connect to your SQL Server DB instance:

- Force SSL for all connections — this happens transparently to the client, and the client doesn't have to do any work to use SSL.
- Encrypt specific connections — this sets up an SSL connection from a specific client computer, and you must do work on the client to encrypt connections.

For information about Transport Layer Security (TLS) support for SQL Server, see TLS 1.2 support for Microsoft SQL Server.

Forcing connections to your DB instance to use SSL

You can force all connections to your DB instance to use SSL. If you force connections to use SSL, it happens transparently to the client, and the client doesn't have to do any work to use SSL.

If you want to force SSL, use the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). Set the `rds.force_ssl` parameter to 1 (on) to force connections to use SSL. The `rds.force_ssl` parameter is static, so after you change the value, you must reboot your DB instance for the change to take effect.

To force all connections to your DB instance to use SSL

1. Determine the parameter group that is attached to your DB instance:
   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the top right corner of the Amazon RDS console, choose the AWS Region of your DB instance.
   c. In the navigation pane, choose Databases, and then choose the name of your DB instance to show its details.
   d. Choose the Configuration tab. Find the Parameter group in the section.
2. If necessary, create a new parameter group. If your DB instance uses the default parameter group, you must create a new parameter group. If your DB instance uses a nondefault parameter group, you can choose to edit the existing parameter group or to create a new parameter group. If you edit an existing parameter group, the change affects all DB instances that use that parameter group.
   To create a new parameter group, follow the instructions in Creating a DB parameter group (p. 297).
3. Edit your new or existing parameter group to set the `rds.force_ssl` parameter to true. To edit the parameter group, follow the instructions in Modifying parameters in a DB parameter group (p. 300).
4. If you created a new parameter group, modify your DB instance to attach the new parameter group. Modify the DB Parameter Group setting of the DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 333).
5. Reboot your DB instance. For more information, see Rebooting a DB instance (p. 378).
Encrypting specific connections

You can force all connections to your DB instance to use SSL, or you can encrypting connections from specific client computers only. To use SSL from a specific client, you must obtain certificates for the client computer, import certificates on the client computer, and then encrypt the connections from the client computer.

Note
All SQL Server instances created after August 5, 2014, use the DB instance endpoint in the Common Name (CN) field of the SSL certificate. Prior to August 5, 2014, SSL certificate verification was not available for VPC-based SQL Server instances. If you have a VPC-based SQL Server DB instance that was created before August 5, 2014, and you want to use SSL certificate verification and ensure that the instance endpoint is included as the CN for the SSL certificate for that DB instance, then rename the instance. When you rename a DB instance, a new certificate is deployed and the instance is rebooted to enable the new certificate.

Obtaining certificates for client computers

To encrypt connections from a client computer to an Amazon RDS DB instance running Microsoft SQL Server, you need a certificate on your client computer.

To obtain that certificate, download the certificate to your client computer. You can download a root certificate that works for all regions. You can also download a certificate bundle that contains both the old and new root certificate. In addition, you can download region-specific intermediate certificates. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).

After you have downloaded the appropriate certificate, import the certificate into your Microsoft Windows operating system by following the procedure in the section following.

Importing certificates on client computers

You can use the following procedure to import your certificate into the Microsoft Windows operating system on your client computer.

To import the certificate into your Windows operating system:

1. On the Start menu, type Run in the search box and press Enter.
2. In the Open box, type MMC and then choose OK.
3. In the MMC console, on the File menu, choose Add/Remove Snap-in.
4. In the Add or Remove Snap-ins dialog box, for Available snap-ins, select Certificates, and then choose Add.
5. In the Certificates snap-in dialog box, choose Computer account, and then choose Next.
6. In the Select computer dialog box, choose Finish.
7. In the Add or Remove Snap-ins dialog box, choose OK.
8. In the MMC console, expand Certificates, open the context (right-click) menu for Trusted Root Certification Authorities, choose All Tasks, and then choose Import.
10. On the second page of the Certificate Import Wizard, choose Browse. In the browse window, change the file type to All files (*.*) because .pem is not a standard certificate extension. Locate the .pem file that you downloaded previously.
11. Choose Open to select the certificate file, and then choose Next.
13. On the fourth page of the Certificate Import Wizard, choose Finish. A dialog box appears indicating that the import was successful.
14. In the MMC console, expand **Certificates**, expand **Trusted Root Certification Authorities**, and then choose **Certificates**. Locate the certificate to confirm it exists, as shown here.

![Certificate window](image)

Encrypting connections to an Amazon RDS DB instance running Microsoft SQL Server

After you have imported a certificate into your client computer, you can encrypt connections from the client computer to an Amazon RDS DB instance running Microsoft SQL Server.

For SQL Server Management Studio, use the following procedure. For more information about SQL Server Management Studio, see [Use SQL Server management studio](#).

**To encrypt connections from SQL Server Management Studio**

1. Launch SQL Server Management Studio.
2. For **Connect to server**, type the server information, login user name, and password.
3. Choose **Options**.
4. Select **Encrypt connection**.
5. Choose **Connect**.
6. Confirm that your connection is encrypted by running the following query. Verify that the query returns true for `encrypt_option`.

```sql
select ENCRYPT_OPTION from SYS.DM_EXEC_CONNECTIONS where SESSION_ID = @@SPID
```

For any other SQL client, use the following procedure.

**To encrypt connections from other SQL clients**

1. Append `encrypt=true` to your connection string. This string might be available as an option, or as a property on the connection page in GUI tools.

   **Note**
   To enable SSL encryption for clients that connect using JDBC, you might need to add the Amazon RDS SQL certificate to the Java CA certificate (cacerts) store. You can do this by using the `keytool` utility.

2. Confirm that your connection is encrypted by running the following query. Verify that the query returns true for `encrypt_option`.

```sql
select ENCRYPT_OPTION from SYS.DM_EXEC_CONNECTIONS where SESSION_ID = @@SPID
```
Configuring security protocols and ciphers

You can turn certain security protocols and ciphers on and off using DB parameters. The security parameters that you can configure (except for TLS version 1.2) are shown in the following table.

For parameters other than `rds.fips`, the value of `default` means that the operating system default value is used, whether it is enabled or disabled.

**Note**
You can't disable TLS 1.2, because Amazon RDS uses it internally.

<table>
<thead>
<tr>
<th>DB parameter</th>
<th>Allowed values (default in bold)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rds.tls10</td>
<td>default, enabled, disabled</td>
<td>TLS 1.0.</td>
</tr>
<tr>
<td>rds.tls11</td>
<td>default, enabled, disabled</td>
<td>TLS 1.1.</td>
</tr>
<tr>
<td>rds.tls12</td>
<td>default</td>
<td>TLS 1.2. You can't modify this value.</td>
</tr>
<tr>
<td>rds.fips</td>
<td>0, 1</td>
<td>When you set the parameter to 1, RDS forces the use of modules that are compliant with the Federal Information Processing Standard (FIPS) 140-2 standard. For more information, see Use SQL Server 2016 in FIPS 140-2-compliant mode in the Microsoft documentation. <strong>Note</strong> You must reboot the DB instance after the modification to make it effective.</td>
</tr>
<tr>
<td>rds.rc4</td>
<td>default, enabled, disabled</td>
<td>RC4 stream cipher.</td>
</tr>
<tr>
<td>rds.diffie-hellman</td>
<td>default, enabled, disabled</td>
<td>Diffie-Hellman key-exchange encryption.</td>
</tr>
<tr>
<td>rds.diffie-hellman-min-key-bit-length</td>
<td>default, 1024, 2048, 4096</td>
<td>Minimum bit length for Diffie-Hellman keys.</td>
</tr>
<tr>
<td>rds.curve25519</td>
<td>default, enabled, disabled</td>
<td>Curve25519 elliptic-curve encryption cipher. This parameter isn't supported for all engine versions.</td>
</tr>
<tr>
<td>rds.3des168</td>
<td>default, enabled, disabled</td>
<td>Triple Data Encryption Standard (DES) encryption cipher with a 168-bit key length.</td>
</tr>
</tbody>
</table>
**Note**
For more information on the default values for SQL Server security protocols and ciphers, see Protocols in TLS/SSL (Schannel SSP) and Cipher Suites in TLS/SSL (Schannel SSP) in the Microsoft documentation.
For more information on viewing and setting these values in the Windows Registry, see Transport Layer Security (TLS) best practices with the .NET Framework in the Microsoft documentation.

Use the following process to configure the security protocols and ciphers:

1. Create a custom DB parameter group.
2. Modify the parameters in the parameter group.
3. Associate the DB parameter group with your DB instance.

For more information on DB parameter groups, see Working with parameter groups (p. 295).

**Creating the security-related parameter group**

Create a parameter group for your security-related parameters that corresponds to the SQL Server edition and version of your DB instance.

**Console**

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

**To create the parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
   a. For **Parameter group family**, choose `sqlserver-se-13.0`.
   b. For **Group name**, enter an identifier for the parameter group, such as `sqlserver-ciphers-se-13`.
   c. For **Description**, enter **Parameter group for security protocols and ciphers**.
5. Choose **Create**.

**CLI**

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

**To create the parameter group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
  --db-parameter-group-name sqlserver-ciphers-se-13 \
  --db-parameter-group-family "sqlserver-se-13.0"
```
Modifying security-related parameters

Modify the security-related parameters in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

**Console**

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016. This example turns off TLS version 1.0.

**To modify the parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group, such as `sqlserver-ciphers-se-13`.
4. Under **Parameters**, filter the parameter list for `rds`.
5. Choose **Edit parameters**.
7. For **Values**, choose `disabled`.
8. Choose **Save changes**.

**CLI**

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016. This example turns off TLS version 1.0.

**To modify the parameter group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
    --db-parameter-group-name sqlserver-ciphers-se-13 \
    --parameters "ParameterName='rds.tls10',ParameterValue='disabled',ApplyMethod=pending-reboot"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
```
Associating the security-related parameter group with your DB instance

To associate the parameter group with your DB instance, use the AWS Management Console or the AWS CLI.

Console

You can associate the parameter group with a new or existing DB instance:

- For a new DB instance, associate it when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
- For an existing DB instance, associate it by modifying the instance. For more information, see Modifying an Amazon RDS DB instance (p. 333).

CLI

You can associate the parameter group with a new or existing DB instance.

To create a DB instance with the parameter group

- Specify the same DB engine type and major version as you used when creating the parameter group.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance
    --db-instance-identifier mydbinstance
    --db-instance-class db.m5.2xlarge
    --engine sqlserver-se
    --engine-version 13.00.5426.0.v1
    --allocated-storage 100
    --master-user-password secret123
    --master-username admin
    --storage-type gp2
    --license-model li
    --db-parameter-group-name sqlserver-ciphers-se-13
```

For Windows:

```bash
aws rds create-db-instance
    --db-instance-identifier mydbinstance
    --db-instance-class db.m5.2xlarge
    --engine sqlserver-se
    --engine-version 13.00.5426.0.v1
    --allocated-storage 100
    --master-user-password secret123
    --master-username admin
    --storage-type gp2
    --license-model li
    --db-parameter-group-name sqlserver-ciphers-se-13
```
To modify a DB instance and associate the parameter group

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --db-parameter-group-name sqlserver-ciphers-se-13 \
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --db-parameter-group-name sqlserver-ciphers-se-13 ^
  --apply-immediately
```
Using Windows Authentication with an Amazon RDS for SQL Server DB instance

You can use Microsoft Windows Authentication to authenticate users when they connect to your Amazon RDS for Microsoft SQL Server DB instance. The DB instance works with AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to enable Windows Authentication. When users authenticate with a SQL Server DB instance joined to the trusting domain, authentication requests are forwarded to the domain directory that you create with AWS Directory Service.

Region and version availability

Amazon RDS supports Windows Authentication for SQL Server in all AWS Regions. RDS supports using only AWS Managed Microsoft AD for Windows Authentication. RDS doesn't support using AD Connector. For more information, see the following:

- Application compatibility policy for AWS Managed Microsoft AD
- Application compatibility policy for AD Connector

For more information on version and Region availability of RDS for SQL Server with Kerberos authentication, see Kerberos authentication (p. 105).

Overview of setting up Windows authentication

To set up Windows authentication, complete the following general steps, described in more detail later:

Amazon RDS uses mixed mode for Windows Authentication. This approach means that the master user (the name and password used to create your SQL Server DB instance) uses SQL Authentication. Because the master user account is a privileged credential, you should restrict access to this account.

To get Windows Authentication using an on-premises or self-hosted Microsoft Active Directory, create a forest trust. The trust can be one-way or two-way. For more information on setting up forest trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.

To set up Windows authentication for a SQL Server DB instance, do the following steps, explained in greater detail in Setting up Windows Authentication for SQL Server DB instances (p. 1185):

1. Use AWS Managed Microsoft AD, either from the AWS Management Console or AWS Directory Service API, to create an AWS Managed Microsoft AD directory.

2. If you use the AWS CLI or Amazon RDS API to create your SQL Server DB instance, create an AWS Identity and Access Management (IAM) role. This role uses the managed IAM policy AmazonRDSDirectoryServiceAccess and allows Amazon RDS to make calls to your directory. If you use the console to create your SQL Server DB instance, AWS creates the IAM role for you.

   For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Managing AWS STS in an AWS Region in the IAM User Guide.

3. Create and configure users and groups in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users and groups in your Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

4. If you plan to locate the directory and the DB instance in different VPCs, enable cross-VPC traffic.

5. Use Amazon RDS to create a new SQL Server DB instance either from the console, AWS CLI, or Amazon RDS API. In the create request, you provide the domain identifier ("d-*" identifier) that was generated
when you created your directory and the name of the role you created. You can also modify an existing SQL Server DB instance to use Windows Authentication by setting the domain and IAM role parameters for the DB instance.

6. Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do any other DB instance. Because the DB instance is joined to the AWS Managed Microsoft AD domain, you can provision SQL Server logins and users from the Active Directory users and groups in their domain. (These are known as SQL Server "Windows" logins.) Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.

Creating the endpoint for Kerberos authentication

Kerberos-based authentication requires that the endpoint be the customer-specified host name, a period, and then the fully qualified domain name (FQDN). For example, the following is an example of an endpoint you might use with Kerberos-based authentication. In this example, the SQL Server DB instance host name is ad-test and the domain name is corp-ad.company.com.

ad-test.corp-ad.company.com

If you want to make sure your connection is using Kerberos, run the following query:

```
SELECT net_transport, auth_scheme
FROM sys.dm_exec_connections
WHERE session_id = @spid;
```

Setting up Windows Authentication for SQL Server DB instances

You use AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to set up Windows Authentication for a SQL Server DB instance. To set up Windows Authentication, take the following steps.

Step 1: Create a directory using the AWS Directory Service for Microsoft Active Directory

AWS Directory Service creates a fully managed, Microsoft Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name Service (DNS) servers on your behalf. The directory servers are created in two subnets in two different Availability Zones within a VPC. This redundancy helps ensure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up a Microsoft Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

  **Note**
  Be sure to save this password. AWS Directory Service doesn't store this password, and you can't retrieve or reset it.

- Creates a security group for the directory controllers.

When you launch an AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all your directory's objects. This OU, which has the NetBIOS name that you typed when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.
The admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users, groups, and computers.
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users and groups in your OU.
- Create additional OUs and containers.
- Delegate authority.
- Create and link group policies.
- Restore deleted objects from the Active Directory Recycle Bin.
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service.

The admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders).
- View DNS event logs.
- View security event logs.

To create a directory with AWS Managed Microsoft AD

1. In the AWS Directory Service console navigation pane, choose Directories and choose Set up directory.
2. Choose AWS Managed Microsoft AD. This is the only option currently supported for use with Amazon RDS.
3. Choose Next.
4. On the Enter directory information page, provide the following information:

   **Edition**
   
   Choose the edition that meets your requirements.

   **Directory DNS name**
   
   The fully qualified name for the directory, such as corp.example.com. Names longer than 47 characters aren't supported by SQL Server.

   **Directory NetBIOS name**
   
   An optional short name for the directory, such as CORP.

   **Directory description**
   
   An optional description for the directory.

   **Admin password**
   
   The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

   The directory administrator password can't include the word admin. The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

   - Lowercase letters (a-z)
   - Uppercase letters (A-Z)
   - Numbers (0-9)
   - Non-alphanumeric characters (~!@#$%^&*_-+=`|(){}[ ]:;"'<>,.?/)
Confirm password

Retype the administrator password.

5. Choose Next.

6. On the **Choose VPC and subnets** page, provide the following information:

**VPC**

Choose the VPC for the directory.

**Note**

You can locate the directory and the DB instance in different VPCs, but if you do so, make sure to enable cross-VPC traffic. For more information, see Step 4: Enable cross-VPC traffic between the directory and the DB instance (p. 1190).

**Subnets**

Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose Next.

8. Review the directory information. If changes are needed, choose Previous. When the information is correct, choose **Create directory**.
It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID**. You need this value when you create or modify your SQL Server DB instance.

---

**Step 2: Create the IAM role for use by Amazon RDS**

If you use the console to create your SQL Server DB instance, you can skip this step. If you use the CLI or RDS API to create your SQL Server DB instance, you must create an IAM role that uses the AmazonRDSDirectoryServiceAccess managed IAM policy. This role allows Amazon RDS to make calls to the AWS Directory Service for you.

If you are using a custom policy for joining a domain, rather than using the AWS-managed AmazonRDSDirectoryServiceAccess policy, make sure that you allow the `ds:GetAuthorizedApplicationDetails` action. This requirement is effective starting July 2019, due to a change in the AWS Directory Service API.

The following IAM policy, AmazonRDSDirectoryServiceAccess, provides access to AWS Directory Service.

**Example IAM policy for providing access to AWS Directory Service**

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
```
We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service’s permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For Windows Authentication, make sure to include the DB instances, as shown in the following example.

**Example trust relationship with global condition context key for Windows Authentication**

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceArn": [
                        "arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
                    ]
                }
            }
        }
    ]
}
```

Create an IAM role using this IAM policy and trust relationship. For more information about creating IAM roles, see Creating customer managed policies in the IAM User Guide.

**Step 3: Create and configure users and groups**

You can create users and groups with the Active Directory Users and Computers tool. This tool is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory. Groups are very useful for giving or denying privileges to groups of users, rather than having to apply those privileges to each individual user.
To create users and groups in an AWS Directory Service directory, you must be connected to a Windows EC2 instance that is a member of the AWS Directory Service directory. You must also be logged in as a user that has privileges to create users and groups. For more information, see Add users and groups (Simple AD and AWS Managed Microsoft AD) in the AWS Directory Service Administration Guide.

**Step 4: Enable cross-VPC traffic between the directory and the DB instance**

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to **Step 5: Create or modify a SQL Server DB instance** (p. 1190).

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway.

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the Amazon Virtual Private Cloud Peering Guide.

**To enable cross-VPC traffic using VPC peering**

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance's security group can receive inbound traffic from the directory's security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

**To share the directory between AWS accounts**

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 domain-join in the AWS Directory Service Administration Guide.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the Directory ID value. You use this directory ID to join the DB instance to the domain.

**Step 5: Create or modify a SQL Server DB instance**

Create or modify a SQL Server DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new SQL Server DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.
  
  For instructions, see Creating an Amazon RDS DB instance (p. 236).

- Modify an existing SQL Server DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation.
  
  For instructions, see Modifying an Amazon RDS DB instance (p. 333).

- Restore a SQL Server DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.
  
  For instructions, see Restoring from a DB snapshot (p. 487).

- Restore a SQL Server DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation.
  
  For instructions, see Restoring a DB instance to a specified time (p. 534).
Windows Authentication is only supported for SQL Server DB instances in a VPC.

For the DB instance to be able to use the domain directory that you created, the following is required:

- For **Directory**, you must choose the domain identifier (d-ID) generated when you created the directory.
- Make sure that the VPC security group has an outbound rule that lets the DB instance communicate with the directory.

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the **--domain** parameter, use the domain identifier (d-ID) generated when you created the directory.
- For the **--domain-iam-role-name** parameter, use the role that you created that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --domain d-ID \
  --domain-iam-role-name role-name
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --domain d-ID ^
  --domain-iam-role-name role-name
```

**Important**

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

**Step 6: Create Windows Authentication SQL Server logins**

Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do any other DB instance. Because the DB instance is joined to the AWS Managed Microsoft AD domain, you
can provision SQL Server logins and users. You do this from the Active Directory users and groups in your domain. Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.

For an Active Directory user to authenticate with SQL Server, a SQL Server Windows login must exist for the user or a group that the user is a member of. Fine-grained access control is handled through granting and revoking permissions on these SQL Server logins. A user that doesn't have a SQL Server login or belong to a group with such a login can't access the SQL Server DB instance.

The ALTER ANY LOGIN permission is required to create an Active Directory SQL Server login. If you haven't created any logins with this permission, connect as the DB instance's master user using SQL Server Authentication.

Run a data definition language (DDL) command such as the following example to create a SQL Server login for an Active Directory user or group.

**Note**

Specify users and groups using the pre-Windows 2000 login name in the format `domainName\login_name`. You can't use a user principal name (UPN) in the format `login_name@DomainName`.

```sql
USE [master]
GO
CREATE LOGIN [mydomain\myuser] FROM WINDOWS WITH DEFAULT_DATABASE = [master],
    DEFAULT_LANGUAGE = [us_english];
GO
```

For more information, see [CREATE LOGIN (Transact-SQL)](https://docs.microsoft.com/en-us/sql/t-sql/statements/create-login-transact-sql) in the Microsoft Developer Network documentation.

Users (both humans and applications) from your domain can now connect to the RDS for SQL Server instance from a domain-joined client machine using Windows authentication.

**Managing a DB instance in a Domain**

You can use the console, AWS CLI, or the Amazon RDS API to manage your DB instance and its relationship with your domain. For example, you can move the DB instance into, out of, or between domains.

For example, using the Amazon RDS API, you can do the following:

- To reattempt a domain join for a failed membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID and the new IAM role.
- To remove a DB instance from a domain, use the `ModifyDBInstance` API operation and specify none as the domain parameter.
- To move a DB instance from one domain to another, use the `ModifyDBInstance` API operation and specify the domain identifier of the new domain as the domain parameter.
- To list membership for each DB instance, use the `DescribeDBInstances` API operation.

**Understanding Domain membership**

After you create or modify your DB instance, the instance becomes a member of the domain. The AWS console indicates the status of the domain membership for the DB instance. The status of the DB instance can be one of the following:
Using Windows Authentication with a SQL Server DB instance

- **joined** – The instance is a member of the domain.
- **joining** – The instance is in the process of becoming a member of the domain.
- **pending-join** – The instance membership is pending.
- **pending-maintenance-join** – AWS will attempt to make the instance a member of the domain during the next scheduled maintenance window.
- **pending-removal** – The removal of the instance from the domain is pending.
- **pending-maintenance-removal** – AWS will attempt to remove the instance from the domain during the next scheduled maintenance window.
- **failed** – A configuration problem has prevented the instance from joining the domain. Check and fix your configuration before reissuing the instance modify command.
- **removing** – The instance is being removed from the domain.

A request to become a member of a domain can fail because of a network connectivity issue or an incorrect IAM role. For example, you might create a DB instance or modify an existing instance and have the attempt fail for the DB instance to become a member of a domain. In this case, either reissue the command to create or modify the DB instance or modify the newly created instance to join the domain.

**Connecting to SQL Server with Windows authentication**

To connect to SQL Server with Windows Authentication, you must be logged into a domain-joined computer as a domain user. After launching SQL Server Management Studio, choose Windows Authentication as the authentication type, as shown following.

![Connect to Server](image)

**Restoring a SQL Server DB instance and then adding it to a domain**

You can restore a DB snapshot or do point-in-time recovery (PITR) for a SQL Server DB instance and then add it to a domain. Once the DB instance is restored, modify the instance using the process explained in Step 5: Create or modify a SQL Server DB instance (p. 1190) to add the DB instance to a domain.
Integrating an Amazon RDS for SQL Server DB instance with Amazon S3

You can transfer files between a DB instance running Amazon RDS for SQL Server and an Amazon S3 bucket. By doing this, you can use Amazon S3 with SQL Server features such as BULK INSERT. For example, you can download .csv, xml, .txt, and other files from Amazon S3 to the DB instance host and import the data from D:\S3\ into the database. All files are stored in D:\S3\ on the DB instance.

The following limitations apply:

- Files in the D:\S3 folder are deleted on the standby replica after a failover on Multi-AZ instances. For more information, see Multi-AZ limitations for S3 integration (p. 1206).
- The DB instance and the S3 bucket must be in the same AWS Region.
- If you run more than one S3 integration task at a time, the tasks run sequentially, not in parallel.

**Note**
S3 integration tasks share the same queue as native backup and restore tasks. At maximum, you can have only two tasks in progress at any time in this queue. Therefore, two running native backup and restore tasks will block any S3 integration tasks.

- You must re-enable the S3 integration feature on restored instances. S3 integration isn't propagated from the source instance to the restored instance. Files in D:\S3 are deleted on a restored instance.
- Downloading to the DB instance is limited to 100 files. In other words, there can't be more than 100 files in D:\S3\.
- Only files without file extensions or with the following file extensions are supported for download: .abf, .asdatabase, .bcp, .configsettings, .csv, .dat, .deploymentoptions, .deploymenttargets, .fmt, .info, .ispac, .lst, .tbl, .txt, .xml, and .xmla.
- The S3 bucket must have the same owner as the related AWS Identity and Access Management (IAM) role. Therefore, cross-account S3 integration isn't supported.
- The S3 bucket can't be open to the public.
- The file size for uploads from RDS to S3 is limited to 50 GB per file.
- The file size for downloads from S3 to RDS is limited to the maximum supported by S3.

For more information on working with files in Amazon S3, see Getting started with Amazon Simple Storage Service.
Prerequisites for integrating RDS for SQL Server with S3

Before you begin, find or create the S3 bucket that you want to use. Also, add permissions so that the RDS DB instance can access the S3 bucket. To configure this access, you create both an IAM policy and an IAM role.

Console

To create an IAM policy for access to Amazon S3

1. In the IAM Management Console, choose Policies in the navigation pane.
2. Create a new policy, and use the Visual editor tab for the following steps.
3. For Service, enter S3 and then choose the S3 service.
4. For Actions, choose the following to grant the access that your DB instance requires:
   - ListAllMyBuckets – required
   - ListBucket – required
   - GetBucketACL – required
   - GetBucketLocation – required
   - GetObject – required for downloading files from S3 to D:\S3\n   - PutObject – required for uploading files from D:\S3\ to S3
   - ListMultipartUploadParts – required for uploading files from D:\S3\ to S3
   - AbortMultipartUpload – required for uploading files from D:\S3\ to S3
5. For Resources, the options that display depend on which actions you choose in the previous step. You might see options for bucket, object, or both. For each of these, add the appropriate Amazon Resource Name (ARN).

   For bucket, add the ARN for the bucket that you want to use. For example, if your bucket is named example-bucket, set the ARN to arn:aws:s3:::example-bucket.

   For object, enter the ARN for the bucket and then choose one of the following:

   - To grant access to all files in the specified bucket, choose Any for both Bucket name and Object name.
   - To grant access to specific files or folders in the bucket, provide ARNs for the specific buckets and objects that you want SQL Server to access.

6. Follow the instructions in the console until you finish creating the policy.

The preceding is an abbreviated guide to setting up a policy. For more detailed instructions on creating IAM policies, see Creating IAM policies in the IAM User Guide.

To create an IAM role that uses the IAM policy from the previous procedure

1. In the IAM Management Console, choose Roles in the navigation pane.
2. Create a new IAM role, and choose the following options as they appear in the console:

   - AWS service
   - RDS
   - RDS – Add Role to Database

   Then choose Next:Permissions at the bottom.

3. For Attach permissions policies, enter the name of the IAM policy that you previously created. Then choose the policy from the list.
4. Follow the instructions in the console until you finish creating the role.

The preceding is an abbreviated guide to setting up a role. If you want more detailed instructions on creating roles, see IAM roles in the IAM User Guide.

AWS CLI

To grant Amazon RDS access to an Amazon S3 bucket, use the following process:

1. Create an IAM policy that grants Amazon RDS access to an S3 bucket.
2. Create an IAM role that Amazon RDS can assume on your behalf to access your S3 buckets.

For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.
3. Attach the IAM policy that you created to the IAM role that you created.

To create the IAM policy

Include the appropriate actions to grant the access your DB instance requires:

- ListAllMyBuckets – required
- ListBucket – required
- GetBucketACL – required
- GetBucketLocation – required
- GetObject – required for downloading files from S3 to D:\S3\n- PutObject – required for uploading files from D:\S3\ to S3
- ListMultipartUploadParts – required for uploading files from D:\S3\ to S3
- AbortMultipartUpload – required for uploading files from D:\S3\ to S3

1. The following AWS CLI command creates an IAM policy named rds-s3-integration-policy with these options. It grants access to a bucket named bucket_name.

Example

For Linux, macOS, or Unix:

```
aws iam create-policy --policy-name rds-s3-integration-policy --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3:ListAllMyBuckets",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:GetBucketACL",
                "s3:GetBucketLocation"
            ],
            "Resource": "arn:aws:s3:::bucket_name"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": "arn:aws:s3:::bucket_name:object_name"
        }
    ]
}'
```
"Effect": "Allow",
"Action": [
    "s3:GetObject",
    "s3:PutObject",
    "s3:ListMultipartUploadParts",
    "s3:AbortMultipartUpload"
],
"Resource": "arn:aws:s3:::bucket_name/key_prefix/*"
}
}]

For Windows:

Make sure to change the line endings to the ones supported by your interface (^ instead of \
). Also, in Windows, you must escape all double quotes with a \. To avoid the need to escape the quotes in
the JSON, you can save it to a file instead and pass that in as a parameter.

First, create the policy.json file with the following permission policy:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3:ListAllMyBuckets",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:GetBucketACL",
                "s3:GetBucketLocation"
            ],
            "Resource": "arn:aws:s3:::bucket_name"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:ListMultipartUploadParts",
                "s3:AbortMultipartUpload"
            ],
            "Resource": "arn:aws:s3:::bucket_name/key_prefix/*"
        }
    ]
}
```

Then use the following command to create the policy:

```
aws iam create-policy ^
    --policy-name rds-s3-integration-policy ^
    --policy-document file://file_path/assume_role_policy.json
```

2. After the policy is created, note the Amazon Resource Name (ARN) of the policy. You need the ARN
for a later step.
To create the IAM role

- The following AWS CLI command creates the rds-s3-integration-role IAM role for this purpose.

**Example**

For Linux, macOS, or Unix:

```
aws iam create-role --role-name rds-s3-integration-role --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

For Windows:

Make sure to change the line endings to the ones supported by your interface (\ instead of \). Also, in Windows, you must escape all double quotes with a \. To avoid the need to escape the quotes in the JSON, you can save it to a file instead and pass that in as a parameter.

First, create the assume_role_policy.json file with the following policy:

```
{  
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": ["rds.amazonaws.com"]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Then use the following command to create the IAM role:

```
aws iam create-role --role-name rds-s3-integration-role --assume-role-policy-document file://file_path/assume_role_policy.json
```

**Example of using the global condition context key to create the IAM role**

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.
You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For S3 integration, make sure to include the DB instance ARNs, as shown in the following example.

For Linux, macOS, or Unix:

```
aws iam create-role \
--role-name rds-s3-integration-role \
--assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
      "Condition": {
        "StringEquals": {
          "aws:SourceArn":"arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
        }
      }
    }
  ]
}
```

For Windows:

Add the global condition context key to `assume_role_policy.json`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": ["rds.amazonaws.com"
      ],
      "Action": "sts:AssumeRole"
      "Condition": {
        "StringEquals": {
          "aws:SourceArn":"arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
        }
      }
    }
  ]
}
```
To attach the IAM policy to the IAM role

- The following AWS CLI command attaches the policy to the role named rds-s3-integration-role. Replace your-policy-arn with the policy ARN that you noted in a previous step.

**Example**

For Linux, macOS, or Unix:

```
aws iam attach-role-policy
--policy-arn your-policy-arn
--role-name rds-s3-integration-role
```

For Windows:

```
aws iam attach-role-policy
--policy-arn your-policy-arn
--role-name rds-s3-integration-role
```

Enabling RDS for SQL Server integration with S3

In the following section, you can find how to enable Amazon S3 integration with Amazon RDS for SQL Server. To work with S3 integration, your DB instance must be associated with the IAM role that you previously created before you use the S3_INTEGRATION feature-name parameter.

**Note**
To add an IAM role to a DB instance, the status of the DB instance must be available.

**Console**

To associate your IAM role with your DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the RDS for SQL Server DB instance name to display its details.
3. On the Connectivity & security tab, in the Manage IAM roles section, choose the IAM role to add for Add IAM roles to this instance.
4. For Feature, choose S3_INTEGRATION.
5. Choose Add role.
**AWS CLI**

**To add the IAM role to the RDS for SQL Server DB instance**

- The following AWS CLI command adds your IAM role to an RDS for SQL Server DB instance named *mydbinstance*.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-role-to-db-instance \
  --db-instance-identifier mydbinstance \
  --feature-name S3_INTEGRATION \
  --role-arn your-role-arn
```

For Windows:

```bash
aws rds add-role-to-db-instance ^ \
  --db-instance-identifier mydbinstance ^ \
  --feature-name S3_INTEGRATION ^ \
  --role-arn your-role-arn
```

Replace *your-role-arn* with the role ARN that you noted in a previous step. *S3_INTEGRATION* must be specified for the `--feature-name` option.

**Transferring files between RDS for SQL Server and Amazon S3**

You can use Amazon RDS stored procedures to download and upload files between Amazon S3 and your RDS DB instance. You can also use Amazon RDS stored procedures to list and delete files on the RDS instance.

The files that you download from and upload to S3 are stored in the `D:\S3` folder. This is the only folder that you can use to access your files. You can organize your files into subfolders, which are created for you when you include the destination folder during download.

Some of the stored procedures require that you provide an Amazon Resource Name (ARN) to your S3 bucket and file. The format for your ARN is `arn:aws:s3:::bucket_name/file_name`. Amazon S3 doesn't require an account number or AWS Region in ARNs.

S3 integration tasks run sequentially and share the same queue as native backup and restore tasks. At maximum, you can have only two tasks in progress at any time in this queue. It can take up to five minutes for the task to begin processing.

**Downloading files from an Amazon S3 bucket to a SQL Server DB instance**

To download files from an S3 bucket to an RDS for SQL Server DB instance, use the Amazon RDS stored procedure `msdb.dbo.rds_download_from_s3` with the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@s3_arn_of_file</td>
<td>NVARCHAR</td>
<td>–</td>
<td>Required</td>
<td>The S3 ARN of the file to download, for example: <code>arn:aws:s3:::bucket_name/mydata.csv</code></td>
</tr>
</tbody>
</table>
Amazon Relational Database Service User Guide
Amazon S3 integration

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@rds_file_path</td>
<td>NVARCHAR</td>
<td>–</td>
<td>Optional</td>
<td>The file path for the RDS instance. If not specified, the file path is D:\S3&lt;filename in s3&gt;. RDS supports absolute paths and relative paths. If you want to create a subfolder, include it in the file path.</td>
</tr>
<tr>
<td>@overwrite_file</td>
<td>INT</td>
<td>0</td>
<td>Optional</td>
<td>Overwrite the existing file: 0 = Don't overwrite 1 = Overwrite</td>
</tr>
</tbody>
</table>

You can download files without a file extension and files with the following file extensions: .bcp, .csv, .dat, .fmt, .info, .lst, .tbl, .txt, and .xml.

**Note**
Files with the .ispac file extension are supported for download when SQL Server Integration Services is enabled. For more information on enabling SSIS, see SQL Server Integration Services (p. 1292).
Files with the following file extensions are supported for download when SQL Server Analysis Services is enabled: .abf, .asdatabase, .configsettings, .deploymentoptions, .deploymenttargets, and .xmla. For more information on enabling SSAS, see SQL Server Analysis Services (p. 1273).

The following example shows the stored procedure to download files from S3.

```sql
exec msdb.dbo.rds_download_from_s3
@s3_arn_of_file='arn:aws:s3:::bucket_name/bulk_data.csv',
@rds_file_path='D:\S3\seed_data\data.csv',
@overwrite_file=1;
```

The example rds_download_from_s3 operation creates a folder named seed_data in D:\S3\, if the folder doesn't exist yet. Then the example downloads the source file bulk_data.csv from S3 to a new file named data.csv on the DB instance. If the file previously existed, it's overwritten because the @overwrite_file parameter is set to 1.

**Uploading files from a SQL Server DB instance to an Amazon S3 bucket**

To upload files from an RDS for SQL Server DB instance to an S3 bucket, use the Amazon RDS stored procedure msdb.dbo.rds_upload_to_s3 with the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@s3_arn_of_file</td>
<td>NVARCHAR</td>
<td>–</td>
<td>Required</td>
<td>The S3 ARN of the file to be created in S3, for example: arn:aws:s3:::bucket_name/mydata.csv</td>
</tr>
<tr>
<td>@rds_file_path</td>
<td>NVARCHAR</td>
<td>–</td>
<td>Required</td>
<td>The file path of the file to upload to S3. Absolute and relative paths are supported.</td>
</tr>
</tbody>
</table>
### Parameter names and descriptions

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@overwrite_file</td>
<td>INT</td>
<td>–</td>
<td>Optional</td>
<td>Overwrite the existing file:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>0 = Don't overwrite</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>1 = Overwrite</td>
</tr>
</tbody>
</table>

The following example uploads the file named `data.csv` from the specified location in D:\S3\seed_data\ to a file `new_data.csv` in the S3 bucket specified by the ARN.

```sql
exec msdb.dbo.rds_upload_to_s3
    @rds_file_path='D:\S3\seed_data\data.csv',
    @s3_arn_of_file='arn:aws:s3:::bucket_name/new_data.csv',
    @overwrite_file=1;
```

If the file previously existed in S3, it's overwritten because the @overwrite_file parameter is set to 1.

### Listing files on the RDS DB instance

To list the files available on the DB instance, use both a stored procedure and a function. First, run the following stored procedure to gather file details from the files in D:\S3\.

```sql
exec msdb.dbo.rds_gather_file_details;
```

The stored procedure returns the ID of the task. Like other tasks, this stored procedure runs asynchronously. As soon as the status of the task is SUCCESS, you can use the task ID in the `rds_fn_list_file_details` function to list the existing files and directories in D:\S3\, as shown following.

```sql
SELECT * FROM msdb.dbo.rds_fn_list_file_details(TASK_ID);
```

The `rds_fn_list_file_details` function returns a table with the following columns.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filepath</td>
<td>Absolute path of the file (for example, D:\S3\mydata.csv)</td>
</tr>
<tr>
<td>size_in_bytes</td>
<td>File size (in bytes)</td>
</tr>
<tr>
<td>last_modified_utc</td>
<td>Last modification date and time in UTC format</td>
</tr>
<tr>
<td>is_directory</td>
<td>Option that indicates whether the item is a directory (true/false)</td>
</tr>
</tbody>
</table>

### Deleting files on the RDS DB instance

To delete the files available on the DB instance, use the Amazon RDS stored procedure `msdb.dbo.rds_delete_from_filesystem` with the following parameters.
### Amazon S3 integration

#### Parameter name
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@rds_file_path</td>
<td>NVARCHAR</td>
<td>–</td>
<td>Required</td>
<td>The file path of the file to delete. Absolute and relative paths are supported.</td>
</tr>
<tr>
<td>@force_delete</td>
<td>INT</td>
<td>0</td>
<td>Optional</td>
<td>To delete a directory, this flag must be included and set to 1. 1 = delete a directory.</td>
</tr>
</tbody>
</table>

To delete a directory, the @rds_file_path must end with a backslash (\) and @force_delete must be set to 1.

The following example deletes the file D:\S3\delete_me.txt.

```sql
exec msdb.dbo.rds_delete_from_filesystem
    @rds_file_path='D:\S3\delete_me.txt';
```

The following example deletes the directory D:\S3\example_folder\.

```sql
exec msdb.dbo.rds_delete_from_filesystem
    @rds_file_path='D:\S3\example_folder',
    @force_delete=1;
```

### Monitoring the status of a file transfer task

To track the status of your S3 integration task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to S3 integration. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 42);
```

The `rds_fn_task_status` function returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>task_type</td>
<td>For S3 integration, tasks can have the following task types:</td>
</tr>
<tr>
<td>Output parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>• DOWNLOAD_FROM_S3</td>
</tr>
<tr>
<td></td>
<td>• UPLOAD_TO_S3</td>
</tr>
<tr>
<td></td>
<td>• LIST_FILES_ON_DISK</td>
</tr>
<tr>
<td></td>
<td>• DELETE_FILES_ON_DISK</td>
</tr>
<tr>
<td>database_name</td>
<td>Not applicable to S3 integration tasks.</td>
</tr>
<tr>
<td>% complete</td>
<td>The progress of the task as a percentage.</td>
</tr>
<tr>
<td>duration(mins)</td>
<td>The amount of time spent on the task, in minutes.</td>
</tr>
<tr>
<td>lifecycle</td>
<td>The status of the task. Possible statuses are the following:</td>
</tr>
<tr>
<td></td>
<td>• CREATED – After you call one of the S3 integration stored procedures, a task is created and the status is set to CREATED.</td>
</tr>
<tr>
<td></td>
<td>• IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It can take up to five minutes for the status to change from CREATED to IN_PROGRESS.</td>
</tr>
<tr>
<td></td>
<td>• SUCCESS – After a task completes, the status is set to SUCCESS.</td>
</tr>
<tr>
<td></td>
<td>• ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column.</td>
</tr>
<tr>
<td></td>
<td>• CANCEL_REQUESTED – After you call rds_cancel_task, the status of the task is set to CANCEL_REQUESTED.</td>
</tr>
<tr>
<td></td>
<td>• CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.</td>
</tr>
<tr>
<td>task_info</td>
<td>Additional information about the task. If an error occurs during processing, this column contains information about the error.</td>
</tr>
<tr>
<td>last_updated</td>
<td>The date and time that the task status was last updated.</td>
</tr>
<tr>
<td>created_at</td>
<td>The date and time that the task was created.</td>
</tr>
<tr>
<td>S3_object_arn</td>
<td>The ARN of the S3 object downloaded from or uploaded to.</td>
</tr>
<tr>
<td>overwrite_S3_backup_file</td>
<td>Not applicable to S3 integration tasks.</td>
</tr>
<tr>
<td>KMS_master_key_arn</td>
<td>Not applicable to S3 integration tasks.</td>
</tr>
<tr>
<td>filepath</td>
<td>The file path on the RDS DB instance.</td>
</tr>
<tr>
<td>overwrite_file</td>
<td>An option that indicates if an existing file is overwritten.</td>
</tr>
<tr>
<td>task_metadata</td>
<td>Not applicable to S3 integration tasks.</td>
</tr>
</tbody>
</table>
Canceling a task

To cancel S3 integration tasks, use the `msdb.dbo.rds_cancel_task` stored procedure with the `task_id` parameter. Delete and list tasks that are in progress can't be cancelled. The following example shows a request to cancel a task.

```
exec msdb.dbo.rds_cancel_task @task_id = 1234;
```

To get an overview of all tasks and their task IDs, use the `rds_fn_task_status` function as described in Monitoring the status of a file transfer task (p. 1204).

Multi-AZ limitations for S3 integration

On Multi-AZ instances, files in the `D:\S3` folder are deleted on the standby replica after a failover. A failover can be planned, for example, during DB instance modifications such as changing the instance class or upgrading the engine version. Or a failover can be unplanned, during an outage of the primary.

**Note**

We don't recommend using the `D:\S3` folder for file storage. The best practice is to upload created files to Amazon S3 to make them durable, and download files when you need to import data.

To determine the last failover time, you can use the `msdb.dbo.rds_failover_time` stored procedure. For more information, see Determining the last failover time (p. 1341).

**Example of no recent failover**

This example shows the output when there is no recent failover in the error logs. No failover has happened since 2020-04-29 23:59:00.01.

Therefore, all files downloaded after that time that haven't been deleted using the `rds_delete_from_filesystem` stored procedure are still accessible on the current host. Files downloaded before that time might also be available.

<table>
<thead>
<tr>
<th>errorlog_available_from</th>
<th>recent_failover_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-04-29 23:59:00.0100000</td>
<td>null</td>
</tr>
</tbody>
</table>

**Example of recent failover**

This example shows the output when there is a failover in the error logs. The most recent failover was at 2020-05-05 18:57:51.89.

All files downloaded after that time that haven't been deleted using the `rds_delete_from_filesystem` stored procedure are still accessible on the current host.

<table>
<thead>
<tr>
<th>errorlog_available_from</th>
<th>recent_failover_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-04-29 23:59:00.0100000</td>
<td>2020-05-05 18:57:51.8900000</td>
</tr>
</tbody>
</table>

Disabling RDS for SQL Server integration with S3

Following, you can find how to disable Amazon S3 integration with Amazon RDS for SQL Server. Files in `D:\S3\` aren't deleted when disabling S3 integration.
**Note**  
To remove an IAM role from a DB instance, the status of the DB instance must be available.

**Console**

**To disassociate your IAM role from your DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose the RDS for SQL Server DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the IAM role to remove.
4. Choose **Delete**.

**AWS CLI**

**To remove the IAM role from the RDS for SQL Server DB instance**

- The following AWS CLI command removes the IAM role from a RDS for SQL Server DB instance named *mydbinstance*.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds remove-role-from-db-instance \ 
--db-instance-identifier mydbinstance \ 
--feature-name S3_INTEGRATION \ 
--role-arn your-role-arn
```

For Windows:

```bash
aws rds remove-role-from-db-instance ^
--db-instance-identifier mydbinstance ^
--feature-name S3_INTEGRATION ^
--role-arn your-role-arn
```

Replace *your-role-arn* with the appropriate IAM role ARN for the --feature-name option.
Using Database Mail on Amazon RDS for SQL Server

You can use Database Mail to send email messages to users from your Amazon RDS on SQL Server database instance. The messages can contain files and query results. Database Mail includes the following components:

- **Configuration and security objects** – These objects create profiles and accounts, and are stored in the msdb database.
- **Messaging objects** – These objects include the `sp_send_dbmail` stored procedure used to send messages, and data structures that hold information about messages. They're stored in the msdb database.
- **Logging and auditing objects** – Database Mail writes logging information to the msdb database and the Microsoft Windows application event log.
- **Database Mail executable** – `DatabaseMail.exe` reads from a queue in the msdb database and sends email messages.

RDS supports Database Mail for all SQL Server versions on the Web, Standard, and Enterprise Editions.

**Limitations**

The following limitations apply to using Database Mail on your SQL Server DB instance:

- Database Mail isn't supported for SQL Server Express Edition.
- Modifying Database Mail configuration parameters isn't supported. To see the preset (default) values, use the `sysmail_help_configure_sp` stored procedure.
- File attachments aren't fully supported. For more information, see Working with file attachments (p. 1217).
- The maximum file attachment size is 1 MB.
- Database Mail requires additional configuration on Multi-AZ DB instances. For more information, see Considerations for Multi-AZ deployments (p. 1218).
- Configuring SQL Server Agent to send email messages to predefined operators isn't supported.

**Enabling Database Mail**

Use the following process to enable Database Mail for your DB instance:

1. Create a new parameter group.
2. Modify the parameter group to set the `database mail xps` parameter to 1.
3. Associate the parameter group with the DB instance.

**Creating the parameter group for Database Mail**

Create a parameter group for the `database mail xps` parameter that corresponds to the SQL Server edition and version of your DB instance.

**Note**

You can also modify an existing parameter group. Follow the procedure in Modifying the parameter that enables Database Mail (p. 1209).

**Console**

The following example creates a parameter group for SQL Server Standard Edition 2016.
To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
4. In the Create parameter group pane, do the following:
   a. For Parameter group family, choose sqlserver-se-13.0.
   b. For Group name, enter an identifier for the parameter group, such as dbmail-sqlserver-se-13.
   c. For Description, enter Database Mail XPs.
5. Choose Create.

CLI

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
   --db-parameter-group-name dbmail-sqlserver-se-13 \
   --db-parameter-group-family "sqlserver-se-13.0" \
   --description "Database Mail XPs"
```

For Windows:

```
aws rds create-db-parameter-group ^
   --db-parameter-group-name dbmail-sqlserver-se-13 ^
   --db-parameter-group-family "sqlserver-se-13.0" ^
   --description "Database Mail XPs"
```

Modifying the parameter that enables Database Mail

Modify the database mail xps parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

To enable Database Mail, set the database mail xps parameter to 1.

Console

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group, such as `dbmail-sqlserver-se-13`.
4. Under **Parameters**, filter the parameter list for `mail`.
5. Choose `database mail xps`.
6. Choose **Edit parameters**.
7. Enter `1`.
8. Choose **Save changes**.

**CLI**

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

**To modify the parameter group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group
   --db-parameter-group-name dbmail-sqlserver-se-13
   --parameters "ParameterName='database mail xps',ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group
   --db-parameter-group-name dbmail-sqlserver-se-13
   --parameters "ParameterName='database mail xps',ParameterValue=1,ApplyMethod=immediate"
```

**Associating the parameter group with the DB instance**

You can use the AWS Management Console or the AWS CLI to associate the Database Mail parameter group with the DB instance.

**Console**

You can associate the Database Mail parameter group with a new or existing DB instance.

- For a new DB instance, associate it when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
- For an existing DB instance, associate it by modifying the instance. For more information, see Modifying an Amazon RDS DB instance (p. 333).

**CLI**

You can associate the Database Mail parameter group with a new or existing DB instance.

**To create a DB instance with the Database Mail parameter group**

- Specify the same DB engine type and major version as you used when creating the parameter group.
Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance
   --db-instance-identifier mydbinstance
   --db-instance-class db.m5.2xlarge
   --engine sqlserver-se
   --engine-version 13.00.5426.0.v1
   --allocated-storage 100
   --master-user-password secret123
   --master-username admin
   --storage-type gp2
   --license-model li
   --db-parameter-group-name dbmail-sqlserver-se-13
```

For Windows:

```
aws rds create-db-instance
   --db-instance-identifier mydbinstance
   --db-instance-class db.m5.2xlarge
   --engine sqlserver-se
   --engine-version 13.00.5426.0.v1
   --allocated-storage 100
   --master-user-password secret123
   --master-username admin
   --storage-type gp2
   --license-model li
   --db-parameter-group-name dbmail-sqlserver-se-13
```

To modify a DB instance and associate the Database Mail parameter group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance
   --db-instance-identifier mydbinstance
   --db-parameter-group-name dbmail-sqlserver-se-13
   --apply-immediately
```

For Windows:

```
aws rds modify-db-instance
   --db-instance-identifier mydbinstance
   --db-parameter-group-name dbmail-sqlserver-se-13
   --apply-immediately
```

Configuring Database Mail

You perform the following tasks to configure Database Mail:

1. Create the Database Mail profile.
2. Create the Database Mail account.
3. Add the Database Mail account to the Database Mail profile.
4. Add users to the Database Mail profile.

**Note**
To configure Database Mail, make sure that you have `execute` permission on the stored procedures in the `msdb` database.

### Creating the Database Mail profile

To create the Database Mail profile, you use the `sysmail_add_profile_sp` stored procedure. The following example creates a profile named **Notifications**.

**To create the profile**

- Use the following SQL statement.

```
USE msdb
GO
EXECUTE msdb.dbo.sysmail_add_profile_sp
    @profile_name         = 'Notifications',
    @description          = 'Profile used for sending outgoing notifications using Amazon SES.';
GO
```

### Creating the Database Mail account

To create the Database Mail account, you use the `sysmail_add_account_sp` stored procedure. The following example creates an account named **SES** that uses Amazon Simple Email Service.

Using Amazon SES requires the following parameters:

- `@email_address` – An Amazon SES verified identity. For more information, see [Verified identities in Amazon SES](#).
- `@mailserver_name` – An Amazon SES SMTP endpoint. For more information, see [Connecting to an Amazon SES SMTP endpoint](#).
- `@username` – An Amazon SES SMTP user name. For more information, see [Obtaining Amazon SES SMTP credentials](#).
- `@password` – An Amazon SES SMTP password. For more information, see [Obtaining Amazon SES SMTP credentials](#).

Don't use an AWS Identity and Access Management user name.

**To create the account**

- Use the following SQL statement.

```
USE msdb
GO
EXECUTE msdb.dbo.sysmail_add_account_sp
    @account_name        = 'SES',
    @description         = 'Mail account for sending outgoing notifications.',
```

Adding the Database Mail account to the Database Mail profile

To add the Database Mail account to the Database Mail profile, you use the `sysmail_add_profileaccount_sp` stored procedure. The following example adds the SES account to the Notifications profile.

To add the account to the profile

- Use the following SQL statement.

```sql
USE msdb
GO
EXECUTE msdb.dbo.sysmail_add_profileaccount_sp
    @profile_name = 'Notifications',
    @account_name = 'SES',
    @sequence_number = 1;
GO
```

Adding users to the Database Mail profile

To grant permission for an msdb database principal to use a Database Mail profile, you use the `sysmail_add_principalprofile_sp` stored procedure. A principal is an entity that can request SQL Server resources. The database principal must map to a SQL Server authentication user, a Windows Authentication user, or a Windows Authentication group.

The following example grants public access to the Notifications profile.

To add a user to the profile

- Use the following SQL statement.

```sql
USE msdb
GO
EXECUTE msdb.dbo.sysmail_add_principalprofile_sp
    @profile_name = 'Notifications',
    @principal_name = 'public',
    @is_default = 1;
GO
```

Amazon RDS stored procedures and functions for Database Mail

Microsoft provides stored procedures for using Database Mail, such as creating, listing, updating, and deleting accounts and profiles. In addition, RDS provides the stored procedures and functions for Database Mail shown in the following table.
<table>
<thead>
<tr>
<th>Procedure/Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rds_fn_sysmail_allitems</td>
<td>Shows sent messages, including those submitted by other users.</td>
</tr>
<tr>
<td>rds_fn_sysmail_event_log</td>
<td>Shows events, including those for messages submitted by other users.</td>
</tr>
<tr>
<td>rds_fn_sysmail_mailattachments</td>
<td>Shows attachments, including those to messages submitted by other users.</td>
</tr>
<tr>
<td>rds_sysmail_control</td>
<td>Starts and stops the mail queue (DatabaseMail.exe process).</td>
</tr>
<tr>
<td>rds_sysmail_delete_mailitems_sp</td>
<td>Deletes email messages sent by all users from the Database Mail internal tables.</td>
</tr>
</tbody>
</table>

Sending email messages using Database Mail

You use the `sp_send_dbmail` stored procedure to send email messages using Database Mail.

**Usage**

```sql
EXEC msdb.dbo.sp_send_dbmail
    @profile_name = 'profile_name',
    @recipients = 'recipient1@example.com; recipient2; ... recipientn',
    @subject = 'subject',
    @body = 'message_body',
    @body_format = 'HTML',
    @file_attachments = 'file_path1; file_path2; ... file_pathn',
    @query = 'SQL_query',
    @attach_query_result_as_file = 0|1';
```

The following parameters are required:

- `@profile_name` – The name of the Database Mail profile from which to send the message.
- `@recipients` – The semicolon-delimited list of email addresses to which to send the message.
- `@subject` – The subject of the message.
- `@body` – The body of the message. You can also use a declared variable as the body.

The following parameters are optional:

- `@body_format` – This parameter is used with a declared variable to send email in HTML format.
- `@file_attachments` – The semicolon-delimited list of message attachments. File paths must be absolute paths.
- `@query` – A SQL query to run. The query results can be attached as a file or included in the body of the message.
- `@attach_query_result_as_file` – Whether to attach the query result as a file. Set to 0 for no, 1 for yes. The default is 0.

**Examples**

The following examples demonstrate how to send email messages.
Example of sending a message to a single recipient

USE msdb
GO
EXEC msdb.dbo.sp_send_dbmail
    @profile_name = 'Notifications',
    @recipients = 'nobody@example.com',
    @subject = 'Automated DBMail message - 1',
    @body = 'Database Mail configuration was successful.';
GO

Example of sending a message to multiple recipients

USE msdb
GO
EXEC msdb.dbo.sp_send_dbmail
    @profile_name = 'Notifications',
    @recipients = 'recipient1@example.com;recipient2@example.com',
    @subject = 'Automated DBMail message - 2',
    @body = 'This is a message.';
GO

Example of sending a SQL query result as a file attachment

USE msdb
GO
EXEC msdb.dbo.sp_send_dbmail
    @profile_name = 'Notifications',
    @recipients = 'nobody@example.com',
    @subject = 'Test SQL query',
    @body = 'This is a SQL query test.',
    @query = 'SELECT * FROM abc.dbo.test',
    @attach_query_result_as_file = 1;
GO

Example of sending a message in HTML format

USE msdb
GO
DECLARE @HTML_Body as NVARCHAR(500) = 'Hi, <h4> Heading </h4> </br> See the report. <b> Regards </b>;
EXEC msdb.dbo.sp_send_dbmail
    @profile_name = 'Notifications',
    @recipients = 'nobody@example.com',
    @subject = 'Test HTML message',
    @body = @HTML_Body,
    @body_format = 'HTML';
GO

Example of sending a message using a trigger when a specific event occurs in the database

USE AdventureWorks2017
GO
IF OBJECT_ID (N'Production.iProductNotification', 'TR') IS NOT NULL
    DROP TRIGGER Purchasing.iProductNotification
CREATE TRIGGER iProductNotification ON Production.Product
FOR INSERT
AS
DECLARE @ProductInformation nvarchar(255);
SELECT @ProductInformation = 'A new product, ' + Name + ', is now available for $' +
CAST(StandardCost AS nvarchar(20)) + '!' FROM INSERTED i;
EXEC msdb.dbo.sp_send_dbmail
    @profile_name = 'Notifications',
    @recipients = 'nobody@example.com',
    @subject = 'New product information',
    @body = @ProductInformation;
GO

Viewing messages, logs, and attachments

You use RDS stored procedures to view messages, event logs, and attachments.

To view all email messages
- Use the following SQL query.

```
SELECT * FROM msdb.dbo.rds_fn_sysmail_allitems();
```

To view all email event logs
- Use the following SQL query.

```
SELECT * FROM msdb.dbo.rds_fn_sysmail_event_log();
```

To view all email attachments
- Use the following SQL query.

```
SELECT * FROM msdb.dbo.rds_fn_sysmail_mailattachments();
```

Deleting messages

You use the `rds_sysmail_delete_mailitems_sp` stored procedure to delete messages.

**Note**
RDS automatically deletes mail table items when DBMail history data reaches 1 GB in size, with a retention period of at least 24 hours.
If you want to keep mail items for a longer period, you can archive them. For more information, see Create a SQL Server Agent job to archive Database Mail messages and event logs in the Microsoft documentation.

To delete all email messages
- Use the following SQL statement.
To delete all email messages with a particular status

- Use the following SQL statement to delete all failed messages.

```sql
DECLARE @GETDATE datetime
SET @GETDATE = GETDATE();
EXECUTE msdb.dbo.rds_sysmail_delete_mailitems_sp @sent_status = 'failed';
GO
```

Starting the mail queue

You use the `rds_sysmail_control` stored procedure to start the Database Mail process.

**Note**

Enabling Database Mail automatically starts the mail queue.

**To start the mail queue**

- Use the following SQL statement.

```sql
EXECUTE msdb.dbo.rds_sysmail_control start;
GO
```

Stopping the mail queue

You use the `rds_sysmail_control` stored procedure to stop the Database Mail process.

**To stop the mail queue**

- Use the following SQL statement.

```sql
EXECUTE msdb.dbo.rds_sysmail_control stop;
GO
```

Working with file attachments

The following file attachment extensions aren't supported in Database Mail messages from RDS on SQL Server: .ade, .adp, .apk, .appx, .appxbundle, .bat, .bak, .cab, .chm, .cmd, .com, .cpl, .dll, .dmg, .exe, .hta, .inf1, .ins, .isp, .isr, .ps1, .psc1, .reg, .rgs, .scr, .sct, .shb, .shs, .svg, .sys, .u3p, .vb, .vbe, .vbs, .vbscript, .vxd, .ws, .wsc, .wsf, and .wsh.

Database Mail uses the Microsoft Windows security context of the current user to control access to files. Users who log in with SQL Server Authentication can't attach files using the `@file_attachments` parameter with the `sp_send_dbmail` stored procedure. Windows doesn't allow SQL Server to provide credentials from a remote computer to another remote computer. Therefore, Database Mail can't attach files from a network share when the command is run from a computer other than the computer running SQL Server.
However, you can use SQL Server Agent jobs to attach files. For more information on SQL Server Agent, see Using SQL Server Agent (p. 1346) and SQL Server Agent in the Microsoft documentation.

**Considerations for Multi-AZ deployments**

When you configure Database Mail on a Multi-AZ DB instance, the configuration isn't automatically propagated to the secondary. We recommend converting the Multi-AZ instance to a Single-AZ instance, configuring Database Mail, and then converting the DB instance back to Multi-AZ. Then both the primary and secondary nodes have the Database Mail configuration.

If you create a read replica from your Multi-AZ instance that has Database Mail configured, the replica inherits the configuration, but without the password to the SMTP server. Update the Database Mail account with the password.
Instance store support for the tempdb database on Amazon RDS for SQL Server

An instance store provides temporary block-level storage for your DB instance. This storage is located on disks that are physically attached to the host computer. These disks have Non-Volatile Memory Express (NVMe) instance storage that is based on solid-state drives (SSDs). This storage is optimized for low latency, very high random I/O performance, and high sequential read throughput.

By placing tempdb data files and tempdb log files on the instance store, you can achieve lower read and write latencies compared to standard storage based on Amazon EBS.

Note
SQL Server database files and database log files aren’t placed on the instance store.

Enabling the instance store

When RDS provisions DB instances with one of the following instance classes, the tempdb database is automatically placed onto the instance store:

- db.m5d
- db.r5d

To enable the instance store, do one of the following:

- Create a SQL Server DB instance using one of these instance types. For more information, see Creating an Amazon RDS DB instance (p. 236).
- Modify an existing SQL Server DB instance to use one of them. For more information, see Modifying an Amazon RDS DB instance (p. 333).

The instance store is available in all AWS Regions where one or more of these instance types are supported. For more information on the db.m5d and db.r5d instance classes, see DB instance classes (p. 10). For more information on the instance classes supported by Amazon RDS for SQL Server, see DB instance class support for Microsoft SQL Server (p. 1103).

File location and size considerations

On instances without an instance store, RDS stores the tempdb data and log files in the D:\rdsdbdata\DATA directory. Both files start at 8 MB by default.

On instances with an instance store, RDS stores the tempdb data and log files in the T:\rdsdbdata\DATA directory.

When tempdb has only one data file (tempdb.mdf) and one log file (templog.ldf), templog.ldf starts at 8 MB by default and tempdb.mdf starts at 80% or more of the instance's storage capacity. Twenty percent of the storage capacity or 200 GB, whichever is less, is kept free to start. Multiple tempdb data files split the 80% disk space evenly, while log files always have an 8- MB initial size.

For example, if you modify your DB instance class from db.m5.2xlarge to db.m5d.2xlarge, the size of tempdb data files increases from 8 MB each to 234 GB in total.

Note
Besides the tempdb data and log files on the instance store (T:\rdsdbdata\DATA), you can still create extra tempdb data and log files on the data volume (D:\rdsdbdata\DATA). Those files always have an 8 MB initial size.
Backup considerations

You might need to retain backups for long periods, incurring costs over time. The tempdb data and log blocks can change very often depending on the workload. This can greatly increase the DB snapshot size.

When tempdb is on the instance store, snapshots don't include temporary files. This means that snapshot sizes are smaller and consume less of the free backup allocation compared to EBS-only storage.

Disk full errors

If you use all of the available space in the instance store, you might receive errors such as the following:

- The transaction log for database 'tempdb' is full due to 'ACTIVE_TRANSACTION'.
- Could not allocate space for object 'dbo.SORT temporary run storage: 140738941419520' in database 'tempdb' because the 'PRIMARY' filegroup is full. Create disk space by deleting unneeded files, dropping objects in the filegroup, adding additional files to the filegroup, or setting autogrowth on for existing files in the filegroup.

You can do one or more of the following when the instance store is full:

- Adjust your workload or the way you use tempdb.
- Scale up to use a DB instance class with more NVMe storage.
- Stop using the instance store, and use an instance class with only EBS storage.
- Use a mixed mode by adding secondary data or log files for tempdb on the EBS volume.

Removing the instance store

To remove the instance store, modify your SQL Server DB instance to use an instance type that doesn't support instance store, such as db.m5 or db.r5.

Note

When you remove the instance store, the temporary files are moved to the D:\rdsdbdata\DATA directory and reduced in size to 8 MB.
Using extended events with Amazon RDS for Microsoft SQL Server

You can use extended events in Microsoft SQL Server to capture debugging and troubleshooting information for Amazon RDS for SQL Server. Extended events replace SQL Trace and Server Profiler, which have been deprecated by Microsoft. Extended events are similar to profiler traces but with more granular control on the events being traced. Extended events are supported for SQL Server versions 2014 and later on Amazon RDS. For more information, see Extended events overview in the Microsoft documentation.

Extended events are turned on automatically for users with master user privileges in Amazon RDS for SQL Server.

Topics

- Limitations and recommendations (p. 1221)
- Configuring extended events on RDS for SQL Server (p. 1221)
- Considerations for Multi-AZ deployments (p. 1222)
- Querying extended event files (p. 1223)

Limitations and recommendations

When using extended events on RDS for SQL Server, the following limitations apply:

- Extended events are supported only for the Enterprise and Standard Editions.
- You can’t alter default extended event sessions.
- Make sure to set the session memory partition mode to NONE.
- Session event retention mode can be either ALLOW_SINGLE_EVENT_LOSS or ALLOW_MULTIPLE_EVENT_LOSS.
- Event Tracing for Windows (ETW) targets aren’t supported.
- Make sure that file targets are in the D:\rdsdbdata\log directory.
- For pair matching targets, set the respond_to_memory_pressure property to 1.
- Ring buffer target memory can’t be greater than 4 MB.
- The following actions aren’t supported:
  - debug_break
  - create_dump_all_threads
  - create_dump_single_threads
- The rpc_completed event is supported on the following versions and later: 15.0.4083.2, 14.0.3370.1, 13.0.5865.1, 12.0.6433.1, 11.0.7507.2.

Configuring extended events on RDS for SQL Server

On RDS for SQL Server, you can configure the values of certain parameters of extended event sessions. The following table describes the configurable parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xe_session_max_memory</td>
<td>Specifies the maximum amount of memory allocated to the session for event buffering.</td>
</tr>
<tr>
<td>xe_session_max_event_size</td>
<td>Specifies the maximum memory size allowed for large events.</td>
</tr>
</tbody>
</table>
Using extended events

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xe_session_max_dispatch_latency</td>
<td>Specifies the amount of time that events are buffered in memory before being dispatched to extended event session targets. This value corresponds to the <code>max_dispatch_latency</code> setting of the event session.</td>
</tr>
<tr>
<td>xe_file_target_size</td>
<td>Specifies the maximum size of the file target. This value corresponds to the <code>max_file_size</code> setting of the file target.</td>
</tr>
<tr>
<td>xe_file_retention</td>
<td>Specifies the retention time in days for files generated by the file targets of event sessions.</td>
</tr>
</tbody>
</table>

**Note**

Setting `xe_file_retention` to zero causes .xel files to be removed automatically after the lock on these files is released by SQL Server. The lock is released whenever an .xel file reaches the size limit set in `xe_file_target_size`.

You can use the `rdsadmin.dbo.rds_show_configuration` stored procedure to show the current values of these parameters. For example, use the following SQL statement to view the current setting of `xe_session_max_memory`.

```sql
exec rdsadmin..rds_show_configuration 'xe_session_max_memory'
```

You can use the `rdsadmin.dbo.rds_set_configuration` stored procedure to modify them. For example, use the following SQL statement to set `xe_session_max_memory` to 4 MB.

```sql
exec rdsadmin..rds_set_configuration 'xe_session_max_memory', 4
```

**Considerations for Multi-AZ deployments**

When you create an extended event session on a primary DB instance, it doesn't propagate to the standby replica. You can fail over and create the extended event session on the new primary DB instance. Or you can remove and then re-add the Multi-AZ configuration to propagate the extended event session to the standby replica. RDS stops all nondefault extended event sessions on the standby replica, so that these sessions don't consume resources on the standby. Because of this, after a standby replica becomes the primary DB instance, make sure to manually start the extended event sessions on the new primary.

**Note**

This approach applies to both Always On Availability Groups and Database Mirroring.

You can also use a SQL Server Agent job to track the standby replica and start the sessions if the standby becomes the primary. For example, use the following query in your SQL Server Agent job step to restart event sessions on a primary DB instance.

```sql
BEGIN
IF (DATABASEPROPERTYEX('rdsadmin','Updateability')='READ_WRITE'
AND DATABASEPROPERTYEX('rdsadmin','status')='ONLINE'
AND (DATABASEPROPERTYEX('rdsadmin','Collation') IS NOT NULL OR DATABASEPROPERTYEX('rdsadmin','IsAutoClose')=1))
BEGIN
IF NOT EXISTS (SELECT 1 FROM sys.dm_xe_sessions WHERE name='xe1')
ALTER EVENT SESSION xe1 ON SERVER STATE=START
IF NOT EXISTS (SELECT 1 FROM sys.dm_xe_sessions WHERE name='xe2')
ALTER EVENT SESSION xe2 ON SERVER STATE=START
END
END
```

This query restarts the event sessions `xe1` and `xe2` on a primary DB instance if these sessions are in a stopped state. You can also add a schedule with a convenient interval to this query.
Querying extended event files

You can either use SQL Server Management Studio or the `sys.fn_xe_file_target_read_file` function to view data from extended events that use file targets. For more information on this function, see `sys.fn_xe_file_target_read_file (Transact-SQL)` in the Microsoft documentation.

Extended event file targets can only write files to the `D:\rdsdbdata\log` directory on RDS for SQL Server.

As an example, use the following SQL query to list the contents of all files of extended event sessions whose names start with `xe`.

```
SELECT * FROM sys.fn_xe_file_target_read_file('d:\rdsdbdata\log\xe*', null, null, null);
```
Access to transaction log backups with RDS for SQL Server

With access to transaction log backups for RDS for SQL Server, you can list the transaction log backup files for a database and copy them to a target Amazon S3 bucket. By copying transaction log backups in an Amazon S3 bucket, you can use them in combination with full and differential database backups to perform point in time database restores. You use RDS stored procedures to set up access to transaction log backups, list available transaction log backups, and copy them to your Amazon S3 bucket.

Access to transaction log backups provides the following capabilities and benefits:

- List and view the metadata of available transaction log backups for a database on an RDS for SQL Server DB instance.
- Copy available transaction log backups from RDS for SQL Server to a target Amazon S3 bucket.
- Perform point-in-time restores of databases without the need to restore an entire DB instance. For more information on restoring a DB instance to a point in time, see Restoring a DB instance to a specified time (p. 534).

Availability and support

Access to transaction log backups is supported in all AWS Regions. Access to transaction log backups is available for all editions and versions of Microsoft SQL Server supported on Amazon RDS.

Requirements

The following requirements must be met before enabling access to transaction log backups:

- Automated backups must be enabled on the DB instance and the backup retention must be set to a value of one or more days. For more information on enabling automated backups and configuring a retention policy, see Enabling automated backups (p. 464).
- An Amazon S3 bucket must exist in the same account and Region as the source DB instance. Before enabling access to transaction log backups, choose an existing Amazon S3 bucket or create a new bucket to use for your transaction log backup files.
- An Amazon S3 bucket permissions policy must be configured as follows to allow Amazon RDS to copy transaction log files into it:
  1. Set the object account ownership property on the bucket to Bucket Owner Preferred.
  2. Add the following policy. There will be no policy by default, so use the bucket Access Control Lists (ACL) to edit the bucket policy and add it.

The following example uses an ARN to specify a resource. We recommend using the SourceArn and SourceAccount global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. For more information on working with ARNs, see Amazon resource names (ARNs) and Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 414).

Example of an Amazon S3 permissions policy for access to transaction log backups

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Only allow writes to my bucket with bucket owner full control",
      "Action": "s3:*",
      "Effect": "Allow",
      "Resource": "arn:aws:s3:::my-bucket-name/*",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:s3:::source-bucket-name/*",
          "aws:SourceAccount": "source-account-id"
        }
      }
    }
  ]
}
```
Access to transaction log backups

- An AWS Identity and Access Management (IAM) role to access the Amazon S3 bucket. If you already have an IAM role, you can use that. You can choose to have a new IAM role created for you when you add the SQLSERVER_BACKUP_RESTORE option by using the AWS Management Console. Alternatively, you can create a new one manually. For more information on creating and configuring an IAM role with SQLSERVER_BACKUP_RESTORE, see Manually creating an IAM role for native backup and restore (p. 1143).

- The SQLSERVER_BACKUP_RESTORE option must be added to an option group on your DB instance. For more information on adding the SQLSERVER_BACKUP_RESTORE option, see Support for native backup and restore in SQL Server (p. 1255).

  **Note**

  If your DB instance has storage encryption enabled, the AWS KMS (KMS) actions and key must be provided in the IAM role provided in the native backup and restore option group.

  Optionally, if you intend to use the rds_restore_log stored procedure to perform point in time database restores, we recommend using the same Amazon S3 path for the native backup and restore option group and access to transaction log backups. This method ensures that when Amazon RDS assumes the role from the option group to perform the restore log functions, it has access to retrieve transaction log backups from the same Amazon S3 path.

**Limitations and recommendations**

Access to transaction log backups has the following limitations and recommendations:

- You can list and copy up to the last seven days of transaction log backups for any DB instance that has backup retention configured between one to 35 days.

- The Amazon S3 bucket used for access to transaction log backups must exist in the same account and Region as the source DB instance. Cross-account and cross-region copy is not supported.

- Only one Amazon S3 bucket can be configured as a target to copy transaction log backups into. You can choose a new target Amazon S3 bucket with the rds_tlog_copy_setup stored procedure. For more information on choosing a new target Amazon S3 bucket, see Setting up access to transaction log backups (p. 1226).

- You cannot specify the KMS key when using the rds_tlog_backup_copy_to_S3 stored procedure if your RDS instance is not enabled for storage encryption.

- Multi-account copying is not supported. The IAM role used for copying will only permit write access to Amazon S3 buckets within the owner account of the DB instance.

- Only two concurrent tasks of any type may be run on an RDS for SQL Server DB instance.

- Only one copy task can run for a single database at a given time. If you want to copy transaction log backups for multiple databases on the DB instance, use a separate copy task for each database.
• If you copy a transaction log backup that already exists with the same name in the Amazon S3 bucket, the existing transaction log backup will be overwritten.

• You can only run the stored procedures that are provided with access to transaction log backups on the primary DB instance. You can’t run these stored procedures on an RDS for SQL Server read replica or on a secondary instance of a Multi-AZ DB cluster.

• If the RDS for SQL Server DB instance is rebooted while the rds_tlog_backup_copy_to_S3 stored procedure is running, the task will automatically restart from the beginning when the DB instance is back online. Any transaction log backups that had been copied to the Amazon S3 bucket while the task was running before the reboot will be overwritten.

• The Microsoft SQL Server system databases and the RDSAdmin database cannot be configured for access to transaction log backups.

**Setting up access to transaction log backups**

To set up access to transaction log backups, complete the list of requirements in the [Requirements](#) section, and then run the rds_tlog_copy_setup stored procedure. The procedure will enable the access to transaction log backups feature at the DB instance level. You don’t need to run it for each individual database on the DB instance.

**Important**

The database user must be granted the db_owner role within SQL Server on each database to configure and use the access to transaction log backups feature.

**Example usage:**

```sql
exec msdb.dbo.rds_tlog_copy_setup
@target_s3_arn='arn:aws:s3:::mybucket/myfolder';
```

The following parameter is required:

• @target_s3_arn – The ARN of the target Amazon S3 bucket to copy transaction log backups files to.

**Example of setting an Amazon S3 target bucket:**

```sql
exec msdb.dbo.rds_tlog_copy_setup @target_s3_arn='arn:aws:s3:::accessstlogs-testbucket/mytestdb1';
```

To validate the configuration, call the rds_show_configuration stored procedure.

**Example of validating the configuration:**

```sql
exec rdsadmin.dbo.rds_show_configuration @name='target_s3_arn_for_tlog_copy';
```

To modify access to transaction log backups to point to a different Amazon S3 bucket, you can view the current Amazon S3 bucket value and re-run the rds_tlog_copy_setup stored procedure using a new value for the @target_s3_arn.

**Example of viewing the existing Amazon S3 bucket configured for access to transaction log backups**

```sql
```
exec rdsadmin.dbo.rds_show_configuration @name='target_s3_arn_for_tlog_copy';

**Example of updating to a new target Amazon S3 bucket**

exec msdb.dbo.rds_tlog_copy_setup @target_s3_arn='arn:aws:s3:::mynewbucket/mynewfolder';

**Listing available transaction log backups**

With RDS for SQL Server, databases configured to use the full recovery model and a DB instance backup retention set to one or more days have transaction log backups automatically enabled. By enabling access to transaction log backups, up to seven days of those transaction log backups are made available for you to copy into your Amazon S3 bucket.

After you have enabled access to transaction log backups, you can start using it to list and copy available transaction log backup files.

**Listing transaction log backups**

To list all transaction log backups available for an individual database, call the `rds_fn_list_tlog_backup_metadata` function. You can use an `ORDER BY` or a `WHERE` clause when calling the function.

**Example of listing and filtering available transaction log backup files**

```sql
SELECT * FROM msdb.dbo.rds_fn_list_tlog_backup_metadata('mydatabasename');
SELECT * FROM msdb.dbo.rds_fn_list_tlog_backup_metadata('mydatabasename') WHERE rds_backup_seq_id = 3507;
SELECT * FROM msdb.dbo.rds_fn_list_tlog_backup_metadata('mydatabasename') WHERE backup_file_time_utc > '2022-09-15 20:44:01' ORDER BY backup_file_time_utc DESC;
```
The `rds_fn_list_tlog_backup_metadata` function returns the following output:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>db_name</td>
<td>sysname</td>
<td>The database name provided to list the transaction log backups for.</td>
</tr>
<tr>
<td>db_id</td>
<td>int</td>
<td>The internal database identifier for the input parameter <code>db_name</code>.</td>
</tr>
<tr>
<td>family_guid</td>
<td>uniqueidentifier</td>
<td>The unique ID of the original database at creation. This value remains the same when the database is restored, even to a different database name.</td>
</tr>
<tr>
<td>rds_backup_seq_id</td>
<td>int</td>
<td>The ID that RDS uses internally to maintain a sequence number for each transaction log backup file.</td>
</tr>
<tr>
<td>backup_file_epoch</td>
<td>bigint</td>
<td>The epoch time that a transaction backup file was generated.</td>
</tr>
<tr>
<td>backup_file_time_utc</td>
<td>datetime</td>
<td>The UTC time-converted value for the <code>backup_file_epoch</code> value.</td>
</tr>
<tr>
<td>starting_lsn</td>
<td>numeric(25,0)</td>
<td>The log sequence number of the first or oldest log record of a transaction log backup file.</td>
</tr>
<tr>
<td>ending_lsn</td>
<td>numeric(25,0)</td>
<td>The log sequence number of the last or next log record of a transaction log backup file.</td>
</tr>
<tr>
<td>is_log_chain_broken</td>
<td>bit</td>
<td>A boolean value indicating if the log chain is broken between the current transaction log backup file and the previous transaction log backup file.</td>
</tr>
<tr>
<td>file_size_bytes</td>
<td>bigint</td>
<td>The size of the transactional backup set in bytes.</td>
</tr>
<tr>
<td>Error</td>
<td>varchar(4000)</td>
<td>Error message if the <code>rds_fn_list_tlog_backup_metadata</code> function throws an exception. NULL if no exceptions.</td>
</tr>
</tbody>
</table>

### Copying transaction log backups

To copy a set of available transaction log backups for an individual database to your Amazon S3 bucket, call the `rds_tlog_backup_copy_to_S3` stored procedure. The `rds_tlog_backup_copy_to_S3` stored procedure will initiate a new task to copy transaction log backups.

**Note**
The `rds_tlog_backup_copy_to_S3` stored procedure will copy the transaction log backups without validating against `is_log_chain_broken` attribute. For this reason, you should manually confirm an unbroken log chain before running the `rds_tlog_backup_copy_to_S3` stored procedure. For further explanation, see Validating the transaction log backup log chain (p. 1232).

**Example usage of the `rds_tlog_backup_copy_to_S3` stored procedure**

```
exec msdb.dbo.rds_tlog_backup_copy_to_S3
@db_name='mydatabasename',
[@kms_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@backup_file_start_time='2022-09-01 01:00:15'],
[@backup_file_end_time='2022-09-01 21:30:45'],
```
The following input parameters are available:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@db_name</td>
<td>The name of the database to copy transaction log backups for</td>
</tr>
<tr>
<td>@kms_key_arn</td>
<td>The ARN of the KMS key used to encrypt a storage-encrypted DB instance.</td>
</tr>
<tr>
<td>@backup_file_start_time</td>
<td>The UTC timestamp as provided from the [backup_file_time_utc] column of the rds_fn_list_tlog_backup_metadata function.</td>
</tr>
<tr>
<td>@backup_file_end_time</td>
<td>The UTC timestamp as provided from the [backup_file_time_utc] column of the rds_fn_list_tlog_backup_metadata function.</td>
</tr>
<tr>
<td>@starting_lsn</td>
<td>The log sequence number (LSN) as provided from the [starting_lsn] column of the rds_fn_list_tlog_backup_metadata function</td>
</tr>
<tr>
<td>@ending_lsn</td>
<td>The log sequence number (LSN) as provided from the [ending_lsn] column of the rds_fn_list_tlog_backup_metadata function</td>
</tr>
<tr>
<td>@rds_backup_starting_seq_id</td>
<td>The sequence ID as provided from the [rds_backup_seq_id] column of the rds_fn_list_tlog_backup_metadata function.</td>
</tr>
<tr>
<td>@rds_backup_ending_seq_id</td>
<td>The sequence ID as provided from the [rds_backup_seq_id] column of the rds_fn_list_tlog_backup_metadata function.</td>
</tr>
</tbody>
</table>

You can specify a set of either the time, LSN, or sequence ID parameters. Only one set of parameters are required.

You can also specify just a single parameter in any of the sets. For example, by providing a value for only the backup_file_end_time parameter, all available transaction log backup files prior to that time within the seven-day limit will be copied to your Amazon S3 bucket.

Following are the valid input parameter combinations for the rds_tlog_backup_copy_to_S3 stored procedure.

<table>
<thead>
<tr>
<th>Parameters provided</th>
<th>Expected result</th>
</tr>
</thead>
<tbody>
<tr>
<td>exec</td>
<td>Copies transaction log backups from the last seven days and exist between the provided range of backup_file_start_time '2022-08-23' and backup_file_end_time '2022-08-30'. In this example, the stored procedure will copy transaction</td>
</tr>
<tr>
<td>Parameters provided</td>
<td>Expected result</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>log backups that were generated between '2022-08-23 00:00:00' and '2022-08-30 00:00:00'.</td>
</tr>
<tr>
<td><strong>exec</strong></td>
<td>Copies transaction log backups from the last seven days and starting from the provided backup_file_start_time. In this example, the stored procedure will copy transaction log backups from '2022-08-23 00:00:00' up to the latest transaction log backup.</td>
</tr>
<tr>
<td>exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name = 'testdb1', @backup_file_start_time='2022-08-23 00:00:00';</td>
<td></td>
</tr>
<tr>
<td>exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name = 'testdb1', @backup_end_time='2022-08-30 00:00:00';</td>
<td>Copies transaction log backups from the last seven days up to the provided backup_file_end_time. In this example, the stored procedure will copy transaction log backups from '2022-08-23 00:00:00' up to '2022-08-30 00:00:00'.</td>
</tr>
<tr>
<td>exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @starting_lsn =1490000000040007, @ending_lsn =149000000020009;</td>
<td>Copies transaction log backups that are available from the last seven days and are between the provided range of the starting_lsn and ending_lsn. In this example, the stored procedure will copy transaction log backups from the last seven days with an LSN range between 1490000000040007 and 149000000020009.</td>
</tr>
<tr>
<td>Parameters provided</td>
<td>Expected result</td>
</tr>
<tr>
<td>-----------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @starting_lsn = 1490000000040007;</td>
<td>Copies transaction log backups that are available from the last seven days, beginning from the provided starting_lsn. In this example, the stored procedure will copy transaction log backups from LSN 1490000000040007 up to the latest transaction log backup.</td>
</tr>
<tr>
<td>exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @ending_lsn = 1490000000050009;</td>
<td>Copies transaction log backups that are available from the last seven days, up to the provided ending_lsn. In this example, the stored procedure will copy transaction log backups beginning from the last seven days up to lsn 1490000000050009.</td>
</tr>
<tr>
<td>exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @rds_backup_starting_seq_id=2000, @rds_backup_ending_seq_id=5000;</td>
<td>Copies transaction log backups that are available from the last seven days, and exist between the provided range of rds_backup_starting_seq_id and rds_backup_ending_seq_id. In this example, the stored procedure will copy transaction log backups beginning from the last seven days and within the provided rds backup sequence id range, starting from seq_id 2000 up to seq_id 5000.</td>
</tr>
</tbody>
</table>
### Parameters provided

| exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @rds_backup_starting_seq_id=2000; | Copies transaction log backups that are available from the last seven days, beginning from the provided rds_backup_starting_seq_id. In this example, the stored procedure will copy transaction log backups beginning from seq_id 2000, up to the latest transaction log backup. |
| exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @rds_backup_ending_seq_id=5000; | Copies transaction log backups that are available from the last seven days, up to the provided rds_backup_ending_seq_id. In this example, the stored procedure will copy transaction log backups beginning from the last seven days, up to seq_id 5000. |
| exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @rds_backup_starting_seq_id=2000; @rds_backup_ending_seq_id=2000; | Copies a single transaction log backup with the provided rds_backup_starting_seq_id, if available within the last seven days. In this example, the stored procedure will copy a single transaction log backup that has a seq_id of 2000, if it exists within the last seven days. |

### Validating the transaction log backup log chain

Databases configured for access to transaction log backups must have automated backup retention enabled. Automated backup retention sets the databases on the DB instance to the FULL recovery model. To support point in time restore for a database, avoid changing the database recovery model, which can result in a broken log chain. We recommend keeping the database set to the FULL recovery model.
To manually validate the log chain before copying transaction log backups, call the 
>rds_fn_list_tlog_backup_metadata function and review the values in the 
is_log_chain_broken column. A value of "1" indicates the log chain was broken between the current 
log backup and the previous log backup.

The following example shows a broken log chain in the output from the 
rds_fn_list_tlog_backup_metadata stored procedure.

<table>
<thead>
<tr>
<th>rds_sequence_id</th>
<th>first_lsn</th>
<th>last_lsn</th>
<th>is_log_chain_broken</th>
</tr>
</thead>
<tbody>
<tr>
<td>43</td>
<td>90023</td>
<td>90457</td>
<td>0</td>
</tr>
<tr>
<td>44</td>
<td>90457</td>
<td>90985</td>
<td>0</td>
</tr>
<tr>
<td>45</td>
<td>90987</td>
<td>92034</td>
<td>1</td>
</tr>
</tbody>
</table>

In a normal log chain, the log sequence number (LSN) value for first_lsn for given rds_sequence_id 
should match the value of last_lsn in the preceding rds_sequence_id. In the image, the rds_sequence_id 
of 45 has a first_lsn value 90987, which does not match the last_lsn value of 90985 for preceeding 
rds_sequence_id 44.

For more information about SQL Server transaction log architecture and log sequence numbers, see 
Transaction Log Logical Architecture in the Microsoft SQL Server documentation.

Amazon S3 bucket folder and file structure

Transaction log backups have the following standard structure and naming convention within an Amazon 
S3 bucket:

- A new folder is created under the target_s3_arn path for each database with the naming structure 
as {db_id}.{family_guid}.
- Within the folder, transaction log backups have a filename structure as {db_id}.{family_guid}. 
{rds_backup_seq_id}.{backup_file_epoch}.
- You can view the details of family_guid, db_id, rds_backup_seq_id and backup_file_epoch 
with the rds_fn_list_tlog_backup_metadata function.

The following example shows the folder and file structure of a set of transaction log backups within an 
Amazon S3 bucket.
Tracking the status of tasks

To track the status of your copy tasks, call the `rds_task_status` stored procedure. If you don't provide any parameters, the stored procedure returns the status of all tasks.

Example usage:

```sql
exec msdb.dbo.rds_task_status
    @db_name='database_name',
    @task_id=ID_number;
```

The following parameters are optional:

- `@db_name` – The name of the database to show the task status for.
- `@task_id` – The ID of the task to show the task status for.
Example of listing the status for a specific task ID:

```
exec msdb.dbo.rds_task_status @task_id=5;
```

Example of listing the status for a specific database and task:

```
exec msdb.dbo.rds_task_status@db_name='my_database',@task_id=5;
```

Example of listing all tasks and their status for a specific database:

```
exec msdb.dbo.rds_task_status @db_name='my_database';
```

Example of listing all tasks and their status on the current DB instance:

```
exec msdb.dbo.rds_task_status;
```

**Canceling a task**

To cancel a running task, call the `rds_cancel_task` stored procedure.

**Example usage:**

```
exec msdb.dbo.rds_cancel_task @task_id=ID_number;
```

The following parameter is required:

- `@task_id` – The ID of the task to cancel. You can view the task ID by calling the `rds_task_status` stored procedure.

For more information on viewing and canceling running tasks, see Importing and exporting SQL Server databases using native backup and restore (p. 1140).

**Troubleshooting access to transaction log backups**

The following are issues you might encounter when you use the stored procedures for access to transaction log backups.

<table>
<thead>
<tr>
<th>Stored Procedure</th>
<th>Error Message</th>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>

</tbody>
</table>
Options for the Microsoft SQL Server database engine

In this section, you can find descriptions for options that are available for Amazon RDS instances running the Microsoft SQL Server DB engine. To enable these options, you add them to an option group, and then associate the option group with your DB instance. For more information, see Working with option groups (p. 279).

If you're looking for optional features that aren't added through RDS option groups (such as SSL, Microsoft Windows Authentication, and Amazon S3 integration), see Additional features for Microsoft SQL Server on Amazon RDS (p. 1175).

Amazon RDS supports the following options for Microsoft SQL Server DB instances.

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>

</tbody>
</table>
Listing the available options for SQL Server versions and editions

You can use the `describe-option-group-options` AWS CLI command to list the available options for SQL Server versions and editions, and the settings for those options.

The following example shows the options and option settings for SQL Server 2019 Enterprise Edition. The `--engine-name` option is required.

```
aws rds describe-option-group-options --engine-name sqlserver-ee --major-engine-version 15.00
```

The output resembles the following:

```
{
    "OptionGroupOptions": [
        {
            "Name": "MSDTC",
            "Description": "Microsoft Distributed Transaction Coordinator",
            "EngineName": "sqlserver-ee",
            "MajorEngineVersion": "15.00",
            "MinimumRequiredMinorEngineVersion": "4043.16.v1",
```
Listing the available options for SQL Server versions and editions

```
Support for Linked Servers with Oracle OLEDB in Amazon RDS for SQL Server

Linked servers with the Oracle Provider for OLEDB on RDS for SQL Server lets you access external data sources on an Oracle database. You can read data from remote Oracle data sources and run commands against remote Oracle database servers outside of your RDS for SQL Server DB instance. Using linked servers with Oracle OLEDB, you can:

- Directly access data sources other than SQL Server
- Query against diverse Oracle data sources with the same query without moving the data
- Issue distributed queries, updates, commands, and transactions on data sources across an enterprise ecosystem
- Integrate connections to an Oracle database from within the Microsoft Business Intelligence suite (SSIS, SSRS, SSAS)
- Migrate from an Oracle database to RDS for SQL Server

You can activate one or more linked servers for Oracle on either an existing or new RDS for SQL Server DB instance. Then you can integrate external Oracle data sources with your DB instance.

Contents

- Supported versions and Regions (p. 1247)
- Limitations and recommendations (p. 1247)
- Activating linked servers with Oracle (p. 1248)
  - Creating the option group for OLEDB_ORACLE (p. 1248)
  - Adding the OLEDB_ORACLE option to the option group (p. 1249)
  - Associating the option group with your DB instance (p. 1250)
- Modifying OLEDB provider properties (p. 1251)
- Modifying OLEDB driver properties (p. 1252)
- Deactivating linked servers with Oracle (p. 1253)

Supported versions and Regions

RDS for SQL Server supports linked servers with Oracle OLEDB in all Regions for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2019, all versions
- SQL Server 2017, all versions

Linked servers with Oracle OLEDB is supported for the following Oracle Database versions:

- Oracle Database 21c, all versions
- Oracle Database 19c, all versions
- Oracle Database 18c, all versions

Limitations and recommendations

Keep in mind the following limitations and recommendations that apply to linked servers with Oracle OLEDB:
Linked Servers with Oracle OLEDB

- Allow network traffic by adding the applicable TCP port in the security group for each RDS for SQL Server DB instance. For example, if you’re configuring a linked server between an EC2 Oracle DB instance and an RDS for SQL Server DB instance, then you must allow traffic from the IP address of the EC2 Oracle DB instance. You also must allow traffic on the port that SQL Server is using to listen for database communication. For more information on security groups, see Controlling access with security groups (p. 2232).

- Perform a reboot of the RDS for SQL Server DB instance after turning on, turning off, or modifying the OLEDB_ORACLE option in your option group. The option group status displays pending_reboot for these events and is required.

- Only simple authentication is supported with a user name and password for the Oracle data source.

- Open Database Connectivity (ODBC) drivers are not supported. Only the latest version of the OLEDB driver is supported.

- Distributed transactions (XA) are supported. To activate distributed transactions, turn on the MSDTC option in the Option Group for your DB instance and make sure XA transactions are turned on. For more information, see Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server (p. 1320).

- Creating data source names (DSNs) to use as a shortcut for a connection string is not supported.

- OLEDB driver tracing is not supported. You can use SQL Server Extended Events to trace OLEDB events. For more information, see Set up Extended Events in RDS for SQL Server.

- Access to the catalogs folder for an Oracle linked server is not supported using SQL Server Management Studio (SSMS).

Activating linked servers with Oracle

Activate linked servers with Oracle by adding the OLEDB_ORACLE option to your RDS for SQL Server DB instance. Use the following process:

1. Create a new option group, or choose an existing option group.
2. Add the OLEDB_ORACLE option to the option group.
3. Choose a version of the OLEDB driver to use.
4. Associate the option group with the DB instance.
5. Reboot the DB instance.

Creating the option group for OLEDB_ORACLE

To work with linked servers with Oracle, create an option group or modify an option group that corresponds to the SQL Server edition and version of the DB instance that you plan to use. To complete this procedure, use the AWS Management Console or the AWS CLI.

Console

The following procedure creates an option group for SQL Server Standard Edition 2019.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose Create group.
4. In the Create option group window, do the following:
a. For **Name** enter a name for the option group that is unique within your AWS account, such as `oracle-oledb-se-2019`. The name can contain only letters, digits, and hyphens.
b. For **Description**, enter a brief description of the option group, such as **OLEDB_ORACLE option group for SQL Server SE 2019**. The description is used for display purposes.
c. For **Engine**, choose `sqlserver-se`.
d. For **Major engine version**, choose `15.00`.

5. Choose **Create**.

**CLI**

The following procedure creates an option group for SQL Server Standard Edition 2019.

**To create the option group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-option-group \
  --option-group-name oracle-oledb-se-2019 \
  --engine-name sqlserver-se \
  --major-engine-version 15.00 \
  --option-group-description "OLEDB_ORACLE option group for SQL Server SE 2019"
```

For Windows:

```bash
aws rds create-option-group ^
  --option-group-name oracle-oledb-se-2019 ^
  --engine-name sqlserver-se ^
  --major-engine-version 15.00 ^
  --option-group-description "OLEDB_ORACLE option group for SQL Server SE 2019"
```

**Adding the OLEDB_ORACLE option to the option group**

Next, use the AWS Management Console or the AWS CLI to add the OLEDB_ORACLE option to your option group.

**Console**

**To add the OLEDB_ORACLE option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, which is `oracle-oledb-se-2019` in this example.
4. Choose **Add option**.
5. Under **Option details**, choose **OLEDB_ORACLE** for **Option name**.
6. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
7. Choose **Add option**.
CLI

To add the OLEDB_ORACLE option

- Add the OLEDB_ORACLE option to the option group.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group --option-group-name oracle-oledb-se-2019 --options OptionName=OLEDB_ORACLE --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group --option-group-name oracle-oledb-se-2019 --options OptionName=OLEDB_ORACLE --apply-immediately
```

Associating the option group with your DB instance

To associate the OLEDB_ORACLE option group and parameter group with your DB instance, use the AWS Management Console or the AWS CLI

Console

To finish activating linked servers for Oracle, associate your OLEDB_ORACLE option group with a new or existing DB instance:

- For a new DB instance, associate them when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
- For an existing DB instance, associate them by modifying the instance. For more information, see Modifying an Amazon RDS DB instance (p. 333).

CLI

You can associate the OLEDB_ORACLE option group and parameter group with a new or existing DB instance.

To create an instance with the OLEDB_ORACLE option group and parameter group

- Specify the same DB engine type and major version that you used when creating the option group.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance --db-instance-identifier mytestsqlserveroracleoledbinstance --db-instance-class db.m5.2xlarge --engine sqlserver-se --engine-version 15.0.4236.7.v1 --allocated-storage 100 --master-user-password secret123
```
For Windows:

```bash
aws rds create-db-instance
  --db-instance-identifier mytestsqlserveroracleoledbinstance
  --db-instance-class db.m5.2xlarge
  --engine sqlserver-se
  --engine-version 15.0.4236.7.v1
  --allocated-storage 100
  --master-user-password secret123
  --master-username admin
  --storage-type gp2
  --license-model li
  --domain-iam-role-name my-directory-iam-role
  --domain my-domain-id
  --option-group-name oracle-oledb-se-2019
  --db-parameter-group-name my-parameter-group-name
```

To modify an instance and associate the OLEDB_ORACLE option group

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
  --db-instance-identifier mytestsqlserveroracleoledbinstance
  --option-group-name oracle-oledb-se-2019
  --db-parameter-group-name my-parameter-group-name
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance
  --db-instance-identifier mytestsqlserveroracleoledbinstance
  --option-group-name oracle-oledb-se-2019
  --db-parameter-group-name my-parameter-group-name
  --apply-immediately
```

Modifying OLEDB provider properties

You can view and change the properties of the OLEDB provider. Only the master user can perform this task. All linked servers for Oracle that are created on the DB instance use the same properties of that OLEDB provider. Call the sp_MSset_oledb_prop stored procedure to change the properties of the OLEDB provider.

To change the OLEDB provider properties
USE [master]
GO
EXEC sp_MSset_oledb_prop N'OraOLEDB.Oracle', N'AllowInProcess', 1
EXEC sp_MSset_oledb_prop N'OraOLEDB.Oracle', N'DynamicParameters', 0
GO
The following properties can be modified:

<table>
<thead>
<tr>
<th>Property name</th>
<th>Recommended Value (1 = On, 0 = Off)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic parameter</td>
<td>1</td>
<td>Allows SQL placeholders (represented by '?' in parameterized queries.</td>
</tr>
<tr>
<td>Nested queries</td>
<td>1</td>
<td>Allows nested SELECT statements in the FROM clause, such as sub-queries.</td>
</tr>
<tr>
<td>Level zero only</td>
<td>0</td>
<td>Only base-level OLEDB interfaces are called against the provider.</td>
</tr>
<tr>
<td>Allow inprocess</td>
<td>1</td>
<td>If turned on, Microsoft SQL Server allows the provider to be instantiated as an in-process server. Set this property to 1 to use Oracle linked servers.</td>

<td>If non-zero, SQL Server attempts to use indexes of the provider to fetch data.</td>
</tr>
<tr>
<td>Disallow adhoc access</td>
<td>False</td>
<td>If set, SQL Server does not allow running pass-through queries against the OLEDB provider. While this option can be checked, it is sometimes appropriate to run pass-through queries.</td>
</tr>
<tr>
<td>Supports LIKE operator</td>
<td>1</td>
<td>Indicates that the provider supports queries using the LIKE keyword.</td>
</tr>
</tbody>
</table>

Modifying OLEDB driver properties

You can view and change the properties of the OLEDB driver when creating a linked server for Oracle. Only the master user can perform this task. Driver properties define how the OLEDB driver handles data when working with a remote Oracle data source. Driver properties are specific to each Oracle linked server created on the DB instance. Call the master.dbo.sp_addlinkedserver stored procedure to change the properties of the OLEDB driver.

Example: To create a linked server and change the OLEDB driver FetchSize property

EXEC master.dbo.sp_addlinkedserver
@server = N'Oracle_link2',
@srvproduct=N'Oracle',
@provider=N'OraOLEDB.Oracle',
@datasrc=N'my-oracle-test.cnetsipka.us-west-2.rds.amazonaws.com:1521/ORCL',
@provstr='FetchSize=200'
GO
Deactivating linked servers with Oracle

To deactivate linked servers with Oracle, remove the OLEDB_ORACLE option from its option group.

Important
Removing the option doesn't delete the existing linked server configurations on the DB instance. You must manually drop them to remove them from the DB instance. You can reactivate the OLEDB_ORACLE option after removal to reuse the linked server configurations that were previously configured on the DB instance.

Console

The following procedure removes the OLEDB_ORACLE option.

To remove the OLEDB_ORACLE option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the option group with the OLEDB_ORACLE option (oracleoledb-se-2019 in the previous examples).
4. Choose Delete option.
5. Under Deletion options, choose OLEDB_ORACLE for Options to delete.
6. Under Apply immediately, choose Yes to delete the option immediately, or No to delete it during the next maintenance window.
7. Choose Delete.

CLI

The following procedure removes the OLEDB_ORACLE option.

To remove the OLEDB_ORACLE option from its option group

• Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \   
   --option-group-name oracleoledb-se-2019 \   
   --options OLEDB_ORACLE \   
   --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^
   --option-group-name oracleoledb-se-2019 ^
```
--options OLEDB_ORACLE ^
--apply-immediately
Support for native backup and restore in SQL Server

By using native backup and restore for SQL Server databases, you can create a differential or full backup of your on-premises database and store the backup files on Amazon S3. You can then restore to an existing Amazon RDS DB instance running SQL Server. You can also back up an RDS for SQL Server database, store it on Amazon S3, and restore it in other locations. In addition, you can restore the backup to an on-premises server, or a different Amazon RDS DB instance running SQL Server. For more information, see Importing and exporting SQL Server databases using native backup and restore (p. 1140).

Amazon RDS supports native backup and restore for Microsoft SQL Server databases by using differential and full backup files (.bak files).

Adding the native backup and restore option

The general process for adding the native backup and restore option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the SQLSERVER_BACKUP_RESTORE option to the option group.
3. Associate an AWS Identity and Access Management (IAM) role with the option. The IAM role must have access to an S3 bucket to store the database backups.

That is, the option must have as its option setting a valid Amazon Resource Name (ARN) in the format arn:aws:iam::account-id:role/role-name. For more information, see Amazon Resource Names (ARNs) in the AWS General Reference.

The IAM role must also have a trust relationship and a permissions policy attached. The trust relationship allows RDS to assume the role, and the permissions policy defines the actions that the role can perform. For more information, see Manually creating an IAM role for native backup and restore (p. 1143).

4. Associate the option group with the DB instance.

After you add the native backup and restore option, you don't need to restart your DB instance. As soon as the option group is active, you can begin backing up and restoring immediately.

Console

To add the native backup and restore option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Create a new option group or use an existing option group. For information on how to create a custom DB option group, see Creating an option group (p. 280).

To use an existing option group, skip to the next step.

4. Add the SQLSERVER_BACKUP_RESTORE option to the option group. For more information about adding options, see Adding an option to an option group (p. 283).

5. Do one of the following:

   - To use an existing IAM role and Amazon S3 settings, choose an existing IAM role for IAM Role. If you use an existing IAM role, RDS uses the Amazon S3 settings configured for this role.
   - To create a new role and configure Amazon S3 settings, do the following:
     1. For IAM role, choose Create a new role.
2. For **S3 bucket**, choose an S3 bucket from the list.

3. For **S3 prefix (optional)**, specify a prefix to use for the files stored in your Amazon S3 bucket.

   This prefix can include a file path but doesn't have to. If you provide a prefix, RDS attaches that prefix to all backup files. RDS then uses the prefix during a restore to identify related files and ignore irrelevant files. For example, you might use the S3 bucket for purposes besides holding backup files. In this case, you can use the prefix to have RDS perform native backup and restore only on a particular folder and its subfolders.

   If you leave the prefix blank, then RDS doesn't use a prefix to identify backup files or files to restore. As a result, during a multiple-file restore, RDS attempts to restore every file in every folder of the S3 bucket.

4. Choose the **Enable encryption** check box to encrypt the backup file. Leave the check box cleared (the default) to have the backup file unencrypted.

   If you chose **Enable encryption**, choose an encryption key for **AWS KMS key**. For more information about encryption keys, see **Getting started** in the **AWS Key Management Service Developer Guide**.

6. Choose **Add option**.

7. Apply the option group to a new or existing DB instance:

   - For a new DB instance, apply the option group when you launch the instance. For more information, see **Creating an Amazon RDS DB instance (p. 236)**.
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see **Modifying an Amazon RDS DB instance (p. 333)**.

**CLI**

This procedure makes the following assumptions:

- You're adding the SQLSERVER_BACKUP_RESTORE option to an option group that already exists. For more information about adding options, see **Adding an option to an option group (p. 283)**.
- You're associating the option with an IAM role that already exists and has access to an S3 bucket to store the backups.
- You're applying the option group to a DB instance that already exists. For more information, see **Modifying an Amazon RDS DB instance (p. 333)**.

**To add the native backup and restore option**

1. Add the SQLSERVER_BACKUP_RESTORE option to the option group.

   **Example**

   For Linux, macOS, or Unix:

   ```bash
   aws rds add-option-to-option-group \\
   --apply-immediately \\
   --option-group-name mybackupgroup \\
   --options "OptionName=SQLSERVER_BACKUP_RESTORE, \\
   OptionSettings=[{"Name=IAM_ROLE_ARN,Value=arn:aws:iam::account-id:role/role-name}]"
   ```

   For Windows:

   ```bash
   aws rds add-option-to-option-group ^
   --option-group-name mybackupgroup ^
   ```
2. Apply the option group to the DB instance.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --option-group-name mybackupgroup \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --option-group-name mybackupgroup ^
  --apply-immediately
```

Modifying native backup and restore option settings

After you enable the native backup and restore option, you can modify the settings for the option. For more information about how to modify option settings, see Modifying an option setting (p. 288).

Removing the native backup and restore option

You can turn off native backup and restore by removing the option from your DB instance. After you remove the native backup and restore option, you don't need to restart your DB instance.

To remove the native backup and restore option from a DB instance, do one of the following:

- Remove the option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 291).
- Modify the DB instance and specify a different option group that doesn't include the native backup and restore option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).
Support for Transparent Data Encryption in SQL Server

Amazon RDS supports using Transparent Data Encryption (TDE) to encrypt stored data on your DB instances running Microsoft SQL Server. TDE automatically encrypts data before it is written to storage, and automatically decrypts data when the data is read from storage.

Amazon RDS supports TDE for the following SQL Server versions and editions:

- SQL Server 2019 Standard and Enterprise Editions
- SQL Server 2017 Enterprise Edition
- SQL Server 2016 Enterprise Edition
- SQL Server 2014 Enterprise Edition

Transparent Data Encryption for SQL Server provides encryption key management by using a two-tier key architecture. A certificate, which is generated from the database master key, is used to protect the data encryption keys. The database encryption key performs the actual encryption and decryption of data on the user database. Amazon RDS backs up and manages the database master key and the TDE certificate.

Transparent Data Encryption is used in scenarios where you need to encrypt sensitive data. For example, you might want to provide data files and backups to a third party, or address security-related regulatory compliance issues. You can't encrypt the system databases for SQL Server, such as the model or master databases.

A detailed discussion of Transparent Data Encryption is beyond the scope of this guide, but make sure that you understand the security strengths and weaknesses of each encryption algorithm and key. For information about Transparent Data Encryption for SQL Server, see Transparent Data Encryption (TDE) in the Microsoft documentation.

Topics

- Turning on TDE for RDS for SQL Server (p. 1258)
- Encrypting data on RDS for SQL Server (p. 1259)
- Backing up and restoring TDE certificates on RDS for SQL Server (p. 1260)
- Backing up and restoring TDE certificates for on-premises databases (p. 1263)
- Turning off TDE for RDS for SQL Server (p. 1265)

Turning on TDE for RDS for SQL Server

To turn on Transparent Data Encryption for an RDS for SQL Server DB instance, specify the TDE option in an RDS option group that's associated with that DB instance:

1. Determine whether your DB instance is already associated with an option group that has the TDE option. To view the option group that a DB instance is associated with, use the RDS console, the describe-db-instance AWS CLI command, or the API operation DescribeDBInstances.

2. If the DB instance isn't associated with an option group that has TDE turned on, you have two choices. You can create an option group and add the TDE option, or you can modify the associated option group to add it.

   Note
   In the RDS console, the option is named TRANSPARENT_DATA_ENCRYPTION. In the AWS CLI and RDS API, it's named TDE.

1258
For information about creating or modifying an option group, see Working with option groups (p. 279). For information about adding an option to an option group, see Adding an option to an option group (p. 283).

3. Associate the DB instance with the option group that has the TDE option. For information about associating a DB instance with an option group, see Modifying an Amazon RDS DB instance (p. 333).

Option group considerations

The TDE option is a persistent option. You can't remove it from an option group unless all DB instances and backups are no longer associated with the option group. After you add the TDE option to an option group, the option group can be associated only with DB instances that use TDE. For more information about persistent options in an option group, see Option groups overview (p. 279).

Because the TDE option is a persistent option, you can have a conflict between the option group and an associated DB instance. You can have a conflict in the following situations:

- The current option group has the TDE option, and you replace it with an option group that doesn't have the TDE option.
- You restore from a DB snapshot to a new DB instance that doesn't have an option group that contains the TDE option. For more information about this scenario, see Option group considerations (p. 498).

SQL Server performance considerations

Using Transparent Data Encryption can affect the performance of a SQL Server DB instance.

Performance for unencrypted databases can also be degraded if the databases are on a DB instance that has at least one encrypted database. As a result, we recommend that you keep encrypted and unencrypted databases on separate DB instances.

Encrypting data on RDS for SQL Server

When the TDE option is added to an option group, Amazon RDS generates a certificate that's used in the encryption process. You can then use the certificate to run SQL statements that encrypt data in a database on the DB instance.

The following example uses the RDS-created certificate called RDSTDECertificateName to encrypt a database called myDatabase.

```
---------- Turning on TDE ----------
-- Find an RDS TDE certificate to use
USE [master]
GO
SELECT name FROM sys.certificates WHERE name LIKE 'RDSTDECertificate%'
GO

USE [myDatabase]
GO
-- Create a database encryption key (DEK) using one of the certificates from the previous step
CREATE DATABASE ENCRYPTION KEY WITH ALGORITHM = AES_256 ENCRYPTION BY SERVER CERTIFICATE [RDSTDECertificateName]
GO

-- Turn on encryption for the database
ALTER DATABASE [myDatabase] SET ENCRYPTION ON
GO
```
The time that it takes to encrypt a SQL Server database using TDE depends on several factors. These include the size of the DB instance, whether the instance uses Provisioned IOPS storage, the amount of data, and other factors.

**Back up and restoring TDE certificates on RDS for SQL Server**

RDS for SQL Server provides stored procedures for backing up, restoring, and dropping TDE certificates. RDS for SQL Server also provides a function for viewing restored user TDE certificates.

User TDE certificates are used to restore databases to RDS for SQL Server that are on-premises and have TDE turned on. These certificates have the prefix `UserTDECertificate_`. After restoring databases, and before making them available to use, RDS modifies the databases that have TDE turned on to use RDS-generated TDE certificates. These certificates have the prefix `RDSTDECertificate`.

User TDE certificates remain on the RDS for SQL Server DB instance, unless you drop them using the `rds_drop_tde_certificate` stored procedure. For more information, see [Dropping restored TDE certificates](p. 1263).

You can use a user TDE certificate to restore other databases from the source DB instance. The databases to restore must use the same TDE certificate and have TDE turned on. You don't have to import (restore) the same certificate again.

**Topics**

- Prerequisites (p. 1260)
- Limitations (p. 1261)
- Backing up a TDE certificate (p. 1261)
- Restoring a TDE certificate (p. 1262)
- Viewing restored TDE certificates (p. 1262)
- Dropping restored TDE certificates (p. 1263)

**Prerequisites**

Before you can back up or restore TDE certificates on RDS for SQL Server, make sure to perform the following tasks. The first three are described in [Setting up for native backup and restore](p. 1142).

1. Create Amazon S3 buckets for storing files to back up and restore.

   We recommend that you use separate buckets for database backups and for TDE certificate backups.

2. Create an IAM role for backing up and restoring files.

   The IAM role must be both a user and an administrator for the AWS KMS key.

   In addition to the permissions required for SQL Server native backup and restore, the IAM role also requires the following permissions:
   - `s3:GetBucketACL`, `s3:GetBucketLocation`, and `s3:ListBucket` on the S3 bucket resource
   - `s3:ListAllMyBuckets` on the `*` resource

3. Add the `SQLSERVER_BACKUP_RESTORE` option to an option group on your DB instance.
This is in addition to the TRANSPARENT_DATA_ENCRYPTION (TDE) option.

4. Make sure that you have a symmetric encryption KMS key. You have the following options:
   - If you have an existing KMS key in your account, you can use it. No further action is necessary.
   - If you don't have an existing symmetric encryption KMS key in your account, create a KMS key by following the instructions in Creating keys in the AWS Key Management Service Developer Guide.

Limitations

Using stored procedures to back up and restore TDE certificates has the following limitations:

- Both the SQLSERVER_BACKUP_RESTORE and TRANSPARENT_DATA_ENCRYPTION (TDE) options must be added to the option group that you associated with your DB instance.
- TDE certificate backup and restore aren't supported on Multi-AZ DB instances.
- Canceling TDE certificate backup and restore tasks isn't supported.
- You can't use a user TDE certificate for TDE encryption of any other database on your RDS for SQL Server DB instance. You can use it to restore only other databases from the source DB instance that have TDE turned on and that use the same TDE certificate.
- You can drop only user TDE certificates.
- The maximum number of user TDE certificates supported on RDS is 10. If the number exceeds 10, drop unused TDE certificates and try again.
- The certificate name can't be empty or null.
- When restoring a certificate, the certificate name can't include the keyword RDSTDECERTIFICATE, and must start with the UserTDECertificate_ prefix.
- The @certificate_name parameter can include only the following characters: a-z, 0-9, @, $, #, and underscore (_).
- The file extension for @certificate_file_s3_arn must be .cer (case-insensitive).
- The file extension for @private_key_file_s3_arn must be .pvk (case-insensitive).
- The S3 metadata for the private key file must include the x-amz-meta-rds-tde-pwd tag. For more information, see Backing up and restoring TDE certificates for on-premises databases (p. 1263).

Backing up a TDE certificate

To back up TDE certificates, use the rds_backup_tde_certificate stored procedure. It has the following syntax.

```sql
EXECUTE msdb.dbo.rds_backup_tde_certificate
   @certificate_name='UserTDECertificate_certificate_name | RDSTDECertificatetimestamp',
   @certificate_file_s3_arn='arn:aws:s3:::bucket_name/certificate_file_name.cer',
   @private_key_file_s3_arn='arn:aws:s3:::bucket_name/key_file_name.pvk',
   @kms_password_key_arn='arn:aws:kms:region:account-id:key/key-id',
   [@overwrite_s3_files=0|1];
```

The following parameters are required:

- @certificate_name – The name of the TDE certificate to back up.
- @certificate_file_s3_arn – The destination Amazon Resource Name (ARN) for the certificate backup file in Amazon S3.
- @private_key_file_s3_arn – The destination S3 ARN of the private key file that secures the TDE certificate.
- @kms_password_key_arn – The ARN of the symmetric KMS key used to encrypt the private key password.
The following parameter is optional:

- @overwrite_s3_files – Indicates whether to overwrite the existing certificate and private key files in S3:
  - 0 – Doesn't overwrite the existing files. This value is the default.
  - 1 – Overwrites an existing file that has the specified name, even if it isn't a backup file.

Setting @overwrite_s3_files to 0 returns an error if a file already exists.

Example of backing up a TDE certificate

```sql
EXECUTE msdb.dbo.rds_backup_tde_certificate
@certificate_name='RDSTDECertificate20211115T185333',
@certificate_file_s3_arn='arn:aws:s3:::TDE_certs/mycertfile.cer',
@private_key_file_s3_arn='arn:aws:s3:::TDE_certs/mykeyfile.pvk',
@kms_password_key_arn='arn:aws:kms:us-west-2:123456789012:key/AKIAIOSFODNN7EXAMPLE',
@overwrite_s3_files=1;
```

Restoring a TDE certificate

You use the `rds_restore_tde_certificate` stored procedure to restore (import) user TDE certificates. It has the following syntax.

```sql
EXECUTE msdb.dbo.rds_restore_tde_certificate
@certificate_name='UserTDECertificate_certificate_name',
@certificate_file_s3_arn='arn:aws:s3:::bucket_name/certificate_file_name.cer',
@private_key_file_s3_arn='arn:aws:s3:::bucket_name/key_file_name.pvk',
@kms_password_key_arn='arn:aws:kms:region:account-id:key/key-id';
```

The following parameters are required:

- @certificate_name – The name of the TDE certificate to restore. The name must start with the UserTDECertificate_ prefix.
- @certificate_file_s3_arn – The S3 ARN of the backup file used to restore the TDE certificate.
- @private_key_file_s3_arn – The S3 ARN of the private key backup file of the TDE certificate to be restored.
- @kms_password_key_arn – The ARN of the symmetric KMS key used to encrypt the private key password.

Example of restoring a TDE certificate

```sql
EXECUTE msdb.dbo.rds_restore_tde_certificate
@certificate_name='UserTDECertificate_myTDEcertificate',
@certificate_file_s3_arn='arn:aws:s3:::TDE_certs/mycertfile.cer',
@private_key_file_s3_arn='arn:aws:s3:::TDE_certs/mykeyfile.pvk',
@kms_password_key_arn='arn:aws:kms:us-west-2:123456789012:key/AKIAIOSFODNN7EXAMPLE';
```

Viewing restored TDE certificates

You use the `rds_fn_list_user_tde_certificates` function to view restored (imported) user TDE certificates. It has the following syntax.

```sql
SELECT * FROM msdb.dbo.rds_fn_list_user_tde_certificates();
```
The output resembles the following. Not all columns are shown here.

<table>
<thead>
<tr>
<th>name</th>
<th>certificate_id</th>
<th>principal_id</th>
<th>pvt_key_encryption_type_desc</th>
<th>issuer_name</th>
<th>cert_serial_number</th>
<th>thumbprint</th>
<th>subject</th>
<th>start_date</th>
<th>expiry_date</th>
<th>pvt_key_last_backup_date</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserTDECertificate_tde_certificate</td>
<td>343</td>
<td>1</td>
<td>ENCRYPTED_BY_MASTER_KEY</td>
<td>AnyCompany</td>
<td>Shipping</td>
<td>79 3e 69 fd 1d 9e 47 2c 32 67 1d 9c ca af</td>
<td>0x6BB218B34110388680B FE1BA2D865E505809589</td>
<td>2022-04-05 19:49:45.0000000</td>
<td>2023-04-05 19:49:45.0000000</td>
<td>NULL</td>
</tr>
</tbody>
</table>

### Dropping restored TDE certificates

To drop restored (imported) user TDE certificates that you aren't using, use the `rds_drop_tde_certificate` stored procedure. It has the following syntax.

```sql
EXECUTE msdb.dbo.rds_drop_tde_certificate
@certificate_name='UserTDECertificate_certificate_name';
```

The following parameter is required:

- `@certificate_name` – The name of the TDE certificate to drop.

You can drop only restored (imported) TDE certificates. You can't drop RDS-created certificates.

**Example of dropping a TDE certificate**

```sql
EXECUTE msdb.dbo.rds_drop_tde_certificate
@certificate_name='UserTDECertificate_myTDEcertificate';
```

### Backing up and restoring TDE certificates for on-premises databases

You can back up TDE certificates for on-premises databases, then later restore them to RDS for SQL Server. You can also restore an RDS for SQL Server TDE certificate to an on-premises DB instance.

The following procedure backs up a TDE certificate and private key. The private key is encrypted using a data key generated from your symmetric encryption KMS key.

**To back up an on-premises TDE certificate**

1. Generate the data key using the AWS CLI `generate-data-key` command.

```bash
aws kms generate-data-key
   --key-id my_KMS_key_ID
   --key-spec AES_256
```

The output resembles the following.

```
{
```
You use the plain text output in the next step as the private key password.

2. Back up your TDE certificate as shown in the following example.

```
BACKUP CERTIFICATE myOnPremTDEcertificate TO FILE = 'D:\tde-cert-backup.cer'
WITH PRIVATE KEY (FILE = 'C:\Program Files\Microsoft SQL Server\MSSQL14.MSSQLSERVER\MSSQL\DATA\cert-backup-key.pvk', ENCRYPTION BY PASSWORD = 'U/fpGtmzGCYBi8A2+0/9qcRQRK2zmG/a0n939ZnKi/0=');
```

3. Save the certificate backup file to your Amazon S3 certificate bucket.

4. Save the private key backup file to your S3 certificate bucket, with the following tag in the file's metadata:

   - Key – x-amz-meta-rds-tde-pwd
   - Value – The CiphertextBlob value from generating the data key, as in the following example.

```
AQIDAHimL2NEoAlOY6Bn7LJfXniO/0Ze9kTQo/QXQXDuugL1mervGIL7guyEav9GFzLxYTDATAAAAfjbB8gqkGk1G9w0B
Bwagb2HaAeGmggQSgsS1bSDQEHATABAeBq1ghkbgBZQMEASwEQQMyCxLM17GRZkG6SgEQQDjvZLJo2cQ31Vetngzm2ybHdO
2RezQy3sASG62HzCjfhn0c65BFdhsXjSMwuiY7AKw==
```

The following procedure restores an RDS for SQL Server TDE certificate to an on-premises DB instance. You copy and restore the TDE certificate on your destination DB instance using the certificate backup, corresponding private key file, and data key. The restored certificate is encrypted by the database master key of the new server.

**To restore a TDE certificate**

1. Copy the TDE certificate backup file and private key file from Amazon S3 to the destination instance.
2. Use your KMS key to decrypt the output cipher text to retrieve the plain text of the data key. The cipher text is located in the S3 metadata of the private key backup file.

```
aws kms decrypt
--key-id my_KMS_key_ID
--ciphertext-blob fileb://exampleCiphertextFile | base64 -d
--output text
--query Plaintext
```

You use the plain text output in the next step as the private key password.

3. Use the following SQL command to restore your TDE certificate.

```
CREATE CERTIFICATE myOnPremTDEcertificate FROM FILE='D:\tde-cert-backup.cer'
WITH PRIVATE KEY (FILE = N'D:\tde-cert-key.pvk', DECRYPTION BY PASSWORD = 'plain_text_output');
```

For more information on KMS decryption, see decrypt in the KMS section of the AWS CLI Command Reference.
After the TDE certificate is restored on the destination DB instance, you can restore encrypted databases with that certificate.

**Note**
You can use the same TDE certificate to encrypt multiple SQL Server databases on the source DB instance. To migrate multiple databases to a destination instance, copy the TDE certificate associated with them to the destination instance only once.

**Turning off TDE for RDS for SQL Server**

To turn off TDE for an RDS for SQL Server DB instance, first make sure that there are no encrypted objects left on the DB instance. To do so, either decrypt the objects or drop them. If any encrypted objects exist on the DB instance, you can't turn off TDE for the DB instance. When you use the console to remove the TDE option from an option group, the console indicates that it's processing. In addition, an error event is created if the option group is associated with an encrypted DB instance or DB snapshot.

The following example removes the TDE encryption from a database called `customerDatabase`.

```
------------- Removing TDE ----------------
USE [customerDatabase]
GO
-- Turn off encryption of the database
ALTER DATABASE [customerDatabase]
SET ENCRYPTION OFF
GO

-- Wait until the encryption state of the database becomes 1. The state is 5 (Decryption in progress) for a while
SELECT db_name(database_id) as DatabaseName, * FROM sys.dm_database_encryption_keys
GO

-- Drop the DEK used for encryption
DROP DATABASE ENCRYPTION KEY
GO

-- Alter to SIMPLE Recovery mode so that your encrypted log gets truncated
USE [master]
GO
ALTER DATABASE [customerDatabase] SET RECOVERY SIMPLE
GO
```

When all objects are decrypted, you have two options:

1. You can modify the DB instance to be associated with an option group without the TDE option.
2. You can remove the TDE option from the option group.
SQL Server Audit

In Amazon RDS, you can audit Microsoft SQL Server databases by using the built-in SQL Server auditing mechanism. You can create audits and audit specifications in the same way that you create them for on-premises database servers.

RDS uploads the completed audit logs to your S3 bucket, using the IAM role that you provide. If you enable retention, RDS keeps your audit logs on your DB instance for the configured period of time.

For more information, see SQL Server Audit (database engine) in the Microsoft SQL Server documentation.

Topics

- Support for SQL Server Audit (p. 1266)
- Adding SQL Server Audit to the DB instance options (p. 1267)
- Using SQL Server Audit (p. 1268)
- Viewing audit logs (p. 1268)
- Using SQL Server Audit with Multi-AZ instances (p. 1269)
- Configuring an S3 bucket (p. 1269)
- Manually creating an IAM role for SQL Server Audit (p. 1270)

Support for SQL Server Audit

In Amazon RDS, starting with SQL Server 2014, all editions of SQL Server support server-level audits, and the Enterprise edition also supports database-level audits. Starting with SQL Server 2016 (13.x) SP1, all editions support both server-level and database-level audits. For more information, see SQL Server Audit (database engine) in the SQL Server documentation.

RDS supports configuring the following option settings for SQL Server Audit.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IAM_ROLE_ARN</td>
<td>A valid Amazon Resource Name (ARN) in the format arn:aws:iam::account-id:role(role-name).</td>
<td>The ARN of the IAM role that grants access to the S3 bucket where you want to store your audit logs. For more information, see Amazon Resource Names (ARNs) in the AWS General Reference.</td>
</tr>
<tr>
<td>S3_BUCKET_ARN</td>
<td>A valid ARN in the format arn:aws:s3:::bucket-name or arn:aws:s3:::bucket-name/key-prefix</td>
<td>The ARN for the S3 bucket where you want to store your audit logs.</td>
</tr>
<tr>
<td>ENABLE_COMPRESSION</td>
<td>true or false</td>
<td>Controls audit log compression. By default, compression is enabled (set to true).</td>
</tr>
<tr>
<td>RETENTION_TIME</td>
<td>0 to 840</td>
<td>The retention time (in hours) that SQL Server audit records are kept on your RDS instance. By default, retention is disabled.</td>
</tr>
</tbody>
</table>
RDS supports SQL Server Audit in all AWS Regions except Middle East (Bahrain).

**Adding SQL Server Audit to the DB instance options**

Enabling SQL Server Audit requires two steps: enabling the option on the DB instance, and enabling the feature inside SQL Server. The process for adding the SQL Server Audit option to a DB instance is as follows:

1. Create a new option group, or copy or modify an existing option group.
2. Add and configure all required options.
3. Associate the option group with the DB instance.

After you add the SQL Server Audit option, you don't need to restart your DB instance. As soon as the option group is active, you can create audits and store audit logs in your S3 bucket.

**To add and configure SQL Server Audit on a DB instance's option group**

1. Choose one of the following:
   - Use an existing option group.
   - Create a custom DB option group and use that option group. For more information, see [Creating an option group](p. 280).
2. Add the `SQLSERVER_AUDIT` option to the option group, and configure the option settings. For more information about adding options, see [Adding an option to an option group](p. 283).
   - For **IAM role**, if you already have an IAM role with the required policies, you can choose that role. To create a new IAM role, choose **Create a New Role**. For information about the required policies, see [Manually creating an IAM role for SQL Server Audit](p. 1270).
   - For **Select S3 destination**, if you already have an S3 bucket that you want to use, choose it. To create an S3 bucket, choose **Create a New S3 Bucket**.
   - For **Enable Compression**, leave this option chosen to compress audit files. Compression is enabled by default. To disable compression, clear **Enable Compression**.
   - For **Audit log retention**, to keep audit records on the DB instance, choose this option. Specify a retention time in hours. The maximum retention time is 35 days.
3. Apply the option group to a new or existing DB instance. Choose one of the following:
   - If you are creating a new DB instance, apply the option group when you launch the instance.
   - On an existing DB instance, apply the option group by modifying the instance and then attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](p. 333).

**Modifying the SQL Server Audit option**

After you enable the SQL Server Audit option, you can modify the settings. For information about how to modify option settings, see [Modifying an option setting](p. 288).

**Removing SQL Server Audit from the DB instance options**

You can turn off the SQL Server Audit feature by disabling audits and then deleting the option.

**To remove auditing**

1. Disable all of the audit settings inside SQL Server. To learn where audits are running, query the SQL Server security catalog views. For more information, see Security catalog views in the Microsoft SQL Server documentation.
2. Delete the SQL Server Audit option from the DB instance. Choose one of the following:
   - Delete the SQL Server Audit option from the option group that the DB instance uses. This change affects all DB instances that use the same option group. For more information, see Removing an option from an option group (p. 291).
   - Modify the DB instance, and then choose an option group without the SQL Server Audit option. This change affects only the DB instance that you modify. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).

3. After you delete the SQL Server Audit option from the DB instance, you don't need to restart the instance. Remove unneeded audit files from your S3 bucket.

### Using SQL Server Audit

You can control server audits, server audit specifications, and database audit specifications the same way that you control them for on-premises database servers.

#### Creating audits

You create server audits in the same way that you create them for on-premises database servers. For information about how to create server audits, see CREATE SERVER AUDIT in the Microsoft SQL Server documentation.

To avoid errors, adhere to the following limitations:

- Don't exceed the maximum number of supported server audits per instance of 50.
- Instruct SQL Server to write data to a binary file.
- Don't use RDS_ as a prefix in the server audit name.
- For FILEPATH, specify D:\rdmdbdata\SQLAudit.
- For MAXSIZE, specify a size between 2 MB and 50 MB.
- Don't configure MAX_ROLLOVER_FILES or MAX_FILES.
- Don't configure SQL Server to shut down the DB instance if it fails to write the audit record.

#### Creating audit specifications

You create server audit specifications and database audit specifications the same way that you create them for on-premises database servers. For information about creating audit specifications, see CREATE SERVER AUDIT SPECIFICATION and CREATE DATABASE AUDIT SPECIFICATION in the Microsoft SQL Server documentation.

To avoid errors, don't use RDS_ as a prefix in the name of the database audit specification or server audit specification.

#### Viewing audit logs

Your audit logs are stored in D:\rdmdbdata\SQLAudit.

After SQL Server finishes writing to an audit log file—when the file reaches its size limit—Amazon RDS uploads the file to your S3 bucket. If retention is enabled, Amazon RDS moves the file into the retention folder: D:\rdmdbdata\SQLAudit\transmitted.

For information about configuring retention, see Adding SQL Server Audit to the DB instance options (p. 1267).
Audit records are kept on the DB instance until the audit log file is uploaded. You can view the audit records by running the following command.

```
SELECT   * 
FROM     msdb.dbo.rds_fn_get_audit_file
         ('D:\rdsdbdata\SQLAudit\*.sqlaudit'
          , default 
          , default )
```

You can use the same command to view audit records in your retention folder by changing the filter to
D:\rdsdbdata\SQLAudit\transmitted\*.sqlaudit.

```
SELECT   * 
FROM     msdb.dbo.rds_fn_get_audit_file
         ('D:\rdsdbdata\SQLAudit\transmitted\*.sqlaudit'
          , default 
          , default )
```

### Using SQL Server Audit with Multi-AZ instances

For Multi-AZ instances, the process for sending audit log files to Amazon S3 is similar to the process for Single-AZ instances. However, there are some important differences:

- Database audit specification objects are replicated to all nodes.
- Server audits and server audit specifications aren't replicated to secondary nodes. Instead, you have to create or modify them manually.

To capture server audits or a server audit specification from both nodes:

1. Create a server audit or a server audit specification on the primary node.
2. Fail over to the secondary node and create a server audit or a server audit specification with the same name and GUID on the secondary node. Use the `AUDIT_GUID` parameter to specify the GUID.

### Configuring an S3 bucket

The audit log files are automatically uploaded from the DB instance to your S3 bucket. The following restrictions apply to the S3 bucket that you use as a target for audit files:

- It must be in the same AWS Region as the DB instance.
- It must not be open to the public.
- It can't use `S3 Object Lock`.
- The bucket owner must also be the IAM role owner.

The target key that is used to store the data follows this naming schema: `bucket-name/key-prefix/instance-name/audit-name/node_file-name.ext`

**Note**

You set both the bucket name and the key prefix values with the `(S3_BUCKET_ARN)` option setting.

The schema is composed of the following elements:

- `bucket-name` – The name of your S3 bucket.
- `key-prefix` – The custom key prefix you want to use for audit logs.
• **instance-name** – The name of your Amazon RDS instance.
• **audit-name** – The name of the audit.
• **node** – The identifier of the node that is the source of the audit logs (node1 or node2). There is one node for a Single-AZ instance and two replication nodes for a Multi-AZ instance. These are not primary and secondary nodes, because the roles of primary and secondary change over time. Instead, the node identifier is a simple label.
  • **node1** – The first replication node (Single-AZ has one node only).
  • **node2** – The second replication node (Multi-AZ has two nodes).
• **file-name** – The target file name. The file name is taken as-is from SQL Server.
• **ext** – The extension of the file (zip or sqlaudit):
  • **zip** – If compression is enabled (default).
  • **sqlaudit** – If compression is disabled.

**Manually creating an IAM role for SQL Server Audit**

Typically, when you create a new option, the AWS Management Console creates the IAM role and the IAM trust policy for you. However, you can manually create a new IAM role to use with SQL Server Audits, so that you can customize it with any additional requirements you might have. To do this, you create an IAM role and delegate permissions so that the Amazon RDS service can use your Amazon S3 bucket. When you create this IAM role, you attach trust and permissions policies. The trust policy allows Amazon RDS to assume this role. The permission policy defines the actions that this role can do. For more information, see [Creating a role to delegate permissions to an AWS service](https://docs.aws.amazon.com/IAM/latest/UserGuide/idBilling-Restrictions.html) in the *AWS Identity and Access Management User Guide*.

You can use the examples in this section to create the trust relationships and permissions policies you need.

The following example shows a trust relationship for SQL Server Audit. It uses the *service principal* rds.amazonaws.com to allow RDS to write to the S3 bucket. A *service principal* is an identifier that is used to grant permissions to a service. Anytime you allow access to rds.amazonaws.com in this way, you are allowing RDS to perform an action on your behalf. For more information about service principals, see [AWS JSON policy elements: Principal](https://docs.aws.amazon.com/IAM/latest/UserGuide/idPermissions Policylevel-Principal.html).

**Example trust relationship for SQL Server Audit**

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
      }
   ]
}
```

We recommend using the **aws:SourceArn** and **aws:SourceAccount** global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the [confused deputy problem](https://docs.aws.amazon.com/IAM/latest/UserGuide/idBilling-Restrictions.html).

You might use both global condition context keys and have the **aws:SourceArn** value contain the account ID. In this case, the **aws:SourceAccount** value and the account in the **aws:SourceArn** value must use the same account ID when used in the same statement.
• Use `aws:SourceArn` if you want cross-service access for a single resource.
• Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For SQL Server Audit, make sure to include both the DB option group and the DB instances, as shown in the following example.

**Example trust relationship with global condition context key for SQL Server Audit**

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceArn": [
            "arn:aws:rds:Region:my_account_ID:og:option_group_name"
          ]
        }
      }
    }
  ]
}
```

In the following example of a permissions policy for SQL Server Audit, we specify an ARN for the Amazon S3 bucket. You can use ARNs to identify a specific account, user, or role that you want grant access to. For more information about using ARNs, see [Amazon resource names (ARNs)](https://docs.aws.amazon.com/IAM/latest/UserGuide/index.html#arns).

**Example permissions policy for SQL Server Audit**

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket",
        "s3:GetBucketACL",
        "s3:GetBucketLocation"
      ],
      "Resource": "arn:aws:s3:::bucket_name"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:ListMultipartUploadParts",
        "s3:AbortMultipartUpload"
      ],
      "Resource": "arn:aws:s3:::bucket_name"
    }
  ]
}
```
"Resource": "arn:aws:s3:::bucket_name/key_prefix/"
}
]}
}

**Note**
The `s3:ListAllMyBuckets` action is required for verifying that the same AWS account owns both the S3 bucket and the SQL Server DB instance. The action lists the names of the buckets in the account.

S3 bucket namespaces are global. If you accidentally delete your bucket, another user can create a bucket with the same name in a different account. Then the SQL Server Audit data is written to the new bucket.
Support for SQL Server Analysis Services in Amazon RDS for SQL Server

Microsoft SQL Server Analysis Services (SSAS) is part of the Microsoft Business Intelligence (MSBI) suite. SSAS is an online analytical processing (OLAP) and data mining tool that is installed within SQL Server. You use SSAS to analyze data to help make business decisions. SSAS differs from the SQL Server relational database because SSAS is optimized for queries and calculations common in a business intelligence environment.

You can turn on SSAS for existing or new DB instances. It's installed on the same DB instance as your database engine. For more information on SSAS, see the Microsoft Analysis services documentation.

Amazon RDS supports SSAS for SQL Server Standard and Enterprise Editions on the following versions:

- Tabular mode:
  - SQL Server 2019, version 15.00.4043.16.v1 and higher
  - SQL Server 2017, version 14.00.3223.3.v1 and higher
  - SQL Server 2016, version 13.00.5426.0.v1 and higher

- Multidimensional mode:
  - SQL Server 2017, version 14.00.3381.3.v1 and higher
  - SQL Server 2016, version 13.00.5882.1.v1 and higher

Limitations

The following limitations apply to using SSAS on RDS for SQL Server:
RDS for SQL Server supports running SSAS in Tabular or Multidimensional mode. For more information, see Comparing tabular and multidimensional solutions in the Microsoft documentation.

You can only use one SSAS mode at a time. Before changing modes, make sure to delete all of the SSAS databases.

For more information, see Changing the SSAS mode (p. 1287).

Multidimensional mode isn’t supported on SQL Server 2019.

Multi-AZ instances aren’t supported.

Instances must use AWS Directory Service for Microsoft Active Directory for SSAS authentication.

Users aren’t given SSAS server administrator access, but they can be granted database-level administrator access.

The only supported port for accessing SSAS is 2383.

You can’t deploy projects directly. We provide an RDS stored procedure to do this. For more information, see Deploying SSAS projects on Amazon RDS (p. 1278).

Processing during deployment isn’t supported.

Using .xmla files for deployment isn’t supported.

SSAS project input files and database backup output files can only be in the D:\S3 folder on the DB instance.

Turning on SSAS

Use the following process to turn on SSAS for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the SSAS option to the option group.
3. Associate the option group with the DB instance.
4. Allow inbound access to the virtual private cloud (VPC) security group for the SSAS listener port.
5. Turn on Amazon S3 integration.

Creating an option group for SSAS

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of the DB instance that you plan to use.

Note
You can also use an existing option group if it’s for the correct SQL Server engine and version.

Console

The following console procedure creates an option group for SQL Server Standard Edition 2017.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose Create group.
4. In the Create option group pane, do the following:

   a. For Name, enter a name for the option group that is unique within your AWS account, such as ssas-se-2017. The name can contain only letters, digits, and hyphens.
   b. For Description, enter a brief description of the option group, such as SSAS option group for SQL Server SE 2017. The description is used for display purposes.
c. For **Engine**, choose `sqlserver-se`.
d. For **Major engine version**, choose `14.00`.

5. Choose **Create**.

**CLI**

The following CLI example creates an option group for SQL Server Standard Edition 2017.

**To create the option group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-option-group
  --option-group-name ssas-se-2017
  --engine-name sqlserver-se
  --major-engine-version 14.00
  --option-group-description "SSAS option group for SQL Server SE 2017"
```

For Windows:

```
aws rds create-option-group ^
  --option-group-name ssas-se-2017 ^
  --engine-name sqlserver-se ^
  --major-engine-version 14.00 ^
  --option-group-description "SSAS option group for SQL Server SE 2017"
```

**Adding the SSAS option to the option group**

Next, use the AWS Management Console or the AWS CLI to add the SSAS option to the option group.

**Console**

**To add the SSAS option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose SSAS for **Option name**.
6. Under **Option settings**, do the following:
   a. For **Max memory**, enter a value in the range 10–80.
      
      **Max memory** specifies the upper threshold above which SSAS begins releasing memory more aggressively to make room for requests that are running, and also new high-priority requests. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80, and the default is 45.
   b. For **Mode**, choose the SSAS server mode, **Tabular** or **Multidimensional**.
If you don't see the **Mode** option setting, it means that Multidimensional mode isn't supported in your AWS Region. For more information, see Limitations (p. 1273).

**Tabular** is the default.

c. For **Security groups**, choose the VPC security group to associate with the option.

**Note**
The port for accessing SSAS, 2383, is prepopulated.

7. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.

8. Choose **Add option**.

**CLI**

**To add the SSAS option**

1. Create a JSON file, for example `ssas-option.json`, with the following parameters:

   • **OptionGroupName** – The name of option group that you created or chose previously (`ssas-se-2017` in the following example).
   • **Port** – The port that you use to access SSAS. The only supported port is 2383.
   • **VpcSecurityGroupMemberships** – Memberships for VPC security groups for your RDS DB instance.
   • **MAX_MEMORY** – The upper threshold above which SSAS should begin releasing memory more aggressively to make room for requests that are running, and also new high-priority requests. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80, and the default is 45.
   • **MODE** – The SSAS server mode, either **Tabular** or **Multidimensional**. **Tabular** is the default.

   If you receive an error that the **MODE** option setting isn't valid, it means that Multidimensional mode isn't supported in your AWS Region. For more information, see Limitations (p. 1273).

   The following is an example of a JSON file with SSAS option settings.

   ```json
   {
   "OptionGroupName": "ssas-se-2017",
   "OptionsToInclude": [
   {
   "OptionName": "SSAS",
   "Port": 2383,
   "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
   "OptionSettings": [
   {"Name": "MAX_MEMORY", "Value": "60"},
   {"Name": "MODE", "Value": "Multidimensional"}
   ]
   },
   "ApplyImmediately": true
   }
   ```

2. Add the SSAS option to the option group.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group
```
Associating the option group with your DB instance

You can use the console or the CLI to associate the option group with your DB instance.

Console

Associate your option group with a new or existing DB instance:

- For a new DB instance, associate the option group with the DB instance when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
- For an existing DB instance, modify the instance and associate the new option group with it. For more information, see Modifying an Amazon RDS DB instance (p. 333).

  **Note**
  If you use an existing instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1184).

CLI

You can associate your option group with a new or existing DB instance.

  **Note**
  If you use an existing instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1184).

To create a DB instance that uses the option group

- Specify the same DB engine type and major version that you used when creating the option group.

  **Example**

  For Linux, macOS, or Unix:

  ```bash
  aws rds create-db-instance
  --db-instance-identifier myssasinstance
  --db-instance-class db.m5.2xlarge
  --engine sqlserver-se
  --engine-version 14.00.3223.3.v1
  --allocated-storage 100
  --master-user-password secret123
  --master-username admin
  --storage-type gp2
  --license-model li
  --domain-iam-role-name my-directory-iam-role
  --domain my-domain-id
  ```
For Windows:

```bash
aws rds create-db-instance 
  --db-instance-identifier myssasinstance 
  --db-instance-class db.m5.2xlarge 
  --engine sqlserver-se 
  --engine-version 14.00.3223.3.v1 
  --allocated-storage 100 
  --master-user-password secret123 
  --master-username admin 
  --storage-type gp2 
  --license-model li 
  --domain-iam-role-name my-directory-iam-role 
  --domain my-domain-id 
  --option-group-name ssas-se-2017
```

To modify a DB instance to associate the option group

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance 
  --db-instance-identifier myssasinstance 
  --option-group-name ssas-se-2017 
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance 
  --db-instance-identifier myssasinstance 
  --option-group-name ssas-se-2017 
  --apply-immediately
```

Allowing inbound access to your VPC security group

Create an inbound rule for the specified SSAS listener port in the VPC security group associated with your DB instance. For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group (p. 156).

Enabling Amazon S3 integration

To download model configuration files to your host for deployment, use Amazon S3 integration. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 (p. 1194).

Deploying SSAS projects on Amazon RDS

On RDS, you can't deploy SSAS projects directly by using SQL Server Management Studio (SSMS). To deploy projects, use an RDS stored procedure.

**Note**

Using .xmla files for deployment isn't supported.
Before you deploy projects, make sure of the following:

- Amazon S3 integration is turned on. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 (p. 1194).
- The Processing Option configuration setting is set to Do Not Process. This setting means that no processing happens after deployment.
- You have both the `myssasproject.asdatabase` and `myssasproject.deploymentoptions` files. They're automatically generated when you build the SSAS project.

To deploy an SSAS project on RDS

1. Download the .asdatabase (SSAS model) file from your S3 bucket to your DB instance, as shown in the following example. For more information on the download parameters, see Downloading files from an Amazon S3 bucket to a SQL Server DB instance (p. 1201).

   ```sql
   exec msdb.dbo.rds_download_from_s3
   @s3_arn_of_file='arn:aws:s3:::bucket_name/myssasproject.asdatabase',
   [@rds_file_path='D:\S3\myssasproject.asdatabase'],
   [@overwrite_file=1];
   ```

2. Download the .deploymentoptions file from your S3 bucket to your DB instance.

   ```sql
   exec msdb.dbo.rds_download_from_s3
   @s3_arn_of_file='arn:aws:s3:::bucket_name/myssasproject.deploymentoptions',
   [@rds_file_path='D:\S3\myssasproject.deploymentoptions'],
   [@overwrite_file=1];
   ```

3. Deploy the project.

   ```sql
   exec msdb.dbo.rds_msbi_task
   @task_type='SSAS_DEPLOY_PROJECT',
   @file_path='D:\S3\myssasproject.asdatabase';
   ```

Monitoring the status of a deployment task

To track the status of your deployment (or download) task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to SSAS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 42);
```

The `rds_fn_task_status` function returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>Output parameter</td>
<td>Description</td>
</tr>
<tr>

## Using SSAS on Amazon RDS

After deploying the SSAS project, you can directly process the OLAP database on SSMS.

### To use SSAS on RDS

1. In SSMS, connect to SSAS using the user name and password for the Active Directory domain.
2. Expand **Databases**. The newly deployed SSAS database appears.
3. Locate the connection string, and update the user name and password to give access to the source SQL database. Doing this is required for processing SSAS objects.
   a. For Tabular mode, do the following:
      1. Expand the **Connections** tab.
      2. Open the context (right-click) menu for the connection object, and then choose **Properties**.
      3. Update the user name and password in the connection string.
   b. For Multidimensional mode, do the following:
      1. Expand the **Data Sources** tab.
      2. Open the context (right-click) menu for the data source object, and then choose **Properties**.
      3. Update the user name and password in the connection string.
4. Open the context (right-click) menu for the SSAS database that you created and choose **Process Database**.

Depending on the size of the input data, the processing operation might take several minutes to complete.

### Topics

- Setting up a Windows-authenticated user for SSAS (p. 1281)
- Adding a domain user as a database administrator (p. 1282)
- Creating an SSAS proxy (p. 1283)
- Scheduling SSAS database processing using SQL Server Agent (p. 1284)
- Revoking SSAS access from the proxy (p. 1285)

### Setting up a Windows-authenticated user for SSAS

The main administrator user (sometimes called the master user) can use the following code example to set up a Windows-authenticated login and grant the required procedure permissions. Doing this grants permissions to the domain user to run SSAS customer tasks, use S3 file transfer procedures, create credentials, and work with the SQL Server Agent proxy. For more information, see [Credentials (database engine)](https://docs.microsoft.com/en-us/sql/relational-databases/credentials) and [Create a SQL Server Agent proxy](https://docs.microsoft.com/en-us/sql/relational-databases/agents/create-sql-server-agent-proxy) in the Microsoft documentation.

You can grant some or all of the following permissions as needed to Windows-authenticated users.

### Example

```
-- Create a server-level domain user login, if it doesn't already exist
```
USE [master]
GO
CREATE LOGIN [mydomain\user_name] FROM WINDOWS
GO
-- Create domain user, if it doesn't already exist
USE [msdb]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]
GO
-- Grant necessary privileges to the domain user
USE [master]
GO
GRANT ALTER ANY CREDENTIAL TO [mydomain\user_name]
GO
USE [msdb]
GO
GRANT EXEC ON msdb.dbo.rds_msbi_task TO [mydomain\user_name] with grant option
GRANT SELECT ON msdb.dbo.rds_fn_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_cancel_task TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_download_from_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_upload_to_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_delete_from_filesystem TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_gather_file_details TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_add_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_update_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_grant_login_to_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_revoke_login_from_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_delete_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_login_for_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_proxy_for_subsystem TO [mydomain\user_name] with grant option
ALTER ROLE [SQLAgentUserRole] ADD MEMBER [mydomain\user_name]
GO

Adding a domain user as a database administrator

You can add a domain user as an SSAS database administrator in the following ways:

- A database administrator can use SSMS to create a role with admin privileges, then add users to that role.
- You can use the following stored procedure.

```powershell
exec msdb.dbo.rds_msbi_task
    @task_type='SSAS_ADD_DB_ADMIN_MEMBER',
    @database_name='mysasmdb',
    @ssas_role_name='exampleRole',
    @ssas_role_member='domain_name\domain_user_name';
```

The following parameters are required:

- `@task_type` – The type of the MSBI task, in this case SSAS_ADD_DB_ADMIN_MEMBER.
- `@database_name` – The name of the SSAS database to which you're granting administrator privileges.
- `@ssas_role_name` – The SSAS database administrator role name. If the role doesn't already exist, it's created.
- `@ssas_role_member` – The SSAS database user that you're adding to the administrator role.
Creating an SSAS proxy

To be able to schedule SSAS database processing using SQL Server Agent, create an SSAS credential and an SSAS proxy. Run these procedures as a Windows-authenticated user.

To create the SSAS credential

- Create the credential for the proxy. To do this, you can use SSMS or the following SQL statement.

```sql
USE [master]
GO
CREATE CREDENTIAL [SSAS_Credential] WITH IDENTITY = N'\mydomain\user_name', SECRET = N'mysecret'
GO
```

**Note**
IDENTITY must be a domain-authenticated login. Replace `mysecret` with the password for the domain-authenticated login.

To create the SSAS proxy

1. Use the following SQL statement to create the proxy.

```sql
USE [msdb]
GO
EXEC msdb.dbo.sp_add_proxy
@proxy_name=N'SSAS_Proxy',@credential_name=N'SSAS_Credential',@description=N''
GO
```

2. Use the following SQL statement to grant access to the proxy to other users.

```sql
USE [msdb]
GO
EXEC msdb.dbo.sp_grant_login_to_proxy
@proxy_name=N'SSAS_Proxy',@login_name=N'\mydomain\user_name'
GO
```

3. Use the following SQL statement to give the SSAS subsystem access to the proxy.

```sql
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
@task_type='GRANT_SUBSYSTEM_ACCESS',@proxy_name='SSAS_Proxy',@proxy_subsystem='SSAS'
GO
```

To view the proxy and grants on the proxy

1. Use the following SQL statement to view the grantees of the proxy.

```sql
USE [msdb]
GO
EXEC sp_help_proxy
```

2. Use the following SQL statement to view the subsystem grants.

```sql
USE [msdb]
```
Scheduling SSAS database processing using SQL Server Agent

After you create the credential and proxy and grant SSAS access to the proxy, you can create a SQL Server Agent job to schedule SSAS database processing.

To schedule SSAS database processing

• Use SSMS or T-SQL for creating the SQL Server Agent job. The following example uses T-SQL. You can further configure its job schedule through SSMS or T-SQL.

  • The @command parameter outlines the XML for Analysis (XMLA) command to be run by the SQL Server Agent job. This example configures SSAS Multidimensional database processing.

  • The @server parameter outlines the target SSAS server name of the SQL Server Agent job.

To call the SSAS service within the same RDS DB instance where the SQL Server Agent job resides, use localhost:2383.

To call the SSAS service from outside the RDS DB instance, use the RDS endpoint. You can also use the Kerberos Active Directory (AD) endpoint (*your-DB-instance-name*, *your-AD-domain-name*) if the RDS DB instances are joined by the same domain. For external DB instances, make sure to properly configure the VPC security group associated with the RDS DB instance for a secure connection.

You can further edit the query to support various XMLA operations. Make edits either by directly modifying the T-SQL query or by using the SSMS UI following SQL Server Agent job creation.

```sql
USE [msdb]
GO
DECLARE @jobId BINARY(16)
EXEC msdb.dbo.sp_add_job @job_name=N'SSAS_Job',
    @enabled=1,
    @notify_level_eventlog=0,
    @notify_level_email=0,
    @notify_level_netsend=0,
    @notify_level_page=0,
    @delete_level=0,
    @category_name=N'[Uncategorized (Local)]',
    @job_id = @jobId OUTPUT
GO
EXEC msdb.dbo.sp_add_jobserver
    @job_name=N'SSAS_Job',
    @server_name = N'(local)'
GO
EXEC msdb.dbo.sp_add_jobstep @job_name=N'SSAS_Job', @step_name=N'Process_SSAS_Object',
    @step_id=1,
    @cmdexec_success_code=0,
    @on_success_action=1,
    @on_success_step_id=0,
    @on_fail_action=2,
    @on_fail_step_id=0,
    @retry_attempts=0,
    @retry_interval=0,
    @os_run_priority=0, @subsystem=N'ANALYSISCOMMAND',
    @command=N'<Batch xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
        <Parallel>
            
        </Parallel>
    </Batch>'
```
Revoking SSAS access from the proxy

You can revoke access to the SSAS subsystem and delete the SSAS proxy using the following stored procedures.

**To revoke access and delete the proxy**

1. Revoke subsystem access.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
    @task_type='REVOKE_SUBSYSTEM_ACCESS',@proxy_name='SSAS_Proxy',@proxy_subsystem='SSAS'
GO
```

2. Revoke the grants on the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_revoke_login_from_proxy
    @proxy_name=N'SSAS_Proxy',@name=N'mydomain\user_name'
GO
```

3. Delete the proxy.

```
USE [msdb]
GO
EXEC dbo.sp_delete_proxy @proxy_name = N'SSAS_Proxy'
GO
```
Back up an SSAS database

You can create SSAS database backup files only in the D:\S3 folder on the DB instance. To move the backup files to your S3 bucket, use Amazon S3.

You can back up an SSAS database as follows:

- A domain user with the admin role for a particular database can use SSMS to back up the database to the D:\S3 folder.

  For more information, see Adding a domain user as a database administrator (p. 1282).

- You can use the following stored procedure. This stored procedure doesn't support encryption.

  ```sql
  exec msdb.dbo.rds_msbi_task
  @task_type='SSAS_BACKUP_DB',
  @database_name='myssasdb',
  @file_path='D:\S3\ssas_db_backup.abf',
  [@ssas_apply_compression=1],
  [@ssas_overwrite_file=1];
  ```

  The following parameters are required:
  - @task_type – The type of the MSBI task, in this case SSAS_BACKUP_DB.
  - @database_name – The name of the SSAS database that you’re backing up.
  - @file_path – The path for the SSAS backup file. The .abf extension is required.

  The following parameters are optional:
  - @ssas_apply_compression – Whether to apply SSAS backup compression. Valid values are 1 (Yes) and 0 (No).
  - @ssas_overwrite_file – Whether to overwrite the SSAS backup file. Valid values are 1 (Yes) and 0 (No).

Restoring an SSAS database

Use the following stored procedure to restore an SSAS database from a backup.

You can’t restore a database if there is an existing SSAS database with the same name. The stored procedure for restoring doesn’t support encrypted backup files.

```sql
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_RESTORE_DB',
@database_name='mynewssasdb',
@file_path='D:\S3\ssas_db_backup.abf';
```

The following parameters are required:

- @task_type – The type of the MSBI task, in this case SSAS_RESTORE_DB.
- @database_name – The name of the new SSAS database that you’re restoring to.
- @file_path – The path to the SSAS backup file.

Restoring a DB instance to a specified time

Point-in-time recovery (PITR) doesn’t apply to SSAS databases. If you do PITR, only the SSAS data in the last snapshot before the requested time is available on the restored instance.
To have up-to-date SSAS databases on a restored DB instance

1. Back up your SSAS databases to the D:\S3 folder on the source instance.
2. Transfer the backup files to the S3 bucket.
3. Transfer the backup files from the S3 bucket to the D:\S3 folder on the restored instance.
4. Run the stored procedure to restore the SSAS databases onto the restored instance.

You can also reprocess the SSAS project to restore the databases.

Changing the SSAS mode

You can change the mode in which SSAS runs, either Tabular or Multidimensional. To change the mode, use the AWS Management Console or the AWS CLI to modify the options settings in the SSAS option.

Important
You can only use one SSAS mode at a time. Make sure to delete all of the SSAS databases before changing the mode, or you receive an error.

Console

The following Amazon RDS console procedure changes the SSAS mode to Tabular and sets the MAX_MEMORY parameter to 70 percent.

To modify the SSAS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the option group with the SSAS option that you want to modify (ssas-se-2017 in the previous examples).
4. Choose Modify option.
5. Change the option settings:
   a. For Max memory, enter 70.
   b. For Mode, choose Tabular.
6. Choose Modify option.

AWS CLI

The following AWS CLI example changes the SSAS mode to Tabular and sets the MAX_MEMORY parameter to 70 percent.

For the CLI command to work, make sure to include all of the required parameters, even if you're not modifying them.

To modify the SSAS option

- Use one of the following commands.

  **Example**

  For Linux, macOS, or Unix:

  ```bash
  aws rds add-option-to-option-group \
  ```
---option-group-name ssas-se-2017 \
--options
"OptionName=SSAS,VpcSecurityGroupMemberships=sg-12345e67,OptionSettings=\{[Name=MAX_MEMORY,Value=70],\} [Name=MODE,Value=Tabular]]" \
--apply-immediately

For Windows:

aws rds add-option-to-option-group ^
--option-group-name ssas-se-2017 ^
--options OptionName=SSAS,VpcSecurityGroupMemberships=sg-12345e67,OptionSettings=\{[Name=MAX_MEMORY,Value=70],\} [Name=MODE,Value=Tabular]] ^
--apply-immediately

**Turning off SSAS**

To turn off SSAS, remove the SSAS option from its option group.

**Important**

Before you remove the SSAS option, delete your SSAS databases. We highly recommend that you back up your SSAS databases before deleting them and removing the SSAS option.

**Console**

**To remove the SSAS option from its option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSAS option that you want to remove (ssas-se-2017 in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSAS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

**AWS CLI**

**To remove the SSAS option from its option group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

aws rds remove-option-from-option-group \
--option-group-name ssas-se-2017 \
--options SSAS \ 
--apply-immediately

For Windows:
Troubleshooting SSAS issues

You might encounter the following issues when using SSAS.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Type</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unable to configure the SSAS option. The requested SSAS mode is <code>new_mode</code>, but the current DB instance has <code>number current_mode</code> databases. Delete the existing databases before switching to <code>new_mode</code> mode. To regain access to <code>current_mode</code> mode for database deletion, either update the current DB option group, or attach a new option group with <code>%s</code> as the MODE option setting value for the SSAS option.</td>
<td>RDS event</td>
<td>You can't change the SSAS mode if you still have SSAS databases that use the current mode. Delete the SSAS databases, then try again.</td>
</tr>
<tr>
<td>Unable to remove the SSAS option because there are <code>number existing mode</code> databases. The SSAS option can't be removed until all SSAS databases are deleted. Add the SSAS option again, delete all SSAS databases, and try again.</td>
<td>RDS event</td>
<td>You can't turn off SSAS if you still have SSAS databases. Delete the SSAS databases, then try again.</td>
</tr>
<tr>
<td>The SSAS option isn't enabled or is in the process of being enabled. Try again later.</td>
<td>RDS stored procedure</td>
<td>You can't run SSAS stored procedures when the option is turned off, or when it's being turned on.</td>
</tr>
<tr>
<td>The SSAS option is configured incorrectly. Make sure that the option group membership status is &quot;in-sync&quot;, and review the RDS event logs for relevant SSAS configuration error messages. Following these investigations, try again. If errors continue to occur, contact AWS Support.</td>
<td>RDS stored procedure</td>
<td>You can't run SSAS stored procedures when your option group membership isn't in the in-sync status. This puts the SSAS option in an incorrect configuration state. If your option group membership status changes to failed due to SSAS option modification, there are two possible reasons: 1. The SSAS option was removed without the SSAS databases being deleted. 2. The SSAS mode was updated from Tabular to Multidimensional, or from Multidimensional to Tabular, without the existing SSAS databases being deleted. Reconfigure the SSAS option, because RDS allows only one SSAS mode at a time, and doesn't support SSAS option removal with SSAS databases present.</td>
</tr>
<tr>
<td>Issue</td>
<td>Type</td>
<td>Troubleshooting suggestions</td>
</tr>
<tr>
<td>----------------------------------------------------------------------</td>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Deployment failed. The change can only be deployed on a server running in deployment_file_mode mode. The current server mode is current_mode.</td>
<td>RDS stored procedure</td>
<td>You can't deploy a Tabular database to a Multidimensional server, or a Multidimensional database to a Tabular server. Make sure that you're using files with the correct mode, and verify that the MODE option setting is set to the appropriate value.</td>
</tr>
<tr>
<td>The restore failed. The backup file can only be restored on a server running in restore_file_mode mode. The current server mode is current_mode.</td>
<td>RDS stored procedure</td>
<td>You can't restore a Tabular database to a Multidimensional server, or a Multidimensional database to a Tabular server. Make sure that you're using files with the correct mode, and verify that the MODE option setting is set to the appropriate value.</td>
</tr>
<tr>
<td>The restore failed. The backup file and the RDS DB instance versions are incompatible.</td>

1291
Support for SQL Server Integration Services in Amazon RDS for SQL Server

Microsoft SQL Server Integration Services (SSIS) is a component that you can use to perform a broad range of data migration tasks. SSIS is a platform for data integration and workflow applications. It features a data warehousing tool used for data extraction, transformation, and loading (ETL). You can also use this tool to automate maintenance of SQL Server databases and updates to multidimensional cube data.

SSIS projects are organized into packages saved as XML-based .dtsx files. Packages can contain control flows and data flows. You use data flows to represent ETL operations. After deployment, packages are stored in SQL Server in the SSISDB database. SSISDB is an online transaction processing (OLTP) database in the full recovery mode.

Amazon RDS for SQL Server supports running SSIS directly on an RDS DB instance. You can enable SSIS on an existing or new DB instance. SSIS is installed on the same DB instance as your database engine.

RDS supports SSIS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2019, version 15.00.4043.16.v1 and higher
- SQL Server 2017, version 14.00.3223.3.v1 and higher
- SQL Server 2016, version 13.00.5426.0.v1 and higher

- Monitoring the status of a deployment task (p. 1301)
- Using SSIS (p. 1302)
  - Setting database connection managers for SSIS projects (p. 1302)
  - Creating an SSIS proxy (p. 1303)
  - Scheduling an SSIS package using SQL Server Agent (p. 1304)
  - Revoking SSIS access from the proxy (p. 1304)
- Disabling SSIS (p. 1305)
- Dropping the SSISDB database (p. 1306)

Limitations and recommendations

The following limitations and recommendations apply to running SSIS on RDS for SQL Server:

- The DB instance must use AWS Managed Microsoft AD for SSIS authentication.
• The DB instance must have an associated parameter group with the `clr enabled` parameter set to 1. For more information, see Modifying the parameter for SSIS (p. 1297).

  Note
  If you enable the `clr enabled` parameter on SQL Server 2017 or 2019, you can't use the common language runtime (CLR) on your DB instance. For more information, see Features not supported and features with limited support (p. 1112).

• The following control flow tasks are supported:
  • Analysis Services Execute DDL Task
  • Analysis Services Processing Task
  • Bulk Insert Task
  • Check Database Integrity Task
  • Data Flow Task
  • Data Mining Query Task
  • Data Profiling Task
  • Execute Package Task
  • Execute SQL Server Agent Job Task
  • Execute SQL Task
  • Execute T-SQL Statement Task
  • Notify Operator Task
  • Rebuild Index Task
  • Reorganize Index Task
  • Shrink Database Task
  • Transfer Database Task
  • Transfer Jobs Task
  • Transfer Logins Task
  • Transfer SQL Server Objects Task
  • Update Statistics Task

• Only project deployment is supported.
• Running SSIS packages by using SQL Server Agent is supported.
• SSIS log records can be inserted only into user-created databases.
• Use only the `D:\S3` folder for working with files. Files placed in any other directory are deleted. Be aware of a few other file location details:
  • Place SSIS project input and output files in the `D:\S3` folder.
  • For the Data Flow Task, change the location for BLOBTempStoragePath and BufferTempStoragePath to a file inside the `D:\S3` folder. The file path must start with `D:\S3\`.
  • Ensure that all parameters, variables, and expressions used for file connections point to the `D:\S3` folder.
  • On Multi-AZ instances, files created by SSIS in the `D:\S3` folder are deleted after a failover. For more information, see Multi-AZ limitations for S3 integration (p. 1206).
  • Upload the files created by SSIS in the `D:\S3` folder to your Amazon S3 bucket to make them durable.
  • Import Column and Export Column transformations and the Script component on the Data Flow Task aren't supported.
  • You can't enable dump on running SSIS packages, and you can't add data taps on SSIS packages.
  • The SSIS Scale Out feature isn't supported.

• You can't deploy projects directly. We provide RDS stored procedures to do this. For more information, see Deploying an SSIS project (p. 1300).
• Build SSIS project (.ispac) files with the DoNotSavePasswords protection mode for deploying on RDS.
• SSIS isn't supported on Always On instances with read replicas.
• You can't back up the SSISDB database that is associated with the SSIS option.
• Importing and restoring the SSISDB database from other instances of SSIS isn't supported.
• You can connect to other SQL Server DB instances or to an Oracle data source. Connecting to other database engines, such as MySQL or PostgreSQL, isn't supported for SSIS on RDS for SQL Server. For more information on connecting to an Oracle data source, see Linked Servers with Oracle OLEDB (p. 1247).

Enabling SSIS

You enable SSIS by adding the SSIS option to your DB instance. Use the following process:

1. Create a new option group, or choose an existing option group.
2. Add the SSIS option to the option group.
3. Create a new parameter group, or choose an existing parameter group.
4. Modify the parameter group to set the clr enabled parameter to 1.
5. Associate the option group and parameter group with the DB instance.
6. Enable Amazon S3 integration.

Note
If a database with the name SSISDB or a reserved SSIS login already exists on the DB instance, you can't enable SSIS on the instance.

Creating the option group for SSIS

To work with SSIS, create an option group or modify an option group that corresponds to the SQL Server edition and version of the DB instance that you plan to use. To do this, use the AWS Management Console or the AWS CLI.

Console

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose Create group.
4. In the Create option group window, do the following:
   a. For Name, enter a name for the option group that is unique within your AWS account, such as ssis-se-2016. The name can contain only letters, digits, and hyphens.
   b. For Description, enter a brief description of the option group, such as SSIS option group for SQL Server SE 2016. The description is used for display purposes.
   c. For Engine, choose sqlserver-se.
   d. For Major engine version, choose 13.00.
5. Choose Create.
The following procedure creates an option group for SQL Server Standard Edition 2016.

**To create the option group**

- Run one of the following commands.

  **Example**

  For Linux, macOS, or Unix:

  ```bash
  aws rds create-option-group
  --option-group-name ssis-se-2016
  --engine-name sqlserver-se
  --major-engine-version 13.00
  --option-group-description "SSIS option group for SQL Server SE 2016"
  ```

  For Windows:

  ```bash
  aws rds create-option-group
  --option-group-name ssis-se-2016
  --engine-name sqlserver-se
  --major-engine-version 13.00
  --option-group-description "SSIS option group for SQL Server SE 2016"
  ```

**Adding the SSIS option to the option group**

Next, use the AWS Management Console or the AWS CLI to add the SSIS option to your option group.

**Console**

**To add the SSIS option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Option groups.
3. Choose the option group that you just created, ssis-se-2016 in this example.
4. Choose Add option.
5. Under Option details, choose SSIS for Option name.
6. Under Scheduling, choose whether to add the option immediately or at the next maintenance window.
7. Choose Add option.

**CLI**

**To add the SSIS option**

- Add the SSIS option to the option group.

  **Example**

  For Linux, macOS, or Unix:

  ```bash
  aws rds add-option-to-option-group
  ```
Creating the parameter group for SSIS

Create or modify a parameter group for the clr enabled parameter that corresponds to the SQL Server edition and version of the DB instance that you plan to use for SSIS.

**Console**

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

**To create the parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
4. In the Create parameter group pane, do the following:
   a. For Parameter group family, choose sqlserver-se-13.0.
   b. For Group name, enter an identifier for the parameter group, such as ssis-sqlserver-se-13.
   c. For Description, enter clr enabled parameter group.
5. Choose Create.

**CLI**

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

**To create the parameter group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
    --db-parameter-group-name ssis-sqlserver-se-13 \
    --db-parameter-group-family "sqlserver-se-13.0" \
    --description "clr enabled parameter group"
```

For Windows:

```
avs rds create-db-parameter-group ^
```
Modifying the parameter for SSIS

Modify the `clr enabled` parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance. For SSIS, set the `clr enabled` parameter to 1.

Console

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016.

**To modify the parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group, such as `ssis-sqlserver-se-13`.
4. Under Parameters, filter the parameter list for `clr`.
5. Choose `clr enabled`.
6. Choose Edit parameters.
7. From Values, choose 1.
8. Choose Save changes.

CLI

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016.

**To modify the parameter group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group
   --db-parameter-group-name ssis-sqlserver-se-13
   --parameters "ParameterName='clr enabled',ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group
   --db-parameter-group-name ssis-sqlserver-se-13
   --parameters "ParameterName='clr enabled',ParameterValue=1,ApplyMethod=immediate"
```

Associating the option group and parameter group with your DB instance

To associate the SSIS option group and parameter group with your DB instance, use the AWS Management Console or the AWS CLI.
**Note**
If you use an existing instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1184).

**Console**

To finish enabling SSIS, associate your SSIS option group and parameter group with a new or existing DB instance:

- For a new DB instance, associate them when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
- For an existing DB instance, associate them by modifying the instance. For more information, see Modifying an Amazon RDS DB instance (p. 333).

**CLI**

You can associate the SSIS option group and parameter group with a new or existing DB instance.

**To create an instance with the SSIS option group and parameter group**

- Specify the same DB engine type and major version as you used when creating the option group.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance
  --db-instance-identifier myssisinstance
  --db-instance-class db.m5.2xlarge
  --engine sqlserver-se
  --engine-version 13.00.5426.0.v1
  --allocated-storage 100
  --master-user-password secret123
  --master-username admin
  --storage-type gp2
  --license-model li
  --domain-iam-role-name my-directory-iam-role
  --domain my-domain-id
  --option-group-name ssis-se-2016
  --db-parameter-group-name ssis-sqlserver-se-13
```

For Windows:

```bash
aws rds create-db-instance
  --db-instance-identifier myssisinstance
  --db-instance-class db.m5.2xlarge
  --engine sqlserver-se
  --engine-version 13.00.5426.0.v1
  --allocated-storage 100
  --master-user-password secret123
  --master-username admin
  --storage-type gp2
  --license-model li
  --domain-iam-role-name my-directory-iam-role
  --domain my-domain-id
  --option-group-name ssis-se-2016
  --db-parameter-group-name ssis-sqlserver-se-13
```
To modify an instance and associate the SSIS option group and parameter group

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance --db-instance-identifier myssisinstance --option-group-name ssis-se-2016 --db-parameter-group-name ssis-sqlserver-se-13 --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^ --db-instance-identifier myssisinstance ^ --option-group-name ssis-se-2016 ^ --db-parameter-group-name ssis-sqlserver-se-13 ^ --apply-immediately
```

**Enabling S3 integration**

To download SSIS project (.ispac) files to your host for deployment, use S3 file integration. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 (p. 1194).

**Administrative permissions on SSISDB**

When the instance is created or modified with the SSIS option, the result is an SSISDB database with the ssis_admin and ssis_logreader roles granted to the master user. The master user has the following privileges in SSISDB:

- alter on ssis_admin role
- alter on ssis_logreader role
- alter any user

Because the master user is a SQL-authenticated user, you can't use the master user for executing SSIS packages. The master user can use these privileges to create new SSISDB users and add them to the ssis_admin and ssis_logreader roles. Doing this is useful for giving access to your domain users for using SSIS.

**Setting up a Windows-authenticated user for SSIS**

The master user can use the following code example to set up a Windows-authenticated login in SSISDB and grant the required procedure permissions. Doing this grants permissions to the domain user to deploy and run SSIS packages, use S3 file transfer procedures, create credentials, and work with the SQL Server Agent proxy. For more information, see Credentials (database engine) and Create a SQL Server Agent proxy in the Microsoft documentation.

**Note**

You can grant some or all of the following permissions as needed to Windows-authenticated users.
Example

USE [SSISDB]
GO
CREATE USER [mydomain\username] FOR LOGIN [mydomain\username]
ALTER ROLE [ssis_admin] ADD MEMBER [mydomain\username]
ALTER ROLE [ssis_logreader] ADD MEMBER [mydomain\username]
GO

USE [msdb]
GO
CREATE USER [mydomain\username] FOR LOGIN [mydomain\username]
GRANT EXEC ON msdb.dbo.rds_msbi_task TO [mydomain\username] with grant option
GRANT SELECT ON msdb.dbo.rds_fn_task_status TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.rds_task_status TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.rds_cancel_task TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.rds_download_from_s3 TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.rds_upload_to_s3 TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.rds_delete_from_filesystem TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.rds_gather_file_details TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.sp_add_proxy TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.sp_update_proxy TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.sp_revoke_proxy TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.sp_add_proxy TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.sp_update_proxy TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.sp_grant_proxy TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.sp_revoke_proxy TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.sp_delete_proxy TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_proxy TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_proxy TO [mydomain\username] with grant option
GRANT EXEC ON msdb.dbo.rds_sqlagent_proxy TO [mydomain\username] WITH GRANT OPTION
ALTER ROLE [SQLAgentUserRole] ADD MEMBER [mydomain\username]
GO

USE [master]
GO
GRANT ALTER ANY CREDENTIAL TO [mydomain\username]
GO

Deploying an SSIS project

On RDS, you can't deploy SSIS projects directly by using SQL Server Management Studio (SSMS) or SSIS procedures. To download project files from Amazon S3 and then deploy them, use RDS stored procedures.

To run the stored procedures, log in as any user that you granted permissions for running the stored procedures. For more information, see Setting up a Windows-authenticated user for SSIS (p. 1299).

To deploy the SSIS project

1. Download the project (.ispac) file.

   ```sql
   exec msdb.dbo.rds_download_from_s3
   @s3_arn_of_file='arn:aws:s3:::bucket_name/ssisproject.ispac',
   [@rds_file_path='D:\SS\ssisproject.ispac'],
   [@overwrite_file=1];
   ```

2. Submit the deployment task, making sure of the following:
   - The folder is present in the SSIS catalog.
   - The project name matches the project name that you used while developing the SSIS project.
Monitoring the status of a deployment task

To track the status of your deployment task, call the rds_fn_task_status function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to SSIS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 42);
```

The rds_fn_task_status function returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>task_type</td>
<td>SSIS_DEPLOY_PROJECT</td>
</tr>
<tr>
<td>database_name</td>
<td>Not applicable to SSIS tasks.</td>
</tr>
<tr>
<td>% complete</td>
<td>The progress of the task as a percentage.</td>
</tr>
<tr>
<td>duration (mins)</td>
<td>The amount of time spent on the task, in minutes.</td>
</tr>
<tr>
<td>lifecycle</td>
<td>The status of the task. Possible statuses are the following:</td>
</tr>
<tr>
<td></td>
<td>• CREATED – After you call the msdb.dbo.rds_msbi_task stored procedure,</td>
</tr>
<tr>
<td></td>
<td>a task is created and the status is set to CREATED.</td>
</tr>
<tr>
<td></td>
<td>• IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It</td>
</tr>
<tr>
<td></td>
<td>can take up to five minutes for the status to change from CREATED to</td>
</tr>
<tr>
<td></td>
<td>IN_PROGRESS.</td>
</tr>
<tr>
<td></td>
<td>• SUCCESS – After a task completes, the status is set to SUCCESS.</td>
</tr>
<tr>
<td></td>
<td>• ERROR – If a task fails, the status is set to ERROR. For more information</td>
</tr>
<tr>
<td></td>
<td>about the error, see the task_info column.</td>
</tr>
</tbody>
</table>
### Output parameter

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• CANCEL_REQUESTED – After you call <code>rds_cancel_task</code>, the status of the task is set to CANCEL_REQUESTED.</td>
</tr>
<tr>
<td></td>
<td>• CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.</td>
</tr>
<tr>
<td>task_info</td>
<td>Additional information about the task. If an error occurs during processing, this column contains information about the error.</td>
</tr>
<tr>
<td>last_updated</td>
<td>The date and time that the task status was last updated.</td>
</tr>
<tr>
<td>created_at</td>
<td>The date and time that the task was created.</td>
</tr>
<tr>
<td>S3_object_arn</td>
<td>Not applicable to SSIS tasks.</td>
</tr>
<tr>

<td>Not applicable to SSIS tasks.</td>
</tr>
<tr>
<td>KMS_master_key_arn</td>
<td>Not applicable to SSIS tasks.</td>
</tr>
<tr>
<td>filepath</td>
<td>Not applicable to SSIS tasks.</td>
</tr>
<tr>
<td>overwrite_file</td>
<td>Not applicable to SSIS tasks.</td>
</tr>
<tr>
<td>task_metadata</td>
<td>Metadata associated with the SSIS task.</td>
</tr>
</tbody>
</table>

### Using SSIS

After deploying the SSIS project into the SSIS catalog, you can run packages directly from SSMS or schedule them by using SQL Server Agent. You must use a Windows-authenticated login for executing SSIS packages. For more information, see Setting up a Windows-authenticated user for SSIS (p. 1299).

### Topics

- Setting database connection managers for SSIS projects (p. 1302)
- Creating an SSIS proxy (p. 1303)
- Scheduling an SSIS package using SQL Server Agent (p. 1304)
- Revoking SSIS access from the proxy (p. 1304)

### Setting database connection managers for SSIS projects

When you use a connection manager, you can use these types of authentication:

- For local database connections, you can use SQL authentication or Windows authentication. For Windows authentication, use `DB_instance_name.fully_qualified_domain_name` as the server name of the connection string.

  An example is `myssisinstance.corp-ad.example.com`, where myssisinstance is the DB instance name and corp-ad.example.com is the fully qualified domain name.

- For remote connections, always use SQL authentication.
Creating an SSIS proxy

To be able to schedule SSIS packages using SQL Server Agent, create an SSIS credential and an SSIS proxy. Run these procedures as a Windows-authenticated user.

To create the SSIS credential

- Create the credential for the proxy. To do this, you can use SSMS or the following SQL statement.

```sql
USE [master]
GO
CREATE CREDENTIAL [SSIS_Credential] WITH IDENTITY = N'mydomain\user_name', SECRET = N'mysecret'
GO
```

**Note**

IDENTITY must be a domain-authenticated login. Replace *mysecret* with the password for the domain-authenticated login. Whenever the SSISDB primary host is changed, alter the SSIS proxy credentials to allow the new host to access them.

To create the SSIS proxy

1. Use the following SQL statement to create the proxy.

```sql
USE [msdb]
GO
EXEC msdb.dbo.sp_add_proxy
    @proxy_name=N'SSIS_Proxy',@credential_name=N'SSIS_Credential',@description=N''
GO
```

2. Use the following SQL statement to grant access to the proxy to other users.

```sql
USE [msdb]
GO
EXEC msdb.dbo.sp_grant_login_to_proxy
    @proxy_name=N'SSIS_Proxy',@login_name=N'mydomain\user_name'
GO
```

3. Use the following SQL statement to give the SSIS subsystem access to the proxy.

```sql
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
    @task_type='GRANT_SUBSYSTEM_ACCESS',@proxy_name='SSIS_Proxy',@proxy_subsystem='SSIS'
GO
```

To view the proxy and grants on the proxy

1. Use the following SQL statement to view the grantees of the proxy.

```sql
USE [msdb]
GO
EXEC sp_help_proxy
GO
```

2. Use the following SQL statement to view the subsystem grants.
Scheduling an SSIS package using SQL Server Agent

After you create the credential and proxy and grant SSIS access to the proxy, you can create a SQL Server Agent job to schedule the SSIS package.

To schedule the SSIS package

• You can use SSMS or T-SQL for creating the SQL Server Agent job. The following example uses T-SQL.

```
USE [msdb]
GO
DECLARE @jobId BINARY(16)
EXEC msdb.dbo.sp_add_job @job_name=N'MYSSISJob',
@enabled=1,
@notify_level_eventlog=0,
@notify_level_email=2,
@notify_level_page=2,
@delete_level=0,
@category_name=N'Uncategorized (Local)]',
@job_id = @jobId OUTPUT
GO
EXEC msdb.dbo.sp_add_jobserver @job_name=N'MYSSISJob',@server_name=N'(local)
GO
EXEC msdb.dbo.sp_add_jobstep @job_name=N'MYSSISJob',@step_name=N'ExecuteSSISPackage',
@step_id=1,
@cmdexec_success_code=0,
@on_success_action=1,
@on_fail_action=2,
@retry_attempts=0,
@retry_interval=0,
@os_run_priority=0,
@subsystem=N'SSIS',
@command=N'"\\SSISDB\MySSISFolder\MySSISProject\MySSISPackage.dtsx" /SERVER "\\my-rds-ssis-instance.corp-ad.company.com/" /Par ""\$ServerOption::LOGGING_LEVEL(Int16)"":1 /Par ""\$ServerOption::SYNCHRONIZED(Boolean)"":True /CALLERINFO SQLAGENT /REPORTING E',
@database_name=N'master',
@flags=0,
@proxy_name=N'SSIS_Proxy'
GO
```

Revoking SSIS access from the proxy

You can revoke access to the SSIS subsystem and delete the SSIS proxy using the following stored procedures.

To revoke access and delete the proxy

1. Revoke subsystem access.

```
USE [msdb]
GO
```
2. Revoke the grants on the proxy.

```sql
USE [msdb]
GO
EXEC msdb.dbo.sp_revoke_login_from_proxy
    @proxy_name=N'SSIS_Proxy',@name=N'\mydomain\user_name'
GO
```

3. Delete the proxy.

```sql
USE [msdb]
GO
EXEC dbo.sp_delete_proxy @proxy_name = N'SSIS_Proxy'
GO
```

### Disabling SSIS

To disable SSIS, remove the SSIS option from its option group.

**Important**
- Removing the option doesn't delete the SSISDB database, so you can safely remove the option without losing the SSIS projects.
- You can re-enable the SSIS option after removal to reuse the SSIS projects that were previously deployed to the SSIS catalog.

**Console**

The following procedure removes the SSIS option.

**To remove the SSIS option from its option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSIS option (sis-se-2016 in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSIS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

**CLI**

The following procedure removes the SSIS option.

**To remove the SSIS option from its option group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:
aws rds remove-option-from-option-group \
  --option-group-name ssis-se-2016 \
  --options SSIS \
  --apply-immediately

For Windows:

aws rds remove-option-from-option-group ^
  --option-group-name ssis-se-2016 ^
  --options SSIS ^
  --apply-immediately

Dropping the SSISDB database

After removing the SSIS option, the SSISDB database isn’t deleted. To drop the SSISDB database, use the `rds_drop_ssis_database` stored procedure after removing the SSIS option.

To drop the SSIS database

- Use the following stored procedure.

  USE [msdb]
  GO
  EXEC dbo.rds_drop_ssis_database
  GO

After dropping the SSISDB database, if you re-enable the SSIS option you get a fresh SSISDB catalog.
Support for SQL Server Reporting Services in Amazon RDS for SQL Server

Microsoft SQL Server Reporting Services (SSRS) is a server-based application used for report generation and distribution. It's part of a suite of SQL Server services that also includes SQL Server Analysis Services (SSAS) and SQL Server Integration Services (SSIS). SSRS is a service built on top of SQL Server. You can use it to collect data from various data sources and present it in a way that's easily understandable and ready for analysis.

Amazon RDS for SQL Server supports running SSRS directly on RDS DB instances. You can use SSRS with existing or new DB instances.

RDS supports SSRS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2019, version 15.00.4043.16.v1 and higher
- SQL Server 2017, version 14.00.3223.3.v1 and higher
- SQL Server 2016, version 13.00.5820.21.v1 and higher

Limitations and recommendations

The following limitations and recommendations apply to running SSRS on RDS for SQL Server:

- You can't use SSRS on DB instances that have read replicas.
- Instances must use AWS Managed Microsoft AD for SSRS web portal and web server authentication.
- Importing and restoring report server databases from other instances of SSRS isn't supported.

Make sure to use the databases that are created when the SSRS option is added to the RDS DB instance. For more information, see Report server databases (p. 1313).
• You can’t configure SSRS to listen on the default SSL port (443). The allowed values are 1150–49511, except 1234, 1434, 3260, 3343, 3389, and 47001.
• Subscriptions through a Microsoft Windows file share aren’t supported.
• Using Reporting Services Configuration Manager isn’t supported.
• Creating and modifying roles isn’t supported.
• Modifying report server properties isn’t supported.
• System administrator and system user roles aren’t granted.
• You can’t edit system-level role assignments through the web portal.

Turning on SSRS

Use the following process to turn on SSRS for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the SSRS option to the option group.
3. Associate the option group with the DB instance.
4. Allow inbound access to the virtual private cloud (VPC) security group for the SSRS listener port.

Creating an option group for SSRS

To work with SSRS, create an option group that corresponds to the SQL Server engine and version of the DB instance that you plan to use. To do this, use the AWS Management Console or the AWS CLI.

Note
You can also use an existing option group if it’s for the correct SQL Server engine and version.

Console

The following procedure creates an option group for SQL Server Standard Edition 2017.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose Create group.
4. In the Create option group pane, do the following:
   a. For Name, enter a name for the option group that is unique within your AWS account, such as ssrs-se-2017. The name can contain only letters, digits, and hyphens.
   b. For Description, enter a brief description of the option group, such as SSRS option group for SQL Server SE 2017. The description is used for display purposes.
   c. For Engine, choose sqlserver-se.
   d. For Major engine version, choose 14.00.
5. Choose Create.

CLI

The following procedure creates an option group for SQL Server Standard Edition 2017.

To create the option group

• Run one of the following commands.
Example

For Linux, macOS, or Unix:

```bash
aws rds create-option-group
  --option-group-name ssrs-se-2017
  --engine-name sqlserver-se
  --major-engine-version 14.00
  --option-group-description "SSRS option group for SQL Server SE 2017"
```

For Windows:

```bash
aws rds create-option-group
  --option-group-name ssrs-se-2017
  --engine-name sqlserver-se
  --major-engine-version 14.00
  --option-group-description "SSRS option group for SQL Server SE 2017"
```

Adding the SSRS option to your option group

Next, use the AWS Management Console or the AWS CLI to add the SSRS option to your option group.

**Console**

**To add the SSRS option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, then choose **Add option**.
4. Under **Option details**, choose **SSRS** for **Option name**.
5. Under **Option settings**, do the following:
   a. Enter the port for the SSRS service to listen on. The default is 8443. For a list of allowed values, see **Limitations and recommendations (p. 1307)**.
   b. Enter a value for **Max memory**.
      
      **Max memory** specifies the upper threshold above which no new memory allocation requests are granted to report server applications. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80.
   c. For **Security groups**, choose the VPC security group to associate with the option. Use the same security group that is associated with your DB instance.
6. To use SSRS Email to send reports, choose the **Configure email delivery options** check box under **Email delivery in reporting services**, and then do the following:
   a. For **Sender email address**, enter the email address to use in the **From** field of messages sent by SSRS Email.
      Specify a user account that has permission to send mail from the SMTP server.
   b. For **SMTP server**, specify the SMTP server or gateway to use.
      It can be an IP address, the NetBIOS name of a computer on your corporate intranet, or a fully qualified domain name.
   c. For **SMTP port**, enter the port to use to connect to the mail server. The default is 25.
   d. To use authentication:
      i. Select the **Use authentication** check box.
ii. For **Secret Amazon Resource Name (ARN)** enter the AWS Secrets Manager ARN for the user credentials.

   Use the following format:

   `arn:aws:secretsmanager:Region:AccountId:secret:SecretName-6RandomCharacters`

   For example:

   `arn:aws:secretsmanager:us-west-2:123456789012:secret:MySecret-a1b2c3`

   For more information on creating the secret, see "Using SSRS Email to send reports" (p. 1315).

   e. Select the **Use Secure Sockets Layer (SSL)** check box to encrypt email messages using SSL.

7. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.

8. Choose **Add option**.

---

**CLI**

**To add the SSRS option**

1. Create a JSON file, for example `ssrs-option.json`.

   a. Set the following required parameters:

      • **OptionGroupName** – The name of option group that you created or chose previously (ssrs-se-2017 in the following example).
      • **Port** – The port for the SSRS service to listen on. The default is 8443. For a list of allowed values, see "Limitations and recommendations" (p. 1307).
      • **VpcSecurityGroupMemberships** – VPC security group memberships for your RDS DB instance.
      • **MAX_MEMORY** – The upper threshold above which no new memory allocation requests are granted to report server applications. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80.

   b. (Optional) Set the following parameters to use SSRS Email:

      • **SMTP_ENABLE_EMAIL** – Set to `true` to use SSRS Email. The default is `false`.
      • **SMTP_SENDER_EMAIL_ADDRESS** – The email address to use in the From field of messages sent by SSRS Email. Specify a user account that has permission to send mail from the SMTP server.
      • **SMTP_SERVER** – The SMTP server or gateway to use. It can be an IP address, the NetBIOS name of a computer on your corporate intranet, or a fully qualified domain name.
      • **SMTP_PORT** – The port to use to connect to the mail server. The default is 25.
      • **SMTP_USE_SSL** – Set to `true` to encrypt email messages using SSL. The default is `true`.
      • **SMTP_EMAIL_CREDENTIALS_SECRET_ARN** – The Secrets Manager ARN that holds the user credentials. Use the following format:

        `arn:aws:secretsmanager:Region:AccountId:secret:SecretName-6RandomCharacters`

        For more information on creating the secret, see "Using SSRS Email to send reports" (p. 1315).

        • **SMTP_USE_ANONYMOUS_AUTHENTICATION** – Set to `true` and don't include **SMTP_EMAIL_CREDENTIALS_SECRET_ARN** if you don't want to use authentication.

        The default is `false` when SMTP_ENABLE_EMAIL is `true`. 
The following example includes the SSRS Email parameters, using the secret ARN.

```json
{
    "OptionGroupName": "ssrs-se-2017",
    "OptionsToInclude": [
        {
            "OptionName": "SSRS",
            "Port": 8443,
            "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
            "OptionSettings": [
                {"Name": "MAX_MEMORY","Value": "60"},
                {"Name": "SMTP_ENABLE_EMAIL","Value": "true"},
                {"Name": "SMTP_SENDER_EMAIL_ADDRESS","Value": "nobody@example.com"},
                {"Name": "SMTP_SERVER","Value": "email-smtp.us-west-2.amazonaws.com"},
                {"Name": "SMTP_PORT","Value": "25"},
                {"Name": "SMTP_USE_SSL","Value": "true"},
                {"Name": "SMTP_EMAIL_CREDENTIALS_SECRET_ARN","Value": "arn:aws:secretsmanager:us-west-2:123456789012:secret:MySecret-a1b2c3"}
            ]
        }
    ],
    "ApplyImmediately": true
}
```

2. Add the SSRS option to the option group.

**Example**

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --cli-input-json file://ssrs-option.json \n    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --cli-input-json file://ssrs-option.json ^
    --apply-immediately
```

**Associating your option group with your DB instance**

Use the AWS Management Console or the AWS CLI to associate your option group with your DB instance.

If you use an existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1184).

**Console**

You can associate your option group with a new or existing DB instance:

- For a new DB instance, associate the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
- For an existing DB instance, modify the instance and associate the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).
CLI

You can associate your option group with a new or existing DB instance.

To create a DB instance that uses your option group

- Specify the same DB engine type and major version as you used when creating the option group.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance
  --db-instance-identifier myssrsinstance
  --db-instance-class db.m5.2xlarge
  --engine sqlserver-se
  --engine-version 14.00.3223.3.v1
  --allocated-storage 100
  --master-user-password secret123
  --master-username admin
  --storage-type gp2
  --license-model li
  --domain-iam-role-name my-directory-iam-role
  --domain my-domain-id
  --option-group-name ssrs-se-2017
```

For Windows:

```bash
aws rds create-db-instance
  --db-instance-identifier myssrsinstance
  --db-instance-class db.m5.2xlarge
  --engine sqlserver-se
  --engine-version 14.00.3223.3.v1
  --allocated-storage 100
  --master-user-password secret123
  --master-username admin
  --storage-type gp2
  --license-model li
  --domain-iam-role-name my-directory-iam-role
  --domain my-domain-id
  --option-group-name ssrs-se-2017
```

To modify a DB instance to use your option group

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
  --db-instance-identifier myssrsinstance
  --option-group-name ssrs-se-2017
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance
  --db-instance-identifier myssrsinstance
```

1312
Allowing inbound access to your VPC security group

To allow inbound access to the VPC security group associated with your DB instance, create an inbound rule for the specified SSRS listener port. For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group (p. 156).

Report server databases

When your DB instance is associated with the SSRS option, two new databases are created on your DB instance: rdsadmin_ReportServer and rdsadmin_ReportServerTempDB. These databases act as the ReportServer and ReportServerTempDB databases. SSRS stores its data in the ReportServer database and caches its data in the ReportServerTempDB database.

RDS owns and manages these databases, so database operations on them such as ALTER and DROP aren't permitted. However, you can perform read operations on the rdsadmin_ReportServer database.

SSRS log files

You can access ReportServerService_timestamp.log files. These report server logs can be found in the D:\rdsdbdata\Log\SSRS directory. (The D:\rdsdbdata\Log directory is also the parent directory for error logs and SQL Server Agent logs.)

For existing SSRS instances, restarting the SSRS service might be necessary to access report server logs. You can restart the service by updating the SSRS option.

For more information, see Working with Microsoft SQL Server logs (p. 1349).

Accessing the SSRS web portal

Use the following process to access the SSRS web portal:

1. Turn on Secure Sockets Layer (SSL).
2. Grant access to domain users.
3. Access the web portal using a browser and the domain user credentials.

Using SSL on RDS

SSRS uses the HTTPS SSL protocol for its connections. To work with this protocol, import an SSL certificate into the Microsoft Windows operating system on your client computer.

For more information on SSL certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152). For more information about using SSL with SQL Server, see Using SSL with a Microsoft SQL Server DB instance (p. 1176).

Granting access to domain users

In a new SSRS activation, there are no role assignments in SSRS. To give a domain user or user group access to the web portal, RDS provides a stored procedure.

To grant access to a domain user on the web portal

• Use the following stored procedure.
exec msdb.dbo.rds_msbi_task
@task_type='SSRS_GRANT_PORTAL_PERMISSION',
@ssrs_group_or_username=N'AD_domain\user';

The domain user or user group is granted the RDS_SSRS_ROLE system role. This role has the following system-level tasks granted to it:

- Run reports
- Manage jobs
- Manage shared schedules
- View shared schedules

The item-level role of Content Manager on the root folder is also granted.

**Accessing the web portal**

After the SSRS_GRANT_PORTAL_PERMISSION task finishes successfully, you have access to the portal using a web browser. The web portal URL has the following format.

```
https://rds_endpoint:port/Reports
```

In this format, the following applies:

- **rds_endpoint** – The endpoint for the RDS DB instance that you’re using with SSRS.
  
  You can find the endpoint on the Connectivity & security tab for your DB instance. For more information, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 1125).
- **port** – The listener port for SSRS that you set in the SSRS option.

**To access the web portal**

1. Enter the web portal URL in your browser.

   ```
   https://myssrsinstance.cg034itsfake.us-east-1.rds.amazonaws.com:8443/Reports
   ```

2. Log in with the credentials for a domain user that you granted access with the SSRS_GRANT_PORTAL_PERMISSION task.

**Deploying reports to SSRS**

After you have access to the web portal, you can deploy reports to it. You can use the Upload tool in the web portal to upload reports, or deploy directly from SQL Server data tools (SSDT). When deploying from SSDT, ensure the following:

- The user who launched SSDT has access to the SSRS web portal.
- The TargetServerURL value in the SSRS project properties is set to the HTTPS endpoint of the RDS DB instance suffixed with ReportServer, for example:

  ```
  ```
Using SSRS Email to send reports

SSRS includes the SSRS Email extension, which you can use to send reports to users.

To configure SSRS Email, use the SSRS option settings. For more information, see Adding the SSRS option to your option group (p. 1309).

After configuring SSRS Email, you can subscribe to reports on the report server. For more information, see Email delivery in Reporting Services in the Microsoft documentation.

Integration with AWS Secrets Manager is required for SSRS Email to function on RDS. To integrate with Secrets Manager, you create a secret.

**Note**
If you change the secret later, you also have to update the SSRS option in the option group.

To create a secret for SSRS Email

1. Follow the steps in Create a secret in the AWS Secrets Manager User Guide.
   a. For Select secret type, choose Other type of secrets.
   b. For Key/value pairs, enter the following:
      - **SMTP_USERNAME** – Enter a user with permission to send mail from the SMTP server.
      - **SMTP_PASSWORD** – Enter a password for the SMTP user.
   c. For Encryption key, don’t use the default AWS KMS key. Use your own existing key, or create a new one.

The KMS key policy must allow the kms:Decrypt action, for example:

```json
{
"Sid": "Allow use of the key",
"Effect": "Allow",
"Principal": {
"Service": [
  "rds.amazonaws.com"
],
"Action": [
  "kms:Decrypt"
],
"Resource": "*"
}
```

2. Follow the steps in Attach a permissions policy to a secret in the AWS Secrets Manager User Guide. The permissions policy gives the secretsmanager:GetSecretValue action to the rds.amazonaws.com service principal.

   We recommend that you use the aws:sourceAccount and aws:sourceArn conditions in the policy to avoid the confused deputy problem. Use your AWS account for aws:sourceAccount and the option group ARN for aws:sourceArn. For more information, see Preventing cross-service confused deputy problems (p. 2193).

   The following example shows a permissions policy.

```json
{
"Version": "2012-10-17",
"Statement": [
  "Effect": "Allow",
  "Principal": {
```

1315
Revoking system-level permissions

The RDS_SSRS_ROLE system role doesn't have sufficient permissions to delete system-level role assignments. To remove a user or user group from RDS_SSRS_ROLE, use the same stored procedure that you used to grant the role but use the SSRS_REVOKE_PORTAL_PERMISSION task type.

To revoke access from a domain user for the web portal

- Use the following stored procedure.

  ```
  exec msdb.dbo.rds_msbi_task
  @task_type='SSRS_REVOKE_PORTAL_PERMISSION',
  @ssrs_group_or_username=N'AD_domain\user';
  ```

  Doing this deletes the user from the RDS_SSRS_ROLE system role. It also deletes the user from the Content Manager item-level role if the user has it.

Monitoring the status of a task

To track the status of your granting or revoking task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to SSRS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

  ```
  SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
  ```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

  ```
  SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
  ```

The `rds_fn_task_status` function returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>Output parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>task_type</td>
<td>For SSRS, tasks can have the following task types:</td>
</tr>
<tr>
<td></td>
<td>• SSRS_GRANT_PORTAL_PERMISSION</td>
</tr>
<tr>
<td></td>
<td>• SSRS_REVOKE_PORTAL_PERMISSION</td>
</tr>
<tr>
<td>database_name</td>
<td>Not applicable to SSRS tasks.</td>
</tr>
<tr>
<td>% complete</td>
<td>The progress of the task as a percentage.</td>
</tr>
<tr>
<td>duration (mins)</td>
<td>The amount of time spent on the task, in minutes.</td>
</tr>
<tr>
<td>lifecycle</td>
<td>The status of the task. Possible statuses are the following:</td>
</tr>
<tr>
<td></td>
<td>• CREATED – After you call one of the SSRS stored procedures, a task is created and the status is set to CREATED.</td>
</tr>
<tr>
<td></td>
<td>• IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It can take up to five minutes for the status to change from CREATED to IN_PROGRESS.</td>
</tr>
<tr>
<td></td>
<td>• SUCCESS – After a task completes, the status is set to SUCCESS.</td>
</tr>
<tr>
<td></td>
<td>• ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column.</td>
</tr>
<tr>
<td></td>
<td>• CANCEL_REQUESTED – After you call the rds_cancel_task stored procedure, the status of the task is set to CANCEL_REQUESTED.</td>
</tr>
<tr>
<td></td>
<td>• CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.</td>
</tr>
<tr>
<td>task_info</td>
<td>Additional information about the task. If an error occurs during processing, this column contains information about the error.</td>
</tr>
<tr>
<td>last_updated</td>
<td>The date and time that the task status was last updated.</td>

</tbody>
</table>
### Turning off SSRS

To turn off SSRS, remove the SSRS option from its option group. Removing the option doesn't delete the SSRS databases. For more information, see Deleting the SSRS databases (p. 1318).

You can turn SSRS on again by adding back the SSRS option. If you have also deleted the SSRS databases, readding the option on the same DB instance creates new report server databases.

**Console**

**To remove the SSRS option from its option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSRS option (ssrs-se-2017 in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose SSRS for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

**CLI**

**To remove the SSRS option from its option group**

- Run one of the following commands.

  **Example**

  For Linux, macOS, or Unix:
  ```
  aws rds remove-option-from-option-group  
  --option-group-name ssrs-se-2017  
  --options SSRS  
  --apply-immediately
  ```

  For Windows:
  ```
  aws rds remove-option-from-option-group  
  --option-group-name ssrs-se-2017  
  --options SSRS  
  --apply-immediately
  ```

**Deleting the SSRS databases**

Removing the SSRS option doesn't delete the report server databases. To delete them, use the following stored procedure.

To delete the report server databases, be sure to remove the SSRS option first.

**To delete the SSRS databases**

- Use the following stored procedure.
exec msdb.dbo.rds_drop_ssrs_databases
Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server

A distributed transaction is a database transaction in which two or more network hosts are involved. RDS for SQL Server supports distributed transactions among hosts, where a single host can be one of the following:

- RDS for SQL Server DB instance
- On-premises SQL Server host
- Amazon EC2 host with SQL Server installed
- Any other EC2 host or RDS DB instance with a database engine that supports distributed transactions

In RDS, starting with SQL Server 2012 (version 11.00.5058.0.v1 and later), all editions of RDS for SQL Server support distributed transactions. The support is provided using Microsoft Distributed Transaction Coordinator (MSDTC). For in-depth information about MSDTC, see Distributed Transaction Coordinator in the Microsoft documentation.

Contents

- Limitations (p. 1320)
- Enabling MSDTC (p. 1321)
  - Creating the option group for MSDTC (p. 1321)
  - Adding the MSDTC option to the option group (p. 1322)
  - Creating the parameter group for MSDTC (p. 1324)
  - Modifying the parameter for MSDTC (p. 1324)
  - Associating the option group and parameter group with the DB instance (p. 1325)
- Using distributed transactions (p. 1327)
- Using XA transactions (p. 1327)
- Using transaction tracing (p. 1328)
- Modifying the MSDTC option (p. 1329)
- Disabling MSDTC (p. 1329)
- Troubleshooting MSDTC for RDS for SQL Server (p. 1330)

Limitations

The following limitations apply to using MSDTC on RDS for SQL Server:

- MSDTC isn't supported on instances using SQL Server Database Mirroring. For more information, see Transactions - availability groups and database mirroring.
- The in-doubt xact resolution parameter must be set to 1 or 2. For more information, see Modifying the parameter for MSDTC (p. 1324).
- MSDTC requires all hosts participating in distributed transactions to be resolvable using their host names. RDS automatically maintains this functionality for domain-joined instances. However, for standalone instances make sure to configure the DNS server manually.
- Java Database Connectivity (JDBC) XA transactions are supported for SQL Server 2017 version 14.00.3223.3 and higher, and SQL Server 2019.
- Distributed transactions that depend on client dynamic link libraries (DLLs) on RDS instances aren't supported.
- Using custom XA dynamic link libraries isn't supported.
Enabling MSDTC

Use the following process to enable MSDTC for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the MSDTC option to the option group.
3. Create a new parameter group, or choose an existing parameter group.
4. Modify the parameter group to set the in-doubt xact resolution parameter to 1 or 2.
5. Associate the option group and parameter group with the DB instance.

Creating the option group for MSDTC

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of your DB instance.

Note
You can also use an existing option group if it's for the correct SQL Server engine and version.

Console

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose Create group.
4. In the Create option group pane, do the following:
   a. For Name, enter a name for the option group that is unique within your AWS account, such as msdtc-se-2016. The name can contain only letters, digits, and hyphens.
   b. For Description, enter a brief description of the option group, such as MSDTC option group for SQL Server SE 2016. The description is used for display purposes.
   c. For Engine, choose sqlserver-se.
   d. For Major engine version, choose 13.00.
5. Choose Create.

CLI

The following example creates an option group for SQL Server Standard Edition 2016.

To create the option group

• Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-option-group \
  --option-group-name msdtc-se-2016 \
  --engine-name sqlserver-se \
  --major-engine-version 13.00 \
```
For Windows:

```bash
aws rds create-option-group
--option-group-name msdtc-se-2016
--engine-name sqlserver-se
--major-engine-version 13.00
--option-group-description "MSDTC option group for SQL Server SE 2016"
```

### Adding the MSDTC option to the option group

Next, use the AWS Management Console or the AWS CLI to add the MSDTC option to the option group.

The following option settings are required:

- **Port** – The port that you use to access MSDTC. Allowed values are 1150–49151 except for 1234, 1434, 3260, 3343, 3389, and 47001. The default value is 5000.

  Make sure that the port you want to use is enabled in your firewall rules. Also, make sure as needed that this port is enabled in the inbound and outbound rules for the security group associated with your DB instance. For more information, see [Can't connect to Amazon RDS DB instance](p. 2289).

- **Security groups** – The VPC security group memberships for your RDS DB instance.

- **Authentication type** – The authentication mode between hosts. The following authentication types are supported:
  - **Mutual** – The RDS instances are mutually authenticated to each other using integrated authentication. If this option is selected, all instances associated with this option group must be domain-joined.
  - **None** – No authentication is performed between hosts. We don't recommend using this mode in production environments.

- **Transaction log size** – The size of the MSDTC transaction log. Allowed values are 4–1024 MB. The default size is 4 MB.

The following option settings are optional:

- **Enable inbound connections** – Whether to allow inbound MSDTC connections to instances associated with this option group.

- **Enable outbound connections** – Whether to allow outbound MSDTC connections from instances associated with this option group.

- **Enable SNA LU** – Whether to allow the SNA LU protocol to be used for distributed transactions. For more information on SNA LU protocol support, see [Managing IBM CICS LU 6.2 transactions](https://docs.microsoft.com/en-us/dynamics-crm/crm-technical-reference/managing-ibm-cics-lu-6-2-transactions) in the Microsoft documentation.

### Console

**To add the MSDTC option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **MSDTC** for **Option name**.
6. Under **Option settings**:
   a. For **Port**, enter the port number for accessing MSDTC. The default is **5000**.
   b. For **Security groups**, choose the VPC security group to associate with the option.
   c. For **Authentication type**, choose **Mutual** or **None**.
   d. For **Transaction log size**, enter a value from 4–1024. The default is **4**.
7. Under **Additional configuration**, do the following:
   a. For **Connections**, as needed choose **Enable inbound connections** and **Enable outbound connections**.
   b. For **Allowed protocols**, as needed choose **Enable XA** and **Enable SNA LU**.
8. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
9. Choose **Add option**.

To add this option, no reboot is required.

**CLI**

**To add the MSDTC option**

1. Create a JSON file, for example **msdtc-option.json**, with the following required parameters.

   ```json
   {
   "OptionGroupName": "msdtc-se-2016",
   "OptionsToInclude": [
   {
   "OptionName": "MSDTC",
   "Port": 5000,
   "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
   "OptionSettings": [
   {"Name": "AUTHENTICATION", "Value": "MUTUAL"},
   {"Name": "TRANSACTION_LOG_SIZE", "Value": "4"}
   ]
   },
   "ApplyImmediately": true
   }
   }
   ```

2. Add the MSDTC option to the option group.

   **Example**

   For Linux, macOS, or Unix:

   ```bash
   aws rds add-option-to-option-group
   --cli-input-json file://msdtc-option.json
   --apply-immediately
   ```

   For Windows:

   ```bash
   aws rds add-option-to-option-group ^
   --cli-input-json file://msdtc-option.json ^
   --apply-immediately
   ```

   No reboot is required.
Creating the parameter group for MSDTC

Create or modify a parameter group for the in-doubt xact resolution parameter that corresponds to the SQL Server edition and version of your DB instance.

Console

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
4. In the Create parameter group pane, do the following:
   a. For Parameter group family, choose sqlserver-se-13.0.
   b. For Group name, enter an identifier for the parameter group, such as msdtc-sqlserver-se-13.
   c. For Description, enter in-doubt xact resolution.
5. Choose Create.

CLI

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-parameter-group \
  --db-parameter-group-name msdtc-sqlserver-se-13 \
  --db-parameter-group-family "sqlserver-se-13.0" \
  --description "in-doubt xact resolution"
```

For Windows:

```bash
aws rds create-db-parameter-group ^
  --db-parameter-group-name msdtc-sqlserver-se-13 ^
  --db-parameter-group-family "sqlserver-se-13.0" ^
  --description "in-doubt xact resolution"
```

Modifying the parameter for MSDTC

Modify the in-doubt xact resolution parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

For MSDTC, set the in-doubt xact resolution parameter to one of the following:

- 1 – Presume commit. Any MSDTC in-doubt transactions are presumed to have committed.
• 2 – Presume abort. Any MSDTC in-doubt transactions are presumed to have stopped.

For more information, see in-doubt xact resolution server configuration option in the Microsoft documentation.

**Console**

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

**To modify the parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group, such as msdtc-sqlserver-se-13.
4. Under Parameters, filter the parameter list for xact.
5. Choose in-doubt xact resolution.
6. Choose Edit parameters.
7. Enter 1 or 2.
8. Choose Save changes.

**CLI**

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

**To modify the parameter group**

• Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name msdtc-sqlserver-se-13 \
   --parameters "ParameterName='in-doubt xact resolution',ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
   --db-parameter-group-name msdtc-sqlserver-se-13 ^
   --parameters "ParameterName='in-doubt xact resolution',ParameterValue=1,ApplyMethod=immediate"
```

**Associating the option group and parameter group with the DB instance**

You can use the AWS Management Console or the AWS CLI to associate the MSDTC option group and parameter group with the DB instance.

**Console**

You can associate the MSDTC option group and parameter group with a new or existing DB instance.
For a new DB instance, associate them when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).

For an existing DB instance, associate them by modifying the instance. For more information, see Modifying an Amazon RDS DB instance (p. 333).

**Note**

If you use an domain-joined existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1184).

**CLI**

You can associate the MSDTC option group and parameter group with a new or existing DB instance.

**Note**

If you use an existing domain-joined DB instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1184).

**To create a DB instance with the MSDTC option group and parameter group**

- Specify the same DB engine type and major version as you used when creating the option group.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance
   --db-instance-identifier mydbinstance
   --db-instance-class db.m5.2xlarge
   --engine sqlserver-se
   --engine-version 13.00.5426.0.v1
   --allocated-storage 100
   --master-user-password secret123
   --master-username admin
   --storage-type gp2
   --license-model li
   --domain-iam-role-name my-directory-iam-role
   --domain my-domain-id
   --option-group-name msdtc-se-2016
   --db-parameter-group-name msdtc-sqlserver-se-13
```

For Windows:

```bash
aws rds create-db-instance
   --db-instance-identifier mydbinstance
   --db-instance-class db.m5.2xlarge
   --engine sqlserver-se
   --engine-version 13.00.5426.0.v1
   --allocated-storage 100
   --master-user-password secret123
   --master-username admin
   --storage-type gp2
   --license-model li
   --domain-iam-role-name my-directory-iam-role
   --domain my-domain-id
   --option-group-name msdtc-se-2016
```

1326
To modify a DB instance and associate the MSDTC option group and parameter group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \\
  --db-instance-identifier mydbinstance \\
  --option-group-name msdtc-se-2016 \\
  --db-parameter-group-name msdtc-sqlserver-se-13 \\
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --option-group-name msdtc-se-2016 ^
  --db-parameter-group-name msdtc-sqlserver-se-13 ^
  --apply-immediately
```

Using distributed transactions

In Amazon RDS for SQL Server, you run distributed transactions in the same way as distributed transactions running on-premises:

- Using .NET framework `System.Transactions` promotable transactions, which optimizes distributed transactions by deferring their creation until they're needed.

In this case, promotion is automatic and doesn't require you to make any intervention. If there's only one resource manager within the transaction, no promotion is performed. For more information about implicit transaction scopes, see Implementing an implicit transaction using transaction scope in the Microsoft documentation.

Promotable transactions are supported with these .NET implementations:

- Starting with ADO.NET 2.0, `System.Data.SqlClient` supports promotable transactions with SQL Server. For more information, see System.Transactions integration with SQL Server in the Microsoft documentation.

- ODP.NET supports `System.Transactions`. A local transaction is created for the first connection opened in the TransactionsScope scope to Oracle Database 11g release 1 (version 11.1) and later. When a second connection is opened, this transaction is automatically promoted to a distributed transaction. For more information about distributed transaction support in ODP.NET, see Microsoft Distributed Transaction Coordinator integration in the Microsoft documentation.

- Using the `BEGIN DISTRIBUTED TRANSACTION` statement. For more information, see BEGIN DISTRIBUTED TRANSACTION (Transact-SQL) in the Microsoft documentation.

Using XA transactions

Starting from RDS for SQL Server 2017 version 14.00.3223.3, you can control distributed transactions using JDBC. When you set the Enable XA option setting to true in the MSDTC option, RDS
automatically enables JDBC transactions and grants the SqlJDBCXAUser role to the guest user. This allows executing distributed transactions through JDBC. For more information, including a code example, see Understanding XA transactions in the Microsoft documentation.

Using transaction tracing

RDS supports controlling MSDTC transaction traces and downloading them from the RDS DB instance for troubleshooting. You can control transaction tracing sessions by running the following RDS stored procedure.

```sql
exec msdb.dbo.rds_msdtc_transaction_tracing 'trace_action',
[@traceall='0|1'],
[@traceaborted='0|1'],
[@tracelong='0|1'];
```

The following parameter is required:

- `trace_action` – The tracing action. It can be START, STOP, or STATUS.

The following parameters are optional:

- `@traceall` – Set to 1 to trace all distributed transactions. The default is 0.
- `@traceaborted` – Set to 1 to trace canceled distributed transactions. The default is 0.
- `@tracelong` – Set to 1 to trace long-running distributed transactions. The default is 0.

**Example of START tracing action**

To start a new transaction tracing session, run the following example statement.

```sql
exec msdb.dbo.rds_msdtc_transaction_tracing 'START',
@traceall='0',
@traceaborted='1',
@tracelong='1';
```

**Note**

Only one transaction tracing session can be active at one time. If a new tracing session START command is issued while a tracing session is active, an error is returned and the active tracing session remains unchanged.

**Example of STOP tracing action**

To stop a transaction tracing session, run the following statement.

```sql
exec msdb.dbo.rds_msdtc_transaction_tracing 'STOP'
```

This statement stops the active transaction tracing session and saves the transaction trace data into the log directory on the RDS DB instance. The first row of the output contains the overall result, and the following lines indicate details of the operation.

The following is an example of a successful tracing session stop.

**OK: Trace session has been successfully stopped.**

Setting log file to: D:\\rdsdbdata\\MSDTC\\Trace\\dtctrace.log
Examining D:\\rdsdbdata\\MSDTC\\Trace\\msdtctr.mof for message formats, 8 found.
Searching for TMF files on path: (null)
Logfile D:\rdsdbdata\MSDTC\Trace\dtctrace.log:
OS version 10.0.14393 (Currently running on 6.2.9200)
Start Time <timestamp>
End Time <timestamp>
Timezone is @tzres.dll,-932 (Bias is 0mins)
BufferSize 16384 B
Maximum File Size 10 MB
Buffers Written Not set (Logger may not have been stopped).
Logger Mode Settings (11000002) (circular paged)
ProcessorCount 1
Processing completed Buffers: 1, Events: 3, EventsLost: 0 :: Format Errors: 0, Unknowns: 3
Event traces dumped to d:\rdsdbdata\Log\msdtc_<timestamp>.log

You can use the detailed information to query the name of the generated log file. For more information about downloading log files from the RDS DB instance, see Monitoring Amazon RDS log files (p. 716).

The trace session logs remain on the instance for 35 days. Any older trace session logs are automatically deleted.

**Example of STATUS tracing action**

To trace the status of a transaction tracing session, run the following statement.

```sql
exec msdb.dbo.rds_msdtc_transaction_tracing 'STATUS'
```

This statement outputs the following as separate rows of the result set.

```
| SessionStatus: <Started|Stopped> |
| TraceAll: <True|False> |
| TraceAborted: <True|False> |
| TraceLongLived: <True|False> |
```

The first line indicates the overall result of the operation: OK or ERROR with details, if applicable. The subsequent lines indicate details about the tracing session status:

- **SessionStatus** can be one of the following:
  - Started if a tracing session is running.
  - Stopped if no tracing session is running.
- The tracing session flags can be True or False depending on how they were set in the START command.

**Modifying the MSDTC option**

After you enable the MSDTC option, you can modify its settings. For information about how to modify option settings, see Modifying an option setting (p. 288).

**Note**

Some changes to MSDTC option settings require the MSDTC service to be restarted. This requirement can affect running distributed transactions.

**Disabling MSDTC**

To disable MSDTC, remove the MSDTC option from its option group.
Console

To remove the MSDTC option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the option group with the MSDTC option (msdtc-se-2016 in the previous examples).
4. Choose Delete option.
5. Under Deletion options, choose MSDTC for Options to delete.
6. Under Apply immediately, choose Yes to delete the option immediately, or No to delete it at the next maintenance window.
7. Choose Delete.

CLI

To remove the MSDTC option from its option group

• Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

  ```
  aws rds remove-option-from-option-group
  --option-group-name msdtc-se-2016
  --options MSDTC
  --apply-immediately
  ```

  For Windows:

  ```
  aws rds remove-option-from-option-group
  --option-group-name msdtc-se-2016
  --options MSDTC
  --apply-immediately
  ```

Troubleshooting MSDTC for RDS for SQL Server

In some cases, you might have trouble establishing a connection between MSDTC running on a client computer and the MSDTC service running on an RDS for SQL Server DB instance. If so, make sure of the following:

• The inbound rules for the security group associated with the DB instance are configured correctly. For more information, see Can't connect to Amazon RDS DB instance (p. 2289).
• Your client computer is configured correctly.
• The MSDTC firewall rules on your client computer are enabled.

To configure the client computer

1. Open Component Services.
   Or, in Server Manager, choose Tools, and then choose Component Services.
2. Expand **Component Services**, expand **Computers**, expand **My Computer**, and then expand **Distributed Transaction Coordinator**.

3. Open the context (right-click) menu for **Local DTC** and choose **Properties**.

4. Choose the **Security** tab.

5. Choose all of the following:
   - **Network DTC Access**
   - **Allow Inbound**
   - **Allow Outbound**

6. Make sure that the correct authentication mode is chosen:
   - **Mutual Authentication Required** – The client machine is joined to the same domain as other nodes participating in distributed transaction, or there is a trust relationship configured between domains.
   - **No Authentication Required** – All other cases.

7. Choose **OK** to save your changes.

8. If prompted to restart the service, choose **Yes**.

**To enable MSDTC firewall rules**

1. Open Windows Firewall, then choose **Advanced settings**.

   Or, in **Server Manager**, choose **Tools**, and then choose **Windows Firewall with Advanced Security**.

   **Note**
   Depending on your operating system, Windows Firewall might be called Windows Defender Firewall.

2. Choose **Inbound Rules** in the left pane.

3. Enable the following firewall rules, if they are not already enabled:
   - **Distributed Transaction Coordinator (RPC)**
   - **Distributed Transaction Coordinator (RPC)-EPMAP**
   - **Distributed Transaction Coordinator (TCP-In)**

Common DBA tasks for Microsoft SQL Server

This section describes the Amazon RDS-specific implementations of some common DBA tasks for DB instances that are running the Microsoft SQL Server database engine. In order to deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges.

**Note**
When working with a SQL Server DB instance, you can run scripts to modify a newly created database, but you cannot modify the [model] database, the database used as the model for new databases.

**Topics**
- Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS (p. 1333)
- Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor (p. 1335)
- Collations and character sets for Microsoft SQL Server (p. 1337)
- Creating a database user (p. 1340)
- Determining a recovery model for your Microsoft SQL Server database (p. 1341)
- Determining the last failover time (p. 1341)
- Disabling fast inserts during bulk loading (p. 1342)
- Dropping a Microsoft SQL Server database (p. 1342)
- Renaming a Microsoft SQL Server database in a Multi-AZ deployment (p. 1342)
- Resetting the db_owner role password (p. 1343)
- Restoring license-terminated DB instances (p. 1343)
- Transitioning a Microsoft SQL Server database from OFFLINE to ONLINE (p. 1344)
- Using change data capture (p. 1344)
- Using SQL Server Agent (p. 1346)
- Working with Microsoft SQL Server logs (p. 1349)
- Working with trace and dump files (p. 1350)
Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS

You can access the tempdb database on your Microsoft SQL Server DB instances on Amazon RDS. You can run code on tempdb by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information about connecting to your DB instance, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 1125).

The master user for your DB instance is granted CONTROL access to tempdb so that this user can modify the tempdb database options. The master user isn't the database owner of the tempdb database. If necessary, the master user can grant CONTROL access to other users so that they can also modify the tempdb database options.

**Note**
You can't run Database Console Commands (DBCC) on the tempdb database.

Modifying tempdb database options

You can modify the database options on the tempdb database on your Amazon RDS DB instances. For more information about which options can be modified, see tempdb database in the Microsoft documentation.

Database options such as the maximum file size options are persistent after you restart your DB instance. You can modify the database options to optimize performance when importing data, and to prevent running out of storage.

Optimizing performance when importing data

To optimize performance when importing large amounts of data into your DB instance, set the SIZE and FILEGROWTH properties of the tempdb database to large numbers. For more information about how to optimize tempdb, see Optimizing tempdb performance in the Microsoft documentation.

The following example demonstrates setting the size to 100 GB and file growth to 10 percent.

```sql
alter database[tempdb] modify file (NAME = N'templog', SIZE=100GB, FILEGROWTH = 10%)
```

Preventing storage problems

To prevent the tempdb database from using all available disk space, set the MAXSIZE property. The following example demonstrates setting the property to 2048 MB.

```sql
alter database [tempdb] modify file (NAME = N'templog', MAXSIZE = 2048MB)
```

Shrinking the tempdb database

There are two ways to shrink the tempdb database on your Amazon RDS DB instance. You can use the rds_shrink_tempdbfile procedure, or you can set the SIZE property.

**Using the rds_shrink_tempdbfile procedure**

You can use the Amazon RDS procedure msdb..dbo..rds_shrink_tempdbfile to shrink the tempdb database. You can only call rds_shrink_tempdbfile if you have CONTROL access to tempdb. When you call rds_shrink_tempdbfile, there is no downtime for your DB instance.
The `rds_shrink_tempdbfile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@temp_filename</td>
<td>SYSNAME</td>
<td>—</td>
<td>required</td>
<td>The logical name of the file to shrink.</td>
</tr>
<tr>
<td>@target_size</td>
<td>int</td>
<td>null</td>
<td>optional</td>
<td>The new size for the file, in megabytes.</td>
</tr>
</tbody>
</table>

The following example gets the names of the files for the `tempdb` database.

```
use tempdb;
GO
select name, * from sys.sysfiles;
GO
```

The following example shrinks a `tempdb` database file named `test_file`, and requests a new size of 10 megabytes:

```
exec msdb.dbo.rds_shrink_tempdbfile @temp_filename = N'test_file', @target_size = 10;
```

**Setting the SIZE property**

You can also shrink the `tempdb` database by setting the SIZE property and then restarting your DB instance. For more information about restarting your DB instance, see Rebooting a DB instance (p. 378).

The following example demonstrates setting the SIZE property to 1024 MB.

```
alter database [tempdb] modify file (NAME = N'templog', SIZE = 1024MB)
```

**Considerations for Multi-AZ deployments**

If your Amazon RDS DB instance is in a Multi-AZ Deployment for Microsoft SQL Server with Database Mirroring (DBM) or Always On Availability Groups (AGs), there are some things to consider.

The `tempdb` database can't be replicated. No data that you store on your primary instance is replicated to your secondary instance.

If you modify any database options on the `tempdb` database, you can capture those changes on the secondary by using one of the following methods:

- First modify your DB instance and turn Multi-AZ off, then modify tempdb, and finally turn Multi-AZ back on. This method doesn't involve any downtime.
  For more information, see Modifying an Amazon RDS DB instance (p. 333).
- First modify `tempdb` in the original primary instance, then fail over manually, and finally modify `tempdb` in the new primary instance. This method involves downtime.
  For more information, see Rebooting a DB instance (p. 378).
Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor

Database Engine Tuning Advisor is a client application provided by Microsoft that analyzes database workload and recommends an optimal set of indexes for your Microsoft SQL Server databases based on the kinds of queries you run. Like SQL Server Management Studio, you run Tuning Advisor from a client computer that connects to your Amazon RDS DB instance that is running SQL Server. The client computer can be a local computer that you run on premises within your own network or it can be an Amazon EC2 Windows instance that is running in the same region as your Amazon RDS DB instance.

This section shows how to capture a workload for Tuning Advisor to analyze. This is the preferred process for capturing a workload because Amazon RDS restricts host access to the SQL Server instance. For more information, see Database Engine Tuning Advisor in the Microsoft documentation.

To use Tuning Advisor, you must provide what is called a workload to the advisor. A workload is a set of Transact-SQL statements that run against a database or databases that you want to tune. Database Engine Tuning Advisor uses trace files, trace tables, Transact-SQL scripts, or XML files as workload input when tuning databases. When working with Amazon RDS, a workload can be a file on a client computer or a database table on an Amazon RDS for SQL Server DB accessible to your client computer. The file or the table must contain queries against the databases you want to tune in a format suitable for replay.

For Tuning Advisor to be most effective, a workload should be as realistic as possible. You can generate a workload file or table by performing a trace against your DB instance. While a trace is running, you can either simulate a load on your DB instance or run your applications with a normal load.

There are two types of traces: client-side and server-side. A client-side trace is easier to set up and you can watch trace events being captured in real-time in SQL Server Profiler. A server-side trace is more complex to set up and requires some Transact-SQL scripting. In addition, because the trace is written to a file on the Amazon RDS DB instance, storage space is consumed by the trace. It is important to track of how much storage space a running server-side trace uses because the DB instance could enter a storage-full state and would no longer be available if it runs out of storage space.

For a client-side trace, when a sufficient amount of trace data has been captured in the SQL Server Profiler, you can then generate the workload file by saving the trace to either a file on your local computer or in a database table on a DB instance that is available to your client computer. The main disadvantage of using a client-side trace is that the trace may not capture all queries when under heavy loads. This could weaken the effectiveness of the analysis performed by the Database Engine Tuning Advisor. If you need to run a trace under heavy loads and you want to ensure that it captures every query during a trace session, you should use a server-side trace.

For a server-side trace, you must get the trace files on the DB instance into a suitable workload file or you can save the trace to a table on the DB instance after the trace completes. You can use the SQL Server Profiler to save the trace to a file on your local computer or have the Tuning Advisor read from the trace table on the DB instance.

Running a client-side trace on a SQL Server DB instance

To run a client-side trace on a SQL Server DB instance

1. Start SQL Server Profiler. It is installed in the Performance Tools folder of your SQL Server instance folder. You must load or define a trace definition template to start a client-side trace.
2. In the SQL Server Profiler File menu, choose New Trace. In the Connect to Server dialog box, enter the DB instance endpoint, port, master user name, and password of the database you would like to run a trace on.
3. In the **Trace Properties** dialog box, enter a trace name and choose a trace definition template. A default template, TSQL_Replay, ships with the application. You can edit this template to define your trace. Edit events and event information under the **Events Selection** tab of the **Trace Properties** dialog box.

   For more information about trace definition templates and using the SQL Server Profiler to specify a client-side trace, see *Database Engine Tuning Advisor* in the Microsoft documentation.

4. Start the client-side trace and watch SQL queries in real-time as they run against your DB instance.

5. Select **Stop Trace** from the **File** menu when you have completed the trace. Save the results as a file or as a trace table on your DB instance.

### Running a server-side trace on a SQL Server DB instance

Writing scripts to create a server-side trace can be complex and is beyond the scope of this document. This section contains sample scripts that you can use as examples. As with a client-side trace, the goal is to create a workload file or trace table that you can open using the Database Engine Tuning Advisor.

The following is an abridged example script that starts a server-side trace and captures details to a workload file. The trace initially saves to the file RDSTrace.trc in the D:\RDSDBDATA\Log directory and rolls-over every 100 MB so subsequent trace files are named RDSTrace_1.trc, RDSTrace_2.trc, etc.

```sql
DECLARE @file_name NVARCHAR(245) = 'D:\RDSDBDATA\Log\RDSTrace';
DECLARE @max_file_size BIGINT = 100;
DECLARE @on BIT = 1
DECLARE @rc INT
DECLARE @traceid INT
EXEC @rc = sp_trace_create @traceid OUTPUT, 2, @file_name, @max_file_size
IF (@rc = 0) BEGIN
  EXEC sp_trace_setevent @traceid, 10, 1, @on
  EXEC sp_trace_setevent @traceid, 10, 2, @on
  EXEC sp_trace_setevent @traceid, 10, 3, @on
  ... EXEC sp_trace_setfilter @traceid, 10, 0, 7, N'SQL Profiler'
  EXEC sp_trace_setstatus @traceid, 1
END

The following example is a script that stops a trace. Note that a trace created by the previous script continues to run until you explicitly stop the trace or the process runs out of disk space.

```sql
DECLARE @traceid INT
SELECT @traceid = traceid FROM ::fn_trace_getinfo(default)
WHERE property = 5 AND value = 1 AND traceid <> 1
IF @traceid IS NOT NULL BEGIN
  EXEC sp_trace_setstatus @traceid, 0
  EXEC sp_trace_setstatus @traceid, 2
END
```

You can save server-side trace results to a database table and use the database table as the workload for the Tuning Advisor by using the fn_trace_gettable function. The following commands load the results of all files named RDSTrace.trc in the D:\rdsdbdata\Log directory, including all rollover files like RDSTrace_1.trc, into a table named RDSTrace in the current database.

```sql
SELECT * INTO RDSTrace
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace.trc', default);
```
To save a specific rollover file to a table, for example the RDSTrace_1.trc file, specify the name of the rollover file and substitute 1 instead of default as the last parameter to fn_trace_gettable.

```
SELECT * INTO RDSTrace_1
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace_1.trc', 1);
```

**Running Tuning Advisor with a trace**

Once you create a trace, either as a local file or as a database table, you can then run Tuning Advisor against your DB instance. Using Tuning Advisor with Amazon RDS is the same process as when working with a standalone, remote SQL Server instance. You can either use the Tuning Advisor UI on your client machine or use the dta.exe utility from the command line. In both cases, you must connect to the Amazon RDS DB instance using the endpoint for the DB instance and provide your master user name and master user password when using Tuning Advisor.

The following code example demonstrates using the dta.exe command line utility against an Amazon RDS DB instance with an endpoint of dta.cnazcmklsdei.us-east-1.rds.amazonaws.com. The example includes the master user name admin and the master user password test, the example database to tune is named machine named C:\RDSTrace.trc. The example command line code also specifies a trace session named RDSTrace1 and specifies output files to the local machine named RDSTrace.sql for the SQL output script, RDSTrace.txt for a result file, and RDSTrace.xml for an XML file of the analysis. There is also an error table specified on the RDSDTA database named RDSTraceErrors.

```
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RDSDTA -if C:\RDSTrace.trc -s RDSTrace1 -of C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\ RDSTrace.xml -e RDSDTA.dbo.RDSTraceErrors
```

Here is the same example command line code except the input workload is a table on the remote Amazon RDS instance named RDSTrace which is on the RDSDTA database.

```
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RDSDTA -it RDSDTA.dbo.RDSTrace -s RDSTrace1 -of C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\ RDSTrace.xml -e RDSDTA.dbo.RDSTraceErrors
```

For a full list of dta utility command-line parameters, see dta Utility in the Microsoft documentation.

**Collations and character sets for Microsoft SQL Server**

SQL Server supports collations at multiple levels. You set the default server collation when you create the DB instance. You can override the collation in the database, table, or column level.

**Topics**
- Server-level collation for Microsoft SQL Server (p. 1337)
- Database-level collation for Microsoft SQL Server (p. 1340)

**Server-level collation for Microsoft SQL Server**

When you create a Microsoft SQL Server DB instance, you can set the server collation that you want to use. If you don't choose a different collation, the server-level collation defaults to SQL_Latin1_General_CP1_CI_AS. The server collation is applied by default to all databases and database objects.
**Note**
You can't change the collation when you restore from a DB snapshot.

Currently, Amazon RDS supports the following server collations:

<table>
<thead>
<tr>
<th>Collation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chinese_PRC_BIN2</td>
<td>Chinese-PRC, binary code point sort order</td>
</tr>
<tr>
<td>Chinese_PRC_CI_AS</td>
<td>Chinese-PRC, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Chinese_Taiwan_Stroke_CI_AS</td>
<td>Chinese-Taiwan-Stroke, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Danish_Norwegian_CI_AS</td>
<td>Danish-Norwegian, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Finnish_Swedish_CI_AS</td>
<td>Finnish, Swedish, and Swedish (Finland), case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>French_CI_AS</td>
<td>French, case-insensitive, accent-sensitive, kanatype-insensitive</td>
</tr>
<tr>
<td>Hebrew_BIN</td>
<td>Hebrew, binary sort</td>
</tr>
<tr>
<td>Hebrew_CI_AS</td>
<td>Hebrew, case-insensitive, accent-sensitive, kanatype-insensitive</td>
</tr>
<tr>
<td>Japanese_BIN</td>
<td>Japanese, binary sort</td>
</tr>
<tr>
<td>Japanese_CI_AS</td>
<td>Japanese, case-insensitive, accent-sensitive, kanatype-insensitive</td>
</tr>
<tr>
<td>Japanese_CS_AS</td>
<td>Japanese, case-sensitive, accent-sensitive, kanatype-insensitive</td>
</tr>
<tr>
<td>Korean_Wansung_CI_AS</td>
<td>Korean-Wansung, case-insensitive, accent-sensitive, kanatype-insensitive</td>
</tr>
<tr>
<td>Latin1_General_100_BIN</td>
<td>Latin1-General-100, binary sort</td>
</tr>
<tr>
<td>Latin1_General_100_BIN2</td>
<td>Latin1-General-100, binary code point sort order</td>
</tr>
<tr>
<td>Latin1_General_100_CI_AS</td>
<td>Latin1-General-100, case-insensitive, accent-sensitive, kanatype-insensitive</td>
</tr>
<tr>
<td>Latin1_General_BIN</td>
<td>Latin1-General, binary sort</td>
</tr>
<tr>
<td>Latin1_General_BIN2</td>
<td>Latin1-General, binary code point sort order</td>
</tr>
<tr>
<td>Latin1_General_CI_AI</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive</td>
</tr>
<tr>
<td>Latin1_General_CI_AS</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive</td>
</tr>
<tr>
<td>Latin1_General_CI_AS_KS</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-sensitive</td>
</tr>
</tbody>
</table>
# Collations and character sets

<table>
<thead>
<tr>
<th>Collation</th>

</tr>
<tr>
<td>Thai_CI_AS</td>
<td>Thai, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
</tbody>
</table>

To choose the collation:

- If you’re using the Amazon RDS console, when creating a new DB instance choose **Additional configuration**, then choose the collation from the **Collation** menu under **Database options**. For more information, see Creating an Amazon RDS DB instance (p. 236).
- If you’re using the AWS CLI, use the `--character-set-name` option with the `create-db-instance` command. For more information, see `create-db-instance`.  

1339
• If you're using the Amazon RDS API, use the CharacterSetName parameter with the CreateDBInstance operation. For more information, see CreateDBInstance.

Database-level collation for Microsoft SQL Server

You can change the default collation at the database, table, or column level by overriding the collation when creating a new database or database object. For example, if your default server collation is SQL_Latin1_General_CP1_CI_AS, you can change it to Mohawk_100_CI_AS for Mohawk collation support. Even arguments in a query can be type-cast to use a different collation if necessary.

For example, the following query would change the default collation for the AccountName column to Mohawk_100_CI_AS

```sql
CREATE TABLE [dbo].[Account]
(
    [AccountID] [nvarchar](10) NOT NULL,
    [AccountName] [nvarchar](100) COLLATE Mohawk_100_CI_AS NOT NULL
) ON [PRIMARY];
```

The Microsoft SQL Server DB engine supports Unicode by the built-in NCHAR, NVARCHAR, and NTEXT data types. For example, if you need CJK support, use these Unicode data types for character storage and override the default server collation when creating your databases and tables. Here are several links from Microsoft covering collation and Unicode support for SQL Server:

- Working with collations
- Collation and international terminology
- Using SQL Server collations
- International considerations for databases and database engine applications

Creating a database user

You can create a database user for your Amazon RDS for Microsoft SQL Server DB instance by running a T-SQL script like the following example. Use an application such as SQL Server Management Suite (SSMS). You log into the DB instance as the master user that was created when you created the DB instance.

```sql
--Initially set context to master database
USE [master];
GO
--Create a server-level login named theirname with password theirpassword
CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';
GO
--Set context to msdb database
USE [msdb];
GO
--Create a database user named theirname and link it to server-level login theirname
CREATE USER [theirname] FOR LOGIN [theirname];
GO
```

For an example of adding a database user to a role, see Adding a user to the SQLAgentUser role (p. 1348).

Note
If you get permission errors when adding a user, you can restore privileges by modifying the DB instance master user password. For more information, see Resetting the db_owner role password (p. 1343).
Determining a recovery model for your Microsoft SQL Server database

In Amazon RDS, the recovery model, retention period, and database status are linked.

It's important to understand the consequences before making a change to one of these settings. Each setting can affect the others. For example:

- If you change a database's recovery model to SIMPLE or BULK_LOGGED while backup retention is enabled, Amazon RDS resets the recovery model to FULL within five minutes. This also results in RDS taking a snapshot of the DB instance.
- If you set backup retention to 0 days, RDS sets the recovery mode to SIMPLE.
- If you change a database's recovery model from SIMPLE to any other option while backup retention is set to 0 days, RDS resets the recovery model to SIMPLE.

**Important**

Never change the recovery model on Multi-AZ instances, even if it seems you can do so—for example, by using ALTER DATABASE. Backup retention, and therefore FULL recovery mode, is required for Multi-AZ. If you alter the recovery model, RDS immediately changes it back to FULL. This automatic reset forces RDS to completely rebuild the mirror. During this rebuild, the availability of the database is degraded for about 30-90 minutes until the mirror is ready for failover. The DB instance also experiences performance degradation in the same way it does during a conversion from Single-AZ to Multi-AZ. How long performance is degraded depends on the database storage size—the bigger the stored database, the longer the degradation.

For more information on SQL Server recovery models, see Recovery models (SQL Server) in the Microsoft documentation.

Determining the last failover time

To determine the last failover time, use the following stored procedure:

```
execute msdb.dbo.rds_failover_time;
```

This procedure returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>errorlog_available_from</td>
<td>Shows the time from when error logs are available in the log directory.</td>
</tr>
<tr>
<td>recent_failover_time</td>
<td>Shows the last failover time if it's available from the error logs. Otherwise it shows null.</td>
</tr>
</tbody>
</table>

**Note**

The stored procedure searches all of the available SQL Server error logs in the log directory to retrieve the most recent failover time. If the failover messages have been overwritten by SQL Server, then the procedure doesn't retrieve the failover time.

**Example of no recent failover**

This example shows the output when there is no recent failover in the error logs. No failover has happened since 2020-04-29 23:59:00.01.
Disabling fast inserts during bulk loading

Starting with SQL Server 2016, fast inserts are enabled by default. Fast inserts leverage the minimal logging that occurs while the database is in the simple or bulk logged recovery model to optimize insert performance. With fast inserts, each bulk load batch acquires new extents, bypassing the allocation lookup for existing extents with available free space to optimize insert performance.

However, with fast inserts bulk loads with small batch sizes can lead to increased unused space consumed by objects. If increasing batch size isn't feasible, enabling trace flag 692 can help reduce unused reserved space, but at the expense of performance. Enabling this trace flag disables fast inserts while bulk loading data into heap or clustered indexes.

You enable trace flag 692 as a startup parameter using DB parameter groups. For more information, see Working with parameter groups (p. 295).

Trace flag 692 is supported for Amazon RDS on SQL Server 2016 and later. For more information on trace flags, see DBCC TRACEON - trace flags in the Microsoft documentation.

Dropping a Microsoft SQL Server database

You can drop a database on an Amazon RDS DB instance running Microsoft SQL Server in a Single-AZ or Multi-AZ deployment. To drop the database, use the following command:

```
--replace your-database-name with the name of the database you want to drop
EXECUTE msdb.dbo.rds_drop_database N'your-database-name'
```

**Note**
Use straight single quotes in the command. Smart quotes will cause an error.

After you use this procedure to drop the database, Amazon RDS drops all existing connections to the database and removes the database's backup history.

Renaming a Microsoft SQL Server database in a Multi-AZ deployment

To rename a Microsoft SQL Server database instance that uses Multi-AZ, use the following procedure:

1. First, turn off Multi-AZ for the DB instance.
2. Rename the database by running rdsadmin.dbo.rds_modify_db_name.
3. Then, turn on Multi-AZ Mirroring or Always On Availability Groups for the DB instance, to return it to its original state.

For more information, see Adding Multi-AZ to a Microsoft SQL Server DB instance (p. 1171).

**Note**
If your instance doesn't use Multi-AZ, you don't need to change any settings before or after running `rdsadmin.dbo.rds_modify_db_name`.

**Example:** In the following example, the `rdsadmin.dbo.rds_modify_db_name` stored procedure renames a database from **M00** to **ZAR**. This is similar to running the statement DDL: `ALTER DATABASE [M00] MODIFY NAME = [ZAR].`

```
EXEC rdsadmin.dbo.rds_modify_db_name 'M00', 'ZAR'
GO
```

## Resetting the db_owner role password

If you lock yourself out of the `db_owner` role on your Microsoft SQL Server database, you can reset the `db_owner` role password by modifying the DB instance master password. By changing the DB instance master password, you can regain access to the DB instance, access databases using the modified password for the `db_owner` role, and restore privileges for the `db_owner` role that may have been accidentally revoked. You can change the DB instance password by using the Amazon RDS console, the AWS CLI command `modify-db-instance`, or by using the `ModifyDBInstance` operation. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 333).

## Restoring license-terminated DB instances

Microsoft has requested that some Amazon RDS customers who did not report their Microsoft License Mobility information terminate their DB instance. Amazon RDS takes snapshots of these DB instances, and you can restore from the snapshot to a new DB instance that has the License Included model.

**To restore from a SQL Server snapshot after Amazon RDS has created a final snapshot of your instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at `https://console.aws.amazon.com/rds/`.
2. In the navigation pane, choose **Snapshots**.
3. Choose the snapshot of your SQL Server DB instance. Amazon RDS creates a final snapshot of your DB instance. The name of the terminated instance snapshot is in the format `instance_name-final-snapshot`. For example, if your DB instance name is `mytest.cdxgahs1ksma.us-east-1.rds.com`, the final snapshot is called `mytest-final-snapshot` and is located in the same AWS Region as the original DB instance.
4. For **Actions**, choose **Restore Snapshot**.
   The **Restore DB Instance** window appears.
5. For **License Model**, choose **license-included**.
6. Choose the SQL Server DB engine that you want to use.
7. For **DB Instance Identifier**, enter the name for the restored DB instance.
8. Choose Restore DB Instance.

For more information about restoring from a snapshot, see Restoring from a DB snapshot (p. 487).

**Transitioning a Microsoft SQL Server database from OFFLINE to ONLINE**

You can transition your Microsoft SQL Server database on an Amazon RDS DB instance from OFFLINE to ONLINE.

<table>
<thead>
<tr>
<th>SQL Server method</th>
<th>Amazon RDS method</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER DATABASE <em>db_name</em> SET ONLINE;</td>
<td>EXEC rdsadmin.dbo.rds_set_database_online <em>db_name</em></td>
</tr>
</tbody>
</table>

**Using change data capture**

Amazon RDS supports change data capture (CDC) for your DB instances running Microsoft SQL Server. CDC captures changes that are made to the data in your tables. It stores metadata about each change, which you can access later. For more information about how CDC works, see Change data capture in the Microsoft documentation.

Before you use CDC with your Amazon RDS DB instances, enable it in the database by running `msdb.dbo.rds_cdc_enable_db`. You must have master user privileges to enable CDC in the Amazon RDS DB instance. After CDC is enabled, any user who is *db_owner* of that database can enable or disable CDC on tables in that database.

**Important**

During restores, CDC will be disabled. All of the related metadata is automatically removed from the database. This applies to snapshot restores, point-in-time restores, and SQL Server Native restores from S3. After performing one of these types of restores, you can re-enable CDC and re-specify tables to track.

To enable CDC for a DB instance, run the `msdb.dbo.rds_cdc_enable_db` stored procedure.

```sql
exec msdb.dbo.rds_cdc_enable_db 'database_name'
```

To disable CDC for a DB instance, run the `msdb.dbo.rds_cdc_disable_db` stored procedure.

```sql
exec msdb.dbo.rds_cdc_disable_db 'database_name'
```

**Topics**

- Tracking tables with change data capture (p. 1344)
- Change data capture jobs (p. 1345)
- Change data capture for Multi-AZ instances (p. 1345)

**Tracking tables with change data capture**

After CDC is enabled on the database, you can start tracking specific tables. You can choose the tables to track by running `sys.sp_cdc_enable_table`.

1344
--Begin tracking a table
exec sys.sp_cdc_enable_table
    @source_schema           = N'\source_schema'
,  @source_name             = N'\source_name'
,  @role_name               = N'\role_name'
--The following parameters are optional:
    --, @capture_instance       = 'capture_instance'
    --, @supports_net_changes   = supports_net_changes
    --, @index_name             = 'index_name'
    --, @captured_column_list   = 'captured_column_list'
    --, @filegroup_name         = 'filegroup_name'
    --, @allow_partition_switch = 'allow_partition_switch'
;
To view the CDC configuration for your tables, run sys.sp_cdc_help_change_data_capture.

--View CDC configuration
exec sys.sp_cdc_help_change_data_capture
--The following parameters are optional and must be used together.
--  'schema_name', 'table_name'
;
For more information on CDC tables, functions, and stored procedures in SQL Server documentation, see the following:

• Change data capture stored procedures (Transact-SQL)
• Change data capture functions (Transact-SQL)
• Change data capture tables (Transact-SQL)

**Change data capture jobs**

When you enable CDC, SQL Server creates the CDC jobs. Database owners (db_owner) can view, create, modify, and delete the CDC jobs. However, the RDS system account owns them. Therefore, the jobs aren't visible from native views, procedures, or in SQL Server Management Studio.

To control behavior of CDC in a database, use native SQL Server procedures such as sp_cdc_enable_table and sp_cdc_start_job. To change CDC job parameters, like maxtrans and maxscans, you can use sp_cdc_change_job.

To get more information regarding the CDC jobs, you can query the following dynamic management views:

• sys.dm_cdc_errors
• sys.dm_cdc_log_scan_sessions
• sysjobs
• sysjobhistory

**Change data capture for Multi-AZ instances**

If you use CDC on a Multi-AZ instance, make sure the mirror's CDC job configuration matches the one on the principal. CDC jobs are mapped to the database_id. If the database IDs on the secondary
are different from the principal, then the jobs won't be associated with the correct database. To try to prevent errors after failover, RDS drops and recreates the jobs on the new principal. The recreated jobs use the parameters that the principal recorded before failover.

Although this process runs quickly, it's still possible that the CDC jobs might run before RDS can correct them. Here are three ways to force parameters to be consistent between primary and secondary replicas:

- Use the same job parameters for all the databases that have CDC enabled.
- Before you change the CDC job configuration, convert the Multi-AZ instance to Single-AZ.
- Manually transfer the parameters whenever you change them on the principal.

To view and define the CDC parameters that are used to recreate the CDC jobs after a failover, use `rds_show_configuration` and `rds_set_configuration`.

The following example returns the value set for `cdc_capture_maxtrans`. For any parameter that is set to `RDS_DEFAULT`, RDS automatically configures the value.

```sql
-- Show configuration for each parameter on either primary and secondary replicas.
exec rdsadmin.dbo.rds_show_configuration 'cdc_capture_maxtrans';
```

To set the configuration on the secondary, run `rdsadmin.dbo.rds_set_configuration`. This procedure sets the parameter values for all of the databases on the secondary server. These settings are used only after a failover. The following example sets the `maxtrans` for all CDC capture jobs to 1000:

```sql
--To set values on secondary. These are used after failover.
exec rdsadmin.dbo.rds_set_configuration 'cdc_capture_maxtrans', 1000;
```

To set the CDC job parameters on the principal, use `sys.sp_cdc_change_job` instead.

### Using SQL Server Agent

With Amazon RDS, you can use SQL Server Agent on a DB instance running Microsoft SQL Server Enterprise Edition, Standard Edition, or Web Edition. SQL Server Agent is a Microsoft Windows service that runs scheduled administrative tasks that are called jobs. You can use SQL Server Agent to run T-SQL jobs to rebuild indexes, run corruption checks, and aggregate data in a SQL Server DB instance.

When you create a SQL Server DB instance, the master user is enrolled in the `SQLAgentUserRole` role.

SQL Server Agent can run a job on a schedule, in response to a specific event, or on demand. For more information, see [SQL Server Agent](https://docs.microsoft.com/en-us/sql-server/reporting-services/) in the Microsoft documentation.

**Note**

Avoid scheduling jobs to run during the maintenance and backup windows for your DB instance. The maintenance and backup processes that are launched by AWS could interrupt a job or cause it to be canceled.

In Multi-AZ deployments, SQL Server Agent jobs are replicated from the primary host to the secondary host when the job replication feature is turned on. For more information, see [Turning on SQL Server Agent job replication](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_SQLServer-Agent.html#USER_SQLServer-Agent-TurnOnReplication).

Multi-AZ deployments have a limit of 100 SQL Server Agent jobs. If you need a higher limit, request an increase by contacting AWS Support. Open the [AWS Support Center](https://console.aws.amazon.com/support/home) page, sign in if necessary, and choose **Create case**. Choose **Service limit increase**. Complete and submit the form.

To view the history of an individual SQL Server Agent job in SQL Server Management Studio (SSMS), open Object Explorer, right-click the job, and then choose **View History**.
Because SQL Server Agent is running on a managed host in a DB instance, some actions aren't supported:

- Running replication jobs and running command-line scripts by using ActiveX, Windows command shell, or Windows PowerShell aren't supported.
- You can't manually start, stop, or restart SQL Server Agent.
- Email notifications through SQL Server Agent aren't available from a DB instance.
- SQL Server Agent alerts and operators aren't supported.
- Using SQL Server Agent to create backups isn't supported. Use Amazon RDS to back up your DB instance.

### Turning on SQL Server Agent job replication

You can turn on SQL Server Agent job replication by using the following stored procedure:

```sql
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types = 'SQLAgentJob';
```

You can run the stored procedure on all SQL Server versions supported by Amazon RDS for SQL Server. Jobs in the following categories are replicated:

- [Uncategorized (Local)]
- [Uncategorized (Multi-Server)]
- [Uncategorized]
- Data Collector
- Database Engine Tuning Advisor
- Database Maintenance
- Full-Text

Only jobs that use T-SQL job steps are replicated. Jobs with step types such as SQL Server Integration Services (SSIS), SQL Server Reporting Services (SSRS), Replication, and PowerShell aren't replicated. Jobs that use Database Mail and server-level objects aren't replicated.

**Important**

The primary host is the source of truth for replication. Before turning on job replication, make sure that your SQL Server Agent jobs are on the primary. If you don't do this, it could lead to the deletion of your SQL Server Agent jobs if you turn on the feature when newer jobs are on the secondary host.

You can use the following function to confirm whether replication is turned on.

```sql
SELECT * from msdb.dbo.rds_fn_get_system_database_sync_objects();
```

The T-SQL query returns the following if SQL Server Agent jobs are replicating. If they're not replicating, it returns nothing for object_class.

You can use the following function to find the last time objects were synchronized.

```sql
SELECT * from msdb.dbo.rds_fn_server_object_last_sync_time();
```
For example, suppose that you modify a SQL Server Agent job at 01:00. You expect the most recent synchronization time to be after 01:00, indicating that synchronization has taken place.

![Image](image)

Adding a user to the SQLAgentUserRole role

To allow an additional login or user to use SQL Server Agent, log in as the master user and do the following:

1. Create another server-level login by using the `CREATE LOGIN` command.
2. Create a user in `msdb` using `CREATE USER` command, and then link this user to the login that you created in the previous step.
3. Add the user to the SQLAgentUserRole using the `sp_addrolemember` system stored procedure.

For example, suppose that your master user name is `admin` and you want to give access to SQL Server Agent to a user named `theirname` with a password `theirpassword`. In that case, you can use the following procedure.

**To add a user to the SQLAgentUserRole role**

1. Log in as the master user.
2. Run the following commands:

   ```sql
   --Initially set context to master database
   USE [master];
   GO
   --Create a server-level login named theirname with password theirpassword
   CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';
   GO
   --Set context to msdb database
   USE [msdb];
   GO
   --Create a database user named theirname and link it to server-level login theirname
   CREATE USER [theirname] FOR LOGIN [theirname];
   GO
   --Added database user theirname in msdb to SQLAgentUserRole in msdb
   EXEC sp_addrolemember [SQLAgentUserRole], [theirname];
   ```

Deleting a SQL Server Agent job

You use the `sp_delete_job` stored procedure to delete SQL Server Agent jobs on Amazon RDS for Microsoft SQL Server.

You can't use SSMS to delete SQL Server Agent jobs. If you try to do so, you get an error message similar to the following:

```
The EXECUTE permission was denied on the object 'xp_regread', database 'mssqlsystemresource', schema 'sys'.
```

As a managed service, RDS is restricted from running procedures that access the Windows registry. When you use SSMS, it tries to run a process (xp_regread) for which RDS isn't authorized.
Note
On RDS for SQL Server, only members of the sysadmin role are allowed to update or delete jobs owned by a different login.

To delete a SQL Server Agent job

- Run the following T-SQL statement:

\[
\text{EXEC msdb..sp_delete_job @job_name = 'job_name';}
\]

Working with Microsoft SQL Server logs

You can use the Amazon RDS console to view, watch, and download SQL Server Agent logs, Microsoft SQL Server error logs, and SQL Server Reporting Services (SSRS) logs.

Watching log files

If you view a log in the Amazon RDS console, you can see its contents as they exist at that moment. Watching a log in the console opens it in a dynamic state so that you can see updates to it in near-real time.

Only the latest log is active for watching. For example, suppose you have the following logs shown:

Only log/ERROR, as the most recent log, is being actively updated. You can choose to watch others, but they are static and will not update.

Archiving log files

The Amazon RDS console shows logs for the past week through the current day. You can download and archive logs to keep them for reference past that time. One way to archive logs is to load them into an Amazon S3 bucket. For instructions on how to set up an Amazon S3 bucket and upload a file, see Amazon S3 basics in the Amazon Simple Storage Service Getting Started Guide and click Get Started.

Viewing error and agent logs

To view Microsoft SQL Server error and agent logs, use the Amazon RDS stored procedure rds_read_error_log with the following parameters:

- `@index` – the version of the log to retrieve. The default value is 0, which retrieves the current error log. Specify 1 to retrieve the previous log, specify 2 to retrieve the one before that, and so on.
- `@type` – the type of log to retrieve. Specify 1 to retrieve an error log. Specify 2 to retrieve an agent log.

Example

The following example requests the current error log.
For more information on SQL Server errors, see Database engine errors in the Microsoft documentation.

### Working with trace and dump files

This section describes working with trace files and dump files for your Amazon RDS DB instances running Microsoft SQL Server.

#### Generating a trace SQL query

```sql
DECLARE @rc INT
DECLARE @TraceID INT
DECLARE @maxfilesize BIGINT
SET @maxfilesize = 5
EXEC @rc = SP_TRACE_CREATE @TraceID OUTPUT, 0, N'D:\rdsdbdata\log\rdstest', @maxfilesize, NULL
```

#### Viewing an open trace

```sql
SELECT * FROM ::FN_TRACE_GETINFO(DEFAULT)
```

#### Viewing trace contents

```sql
SELECT * FROM ::FN_TRACE_GETTABLE('D:\rdsdbdata\log\rdstest.trc', default)
```

#### Setting the retention period for trace and dump files

Trace and dump files can accumulate and consume disk space. By default, Amazon RDS purges trace and dump files that are older than seven days.

To view the current trace and dump file retention period, use the `rds_show_configuration` procedure, as shown in the following example.

```sql
EXEC rdsadmin..rds_show_configuration;
```

To modify the retention period for trace files, use the `rds_set_configuration` procedure and set the `tracefile retention` in minutes. The following example sets the trace file retention period to 24 hours.

```sql
EXEC rdsadmin..rds_set_configuration 'tracefile retention', 1440;
```

To modify the retention period for dump files, use the `rds_set_configuration` procedure and set the `dumpfile retention` in minutes. The following example sets the dump file retention period to 3 days.

```sql
EXEC rdsadmin..rds_set_configuration 'dumpfile retention', 4320;
```

For security reasons, you cannot delete a specific trace or dump file on a SQL Server DB instance. To delete all unused trace or dump files, set the retention period for the files to 0.
Amazon RDS for MySQL

Amazon RDS supports DB instances that run the following versions of MySQL:

- MySQL 8.0
- MySQL 5.7

For more information about minor version support, see MySQL on Amazon RDS versions (p. 1356).

To create an Amazon RDS for MySQL DB instance, use the Amazon RDS management tools or interfaces. You can then do the following:

- Resize your DB instance
- Authorize connections to your DB instance
- Create and restore from backups or snapshots
- Create Multi-AZ secondaries
- Create read replicas
- Monitor the performance of your DB instance

To store and access the data in your DB instance, you use standard MySQL utilities and applications.

Amazon RDS for MySQL is compliant with many industry standards. For example, you can use RDS for MySQL databases to build HIPAA-compliant applications. You can use RDS for MySQL databases to store healthcare related information, including protected health information (PHI) under a Business Associate Agreement (BAA) with AWS. Amazon RDS for MySQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements. In addition, Amazon RDS for MySQL has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see AWS cloud compliance.

For information about the features in each version of MySQL, see The main features of MySQL in the MySQL documentation.

Before creating a DB instance, complete the steps in Setting up for Amazon RDS (p. 153). When you create a DB instance, the RDS master user gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running MySQL inside a virtual private cloud (VPC) based on Amazon VPC. You can also add features to your MySQL DB instance by turning on various options. Amazon RDS supports Multi-AZ deployments for MySQL as a high-availability, failover solution.

Important:
To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced
privileges. You can access your database using standard SQL clients such as the mysql client. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

MySQL feature support on Amazon RDS

RDS for MySQL supports most of the features and capabilities of MySQL. Some features might have limited support or restricted privileges.

You can filter new Amazon RDS features on the What’s New with Database? page. For Products, choose Amazon RDS. Then search using keywords such as MySQL 2022.

Note
The following lists are not exhaustive.

Topics

• Supported storage engines for RDS for MySQL (p. 1353)
• Using memcached and other options with MySQL on Amazon RDS (p. 1353)
• InnoDB cache warming for MySQL on Amazon RDS (p. 1354)
• MySQL features not supported by Amazon RDS (p. 1354)

Supported storage engines for RDS for MySQL

While MySQL supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. Amazon RDS fully supports the InnoDB storage engine for MySQL DB instances. Amazon RDS features such as Point-In-Time restore and snapshot restore require a recoverable storage engine and are supported for the InnoDB storage engine only. For more information, see MySQL memcached support.

The Federated Storage Engine is currently not supported by Amazon RDS for MySQL.

For user-created schemas, the MyISAM storage engine does not support reliable recovery and can result in lost or corrupt data when MySQL is restarted after a recovery, preventing Point-In-Time restore or snapshot restore from working as intended. However, if you still choose to use MyISAM with Amazon RDS, snapshots can be helpful under some conditions.

Note
System tables in the mysql schema can be in MyISAM storage.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the ALTER TABLE command (for example, alter table TABLE_NAME engine=innodb;). Bear in mind that MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

MySQL 5.1, 5.5, and 5.6 are no longer supported in Amazon RDS. However, you can restore existing MySQL 5.1, 5.5, and 5.6 snapshots. When you restore a MySQL 5.1, 5.5, or 5.6 snapshot, the DB instance is automatically upgraded to MySQL 5.7.

Using memcached and other options with MySQL on Amazon RDS

Most Amazon RDS DB engines support option groups that allow you to select additional features for your DB instance. RDS for MySQL DB instances support the memcached option, a simple, key-based cache. For more information about memcached and other options, see Options for MySQL DB instances (p. 1463). For more information about working with option groups, see Working with option groups (p. 279).
**InnoDB cache warming for MySQL on Amazon RDS**

InnoDB cache warming can provide performance gains for your MySQL DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This bypasses the need for the buffer pool to "warm up" from normal database use and instead preloads the buffer pool with the pages for known common queries. The file that stores the saved buffer pool information only stores metadata for the pages that are in the buffer pool, and not the pages themselves. As a result, the file does not require much storage space. The file size is about 0.2 percent of the cache size. For example, for a 64 GiB cache, the cache warming file size is 128 MiB. For more information on InnoDB cache warming, see [Saving and restoring the buffer pool state](https://dev.mysql.com/doc/refman/8.0/en/mysqld-binlog.html) in the MySQL documentation.

RDS for MySQL DB instances support InnoDB cache warming. To enable InnoDB cache warming, set the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group will affect all MySQL DB instances that use that parameter group. To enable InnoDB cache warming for specific MySQL DB instances, you might need to create a new parameter group for those instances. For information on parameter groups, see [Working with parameter groups](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_Configure.html) (p. 295).

InnoDB cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you do not commonly see a significant performance benefit.

**Important**

If your MySQL DB instance does not shut down normally, such as during a failover, then the buffer pool state will not be saved to disk. In this case, MySQL loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might not reflect the most recent state of the buffer pool prior to the restart. To ensure that you have a recent state of the buffer pool available to warm the InnoDB cache on startup, we recommend that you periodically dump the buffer pool "on demand."

You can create an event to dump the buffer pool automatically and on a regular interval. For example, the following statement creates an event named `periodic_buffer_pool_dump` that dumps the buffer pool every hour.

```sql
CREATE EVENT periodic_buffer_pool_dump
ON SCHEDULE EVERY 1 HOUR
DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information on MySQL events, see [Event syntax](https://dev.mysql.com/doc/refman/8.0/en/event-syntax.html) in the MySQL documentation.

**Dumping and loading the buffer pool on demand**

You can save and load the InnoDB cache "on demand."

- To dump the current state of the buffer pool to disk, call the `mysql.rds_innodb_buffer_pool_dump_now` stored procedure.
- To load the saved state of the buffer pool from disk, call the `mysql.rds_innodb_buffer_pool_load_now` stored procedure.
- To cancel a load operation in progress, call the `mysql.rds_innodb_buffer_pool_load_abort` stored procedure.

**MySQL features not supported by Amazon RDS**

Amazon RDS doesn't currently support the following MySQL features:

- Authentication Plugin
• Error Logging to the System Log
• Group Replication Plugin
• InnoDB Tablespace Encryption
• Password Strength Plugin
• Persisted system variables
• Rewriter Query Rewrite Plugin
• Semisynchronous replication
• Transportable tablespace
• X Plugin

Note
Global transaction IDs are supported for all RDS for MySQL 5.7 versions, and for RDS for MySQL 8.0.26 and higher 8.0 versions.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection. When you create a DB instance, you are assigned to the db_owner role for all databases on that instance, and you have all database-level permissions except for those used for backups. Amazon RDS manages backups for you.
MySQL on Amazon RDS versions

For MySQL, version numbers are organized as version = X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes—for example, going from version 5.7 to 8.0. A version change is considered minor if only the minor version number changes—for example, going from version 8.0.27 to 8.0.30.

Topics
- Supported MySQL versions on Amazon RDS (p. 1356)
- RDS for MySQL release calendar (p. 1357)
- Deprecated versions for Amazon RDS for MySQL (p. 1358)

Supported MySQL versions on Amazon RDS

Amazon RDS currently supports the following versions of MySQL.

Note
Dates with only a month and a year are approximate and are updated with an exact date when it’s known.

<table>
<thead>
<tr>
<th>MySQL engine version</th>

<tr>
<td>5.7.34</td>
<td>20 April 2021</td>
<td>9 July 2021</td>
<td>20 March 2023</td>
</tr>
<tr>
<td>5.7.33</td>
<td>18 January 2021</td>
<td>31 March 2021</td>
<td>20 March 2023</td>
</tr>
</tbody>
</table>
You can specify any currently supported MySQL version when creating a new DB instance. You can specify the major version (such as MySQL 5.7), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

For example, to list the supported engine versions for RDS for MySQL, run the following CLI command:

```bash
```

The default MySQL version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region using the following AWS CLI command:

```bash
```

Replace `major-engine-version` with the major engine version, and replace `region` with the AWS Region. For example, the following AWS CLI command returns the default MySQL minor engine version for the 5.7 major version and the US West (Oregon) AWS Region (us-west-2):

```bash
```

With Amazon RDS, you control when to upgrade your MySQL instance to a new major version supported by Amazon RDS. You can maintain compatibility with specific MySQL versions, test new versions with your application before deploying in production, and perform major version upgrades at times that best fit your schedule.

When automatic minor version upgrade is enabled, your DB instance will be upgraded automatically to new MySQL minor versions as they are supported by Amazon RDS. This patching occurs during your scheduled maintenance window. You can modify a DB instance to enable or disable automatic minor version upgrades.

If you opt out of automatically scheduled upgrades, you can manually upgrade to a supported minor version release by following the same procedure as you would for a major version update. For information, see Upgrading a DB instance engine version (p. 369).

Amazon RDS currently supports the major version upgrades from MySQL version 5.6 to version 5.7, and from MySQL version 5.7 to version 8.0. Because major version upgrades involve some compatibility risk, they do not occur automatically; you must make a request to modify the DB instance. You should thoroughly test any upgrade before upgrading your production instances. For information about upgrading a MySQL DB instance, see Upgrading the MySQL DB engine (p. 1392).

You can test a DB instance against a new version before upgrading by creating a DB snapshot of your existing DB instance, restoring from the DB snapshot to create a new DB instance, and then initiating a version upgrade for the new DB instance. You can then experiment safely on the upgraded clone of your DB instance before deciding whether or not to upgrade your original DB instance.

### RDS for MySQL release calendar

RDS for MySQL major versions remain available at least until community end of life for the corresponding community version. You can use the following dates to plan your testing and upgrade...
cycles. If Amazon extends support for an RDS for MySQL version for longer than originally stated, we plan to update this table to reflect the later date.

**Note**

Dates with only a month and a year are approximate and are updated with an exact date when it's known.

<table>

**Deprecated versions for Amazon RDS for MySQL**

Amazon RDS for MySQL version 5.1, 5.5, and 5.6 are deprecated.

For information about the Amazon RDS deprecation policy for MySQL, see Amazon RDS FAQs.
Connecting to a DB instance running the MySQL database engine

Before you can connect to a DB instance running the MySQL database engine, you must create a DB instance. For information, see Creating an Amazon RDS DB instance (p. 236). After Amazon RDS provisions your DB instance, you can use any standard MySQL client application or utility to connect to the instance. In the connection string, you specify the DNS address from the DB instance endpoint as the host parameter, and specify the port number from the DB instance endpoint as the port parameter.

To authenticate to your RDS DB instance, you can use one of the authentication methods for MySQL and AWS Identity and Access Management (IAM) database authentication:

- To learn how to authenticate to MySQL using one of the authentication methods for MySQL, see Authentication method in the MySQL documentation.
- To learn how to authenticate to MySQL using IAM database authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2195).

You can connect to a MySQL DB instance by using tools like the MySQL command-line client. For more information on using the MySQL command-line client, see mysql - the MySQL command-line client in the MySQL documentation. One GUI-based application you can use to connect is MySQL Workbench. For more information, see the Download MySQL Workbench page. For information about installing MySQL (including the MySQL command-line client), see Installing and upgrading MySQL.

Most Linux distributions include the MariaDB client instead of the Oracle MySQL client. To install the MySQL command-line client on most RPM-based Linux distributions, including Amazon Linux 2, run the following command:

    yum install mariadb

To install the MySQL command-line client on most DEB-based Linux distributions, run the following command:

    apt-get install mariadb-client

To check the version of your MySQL command-line client, run the following command:

    mysql --version

To read the MySQL documentation for your current client version, run the following command:

    man mysql

To connect to a DB instance from outside of its Amazon VPC, the DB instance must be publicly accessible, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance (p. 2289).

You can use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) encryption on connections to a MySQL DB instance. For information, see Using SSL/TLS with a MySQL DB instance (p. 1368). If you are using AWS Identity and Access Management (IAM) database authentication, make sure to use an SSL/TLS connection. For information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2195).
You can also connect to a DB instance from a web server. For more information, see Tutorial: Create a web server and an Amazon RDS DB instance (p. 204).

**Note**
For information on connecting to a MariaDB DB instance, see Connecting to a DB instance running the MariaDB database engine (p. 1027).

**Topics**
- Finding the connection information for a MySQL DB instance (p. 1360)
- Connecting from the MySQL command-line client (unencrypted) (p. 1362)
- Connecting from MySQL Workbench (p. 1363)
- Connecting with the Amazon Web Services JDBC Driver for MySQL (p. 1364)
- Troubleshooting connections to your MySQL DB instance (p. 1365)

**Finding the connection information for a MySQL DB instance**

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is mydb.123456789012.us-east-1.rds.amazonaws.com. In this case, the port value is 3306, and the database user is admin. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify mydb.123456789012.us-east-1.rds.amazonaws.com.
- For port, specify 3306.
- For user, specify admin.

To connect to a DB instance, use any client for the MySQL DB engine. For example, you might use the MySQL command-line client or MySQL Workbench.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS CLI `describe-db-instances` command, or the Amazon RDS API `DescribeDBInstances` operation to list its details.

**Console**

**To find the connection information for a DB instance in the AWS Management Console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases** to display a list of your DB instances.
3. Choose the name of the MySQL DB instance to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
5. If you need to find the master user name, choose the Configuration tab and view the Master username value.

**AWS CLI**

To find the connection information for a MySQL DB instance by using the AWS CLI, call the `describe-db-instances` command. In the call, query for the DB instance ID, endpoint, port, and master user name.
For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
  --filters "Name=engine,Values=mysql" \
  --query "[*][DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```
aws rds describe-db-instances ^
  --filters "Name=engine,Values=mysql" ^
  --query "[*][DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```
[
  [
    "mydb1",
    "mydb1.123456789012.us-east-1.rds.amazonaws.com",
    3306,
    "admin"
  ],
  [
    "mydb2",
    "mydb2.123456789012.us-east-1.rds.amazonaws.com",
    3306,
    "admin"
  ]
]
```

**RDS API**

To find the connection information for a DB instance by using the Amazon RDS API, call the `DescribeDBInstances` operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

**Connecting from the MySQL command-line client (unencrypted)**

**Important**

Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting from the MySQL command-line client with SSL/TLS (encrypted) (p. 1369).

To connect to a DB instance using the MySQL command-line client, enter the following command at the command prompt. For the `-h` parameter, substitute the DNS name (endpoint) for your DB instance. For the `-P` parameter, substitute the port for your DB instance. For the `-u` parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com -P 3306 -u mymasteruser -p
```

After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MySQL monitor. Commands end with ; or \g.
```
Connecting from MySQL Workbench

To connect from MySQL Workbench

1. Download and install MySQL Workbench at Download MySQL Workbench.
2. Open MySQL Workbench.
3. From Database, choose Manage Connections.
4. In the Manage Server Connections window, choose New.
5. In the Connect to Database window, enter the following information:
   - **Stored Connection** – Enter a name for the connection, such as MyDB.
   - **Hostname** – Enter the DB instance endpoint.
   - **Port** – Enter the port used by the DB instance.
   - **Username** – Enter the user name of a valid database user, such as the master user.
   - **Password** – Optionally, choose Store in Vault and then enter and save the password for the user.

The window looks similar to the following:
You can use the features of MySQL Workbench to customize connections. For example, you can use the SSL tab to configure SSL/TLS connections. For information about using MySQL Workbench, see the MySQL Workbench documentation. Encrypting client connections to MySQL DB instances with SSL/TLS, see Encrypting client connections to MySQL DB instances with SSL/TLS (p. 1368).

6. Optionally, choose Test Connection to confirm that the connection to the DB instance is successful.
7. Choose Close.
8. From Database, choose Connect to Database.
9. From Stored Connection, choose your connection.
10. Choose OK.

Connecting with the Amazon Web Services JDBC Driver for MySQL

The AWS JDBC Driver for MySQL is a client driver designed for RDS for MySQL. By default, the driver has settings that are optimized for use with RDS for MySQL. For more information about the driver and complete instructions for using it, see the AWS JDBC Driver for MySQL GitHub repository.

The driver is drop-in compatible with the MySQL Connector/J driver. To install or upgrade your connector, replace the MySQL connector .jar file (located in the application CLASSPATH) with the AWS JDBC Driver for MySQL .jar file, and update the connection URL prefix from jdbc:mysql:// to jdbc:mysql:aws://.

The AWS JDBC Driver for MySQL supports IAM database authentication. For more information, see AWS IAM Database Authentication in the AWS JDBC Driver for MySQL GitHub repository. For more information about IAM database authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2195).
Troubleshooting connections to your MySQL DB instance

Two common causes of connection failures to a new DB instance are:

- The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MySQL application or utility is running. The DB instance must have a VPC security group that authorizes the connections. For more information, see Amazon VPC VPCs and Amazon RDS (p. 2251).

  You can add or edit an inbound rule in the security group. For Source, choose My IP. This allows access to the DB instance from the IP address detected in your browser.

- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see Can't connect to Amazon RDS DB instance (p. 2289).
Securing MySQL DB instance connections

You can manage the security of your MySQL DB instances.

Topics

- MySQL security on Amazon RDS (p. 1366)
- Using the Password Validation Plugin for RDS for MySQL (p. 1367)
- Encrypting client connections to MySQL DB instances with SSL/TLS (p. 1368)
- Using new SSL/TLS certificates for MySQL DB instances (p. 1371)
- Using Kerberos authentication for MySQL (p. 1374)

MySQL security on Amazon RDS

Security for MySQL DB instances is managed at three levels:

- AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management for Amazon RDS (p. 2162).
- When you create a DB instance, you use a VPC security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance. These connections can be made using Secure Sockets Layer (SSL) and Transport Layer Security (TLS). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.
- To authenticate login and permissions for a MySQL DB instance, you can take either of the following approaches, or a combination of them.

You can take the same approach as with a stand-alone instance of MySQL. Commands such as CREATE USER, RENAME USER, GRANT, REVOKE, and SET PASSWORD work just as they do in on-premises databases, as does directly modifying database schema tables. For information, see Access control and account management in the MySQL documentation.

You can also use IAM database authentication. With IAM database authentication, you authenticate to your DB instance by using an IAM user or IAM role and an authentication token. An authentication token is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control access to your AWS resources and your databases. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2195).

Another option is Kerberos authentication for RDS for MySQL. The DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users authenticate with a MySQL DB instance joined to the trusting domain, authentication requests are forwarded. Forwarded requests go to the domain directory that you create with AWS Directory Service. For more information, see Using Kerberos authentication for MySQL (p. 1374).

When you create an Amazon RDS DB instance, the master user has the following default privileges:

- alter
- alter routine
- create
- create routine
• create temporary tables
• create user
• create view
• delete
• drop
• event
• execute
• grant option
• index
• insert
• lock tables
• process
• references
• replication client
• replication slave
• select
• show databases
• show view
• trigger
• update

**Note**
Although it is possible to delete the master user on the DB instance, it is not recommended. To recreate the master user, use the `ModifyDBInstance` RDS API operation or the `modify-db-instance` AWS CLI command and specify a new master user password with the appropriate parameter. If the master user does not exist in the instance, the master user is created with the specified password.

To provide management services for each DB instance, the `rdsadmin` user is created when the DB instance is created. Attempting to drop, rename, change the password, or change privileges for the `rdsadmin` account will result in an error.

To allow management of the DB instance, the standard `kill` and `kill_query` commands have been restricted. The Amazon RDS commands `rds_kill` and `rds_kill_query` are provided to allow you to end user sessions or queries on DB instances.

### Using the Password Validation Plugin for RDS for MySQL

MySQL provides the `validate_password` plugin for improved security. The plugin enforces password policies using parameters in the DB parameter group for your MySQL DB instance. The plugin is supported for DB instances running MySQL version 5.7 and 8.0. For more information about the `validate_password` plugin, see The Password Validation Plugin in the MySQL documentation.

**To enable the validate_password plugin for a MySQL DB instance**

1. Connect to your MySQL DB instance and run the following command.
INSTALL PLUGIN validate_password SONAME 'validate_password.so';

2. Configure the parameters for the plugin in the DB parameter group used by the DB instance.

   For more information about the parameters, see Password Validation Plugin options and variables in the MySQL documentation.

   For more information about modifying DB instance parameters, see Modifying parameters in a DB parameter group (p. 300).

After installing and enabling the password_validate plugin, reset existing passwords to comply with your new validation policies.

Amazon RDS doesn't validate passwords. The MySQL DB instance performs password validation. If you set a user password with the AWS Management Console, the modify-db-instance AWS CLI command, or the ModifyDBInstance RDS API operation, the change can succeed even if the new password doesn't satisfy your password policies. However, a new password is set in the MySQL DB instance only if it satisfies the password policies. In this case, Amazon RDS records the following event.

"RDS-EVENT-0067" - An attempt to reset the master password for the DB instance has failed.

For more information about Amazon RDS events, see Working with Amazon RDS event notification (p. 685).

### Encrypting client connections to MySQL DB instances with SSL/TLS

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS). Amazon RDS supports SSL/TLS encryption for MySQL DB instances. Using SSL/TLS, you can encrypt a connection between your application client and your MySQL DB instance. SSL/TLS support is available in all AWS Regions for MySQL.

**Topics**

- Using SSL/TLS with a MySQL DB instance (p. 1368)
- Requiring SSL/TLS for all connections to a MySQL DB instance (p. 1369)
- Connecting from the MySQL command-line client with SSL/TLS (encrypted) (p. 1369)

**Using SSL/TLS with a MySQL DB instance**

Amazon RDS creates an SSL/TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL/TLS certificate includes the DB instance endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

An SSL/TLS certificate created by Amazon RDS is the trusted root entity and should work in most cases but might fail if your application does not accept certificate chains. If your application does not accept certificate chains, you might need to use an intermediate certificate to connect to your AWS Region. For example, you must use an intermediate certificate to connect to the AWS GovCloud (US) Regions using SSL/TLS.
For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152). For more information about using SSL/TLS with MySQL, see Using new SSL/TLS certificates for MySQL DB instances (p. 1371).

MySQL uses OpenSSL for secure connections. Amazon RDS for MySQL supports Transport Layer Security (TLS) versions 1.0, 1.1, and 1.2. The following table shows the TLS support for MySQL versions.

<table>
<thead>
<tr>
<th>MySQL version</th>
<th>TLS 1.0</th>
<th>TLS 1.1</th>
<th>TLS 1.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 8.0</td>
<td>Supported for MySQL 8.0.27 and lower</td>
<td>Supported for MySQL 8.0.27 and lower</td>
<td>Supported</td>
</tr>
<tr>
<td>MySQL 5.7</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>

You can require SSL/TLS connections for specific user accounts. For example, you can use one of the following statements, depending on your MySQL version, to require SSL/TLS connections on the user account encrypted_user.

To do so, use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL/TLS connections with MySQL, see the Using encrypted connections in the MySQL documentation.

**Requiring SSL/TLS for all connections to a MySQL DB instance**

You can require that all user connections to your MySQL DB instance use SSL/TLS by using the require_secure_transport parameter. By default, the require_secure_transport parameter is set to OFF. You can set the require_secure_transport parameter to ON to require SSL/TLS for connections to your DB instance.

You can set the require_secure_transport parameter value by updating the DB parameter group for your DB instance. You don't need to reboot your DB instance for the change to take effect.

When the require_secure_transport parameter is set to ON for a DB instance, a database client can connect to it if it can establish an encrypted connection. Otherwise, an error message similar to the following is returned to the client:

```
MySQL Error 3159 (HY000): Connections using insecure transport are prohibited while --require_secure_transport=ON.
```

For information about setting parameters, see Modifying parameters in a DB parameter group (p. 300).

For more information about the require_secure_transport parameter, see the MySQL documentation.

**Connecting from the MySQL command-line client with SSL/TLS (encrypted)**

The mysql client program parameters are slightly different if you are using the MySQL 5.7 version, the MySQL 8.0 version, or the MariaDB version.
To find out which version you have, run the `mysql` command with the `--version` option. In the following example, the output shows that the client program is from MariaDB.

```
$ mysql --version
mysql Ver 15.1 Distrib 10.5.15-MariaDB, for osx10.15 (x86_64) using readline 5.1
```

Most Linux distributions, such as Amazon Linux, CentOS, SUSE, and Debian have replaced MySQL with MariaDB, and the `mysql` version in them is from MariaDB.

To connect to your DB instance using SSL/TLS, follow these steps:

**To connect to a DB instance with SSL/TLS using the MySQL command-line client**

1. Download a root certificate that works for all AWS Regions.
   
   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).

2. Use a MySQL command-line client to connect to a DB instance with SSL/TLS encryption. For the `-h` parameter, substitute the DNS name (endpoint) for your DB instance. For the `--ssl-ca` parameter, substitute the SSL/TLS certificate file name. For the `-P` parameter, substitute the port for your DB instance. For the `-u` parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

   The following example shows how to launch the client using the `--ssl-ca` parameter using the MySQL 5.7 client or later:

   ```
   mysql -h `mysql-instance1.123456789012.us-east-1.rds.amazonaws.com` --ssl-ca=global-bundle.pem --ssl-mode=REQUIRED -P 3306 -u myadmin -p
   ```

   To require that the SSL/TLS connection verifies the DB instance endpoint against the endpoint in the SSL/TLS certificate, enter the following command:

   ```
   mysql -h `mysql-instance1.123456789012.us-east-1.rds.amazonaws.com` --ssl-ca=global-bundle.pem --ssl-mode=VERIFY_IDENTITY -P 3306 -u myadmin -p
   ```

   The following example shows how to launch the client using the `--ssl-ca` parameter using the MariaDB client:

   ```
   mysql -h `mysql-instance1.123456789012.us-east-1.rds.amazonaws.com` --ssl-ca=global-bundle.pem -s -P 3306 -u myadmin -p
   ```

3. Enter the master user password when prompted.

   You will see output similar to the following.

   ```
   Welcome to the MySQL monitor. Commands end with ; or \g.
   Your MySQL connection id is 9738
   Server version: 8.0.23 Source distribution
   Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
   mysql>
   ```
Using new SSL/TLS certificates for MySQL DB instances

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances. If they do, you can further check whether those applications require certificate verification to connect.

**Note**

Some applications are configured to connect to MySQL DB instances only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.

You can specify the following SSL modes: disabled, preferred, and required. When you use the preferred SSL mode and the CA certificate doesn't exist or isn't up to date, the connection falls back to not using SSL and connects without encryption.

Because these later versions use the OpenSSL protocol, an expired server certificate doesn't prevent successful connections unless the required SSL mode is specified.

We recommend avoiding preferred mode. In preferred mode, if the connection encounters an invalid certificate, it stops using encryption and proceeds unencrypted.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 2154). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152). For information about using SSL/TLS with MySQL DB instances, see Using SSL/TLS with a MySQL DB instance (p. 1368).

**Topics**

- Determining whether any applications are connecting to your MySQL DB instance using SSL (p. 1371)
- Determining whether a client requires certificate verification to connect (p. 1372)
- Updating your application trust store (p. 1373)
- Example Java code for establishing SSL connections (p. 1373)

**Determining whether any applications are connecting to your MySQL DB instance using SSL**

If you are using Amazon RDS for MySQL version 5.7 or 8.0 and the Performance Schema is enabled, run the following query to check if connections are using SSL/TLS. For information about enabling the Performance Schema, see Performance Schema quick start in the MySQL documentation.

```sql
mysql> SELECT id, user, host, connection_type
    FROM performance_schema.threads pst
    INNER JOIN information_schema.processlist isp
    ON pst.processlist_id = isp.id;
```

In this sample output, you can see both your own session (admin) and an application logged in as webapp1 are using SSL.
Determining whether a client requires certificate verification to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

**JDBC**

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see Configuration properties in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the server CA certificate if your connection properties have sslMode set to VERIFY_CA or VERIFY_IDENTITY, as in the following example.

```java
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

**Note**

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

**MySQL**

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see Client-side configuration for encrypted connections in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the --ssl-mode option you specify VERIFY_CA or VERIFY_IDENTITY, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-mode=VERIFY_CA
```
When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the `--ssl-verify-server-cert` option, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-verify-server-cert
```

### Updating your application trust store

For information about updating the trust store for MySQL applications, see Installing SSL certificates in the MySQL documentation.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).

For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 2160).

**Note**

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

If you are using the mysql JDBC driver in an application, set the following properties in the application.

```
System.setProperty("javax.net.ssl.trustStore", certs);
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

When you start the application, set the following properties.

```
java -Djavax.net.ssl.trustStore=/path_to_truststore/MyTruststore.jks -Djavax.net.ssl.trustStorePassword=my_truststore_password com.companyName.MyApplication
```

### Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection that validates the server certificate using JDBC.

```java
public class MySQLSSLSSTest {
    private static final String DB_USER = "username";
    private static final String DB_PASSWORD = "password";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
    private static final String KEY_STORE_PASS = "keystore-password";

    public static void test(String[] args) throws Exception {
        Class.forName("com.mysql.jdbc.Driver");

        System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);

        Properties properties = new Properties();
        properties.setProperty("sslMode", "VERIFY_IDENTITY");
```
Using Kerberos authentication for MySQL

You can use Kerberos authentication to authenticate users when they connect to your MySQL DB instance. The DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users authenticate with a MySQL DB instance joined to the trusting domain, authentication requests are forwarded. Forwarded requests go to the domain directory that you create with AWS Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. With this approach, you have a centralized place for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with Kerberos authentication, see Kerberos authentication (p. 105).
Overview of Setting up Kerberos authentication for MySQL DB instances

To set up Kerberos authentication for a MySQL DB instance, complete the following general steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service to create the directory. For details about doing so, see Create your AWS Managed Microsoft AD directory in the AWS Directory Service Administration Guide.

2. Create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess. The role allows Amazon RDS to make calls to your directory.

   For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS managed Microsoft AD in the AWS Directory Service Administration Guide.

4. Create or modify a MySQL DB instance. If you use either the CLI or RDS API in the create request, specify a domain identifier with the Domain parameter. Use the d-* identifier that was generated when you created your directory and the name of the role that you created.

   If you modify an existing MySQL DB instance to use Kerberos authentication, set the domain and IAM role parameters for the DB instance. Locate the DB instance in the same VPC as the domain directory.

5. Use the Amazon RDS master user credentials to connect to the MySQL DB instance. Create the user in MySQL using the CREATE USER clause IDENTIFIED WITH 'auth_pam'. Users that you create this way can log in to the MySQL DB instance using Kerberos authentication.

Setting up Kerberos authentication for MySQL DB instances

You use AWS Managed Microsoft AD to set up Kerberos authentication for a MySQL DB instance. To set up Kerberos authentication, you take the following steps.

Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

  **Note**
  Be sure to save this password. AWS Directory Service doesn't store it. You can reset it, but you can't retrieve it.

- Creates a security group for the directory controllers.
When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you created your directory and is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

**To create a directory with AWS Managed Microsoft AD**

2. In the navigation pane, choose **Directories** and choose **Set up Directory**.
3. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

   **Directory DNS name**
   
   The fully qualified name for the directory, such as `corp.example.com`.

   **Directory NetBIOS name**
   
   The short name for the directory, such as `CORP`.

   **Directory description**
   
   (Optional) A description for the directory.

   **Admin password**
   
   The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.
   
   The directory administrator password and can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:
   - Lowercase letters (a–z)
   - Uppercase letters (A–Z)
   - Numbers (0–9)
   - Non-alphanumeric characters (~!@#$%^&*-_+-=\`|(){}[]:;'",<>./)
Confirm password

The administrator password retyped.

5. Choose Next.

6. Enter the following information in the Networking section and then choose Next:

VPC

The VPC for the directory. Create the MySQL DB instance in this same VPC.

Subnets

Subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Review the directory information and make any necessary changes. When the information is correct, choose Create directory.

It takes several minutes for the directory to be created. When it has been successfully created, the Status value changes to Active.
To see information about your directory, choose the directory name in the directory listing. Note the Directory ID value because you need this value when you create or modify your MySQL DB instance.

![Directory Service screenshot](image)

**Step 2: Create the IAM role for use by Amazon RDS**

For Amazon RDS to call AWS Directory Service for you, an IAM role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess is required. This role allows Amazon RDS to make calls to the AWS Directory Service.

When a DB instance is created using the AWS Management Console and the console user has the iam:CreateRole permission, the console creates this role automatically. In this case, the role name is rds-directoryservice-kerberos-access-role. Otherwise, you must create the IAM role manually. When you create this IAM role, choose Directory Service, and attach the AWS managed policy AmazonRDSDirectoryServiceAccess to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

**Note**

The IAM role used for Windows Authentication for RDS for SQL Server can't be used for RDS for MySQL.

Optionally, you can create policies with the required permissions instead of using the managed IAM policy AmazonRDSDirectoryServiceAccess. In this case, the IAM role must have the following IAM trust policy.
Using Kerberos authentication for MySQL

The role must also have the following IAM role policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

**Step 3: Create and configure users**

You can create users with the Active Directory Users and Computers tool. This tool is part of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to an Amazon EC2 instance based on Microsoft Windows. This instance must be a member of the AWS Directory Service directory and be logged in as a user that has privileges to create users. For more information, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

**Step 4: Create or modify a MySQL DB instance**

Create or modify a MySQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new MySQL DB instance using the console, the `create-db-instance` CLI command, or the `CreateDBInstance` RDS API operation.
  
  For instructions, see Creating an Amazon RDS DB instance (p. 236).

- Modify an existing MySQL DB instance using the console, the `modify-db-instance` CLI command, or the `ModifyDBInstance` RDS API operation.
  
  For instructions, see Modifying an Amazon RDS DB instance (p. 333).
• Restore a MySQL DB instance from a DB snapshot using the console, the `restore-db-instance-from-db-snapshot` CLI command, or the `RestoreDBInstanceFromDBSnapshot` RDS API operation.

For instructions, see Restoring from a DB snapshot (p. 487).

• Restore a MySQL DB instance to a point-in-time using the console, the `restore-db-instance-to-point-in-time` CLI command, or the `RestoreDBInstanceToPointInTime` RDS API operation.

For instructions, see Restoring a DB instance to a specified time (p. 534).

Kerberos authentication is only supported for MySQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows egress within the directory's VPC so the DB instance can communicate with the directory.

When you use the console to create a DB instance, choose Password and Kerberos authentication in the Database authentication section. Choose Browse Directory and then select the directory, or choose Create a new directory.

When you use the console to modify or restore a DB instance, choose the directory in the Kerberos authentication section, or choose Create a new directory.

Use the CLI or RDS API to associate a DB instance with a directory. The following parameters are required for the DB instance to be able to use the domain directory you created:

• For the `-domain` parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.

• For the `-domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.
For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --domain d-ID \
    --domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^ \
    --db-instance-identifier mydbinstance ^ \
    --domain d-ID ^ \
    --domain-iam-role-name role-name
```

**Important**

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

**Step 5: Create Kerberos authentication MySQL logins**

Use the Amazon RDS master user credentials to connect to the MySQL DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision MySQL logins and users from the Active Directory users in your domain. Database permissions are managed through standard MySQL permissions that are granted to and revoked from these logins.

You can allow an Active Directory user to authenticate with MySQL. To do this, first use the Amazon RDS master user credentials to connect to the MySQL DB instance as with any other DB instance. After you're logged in, create an externally authenticated user with PAM (Pluggable Authentication Modules) in MySQL as shown following.

```
CREATE USER 'testuser'@'%' IDENTIFIED WITH 'auth_pam';
```

Replace `testuser` with the user name. Users (both humans and applications) from your domain can now connect to the DB instance from a domain joined client machine using Kerberos authentication.

**Important**

We strongly recommended that clients use SSL/TLS connections when using PAM authentication. If they don't use SSL/TLS connections, the password might be sent as clear text in some cases. To require an SSL/TLS encrypted connection for your AD user, run the following command:

```
UPDATE mysql.user SET ssl_type = 'any' WHERE ssl_type = '' AND PLUGIN = 'auth_pam' and USER = 'testuser';
FLUSH PRIVILEGES;
```

For more information, see Using SSL/TLS with a MySQL DB instance (p. 1368).

**Managing a DB instance in a domain**

You can use the CLI or the RDS API to manage your DB instance and its relationship with your managed Active Directory. For example, you can associate an Active Directory for Kerberos authentication and disassociate an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Active Directory to another.

For example, using the Amazon RDS API, you can do the following:
To reattempt enabling Kerberos authentication for a failed membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID.

To update the IAM role name for membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID and the new IAM role.

To disable Kerberos authentication on a DB instance, use the `ModifyDBInstance` API operation and specify none as the domain parameter.

To move a DB instance from one domain to another, use the `ModifyDBInstance` API operation and specify the domain identifier of the new domain as the domain parameter.

To list membership for each DB instance, use the `DescribeDBInstances` API operation.

Understanding domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership for the DB instance by running the `describe-db-instances` CLI command. The status of the DB instance can be one of the following:

- **kerberos-enabled** – The DB instance has Kerberos authentication enabled.
- **enabling-kerberos** – AWS is in the process of enabling Kerberos authentication on this DB instance.
- **pending-enable-kerberos** – The enabling of Kerberos authentication is pending on this DB instance.
- **pending-maintenance-enable-kerberos** – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- **pending-disable-kerberos** – The disabling of Kerberos authentication is pending on this DB instance.
- **pending-maintenance-disable-kerberos** – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- **enable-kerberos-failed** – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Check and fix your configuration before reissuing the DB instance modify command.
- **disabling-kerberos** – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. For example, suppose that you create a DB instance or modify an existing DB instance and the attempt to enable Kerberos authentication fails. If this happens, re-issue the modify command or modify the newly created DB instance to join the domain.

Connecting to MySQL with Kerberos authentication

To connect to MySQL with Kerberos authentication, you must log in using the Kerberos authentication type.

To create a database user that you can connect to using Kerberos authentication, use an IDENTIFIED WITH clause on the `CREATE USER` statement. For instructions, see Step 5: Create Kerberos authentication MySQL logins (p. 1381).

To avoid errors, use the MariaDB `mysql` client. You can download MariaDB software at https://downloads.mariadb.org/.

At a command prompt, connect to one of the endpoints associated with your MySQL DB instance. Follow the general procedures in Connecting to a DB instance running the MySQL database engine (p. 1359). When you're prompted for the password, enter the Kerberos password associated with that user name.
Restoring a MySQL DB instance and adding it to a domain

You can restore a DB snapshot or complete a point-in-time restore for a MySQL DB instance and then add it to a domain. After the DB instance is restored, modify the DB instance using the process explained in Step 4: Create or modify a MySQL DB instance (p. 1379) to add the DB instance to a domain.

Kerberos authentication MySQL limitations

The following limitations apply to Kerberos authentication for MySQL:

- Only an AWS Managed Microsoft AD is supported. However, you can join RDS for MySQL DB instances to shared Managed Microsoft AD domains owned by different accounts in the same AWS Region.
- You must reboot the DB instance after enabling the feature.
- The domain name length can't be longer than 61 characters.
- You can't enable Kerberos authentication and IAM authentication at the same time. Choose one authentication method or the other for your MySQL DB instance.
- Don't modify the DB instance port after enabling the feature.
- Don't use Kerberos authentication with read replicas.
- If you have auto minor version upgrade turned on for a MySQL DB instance that is using Kerberos authentication, you must turn off Kerberos authentication and then turn it back on after an automatic upgrade. For more information about auto minor version upgrades, see Automatic minor version upgrades for MySQL (p. 1397).
- To delete a DB instance with this feature enabled, first disable the feature. To do this, use the modify-db-instance CLI command for the DB instance and specify none for the --domain parameter.

  If you use the CLI or RDS API to delete a DB instance with this feature enabled, expect a delay.
Improving query performance with Amazon RDS Optimized Reads

You can achieve faster query processing with Amazon RDS Optimized Reads. An RDS for MySQL DB instance that uses RDS Optimized Reads can achieve up to 50 percent faster query processing compared to a DB instance that doesn't use it.

Topics
- Overview of RDS Optimized Reads (p. 1384)
- Use cases for RDS Optimized Reads (p. 1384)
- Best practices for RDS Optimized Reads (p. 1385)
- Using RDS Optimized Reads (p. 1385)
- Monitoring DB instances that use RDS Optimized Reads (p. 1386)
- Limitations for RDS Optimized Reads (p. 1386)

Overview of RDS Optimized Reads

When you use an RDS for MySQL DB instance that has RDS Optimized Reads turned on, your DB instance achieves faster query performance through the use of an instance store. An *instance store* provides temporary block-level storage for your DB instance. The storage is located on Non-Volatile Memory Express (NVMe) solid state drives (SSDs) that are physically attached to the host server. This storage is optimized for low latency, high random I/O performance, and high sequential read throughput.

RDS Optimized Reads is turned on by default when a DB instance uses a DB instance class with an instance store, such as db.m5d or db.m6gd. With RDS Optimized Reads, some temporary objects are stored on the instance store. These temporary objects include internal temporary files, internal on-disk temp tables, memory map files, and binlog cache files. For more information about the instance store, see [Amazon EC2 instance store](https://docs.aws.amazon.com/AmazonECS/latest/ug/instance-store.html) in the *Amazon Elastic Compute Cloud User Guide for Linux Instances*.

The workloads that generate temporary objects in MySQL for query processing can take advantage of the instance store for faster query processing. This type of workload includes queries involving sorts, hash aggregations, high-load joins, Common Table Expressions (CTEs), and queries on unindexed columns. These instance store volumes provide higher IOPS and performance, regardless of the storage configurations used for persistent Amazon EBS storage. Because RDS Optimized Reads offloads operations on temporary objects to the instance store, the input/output operations per second (IOPS) or throughput of the persistent storage (Amazon EBS) can now be used for operations on persistent objects. These operations include regular data file reads and writes, and background engine operations, such as flushing and insert buffer merges.

**Note**
Both manual and automated RDS snapshots only contain engine files for persistent objects. The temporary objects created in the instance store aren't included in RDS snapshots.

Use cases for RDS Optimized Reads

If you have workloads that rely heavily on temporary objects, such as internal tables or files, for their query execution, then you can benefit from turning on RDS Optimized Reads. The following use cases are candidates for RDS Optimized Reads:

- Applications that run analytical queries with complex common table expressions (CTEs), derived tables, and grouping operations
Best practices

- Read replicas that serve heavy read traffic with unoptimized queries
- Applications that run on-demand or dynamic reporting queries that involve complex operations, such as queries with `GROUP BY` and `ORDER BY` clauses
- Workloads that use internal temporary tables for query processing

You can monitor the engine status variable `created_tmp_disk_tables` to determine the number of disk-based temporary tables created on your DB instance.

- Applications that create large temporary tables, either directly or in procedures, to store intermediate results
- Database queries that perform grouping or ordering on non-indexed columns

Best practices for RDS Optimized Reads

Following are best practices for using RDS Optimized Reads:

- Add retry logic for read-only queries in case they fail because of a storage full error on the instance store during the execution.
- Monitor the storage space available on the instance store with the CloudWatch metric `FreeLocalStorage`. If the instance store is reaching its limit because of workload on the DB instance, modify the DB instance to use a larger DB instance class.
- When your DB instance has sufficient memory but is still reaching the storage limit on the instance store, increase the `binlog_cache_size` value to maintain the session-specific binlog entries in memory. This configuration prevents writing the binlog entries to temporary binlog cache files on disk.

The `binlog_cache_size` parameter is session-specific. You can change the value for each new session. The setting for this parameter can increase the memory utilization on the DB instance during peak workload. Therefore, consider increasing the parameter value based on the workload pattern of your application and available memory on the DB instance.

- Use the default value of `MIXED` for the `binlog_format`. Depending on the size of the transactions, setting `binlog_format` to `ROW` can result in large binlog cache files on the instance store.
- Set the `internal_tmp_mem_storage_engine` parameter to `TempTable`, and set the `temptable_max_mmap` parameter to match the size of the available storage on the instance store.
- Avoid performing bulk changes in a single transaction. These types of transactions can generate large binlog cache files on the instance store and can cause issues when the instance store is full. Consider splitting writes into multiple small transactions to minimize storage use for binlog cache files.
- Use the default value of `ABORT_SERVER` for the `binlog_error_action` parameter. Doing so avoids issues with the binary logging on DB instances with backups enabled.

Using RDS Optimized Reads

When you provision an RDS for MySQL DB instance with one of the following DB instance classes in a Single-AZ DB instance deployment or Multi-AZ DB instance deployment, the DB instance automatically uses RDS Optimized Reads:

- `db.m6gd`
- `db.r6gd`
- `db.m5d`
- `db.r5d`

To turn on RDS Optimized Reads, do one of the following:
• Create an RDS for MySQL DB instance using one of these DB instance classes. For more information, see Creating an Amazon RDS DB instance (p. 236).
• Modify an existing RDS for MySQL DB instance to use one of these DB instance classes. For more information, see Modifying an Amazon RDS DB instance (p. 333).

RDS Optimized Reads is available in all AWS Regions where one or more of these DB instance classes are supported. For more information, see DB instance classes (p. 10).

If you don't want to use RDS Optimized Reads, modify your DB instance so that it doesn't use a DB instance class that supports the feature.

**Monitoring DB instances that use RDS Optimized Reads**

You can monitor DB instances that use RDS Optimized Reads with the following CloudWatch metrics:

- FreeLocalStorage
- ReadIOPSLocalStorage
- ReadLatencyLocalStorage
- ReadThroughputLocalStorage
- WriteIOPSLocalStorage
- WriteLatencyLocalStorage
- WriteThroughputLocalStorage

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS (p. 644).

**Limitations for RDS Optimized Reads**

The following limitations apply to RDS Optimized Reads:

- RDS Optimized Reads is supported for RDS for MySQL version 8.0.28 and higher. For information about RDS for MySQL versions, see MySQL on Amazon RDS versions (p. 1356).
- You can't change the location of temporary objects to persistent storage (Amazon EBS) on the DB instance classes that support RDS Optimized Reads.
- When binary logging is enabled on a DB instance, the maximum transaction size is limited by the size of the instance store. In this case, any session that requires more storage than the value of binlog_cache_size writes transaction changes to temporary binlog cache files, which are created on the instance store.
- Transactions can fail when the instance store is full.
- RDS Optimized Reads isn't supported for Multi-AZ DB cluster deployments.
Improving write performance with Amazon RDS Optimized Writes

You can improve the performance of write transactions with Amazon RDS Optimized Writes. When your RDS for MySQL database uses RDS Optimized Writes, it can achieve up to two times higher write transaction throughput.

Topics
- Overview of RDS Optimized Writes (p. 1387)
- Using RDS Optimized Writes (p. 1388)
- Limitations for RDS Optimized Writes (p. 1391)

Overview of RDS Optimized Writes

When you turn on Amazon RDS Optimized Writes, your RDS for MySQL databases write only once when flushing data to durable storage without the need for the doublewrite buffer. The databases continue to provide ACID property protections for reliable database transactions, along with improved performance.

Relational databases, like MySQL, provide the ACID properties of atomicity, consistency, isolation, and durability for reliable database transactions. To help provide these properties, MySQL uses a data storage area called the doublewrite buffer that prevents partial page write errors. These errors occur when there is a hardware failure while the database is updating a page, such as in the case of a power outage. A MySQL database can detect partial page writes and recover with a copy of the page in the doublewrite buffer. While this technique provides protection, it also results in extra write operations. For more information about the MySQL doublewrite buffer, see Doublewrite Buffer in the MySQL documentation.

With RDS Optimized Writes turned on, RDS for MySQL databases write only once when flushing data to durable storage without using the doublewrite buffer. RDS Optimized Writes is useful if you run write-heavy workloads on your RDS for MySQL databases. Examples of databases with write-heavy workloads include ones that support digital payments, financial trading, and gaming applications.

These databases run on DB instance classes that use the AWS Nitro System. Because of the hardware configuration in these systems, the database can write 16 KiB pages directly to data files reliably and durably in one step. The AWS Nitro System makes RDS Optimized Writes possible.

You can set the new database parameter rds.optimized_writes to control the RDS Optimized Writes feature for RDS for MySQL databases. Access this parameter in the DB parameter groups of RDS for MySQL version 8.0. Set the parameter using the following values:

- AUTO – Turn on RDS Optimized Writes if the database supports it. Turn off RDS Optimized Writes if the database doesn't support it. This setting is the default.
- OFF – Turn off RDS Optimized Writes even if the database supports it.

If you migrate an RDS for MySQL database that is configured to use RDS Optimized Writes to a DB instance class that doesn't support the feature, RDS automatically turns off RDS Optimized Writes for the database.

When RDS Optimized Writes is turned off, the database uses the MySQL doublewrite buffer.

To determine whether an RDS for MySQL database is using RDS Optimized Writes, view the current value of the innodb_doublewrite parameter for the database. If the database is using RDS Optimized Writes, this parameter is set to FALSE (0).
Using RDS Optimized Writes

You can turn on RDS Optimized Writes when you create an RDS for MySQL database with the RDS console, the AWS CLI, or the RDS API. RDS Optimized Writes is turned on automatically when both of the following conditions apply during database creation:

- You specify a DB engine version and DB instance class that support RDS Optimized Writes. For information about the DB engine versions and DB instance classes that support RDS Optimized Writes, see Limitations for RDS Optimized Writes (p. 1391).
- In the parameter group associated with the database, the rds.optimized_writes parameter is set to AUTO. In default parameter groups, this parameter is always set to AUTO.

You might want to use a DB engine version and DB instance class that support RDS Optimized Writes, but you don't want to use this feature. In this case, specify a custom parameter group that has the rds.optimized_writes parameter set to OFF when you create the database. If you want the database to use RDS Optimized Writes later, you can set the parameter to AUTO to turn it on. For information about creating custom parameter groups and setting parameters, see Working with parameter groups (p. 295).

For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 236).

Console

When you use the RDS console to create an RDS for MySQL database, you can filter for the DB engine versions and DB instance classes that support RDS Optimized Writes. After you turn on the filters, you can choose from the available DB engine versions and DB instance classes.

To choose a DB engine version that supports RDS Optimized Writes, filter for the RDS for MySQL DB engine versions that support it in Engine version, and then choose a version.
In the Instance configuration section, filter for the DB instance classes that support RDS Optimized Writes, and then choose a DB instance class.
After you make these selections, you can choose other settings that meet your requirements and finish creating the RDS for MySQL database with the console.

**AWS CLI**

To create a DB instance by using the AWS CLI, use the `create-db-instance` command. Make sure the `--engine-version` and `--db-instance-class` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to `AUTO`. This example associates the default parameter group with the DB instance.

**Example Creating a DB instance that uses RDS Optimized Writes**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance "
   --db-instance-identifier mydbinstance 
   --engine mysql 
   --engine-version 8.0.30 
   --db-instance-class db.r5b.large 
   --master-user-password password 
   --master-username admin 
   --allocated-storage 200"
```

For Windows:

```bash
aws rds create-db-instance ^
   --db-instance-identifier mydbinstance ^
   --engine mysql ^
   --engine-version 8.0.30 ^
   --db-instance-class db.r5b.large ^
   --master-user-password password ^
   --master-username admin ^
   --allocated-storage 200
```

**RDS API**

You can create a DB instance using the `CreateDBInstance` operation. When you use this operation, make sure the `EngineVersion` and `DBInstanceClass` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to `AUTO`. 
Limitations for RDS Optimized Writes

The following limitations apply to RDS Optimized Writes:

- RDS Optimized Writes is supported for RDS for MySQL version 8.0.30 and higher. For information about RDS for MySQL versions, see MySQL on Amazon RDS versions (p. 1356).
- RDS Optimized Writes is supported for RDS for MySQL databases that use the following DB instance classes:
  - db.x2i
  - db.r6i
  - db.r6g
  - db.r6gd
  - db.r5b

For information about DB instance classes, see DB instance classes (p. 10).

- You can only modify a database to turn on RDS Optimized Writes if the database was created with a DB engine version and DB instance class that support the feature. In this case, if RDS Optimized Writes is turned off for the database, you can turn it on by setting the rds.optimized_writes parameter to AUTO.

- When you are restoring an RDS for MySQL database from a snapshot, you can only turn on RDS Optimized Writes for the database if all of the following conditions apply:
  - The snapshot was created from a database that supports RDS Optimized Writes.
  - The snapshot is restored to a database that supports RDS Optimized Writes.
  - The restored database is associated with a parameter group with the rds.optimized_writes parameter set to AUTO.
Upgrading the MySQL DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MySQL DB instances: major version upgrades and minor version upgrades.

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you follow the instructions in Major version upgrades for MySQL (p. 1393).

In contrast, minor version upgrades include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or you can enable the Auto minor version upgrade option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. For information about performing an upgrade, see Upgrading a DB instance engine version (p. 369).

If your MySQL DB instance is using read replicas, you must upgrade all of the read replicas before upgrading the source instance. If your DB instance is in a Multi-AZ deployment, both the primary and standby replicas are upgraded. Your DB instance will not be available until the upgrade is complete.

Database engine upgrades require downtime. The duration of the downtime varies based on the size of your DB instance.

Tip
You can minimize the downtime required for DB instance upgrade by using a blue/green deployment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates (p. 438).

Topics
- Overview of upgrading (p. 1392)
- Major version upgrades for MySQL (p. 1393)
- Testing an upgrade (p. 1397)
- Upgrading a MySQL DB instance (p. 1397)
- Automatic minor version upgrades for MySQL (p. 1397)
- Using a read replica to reduce downtime when upgrading a MySQL database (p. 1399)

Overview of upgrading

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
  --engine mysql \
  --engine-version version-number \
  --query "DBEngineVersions[1].ValidUpgradeTarget[1].{EngineVersion:EngineVersion}" --output text
```

For Windows:
For example, to identify the valid upgrade targets for a MySQL version 8.0.23 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions
  --engine mysql
  --engine-version 8.0.23
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:

```
aws rds describe-db-engine-versions
  --engine mysql
  --engine-version 8.0.23
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. If the upgrade doesn't work for your databases, you can restore this snapshot to create a DB instance running the old version. The second DB snapshot is taken when the upgrade completes.

**Note**

Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see [Modifying an Amazon RDS DB instance](#).

After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance is using read replication, you must upgrade all of the Read Replicas before upgrading the source instance.

If your DB instance is in a Multi-AZ deployment, both the primary and standby DB instances are upgraded. The primary and standby DB instances are upgraded at the same time and you will experience an outage until the upgrade is complete. The time for the outage varies based on your database engine, engine version, and the size of your DB instance.

**Major version upgrades for MySQL**

Amazon RDS supports the following in-place upgrades for major versions of the MySQL database engine:

- MySQL 5.6 to MySQL 5.7
- MySQL 5.7 to MySQL 8.0
Note
You can only create MySQL version 5.7 and 8.0 DB instances with latest-generation and current-generation DB instance classes, in addition to the db.m3 previous-generation DB instance class. In some cases, you want to upgrade a MySQL version 5.6 DB instance running on a previous-generation DB instance class (other than db.m3) to a MySQL version 5.7 DB instance. In these cases, first modify the DB instance to use a latest-generation or current-generation DB instance class. After you do this, you can then modify the DB instance to use the MySQL version 5.7 database engine. For information on Amazon RDS DB instance classes, see DB instance classes (p. 10).

Topics
• Overview of MySQL major version upgrades (p. 1394)
• Upgrades to MySQL version 5.7 might be slow (p. 1394)
• Prechecks for upgrades from MySQL 5.7 to 8.0 (p. 1395)
• Rollback after failure to upgrade from MySQL 5.7 to 8.0 (p. 1396)

Overview of MySQL major version upgrades
Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically; you must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.

To perform a major version upgrade for a MySQL version 5.6 DB instance on Amazon RDS to MySQL version 5.7 or later, first perform any available OS updates. After OS updates are complete, upgrade to each major version: 5.6 to 5.7 and then 5.7 to 8.0. MySQL DB instances created before April 24, 2014, show an available OS update until the update has been applied. For more information on OS updates, see Applying updates for a DB instance (p. 361).

During a major version upgrade of MySQL, Amazon RDS runs the MySQL binary mysql_upgrade to upgrade tables, if necessary. Also, Amazon RDS empties the slow_log and general_log tables during a major version upgrade. To preserve log information, save the log contents before the major version upgrade.

MySQL major version upgrades typically complete in about 10 minutes. Some upgrades might take longer because of the DB instance class size or because the instance doesn't follow certain operational guidelines in Best practices for Amazon RDS (p. 222). If you upgrade a DB instance from the Amazon RDS console, the status of the DB instance indicates when the upgrade is complete. If you upgrade using the AWS Command Line Interface (AWS CLI), use the describe-db-instances command and check the Status value.

Upgrades to MySQL version 5.7 might be slow
MySQL version 5.6.4 introduced a new date and time format for the datetime, time, and timestamp columns that allows fractional components in date and time values. When upgrading a DB instance to MySQL version 5.7, MySQL forces the conversion of all date and time column types to the new format.

Because this conversion rebuilds your tables, it might take a considerable amount of time to complete the DB instance upgrade. The forced conversion occurs for any DB instances that are running a version before MySQL version 5.6.4. It also occurs for any DB instances that were upgraded from a version before MySQL version 5.6.4 to a version other than 5.7.

If your DB instance runs a version before MySQL version 5.6.4, or was upgraded from a version before 5.6.4, we recommend an extra step. In these cases, we recommend that you convert the datetime, time, and timestamp columns in your database before upgrading your DB instance to MySQL version 5.7. This conversion can significantly reduce the amount of time required to upgrade the DB instance to MySQL version 5.7. To upgrade your date and time columns to the new format, issue the ALTER TABLE
<table_name> FORCE; command for each table that contains date or time columns. Because altering a table locks the table as read-only, we recommend that you perform this update during a maintenance window.

To find all tables in your database that have datetime, time, or timestamp columns and create an ALTER TABLE <table_name> FORCE; command for each table, use the following query.

```
SET show_old_temporals = ON;
SELECT table_schema, table_name, column_name, column_type
FROM information_schema.columns
WHERE column_type LIKE '%/* 5.5 binary format */';
SET show_old_temporals = OFF;
```

**Prechecks for upgrades from MySQL 5.7 to 8.0**

MySQL 8.0 includes a number of incompatibilities with MySQL 5.7. These incompatibilities can cause problems during an upgrade from MySQL 5.7 to MySQL 8.0. So, some preparation might be required on your database for the upgrade to be successful. The following is a general list of these incompatibilities:

- There must be no tables that use obsolete data types or functions.
- There must be no orphan *.frm files.
- Triggers must not have a missing or empty definer or an invalid creation context.
- There must be no partitioned table that uses a storage engine that does not have native partitioning support.
- There must be no keyword or reserved word violations. Some keywords might be reserved in MySQL 8.0 that were not reserved previously.

For more information, see [Keywords and reserved words](https://dev.mysql.com/doc/refman/5.7/en/keywords.html) in the MySQL documentation.

- There must be no tables in the MySQL 5.7 mysql system database that have the same name as a table used by the MySQL 8.0 data dictionary.
- There must be no obsolete SQL modes defined in your sql_mode system variable setting.
- There must be no tables or stored procedures with individual ENUM or SET column elements that exceed 255 characters or 1020 bytes in length.
- Before upgrading to MySQL 8.0.13 or higher, there must be no table partitions that reside in shared InnoDB tablespaces.
- There must be no queries and stored program definitions from MySQL 8.0.12 or lower that use ASC or DESC qualifiers for GROUP BY clauses.
- Your MySQL 5.7 installation must not use features that are not supported in MySQL 8.0.

For more information, see [Features removed in MySQL 8.0](https://dev.mysql.com/doc/refman/8.0/en/removed-features.html) in the MySQL documentation.

- There must be no foreign key constraint names longer than 64 characters.
- For improved Unicode support, consider converting objects that use the utf8mb3 charset to use the utf8mb4 charset. The utf8mb3 character set is deprecated. Also, consider using utf8mb4 for character set references instead of utf8, because currently utf8 is an alias for the utf8mb3 charset.

For more information, see [The utf8mb3 character set](https://dev.mysql.com/doc/refman/8.0/en/character-sets.html#character-set-utf8mb3) and [The utf8mb4 character set](https://dev.mysql.com/doc/refman/8.0/en/character-sets.html#character-set-utf8mb4) in the MySQL documentation.

When you start an upgrade from MySQL 5.7 to 8.0, Amazon RDS runs prechecks automatically to detect these incompatibilities. For information about upgrading to MySQL 8.0, see [Upgrading MySQL](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Concepts.MysqlUpgrade.html) in the MySQL documentation.

These prechecks are mandatory. You can't choose to skip them. The prechecks provide the following benefits:
They enable you to avoid unplanned downtime during the upgrade.

If there are incompatibilities, Amazon RDS prevents the upgrade and provides a log for you to learn about them. You can then use the log to prepare your database for the upgrade to MySQL 8.0 by eliminating the incompatibilities. For detailed information about removing incompatibilities, see Preparing your installation for upgrade in the MySQL documentation and Upgrading to MySQL 8.0? here is what you need to know... on the MySQL Server Blog.

The prechecks include some that are included with MySQL and some that were created specifically by the Amazon RDS team. For information about the prechecks provided by MySQL, see Upgrade checker utility.

The prechecks run before the DB instance is stopped for the upgrade, meaning that they don't cause any downtime when they run. If the prechecks find an incompatibility, Amazon RDS automatically cancels the upgrade before the DB instance is stopped. Amazon RDS also generates an event for the incompatibility. For more information about Amazon RDS events, see Working with Amazon RDS event notification (p. 685).

Amazon RDS records detailed information about each incompatibility in the log file PrePatchCompatibility.log. In most cases, the log entry includes a link to the MySQL documentation for correcting the incompatibility. For more information about viewing log files, see Viewing and listing database log files (p. 716).

Due to the nature of the prechecks, they analyze the objects in your database. This analysis results in resource consumption and increases the time for the upgrade to complete.

Note

Amazon RDS runs all of these prechecks only for an upgrade from MySQL 5.7 to MySQL 8.0. For an upgrade from MySQL 5.6 to MySQL 5.7, prechecks are limited to confirming that there are no orphan tables and that there is enough storage space to rebuild tables. Prechecks aren't run for upgrades to releases lower than MySQL 5.7.

Rollback after failure to upgrade from MySQL 5.7 to 8.0

When you upgrade a DB instance from MySQL version 5.7 to MySQL version 8.0, the upgrade can fail. In particular, it can fail if the data dictionary contains incompatibilities that weren't captured by the prechecks. In this case, the database fails to start up successfully in the new MySQL 8.0 version. At this point, Amazon RDS rolls back the changes performed for the upgrade. After the rollback, the MySQL DB instance is running MySQL version 5.7. When an upgrade fails and is rolled back, Amazon RDS generates an event with the event ID RDS-EVENT-0188.

Typically, an upgrade fails because there are incompatibilities in the metadata between the databases in your DB instance and the target MySQL version. When an upgrade fails, you can view the details about these incompatibilities in the upgradeFailure.log file. Resolve the incompatibilities before attempting to upgrade again.

During an unsuccessful upgrade attempt and rollback, your DB instance is restarted. Any pending parameter changes are applied during the restart and persist after the rollback.

For more information about upgrading to MySQL 8.0, see the following topics in the MySQL documentation:

• Preparing Your Installation for Upgrade
• Upgrading to MySQL 8.0? Here is what you need to know...

Note

Currently, automatic rollback after upgrade failure is supported only for MySQL 5.7 to 8.0 major version upgrades.
Testing an upgrade

Before you perform a major version upgrade on your DB instance, thoroughly test your database for compatibility with the new version. In addition, thoroughly test all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.

**To test a major version upgrade**

1. Review the upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications:
   - Changes in MySQL 5.6
   - Changes in MySQL 5.7
   - Changes in MySQL 8.0
2. If your DB instance is a member of a custom DB parameter group, create a new DB parameter group with your existing settings that is compatible with the new major version. Specify the new DB parameter group when you upgrade your test instance, so your upgrade testing ensures that it works correctly. For more information about creating a DB parameter group, see [Working with parameter groups](p. 295).
3. Create a DB snapshot of the DB instance to be upgraded. For more information, see [Creating a DB snapshot](p. 483).
4. Restore the DB snapshot to create a new test DB instance. For more information, see [Restoring from a DB snapshot](p. 487).
5. Modify this new test DB instance to upgrade it to the new version, using one of the methods detailed following. If you created a new parameter group in step 2, specify that parameter group.
6. Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage.
7. Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version. Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1. Test all stored procedures and functions. Direct test versions of your applications to the upgraded DB instance.
8. If all tests pass, then perform the upgrade on your production DB instance. We recommend that you don't allow write operations to the DB instance until you confirm that everything is working correctly.

Upgrading a MySQL DB instance

For information about manually or automatically upgrading a MySQL DB instance, see [Upgrading a DB instance engine version](p. 369).

Automatic minor version upgrades for MySQL

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.

In the AWS Management Console, these settings are under [Additional configuration](p. 369). The following image shows the **Auto minor version upgrade** setting.
For more information about these settings, see Settings for DB instances (p. 334).

For some RDS for MySQL major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the MySQL community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified MySQL minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
--engine mysql
--engine-version minor-version
--region region
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}"
--output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
--engine mysql ^
--engine-version minor-version ^
--region region ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MySQL minor version 8.0.11 in the US East (Ohio) AWS Region (us-east-2).
For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
  --engine mysql \
  --engine-version 8.0.11 \
  --region us-east-2 \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].\n  {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
  --output table
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
  --engine mysql ^
  --engine-version 8.0.11 ^
  --region us-east-2 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].\n  {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
  --output table
```

Your output is similar to the following.

```
<table>
<thead>
<tr>
<th>DescribeDBEngineVersions</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>AutoUpgrade</td>
<td>EngineVersion</td>
</tr>
<tr>
<td>True</td>
<td>8.0.23</td>
</tr>
<tr>
<td>False</td>
<td>8.0.25</td>
</tr>
</tbody>
</table>
```

In this example, the `AutoUpgrade` value is `True` for MySQL version 8.0.23. So, the automatic minor upgrade target is MySQL version 8.0.23, which is highlighted in the output.

A MySQL DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The `Auto minor version upgrade` setting is enabled.
- The `Backup retention period` setting is greater than 0.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see [Automatically upgrading the minor engine version](#).

**Using a read replica to reduce downtime when upgrading a MySQL database**

If your MySQL DB instance is currently in use with a production application, you can use the following procedure to upgrade the database version for your DB instance. This procedure can reduce the amount of downtime for your application.
By using a read replica, you can perform most of the maintenance steps ahead of time and minimize the necessary changes during the actual outage. With this technique, you can test and prepare the new DB instance without making any changes to your existing DB instance.

The following procedure shows an example of upgrading from MySQL version 5.7 to MySQL version 8.0. You can use the same general steps for upgrades to other major versions.

**Note**
When you are upgrading from MySQL version 5.7 to MySQL version 8.0, complete the prechecks before performing the upgrade. For more information, see [Prechecks for upgrades from MySQL 5.7 to 8.0](p. 1395).

**To upgrade an MySQL database while a DB instance is in use**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

2. Create a read replica of your MySQL 5.7 DB instance. This process creates an upgradable copy of your database. Other read replicas of the DB instance might also exist.
   a. In the console, choose **Databases**, and then choose the DB instance that you want to upgrade.
   b. For **Actions**, choose **Create read replica**.
   c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MySQL 5.7 DB instance.
   d. Choose **Create read replica**.

3. (Optional) When the read replica has been created and **Status** shows **Available**, convert the read replica into a Multi-AZ deployment and enable backups.
   By default, a read replicas is created as a single-AZ deployment with backups disabled. Because the read replica will ultimately become the production DB instance, it is a best practice to configure a Multi-AZ deployment and enable backups now.
   a. In the console, choose **Databases**, and then choose the read replica that you just created.
   b. Choose **Modify**.
   c. For **Multi-AZ deployment**, choose **Create a standby instance**.
   d. For **Backup Retention Period**, choose a positive nonzero value, for example 3 days, and then choose **Continue**.
   e. For **Scheduling of modifications**, choose **Apply immediately**.
   f. Choose **Modify DB instance**.

4. When the read replica **Status** shows **Available**, upgrade the read replica to MySQL 8.0:
   a. In the console, choose **Databases**, and then choose the read replica that you just created.
   b. Choose **Modify**.
   c. For **DB engine version**, choose the MySQL 8.0 version to upgrade to, and then choose **Continue**.
   d. For **Scheduling of modifications**, choose **Apply immediately**.
   e. Choose **Modify DB instance** to start the upgrade.

5. When the upgrade is complete and **Status** shows **Available**, verify that the upgraded read replica is up-to-date with the source MySQL 5.7 DB instance. You can do this by connecting to the read replica and issuing the **SHOW REPLICA STATUS** command. If the **Seconds_Behind_Master** field is 0, then replication is up-to-date.

   **Note**
   Previous versions of MySQL used **SHOW SLAVE STATUS** instead of **SHOW REPLICA STATUS**. If you are using a MySQL version before 8.0.23, then use **SHOW SLAVE STATUS**.

6. (Optional) Create a read replica of your read replica.
If you want the DB instance to have a read replica after it is promoted to a standalone DB instance, you can create the read replica now.

a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.
b. For **Actions**, choose **Create read replica**.
c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MySQL 5.7 DB instance.
d. Choose **Create read replica**.

7. **(Optional) Configure a custom DB parameter group for the read replica.**

If you want the DB instance to use a custom parameter group after it is promoted to a standalone DB instance, you can create the DB parameter group now can associate it with the read replica.

a. Create a custom DB parameter group for MySQL 8.0. For instructions, see **Creating a DB parameter group** (p. 297).
b. Modify the parameters that you want to change in the DB parameter group you just created. For instructions, see **Modifying parameters in a DB parameter group** (p. 300).
c. In the console, choose **Databases**, and then choose the read replica.
d. Choose **Modify**.
e. For **DB parameter group**, choose the MySQL 8.0 DB parameter group you just created, and then choose **Continue**.
f. For **Scheduling of modifications**, choose **Apply immediately**.
g. Choose **Modify DB instance** to start the upgrade.

8. **Make your MySQL 8.0 read replica a standalone DB instance.**

**Important**
When you promote your MySQL 8.0 read replica to a standalone DB instance, it no longer is a replica of your MySQL 5.7 DB instance. We recommend that you promote your MySQL 8.0 read replica during a maintenance window when your source MySQL 5.7 DB instance is in read-only mode and all write operations are suspended. When the promotion is completed, you can direct your write operations to the upgraded MySQL 8.0 DB instance to ensure that no write operations are lost.
In addition, we recommend that, before promoting your MySQL 8.0 read replica, you perform all necessary data definition language (DDL) operations on your MySQL 8.0 read replica. An example is creating indexes. This approach avoids negative effects on the performance of the MySQL 8.0 read replica after it has been promoted. To promote a read replica, use the following procedure.

a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.
b. For **Actions**, choose **Promote**.
c. Choose **Yes** to enable automated backups for the read replica instance. For more information, see **Working with backups** (p. 462).
d. Choose **Continue**.
e. Choose **Promote Read Replica**.

9. **You now have an upgraded version of your MySQL database. At this point, you can direct your applications to the new MySQL 8.0 DB instance.**
# Importing data into a MySQL DB instance

You can use several different techniques to import data into an RDS for MySQL DB instance. The best approach depends on the source of the data, the amount of data, and whether the import is done one time or is ongoing. If you are migrating an application along with the data, also consider the amount of downtime that you are willing to experience.

## Overview

Find techniques to import data into an RDS for MySQL DB instance in the following table.

<table>
<thead>
<tr>
<th>Source</th>
<th>Amount of data</th>
<th>One time or ongoing</th>
<th>Applicatio downtime</th>
<th>Technique</th>
<th>More information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Existing MySQL database on premises or on Amazon EC2</td>
<td>Any</td>
<td>One time</td>
<td>Some</td>
<td>Create a backup of your on-premises database, store it on Amazon S3, and then restore the backup file to a new Amazon RDS DB instance running MySQL.</td>
<td>Restoring a backup into a MySQL DB instance (p. 1408)</td>
</tr>
<tr>
<td>Any existing database</td>
<td>Any</td>
<td>One time or ongoing</td>
<td>Minimal</td>
<td>Use AWS Database Migration Service to migrate the database with minimal downtime and, for many database DB engines, continue ongoing replication.</td>
<td>What is AWS Database Migration Service and Using a MySQL-compatible database as a target for AWS DMS in the AWS Database Migration Service User Guide</td>

<tr>
<td>Existing MariaDB or MySQL database on premises or on Amazon EC2</td>
<td>Any</td>
<td>Ongoing</td>
<td>Minimal</td>
<td>Configure replication with an existing MariaDB or MySQL database as the replication source.</td>
<td>Configuring binary log file position replication with an external source instance (p. 1455)</td>
</tr>
</tbody>
</table>

**Note**
The 'mysql' system database contains authentication and authorization information required to log in to your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the 'mysql' database in your DB instance can result in error and might render the DB instance and your data inaccessible. If this occurs, you can restore the DB instance from a snapshot using the AWS CLI `restore-db-instance-from-db-snapshot` command. You can recover the DB instance using the AWS CLI `restore-db-instance-to-point-in-time` command.
Importing data considerations

Following, you can find additional technical information related to loading data into MySQL. This information is intended for advanced users who are familiar with the MySQL server architecture. All comments related to LOAD DATA LOCAL INFILE also apply to mysqlimport.

Binary log

Data loads incur a performance penalty and require additional free disk space (up to four times more) when binary logging is enabled versus loading the same data with binary logging turned off. The severity of the performance penalty and the amount of free disk space required is directly proportional to the size of the transactions used to load the data.

Transaction size

Transaction size plays an important role in MySQL data loads. It has a major influence on resource consumption, disk space utilization, resume process, time to recover, and input format (flat files or SQL). This section describes how transaction size affects binary logging and makes the case for disabling binary logging during large data loads. As noted earlier, binary logging is enabled and disabled by setting the Amazon RDS automated backup retention period. Non-zero values enable binary logging, and zero disables it. We also describe the impact of large transactions on InnoDB and why it's important to keep transaction sizes small.

Small transactions

For small transactions, binary logging doubles the number of disk writes required to load the data. This effect can severely degrade performance for other database sessions and increase the time required to load the data. The degradation experienced depends in part upon the upload rate, other database activity taking place during the load, and the capacity of your Amazon RDS DB instance.

The binary logs also consume disk space roughly equal to the amount of data loaded until they are backed up and removed. Fortunately, Amazon RDS minimizes this by backing up and removing binary logs on a frequent basis.

Large transactions

Large transactions incur a 3X penalty for IOPS and disk consumption with binary logging enabled. This is due to the binary log cache spilling to disk, consuming disk space and incurring additional IO for each write. The cache cannot be written to the binlog until the transaction commits or rolls back, so it consumes disk space in proportion to the amount of data loaded. When the transaction commits, the cache must be copied to the binlog, creating a third copy of the data on disk.

Because of this, there must be at least three times as much free disk space available to load the data compared to loading with binary logging disabled. For example, 10 GiB of data loaded as a single transaction consumes at least 30 GiB disk space during the load. It consumes 10 GiB for the table + 10 GiB for the binary log cache + 10 GiB for the binary log itself. The cache file remains on disk until the session that created it terminates or the session fills its binary log cache again during another transaction. The binary log must remain on disk until backed up, so it might be some time before the extra 20 GiB is freed.

If the data was loaded using LOAD DATA LOCAL INFILE, yet another copy of the data is created if the database has to be recovered from a backup made before the load. During recovery, MySQL extracts the data from the binary log into a flat file. MySQL then runs LOAD DATA LOCAL INFILE, just as in the original transaction. However, this time the input file is local to the database server. Continuing with the example preceding, recovery fails unless there is at least 40 GiB free disk space available.
Disable binary logging

Whenever possible, disable binary logging during large data loads to avoid the resource overhead and addition disk space requirements. In Amazon RDS, disabling binary logging is as simple as setting the backup retention period to zero. If you do this, we recommend that you take a DB snapshot of the database instance immediately before the load. By doing this, you can quickly and easily undo changes made during loading if you need to.

After the load, set the backup retention period back to an appropriate (no zero) value.

You can't set the backup retention period to zero if the DB instance is a source DB instance for read replicas.

InnoDB

The information in this section provides a strong argument for keeping transaction sizes small when using InnoDB.

Undo

InnoDB generates undo to support features such as transaction rollback and MVCC. Undo is stored in the InnoDB system tablespace (usually ibdata1) and is retained until removed by the purge thread. The purge thread cannot advance beyond the undo of the oldest active transaction, so it is effectively blocked until the transaction commits or completes a rollback. If the database is processing other transactions during the load, their undo also accumulates in the system tablespace and cannot be removed even if they commit and no other transaction needs the undo for MVCC. In this situation, all transactions (including read-only transactions) that access any of the rows changed by any transaction (not just the load transaction) slow down. The slowdown occurs because transactions scan through undo that could have been purged if not for the long-running load transaction.

Undo is stored in the system tablespace, and the system tablespace never shrinks in size. Thus, large data load transactions can cause the system tablespace to become quite large, consuming disk space that you can't reclaim without recreating the database from scratch.

Rollback

InnoDB is optimized for commits. Rolling back a large transaction can take a very, very long time. In some cases, it might be faster to perform a point-in-time recovery or restore a DB snapshot.

Input data format

MySQL can accept incoming data in one of two forms: flat files and SQL. This section points out some key advantages and disadvantages of each.

Flat files

Loading flat files with LOAD DATA LOCAL INFILE can be the fastest and least costly method of loading data as long as transactions are kept relatively small. Compared to loading the same data with SQL, flat files usually require less network traffic, lowering transmission costs and load much faster due to the reduced overhead in the database.

One big transaction

LOAD DATA LOCAL INFILE loads the entire flat file as one transaction. This isn't necessarily a bad thing. If the size of the individual files can be kept small, this has a number of advantages:

- Resume capability – Keeping track of which files have been loaded is easy. If a problem arises during the load, you can pick up where you left off with little effort. Some data might have to be retransmitted to Amazon RDS, but with small files, the amount retransmitted is minimal.
• Load data in parallel – If you've got IOPS and network bandwidth to spare with a single file load, loading in parallel might save time.
• Throttle the load rate – Data load having a negative impact on other processes? Throttle the load by increasing the interval between files.

Be careful

The advantages of LOAD DATA LOCAL INFILE diminish rapidly as transaction size increases. If breaking up a large set of data into smaller ones isn't an option, SQL might be the better choice.

SQL

SQL has one main advantage over flat files: it's easy to keep transaction sizes small. However, SQL can take significantly longer to load than flat files and it can be difficult to determine where to resume the load after a failure. For example, mysqldump files are not restartable. If a failure occurs while loading a mysqldump file, the file requires modification or replacement before the load can resume. The alternative is to restore to the point in time before the load and replay the file after the cause of the failure has been corrected.

Take checkpoints using Amazon RDS snapshots

If you have a load that's going to take several hours or even days, loading without binary logging isn't a very attractive prospect unless you can take periodic checkpoints. This is where the Amazon RDS DB snapshot feature comes in very handy. A DB snapshot creates a point-in-time consistent copy of your database instance which can be used restore the database to that point in time after a crash or other mishap.

To create a checkpoint, simply take a DB snapshot. Any previous DB snapshots taken for checkpoints can be removed without affecting durability or restore time.

Snapshots are fast too, so frequent checkpointing doesn't add significantly to load time.

Decreasing load time

Here are some additional tips to reduce load times:

• Create all secondary indexes before loading. This is counter-intuitive for those familiar with other databases. Adding or modifying a secondary index causes MySQL to create a new table with the index changes, copy the data from the existing table to the new table, and drop the original table.
• Load data in PK order. This is particularly helpful for InnoDB tables, where load times can be reduced by 75–80 percent and data file size cut in half.
• Disable foreign key constraints foreign_key_checks=0. For flat files loaded with LOAD DATA LOCAL INFILE, this is required in many cases. For any load, disabling FK checks provides significant performance gains. Just be sure to enable the constraints and verify the data after the load.
• Load in parallel unless already near a resource limit. Use partitioned tables when appropriate.
• Use multi-value inserts when loading with SQL to minimize overhead when running statements. When using mysqldump, this is done automatically.
• Reduce InnoDB log IO innodb_flush_log_at_trx_commit=0
• If you are loading data into a DB instance that does not have read replicas, set the sync_binlog parameter to 0 while loading data. When data loading is complete, set the sync_binlog parameter to back to 1.
• Load data before converting the DB instance to a Multi-AZ deployment. However, if the DB instance already uses a Multi-AZ deployment, switching to a Single-AZ deployment for data loading is not recommended, because doing so only provides marginal improvements.
Note
Using innodb_flush_log_at_trx_commit=0 causes InnoDB to flush its logs every second instead of at each commit. This provides a significant speed advantage, but can lead to data loss during a crash. Use with caution.

Topics
- Restoring a backup into a MySQL DB instance (p. 1408)
- Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance (p. 1416)
- Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1418)
- Importing data from any source to a MariaDB or MySQL DB instance (p. 1431)
Restoring a backup into a MySQL DB instance

Amazon RDS supports importing MySQL databases by using backup files. You can create a backup of your database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL.

The scenario described in this section restores a backup of an on-premises database. You can use this technique for databases in other locations, such as Amazon EC2 or non-AWS cloud services, as long as the database is accessible.

You can find the supported scenario in the following diagram.

Importing backup files from Amazon S3 is supported for MySQL in all AWS Regions.

We recommend that you import your database to Amazon RDS by using backup files if your on-premises database can be offline while the backup file is created, copied, and restored. If your database can't be offline, you can use binary log (binlog) replication to update your database after you have migrated to Amazon RDS through Amazon S3 as explained in this topic. For more information, see Configuring binary log file position replication with an external source instance (p. 1455). You can also use the AWS Database Migration Service to migrate your database to Amazon RDS. For more information, see What is AWS Database Migration Service?

Limitations and recommendations for importing backup files from Amazon S3 to Amazon RDS

The following are some limitations and recommendations for importing backup files from Amazon S3:

- You can only import your data to a new DB instance, not an existing DB instance.
- You must use Percona XtraBackup to create the backup of your on-premises database.
- You can't import data from a DB snapshot export to Amazon S3.
- You can't migrate from a source database that has tables defined outside of the default MySQL data directory.
- You must import your data to the default minor version of your MySQL major version in your AWS Region. For example, if your major version is MySQL 8.0, and the default minor version for your AWS Region is 8.0.28, then you must import your data into a MySQL version 8.0.28 DB instance. You can
upgrade your DB instance after importing. For information about determining the default minor version, see MySQL on Amazon RDS versions (p. 1356).

- Backward migration is not supported for both major versions and minor versions. For example, you can't migrate from version 8.0 to version 5.7, and you can't migrate from version 8.0.28 to version 8.0.27.
- You can't import a MySQL 5.5 or 5.6 database.
- You can't import an on-premises MySQL database from one major version to another. For example, you can't import a MySQL 5.7 database to an RDS for MySQL 8.0 database. You can upgrade your DB instance after you complete the import.
- You can't restore from an encrypted source database, but you can restore to an encrypted Amazon RDS DB instance.
- You can't restore from an encrypted backup in the Amazon S3 bucket.
- You can't restore from an Amazon S3 bucket in a different AWS Region than your Amazon RDS DB instance.
- Importing from Amazon S3 is not supported on the db.t2.micro DB instance class. However, you can restore to a different DB instance class, and change the DB instance class later. For more information about instance classes, see Hardware specifications for DB instance classes (p. 62).
- Amazon S3 limits the size of a file uploaded to an Amazon S3 bucket to 5 TB. If a backup file exceeds 5 TB, then you must split the backup file into smaller files.
- When you restore the database, the backup is copied and then extracted on your DB instance. Therefore, provision storage space for your DB instance that is equal to or greater than the sum of the backup size, plus the original database's size on disk.
- Amazon RDS limits the number of files uploaded to an Amazon S3 bucket to 1 million. If the backup data for your database, including all full and incremental backups, exceeds 1 million files, use a Gzip (.gz), tar (.tar.gz), or Percona xbstream (.xbstream) file to store full and incremental backup files in the Amazon S3 bucket. Percona XtraBackup 8.0 only supports Percona xbstream for compression.
- User accounts are not imported automatically. Save your user accounts from your source database and add them to your new DB instance later.
- Functions are not imported automatically. Save your functions from your source database and add them to your new DB instance later.
- Stored procedures are not imported automatically. Save your stored procedures from your source database and add them to your new DB instance later.
- Time zone information is not imported automatically. Record the time zone information for your source database, and set the time zone of your new DB instance later. For more information, see Local time zone for MySQL DB instances (p. 1480).
- The innodb_data_file_path parameter must be configured with only one data file that uses the default data file name "ibdata1:12M:autoextend". Databases with two data files, or with a data file with a different name, can't be migrated using this method.

The following are examples of file names that are not allowed:
"innodb_data_file_path=ibdata1:50M; ibdata2:50M:autoextend" and "innodb_data_file_path=ibdata01:50M:autoextend".

- The maximum size of the restored database is the maximum database size supported minus the size of the backup. So, if the maximum database size supported is 64 TiB, and the size of the backup is 30 TiB, then the maximum size of the restored database is 34 TiB, as in the following example:

\[
64 \text{ TiB} - 30 \text{ TiB} = 34 \text{ TiB}
\]

For information about the maximum database size supported by Amazon RDS for MySQL, see General Purpose SSD storage (p. 71) and Provisioned IOPS SSD storage (p. 73).
Overview of setting up to import backup files from Amazon S3 to Amazon RDS

These are the components you need to set up to import backup files from Amazon S3 to Amazon RDS:

- An Amazon S3 bucket to store your backup files.
- A backup of your on-premises database created by Percona XtraBackup.
- An AWS Identity and Access Management (IAM) role to allow Amazon RDS to access the bucket.

If you already have an Amazon S3 bucket, you can use that. If you don't have an Amazon S3 bucket, you can create a new one. If you want to create a new bucket, see Creating a bucket.

Use the Percona XtraBackup tool to create your backup. For more information, see Creating your database backup (p. 1410).

If you already have an IAM role, you can use that. If you don't have an IAM role, you can create a new one manually. Alternatively, you can choose to have a new IAM role created for you in your account by the wizard when you restore the database by using the AWS Management Console. If you want to create a new IAM role manually, or attach trust and permissions policies to an existing IAM role, see Creating an IAM role manually (p. 1412). If you want to have a new IAM role created for you, follow the procedure in Console (p. 1413).

Creating your database backup

Use the Percona XtraBackup software to create your backup. You can install Percona XtraBackup from Download Percona XtraBackup.

**Warning**
When creating a database backup, XtraBackup might save credentials in the xtrabackup_info file. Make sure you examine that file so that the tool_command setting in it doesn't contain any sensitive information.

**Note**
For MySQL 8.0 migration, you must use Percona XtraBackup 8.0. Percona XtraBackup 8.0.12 and higher versions support migration of all versions of MySQL. If you are migrating to RDS for MySQL 8.0.20 or higher, you must use Percona XtraBackup 8.0.12 or higher. For MySQL 5.7 migrations, you can also use Percona XtraBackup 2.4. For migrations of earlier MySQL versions, you can also use Percona XtraBackup 2.3 or 2.4.

You can create a full backup of your MySQL database files using Percona XtraBackup. Alternatively, if you already use Percona XtraBackup to back up your MySQL database files, you can upload your existing full and incremental backup directories and files.

For more information about backing up your database with Percona XtraBackup, see Percona XtraBackup - documentation and The xtrabackup binary on the Percona website.

Creating a full backup with Percona XtraBackup

To create a full backup of your MySQL database files that can be restored from Amazon S3, use the Percona XtraBackup utility (xtrabackup) to back up your database.

For example, the following command creates a backup of a MySQL database and stores the files in the folder /on-premises/s3-restore/backup folder.

```
xtrabackup --backup --user=<myuser> --password=<password> --target-dir=/on-premises/s3-restore/backup
```
If you want to compress your backup into a single file (which can be split later, if needed), you can save your backup in one of the following formats:

- Gzip (.gz)
- tar (.tar)
- Percona xbstream (.xbstream)

**Note**
Percona XtraBackup 8.0 only supports Percona xbstream for compression.

The following command creates a backup of your MySQL database split into multiple Gzip files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar \
   --target-dir=/on-premises/s3-restore/backup | gzip - | split -d --bytes=500MB \
   - /on-premises/s3-restore/backup/backup*.tar.gz
```

The following command creates a backup of your MySQL database split into multiple tar files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar \
   --target-dir=/on-premises/s3-restore/backup | split -d --bytes=500MB \
   - /on-premises/s3-restore/backup/backup*.tar
```

The following command creates a backup of your MySQL database split into multiple xbstream files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=xbstream \
   --target-dir=/on-premises/s3-restore/backup | split -d --bytes=500MB \
   - /on-premises/s3-restore/backup/backup*.xbstream
```

**Using incremental backups with Percona XtraBackup**

If you already use Percona XtraBackup to perform full and incremental backups of your MySQL database files, you don't need to create a full backup and upload the backup files to Amazon S3. Instead, you can save a significant amount of time by copying your existing backup directories and files to your Amazon S3 bucket. For more information about creating incremental backups using Percona XtraBackup, see **Incremental backup**.

When copying your existing full and incremental backup files to an Amazon S3 bucket, you must recursively copy the contents of the base directory. Those contents include the full backup and also all incremental backup directories and files. This copy must preserve the directory structure in the Amazon S3 bucket. Amazon RDS iterates through all files and directories. Amazon RDS uses the `xtrabackup-checkpoints` file that is included with each incremental backup to identify the base directory, and to order incremental backups by log sequence number (LSN) range.

**Backup considerations for Percona XtraBackup**

Amazon RDS consumes your backup files based on the file name. Name your backup files with the appropriate file extension based on the file format—for example, `.xbstream` for files stored using the Percona xbstream format.

Amazon RDS consumes your backup files in alphabetical order and also in natural number order. Use the `split` option when you issue the `xtrabackup` command to ensure that your backup files are written and named in the proper order.

Amazon RDS doesn't support partial backups created using Percona XtraBackup. You can't use the following options to create a partial backup when you back up the source files for your database: --
tables, --tables-exclude, --tables-file, --databases, --databases-exclude, or --databases-file.

Amazon RDS supports incremental backups created using Percona XtraBackup. For more information about creating incremental backups using Percona XtraBackup, see Incremental backup.

Creating an IAM role manually

If you don’t have an IAM role, you can create a new one manually. Alternatively, you can choose to have a new IAM role created for you by the wizard when you restore the database by using the AWS Management Console. If you want to have a new IAM role created for you, follow the procedure in Console (p. 1413).

To manually create a new IAM role for importing your database from Amazon S3, create a role to delegate permissions from Amazon RDS to your Amazon S3 bucket. When you create an IAM role, you attach trust and permissions policies. To import your backup files from Amazon S3, use trust and permissions policies similar to the examples following. For more information about creating the role, see Creating a role to delegate permissions to an AWS service.

Alternatively, you can choose to have a new IAM role created for you by the wizard when you restore the database by using the AWS Management Console. If you want to have a new IAM role created for you, follow the procedure in Console (p. 1413).

The trust and permissions policies require that you provide an Amazon Resource Name (ARN). For more information about ARN formatting, see Amazon Resource Names (ARNs) and AWS service namespaces.

Example Trust policy for importing from Amazon S3

```json
{
  "Version": "2012-10-17",
  "Statement":
  [
    {
      "Effect": "Allow",
      "Principal": {"Service": "rds.amazonaws.com"},
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Example Permissions policy for importing from Amazon S3 — IAM user permissions

```json
{
  "Version": "2012-10-17",
  "Statement":
  [
    {
      "Sid": "AllowS3AccessRole",
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::IAM User ID:role/S3Access"
    }
  ]
}
```

Example Permissions policy for importing from Amazon S3 — role permissions

```json
{
  "Version": "2012-10-17",
}
```
"Statement":
[
  {
    "Effect": "Allow",
    "Action":
    [
      "s3:ListBucket",
      "s3:GetBucketLocation"
    ],
    "Resource": "arn:aws:s3:::bucket_name"
  },
  {
    "Effect": "Allow",
    "Action":
    [
      "s3:GetObject"
    ],
    "Resource": "arn:aws:s3:::bucket_name/prefix*"
  }
]

Note
If you include a file name prefix, include the asterisk (*) after the prefix. If you don't want to specify a prefix, specify only an asterisk.

Importing data from Amazon S3 to a new MySQL DB instance

You can import data from Amazon S3 to a new MySQL DB instance using the AWS Management Console, AWS CLI, or RDS API.

Console

To import data from Amazon S3 to a new MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the top right corner of the Amazon RDS console, choose the AWS Region in which to create your DB instance. Choose the same AWS Region as the Amazon S3 bucket that contains your database backup.
3. In the navigation pane, choose Databases.
4. Choose Restore from S3.

The Create database by restoring from S3 page appears.
5. Under **S3 destination:**

- **S3 bucket:** db-backup-bucket-123.xyz
- **S3 prefix (optional):**

**Engine options**

- **Engine type:**
  - Amazon Aurora
  - MySQL
- **Edition:** MySQL Community
- **Source engine version:** 8.0
- **Engine Version:** MySQL 8.0.28
Choose the **S3 bucket** that contains the backup.

b. (Optional) For **S3 folder path prefix**, enter a file path prefix for the files stored in your Amazon S3 bucket.

If you don't specify a prefix, then RDS creates your DB instance using all of the files and folders in the root folder of the S3 bucket. If you do specify a prefix, then RDS creates your DB instance using the files and folders in the S3 bucket where the path for the file begins with the specified prefix.

For example, suppose that you store your backup files on S3 in a subfolder named backups, and you have multiple sets of backup files, each in its own directory (gzip_backup1, gzip_backup2, and so on). In this case, you specify a prefix of backups/gzip_backup1 to restore from the files in the gzip_backup1 folder.

6. Under **Engine options**:
   a. For **Engine type**, choose **MySQL**.
   b. For **Source engine version**, choose the MySQL major version of your source database.
   c. For **Version**, choose the default minor version of your MySQL major version in your AWS Region.

   In the AWS Management Console, only the default minor version is available. You can upgrade your DB instance after importing.

7. For **IAM role**, you can choose an existing IAM role.

8. (Optional) You can also have a new IAM role created for you by choosing **Create a new role** and entering the **IAM role name**.

9. Specify your DB instance information. For information about each setting, see **Settings for DB instances** (p. 243).

   **Note**
   Be sure to allocate enough memory for your new DB instance so that the restore operation can succeed.
   You can also choose **Enable storage autoscaling** to allow for future growth automatically.

10. Choose additional settings as needed.

11. Choose **Create database**.

**AWS CLI**

To import data from Amazon S3 to a new MySQL DB instance by using the AWS CLI, call the `restore-db-instance-from-s3` command with the following parameters. For information about each setting, see **Settings for DB instances** (p. 243).

   **Note**
   Be sure to allocate enough memory for your new DB instance so that the restore operation can succeed.
   You can also use the `--max-allocated-storage` parameter to enable storage autoscaling and allow for future growth automatically.

- `--allocated-storage`
- `--db-instance-identifier`
- `--db-instance-class`
- `--engine`
- `--master-username`
- `--master-user-password`
- `--s3-bucket-name`
• --s3-ingestion-role-arn
• --s3-prefix
• --source-engine
• --source-engine-version

Example

For Linux, macOS, or Unix:

```bash
aws rds restore-db-instance-from-s3 \
  --allocated-storage 250 \ 
  --db-instance-identifier myidentifier \ 
  --db-instance-class db.m5.large \ 
  --engine mysql \ 
  --master-username admin \ 
  --master-user-password mypassword \ 
  --s3-bucket-name mybucket \ 
  --s3-ingestion-role-arn arn:aws:iam::account-number:role/rolename \ 
  --s3-prefix bucketprefix \ 
  --source-engine mysql \ 
  --source-engine-version 8.0.28 \ 
  --max-allocated-storage 1000
```

For Windows:

```bash
aws rds restore-db-instance-from-s3 ^
  --allocated-storage 250 ^
  --db-instance-identifier myidentifier ^
  --db-instance-class db.m5.large ^
  --engine mysql ^
  --master-username admin ^
  --master-user-password mypassword ^
  --s3-bucket-name mybucket ^
  --s3-ingestion-role-arn arn:aws:iam::account-number:role/rolename ^
  --s3-prefix bucketprefix ^
  --source-engine mysql ^
  --source-engine-version 8.0.28 ^
  --max-allocated-storage 1000
```

RDS API

To import data from Amazon S3 to a new MySQL DB instance by using the Amazon RDS API, call the `RestoreDBInstanceFromS3` operation.

Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance

You can also import data from an existing MariaDB or MySQL database to a MySQL or MariaDB DB instance. You do so by copying the database with `mysqldump` and piping it directly into the MariaDB or MySQL DB instance. The `mysqldump` command line utility is commonly used to make backups and transfer data from one MariaDB or MySQL server to another. It's included with MySQL and MariaDB client software.

**Note**

If you are using a MySQL DB instance and your scenario supports it, it's easier to move data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see Restoring a backup into a MySQL DB instance (p. 1408).
A typical `mysqldump` command to move data from an external database to an Amazon RDS DB instance looks similar to the following.

```sql
mysqldump -u local_user \
    --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary \
    --local_password | mysql -u RDS_user \
    --port=port_number \
    --host=host_name \
    -pRDS_password
```

**Important**

Make sure not to leave a space between the `-p` option and the entered password.

Make sure that you're aware of the following recommendations and considerations:

- Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The `mysqldump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the `pt-show-grants` utility.
- To perform the import, make sure the user doing so has access to the DB instance. For more information, see Controlling access with security groups (p. 2232).

The parameters used are as follows:

- `-u local_user` – Use to specify a user name. In the first usage of this parameter, you specify the name of a user account on the local MariaDB or MySQL database identified by the `--databases` parameter.
- `--databases database_name` – Use to specify the name of the database on the local MariaDB or MySQL instance that you want to import into Amazon RDS.
- `--single-transaction` – Use to ensure that all of the data loaded from the local database is consistent with a single point in time. If there are other processes changing the data while `mysqldump` is reading it, using this parameter helps maintain data integrity.
- `--compress` – Use to reduce network bandwidth consumption by compressing the data from the local database before sending it to Amazon RDS.
- `--order-by-primary` – Use to reduce load time by sorting each table's data by its primary key.
- `--local_password` – Use to specify a password. In the first usage of this parameter, you specify the password for the user account identified by the first `-u` parameter.
- `-u RDS_user` – Use to specify a user name. In the second usage of this parameter, you specify the name of a user account on the default database for the MariaDB or MySQL DB instance identified by the `--host` parameter.
- `--port port_number` – Use to specify the port for your MariaDB or MySQL DB instance. By default, this is 3306 unless you changed the value when creating the instance.
- `--host host_name` – Use to specify the Domain Name System (DNS) name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.
- `--pRDS_password` – Use to specify a password. In the second usage of this parameter, you specify the password for the user account identified by the second `-u` parameter.

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when

1417
you run mysqldump. To do so, include the following parameters with your mysqldump command: --routines=0 --triggers=0 --events=0.

The following example copies the world sample database on the local host to a MySQL DB instance.

For Linux, macOS, or Unix:

```
sudo mysqldump -u localuser
   --databases world
   --single-transaction
   --compress
   --order-by-primary
   --routines=0
   --triggers=0
   --events=0
   -p localpassword | mysql -u rdsuser
   --port=3306
   --host=myinstance.123456789012.us-east-1.rds.amazonaws.com
   -p rdspassword
```

For Windows, run the following command in a command prompt that has been opened by right-clicking Command Prompt on the Windows programs menu and choosing Run as administrator:

```
mysqldump -u localuser
   --databases world
   --single-transaction
   --compress
   --order-by-primary
   --routines=0
   --triggers=0
   --events=0
   -p localpassword | mysql -u rdsuser
   --port=3306
   --host=myinstance.123456789012.us-east-1.rds.amazonaws.com
   -p rdspassword
```

Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime

In some cases, you might need to import data from an external MariaDB or MySQL database that supports a live application to a MariaDB or MySQL DB instance. In these cases, you can use the following procedure to minimize the impact on application availability. This procedure can also help if you are working with a very large database. Here, the procedure helps because you can reduce the cost of the import by reducing the amount of data that is passed across the network to AWS.

In this procedure, you transfer a copy of your database data to an Amazon EC2 instance and import the data into a new Amazon RDS DB instance. You then use replication to bring the Amazon RDS DB instance up-to-date with your live external instance, before redirecting your application to the Amazon RDS DB instance. You configure MariaDB replication based on global transaction identifiers (GTIDs) if the external instance is MariaDB 10.0.24 or higher and the target instance is RDS for MariaDB. Otherwise, you configure replication based on binary log coordinates. We recommend GTID-based replication if your external database supports it due to its enhanced crash-safety features. For more information, see Global transaction ID in the MariaDB documentation.

**Note**

If you want to import data into a MySQL DB instance and your scenario supports it, it is easier to move data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see Restoring a backup into a MySQL DB instance (p. 1408).
Note
We don't recommend that you use this procedure with source MySQL databases from MySQL versions earlier than version 5.5, due to potential replication issues. For more information, see Replication compatibility between MySQL versions in the MySQL documentation.

Create a copy of your existing database

The first step in the process of migrating a large amount of data to an Amazon RDS MariaDB or MySQL DB instance with minimal downtime is to create a copy of the source data.
You can use the mysqldump utility to create a database backup in either SQL or delimited-text format. We recommend that you do a test run with each format in a nonproduction environment to see which method minimizes the amount of time that mysqldump runs.

We also recommend that you weigh mysqldump performance against the benefit offered by using the delimited-text format for loading. A backup using delimited-text format creates a tab-separated text file for each table being dumped. To reduce the amount of time required to import your database, you can load these files in parallel using the `LOAD DATA LOCAL INFILE` command. For more information about choosing a mysqldump format and then loading the data, see Using `mysqldump for backups` in the MySQL documentation.

Before you start the backup operation, make sure to set the replication options on the MariaDB or MySQL database that you are copying to Amazon RDS. The replication options include turning on binary logging and setting a unique server ID. Setting these options causes your server to start logging database transactions and prepares it to be a source replication instance later in this process.

**Note**
Use the `--single-transaction` option with mysqldump because it dumps a consistent state of the database. To ensure a valid dump file, don't run data definition language (DDL) statements while mysqldump is running. You can schedule a maintenance window for these operations.
Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The mysqldump utility excludes these schemas by default.
To migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the `pt-show-grants` utility.

**To set replication options**

1. Edit the `my.cnf` file (this file is usually under `/etc`).

```
sudo vi /etc/my.cnf
```

Add the `log_bin` and `server_id` options to the `[mysqld]` section. The `log_bin` option provides a file name identifier for binary log files. The `server_id` option provides a unique identifier for the server in source-replica relationships.

The following example shows the updated `[mysqld]` section of a `my.cnf` file.

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

For more information, see the MySQL documentation.

2. Restart the `mysql` service.

```
sudo service mysqld restart
```

**To create a backup copy of your existing database**

1. Create a backup of your data using the mysqldump utility, specifying either SQL or delimited-text format.

```
Specify `--master-data=2` to create a backup file that can be used to start replication between servers. For more information, see the `mysqldump` documentation.
```
To improve performance and ensure data integrity, use the `--order-by-primary` and `--single-transaction` options of mysqldump.

To avoid including the MySQL system database in the backup, do not use the `--all-databases` option with mysqldump. For more information, see Creating a data snapshot using mysqldump in the MySQL documentation.

Use `chmod` if necessary to make sure that the directory where the backup file is being created is writeable.

**Important**

On Windows, run the command window as an administrator.

- To produce SQL output, use the following command.

  For Linux, macOS, or Unix:

  ```
  sudo mysqldump \
  --databases database_name \
  --master-data=2 \ 
  --single-transaction \ 
  --order-by-primary \ 
  -r backup.sql \ 
  -u local_user \ 
  -p password
  ```

  For Windows:

  ```
  mysqldump ^ \
  --databases database_name ^ \
  --master-data=2 ^ \
  --single-transaction ^ \
  --order-by-primary ^ \
  -r backup.sql ^ \
  -u local_user ^ \
  -p password
  ```

- To produce delimited-text output, use the following command.

  For Linux, macOS, or Unix:

  ```
  sudo mysqldump \
  --tab=target_directory \
  --fields-terminated-by ',' \
  --fields-enclosed-by '"' \
  --lines-terminated-by 0x0d0a \ 
  database_name \
  --master-data=2 \ 
  --single-transaction \ 
  --order-by-primary \ 
  -p password
  ```

  For Windows:

  ```
  mysqldump ^ \
  --tab=target_directory ^ \
  --fields-terminated-by "," ^ \
  --fields-enclosed-by """ ^ \
  --lines-terminated-by 0x0d0a ^ \
  database_name ^
  ```
Importing data to a DB instance with reduced downtime

```
--master-data=2
--single-transaction
--order-by-primary
-p password
```

**Note**

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, exclude them when you run mysqldump. To do so, include the following arguments with your mysqldump command: `--routines=0 --triggers=0 --events=0`.

When using the delimited-text format, a `CHANGE MASTER TO` comment is returned when you run mysqldump. This comment contains the master log file name and position. If the external instance is other than MariaDB version 10.0.24 or higher, note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`. You need these values when setting up replication.

```
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```

If you are using SQL format, you can get the master log file name and position in the `CHANGE MASTER TO` comment in the backup file. If the external instance is MariaDB version 10.0.24 or higher, you can get the GTID in the next step.

2. If the external instance you are using is MariaDB version 10.0.24 or higher, you use GTID-based replication. Run `SHOW MASTER STATUS` on the external MariaDB instance to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance.

```
SELECT BINLOG_GTID_POS('binary log file name', binary log file position);
```

Note the GTID returned; you need it to configure replication.

3. Compress the copied data to reduce the amount of network resources needed to copy your data to the Amazon RDS DB instance. Take note of the size of the backup file; you need this information when determining how large an Amazon EC2 instance to create. When you are done, compress the backup file using GZIP or your preferred compression utility.

- To compress SQL output, use the following command.

```
gzip backup.sql
```

- To compress delimited-text output, use the following command.

```
tar -zcvf backup.tar.gz target_directory
```

Create an Amazon EC2 instance and copy the compressed database

Copying your compressed database backup file to an Amazon EC2 instance takes fewer network resources than doing a direct copy of uncompressed data between database instances. After your data is in Amazon EC2, you can copy it from there directly to your MariaDB or MySQL DB instance. For you to save on the cost of network resources, your Amazon EC2 instance must be in the same AWS Region as your Amazon RDS DB instance. Having the Amazon EC2 instance in the same AWS Region as your Amazon RDS DB instance also reduces network latency during the import.
To create an Amazon EC2 instance and copy your data

1. In the AWS Region where you plan to create the RDS DB instance to run your MySQL database engine, create a virtual private cloud (VPC), a VPC security group, and a VPC subnet. Ensure that the inbound rules for your VPC security group allow the IP addresses required for your application to connect to AWS. This can be a range of IP addresses (for example, 203.0.113.0/24), or another VPC security group. You can use the Amazon VPC Management Console to create and manage VPCs, subnets, and security groups. For more information, see Getting started with Amazon VPC in the Amazon Virtual Private Cloud Getting Started Guide.

2. Open the Amazon EC2 Management Console and choose the AWS Region to contain both your Amazon EC2 instance and your Amazon RDS DB instance. Launch an Amazon EC2 instance using the VPC, subnet, and security group that you created in Step 1. Ensure that you select an instance type with enough storage for your database backup file when it is uncompressed. For details on Amazon EC2 instances, see Getting started with Amazon EC2 Linux instances in the Amazon Elastic Compute Cloud User Guide for Linux.

3. To connect to your Amazon RDS DB instance from your Amazon EC2 instance, edit your VPC security group. Add an inbound rule specifying the private IP address of your EC2 instance. You can find the private IP address on the Details tab of the Instance pane in the EC2 console window. To edit the VPC security group and add an inbound rule, choose Security Groups in the EC2 console navigation pane, choose your security group, and then add an inbound rule for MySQL or Aurora specifying the private IP address of your EC2 instance. To learn how to add an inbound rule to a VPC security group, see Adding and removing rules in the Amazon VPC User Guide.

4. Copy your compressed database backup file from your local system to your Amazon EC2 instance. Use chmod if necessary to make sure that you have write permission for the target directory of the Amazon EC2 instance. You can use scp or a Secure Shell (SSH) client to copy the file. The following is an example.

   ```
   $ scp -i -r -i key_pair.pem backup.sql.gz ec2-user@EC2 DNS:/target_directory/backup.sql.gz
   ```

   Important
   Be sure to copy sensitive data using a secure network transfer protocol.
5. Connect to your Amazon EC2 instance and install the latest updates and the MySQL client tools using the following commands.

```bash
sudo yum update -y
sudo yum install mysql -y
```

For more information, see Connect to your instance in the Amazon Elastic Compute Cloud User Guide for Linux.

**Important**

This example installs the MySQL client on an Amazon Machine Image (AMI) for an Amazon Linux distribution. To install the MySQL client on a different distribution, such as Ubuntu or RedHat Enterprise Linux, this example doesn't work. For information about installing MySQL, see Installing and Upgrading MySQL in the MySQL documentation.

6. While connected to your Amazon EC2 instance, decompress your database backup file. The following are examples.

- To decompress SQL output, use the following command.

```bash
gzip backup.sql.gz -d
```

- To decompress delimited-text output, use the following command.

```bash
tar xzvf backup.tar.gz
```

**Create a MySQL or MariaDB DB instance and import data from your Amazon EC2 instance**

By creating a MariaDB or MySQL DB instance in the same AWS Region as your Amazon EC2 instance, you can import the database backup file from EC2 faster than over the internet.
To create a MariaDB or MySQL DB instance and import your data

1. Determine which DB instance class and what amount of storage space is required to support the expected workload for this Amazon RDS DB instance. As part of this process, decide what is sufficient space and processing capacity for your data load procedures. Also decide what is required to handle the production workload. You can estimate this based on the size and resources of the source MariaDB or MySQL database. For more information, see DB instance classes (p. 10).

2. Determine if Amazon RDS provisioned I/O operations per second (IOPS) is required to support the workloads. Provisioned IOPS storage delivers fast throughput for online transaction processing (OLTP) workloads, which are I/O intensive. For more information, see Provisioned IOPS SSD storage (p. 73).

3. Open the Amazon RDS console. In the upper-right corner, choose the AWS Region that contains your Amazon EC2 instance.

4. In the navigation pane, choose Databases.

5. Choose Create database, and then go through the steps to choose options for your DB instance:
   a. Make sure that Standard Create is chosen.
   b. In the Engine options section, choose MySQL or MariaDB, as appropriate.
   c. For Version, choose the version that is compatible with your source MySQL instance, as follows:
      - If your source instance is MySQL 5.5.x, the Amazon RDS DB instance must be MySQL.
      - If your source instance is MySQL 5.6.x or 5.7.x, the Amazon RDS DB instance must be MySQL or MariaDB.
      - If your source instance is MySQL 8.0.x, the Amazon RDS DB instance must be MySQL 8.0.x.
      - If your source instance is MariaDB 5.5 or higher, the Amazon RDS DB instance must be MariaDB.
   d. In the Templates section, choose Dev/Test to skip configuring Multi-AZ deployment and provisioned IOPS storage.
   e. In the Settings section, specify the requested DB instance identifier and user information.
   f. In the DB instance class and Storage sections, specify the DB instance class and allocated storage size that you want.
   g. In the Availability & durability section, choose Do not create a standby instance for Multi-AZ deployment.
   h. In the Connectivity section, choose the same virtual private cloud (VPC) and VPC security group as for your Amazon EC2 instance. This approach ensures that your Amazon EC2 instance and your Amazon RDS instance are visible to each other over the network. Set Publicly accessible to Yes. To set up replication with your source database as described later, your DB instance must be publicly accessible.

Use the default values for the other settings in this section.

In the Backup section, set the backup retention period to 0 days.

Use the default values for the other settings in this section.

i. Open the Additional configuration section, and specify an Initial database name.

Set the Backup retention period to 0 days

Use the default values for the other settings in this section.

j. Choose Create database.

Your new DB instance appears in the Databases list with the status Creating. Wait for the Status of your new DB instance to show as Available.
Don't configure multiple Availability Zones, backup retention, or read replicas until after you have imported the database backup. When that import is done, you can set Multi-AZ and backup retention the way that you want them for the production instance. For a detailed walkthrough of creating a DB instance, see Creating an Amazon RDS DB instance (p. 236).

6. Review the default configuration options for the Amazon RDS DB instance. In the RDS console navigation pane, choose Parameter groups, and then choose the magnifying glass icon next to the default.mysqlx.x or default.mariadbx.x parameter group. If this parameter group doesn't have the configuration options that you want, find a different one that does or create a new parameter group. For more information on creating a parameter group, see Working with parameter groups (p. 295).

To use a different parameter group than the default, associate it with your Amazon RDS DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 333).

7. Connect to the new Amazon RDS DB instance as the master user. Create the users required to support the administrators, applications, and services that need to access the instance. The host name for the Amazon RDS DB instance is the Endpoint value for this instance without including the port number. An example is mysampledb.claxc2oy9ak1.us-west-2.rds.amazonaws.com. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

8. Connect to your Amazon EC2 instance. For more information, see Connect to your instance in the Amazon Elastic Compute Cloud User Guide for Linux.

9. Connect to your Amazon RDS DB instance as a remote host from your Amazon EC2 instance using the mysql command. The following is an example.

```
mysql -h host_name -P 3306 -u db_master_user -p
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

10. At the mysql prompt, run the source command and pass it the name of your database dump file to load the data into the Amazon RDS DB instance:

   - For SQL format, use the following command.

```
mysql> source backup.sql;
```

   - For delimited-text format, first create the database, if it isn't the default database you created when setting up the Amazon RDS DB instance.

```
mysql> create database database_name;
$ mysql> use database_name;
```

Then create the tables.

```
mysql> source table1.sql
$ mysql> source table2.sql
etc...
```

Then import the data.

```
mysql> LOAD DATA LOCAL INFILE 'table1.txt' INTO TABLE table1 FIELDS TERMINATED BY ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
$ mysql> LOAD DATA LOCAL INFILE 'table2.txt' INTO TABLE table2 FIELDS TERMINATED BY ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
etc...
```
To improve performance, you can perform these operations in parallel from multiple connections so that all of your tables get created and then loaded at the same time.

**Note**
If you used any data-formatting options with mysqldump when you initially dumped the table, make sure to use the same options with mysqlimport or LOAD DATA LOCAL INFILE to ensure proper interpretation of the data file contents.

11. Run a simple SELECT query against one or two of the tables in the imported database to verify that the import was successful.

If you no longer need the Amazon EC2 instance used in this procedure, terminate the EC2 instance to reduce your AWS resource usage. To terminate an EC2 instance, see Terminating an instance in the Amazon EC2 User Guide.

### Replicate between your external database and new Amazon RDS DB instance

Your source database was likely updated during the time that it took to copy and transfer the data to the MariaDB or MySQL DB instance. That being the case, you can use replication to bring the copied database up-to-date with the source database.

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure to use either the Amazon RDS mysql.rds_set_external_master (p. 1488) command or the mysql.rds_set_external_master_gtid (p. 1091) command to configure replication, and the mysql.rds_start_replication (p. 1504) command to start replication between your live database and your Amazon RDS database.

### To start replication

Earlier, you turned on binary logging and set a unique server ID for your source database. Now you can set up your Amazon RDS DB instance as a replica with your live database as the source replication instance.
1. In the Amazon RDS Management Console, add the IP address of the server that hosts the source database to the VPC security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance, so that it can communicate with your source instance. To find the IP address of the Amazon RDS DB instance, use the `host` command.

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint, for example myinstance.123456789012.us-east-1.rds.amazonaws.com. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

2. Using the client of your choice, connect to the source instance and create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

**MySQL 5.5, 5.6, and 5.7**

```sql
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

**MySQL 8.0**

```sql
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
```

3. For the source instance, grant REPLICATION_CLIENT and REPLICATION_SLAVE privileges to your replication user. For example, to grant the REPLICATION_CLIENT and REPLICATION_SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

**MySQL 5.5, 5.6, and 5.7**

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY 'password';
```

**MySQL 8.0**

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

4. If you used SQL format to create your backup file and the external instance is not MariaDB 10.0.24 or higher, look at the contents of that file.

```
cat backup.sql
```

The file includes a CHANGE MASTER TO comment that contains the master log file name and position. This comment is included in the backup file when you use the --master-data option with mysqldump. Note the values for MASTER_LOG_FILE and MASTER_LOG_POS.

```
--
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;```
If you used delimited text format to create your backup file and the external instance isn't MariaDB 10.0.24 or higher, you should already have binary log coordinates from step 1 of the procedure at "To create a backup copy of your existing database" in this topic.

If the external instance is MariaDB 10.0.24 or higher, you should already have the GTID from which to start replication from step 2 of the procedure at "To create a backup copy of your existing database" in this topic.

5. Make the Amazon RDS DB instance the replica. If the external instance isn't MariaDB 10.0.24 or higher, connect to the Amazon RDS DB instance as the master user and identify the source database as the source replication instance by using the `mysql.rds_set_external_master` (p. 1488) command. Use the master log file name and master log position that you determined in the previous step if you have a SQL format backup file. Or use the name and position that you determined when creating the backup files if you used delimited-text format. The following is an example.

```sql
CALL mysql.rds_set_external_master ('myserver.mydomain.com', 3306,
    'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

If the external instance is MariaDB 10.0.24 or higher, connect to the Amazon RDS DB instance as the master user and identify the source database as the source replication instance by using the `mysql.rds_set_external_master_gtid` (p. 1091) command. Use the GTID that you determined in step 2 of the procedure at "To create a backup copy of your existing database" in this topic. The following is an example.

```sql
CALL mysql.rds_set_external_master_gtid ('source_server_ip_address', 3306,
    'ReplicationUser', 'password', 'GTID', 0);
```

The `source_server_ip_address` is the IP address of source replication instance. An EC2 private DNS address is currently not supported.

6. On the Amazon RDS DB instance, issue the `mysql.rds_start_replication` (p. 1504) command to start replication.

```sql
CALL mysql.rds_start_replication;
```

7. On the Amazon RDS DB instance, run the `SHOW REPLICA STATUS` command to determine when the replica is up-to-date with the source replication instance. The results of the `SHOW REPLICA STATUS` command include the `Seconds_Behind_Master` field. When the `Seconds_Behind_Master` field returns 0, then the replica is up-to-date with the source replication instance.

**Note**

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

For a MariaDB 10.5 or 10.6 DB instance, run the `mysql.rds_replica_status` (p. 1090) procedure instead of the MySQL command.

8. After the Amazon RDS DB instance is up-to-date, turn on automated backups so you can restore that database if needed. You can turn on or modify automated backups for your Amazon RDS DB instance using the Amazon RDS Management Console. For more information, see Working with backups (p. 462).

**Redirect your live application to your Amazon RDS instance**

After the MariaDB or MySQL DB instance is up-to-date with the source replication instance, you can now update your live application to use the Amazon RDS instance.
To redirect your live application to your MariaDB or MySQL DB instance and stop replication

1. To add the VPC security group for the Amazon RDS DB instance, add the IP address of the server that hosts the application. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

2. Verify that the Seconds_Behind_Master field in the SHOW REPLICA STATUS command results is 0, which indicates that the replica is up-to-date with the source replication instance.

   SHOW REPLICA STATUS;

   **Note**
   Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

   For a MariaDB 10.5 or 10.6 DB instance, run the `mysql.rds_replica_status` (p. 1090) procedure instead of the MySQL command.

3. Close all connections to the source when their transactions complete.

4. Update your application to use the Amazon RDS DB instance. This update typically involves changing the connection settings to identify the host name and port of the Amazon RDS DB instance, the user account and password to connect with, and the database to use.

5. Stop replication for the Amazon RDS instance using the `mysql.rds_stop_replication` (p. 1507) command.

   CALL mysql.rds_stop_replication;

6. Run the `mysql.rds_reset_external_master` (p. 1500) command on your Amazon RDS DB instance to reset the replication configuration so this instance is no longer identified as a replica.

   CALL mysql.rds_reset_external_master;
7. Turn on additional Amazon RDS features such as Multi-AZ support and read replicas. For more information, see Multi-AZ deployments for high availability (p. 125) and Working with read replicas (p. 382).

Importing data from any source to a MariaDB or MySQL DB instance

If you have more than 1 GiB of data to load, or if your data is coming from somewhere other than a MariaDB or MySQL database, we recommend creating flat files and loading them with mysqldump. The mysqldump utility is another command line utility bundled with the MySQL and MariaDB client software. Its purpose is to load flat files into MySQL or MariaDB. For information about mysqldump, see mysqldump - a data import program in the MySQL documentation.

We also recommend creating DB snapshots of the target Amazon RDS DB instance before and after the data load. Amazon RDS DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. When you initiate a DB snapshot, I/O operations to your DB instance are momentarily suspended while your database is backed up.

Creating a DB snapshot immediately before the load makes it possible for you to restore the database to its state before the load, if you need to. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap and can also be used to seed new database instances.

The following list shows the steps to take. Each step is discussed in more detail following.

1. Create flat files containing the data to be loaded.
2. Stop any applications accessing the target DB instance.
3. Create a DB snapshot.
4. Consider turning off Amazon RDS automated backups.
5. Load the data using mysqldump.
6. Enable automated backups again.

Step 1: Create flat files containing the data to be loaded

Use a common format, such as comma-separated values (CSV), to store the data to be loaded. Each table must have its own file; you can't combine data for multiple tables in the same file. Give each file the same name as the table it corresponds to. The file extension can be anything you like. For example, if the table name is sales, the file name might be sales.csv or sales.txt, but not sales_01.csv.

Whenever possible, order the data by the primary key of the table being loaded. Doing this drastically improves load times and minimizes disk storage requirements.

The speed and efficiency of this procedure depends on keeping the size of the files small. If the uncompressed size of any individual file is larger than 1 GiB, split it into multiple files and load each one separately.

On Unix-like systems (including Linux), use the split command. For example, the following command splits the sales.csv file into multiple files of less than 1 GiB, splitting only at line breaks (-C 1024m). The new files are named sales_part_00, sales_part_01, and so on.

```
split -C 1024m -d sales.csv sales.part_
```

Similar utilities are available for other operating systems.
Step 2: Stop any applications accessing the target DB instance

Before starting a large load, stop all application activity accessing the target DB instance that you plan to load to. We recommend this particularly if other sessions will be modifying the tables being loaded or tables that they reference. Doing this reduces the risk of constraint violations occurring during the load and improves load performance. It also makes it possible to restore the DB instance to the point just before the load without losing changes made by processes not involved in the load.

Of course, this might not be possible or practical. If you can't stop applications from accessing the DB instance before the load, take steps to ensure the availability and integrity of your data. The specific steps required vary greatly depending upon specific use cases and site requirements.

Step 3: Create a DB snapshot

If you plan to load data into a new DB instance that contains no data, you can skip this step. Otherwise, creating a DB snapshot of your DB instance makes it possible for you to restore the DB instance to the point just before the load, if it becomes necessary. As previously mentioned, when you initiate a DB snapshot, I/O operations to your DB instance are suspended for a few minutes while the database is backed up.

The example following uses the AWS CLI `create-db-snapshot` command to create a DB snapshot of the AcmeRDS instance and give the DB snapshot the identifier "preload".

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
  --db-instance-identifier AcmeRDS \
  --db-snapshot-identifier preload
```

For Windows:

```
aws rds create-db-snapshot ^
  --db-instance-identifier AcmeRDS ^
  --db-snapshot-identifier preload
```

You can also use the restore from DB snapshot functionality to create test DB instances for dry runs or to undo changes made during the load.

Keep in mind that restoring a database from a DB snapshot creates a new DB instance that, like all DB instances, has a unique identifier and endpoint. To restore the DB instance without changing the endpoint, first delete the DB instance so that you can reuse the endpoint.

For example, to create a DB instance for dry runs or other testing, you give the DB instance its own identifier. In the example, AcmeRDS-2 is the identifier. The example connects to the DB instance using the endpoint associated with AcmeRDS-2.

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
  --db-instance-identifier AcmeRDS-2 \
  --db-snapshot-identifier preload
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
  --db-instance-identifier AcmeRDS-2 ^
```
To reuse the existing endpoint, first delete the DB instance and then give the restored database the same identifier.

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
  --db-instance-identifier AcmeRDS \
  --final-db-snapshot-identifier AcmeRDS-Final
aws rds restore-db-instance-from-db-snapshot \
  --db-instance-identifier AcmeRDS \
  --db-snapshot-identifier preload
```

For Windows:

```
aws rds delete-db-instance ^
  --db-instance-identifier AcmeRDS ^
  --final-db-snapshot-identifier AcmeRDS-Final
aws rds restore-db-instance-from-db-snapshot ^
  --db-instance-identifier AcmeRDS ^
  --db-snapshot-identifier preload
```

The preceding example takes a final DB snapshot of the DB instance before deleting it. This is optional but recommended.

**Step 4: Consider turning off Amazon RDS automated backups**

**Warning**

Do not turn off automated backups if you need to perform point-in-time recovery.

Turning off automated backups erases all existing backups, so point-in-time recovery isn't possible after automated backups have been turned off. Disabling automated backups is a performance optimization and isn't required for data loads. Manual DB snapshots aren't affected by turning off automated backups. All existing manual DB snapshots are still available for restore.

Turning off automated backups reduces load time by about 25 percent and reduces the amount of storage space required during the load. If you plan to load data into a new DB instance that contains no data, turning off backups is an easy way to speed up the load and avoid using the additional storage needed for backups. However, in some cases you might plan to load into a DB instance that already contains data. If so, weigh the benefits of turning off backups against the impact of losing the ability to perform point-in-time-recovery.

DB instances have automated backups turned on by default (with a one day retention period). To turn off automated backups, set the backup retention period to zero. After the load, you can turn backups back on by setting the backup retention period to a nonzero value. To turn on or turn off backups, Amazon RDS shuts the DB instance down and restarts it to turn MariaDB or MySQL logging on or off.

Use the AWS CLI `modify-db-instance` command to set the backup retention to zero and apply the change immediately. Setting the retention period to zero requires a DB instance restart, so wait until the restart has completed before proceeding.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier AcmeRDS \
```

```
--apply-immediately \\
--backup-retention-period 0

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier  AcmeRDS ^
  --apply-immediately ^
  --backup-retention-period 0
```

You can check the status of your DB instance with the AWS CLI describe-db-instances command. The following example displays the DB instance status of the AcmeRDS DB instance.

```bash
aws rds describe-db-instances --db-instance-identifier AcmeRDS --query "[].
(DBInstanceStatus:DBInstanceStatus)"
```

When the DB instance status is available, you’re ready to proceed.

**Step 5: Load the data**

Use the mysqlimport utility to load the flat files into Amazon RDS. The following example tells mysqlimport to load all of the files named "sales" with an extension starting with "part_". This is a convenient way to load all of the files created in the "split" example.

Use the --compress option to minimize network traffic. The --fields-terminated-by=',' option is used for CSV files, and the --local option specifies that the incoming data is located on the client. Without the --local option, the Amazon RDS DB instance looks for the data on the database host, so always specify the --local option. For the --host option, specify the DB instance endpoint of the RDS for MySQL DB instance.

In the following examples, replace `master_user` with the master username for your DB instance.

Replace `hostname` with the endpoint for your DB instance. An example of a DB instance endpoint is `my-db-instance.123456789012.us-west-2.rds.amazonaws.com`.

For RDS for MySQL version 8.0.15 and higher, run the following statement before using the mysqlimport utility.

```sql
GRANT SESSION_VARIABLES_ADMIN ON *.* TO master_user;
```

For Linux, macOS, or Unix:

```bash
mysqlimport --local \
  --compress \
  --user=master_user \
  --password \
  --host=hostname \
  --fields-terminated-by=',', 'Acme sales.part_*'
```

For Windows:

```bash
mysqlimport --local ^
  --compress ^
  --user=master_user ^
  --password ^
  --host=hostname ^
  --fields-terminated-by=""," 'Acme sales.part_*'
```
For very large data loads, take additional DB snapshots periodically between loading files and note which files have been loaded. If a problem occurs, you can easily resume from the point of the last DB snapshot, avoiding lengthy reloads.

**Step 6: Turn Amazon RDS automated backups back on**

After the load is finished, turn Amazon RDS automated backups on by setting the backup retention period back to its preload value. As noted earlier, Amazon RDS restarts the DB instance, so be prepared for a brief outage.

The following example uses the AWS CLI modify-db-instance command to turn on automated backups for the AcmeRDS DB instance and set the retention period to one day.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier AcmeRDS \
  --backup-retention-period 1 \
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier AcmeRDS ^
  --backup-retention-period 1 ^
  --apply-immediately
```
Working with MySQL replication in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with read replicas (p. 382). For specific information about working with read replicas on Amazon RDS for MySQL, see Working with MySQL read replicas (p. 1436).

You can use global transaction identifiers (GTIDs) for replication with RDS for MySQL. For more information, see Using GTID-based replication for Amazon RDS for MySQL (p. 1448).

You can also set up replication between an RDS for MySQL DB instance and a MariaDB or MySQL instance that is external to Amazon RDS. For information about configuring replication with an external source, see Configuring binary log file position replication with an external source instance (p. 1455).

For any of these replication options, you can use either row-based replication, statement-based, or mixed replication. Row-based replication only replicates the changed rows that result from a SQL statement. Statement-based replication replicates the entire SQL statement. Mixed replication uses statement-based replication when possible, but switches to row-based replication when SQL statements that are unsafe for statement-based replication are run. In most cases, mixed replication is recommended. The binary log format of the DB instance determines whether replication is row-based, statement-based, or mixed. For information about setting the binary log format, see Configuring MySQL binary logging (p. 742).

Note
You can configure replication to import databases from a MariaDB or MySQL instance that is external to Amazon RDS, or to export databases to such instances. For more information, see Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1418) and Exporting data from a MySQL DB instance by using replication (p. 1459).

Working with MySQL read replicas

Following, you can find specific information about working with read replicas on RDS for MySQL. For general information about read replicas and instructions for using them, see Working with read replicas (p. 382).

Topics
- Configuring read replicas with MySQL (p. 1437)
- Configuring replication filters with MySQL (p. 1437)
- Configuring delayed replication with MySQL (p. 1442)
- Updating read replicas with MySQL (p. 1444)
- Working with Multi-AZ read replica deployments with MySQL (p. 1444)
- Using cascading read replicas with RDS for MySQL (p. 1445)
- Monitoring MySQL read replicas (p. 1445)
- Starting and stopping replication with MySQL read replicas (p. 1446)
- Troubleshooting a MySQL read replica problem (p. 1446)
Configuring read replicas with MySQL

Before a MySQL DB instance can serve as a replication source, make sure to enable automatic backups on the source DB instance. To do this, set the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica. Automatic backups are supported for read replicas running any version of MySQL. You can configure replication based on binary log coordinates for a MySQL DB instance.

On RDS for MySQL version 5.7.23 and higher MySQL 5.7 versions and RDS for MySQL 8.0.26 and higher 8.0 versions, you can configure replication using global transaction identifiers (GTIDs). For more information, see Using GTID-based replication for Amazon RDS for MySQL (p. 1448).

You can create up to 15 read replicas from one DB instance within the same Region. For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

RDS for MySQL supports cascading read replicas. To learn how to configure cascading read replicas, see Using cascading read replicas with RDS for MySQL (p. 1445).

You can run multiple read replica create and delete actions at the same time that reference the same source DB instance. When you perform these actions, stay within the limit of 15 read replicas for each source instance.

A read replica of a MySQL DB instance can't use a lower DB engine version than its source DB instance.

Preparing MySQL DB instances that use MyISAM

If your MySQL DB instance uses a nontransactional engine such as MyISAM, you need to perform the following steps to successfully set up your read replica. These steps are required to make sure that the read replica has a consistent copy of your data. These steps are not required if all of your tables use a transactional engine such as InnoDB.

1. Stop all data manipulation language (DML) and data definition language (DDL) operations on non-transactional tables in the source DB instance and wait for them to complete. SELECT statements can continue running.
2. Flush and lock the tables in the source DB instance.
3. Create the read replica using one of the methods in the following sections.
4. Check the progress of the read replica creation using, for example, the DescribeDBInstances API operation. Once the read replica is available, unlock the tables of the source DB instance and resume normal database operations.

Configuring replication filters with MySQL

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren’t needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB instance that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.
Working with MySQL read replicas

**Note**
You can also use replication filters to specify which databases and tables are replicated with a primary MySQL DB instance that is configured as a replica in an inbound replication topology. For more information about this configuration, see Configuring binary log file position replication with an external source instance (p. 1455).

**Topics**
- Setting replication filtering parameters for RDS for MySQL (p. 1438)
- Replication filtering limitations for RDS for MySQL (p. 1439)
- Replication filtering examples for RDS for MySQL (p. 1439)
- Viewing the replication filters for a read replica (p. 1442)

**Setting replication filtering parameters for RDS for MySQL**

To configure replication filters, set the following replication filtering parameters on the read replica:

- `replicate-do-db` – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- `replicate-ignore-db` – Don't replicate changes to the specified databases. When the `replicate-do-db` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-do-table` – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-ignore-table` – Don't replicate changes to the specified tables. When the `replicate-do-table` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-wild-do-table` – Replicate tables based on the specified database and table name patterns. The `%` and `_` wildcard characters are supported. When the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-wild-ignore-table` – Don't replicate tables based on the specified database and table name patterns. The `%` and `_` wildcard characters are supported. When the `replicate-do-table` or `replicate-wild-do-table` parameter is set for a read replica, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MySQL documentation:

- For general information, see Replica Server Options and Variables.
- For information about how database replication filtering parameters are evaluated, see Evaluation of Database-Level Replication and Binary Logging Options.
- For information about how table replication filtering parameters are evaluated, see Evaluation of Table-Level Replication Options.

By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the `%` and `_` wildcard characters in the `replicate-wild-do-table` and `replicate-wild-ignore-table` parameters. The `%` wildcard matches any number of characters, and the `_` wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the `binlog_format` parameter determines whether the
replication is row-based or statement-based. For more information, see Configuring MySQL binary logging (p. 742).

**Note**

All data definition language (DDL) statements are replicated as statements, regardless of the `binlog_format` setting on the source DB instance.

## Replication filtering limitations for RDS for MySQL

The following limitations apply to replication filtering for RDS for MySQL:

- Each replication filtering parameter has a 2,000-character limit.
- Commas aren't supported in replication filters.
- The MySQL `--binlog-do-db` and `--binlog-ignore-db` options for binary log filtering aren't supported.
- Replication filtering doesn't support XA transactions.

For more information, see Restrictions on XA Transactions in the MySQL documentation.

## Replication filtering examples for RDS for MySQL

To configure replication filtering for a read replica, modify the replication filtering parameters in the parameter group associated with the read replica.

**Note**

You can't modify a default parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB parameter groups, see Working with parameter groups (p. 295).

You can set parameters in a parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see Modifying parameters in a DB parameter group (p. 300). When you set parameters in a parameter group, all of the DB instances associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a parameter group, make sure that the parameter group is associated only with read replicas. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set `ApplyMethod` to `pending-reboot`.

The following examples set replication filters:

- Including databases in replication
- Including tables in replication
- Including tables in replication with wildcard characters
- Escaping wildcard characters in names
- Excluding databases from replication
- Excluding tables from replication
- Excluding tables from replication using wildcard characters

### Example Including databases in replication

The following example includes the `mydb1` and `mydb2` databases in replication.
For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
   --db-parameter-group-name myparametergroup \
   --parameters '[["ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod": "immediate"]]'"``

For Windows:

```bash
aws rds modify-db-parameter-group ^
   --db-parameter-group-name myparametergroup ^
   --parameters '[["ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod": "immediate"]]'"``

**Example Including tables in replication**

The following example includes the `table1` and `table2` tables in database `mydb1` in replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
   --db-parameter-group-name myparametergroup \
   --parameters '[["ParameterName": "replicate-do-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod": "immediate"]]'"``

For Windows:

```bash
aws rds modify-db-parameter-group ^
   --db-parameter-group-name myparametergroup ^
   --parameters '[["ParameterName": "replicate-do-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod": "immediate"]]'"``

**Example Including tables in replication using wildcard characters**

The following example includes tables with names that begin with `orders` and `returns` in database `mydb` in replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
   --db-parameter-group-name myparametergroup \
   --parameters '[["ParameterName": "replicate-wild-do-table", "ParameterValue": "mydb.orders%,mydb.returns%", "ApplyMethod": "immediate"]]'"``

For Windows:

```bash
aws rds modify-db-parameter-group ^
   --db-parameter-group-name myparametergroup ^
   --parameters '[["ParameterName": "replicate-wild-do-table", "ParameterValue": "mydb.orders%,mydb.returns%", "ApplyMethod": "immediate"]]'"``

**Example Escaping wildcard characters in names**

The following example shows you how to use the escape character `\` to escape a wildcard character that is part of a name.
Assume that you have several table names in database mydb1 that start with `my_table`, and you want to include these tables in replication. The table names include an underscore, which is also a wildcard character, so the example escapes the underscore in the table names.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group
   --db-parameter-group-name myparametergroup
   --parameters "["ParameterName": "replicate-wild-do-table", "ParameterValue": "my_table %", "ApplyMethod": "immediate"]"
```

For Windows:

```
aws rds modify-db-parameter-group
   --db-parameter-group-name myparametergroup
   --parameters "["ParameterName": "replicate-wild-do-table", "ParameterValue": "my_table %", "ApplyMethod": "immediate"]"
```

**Example Excluding databases from replication**

The following example excludes the `mydb1` and `mydb2` databases from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group
   --db-parameter-group-name myparametergroup
   --parameters "["ParameterName": "replicate-ignore-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod": "immediate"]"
```

For Windows:

```
aws rds modify-db-parameter-group
   --db-parameter-group-name myparametergroup
   --parameters "["ParameterName": "replicate-ignore-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod": "immediate"]"
```

**Example Excluding tables from replication**

The following example excludes tables `table1` and `table2` in database `mydb1` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group
   --db-parameter-group-name myparametergroup
   --parameters "["ParameterName": "replicate-ignore-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod": "immediate"]"
```

For Windows:

```
aws rds modify-db-parameter-group
   --db-parameter-group-name myparametergroup
   --parameters "["ParameterName": "replicate-ignore-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod": "immediate"]"
```
Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with orders and returns in database mydb from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "["ParameterName": "replicate-wild-ignore-table", "ParameterValue": "mydb.orders%, mydb.returns%", "ApplyMethod": "immediate"]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "["ParameterName": "replicate-wild-ignore-table", "ParameterValue": "mydb.orders%, mydb.returns%", "ApplyMethod": "immediate"]"
```

Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.
  
  For instructions, see Viewing parameter values for a DB parameter group (p. 307).

- In a MySQL client, connect to the read replica and run the SHOW REPLICA STATUS statement.
  
  In the output, the following fields show the replication filters for the read replica:
  - Replicate_Do_DB
  - Replicate_Ignore_DB
  - Replicate_Do_Table
  - Replicate_Ignore_Table
  - Replicate_Wild_Do_Table
  - Replicate_Wild_Ignore_Table

  For more information about these fields, see Checking Replication Status in the MySQL documentation.

  **Note**
  
  Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS.
  
  If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

Configuring delayed replication with MySQL

You can use delayed replication as a strategy for disaster recovery. With delayed replication, you specify the minimum amount of time, in seconds, to delay replication from the source to the read replica. In the event of a disaster, such as a table deleted unintentionally, you complete the following steps to recover from the disaster quickly:

- Stop replication to the read replica before the change that caused the disaster is sent to it.

  Use the mysql.rds_stop_replication (p. 1507) stored procedure to stop replication.
• Start replication and specify that replication stops automatically at a log file location.

You specify a location just before the disaster using the `mysql.rds_start_replication_until` (p. 1505) stored procedure.

• Promote the read replica to be the new source DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 389).

Note

• On RDS for MySQL 8.0, delayed replication is supported for MySQL 8.0.26 and higher. On RDS for MySQL 5.7, delayed replication is supported for MySQL 5.7.22 and higher.

• Use stored procedures to configure delayed replication. You can't configure delayed replication with the AWS Management Console, the AWS CLI, or the Amazon RDS API.

• On RDS for MySQL 5.7.23 and higher MySQL 5.7 versions and RDS for MySQL 8.0.26 and higher 8.0 versions, you can use replication based on global transaction identifiers (GTIDs) in a delayed replication configuration. If you use GTID-based replication, use the `mysql.rds_start_replication_until_gtid` (p. 1506) stored procedure instead of the `mysql.rds_start_replication_until` (p. 1505) stored procedure. For more information about GTID-based replication, see Using GTID-based replication for Amazon RDS for MySQL (p. 1448).

Topics

• Configuring delayed replication during read replica creation (p. 1443)
• Modifying delayed replication for an existing read replica (p. 1443)
• Setting a location to stop replication to a read replica (p. 1444)
• Promoting a read replica (p. 1444)

Configuring delayed replication during read replica creation

To configure delayed replication for any future read replica created from a DB instance, run the `mysql.rds_set_configuration` (p. 1511) stored procedure with the `target delay` parameter.

To configure delayed replication during read replica creation

1. Using a MySQL client, connect to the MySQL DB instance to be the source for read replicas as the master user.
2. Run the `mysql.rds_set_configuration` (p. 1511) stored procedure with the `target delay` parameter.

For example, run the following stored procedure to specify that replication is delayed by at least one hour (3,600 seconds) for any read replica created from the current DB instance.

```sql
CALL mysql.rds_set_configuration('target delay', 3600);
```

Note

After running this stored procedure, any read replica you create using the AWS CLI or Amazon RDS API is configured with replication delayed by the specified number of seconds.

Modifying delayed replication for an existing read replica

To modify delayed replication for an existing read replica, run the `mysql.rds_set_source_delay` (p. 1503) stored procedure.
To modify delayed replication for an existing read replica

1. Using a MySQL client, connect to the read replica as the master user.
2. Use the `mysql.rds_stop_replication` (p. 1507) stored procedure to stop replication.
3. Run the `mysql.rds_set_source_delay` (p. 1503) stored procedure.

   For example, run the following stored procedure to specify that replication to the read replica is delayed by at least one hour (3600 seconds).

   ```sql
   call mysql.rds_set_source_delay(3600);
   ```

4. Use the `mysql.rds_start_replication` (p. 1504) stored procedure to start replication.

Setting a location to stop replication to a read replica

After stopping replication to the read replica, you can start replication and then stop it at a specified binary log file location using the `mysql.rds_start_replication_until` (p. 1505) stored procedure.

To start replication to a read replica and stop replication at a specific location

1. Using a MySQL client, connect to the source MySQL DB instance as the master user.
2. Run the `mysql.rds_start_replication_until` (p. 1505) stored procedure.

   The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file. In a disaster recovery scenario, assume that location 120 is just before the disaster.

   ```sql
   call mysql.rds_start_replication_until('mysql-bin-changelog.000777', 120);
   ```

   Replication stops automatically when the stop point is reached. The following RDS event is generated:
   Replication has been stopped since the replica reached the stop point specified by the rds_start_replication_until stored procedure.

Promoting a read replica

After replication is stopped, in a disaster recovery scenario, you can promote a read replica to be the new source DB instance. For information about promoting a read replica, see Promoting a read replica to be a standalone DB instance (p. 389).

Updating read replicas with MySQL

Read replicas are designed to support read queries, but you might need occasional updates. For example, you might need to add an index to optimize the specific types of queries accessing the replica. You can enable updates by setting the `read_only` parameter to 0 in the DB parameter group for the read replica. Be careful when disabling read-only on a read replica because it can cause problems if the read replica becomes incompatible with the source DB instance. Change the value of the `read_only` parameter back to 1 as soon as possible.

Working with Multi-AZ read replica deployments with MySQL

You can create a read replica from either single-AZ or Multi-AZ DB instance deployments. You use Multi-AZ deployments to improve the durability and availability of critical data, but you can't use the Multi-AZ
secondary to serve read-only queries. Instead, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. If the source instance of a Multi-AZ deployment fails over to the secondary, any associated read replicas automatically switch to use the secondary (now primary) as their replication source. For more information, see Multi-AZ deployments for high availability (p. 125).

You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

### Using cascading read replicas with RDS for MySQL

RDS for MySQL supports cascading read replicas. With *cascading read replicas*, you can scale reads without adding overhead to your source RDS for MySQL DB instance.

With cascading read replicas, your RDS for MySQL DB instance sends data to the first read replica in the chain. That read replica then sends data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for MySQL DB instance, but without the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for MySQL DB instance. For example, suppose that you have an RDS for MySQL DB instance, `mysql-main`. You can do the following:

- Starting with `mysql-main`, create the first read replica in the chain, `read-replica-1`.
- Next, from `read-replica-1`, create the next read replica in the chain, `read-replica-2`.
- Finally, from `read-replica-2`, create the third read replica in the chain, `read-replica-3`.

You can't create another read replica beyond this third cascading read replica in the series for `mysql-main`. A complete series of instances from an RDS for MySQL source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, each source RDS for MySQL DB instance must have automated backups turned on. To turn on automatic backups on a read replica, first create the read replica, and then modify the read replica to turn on automatic backups. For more information, see Creating a read replica (p. 387).

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload from your `mysql-main` DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote `read-replica-2`. The chain is affected as follows:

- Promoting `read-replica-2` removes it from the replication chain.
  - It is now a full read/write DB instance.
  - It continues replicating to `read-replica-3`, just as it was doing before promotion.
  - Your `mysql-main` continues replicating to `read-replica-1`.

For more information about promoting read replicas, see Promoting a read replica to be a standalone DB instance (p. 389).

### Monitoring MySQL read replicas

For MySQL read replicas, you can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric. The ReplicaLag metric reports the value of the Seconds_Behind_Master field of the `SHOW REPLICA STATUS` command.
Note
Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

Common causes for replication lag for MySQL are the following:

- A network outage.
- Writing to tables that have different indexes on a read replica. If the read_only parameter is set to 0 on the read replica, replication can break if the read replica becomes incompatible with the source DB instance. After you've performed maintenance tasks on the read replica, we recommend that you set the read_only parameter back to 1.
- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MySQL.

When the ReplicaLag metric reaches 0, the replica has caught up to the source DB instance. If the ReplicaLag metric returns -1, then replication is currently not active. ReplicaLag = -1 is equivalent to Seconds_Behind_Master = NULL.

Starting and stopping replication with MySQL read replicas

You can stop and restart the replication process on an Amazon RDS DB instance by calling the system stored procedures mysql.rds_stop_replication (p. 1507) and mysql.rds_start_replication (p. 1504). You can do this when replicating between two Amazon RDS instances for long-running operations such as creating large indexes. You also need to stop and start replication when importing or exporting databases. For more information, see Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1418) and Exporting data from a MySQL DB instance by using replication (p. 1459).

If replication is stopped for more than 30 consecutive days, either manually or due to a replication error, Amazon RDS terminates replication between the source DB instance and all read replicas. It does so to prevent increased storage requirements on the source DB instance and long failover times. The read replica DB instance is still available. However, replication can't be resumed because the binary logs required by the read replica are deleted from the source DB instance after replication is terminated. You can create a new read replica for the source DB instance to reestablish replication.

Troubleshooting a MySQL read replica problem

For MySQL DB instances, in some cases read replicas present replication errors or data inconsistencies (or both) between the read replica and its source DB instance. This problem occurs when some binary log (binlog) events or InnoDB redo logs aren't flushed during a failure of the read replica or the source DB instance. In these cases, manually delete and recreate the read replicas. You can reduce the chance of this happening by setting the following parameter values: sync_binlog=1 and innodb_flush_log_at_trx_commit=1. These settings might reduce performance, so test their impact before implementing the changes in a production environment.

Warning
In the parameter group associated with the source DB instance, we recommend keeping these parameters values: sync_binlog=1 and innodb_flush_log_at_trx_commit=1. These parameters are dynamic. If you don't want to use these settings, we recommend temporarily setting those values before executing any operation on the source DB instance that might cause it to restart. These operations include, but are not limited to, rebooting, rebooting with failover, upgrading the database version, and changing the DB instance class or its storage. The same recommendation applies to creating new read replicas for the source DB instance. Failure to follow this guidance increases the risk of read replicas presenting replication errors or data inconsistencies (or both) between the read replica and its source DB instance.
The replication technologies for MySQL are asynchronous. Because they are asynchronous, occasional BinLogDiskUsage increases on the source DB instance and ReplicaLag on the read replica are to be expected. For example, a high volume of write operations to the source DB instance can occur in parallel. In contrast, write operations to the read replica are serialized using a single I/O thread, which can lead to a lag between the source instance and read replica. For more information about read-only replicas in the MySQL documentation, see Replication implementation details.

You can do several things to reduce the lag between updates to a source DB instance and the subsequent updates to the read replica, such as the following:

- Sizing a read replica to have a storage size and DB instance class comparable to the source DB instance.
- Ensuring that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the max_allowed_packet parameter later in this section.

Amazon RDS monitors the replication status of your read replicas and updates the Replication State field of the read replica instance to Error if replication stops for any reason. An example might be if DML queries run on your read replica conflict with the updates made on the source DB instance.

You can review the details of the associated error thrown by the MySQL engine by viewing the Replication Error field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045 (p. 710), RDS-EVENT-0046 (p. 710), and RDS-EVENT-0047 (p. 707). For more information about events and subscribing to events, see Working with Amazon RDS event notification (p. 685). If a MySQL error message is returned, review the error number in the MySQL error message documentation.

One common issue that can cause replication errors is when the value for the max_allowed_packet parameter for a read replica is less than the max_allowed_packet parameter for the source DB instance. The max_allowed_packet parameter is a custom parameter that you can set in a DB parameter group. You use max_allowed_packet to specify the maximum size of DML code that can be run on the database. In some cases, the max_allowed_packet value in the DB parameter group associated with a read replica is smaller than the max_allowed_packet value in the DB parameter group associated with the source DB instance. In these cases, the replication process can throw the error Packet bigger than 'max_allowed_packet' bytes and stop replication. To fix the error, have the source DB instance and read replica use DB parameter groups with the same max_allowed_packet parameter values.

Other common situations that can cause replication errors include the following:

- Writing to tables on a read replica. In some cases, you might create indexes on a read replica that are different from the indexes on the source DB instance. If you do, set the read_only parameter to 0 to create the indexes. If you write to tables on the read replica, it might break replication if the read replica becomes incompatible with the source DB instance. After you perform maintenance tasks on the read replica, we recommend that you set the read_only parameter back to 1.
- Using a non-transactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the InnoDB storage engine on MySQL.
- Using unsafe nondeterministic queries such as SYSDATE(). For more information, see Determination of safe and unsafe statements in binary logging.

If you decide that you can safely skip an error, you can follow the steps described in the section Skipping the current replication error (p. 1475). Otherwise, you can first delete the read replica. Then you create an instance using the same DB instance identifier so that the endpoint remains the same as that of your old read replica. If a replication error is fixed, the Replication State changes to replicating.
Using GTID-based replication for Amazon RDS for MySQL

Following, you can learn how to use global transaction identifiers (GTIDs) with binary log (binlog) replication among Amazon RDS for MySQL DB instances.

If you use binlog replication and aren't familiar with GTID-based replication with MySQL, see Replication with global transaction identifiers in the MySQL documentation for background.

GTID-based replication is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL version 8.0.26 and higher MySQL 8.0 versions. All MySQL DB instances in a replication configuration must meet this requirement.

Topics
- Overview of global transaction identifiers (GTIDs) (p. 1448)
- Parameters for GTID-based replication (p. 1448)
- Configuring GTID-based replication for new read replicas (p. 1449)
- Configuring GTID-based replication for existing read replicas (p. 1450)
- Disabling GTID-based replication for a MySQL DB instance with read replicas (p. 1451)

Note
For information about configuring GTID-based replication with an external database, see Configuring GTID-based replication with an external source instance (p. 1452).

Overview of global transaction identifiers (GTIDs)

*Global transaction identifiers (GTIDs)* are unique identifiers generated for committed MySQL transactions. You can use GTIDs to make binlog replication simpler and easier to troubleshoot.

MySQL uses two different types of transactions for binlog replication:

- *GTID transactions* – Transactions that are identified by a GTID.
- *Anonymous transactions* – Transactions that don't have a GTID assigned.

In a replication configuration, GTIDs are unique across all DB instances. GTIDs simplify replication configuration because when you use them, you don't have to refer to log file positions. GTIDs also make it easier to track replicated transactions and determine whether the source instance and replicas are consistent.

You can use GTID-based replication to replicate data with RDS for MySQL read replicas. You can configure GTID-based replication when you are creating new read replicas, or you can convert existing read replicas to use GTID-based replication.

You can also use GTID-based replication in a delayed replication configuration with RDS for MySQL. For more information, see Configuring delayed replication with MySQL (p. 1442).

Parameters for GTID-based replication

Use the following parameters to configure GTID-based replication.
### Using GTID-based replication

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gtid_mode</td>
<td>OFF, OFF_PERMISSIVE, ON_PERMISSIVE, ON</td>
<td>OFF specifies that new transactions are anonymous transactions (that is, don't have GTIDs), and a transaction must be anonymous to be replicated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>OFF_PERMISSIVE specifies that new transactions are anonymous transactions, but all transactions can be replicated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ON_PERMISSIVE specifies that new transactions are GTID transactions, but all transactions can be replicated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ON specifies that new transactions are GTID transactions, and a transaction must be a GTID transaction to be replicated.</td>
</tr>
<tr>
<td>enforce_gtid_consistency</td>
<td>OFF, ON, WARN</td>
<td>OFF allows transactions to violate GTID consistency.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ON prevents transactions from violating GTID consistency.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>WARN allows transactions to violate GTID consistency but generates a warning when a violation occurs.</td>
</tr>
</tbody>
</table>

**Note**

In the AWS Management Console, the `gtid_mode` parameter appears as `gtid-mode`.

For GTID-based replication, use these settings for the parameter group for your DB instance or read replica:

- ON and ON_PERMISSIVE apply only to outgoing replication from an RDS DB instance. Both of these values cause your RDS DB instance to use GTIDs for transactions that are replicated. ON requires that the target database also use GTID-based replication. ON_PERMISSIVE makes GTID-based replication optional on the target database.
- OFF_PERMISSIVE, if set, means that your RDS DB instances can accept incoming replication from a source database. They can do this regardless of whether the source database uses GTID-based replication.
- OFF, if set, means that your RDS DB instance only accepts incoming replication from source databases that don't use GTID-based replication.

For more information about parameter groups, see [Working with parameter groups](p. 295).

### Configuring GTID-based replication for new read replicas

When GTID-based replication is enabled for an RDS for MySQL DB instance, GTID-based replication is configured automatically for read replicas of the DB instance.

**To enable GTID-based replication for new read replicas**

1. Make sure that the parameter group associated with the DB instance has the following parameter settings:
• `gtid_mode` – ON or ON_PERMISSIVE
• `enforce_gtid_consistency` – ON

For more information about setting configuration parameters using parameter groups, see Working with parameter groups (p. 295).

2. If you changed the parameter group of the DB instance, reboot the DB instance. For more information on how to do so, see Rebooting a DB instance (p. 378).

3. Create one or more read replicas of the DB instance. For more information on how to do so, see Creating a read replica (p. 387).

Amazon RDS attempts to establish GTID-based replication between the MySQL DB instance and the read replicas using the `MASTER_AUTO_POSITION`. If the attempt fails, Amazon RDS uses log file positions for replication with the read replicas. For more information about the `MASTER_AUTO_POSITION`, see GTID auto-positioning in the MySQL documentation.

### Configuring GTID-based replication for existing read replicas

For an existing MySQL DB instance with read replicas that doesn't use GTID-based replication, you can configure GTID-based replication between the DB instance and the read replicas.

**To enable GTID-based replication for existing read replicas**

1. If the DB instance or any read replica is using an 8.0 version of RDS for MySQL version lower than 8.0.26, upgrade the DB instance or read replica to 8.0.26 or a higher MySQL 8.0 version. All RDS for MySQL 5.7 versions support GTID-based replication.

   For more information, see Upgrading the MySQL DB engine (p. 1392).

2. (Optional) Reset the GTID parameters and test the behavior of the DB instance and read replicas:
   a. Make sure that the parameter group associated with the DB instance and each read replica has the `enforce_gtid_consistency` parameter set to WARN.

      For more information about setting configuration parameters using parameter groups, see Working with parameter groups (p. 295).

   b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.

      For more information, see Rebooting a DB instance (p. 378).

   c. Run your DB instance and read replicas with your normal workload and monitor the log files.

      If you see warnings about GTID-incompatible transactions, adjust your application so that it only uses GTID-compatible features. Make sure that the DB instance is not generating any warnings about GTID-incompatible transactions before proceeding to the next step.

3. Reset the GTID parameters for GTID-based replication that allows anonymous transactions until the read replicas have processed all of them.
   a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:

      • `gtid_mode` – ON_PERMISSIVE
      • `enforce_gtid_consistency` – ON

   b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.
4. Wait for all of your anonymous transactions to be replicated. To check that these are replicated, do the following:
   a. Run the following statement on your source DB instance.

   ```sql
   SHOW MASTER STATUS;
   ```

   Note the values in the File and Position columns.
   b. On each read replica, use the file and position information from its source instance in the previous step to run the following query.

   ```sql
   SELECT MASTER_POS_WAIT('file', position);
   ```

   For example, if the file name is `mysql-bin-changelog.000031` and the position is `107`, run the following statement.

   ```sql
   SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
   ```

   If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. Proceed to the next step when the query returns for all read replicas.

5. Reset the GTID parameters for GTID-based replication only.
   a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:
      - `gtid_mode` – ON
      - `enforce_gtid_consistency` – ON
   b. Reboot the DB instance and each read replica.

6. On each read replica, run the following procedure.

   ```sql
   CALL mysql.rds_set_master_auto_position(1);
   ```

**Disabling GTID-based replication for a MySQL DB instance with read replicas**

You can disable GTID-based replication for a MySQL DB instance with read replicas.

**To disable GTID-based replication for a MySQL DB instance with read replicas**

1. On each read replica, run the following procedure.

   ```sql
   CALL mysql.rds_set_master_auto_position(0);  (Aurora MySQL version 1 and 2)
   CALL mysql.rds_set_source_auto_position(0);  (Aurora MySQL version 3 and higher)
   ```

2. Reset the `gtid_mode` to `ON_PERMISSIVE`.
   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has `gtid_mode` set to `ON_PERMISSIVE`.

   For more information about setting configuration parameters using parameter groups, see Working with parameter groups (p. 295).
b. Reboot the MySQL DB instance and each read replica. For more information about rebooting, see Rebooting a DB instance (p. 378).

3. Reset the gtid_mode to OFF_PERMISSIVE:
   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has gtid_mode set to OFF_PERMISSIVE.
   b. Reboot the MySQL DB instance and each read replica.

4. Wait for all of the GTID transactions to be applied on all of the read replicas. To check that these are applied, do the following:

   Wait for all of the GTID transactions to be applied on the Aurora primary instance. To check that these are applied, do the following:
   a. On the MySQL DB instance, run the SHOW MASTER STATUS command.

      Your output should be similar to the following.

      | File                                      | Position |
      |-------------------------------------------|----------|
      | mysql-bin-changelog.000031                | 107      |
      |-------------------------------------------|----------|

      Note the file and position in your output.

   b. On each read replica, use the file and position information from its source instance in the previous step to run the following query.

      SELECT MASTER_POS_WAIT('file', position);

      For example, if the file name is mysql-bin-changelog.000031 and the position is 107, run the following statement.

      SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);

      If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. When the query returns for all read replicas, go to the next step.

5. Reset the GTID parameters to disable GTID-based replication:
   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has the following parameter settings:
      • gtid_mode – OFF
      • enforce_gtid_consistency – OFF
   b. Reboot the MySQL DB instance and each read replica.

Configuring GTID-based replication with an external source instance

You can set up replication based on global transaction identifiers (GTIDs) from an external MySQL instance into an RDS for MySQL DB instance. When you set up an external source instance and a replica on Amazon RDS, monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different
network address. For information on how to monitor failover events, see Working with Amazon RDS event notification (p. 685).

**Important**

GTID-based replication is supported only on RDS for MySQL version 5.7.23 and higher MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

**To configure GTID-based replication with an external source instance**

1. Prepare for GTID-based replication:
   a. Make sure that the external MySQL database has GTID-based replication enabled. To do so, make sure that the external database has the following parameters set to the specified values:
      
      ```
      gtid_mode – ON
      enforce_gtid_consistency – ON
      ``
      
      For more information, see Replication with global transaction identifiers in the MySQL documentation.
   b. Make sure that the parameter group associated with the DB instance has the following parameter settings:
      
      - gtid_mode – ON, ON_PERMISSIVE, or OFF_PERMISSIVE
      - enforce_gtid_consistency – ON
      
      For more information about parameter groups, see Working with parameter groups (p. 295).
   c. If you changed the parameter group of the DB instance, reboot the DB instance. For more information, see Rebooting a DB instance (p. 378).

2. Make the source MySQL instance read-only.

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SET GLOBAL read_only = ON;
   ```

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`. For very large databases, you might want to use the procedure in Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1418).

   For Linux, macOS, or Unix:

   ```
   mysqldump --databases database_name \
   --single-transaction \
   --compress \
   --order-by-primary \
   -u local_user \
   -plocal_password | mysql \
   --host=hostname \
   --port=3306 \
   -u RDS_user_name \
   -pRDS_password
   ```

   For Windows:

   ```
   mysqldump --databases database_name \
   --single-transaction \
   --compress \
   --order-by-primary \
   -u local_user
   ```
Configuring GTID-based replication
with an external source instance

- **local_password** | mysql |
  --host=hostname |
  --port=3306 |
  -u RDS_user_name |
  -pRDS_password

**Note**
Make sure that there isn’t a space between the `-p` option and the entered password.

To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command. The host name is the Domain Name System (DNS) name from the Amazon RDS DB instance endpoint, for example, myinstance.123456789012.us-east-1.rds.amazonaws.com. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL instance writeable again.

```sql
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see the MySQL documentation.

5. On the AWS Management Console, add the IP address of the server that hosts the external database to the virtual private cloud (VPC) security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon VPC User Guide.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL instance. To find the IP address of the Amazon RDS DB instance, use the host command.

```bash
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication and restrict it to your domain to improve security. The following is an example.

```sql
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

7. For the external instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the `repl_user` user for your domain, issue the following command.

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY 'password';
```
8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL database as the replication primary instance by using the `mysql.rds_set_external_master_with_auto_position` command. The following is an example.

```sql
CALL mysql.rds_set_external_master_with_auto_position ('mynamerserver.mydomain.com', 3306, 'repl_user', 'password', 0, 0);
```

Note
---
On RDS for MySQL, you can choose to use delayed replication by running the `mysql.rds_set_external_master_with_delay` stored procedure instead. On RDS for MySQL, one reason to use delayed replication is to enable disaster recovery with the `mysql.rds_start_replication_until_gtid` stored procedure.

9. On the Amazon RDS DB instance, issue the `mysql.rds_start_replication` command to start replication.

```sql
CALL mysql.rds_start_replication;
```

### Configuring binary log file position replication with an external source instance

You can set up replication between an RDS for MySQL or MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS using binary log file replication.

**Topics**
- **Before you begin** (p. 1078)
- **Configuring binary log file position replication with an external source instance** (p. 1078)

### Before you begin

You can configure replication using the binary log file position of replicated transactions.

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure that you use the Amazon RDS `mysql.rds_set_external_master` and `mysql.rds_start_replication` commands to set up replication between your live database and your Amazon RDS database.

To set the binary logging format for a MySQL or MariaDB database, update the `binlog_format` parameter. If your DB instance uses the default DB instance parameter group, create a new DB parameter group to modify `binlog_format` settings. We recommend that you use the default setting for `binlog_format`, which is MIXED. However, you can also set `binlog_format` to ROW or STATEMENT if you need a specific binary log (binlog) format. Reboot your DB instance for the change to take effect.

For information about setting the `binlog_format` parameter, see [Configuring MySQL binary logging](p. 742). For information about the implications of different MySQL replication types, see [Advantages and disadvantages of statement-based and row-based replication](in the MySQL documentation).

### Configuring binary log file position replication with an external source instance

Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:
• Monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification (p. 685).

• Maintain the binlogs on your source instance until you have verified that they have been applied to the replica. This maintenance makes sure that you can restore your source instance in the event of a failure.

• Turn on automated backups on your Amazon RDS DB instance. Turning on automated backups makes sure that you can restore your replica to a particular point in time if you need to re-synchronize your source instance and replica. For information on backups and point-in-time restore, see Backing up and restoring an Amazon RDS DB instance (p. 461).

To configure binary log file replication with an external source instance

1. Make the source MySQL or MariaDB instance read-only.

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SET GLOBAL read_only = ON;
   ```

2. Run the `SHOW MASTER STATUS` command on the source MySQL or MariaDB instance to determine the binlog location.

   You receive output similar to the following example.

<table>
<thead>
<tr>
<th>File</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-bin-changelog.000031</td>
<td>107</td>
</tr>
</tbody>
</table>

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`. For very large databases, you might want to use the procedure in Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1418).

   For Linux, macOS, or Unix:

   ```
   mysqldump --databases database_name \
   --single-transaction \ 
   --compress \ 
   --order-by-primary \ 
   -u local_user \ 
   -plocal_password | mysql \ 
   --host=hostname \ 
   --port=3306 \ 
   -u RDS_user_name \ 
   -pRDS_password
   ```

   For Windows:

   ```
   mysqldump --databases database_name ^ 
   --single-transaction ^ 
   --compress ^ 
   --order-by-primary ^ 
   -u local_user ^ 
   -plocal_password | mysql ^ 
   --host=hostname ^ 
   --port=3306 ^ 
   -u RDS_user_name ^ 
   -pRDS_password
   ```
**Note**
Make sure that there isn't a space between the `-p` option and the entered password.

To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the `--host`, `--user` (`-u`), `--port` and `-p` options in the `mysql` command. The host name is the Domain Name Service (DNS) name from the Amazon RDS DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

```sql
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see the MySQL documentation.

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the virtual private cloud (VPC) security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

The IP address can change when the following conditions are met:
- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the `host` command.

```bash
host  db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication and restrict it to your domain to improve security. The following is an example.

```sql
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

7. For the external instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the source instance by using the `mysql.rds_set_external_master` command. Use the master log file name and master log position that you determined in step 2. The following is an example.
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);

**Note**

On RDS for MySQL, you can choose to use delayed replication by running the `mysql.rds_set_external_master_with_delay` stored procedure instead. On RDS for MySQL, one reason to use delayed replication is to turn on disaster recovery with the `mysql.rds_start_replication_until` stored procedure. Currently, RDS for MariaDB supports delayed replication but doesn't support the `mysql.rds_start_replication_until` procedure.

9. On the Amazon RDS DB instance, issue the `mysql.rds_start_replication` command to start replication.

CALL mysql.rds_start_replication;
Exporting data from a MySQL DB instance by using replication

To export data from an RDS for MySQL DB instance to a MySQL instance running external to Amazon RDS, you can use replication. In this scenario, the MySQL DB instance is the source MySQL DB instance, and the MySQL instance running external to Amazon RDS is the external MySQL database.

The external MySQL database can run either on-premises in your data center, or on an Amazon EC2 instance. The external MySQL database must run the same version as the source MySQL DB instance, or a later version.

Replication to an external MySQL database is only supported during the time it takes to export a database from the source MySQL DB instance. The replication should be terminated when the data has been exported and applications can start accessing the external MySQL instance.

The following list shows the steps to take. Each step is discussed in more detail in later sections.

1. Prepare an external MySQL DB instance.
2. Prepare the source MySQL DB instance for replication.
3. Use the mysqldump utility to transfer the database from the source MySQL DB instance to the external MySQL database.
4. Start replication to the external MySQL database.
5. After the export completes, stop replication.

Prepare an external MySQL database

Perform the following steps to prepare the external MySQL database.

To prepare the external MySQL database

1. Install the external MySQL database.
2. Connect to the external MySQL database as the master user. Then create the users required to support the administrators, applications, and services that access the database.
3. Follow the directions in the MySQL documentation to prepare the external MySQL database as a replica. For more information, see the MySQL documentation.
4. Configure an egress rule for the external MySQL database to operate as a read replica during the export. The egress rule allows the external MySQL database to connect to the source MySQL DB instance during replication. Specify an egress rule that allows Transmission Control Protocol (TCP) connections to the port and IP address of the source MySQL DB instance.

Specify the appropriate egress rules for your environment:

- If the external MySQL database is running in an Amazon EC2 instance in a virtual private cloud (VPC) based on the Amazon VPC service, specify the egress rules in a VPC security group. For more information, see Controlling access with security groups (p. 2232).
- If the external MySQL database is installed on-premises, specify the egress rules in a firewall.
5. If the external MySQL database is running in a VPC, configure rules for the VPC access control list (ACL) rules in addition to the security group egress rule:

- Configure an ACL ingress rule allowing TCP traffic to ports 1024–65535 from the IP address of the source MySQL DB instance.
- Configure an ACL egress rule allowing outbound TCP traffic to the port and IP address of the source MySQL DB instance.
Prepare the source MySQL DB instance

Perform the following steps to prepare the source MySQL DB instance as the replication source.

To prepare the source MySQL DB instance

1. Ensure that your client computer has enough disk space available to save the binary logs while setting up replication.
2. Connect to the source MySQL DB instance, and create a replication account by following the directions in Creating a user for replication in the MySQL documentation.
3. Configure ingress rules on the system running the source MySQL DB instance to allow the external MySQL database to connect during replication. Specify an ingress rule that allows TCP connections to the port used by the source MySQL DB instance from the IP address of the external MySQL database.
4. Specify the egress rules:
   - If the source MySQL DB instance is running in a VPC, specify the ingress rules in a VPC security group. For more information, see Controlling access with security groups (p. 2232).
5. If source MySQL DB instance is running in a VPC, configure VPC ACL rules in addition to the security group ingress rule:
   - Configure an ACL ingress rule to allow TCP connections to the port used by the Amazon RDS instance from the IP address of the external MySQL database.
   - Configure an ACL egress rule to allow TCP connections from ports 1024–65535 to the IP address of the external MySQL database.

For more information about Amazon VPC network ACLs, see Network ACLs in the Amazon VPC User Guide.

6. Ensure that the backup retention period is set long enough that no binary logs are purged during the export. If any of the logs are purged before the export has completed, you must restart replication from the beginning. For more information about setting the backup retention period, see Working with backups (p. 462).
7. Use the mysql.rds_set_configuration stored procedure to set the binary log retention period long enough that the binary logs aren't purged during the export. For more information, see Accessing MySQL binary logs (p. 743).
8. Create an Amazon RDS read replica from the source MySQL DB instance to further ensure that the binary logs of the source MySQL DB instance are not purged. For more information, see Creating a read replica (p. 387).
9. After the Amazon RDS read replica has been created, call the mysql.rds_stop_replication stored procedure to stop the replication process. The source MySQL DB instance no longer purges its binary log files, so they are available for the replication process.
10. (Optional) Set both the max_allowed_packet parameter and the slave_max_allowed_packet parameter to the maximum size to avoid replication errors. The maximum size for both parameters is 1 GB. We recommend this setting for both parameters. For information about setting parameters, see Modifying parameters in a DB parameter group (p. 300).
Copy the database

Perform the following steps to copy the database.

To copy the database

1. Connect to the RDS read replica of the source MySQL DB instance, and run the MySQL SHOW REPLICA STATUS\G statement. Note the values for the following:
   - Master_Host
   - Master_Port
   - Master_Log_File
   - Exec_Master_Log_Pos

   **Note**
   Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

2. Use the mysqldump utility to create a snapshot, which copies the data from Amazon RDS to your local client computer. Ensure that your client computer has enough space to hold the mysqldump files from the databases to be replicated. This process can take several hours for very large databases. Follow the directions in Creating a data snapshot using mysqldump in the MySQL documentation.

   The following example runs mysqldump on a client and writes the dump to a file.

   For Linux, macOS, or Unix:

   ```bash
   mysqldump -h source_MySQL_DB_instance_endpoint
   -u user
   -p password
   --port=3306
   --single-transaction
   --routines
   --triggers
   --databases database database2 > path/rds-dump.sql
   ```

   For Windows:

   ```bash
   mysqldump -h source_MySQL_DB_instance_endpoint
   -u user
   -p password
   --port=3306
   --single-transaction
   --routines
   --triggers
   --databases database database2 > path\rds-dump.sql
   ```

   You can load the backup file into the external MySQL database. For more information, see Reloading SQL-Format Backups in the MySQL documentation. You can run another utility to load the data into the external MySQL database.

Complete the export

Perform the following steps to complete the export.
To complete the export

1. Use the MySQL CHANGE MASTER statement to configure the external MySQL database. Specify the ID and password of the user granted REPLICATION SLAVE permissions. Specify the Master_Host, Master_Port, Relay_Master_Log_File, and Exec_Master_Log_Pos values that you got from the MySQL SHOW REPLICATION STATUS\G statement that you ran on the RDS read replica. For more information, see the MySQL documentation.

   **Note**
   Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICATION STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

2. Use the MySQL START REPLICA command to initiate replication from the source MySQL DB instance to the external MySQL database.

   Doing this starts replication from the source MySQL DB instance and exports all source changes that have occurred after you stopped replication from the Amazon RDS read replica.

   **Note**
   Previous versions of MySQL used START SLAVE instead of START REPLICA. If you are using a MySQL version before 8.0.23, then use START SLAVE.

3. Run the MySQL SHOW REPLICATION STATUS\G command on the external MySQL database to verify that it is operating as a read replica. For more information about interpreting the results, see the MySQL documentation.

4. After replication on the external MySQL database has caught up with the source MySQL DB instance, use the MySQL STOP REPLICA command to stop replication from the source MySQL DB instance.

   **Note**
   Previous versions of MySQL used STOP SLAVE instead of STOP REPLICA. If you are using a MySQL version before 8.0.23, then use STOP SLAVE.

5. On the Amazon RDS read replica, call the mysql.rds_start_replication stored procedure. Doing this allows Amazon RDS to start purging the binary log files from the source MySQL DB instance.
Options for MySQL DB instances

Following, you can find a description of options, or additional features, that are available for Amazon RDS instances running the MySQL DB engine. To enable these options, you can add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see Working with option groups (p. 279).

Amazon RDS supports the following options for MySQL:

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>
<th>Engine versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB Audit Plugin support (p. 1464)</td>
<td>MARIADB_AUDIT_PLUGIN</td>
<td>MySQL 8.0.25 and higher 8.0 versions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>All MySQL 5.7 versions</td>
</tr>
<tr>
<td>MySQL memcached support (p. 1469)</td>
<td>MEMCACHED</td>
<td>All MySQL 5.7 and 8.0 versions</td>
</tr>
</tbody>
</table>
MariaDB Audit Plugin support

Amazon RDS supports using the MariaDB Audit Plugin on MySQL database instances. The MariaDB Audit Plugin records database activity such as users logging on to the database, queries run against the database, and more. The record of database activity is stored in a log file.

Note
Currently, the MariaDB Audit Plugin is only supported for the following RDS for MySQL versions:

- MySQL 8.0.25 and higher 8.0 versions
- All MySQL 5.7 versions

An open source version of this plugin is available, so that you can use it with any MySQL database. For more information, see the [Audit Plugin for MySQL Server GitHub repository](https://github.com/mysql/Audit-Plugin).

Audit Plugin option settings

Amazon RDS supports the following settings for the MariaDB Audit Plugin option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERVER_AUDIT_FILE_PATH</td>
<td>/rdsdbdata/log/audit/</td>
<td>/rdsdbdata/log/audit/</td>
<td>The location of the log file. The log file contains the record of the activity specified in SERVER_AUDIT_EVENTS. For more information, see Viewing and listing database log files (p. 716) and MySQL database log files (p. 736).</td>
</tr>
<tr>
<td>SERVER_AUDIT_FILE_ROTATE_SIZE</td>
<td>1–1000000000</td>
<td>1000000</td>
<td>The size in bytes that when reached, causes the file to rotate. For more information, see Overview of RDS for MySQL database logs (p. 736).</td>
</tr>
<tr>
<td>SERVER_AUDIT_FILE_ROTATIONS</td>
<td>0–100</td>
<td>9</td>
<td>The number of log rotations to save. For more information, see Overview of RDS for MySQL database logs (p. 736) and Downloading a database log file (p. 717).</td>
</tr>
<tr>
<td>SERVER_AUDIT_EVENTS</td>
<td>CONNECT, QUERY, QUERY_DDL, QUERY_DML, QUERY_DML_NO_SELECT, QUERY_DCL</td>
<td>CONNECT, QUERY</td>
<td>The types of activity to record in the log. Installing the MariaDB Audit Plugin is itself logged.</td>
</tr>
</tbody>
</table>

- CONNECT: Log successful and unsuccessful connections to the database, and disconnections from the database.
- QUERY: Log the text of all queries run against the database.
- QUERY_DDL: Similar to the QUERY event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on).
- QUERY_DML: Similar to the QUERY event, but returns only data manipulation language (DML) queries (INSERT, UPDATE, and so on, and also SELECT).
- QUERY_DML_NO_SELECT: Similar to the QUERY_DML event, but doesn't log SELECT queries.
### Option setting | Valid values | Default value | Description
--- | --- | --- | ---
| | | | The QUERY_DML_NO_SELECT setting is supported only for RDS for MySQL 5.7.34 and higher 5.7 versions, and 8.0.25 and higher 8.0 versions.
| | | | • QUERY_DCL: Similar to the QUERY event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on).
| | | | For MySQL, TABLE is not supported.
| SERVER_AUDIT Incl Users | Multiverse comma-separated values | None | Include only activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_INCL_USERS, make sure no values are added to SERVER_AUDIT_EXCL_USERS.
| SERVER_AUDIT Excl Users | Multiverse comma-separated values | None | Exclude activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_EXCL_USERS, make sure no values are added to SERVER_AUDIT_INCL_USERS.
| | | | The rdsadmin user queries the database every second to check the health of the database. Depending on your other settings, this activity can possibly cause the size of your log file to grow very large, very quickly. If you don't need to record this activity, add the rdsadmin user to the SERVER_AUDIT_EXCL_USERS list.
| | | | **Note**
| | | | CONNECT activity is always recorded for all users, even if the user is specified for this option setting.
| | | | Logging is active. The only valid value is ON. Amazon RDS does not support deactivating logging. If you want to deactivate logging, remove the MariaDB Audit Plugin. For more information, see Removing the MariaDB Audit Plugin (p. 1467).
| SERVER_AUDIT QUERY LOGGING | ON | Logging is active. The only valid value is ON. Amazon RDS does not support deactivating logging. If you want to deactivate logging, remove the MariaDB Audit Plugin. For more information, see Removing the MariaDB Audit Plugin (p. 1467).
| SERVER_AUDIT QUERY LOG STRING LIMIT | 0–2147483647 | 1024 | The limit on the length of the query string in a record.

### Adding the MariaDB Audit Plugin

The general process for adding the MariaDB Audit Plugin to a DB instance is the following:
• Create a new option group, or copy or modify an existing option group
• Add the option to the option group
• Associate the option group with the DB instance

After you add the MariaDB Audit Plugin, you don’t need to restart your DB instance. As soon as the option group is active, auditing begins immediately.

Important
Adding the MariaDB Audit Plugin to a DB instance might cause an outage. We recommend adding the MariaDB Audit Plugin during a maintenance window or during a time of low database workload.

To add the MariaDB Audit Plugin
1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group. Choose mysql for Engine, and choose 5.7 or 8.0 for Major engine version. For more information, see Creating an option group (p. 280).
2. Add the MARIADB_AUDIT_PLUGIN option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group (p. 283). For more information about each setting, see Audit Plugin option settings (p. 1464).
3. Apply the option group to a new or existing DB instance.
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).

Audit log format

Log files are represented as comma-separated variable (CSV) files in UTF-8 format. The audit log is stored separately on the local (ephemeral) storage of each RDS for MySQL DB instance.

Tip
Log file entries are not in sequential order. To order the entries, use the timestamp value. To see the latest events, you might have to review all log files. For more flexibility in sorting and searching the log data, turn on the setting to upload the audit logs to CloudWatch and view them using the CloudWatch interface.
To view audit data with more types of fields and with output in JSON format, you can also use the Database Activity Streams feature. For more information, see Monitoring Amazon RDS for Oracle with Database Activity Streams (p. 765).

The audit log files include the following comma-delimited information in rows, in the specified order:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp</td>
<td>The Unix time stamp for the logged event with microsecond precision.</td>
</tr>
<tr>
<td>serverhost</td>
<td>The name of the instance that the event is logged for.</td>
</tr>
<tr>
<td>username</td>
<td>The connected user name of the user.</td>
</tr>
<tr>
<td>host</td>
<td>The host that the user connected from.</td>
</tr>
<tr>
<td>connectionid</td>
<td>The connection ID number for the logged operation.</td>
</tr>
</tbody>
</table>
### Field | Description
--- | ---
queryid | The query ID number, which can be used for finding the relational table events and related queries. For TABLE events, multiple lines are added.
operation | The recorded action type. Possible values are: CONNECT, QUERY, READ, WRITE, CREATE, ALTER, RENAME, and DROP.
database | The active database, as set by the USE command.
object | For QUERY events, this value indicates the query that the database performed. For TABLE events, it indicates the table name.
retcode | The return code of the logged operation.
connection_type | The security state of the connection to the server. Possible values are:
  - 0 – Undefined
  - 1 – TCP/IP
  - 2 – Socket
  - 3 – Named pipe
  - 4 – SSL/TLS
  - 5 – Shared memory
  
  This field is included only for RDS for MySQL version 5.7.34 and higher 5.7 versions, and all 8.0 versions.

---

**Viewing and downloading the MariaDB Audit Plugin log**

After you enable the MariaDB Audit Plugin, you access the results in the log files the same way you access any other text-based log files. The audit log files are located at `/rdsdbdata/log/audit/`. For information about viewing the log file in the console, see Viewing and listing database log files (p. 716). For information about downloading the log file, see Downloading a database log file (p. 717).

**Modifying MariaDB Audit Plugin settings**

After you enable the MariaDB Audit Plugin, you can modify the settings. For more information about how to modify option settings, see Modifying an option setting (p. 288). For more information about each setting, see Audit Plugin option settings (p. 1464).

**Removing the MariaDB Audit Plugin**

Amazon RDS doesn't support turning off logging in the MariaDB Audit Plugin. However, you can remove the plugin from a DB instance. When you remove the MariaDB Audit Plugin, the DB instance is restarted automatically to stop auditing.

To remove the MariaDB Audit Plugin from a DB instance, do one of the following:

- Remove the MariaDB Audit Plugin option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 291)
- Modify the DB instance and specify a different option group that doesn't include the plugin. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).
MySQL memcached support

Amazon RDS supports using the memcached interface to InnoDB tables that was introduced in MySQL 5.6. The memcached API enables applications to use InnoDB tables in a manner similar to NoSQL key-value data stores.

The memcached interface is a simple, key-based cache. Applications use memcached to insert, manipulate, and retrieve key-value data pairs from the cache. MySQL 5.6 introduced a plugin that implements a daemon service that exposes data from InnoDB tables through the memcached protocol. For more information about the MySQL memcached plugin, see InnoDB integration with memcached.

To enable memcached support for an RDS for MySQL DB instance

1. Determine the security group to use for controlling access to the memcached interface. If the set of applications already using the SQL interface are the same set that will access the memcached interface, you can use the existing VPC security group used by the SQL interface. If a different set of applications will access the memcached interface, define a new VPC or DB security group. For more information about managing security groups, see Controlling access with security groups (p. 2232).

2. Create a custom DB option group, selecting MySQL as the engine type and version. For more information about creating an option group, see Creating an option group (p. 280).

3. Add the MEMCACHED option to the option group. Specify the port that the memcached interface will use, and the security group to use in controlling access to the interface. For more information about adding options, see Adding an option to an option group (p. 283).

4. Modify the option settings to configure the memcached parameters, if necessary. For more information about how to modify option settings, see Modifying an option setting (p. 288).

5. Apply the option group to an instance. Amazon RDS enables memcached support for that instance when the option group is applied:
   - You enable memcached support for a new instance by specifying the custom option group when you launch the instance. For more information about launching a MySQL instance, see Creating an Amazon RDS DB instance (p. 236).
   - You enable memcached support for an existing instance by specifying the custom option group when you modify the instance. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 333).

6. Specify which columns in your MySQL tables can be accessed through the memcached interface. The memcached plug-in creates a catalog table named containers in a dedicated database named innodb_memcache. You insert a row into the containers table to map an InnoDB table for access through memcached. You specify a column in the InnoDB table that is used to store the memcached key values, and one or more columns that are used to store the data values associated with the key. You also specify a name that a memcached application uses to refer to that set of columns. For details on inserting rows in the containers table, see InnoDB memcached plugin internals. For an example of mapping an InnoDB table and accessing it through memcached, see Writing applications for the InnoDB memcached plugin.

7. If the applications accessing the memcached interface are on different computers or EC2 instances than the applications using the SQL interface, add the connection information for those computers to the VPC security group associated with the MySQL instance. For more information about managing security groups, see Controlling access with security groups (p. 2232).

You turn off the memcached support for an instance by modifying the instance and specifying the default option group for your MySQL version. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 333).
MySQL memcached security considerations

The memcached protocol does not support user authentication. For more information about MySQL memcached security considerations, see memcached deployment and Using memcached as a MySQL caching layer.

You can take the following actions to help increase the security of the memcached interface:

- Specify a different port than the default of 11211 when adding the MEMCACHED option to the option group.
- Ensure that you associate the memcached interface with a VPC security group that limits access to known, trusted client addresses and EC2 instances. For more information about managing security groups, see Controlling access with security groups (p. 2232).

MySQL memcached connection information

To access the memcached interface, an application must specify both the DNS name of the Amazon RDS instance and the memcached port number. For example, if an instance has a DNS name of my-cache-instance.cg034hpkmjmt.region.rds.amazonaws.com and the memcached interface is using port 11212, the connection information specified in PHP would be:

```php
<?php
$cache = new Memcache;
$cache->connect('my-cache-instance.cg034hpkmjmt.region.rds.amazonaws.com',11212);
?>
```

To find the DNS name and memcached port of a MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the top right corner of the AWS Management Console, select the region that contains the DB instance.
3. In the navigation pane, choose Databases.
4. Choose the MySQL DB instance name to display its details.
5. In the Connect section, note the value of the Endpoint field. The DNS name is the same as the endpoint. Also, note that the port in the Connect section is not used to access the memcached interface.
6. In the Details section, note the name listed in the Option Group field.
7. In the navigation pane, choose Option groups.
8. Choose the name of the option group used by the MySQL DB instance to show the option group details. In the Options section, note the value of the Port setting for the MEMCACHED option.

MySQL memcached option settings

Amazon RDS exposes the MySQL memcached parameters as option settings in the Amazon RDS MEMCACHED option.

MySQL memcached parameters

- DAEMON_MEMCACHED_R_BATCH_SIZE – an integer that specifies how many memcached read operations (get) to perform before doing a COMMIT to start a new transaction. The allowed values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.
• **DAEMON_MEMCACHED_W_BATCH_SIZE** – an integer that specifies how many memcached write operations, such as add, set, or incr, to perform before doing a COMMIT to start a new transaction. The allowed values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.

• **INNODB_API_BK_COMMIT_INTERVAL** – an integer that specifies how often to auto-commit idle connections that use the InnoDB memcached interface. The allowed values are 1 to 1073741824; the default is 5. The option takes effect immediately, without requiring that you restart the instance.

• **INNODB_API_DISABLE_ROWLOCK** – a Boolean that disables (1 (true)) or enables (0 (false)) the use of row locks when using the InnoDB memcached interface. The default is 0 (false). The option does not take effect until the instance is restarted.

• **INNODB_API_ENABLE_MDL** – a Boolean that when set to 0 (false) locks the table used by the InnoDB memcached plugin, so that it cannot be dropped or altered by DDL through the SQL interface. The default is 0 (false). The option does not take effect until the instance is restarted.

• **INNODB_API_TRX_LEVEL** – an integer that specifies the transaction isolation level for queries processed by the memcached interface. The allowed values are 0 to 3. The default is 0. The option does not take effect until the instance is restarted.

Amazon RDS configures these MySQL memcached parameters, and they cannot be modified: **DAEMON_MEMCACHED_LIB_NAME**, **DAEMON_MEMCACHED_LIB_PATH**, and **INNODB_API_ENABLE_BINLOG**. The parameters that MySQL administrators set by using `daemon_memcached_options` are available as individual MEMCACHED option settings in Amazon RDS.

### MySQL daemon_memcached_options parameters

• **BINDING_PROTOCOL** – a string that specifies the binding protocol to use. The allowed values are auto, ascii, or binary. The default is auto, which means the server automatically negotiates the protocol with the client. The option does not take effect until the instance is restarted.

• **BACKLOG_QUEUE_LIMIT** – an integer that specifies how many network connections can be waiting to be processed by memcached. Increasing this limit may reduce errors received by a client that is not able to connect to the memcached instance, but does not improve the performance of the server. The allowed values are 1 to 2048; the default is 1024. The option does not take effect until the instance is restarted.

• **CAS_DISABLED** – a Boolean that enables (1 (true)) or disables (0 (false)) the use of compare and swap (CAS), which reduces the per-item size by 8 bytes. The default is 0 (false). The option does not take effect until the instance is restarted.

• **CHUNK_SIZE** – an integer that specifies the minimum chunk size, in bytes, to allocate for the smallest item's key, value, and flags. The allowed values are 1 to 48. The default is 48 and you can significantly improve memory efficiency with a lower value. The option does not take effect until the instance is restarted.

• **CHUNK_SIZE_GROWTH_FACTOR** – a float that controls the size of new chunks. The size of a new chunk is the size of the previous chunk times **CHUNK_SIZE_GROWTH_FACTOR**. The allowed values are 1 to 2; the default is 1.25. The option does not take effect until the instance is restarted.

• **ERROR_ON_MEMORY_EXHAUSTED** – a Boolean that when set to 1 (true) specifies that memcached will return an error rather than evicting items when there is no more memory to store items. If set to 0 (false), memcached will evict items if there is no more memory. The default is 0 (false). The option does not take effect until the instance is restarted.

• **MAX_SIMULTANEOUS_CONNECTIONS** – an integer that specifies the maximum number of concurrent connections. Setting this value to anything under 10 prevents MySQL from starting. The allowed values are 10 to 1024; the default is 1024. The option does not take effect until the instance is restarted.

• **VERBOSITY** – a string that specifies the level of information logged in the MySQL error log by the memcached service. The default is v. The option does not take effect until the instance is restarted. The allowed values are:
• v – Logs errors and warnings while running the main event loop.
• vv – In addition to the information logged by v, also logs each client command and the response.
• vvv – In addition to the information logged by vv, also logs internal state transitions.

Amazon RDS configures these MySQL DAEMON_MEMCACHED_OPTIONS parameters, they cannot be modified: DAEMON_PROCESS, LARGE_MEMORY_PAGES, MAXIMUM_CORE_FILE_LIMIT, MAX_ITEM_SIZE, LOCK_DOWN_PAGE_MEMORY, MASK, IDFILE, REQUESTS_PER_EVENT, SOCKET, and USER.
Parameters for MySQL

By default, a MySQL DB instance uses a DB parameter group that is specific to a MySQL database. This parameter group contains parameters for the MySQL database engine. For information about working with parameter groups and setting parameters, see Working with parameter groups (p. 295).

RDS for MySQL parameters are set to the default values of the storage engine that you have selected. For more information about MySQL parameters, see the MySQL documentation. For more information about MySQL storage engines, see Supported storage engines for RDS for MySQL (p. 1353).

You can view the parameters available for a specific RDS for MySQL version using the RDS console or the AWS CLI. For information about viewing the parameters in a MySQL parameter group in the RDS console, see Viewing parameter values for a DB parameter group (p. 307).

Using the AWS CLI, you can view the parameters for an RDS for MySQL version by running the describe-engine-default-parameters command. Specify one of the following values for the --db-parameter-group-family option:

- mysql8.0
- mysql5.7

For example, to view the parameters for RDS for MySQL version 8.0, run the following command.

```bash
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0
```

Your output looks similar to the following.

```json
{
   "EngineDefaults": {
      "Parameters": [
         {
            "ParameterName": "activate_all_roles_on_login",
            "ParameterValue": "0",
            "Description": "Automatically set all granted roles as active after the user has authenticated successfully.",
            "Source": "engine-default",
            "ApplyType": "dynamic",
            "DataType": "boolean",
            "AllowedValues": "0,1",
            "IsModifiable": true
         },
         {
            "ParameterName": "allow-suspicious-udfs",
            "Description": "Controls whether user-defined functions that have only an xxx symbol for the main function can be loaded",
            "Source": "engine-default",
            "ApplyType": "static",
            "DataType": "boolean",
            "AllowedValues": "0,1",
            "IsModifiable": false
         },
         {
            "ParameterName": "auto_generate_certs",
            "Description": "Controls whether the server autogenerates SSL key and certificate files in the data directory, if they do not already exist.",
            "Source": "engine-default",
            "ApplyType": "static",
            "DataType": "boolean",
            "AllowedValues": "0,1",
            "IsModifiable": false
         }
      ]
   }
}
```
To list only the modifiable parameters for RDS for MySQL version 8.0, run the following command.

For Linux, macOS, or Unix:

```bash
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0 \
  --query 'EngineDefaults.Parameters[?IsModifiable==true]'
```

For Windows:

```bash
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0 ^
  --query "EngineDefaults.Parameters[?IsModifiable==true]"
```
Common DBA tasks for MySQL DB instances

Following, you can find descriptions of the Amazon RDS–specific implementations of some common DBA tasks for DB instances running the MySQL database engine. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Also, it restricts access to certain system procedures and tables that require advanced privileges.

For information about working with MySQL log files on Amazon RDS, see MySQL database log files (p. 736).

Topics
- Ending a session or query (p. 1475)
- Skipping the current replication error (p. 1475)
- Working with InnoDB tablespaces to improve crash recovery times (p. 1476)
- Managing the global status history (p. 1478)

Ending a session or query

You can end user sessions or queries on DB instances by using the rds_kill and rds_kill_query commands. First connect to your MySQL DB instance, then issue the appropriate command as shown following. For more information, see Connecting to a DB instance running the MySQL database engine (p. 1359).

```
CALL mysql.rds_kill(thread-ID)
CALL mysql.rds_kill_query(thread-ID)
```

For example, to end the session that is running on thread 99, you would type the following:

```
CALL mysql.rds_kill(99);
```

To end the query that is running on thread 99, you would type the following:

```
CALL mysql.rds_kill_query(99);
```

Skipping the current replication error

You can skip an error on your read replica if the error is causing your read replica to stop responding and the error doesn't affect the integrity of your data.

**Note**
First verify that the error in question can be safely skipped. In a MySQL utility, connect to the read replica and run the following MySQL command.

```
SHOW REPLICA STATUS\G
```

For information about the values returned, see the MySQL documentation. Previous versions of and MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

You can skip an error on your read replica in the following ways.

Topics
Amazon RDS provides a stored procedure that you can call to skip an error on your read replicas. First connect to your read replica, then issue the appropriate commands as shown following. For more information, see Connecting to a DB instance running the MySQL database engine (p. 1359).

To skip the error, issue the following command.

```
CALL mysql.rds_skip_repl_error;
```

This command has no effect if you run it on the source DB instance, or on a read replica that hasn’t encountered a replication error.

For more information, such as the versions of MySQL that support `mysql.rds_skip_repl_error`, see `mysql.rds_skip_repl_error` (p. 1508).

**Important**

If you attempt to call `mysql.rds_skip_repl_error` and encounter the following error:

```
ERROR 1305 (42000): PROCEDURE mysql.rds_skip_repl_error does not exist,
```

then upgrade your MySQL DB instance to the latest minor version or one of the minimum minor versions listed in `mysql.rds_skip_repl_error` (p. 1508).

**Setting the slave_skip_errors parameter**

To skip one or more errors, you can set the `slave_skip_errors` static parameter on the read replica. You can set this parameter to skip one or more specific replication error codes. Currently, you can set this parameter only for RDS for MySQL 5.7 DB instances. After you change the setting for this parameter, make sure to reboot your DB instance for the new setting to take effect. For information about setting this parameter, see the MySQL documentation.

We recommend setting this parameter in a separate DB parameter group. You can associate this DB parameter group only with the read replicas that need to skip errors. Following this best practice reduces the potential impact on other DB instances and read replicas.

**Important**

Setting a nondefault value for this parameter can lead to replication inconsistency. Only set this parameter to a nondefault value if you have exhausted other options to resolve the problem and you are sure of the potential impact on your read replica’s data.

**Working with InnoDB tablespaces to improve crash recovery times**

Every table in MySQL consists of a table definition, data, and indexes. The MySQL storage engine InnoDB stores table data and indexes in a *tablespace*. InnoDB creates a global shared tablespace that contains a data dictionary and other relevant metadata, and it can contain table data and indexes. InnoDB can also create separate tablespaces for each table and partition. These separate tablespaces are stored in files with a `.ibd` extension and the header of each tablespace contains a number that uniquely identifies it.

Amazon RDS provides a parameter in a MySQL parameter group called `innodb_file_per_table`. This parameter controls whether InnoDB adds new table data and indexes to the shared tablespace (by setting the parameter value to 0) or to individual tablespaces (by setting the parameter value to 1). Amazon RDS sets the default value for `innodb_file_per_table` parameter to 1, which allows you to
drop individual InnoDB tables and reclaim storage used by those tables for the DB instance. In most use cases, setting the `innodb_file_per_table` parameter to 1 is the recommended setting.

You should set the `innodb_file_per_table` parameter to 0 when you have a large number of tables, such as over 1000 tables when you use standard (magnetic) or general purpose SSD storage or over 10,000 tables when you use Provisioned IOPS storage. When you set this parameter to 0, individual tablespaces are not created and this can improve the time it takes for database crash recovery.

MySQL processes each metadata file, which includes tablespace, during the crash recovery cycle. The time it takes MySQL to process the metadata information in the shared tablespace is negligible compared to the time it takes to process thousands of tablespace files when there are multiple tablespaces. Because the tablespace number is stored within the header of each file, the aggregate time to read all the tablespace files can take up to several hours. For example, a million InnoDB tablespaces on standard storage can take from five to eight hours to process during a crash recovery cycle. In some cases, InnoDB can determine that it needs additional cleanup after a crash recovery cycle so it will begin another crash recovery cycle, which will extend the recovery time. Keep in mind that a crash recovery cycle also entails rolling-back transactions, fixing broken pages, and other operations in addition to the processing of tablespace information.

Since the `innodb_file_per_table` parameter resides in a parameter group, you can change the parameter value by editing the parameter group used by your DB instance without having to reboot the DB instance. After the setting is changed, for example, from 1 (create individual tables) to 0 (use shared tablespace), new InnoDB tables will be added to the shared tablespace while existing tables continue to have individual tablespaces. To move an InnoDB table to the shared tablespace, you must use the `ALTER TABLE` command.

### Migrating multiple tablespaces to the shared tablespace

You can move an InnoDB table's metadata from its own tablespace to the shared tablespace, which will rebuild the table metadata according to the `innodb_file_per_table` parameter setting. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see [Connecting to a DB instance running the MySQL database engine](p. 1359).

```sql
ALTER TABLE `table_name` ENGINE = InnoDB, ALGORITHM=COPY;
```

For example, the following query returns an `ALTER TABLE` statement for every InnoDB table that is not in the shared tablespace.

**For MySQL 5.7 DB instances:**

```sql
SELECT CONCAT('ALTER TABLE `',
REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '`,', '``'), '`.`',
REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '`,', '``'), '` ENGINE=InnoDB,
   ALGORITHM=COPY;') AS Query
FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ('mysql', '');
```

**For MySQL 8.0 DB instances:**

```sql
SELECT CONCAT('ALTER TABLE `',
REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '`,', '``'), '`.`',
REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '`,', '``'), '` ENGINE=InnoDB,
   ALGORITHM=COPY;') AS Query
FROM INFORMATION_SCHEMA.INNODB_TABLES
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ('mysql', '');
```

Rebuilding a MySQL table to move the table's metadata to the shared tablespace requires additional storage space temporarily to rebuild the table, so the DB instance must have storage space available.
During rebuilding, the table is locked and inaccessible to queries. For small tables or tables not frequently accessed, this might not be an issue. For large tables or tables frequently accessed in a heavily concurrent environment, you can rebuild tables on a read replica.

You can create a read replica and migrate table metadata to the shared tablespace on the read replica. While the ALTER TABLE statement blocks access on the read replica, the source DB instance is not affected. The source DB instance will continue to generate its binary logs while the read replica lags during the table rebuilding process. Because the rebuilding requires additional storage space and the replay log file can become large, you should create a read replica with storage allocated that is larger than the source DB instance.

To create a read replica and rebuild InnoDB tables to use the shared tablespace, take the following steps:

1. Make sure that backup retention is enabled on the source DB instance so that binary logging is enabled.
2. Use the AWS Management Console or AWS CLI to create a read replica for the source DB instance. Because the creation of a read replica involves many of the same processes as crash recovery, the creation process can take some time if there is a large number of InnoDB tablespaces. Allocate more storage space on the read replica than is currently used on the source DB instance.
3. When the read replica has been created, create a parameter group with the parameter settings read_only = 0 and innodb_file_per_table = 0. Then associate the parameter group with the read replica.
4. Issue the following SQL statement for all tables that you want migrated on the replica:

   ```sql
   ALTER TABLE name ENGINE = InnoDB
   ```

5. When all of your ALTER TABLE statements have completed on the read replica, verify that the read replica is connected to the source DB instance and that the two instances are in sync.
6. Use the console or CLI to promote the read replica to be the instance. Make sure that the parameter group used for the new standalone DB instance has the innodb_file_per_table parameter set to 0. Change the name of the new standalone DB instance, and point any applications to the new standalone DB instance.

Managing the global status history

MySQL maintains many status variables that provide information about its operation. Their value can help you detect locking or memory issues on a DB instance. The values of these status variables are cumulative since last time the DB instance was started. You can reset most status variables to 0 by using the FLUSH STATUS command.

To allow for monitoring of these values over time, Amazon RDS provides a set of procedures that will snapshot the values of these status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure, called Global Status History (GoSH), is installed on all MySQL DB instances starting with versions 5.5.23. GoSH is disabled by default.

To enable GoSH, you first enable the event scheduler from a DB parameter group by setting the parameter event_scheduler to ON. For information about creating and modifying a DB parameter group, see Working with parameter groups (p. 295).

You can then use the procedures in the following table to enable and configure GoSH. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see Connecting to a DB instance running the MySQL database engine (p. 1359). For each procedure, type the following:

```sql
CALL procedure-name;
```
Where `procedure-name` is one of the procedures in the table.

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysql.rds_enable_gsh_collector</code></td>
<td>Enables GoSH to take default snapshots at intervals specified by <code>rds_set_gsh_collector</code>.</td>
</tr>
<tr>
<td><code>mysql.rds_set_gsh_collector</code></td>
<td>Specifies the interval, in minutes, between snapshots. Default value is 5.</td>
</tr>
<tr>
<td><code>mysql.rds_disable_gsh_collector</code></td>
<td>Disables snapshots.</td>
</tr>
<tr>
<td><code>mysql.rds_collect_global_status_history</code></td>
<td>Takes a snapshot on demand.</td>
</tr>
<tr>
<td><code>mysql.rds_enable_gsh_rotation</code></td>
<td>Enables rotation of the contents of the <code>mysql.rds_global_status_history</code> table to <code>mysql.rds_global_status_history_old</code> at intervals specified by <code>rds_set_gsh_rotation</code>.</td>
</tr>
<tr>
<td><code>mysql.rds_set_gsh_rotation</code></td>
<td>Specifies the interval, in days, between table rotations. Default value is 7.</td>
</tr>
<tr>
<td><code>mysql.rds_disable_gsh_rotation</code></td>
<td>Disables table rotation.</td>
</tr>
<tr>
<td><code>mysql.rds_rotate_global_status_history</code></td>
<td>Rotates the contents of the <code>mysql.rds_global_status_history</code> table to <code>mysql.rds_global_status_history_old</code> on demand.</td>
</tr>
</tbody>
</table>

When GoSH is running, you can query the tables that it writes to. For example, to query the hit ratio of the InnoDB buffer pool, you would issue the following query:

```sql
select a.collection_end, a.collection_start, ((a.variable_Delta-b.variable_delta)/a.variable_delta)*100 as "HitRatio"
from mysql.rds_global_status_history as a join mysql.rds_global_status_history as b on a.collection_end = b.collection_end
where a.variable_name = 'Innodb_buffer_pool_read_requests' and b.variable_name = 'Innodb_buffer_pool_reads'
```
Local time zone for MySQL DB instances

By default, the time zone for a MySQL DB instance is Universal Time Coordinated (UTC). You can set the time zone for your DB instance to the local time zone for your application instead.

To set the local time zone for a DB instance, set the `time_zone` parameter in the parameter group for your DB instance to one of the supported values listed later in this section. When you set the `time_zone` parameter for a parameter group, all DB instances and read replicas that are using that parameter group change to use the new local time zone. For information on setting parameters in a parameter group, see Working with parameter groups (p. 295).

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

You can set a different local time zone for a DB instance and one or more of its read replicas. To do this, use a different parameter group for the DB instance and the replica or replicas and set the `time_zone` parameter in each parameter group to a different local time zone.

If you are replicating across AWS Regions, then the source DB instance and the read replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the `time_zone` parameter in the instance's and read replica's parameter groups.

When you restore a DB instance from a DB snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB instance to a point in time, then the local time zone for the restored DB instance is the time zone setting from the parameter group of the restored DB instance.

You can set your local time zone to one of the following values.

<table>

</table>
Known issues and limitations for Amazon RDS for MySQL

Known issues and limitations for working with Amazon RDS for MySQL are as follows.

Topics

• InnoDB reserved word (p. 1482)
• Storage-full behavior for Amazon RDS for MySQL (p. 1482)
• Inconsistent InnoDB buffer pool size (p. 1483)
• Index merge optimization returns incorrect results (p. 1483)
• Log file size (p. 1484)
• MySQL parameter exceptions for Amazon RDS DB instances (p. 1484)
• MySQL file size limits in Amazon RDS (p. 1484)
• MySQL Keyring Plugin not supported (p. 1485)

InnoDB reserved word

InnoDB is a reserved word for RDS for MySQL. You can't use this name for a MySQL database.

Storage-full behavior for Amazon RDS for MySQL

When storage becomes full for a MySQL DB instance, there can be metadata inconsistencies, dictionary mismatches, and orphan tables. To prevent these issues, Amazon RDS automatically stops a DB instance that reaches the storage-full state.

A MySQL DB instance reaches the storage-full state in the following cases:

• The DB instance has less than 20,000 MiB of storage, and available storage reaches 200 MiB or less.
• The DB instance has more than 102,400 MiB of storage, and available storage reaches 1024 MiB or less.
• The DB instance has between 20,000 MiB and 102,400 MiB of storage, and has less than 1% of storage available.

After Amazon RDS stops a DB instance automatically because it reached the storage-full state, you can still modify it. To restart the DB instance, complete at least one of the following:

• Modify the DB instance to enable storage autoscaling.

For more information about storage autoscaling, see Managing capacity automatically with Amazon RDS storage autoscaling (p. 424).

• Modify the DB instance to increase its storage capacity.

For more information about increasing storage capacity, see Increasing DB instance storage capacity (p. 422).

After you make one of these changes, the DB instance is restarted automatically. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 333).
Inconsistent InnoDB buffer pool size

For MySQL 5.7, there is currently a bug in the way that the InnoDB buffer pool size is managed. MySQL 5.7 might adjust the value of the `innodb_buffer_pool_size` parameter to a large value that can result in the InnoDB buffer pool growing too large and using up too much memory. This effect can cause the MySQL database engine to stop running or can prevent the MySQL database engine from starting. This issue is more common for DB instance classes that have less memory available.

To resolve this issue, set the value of the `innodb_buffer_pool_size` parameter to a multiple of the product of the `innodb_buffer_pool_instances` parameter value and the `innodb_buffer_pool_chunk_size` parameter value. For example, you might set the `innodb_buffer_pool_size` parameter value to a multiple of eight times the product of the `innodb_buffer_pool_instances` and `innodb_buffer_pool_chunk_size` parameter values, as shown in the following example.

```
innodb_buffer_pool_chunk_size = 536870912
innodb_buffer_pool_instances = 4
innodb_buffer_pool_size = (536870912 * 4) * 8 = 17179869184
```

For details on this MySQL 5.7 bug, see https://bugs.mysql.com/bug.php?id=79379 in the MySQL documentation.

Index merge optimization returns incorrect results

Queries that use index merge optimization might return incorrect results due to a bug in the MySQL query optimizer that was introduced in MySQL 5.5.37. When you issue a query against a table with multiple indexes the optimizer scans ranges of rows based on the multiple indexes, but does not merge the results together correctly. For more information on the query optimizer bug, see http://bugs.mysql.com/bug.php?id=72745 and http://bugs.mysql.com/bug.php?id=68194 in the MySQL bug database.

For example, consider a query on a table with two indexes where the search arguments reference the indexed columns.

```
SELECT * FROM table1
WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';
```

In this case, the search engine will search both indexes. However, due to the bug, the merged results are incorrect.

To resolve this issue, you can do one of the following:

- Set the `optimizer_switch` parameter to `index_merge=off` in the DB parameter group for your MySQL DB instance. For information on setting DB parameter group parameters, see Working with parameter groups (p. 295).
- Upgrade your MySQL DB instance to MySQL version 5.7 or 8.0. For more information, see Upgrading the MySQL DB engine (p. 1392).
- If you cannot upgrade your instance or change the `optimizer_switch` parameter, you can work around the bug by explicitly identifying an index for the query, for example:

```
SELECT * FROM table1
USE INDEX covering_index
WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';
```

For more information, see Index merge optimization in the MySQL documentation.
Log file size

For MySQL, there is a size limit on BLOBs written to the redo log. To account for this limit, ensure that the `innodb_log_file_size` parameter for your MySQL DB instance is 10 times larger than the largest BLOB data size found in your tables, plus the length of other variable length fields (VARCHAR, VARBINARY, TEXT) in the same tables. For information on how to set parameter values, see Working with parameter groups (p. 295). For information on the redo log BLOB size limit, see Changes in MySQL 5.6.20.

MySQL parameter exceptions for Amazon RDS DB instances

Some MySQL parameters require special considerations when used with an Amazon RDS DB instance.

lower_case_table_names

Because Amazon RDS uses a case-sensitive file system, setting the value of the `lower_case_table_names` server parameter to 2 (“names stored as given but compared in lowercase”) is not supported. The following are the supported values for Amazon RDS for MySQL DB instances:

- 0 (“names stored as given and comparisons are case-sensitive”) is supported for all Amazon RDS for MySQL versions.
- 1 (“names stored in lowercase and comparisons are not case-sensitive”) is supported for RDS for MySQL version 5.7 and version 8.0.23 and higher 8.0 versions.

Set the `lower_case_table_names` parameter in a custom DB parameter group before creating a DB instance. Then, specify the custom DB parameter group when you create the DB instance.

When a parameter group is associated with a MySQL DB instance with a version lower than 8.0, we recommend that you avoid changing the `lower_case_table_names` parameter in the parameter group. Doing so could cause inconsistencies with point-in-time recovery backups and read replica DB instances.

When a parameter group is associated with a version 8.0 MySQL DB instance, you can’t modify the `lower_case_table_names` parameter in the parameter group.

Read replicas should always use the same `lower_case_table_names` parameter value as the source DB instance.

long_query_time

You can set the `long_query_time` parameter to a floating point value which allows you to log slow queries to the MySQL slow query log with microsecond resolution. You can set a value such as 0.1 seconds, which would be 100 milliseconds, to help when debugging slow transactions that take less than one second.

MySQL file size limits in Amazon RDS

For MySQL DB instances, the maximum provisioned storage limit constrains the size of a table to a maximum size of 16 TB when using InnoDB file-per-table tablespaces. This limit also constrains the system tablespace to a maximum size of 16 TB. InnoDB file-per-table tablespaces (with tables each in their own tablespace) is set by default for MySQL DB instances.
Note
Some existing DB instances have a lower limit. For example, MySQL DB instances created before April 2014 have a file and table size limit of 2 TB. This 2 TB file size limit also applies to DB instances or read replicas created from DB snapshots taken before April 2014, regardless of when the DB instance was created.

There are advantages and disadvantages to using InnoDB file-per-table tablespaces, depending on your application. To determine the best approach for your application, see File-per-table tablespaces in the MySQL documentation.

We don't recommend allowing tables to grow to the maximum file size. In general, a better practice is to partition data into smaller tables, which can improve performance and recovery times.

One option that you can use for breaking a large table up into smaller tables is partitioning. Partitioning distributes portions of your large table into separate files based on rules that you specify. For example, if you store transactions by date, you can create partitioning rules that distribute older transactions into separate files using partitioning. Then periodically, you can archive the historical transaction data that doesn't need to be readily available to your application. For more information, see Partitioning in the MySQL documentation.

To determine the file size of a table

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

```
SELECT TABLE_SCHEMA, TABLE_NAME, 
round(((DATA_LENGTH + INDEX_LENGTH) / 1024 / 1024), 2) As "Approximate size (MB)"
FROM information_schema.TABLES
WHERE TABLE_SCHEMA NOT IN ('mysql', 'information_schema', 'performance_schema');
```

To enable InnoDB file-per-table tablespaces

- To enable InnoDB file-per-table tablespaces, set the `innodb_file_per_table` parameter to 1 in the parameter group for the DB instance.

To disable InnoDB file-per-table tablespaces

- To disable InnoDB file-per-table tablespaces, set the `innodb_file_per_table` parameter to 0 in the parameter group for the DB instance.

For information on updating a parameter group, see Working with parameter groups (p. 295).

When you have enabled or disabled InnoDB file-per-table tablespaces, you can issue an ALTER TABLE command to move a table from the global tablespace to its own tablespace, or from its own tablespace to the global tablespace as shown in the following example:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

MySQL Keyring Plugin not supported

Currently, Amazon RDS for MySQL does not support the MySQL keyring_aws Amazon Web Services Keyring Plugin.
MySQL on Amazon RDS SQL reference

Following, you can find a description of system stored procedures that are available for Amazon RDS instances running the MySQL DB engine.

Overview

The following system stored procedures are supported for Amazon RDS DB instances running MySQL. The master user must run these procedures.

Replication

- `mysql.rds_set_master_auto_position` (p. 1487)
- `mysql.rds_set_external_master` (p. 1488)
- `mysql.rds_set_external_source` (p. 1490)
- `mysql.rds_set_external_master_with_delay` (p. 1493)
- `mysql.rds_set_external_master_with_auto_position` (p. 1495)
- `mysql.rds_set_external_source_with_auto_position` (p. 1498)
- `mysql.rds_reset_external_master` (p. 1500)
- `mysql.rds_reset_external_source` (p. 1501)
- `mysql.rds_import_binlog_ssl_material` (p. 1501)
- `mysql.rds_remove_binlog_ssl_material` (p. 1503)
- `mysql.rds_set_source_delay` (p. 1503)
- `mysql.rds_start_replication` (p. 1504)
- `mysql.rds_start_replication_until` (p. 1505)
- `mysql.rds_start_replication_until_gtid` (p. 1506)
- `mysql.rds_stop_replication` (p. 1507)
- `mysql.rds_skip_transaction_with_gtid` (p. 1507)
- `mysql.rds_skip_repl_error` (p. 1508)
- `mysql.rds_next_master_log` (p. 1509)

InnoDB cache warming

- `mysql.rds_innodb_buffer_pool_dump_now` (p. 1511)
- `mysql.rds_innodb_buffer_pool_load_now` (p. 1511)
- `mysql.rds_innodb_buffer_pool_load_abort` (p. 1511)

Managing additional configuration (for example, binlog file retention)

- `mysql.rds_set_configuration` (p. 1511)
- `mysql.rds_show_configuration` (p. 1513)

Ending a session or query

- `mysql.rds_kill` (p. 1513)
- `mysql.rds_kill_query` (p. 1514)
Logging

SQL reference conventions

Following, you can find explanations for the conventions that are used to describe the syntax of the system stored procedures and tables described in the SQL reference section.

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UPPERCASE</td>
<td>Words in uppercase are keywords.</td>
</tr>
<tr>
<td>[ ]</td>
<td>Square brackets indicate optional arguments.</td>
</tr>
<tr>
<td>{ }</td>
<td>Braces indicate that you are required to choose one of the arguments inside the braces.</td>
</tr>
<tr>
<td></td>
<td>Pipes separate arguments that you can choose.</td>
</tr>
<tr>
<td><em>italics</em></td>
<td>Words in italics indicate placeholders. You must insert the appropriate value in place of the word in italics.</td>
</tr>
<tr>
<td>...</td>
<td>An ellipsis indicates that you can repeat the preceding element.</td>
</tr>
<tr>
<td>'</td>
<td>Words in single quotes indicate that you must type the quotes.</td>
</tr>
</tbody>
</table>

**mysql.rds_set_master_auto_position**

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

**Syntax**

```sql
CALL mysql.rds_set_master_auto_position (
  auto_position_mode
);
```
Parameters

auto_position_mode

A value that indicates whether to use log file position replication or GTID-based replication:
- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.

Usage notes

The master user must run the `mysql.rds_set_master_auto_position` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

`mysql.rds_set_external_master`

Configures a MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. The `mysql.rds_set_external_master` procedure is deprecated and will be removed in a future release. Use `mysql.rds_set_external_source` (p. 1490) instead.

Important
To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group (p. 300).

Note
You can use the `mysql.rds_set_external_master_with_delay` (p. 1493) stored procedure to configure an external source database instance and delayed replication.

Syntax

```sql
CALL mysql.rds_set_external_master (
    host_name,
    host_port,
    replication_user_name,
    replication_user_password,
    mysql_binary_log_file_name,
    mysql_binary_log_file_location,
    ssl_encryption
);```

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.
replication_user_name

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in replication_user_name.

mysql_binary_log_file_name

The name of the binary log on the source database instance that contains the replication information.

mysql_binary_log_file_location

The location in the mysql_binary_log_file_name binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running SHOW MASTER STATUS on the source database instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

Usage notes

The master user must run the mysql.rds_set_external_master procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run mysql.rds_set_external_master, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify replication_user_name and replication_user_password values that indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   MySQL 5.7

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   MySQL 8.0

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
   ```

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.
MySQL 5.7

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY 'password';
```

MySQL 8.0

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

To use encrypted replication, configure source database instance to use SSL connections. Also, import the certificate authority certificate, client certificate, and client key into the DB instance or DB cluster using the `mysql.rds_import_binlog_ssl_material` procedure.

**Note**
We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see [Working with read replicas](p. 382).

After calling `mysql.rds_set_external_master` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` on the read replica to start the replication process. You can call `mysql.rds_reset_external_master` to remove the read replica configuration.

When `mysql.rds_set_external_master` is called, Amazon RDS records the time, user, and an action of `set_master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

**Examples**

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```
call mysql.rds_set_external_master( 'Externaldb.some.com',
  3306, 'repl_user',
  'password',
  'mysql-bin-changelog.0777',
  120,
  0);
```

**mysql.rds_set_external_source**

Configures a MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

**Important**
To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group](p. 300).

**Note**
You can use the `mysql.rds_set_external_master_with_delay` stored procedure to configure an external source database instance and delayed replication.
Amazon Relational Database Service User Guide
mysql.rds_set_external_source

Syntax

CALL mysql.rds_set_external_source (  
    host_name  
    , host_port  
    , replication_user_name  
    , replication_user_password  
    , mysql_binary_log_file_name  
    , mysql_binary_log_file_location  
    , ssl_encryption  
);  

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in replication_user_name.

mysql_binary_log_file_name

The name of the binary log on the source database instance that contains the replication information.

mysql_binary_log_file_location

The location in the mysql_binary_log_file_name binary log at which replication starts reading the replication information. You can determine the binlog file name and location by running SHOW MASTER STATUS on the source database instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

Usage notes

The master user must run the mysql.rds_set_external_source procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.
Before you run `mysql.rds_set_external_source`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify `replication_user_name` and `replication_user_password` values that indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

**To configure an external instance of MySQL as a source database instance**

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   **MySQL 5.7**
   ```sql
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   **MySQL 8.0**
   ```sql
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
   ```

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

   **MySQL 5.7**
   ```sql
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'password';
   ```

   **MySQL 8.0**
   ```sql
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
   ```

To use encrypted replication, configure source database instance to use SSL connections. Also, import the certificate authority certificate, client certificate, and client key into the DB instance or DB cluster using the `mysql.rds_import_binlog_ssl_material` procedure.

**Note**

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see [Working with read replicas](p. 382).

After calling `mysql.rds_set_external_source` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` on the read replica to start the replication process. You can call `mysql.rds_reset_external_master` to remove the read replica configuration.

When `mysql.rds_set_external_source` is called, Amazon RDS records the time, user, and an action of set_master in the `mysql.rds_history` and `mysql.rds_replication_status` tables.
Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```sql
CALL mysql.rds_set_external_source('Externaldb.some.com',
3306,
'repl_user',
'password',
'mysql-bin-changelog.0777',
120,
0);
```

mysql.rds_set_external_master_with_delay

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS and configures delayed replication.

**Important**

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group (p. 300).

Syntax

```sql
CALL mysql.rds_set_external_master_with_delay(
    host_name
    , host_port
    , replication_user_name
    , replication_user_password
    , mysql_binary_log_file_name
    , mysql_binary_log_file_location
    , ssl_encryption
    , delay
);
```

Parameters

**host_name**

The host name or IP address of the MySQL instance running external to Amazon RDS that will become the source database instance.

**host_port**

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.

**replication_user_name**

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

**replication_user_password**

The password of the user ID specified in replication_user_name.
mysql_binary_log_file_name

The name of the binary log on the source database instance contains the replication information.

mysql_binary_log_file_location

The location in the mysql_binary_log_file_name binary log at which replication will start reading the replication information.

You can determine the binlog file name and location by running SHOW MASTER STATUS on the source database instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86400 seconds).

Usage notes

The master user must run the mysql.rds_set_external_master_with_delay procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run mysql.rds_set_external_master_with_delay, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for replication_user_name and replication_user_password. These values must indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   ```sql
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
   ```

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

   ```sql
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'SomePassW0rd'
   ```

For more information, see Configuring binary log file position replication with an external source instance (p. 1455).

Note

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication...
topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with read replicas (p. 382).

After calling mysql.rds_set_external_master_with_delay to configure an Amazon RDS DB instance as a read replica, you can call mysql.rds_start_replication (p. 1504) on the read replica to start the replication process. You can call mysql.rds_reset_external_master (p. 1500) to remove the read replica configuration.

When you call mysql.rds_set_external_master_with_delay, Amazon RDS records the time, the user, and an action of set master in the mysql.rds_history and mysql.rds_replication_status tables.

For disaster recovery, you can use this procedure with the mysql.rds_start_replication_until (p. 1505) or mysql.rds_start_replication_until_gtid (p. 1506) stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the mysql.rds_set_external_master_with_delay procedure. After the mysql.rds_start_replication_until procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 389).

To use the mysql.rds_rds_start_replication_until_gtid procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the mysql.rds_skip_transaction_with_gtid (p. 1507) stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication for Amazon RDS for MySQL (p. 1448).

The mysql.rds_set_external_master_with_delay procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

```
call mysql.rds_set_external_master_with_delay(  
    'Externaldb.some.com',  
    3306,  
    'repl_user',  
    'SomePassW0rd',  
    'mysql-bin-changelog.000777',  
    120,  
    0,  
    3600);  
```

**mysql.rds_set_external_master_with_auto_position**

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. This procedure also configures delayed replication and replication based on global transaction identifiers (GTIDs).
The `mysql.rds_set_external_master_with_auto_position` procedure is deprecated and will be removed in a future release. Use `mysql.rds_set_external_source_with_auto_position (p. 1498)` instead.

**Important**
To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group (p. 300).

**Syntax**

```sql
CALL mysql.rds_set_external_master_with_auto_position (host_name, host_port, replication_user_name, replication_user_password, ssl_encryption, delay);
```

**Parameters**

`host_name`

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

`host_port`

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

`replication_user_name`

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

`replication_user_password`

The password of the user ID specified in `replication_user_name`.

`ssl_encryption`

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

**Note**
The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

`delay`

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86,400 seconds).
Usage notes

The master user must run the `mysql.rds_set_external_master_with_auto_position` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

Before you run `mysql.rds_set_external_master_with_auto_position`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   ```sql
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
   ```

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

   ```sql
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'SomePassW0rd'
   ```

For more information, see Configuring binary log file position replication with an external source instance (p. 1455).

Note

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with read replicas (p. 382).

After calling `mysql.rds_set_external_master_with_auto_position` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` (p. 1504) on the read replica to start the replication process. You can call `mysql.rds_reset_external_master` (p. 1500) to remove the read replica configuration.

When you call `mysql.rds_set_external_master_with_auto_position`, Amazon RDS records the time, the user, and an action of set master in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the `mysql.rds_start_replication_until` (p. 1505) or `mysql.rds_start_replication_until_gtid` (p. 1506) stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_master_with_auto_position` procedure. After the `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 389).
To use the `mysql.rds_set_external_source_with_auto_position` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the `mysql.rds_skip_transaction_with_gtid` (p. 1507) stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication for Amazon RDS for MySQL (p. 1448).

**Examples**

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

```sql
call mysql.rds_set_external_master_with_auto_position(
    'Externaldb.some.com',
    3306,
    'repl_user',
    'SomePassW0rd',
    0,
    3600);
```

**mysql.rds_set_external_source_with_auto_position**

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. This procedure also configures delayed replication and replication based on global transaction identifiers (GTIDs).

Important To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group (p. 300).

**Syntax**

```sql
CALL mysql.rds_set_external_source_with_auto_position (host_name, host_port, replication_user_name, replication_user_password, ssl_encryption, delay);
```

**Parameters**

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.
replication_user_name

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in replication_user_name.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note
The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86,400 seconds).

Usage notes

The master user must run the mysql.rds_set_external_source_with_auto_position procedure. This procedure must be run on the MySQL instance running external to Amazon RDS.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher versions.

Before you run mysql.rds_set_external_source_with_auto_position, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for replication_user_name and replication_user_password. These values must indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
   ```

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'SomePassW0rd'
   ```

For more information, see Configuring binary log file position replication with an external source instance (p. 1455).

Note
We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and
other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with read replicas (p. 382).

After calling `mysql.rds_set_external_source_with_auto_position` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` (p. 1504) on the read replica to start the replication process. You can call `mysql.rds_reset_external_master` (p. 1500) to remove the read replica configuration.

When you call `mysql.rds_set_external_source_with_auto_position`, Amazon RDS records the time, the user, and an action of set master in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the `mysql.rds_start_replication_until` (p. 1505) or `mysql.rds_start_replication_until_gtid` (p. 1506) stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_source_with_auto_position` procedure. After the `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 389).

To use the `mysql.rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the `mysql.rds_skip_transaction_with_gtid` (p. 1507) stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication for Amazon RDS for MySQL (p. 1448).

**Examples**

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

```sql
call mysql.rds_set_external_source_with_auto_position(
    'Externaldb.some.com',
    3306,
    'repl_user',
    'SomePassW0rd',
    0,
    3600);
```

**mysql.rds_reset_external_master**

Reconfigures a MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS. The `mysql.rds_reset_external_master` procedure is deprecated and will be removed in a future release. Use `mysql.rds_reset_external_source` (p. 1501) instead.

**Important**

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group (p. 300).

**Syntax**
CALL mysql.rds_reset_external_master;

Usage notes

The master user must run the `mysql.rds_reset_external_master` procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.

Note

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see *Working with read replicas* (p. 382).

For more information about using replication to import data from an instance of MySQL running external to Amazon RDS, see *Restoring a backup into a MySQL DB instance* (p. 1408).

### `mysql.rds_reset_external_source`

Reconfigures a MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS.

Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to `1`. For information about modifying parameters, see *Modifying parameters in a DB parameter group* (p. 300).

Syntax

CALL mysql.rds_reset_external_source;

Usage notes

The master user must run the `mysql.rds_reset_external_source` procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.

Note

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see *Working with read replicas* (p. 382).

For more information about using replication to import data from an instance of MySQL running external to Amazon RDS, see *Restoring a backup into a MySQL DB instance* (p. 1408).

### `mysql.rds_import_binlog_ssl_material`

Imports the certificate authority certificate, client certificate, and client key into an Aurora MySQL DB cluster. The information is required for SSL communication and encrypted replication.
**Note**
Currently, this procedure is supported for Aurora MySQL version 1; version 2: 2.09.2, 2.10.0, 2.10.1, and 2.11.0; and version 3: 3.01.1 and higher.

**Syntax**

```
CALL mysql.rds_import_binlog_ssl_material (ssl_material);
```

**Parameters**

`ssl_material`

JSON payload that contains the contents of the following .pem format files for a MySQL client:

- "ssl_ca":"Certificate authority certificate"
- "ssl_cert":"Client certificate"
- "ssl_key":"Client key"

**Usage notes**

Prepare for encrypted replication before you run this procedure:

- If you don't have SSL enabled on the external MySQL source database instance and don't have a client key and client certificate prepared, enable SSL on the MySQL database server and generate the required client key and client certificate.
- If SSL is enabled on the external source database instance, supply a client key and certificate for the Aurora MySQL DB cluster. If you don't have these, generate a new key and certificate for the Aurora MySQL DB cluster. To sign the client certificate, you must have the certificate authority key you used to configure SSL on the external MySQL source database instance.

For more information, see [Creating SSL certificates and keys using openssl](#) in the MySQL documentation.

**Important**

After you prepare for encrypted replication, use an SSL connection to run this procedure. The client key must not be transferred across an insecure connection.

This procedure imports SSL information from an external MySQL database into an Aurora MySQL DB cluster. The SSL information is in .pem format files that contain the SSL information for the Aurora MySQL DB cluster. During encrypted replication, the Aurora MySQL DB cluster acts a client to the MySQL database server. The certificates and keys for the Aurora MySQL client are in files in .pem format.

You can copy the information from these files into the `ssl_material` parameter in the correct JSON payload. To support encrypted replication, import this SSL information into the Aurora MySQL DB cluster.

The JSON payload must be in the following format.

```
{"ssl_ca":"-----BEGIN CERTIFICATE-----
ssl_ca_pem_body_code
-----END CERTIFICATE-----\n","ssl_cert":"-----BEGIN CERTIFICATE-----
ssl_cert_pem_body_code
-----END CERTIFICATE-----\n"}
```
Examples

The following example imports SSL information into an Aurora MySQL DB cluster. In .pem format files, the body code typically is longer than the body code shown in the example.

call mysql.rds_import_binlog_ssl_material(
  '{"ssl_ca":"-----BEGIN CERTIFICATE-----
AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYhCe53pcjqP3maAhDFcvBS706V

-----END RSA PRIVATE KEY-----
'});

Note

For information about using Amazon Aurora, see the Amazon Aurora User Guide.

mysql.rds_remove_binlog_ssl_material

Removes the certificate authority certificate, client certificate, and client key for SSL communication and encrypted replication. This information is imported by using mysql.rds_import_binlog_ssl_material (p. 1501).

Note

Currently, this procedure is only supported for Aurora MySQL version 5.6.

Syntax

CALL mysql.rds_remove_binlog_ssl_material;

mysql.rds_set_source_delay

Sets the minimum number of seconds to delay replication from source database instance to the current read replica. Use this procedure when you are connected to a read replica to delay replication from its source database instance.

Syntax

CALL mysql.rds_set_source_delay;
Parameters

delay

The minimum number of seconds to delay replication from the source database instance.

The limit for this parameter is one day (86400 seconds).

Usage notes

The master user must run the mysql.rds_set_source_delay procedure.

For disaster recovery, you can use this procedure with the mysql.rds_start_replication_until (p. 1505) stored procedure or the mysql.rds_start_replication_until_gtid (p. 1506) stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the mysql.rds_set_source_delay procedure. After the mysql.rds_start_replication_until or mysql.rds_start_replication_until_gtid procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 389).

To use the mysql.rds_start_replication_until_gtid procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the mysql.rds_skip_transaction_with_gtid (p. 1507) stored procedure. For more information on GTID-based replication, see Using GTID-based replication for Amazon RDS for MySQL (p. 1448).

The mysql.rds_set_source_delay procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

Examples

To delay replication from source database instance to the current read replica for at least one hour (3,600 seconds), you can call mysql.rds_set_source_delay with the following parameter:

CALL mysql.rds_set_source_delay(3600);

mysql.rds_start_replication

Initiates replication from a MySQL DB instance.

Note

You can use the mysql.rds_start_replication_until (p. 1505) or mysql.rds_start_replication_until_gtid (p. 1506) stored procedure to initiate replication from an RDS for MySQL DB instance and stop replication at the specified binary log file location.

Syntax

CALL mysql.rds_start_replication;
Usage notes

The master user must run the `mysql.rds_start_replication_until` procedure.

If you are configuring replication to import data from an instance of MySQL running external to Amazon RDS, you call `mysql.rds_start_replication` on the read replica to start the replication process after you have called `mysql.rds_set_external_master` (p. 1488) to build the replication configuration. For more information, see Restoring a backup into a MySQL DB instance (p. 1408).

If you are configuring replication to export data to an instance of MySQL external to Amazon RDS, you call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see Exporting data from a MySQL DB instance by using replication (p. 1459).

You can also call `mysql.rds_start_replication` on the read replica to restart any replication process that you previously stopped by calling `mysql.rds_stop_replication` (p. 1507). For more information, see Working with read replicas (p. 382).

`mysql.rds_start_replication_until`

Initiates replication from an RDS for MySQL DB instance and stops replication at the specified binary log file location.

Syntax

```sql
CALL mysql.rds_start_replication_until (replication_log_file, replication_stop_point);
```

Parameters

`replication_log_file`

The name of the binary log on the source database instance contains the replication information.

`replication_stop_point`

The location in the `replication_log_file` binary log at which replication will stop.

Usage notes

The master user must run the `mysql.rds_start_replication_until` procedure.

You can use this procedure with delayed replication for disaster recovery. If you have delayed replication configured, you can use this procedure to roll forward changes to a delayed read replica to the time just before a disaster. After this procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 389).

You can configure delayed replication using the following stored procedures:

- `mysql.rds_set_configuration` (p. 1511)
- `mysql.rds_set_external_master_with_delay` (p. 1493)
- `mysql.rds_set_source_delay` (p. 1503)
The file name specified for the `replication_log_file` parameter must match the source database instance binlog file name.

When the `replication_stop_point` parameter specifies a stop location that is in the past, replication is stopped immediately.

The `mysql.rds_start_replication_until_gtid` procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

**Examples**

The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file.

```
call mysql.rds_start_replication_until('mysql-bin-changelog.000777', 120);
```

**mysql.rds_start_replication_until_gtid**

Initiates replication from an RDS for MySQL DB instance and stops replication immediately after the specified global transaction identifier (GTID).

**Syntax**

```
CALL mysql.rds_start_replication_until_gtid (gtid);
```

**Parameters**

`gtid`

The GTID after which replication is to stop.

**Usage notes**

The master user must run the `mysql.rds_start_replication_until_gtid` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

You can use this procedure with delayed replication for disaster recovery. If you have delayed replication configured, you can use this procedure to roll forward changes to a delayed read replica to the time just before a disaster. After this procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 389).

You can configure delayed replication using the following stored procedures:

- `mysql.rds_set_configuration` (p. 1511)
When the gtid parameter specifies a transaction that has already been run by the replica, replication is stopped immediately.

Examples

The following example initiates replication and replicates changes until it reaches GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23.

```sql
call mysql.rds_start_replication_until_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

### mysql.rds_stop_replication

Stops replication from a MySQL DB instance.

#### Syntax

```sql
CALL mysql.rds_stop_replication;
```

#### Usage notes

The master user must run the `mysql.rds_stop_replication` procedure.

If you are configuring replication to import data from an instance of MySQL running external to Amazon RDS, you call `mysql.rds_stop_replication` on the read replica to stop the replication process after the import has completed. For more information, see [Restoring a backup into a MySQL DB instance](p. 1408).

If you are configuring replication to export data to an instance of MySQL external to Amazon RDS, you call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see [Exporting data from a MySQL DB instance by using replication](p. 1459).

You can also use `mysql.rds_stop_replication` to stop replication between two Amazon RDS DB instances. You typically stop replication to perform a long running operation on the read replica, such as creating a large index on the read replica. You can restart any replication process that you stopped by calling `mysql.rds_start_replication` on the read replica. For more information, see [Working with read replicas](p. 382).

### mysql.rds_skip_transaction_with_gtid

Skips replication of a transaction with the specified global transaction identifier (GTID) on a MySQL DB instance.

You can use this procedure for disaster recovery when a specific GTID transaction is known to cause a problem. Use this stored procedure to skip the problematic transaction. Examples of problematic transactions include transactions that disable replication, delete important data, or cause the DB instance to become unavailable.

#### Syntax
CALL `mysql.rds_skip_transaction_with_gtid` (gtid_to_skip);

**Parameters**

*gtid_to_skip*

The GTID of the replication transaction to skip.

**Usage notes**

The master user must run the `mysql.rds_skip_transaction_with_gtid` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

**Examples**

The following example skips replication of the transaction with the GTID `3E11FA47-71CA-11E1-9E33-C80AA9429562:23`.

```sql
call mysql.rds_skip_transaction_with_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

`mysql.rds_skip_repl_error`

Skips and deletes a replication error on a MySQL DB instance.

**Syntax**

```sql
CALL `mysql.rds_skip_repl_error`;
```

**Usage notes**

The master user must run the `mysql.rds_skip_repl_error` procedure.

To determine if there are errors, run the MySQL `SHOW REPLICA STATUS` command. If a replication error isn't critical, you can run `mysql.rds_skip_repl_error` to skip the error. If there are multiple errors, `mysql.rds_skip_repl_error` deletes the first error, then warns that others are present. You can then use `SHOW REPLICA STATUS` to determine the correct course of action for the next error. For information about the values returned, see the MySQL documentation.

**Note**

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

For more information about addressing replication errors with Amazon RDS, see Troubleshooting a MySQL read replica problem (p. 1446).

**Replication stopped error**

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that the replica is down or disabled.
This error message appears because replication has stopped and could not be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log (binlog) files. In this case, you might encounter a fatal error due to binlog files being purged before they have been replayed on the read replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binlog files are retained on your source database instance. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the `mysql.rds_set_configuration` procedure and specify a configuration parameter of `binlog retention hours` along with the number of hours to retain binlog files on the DB cluster. The following example sets the retention period for binlog files to 48 hours.

```
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

### `mysql.rds_next_master_log`

Changes the source database instance log position to the start of the next binary log on the source database instance. Use this procedure only if you are receiving replication I/O error 1236 on a read replica.

**Syntax**

```
CALL mysql.rds_next_master_log(
    curr_master_log
);
```

**Parameters**

- `curr_master_log`

  The index of the current master log file. For example, if the current file is named `mysql-bin-changeLog.012345`, then the index is 12345. To determine the current master log file name, run the `SHOW REPLICA STATUS` command and view the `Master_Log_File` field.

  **Note**

  Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

**Usage notes**

The master user must run the `mysql.rds_next_master_log` procedure.

**Warning**

Call `mysql.rds_next_master_log` only if replication fails after a failover of a Multi-AZ DB instance that is the replication source, and the `Last_IO_Errno` field of `SHOW REPLICA STATUS` reports I/O error 1236.

Calling `mysql.rds_next_master_log` may result in data loss in the read replica if transactions in the source instance were not written to the binary log on disk before the failover event occurred. You can reduce the chance of this happening by configuring the source instance parameters `sync_binlog = 1` and `innodb_support_xa = 1`, although this may reduce performance. For more information, see [Working with read replicas (p. 382)].
Examples

Assume replication fails on an Amazon RDS read replica. Running `SHOW REPLICA STATUS` on the read replica returns the following result:

```
*************************** 1. row ***************************
Replica_IO_State:        
Source_Host: myhost.XXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com
Source_User: MasterUser
Source_Port: 3306
Connect_Retry: 10
Source_Log_File: mysql-bin-changelog.012345
Read_Source_Log_Pos: 1219393
Relay_Log_File: relaylog.012340
Relay_Log_Pos: 30223388
Relay_Source_Log_File: mysql-bin-changelog.012345
Replica_IO_Running: No
Replica_SQL_Running: Yes
Replicate_Do_DB:        
Replicate_Ignore_DB:    
Replicate_Do_Table:     
Replicate_Ignore_Table: 
Replicate_Wild_Do_Table: 
Replicate_Wild_Ignore_Table: 
Last_Errno: 0
Last_Error:            
Skip_Counter: 0
Exec_Source_Log_Pos: 302233232
Relay_Log_Space: 5248928866
Until_Condition: None
Until_Log_File: 
Until_Log_Pos: 0
Source_SSL_Allowed: No
Source_SSL_CA_File:    
Source_SSL_CA_Path:    
Source_SSL_Cert:    
Source_SSL_Cipher:   
Source_SSL_Key:    
Seconds_Behind_Master: NULL
Source_SSL_Verify_Server_Cert: No
Last_IO_Errno: 1236
Last_IO_Error: Got fatal error 1236 from master when reading data from binary log: 'Client requested master to start replication from impossible position; the first event 'mysql-bin-changelog.013406' at 1219393, the last event read from '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4, the last byte read from '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4.'
Last_SQL_Errno: 0
Last_SQL_Error:        
Replicate_Ignore_Server_Ids: 
Source_Server_Id: 67285976
```

The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Master_Log_File` field shows that the file name is `mysql-bin-changelog.012345`, which means that the log file index is 12345. To resolve the error, you can call `mysql.rds_next_master_log` with the following parameter:

```
CALL mysql.rds_next_master_log(12345);
```

**Note**

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.
mysqld_innodb_buffer_pool_dump_now

Dumps the current state of the buffer pool to disk. For more information, see InnoDB cache warming for MySQL on Amazon RDS (p. 1354).

Syntax

CALL mysqld_innodb_buffer_pool_dump_now();

Usage notes

The master user must run the mysqld_innodb_buffer_pool_dump_now procedure.

mysqld_innodb_buffer_pool_load_now

 Loads the saved state of the buffer pool from disk. For more information, see InnoDB cache warming for MySQL on Amazon RDS (p. 1354).

Syntax

CALL mysqld_innodb_buffer_pool_load_now();

Usage notes

The master user must run the mysqld_innodb_buffer_pool_load_now procedure.

mysqld_innodb_buffer_pool_load_abort

Cancels a load of the saved buffer pool state while in progress. For more information, see InnoDB cache warming for MySQL on Amazon RDS (p. 1354).

Syntax

CALL mysqld_innodb_buffer_pool_load_abort();

Usage notes

The master user must run the mysqld_innodb_buffer_pool_load_abort procedure.

mysqld_set_configuration

Specifies the number of hours to retain binary logs or the number of seconds to delay replication.

Syntax

CALL mysqld_set_configuration(name,value);
Parameters

name
The name of the configuration parameter to set.

dvalue
The value of the configuration parameter.

Usage notes

The `mysql.rds_set_configuration` procedure supports the following configuration parameters:

- Binlog retention hours (p. 1512)
- Target delay (p. 1512)

Binlog retention hours

The `binlog retention hours` parameter is used to specify the number of hours to retain binary log files. Amazon RDS normally purges a binary log as soon as possible, but the binary log might still be required for replication with a MySQL database external to Amazon RDS. The default value of `binlog retention hours` is `NULL`. This default value is interpreted as follows:

- For RDS for MySQL, `NULL` means binary logs are not retained (0 hours).
- For Aurora MySQL, `NULL` means binary logs are cleaned up lazily. Aurora MySQL binary logs might remain in the system for a certain period, usually not longer than a day.

To specify the number of hours for Amazon RDS to retain binary logs on a DB instance, use the `mysql.rds_set_configuration` stored procedure and specify a period with enough time for replication to occur, as shown in the following example.

call `mysql.rds_set_configuration`('binlog retention hours', 24);

For MySQL DB instances, the maximum `binlog retention hours` value is 168 (7 days).

After you set the retention period, monitor storage usage for the DB instance to make sure that the retained binary logs don't take up too much storage.

Target delay

Use the `target delay` parameter to specify the number of seconds to delay replication from source database instance to the read replica. The specified delay applies to new replicas created from the current DB instance. Amazon RDS normally replicates changes as soon as possible, but some environments might want to delay replication. For example, when replication is delayed, you can roll forward a delayed read replica to the time just before a disaster. If a table is dropped accidentally, you can use delayed replication to recover it quickly. The default value of `target delay` is 0 (don't delay replication).

For disaster recovery, you can use this configuration parameter with the `mysql.rds_start_replication_until` (p. 1505) stored procedure or the `mysql.rds_start_replication_until_gtid` (p. 1506) stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_configuration` procedure with this parameter set. After the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read
replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 389).

To use the `mysql.rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the `mysql.rds_skip_transaction_with_gtid` (p. 1507) stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication for Amazon RDS for MySQL (p. 1448).

To specify the number of seconds for Amazon RDS to delay replication to a read replica, use the `mysql.rds_set_configuration` stored procedure and specify the number of seconds to delay replication. The following example specifies that replication is delayed by at least one hour (3,600 seconds).

```sql
call mysql.rds_set_configuration('target delay', 3600);
```

The limit for the `target delay` parameter is one day (86400 seconds).

**Note**
The `target delay` parameter is only supported for RDS for MySQL.
The `target delay` parameter isn't supported for RDS for MySQL version 8.0.

### mysql.rds_show_configuration

The number of hours that binary logs are retained.

#### Syntax

```sql
CALL mysql.rds_show_configuration;
```

#### Usage notes

To verify the number of hours that Amazon RDS retains binary logs, use the `mysql.rds_show_configuration` stored procedure.

#### Examples

The following example displays the retention period:

```sql
CALL mysql.rds_show_configuration;

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>binlog retention hours</td>
<td>24</td>
<td>binlog retention hours specifies the duration in hours before binary logs are automatically deleted.</td>
</tr>
</tbody>
</table>
```

### mysql.rds_kill

Ends a connection to the MySQL server.

#### Syntax

```sql
CALL mysql.rds_kill(processID);
```
mysql.rds_kill_query

Ends a query running against the MySQL server.

Syntax

```
CALL mysql.rds_kill_query(queryID);
```

Parameters

queryID

The identity of the query to be ended.

Usage notes

To stop a query running against the MySQL server, use the `mysql_rds_kill_query` procedure and pass in the ID of that query. To obtain the query ID, query the MySQL INFORMATION_SCHEMA PROCESSLIST table. The connection to the MySQL server is retained.

Examples

The following example stops a query with a thread ID of 230040:

```
call mysql.rds_kill_query(230040);
```
Syntax

```sql
CALL mysql.rds_rotate_general_log;
```

**Usage notes**

You can rotate the `mysql.general_log` table to a backup table by calling the `mysql.rds_rotate_general_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`.

You can run this procedure only when the `log_output` parameter is set to `TABLE`.

### mysql.rds_rotate_slow_log

Rotates the `mysql.slow_log` table to a backup table. For more information, see [MySQL database log files](#).

**Syntax**

```sql
CALL mysql.rds_rotate_slow_log;
```

**Usage notes**

You can rotate the `mysql.slow_log` table to a backup table by calling the `mysql.rds_rotate_slow_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup.

You can query the backup log table if needed. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.

### mysql.rds_enable_gsh_collector

Enables the Global Status History (GoSH) to take default snapshots at intervals specified by `rds_set_gsh_collector`. For more information, see [Managing the global status history](#).

**Syntax**

```sql
CALL mysql.rds_enable_gsh_collector;
```

### mysql.rds_set_gsh_collector

Specifies the interval, in minutes, between snapshots taken by the Global Status History (GoSH). Default value is For more information, see [Managing the global status history](#).

**Syntax**
CALL mysql.rds_set_gsh_rotation(intervalPeriod);

**Parameters**

*intervalPeriod*

The interval, in minutes, between snapshots. Default value is mysql.rds_disable_gsh_collector

Disables snapshots taken by the Global Status History (GoSH). For more information, see Managing the global status history (p. 1478).

**Syntax**

CALL mysql.rds_disable_gsh_collector;

mysql.rds_collect_global_status_history

Takes a snapshot on demand for the Global Status History (GoSH). For more information, see Managing the global status history (p. 1478).

**Syntax**

CALL mysql.rds_collect_global_status_history;

mysql.rds_enable_gsh_rotation

Enables rotation of the contents of the mysql.global_status_history table to mysql.global_status_history_old at intervals specified by rds_set_gsh_rotation. For more information, see Managing the global status history (p. 1478).

**Syntax**

CALL mysql.rds_enable_gsh_rotation;

mysql.rds_set_gsh_rotation

Specifies the interval, in days, between rotations of the mysql.global_status_history table. Default value is 7. For more information, see Managing the global status history (p. 1478).

**Syntax**

CALL mysql.rds_set_gsh_rotation(intervalPeriod);
Parameters

intervalPeriod

The interval, in days, between table rotations. Default value is 7.

mysql.rds_disable_gsh_rotation

Disables rotation of the mysql.global_status_history table. For more information, see Managing the global status history (p. 1478).

Syntax

```
CALL mysql.rds_disable_gsh_rotation;
```

mysql.rds_rotate_global_status_history

Rotates the contents of the mysql.global_status_history table to mysql.global_status_history_old on demand. For more information, see Managing the global status history (p. 1478).

Syntax

```
CALL mysql.rds_rotate_global_status_history;
```
Amazon RDS for Oracle

Amazon RDS supports DB instances that run the following versions and editions of Oracle Database:

- Oracle Database 21c (21.0.0.0)
- Oracle Database 19c (19.0.0.0)

**Note**
Oracle Database 11g, Oracle Database 12c, and Oracle Database 18c are legacy versions that are no longer supported in Amazon RDS.

Before creating a DB instance, complete the steps in the Setting up for Amazon RDS (p. 153) section of this guide. When you create a DB instance using your master account, the account gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts. You can't use SYS, SYSTEM, or other Oracle-supplied administrative accounts.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running Oracle inside a VPC. You can also add features to your Oracle DB instance by enabling various options. Amazon RDS supports Multi-AZ deployments for Oracle as a high-availability, failover solution.

**Important**
To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced privileges. You can access your database using standard SQL clients such as Oracle SQL*Plus. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

**Topics**

- Overview of Oracle on Amazon RDS (p. 1519)
- Connecting to your Oracle DB instance (p. 1540)
- Securing Oracle DB instance connections (p. 1550)
- Administering your Oracle DB instance (p. 1573)
- Configuring advanced RDS for Oracle features (p. 1656)
- Importing data into Oracle on Amazon RDS (p. 1667)
- Working with read replicas for Amazon RDS for Oracle (p. 1682)
- Adding options to Oracle DB instances (p. 1698)
- Upgrading the RDS for Oracle DB engine (p. 1809)
- Using third-party software with your RDS for Oracle DB instance (p. 1818)
Overview of Oracle on Amazon RDS

You can read the following sections to get an overview of RDS for Oracle.

Topics
- RDS for Oracle features (p. 1519)
- RDS for Oracle releases (p. 1522)
- RDS for Oracle licensing options (p. 1526)
- RDS for Oracle instance classes (p. 1529)
- RDS for Oracle architecture (p. 1533)
- RDS for Oracle parameters (p. 1534)
- RDS for Oracle character sets (p. 1535)
- RDS for Oracle limitations (p. 1537)

RDS for Oracle features

Amazon RDS for Oracle supports most of the features and capabilities of Oracle Database. Some features might have limited support or restricted privileges. Some features are only available in Enterprise Edition, and some require additional licenses. For more information about Oracle Database features for specific Oracle Database versions, see the Oracle Database Licensing Information User Manual for the version you’re using.

You can filter new Amazon RDS features on the What’s New with Database? page. For Products, choose Amazon RDS. Then search using keywords such as Oracle 2022.

Note
The following lists are not exhaustive.

Topics
- New features in RDS for Oracle (p. 1519)
- Supported features in RDS for Oracle (p. 1519)
- Unsupported features in RDS for Oracle (p. 1521)

New features in RDS for Oracle

To see new RDS for Oracle features, use the following techniques:

- Search Document history (p. 2305) for the keyword Oracle.
- You can filter new Amazon RDS features on the What’s New with Database? page. For Products, choose Amazon RDS. Then search for Oracle YYYY, where YYYY is a year such as 2022.

Supported features in RDS for Oracle

Amazon RDS for Oracle supports the following Oracle Database features:

- Advanced Compression
• Application Express (APEX)
  For more information, see Oracle Application Express (APEX) (p. 1716).
• Automatic Memory Management
• Automatic Undo Management
• Automatic Workload Repository (AWR)
  For more information, see Generating performance reports with Automatic Workload Repository (AWR) (p. 1601).
• Active Data Guard with Maximum Performance in the same AWS Region or across AWS Regions
  For more information, see Working with read replicas for Amazon RDS for Oracle (p. 1682).
• Blockchain tables (Oracle Database 21c and higher)
  For more information, see Managing Blockchain Tables in the Oracle Database documentation.
• Continuous Query Notification (version 12.1.0.2.v7 and higher)
  For more information, see Using Continuous Query Notification (CQN) in the Oracle documentation.
• Data Redaction
• Database Change Notification
  For more information, see Database Change Notification in the Oracle documentation.

  **Note**
  This feature changes to Continuous Query Notification in Oracle Database 12c Release 1 (12.1) and higher.
• Database In-Memory (Oracle Database 12c and higher)
• Distributed Queries and Transactions
• Edition-Based Redefinition
  For more information, see Setting the default edition for a DB instance (p. 1605).
• EM Express (12c and higher)
  For more information, see Oracle Enterprise Manager (p. 1740).
• Fine-Grained Auditing
• Flashback Table, Flashback Query, Flashback Transaction Query
• Gradual password rollover for applications (Oracle Database 21c and higher)
  For more information, see Managing Gradual Database Password Rollover for Applications in the Oracle Database documentation.
• HugePages
  For more information, see Turning on HugePages for an RDS for Oracle instance (p. 1662).
• Import/export (legacy and Data Pump) and SQL*Loader
  For more information, see Importing data into Oracle on Amazon RDS (p. 1667).
• Java Virtual Machine (JVM)
  For more information, see Oracle Java virtual machine (p. 1737).
• JavaScript (Oracle Database 21c and higher)
  For more information, see DBMS_MLE in the Oracle Database documentation.
• Label Security (Oracle Database 12c and higher)
For more information, see Oracle Label Security (p. 1755).

- Locator
  For more information, see Oracle Locator (p. 1758).
- Materialized Views
- Multimedia
  For more information, see Oracle Multimedia (p. 1761).
- Multitenant (single-tenant architecture only)

  This feature is available for all Oracle Database 19c and higher releases. For more information, see RDS for Oracle architecture (p. 1533) and Limitations of a single-tenant CDB (p. 1539).
- Network encryption
  For more information, see Oracle native network encryption (p. 1763) and Oracle Secure Sockets Layer (p. 1774).
- Partitioning
- Sharding
- Spatial and Graph
  For more information, see Oracle Spatial (p. 1782).
- Star Query Optimization
- Streams and Advanced Queuing
- Summary Management – Materialized View Query Rewrite
- Text (File and URL data store types are not supported)
- Total Recall
- Transparent Data Encryption (TDE)
  For more information, see Oracle Transparent Data Encryption (p. 1803).
- Unified Auditing, Mixed Mode
  For more information, see Mixed mode auditing in the Oracle documentation.
- XML DB (without the XML DB Protocol Server)
  For more information, see Oracle XML DB (p. 1808).
- Virtual Private Database

**Unsupported features in RDS for Oracle**

Amazon RDS for Oracle doesn’t support the following Oracle Database features:

- Automatic Storage Management (ASM)
- Database Vault
- Flashback Database
- FTP and SFTP
- Hybrid partitioned tables
- Messaging Gateway
- Oracle Enterprise Manager Cloud Control Management Repository
- Real Application Clusters (Oracle RAC)
• Real Application Testing
• Unified Auditing, Pure Mode
• Workspace Manager (WMSYS) schema

_**Note**_
The preceding list is not exhaustive.

_**Warning**_
In general, Amazon RDS doesn't prevent you from creating schemas for unsupported features. However, if you create schemas for Oracle features and components that require SYSDBA privileges, you can damage the data dictionary and affect the availability of your DB instance. Use only supported features and schemas that are available in Adding options to Oracle DB instances (p. 1698).

### RDS for Oracle releases

Amazon RDS for Oracle supports multiple Oracle Database releases.

_**Note**_
For information about upgrading your releases, see Upgrading the RDS for Oracle DB engine (p. 1809).

**Topics**
- Oracle Database 21c with Amazon RDS (p. 1522)
- Oracle Database 19c with Amazon RDS (p. 1524)
- Oracle Database 12c with Amazon RDS (p. 1525)

### Oracle Database 21c with Amazon RDS

Amazon RDS supports Oracle Database 21c, which includes Oracle Enterprise Edition and Oracle Standard Edition Two. Oracle Database 21c (21.0.0.0) includes many new features and updates from the previous version. A key change is that Oracle Database 21c supports only the multitenant architecture: you can no longer create a database as a traditional non-CDB. To learn more about the differences between CDBs and non-CDBs, see Limitations of a single-tenant CDB (p. 1539).

In this section, you can find the features and changes important to using Oracle Database 21c (21.0.0.0) on Amazon RDS. For a complete list of the changes, see the Oracle database 21c documentation. For a complete list of features supported by each Oracle Database 21c edition, see Permitted features, options, and management packs by Oracle database offering in the Oracle documentation.

### Amazon RDS parameter changes for Oracle Database 21c (21.0.0.0)

Oracle Database 21c (21.0.0.0) includes several new parameters and parameters with new ranges and new default values.

**Topics**
- New parameters (p. 1522)
- Changes for the compatible parameter (p. 1524)
- Removed parameters (p. 1524)

**New parameters**

The following table shows the new Amazon RDS parameters for Oracle Database 21c (21.0.0.0).
<table>
<thead>
<tr>
<th>Name</th>
<th>Range of values</th>
<th>Default value</th>
<th>Modifiable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>blockchain_table_max_no_drop</td>
<td>NONE</td>
<td>0</td>
<td>NONE</td>
<td>Y</td>
</tr>
<tr>
<td>dbnest_enable</td>
<td>NONE</td>
<td>CDBRESOURCE_PDB_ALL</td>
<td>NONE</td>
<td>N</td>
</tr>
<tr>
<td>dbnest_pdb_fs_conf</td>
<td>NONE</td>
<td>pathname</td>
<td>NONE</td>
<td>N</td>
</tr>
<tr>
<td>diagnostics_control</td>
<td>ERROR</td>
<td>WARNING</td>
<td>IGNORE</td>
<td>Y</td>
</tr>
<tr>
<td>drcp_dedicated_opt</td>
<td>YES</td>
<td>NO</td>
<td>YES</td>
<td>Y</td>
</tr>
<tr>
<td>enable_per_pdb_drcp</td>
<td>true</td>
<td>false</td>
<td>true</td>
<td>N</td>
</tr>
<tr>
<td>inmemory_deep_vectorization</td>
<td>true</td>
<td>false</td>
<td>true</td>
<td>Y</td>
</tr>
<tr>
<td>mandatory_user_profile</td>
<td>profile_name</td>
<td>N/A</td>
<td>N</td>
<td>Specifies the mandatory user profile for a CDB or PDB.</td>
</tr>
<tr>
<td>optimizer_capture_sql_quarantine</td>
<td>true</td>
<td>false</td>
<td>false</td>
<td>Y</td>
</tr>
<tr>
<td>optimizer_use_sql_quarantine</td>
<td>true</td>
<td>false</td>
<td>false</td>
<td>Y</td>
</tr>
<tr>
<td>result_cache_execution_threshold</td>
<td>0 to 68719476736</td>
<td>2</td>
<td>Y</td>
<td>Specifies the maximum number of times a PL/SQL function can be executed before its result is stored in the result cache.</td>
</tr>
<tr>
<td>result_cache_max_temp_result</td>
<td>0 to 100</td>
<td>5</td>
<td>Y</td>
<td>Specifies the percentage of RESULT_CACHE_MAX_TEMP_SIZE that any single cached query result can consume.</td>
</tr>
<tr>
<td>result_cache_max_temp_size</td>
<td>0 to 2199023255552</td>
<td>RESULT_CACHE_SIZE * 10</td>
<td>Y</td>
<td>Specifies the maximum amount of temporary tablespace (in bytes)</td>
</tr>
<tr>
<td>Name</td>
<td>Range of values</td>
<td>Default value</td>
<td>Modifiable</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------------------------------------</td>
<td>---------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sga_min_size</td>
<td>0 to 2199023255552 (maximum value is 50% of sga_target)</td>
<td>0</td>
<td>Y</td>
<td>Indicates a possible minimum value for SGA usage of a pluggable database (PDB).</td>
</tr>
<tr>
<td>tablespace_encryption_default_algorithm</td>
<td>GOST256</td>
<td>SEED128</td>
<td>ARIA256</td>
<td>ARIA192</td>
</tr>
</tbody>
</table>

### Changes for the compatible parameter

The `compatible` parameter has a new maximum value for Oracle Database 21c (21.0.0.0) on Amazon RDS. The following table shows the new default value.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Oracle Database 21c (21.0.0.0) maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>compatible</td>
<td>21.0.0</td>
</tr>
</tbody>
</table>

### Removed parameters

The following parameters were removed in Oracle Database 21c (21.0.0.0):
- `remote_os_authent`
- `sec_case_sensitive_logon`
- `unified_audit_sga_queue_size`

### Oracle Database 19c with Amazon RDS

Amazon RDS supports Oracle Database 19c, which includes Oracle Enterprise Edition and Oracle Standard Edition Two.

Oracle Database 19c (19.0.0.0) includes many new features and updates from the previous version. In this section, you can find the features and changes important to using Oracle Database 19c (19.0.0.0) on Amazon RDS. For a complete list of the changes, see the Oracle database 19c documentation. For a complete list of features supported by each Oracle Database 19c edition, see Permitted features, options, and management packs by Oracle database offering in the Oracle documentation.

### Amazon RDS parameter changes for Oracle Database 19c (19.0.0.0)

Oracle Database 19c (19.0.0.0) includes several new parameters and parameters with new ranges and new default values.
New parameters

The following table shows the new Amazon RDS parameters for Oracle Database 19c (19.0.0.0).

<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Modifiable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_signature_enable</td>
<td>TRUE, FALSE (default)</td>
<td>Y</td>
<td>Enables or disables the LOB locator signature feature.</td>
</tr>
<tr>
<td>max_datapump_parallel_per_job</td>
<td>1 to 1024, or AUTO</td>
<td>Y</td>
<td>Specifies the maximum number of parallel processes allowed for each Oracle Data Pump job.</td>
</tr>
</tbody>
</table>

Changes to the compatible parameter

The compatible parameter has a new maximum value for Oracle Database 19c (19.0.0.0) on Amazon RDS. The following table shows the new default value.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Oracle Database 19c (19.0.0.0) maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>compatible</td>
<td>19.0.0</td>
</tr>
</tbody>
</table>

Removed parameters

The following parameters were removed in Oracle Database 19c (19.0.0.0):

- exafusion_enabled
- max_connections
- o7_dictionary_access

Oracle Database 12c with Amazon RDS

Amazon RDS has deprecated support for Oracle Database 12c on both Oracle Enterprise Edition and Oracle Standard Edition 2.

Topics

- Oracle Database 12c Release 2 (12.2.0.1) with Amazon RDS (p. 1525)
- Oracle Database 12c Release 1 (12.1.0.2) with Amazon RDS (p. 1526)

Oracle Database 12c Release 2 (12.2.0.1) with Amazon RDS

On March 31, 2022, Oracle Corporation deprecated support for Oracle Database 12c Release 2 (12.2.0.1) for BYOL and LI. On this date, the release moved from Oracle Extended Support to Oracle Sustaining Support, indicating the end of support for this release. For more information, see the end of support timeline on AWS re:Post and Oracle Database 12c upgrade considerations (p. 1814).
<table>
<thead>
<tr>
<th>Date</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>April 1, 2022</td>
<td>Amazon RDS began automatic upgrades of your Oracle Database 12c Release 2 (12.2.0.1) instances to Oracle Database 19c.</td>
</tr>
<tr>
<td>April 1, 2022</td>
<td>Amazon RDS began automatic upgrades to Oracle Database 19c for any Oracle Database 12c Release 2 (12.2.0.1) DB instances restored from snapshots. The automatic upgrade occurs during maintenance windows. If maintenance windows aren't available when the upgrade needs to occur, Amazon RDS upgrades the engine immediately.</td>
</tr>
</tbody>
</table>

**Oracle Database 12c Release 1 (12.1.0.2) with Amazon RDS**

On July 31, 2022, Amazon RDS deprecated support for Oracle Database 12c Release 1 (12.1.0.2) for BYOL and LI. The release moved from Oracle Extended Support to Oracle Sustaining Support, indicating that Oracle Support will no longer release critical patch updates for this release. For more information, see the end of support timeline on AWS re:Post and Oracle Database 12c upgrade considerations (p. 1814).

<table>
<thead>
<tr>
<th>Date</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>August 1, 2022</td>
<td>Amazon RDS began automatic upgrades of your Oracle Database 12c Release 1 (12.1.0.2) instances to the latest Release Update (RU) for Oracle Database 19c. The automatic upgrade occurs during maintenance windows. If maintenance windows aren't available when the upgrade needs to occur, Amazon RDS upgrades the engine immediately.</td>
</tr>
<tr>
<td>August 1, 2022</td>
<td>Amazon RDS began automatic upgrades to Oracle Database 19c for any Oracle Database 12c Release 1 (12.1.0.2) DB instances restored from snapshots.</td>
</tr>
</tbody>
</table>

**RDS for Oracle licensing options**

Amazon RDS for Oracle has two licensing options: License Included (LI) and Bring Your Own License (BYOL). After you create an Oracle DB instance on Amazon RDS, you can change the licensing model by modifying the DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 333).

**License Included**

In the License Included model, you don't need to purchase Oracle Database licenses separately. AWS holds the license for the Oracle database software. In this model, if you have an AWS Support account with case support, contact AWS Support for both Amazon RDS and Oracle Database service requests. The License Included model is only supported on Amazon RDS for Oracle Database Standard Edition Two (SE2).

**Bring Your Own License (BYOL)**

In the BYOL model, you can use your existing Oracle Database licenses to deploy databases on Amazon RDS. Make sure that you have the appropriate Oracle Database license (with Software Update License and Support) for the DB instance class and Oracle Database edition you wish to run. You must also follow Oracle's policies for licensing Oracle Database software in the cloud computing environment. For more information on Oracle's licensing policy for Amazon EC2, see Licensing Oracle software in the cloud computing environment.
In this model, you continue to use your active Oracle support account, and you contact Oracle directly for Oracle Database service requests. If you have an AWS Support account with case support, you can contact AWS Support for Amazon RDS issues. Amazon Web Services and Oracle have a multi-vendor support process for cases that require assistance from both organizations.

Amazon RDS supports the BYOL model only for Oracle Database Enterprise Edition (EE) and Oracle Database Standard Edition Two (SE2).

**Integrating with AWS License Manager**

To make it easier to monitor Oracle license usage in the BYOL model, [AWS License Manager](https://aws.amazon.com/managedservices/license-manager/) integrates with Amazon RDS for Oracle. License Manager supports tracking of RDS for Oracle engine editions and licensing packs based on virtual cores (vCPUs). You can also use License Manager with AWS Organizations to manage all of your organizational accounts centrally.

The following table shows the product information filters for RDS for Oracle.

<table>
<thead>
<tr>
<th>Filter</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Engine Edition</td>
<td>oracle-ee</td>
<td>Oracle Database Enterprise Edition (EE)</td>
</tr>
<tr>
<td></td>
<td>oracle-se2</td>
<td>Oracle Database Standard Edition Two (SE2)</td>
</tr>
<tr>
<td>License Pack</td>
<td>data guard</td>
<td>See [Working with read replicas for Amazon RDS for Oracle (p. 1682)] (Oracle Active Data Guard)</td>
</tr>
<tr>
<td></td>
<td>olap</td>
<td>See Oracle OLAP (p. 1771)</td>
</tr>
<tr>
<td></td>
<td>ols</td>
<td>See Oracle Label Security (p. 1755)</td>
</tr>
<tr>
<td></td>
<td>diagnostic pack</td>
<td>See Oracle SQLT (p. 1785)</td>
</tr>
<tr>
<td></td>
<td>sqlt</td>
<td>See Oracle SQLT (p. 1785)</td>
</tr>
<tr>
<td></td>
<td>tuning pack sqlt</td>
<td>See Oracle SQLT (p. 1785)</td>
</tr>
</tbody>
</table>

To track license usage of your Oracle DB instances, you can create a license configuration. In this case, RDS for Oracle resources that match the product information filter are automatically associated with the license configuration. Discovery of Oracle DB instances can take up to 24 hours.

**Console**

**To create a license configuration to track the license usage of your Oracle DB instances**

2. Create a license configuration.

   For instructions, see [Create a license configuration](https://aws.amazon.com/managedservices/license-manager/) in the [AWS License Manager User Guide](https://aws.amazon.com/managedservices/license-manager/).

   Add a rule for an **RDS Product Information Filter** in the **Product Information** panel.

   For more information, see [ProductInformation](https://aws.amazon.com/managedservices/license-manager/) in the [AWS License Manager API Reference](https://aws.amazon.com/managedservices/license-manager/).

**AWS CLI**

To create a license configuration by using the AWS CLI, call the `create-license-configuration` command. Use the `--cli-input-json` or `--cli-input-yaml` parameters to pass the parameters to the command.
Example

The following code creates a license configuration for Oracle Enterprise Edition.

```bash
aws license-manager create-license-configuration --cli-input-json file://rds-oracle-ee.json
```

The following is the sample `rds-oracle-ee.json` file used in the example.

```json
{
  "Name": "rds-oracle-ee",
  "Description": "RDS Oracle Enterprise Edition",
  "LicenseCountingType": "vCPU",
  "LicenseCountHardLimit": false,
  "ProductInformationList": [
    {

For more information about product information, see Automated discovery of resource inventory in the AWS License Manager User Guide.

For more information about the `--cli-input` parameter, see Generating AWS CLI skeleton and input parameters from a JSON or YAML input file in the AWS CLI User Guide.

Migrating between Oracle editions

If you have an unused BYOL Oracle license appropriate for the edition and class of DB instance that you plan to run, you can migrate from Standard Edition 2 (SE2) to Enterprise Edition (EE). You can't migrate from Enterprise Edition to other editions.

To change the edition and retain your data

1. Create a snapshot of the DB instance.
   
   For more information, see Creating a DB snapshot (p. 483).

2. Restore the snapshot to a new DB instance, and select the Oracle database edition you want to use.
   
   For more information, see Restoring from a DB snapshot (p. 487).

3. (Optional) Delete the old DB instance, unless you want to keep it running and have the appropriate Oracle Database licenses for it.
   
   For more information, see Deleting a DB instance (p. 433).

Licensing Oracle Multi-AZ deployments

Amazon RDS supports Multi-AZ deployments for Oracle as a high-availability, failover solution. We recommend Multi-AZ for production workloads. For more information, see Multi-AZ deployments for high availability (p. 125).
If you use the Bring Your Own License model, you must have a license for both the primary DB instance and the standby DB instance in a Multi-AZ deployment.

**RDS for Oracle instance classes**

The computation and memory capacity of a DB instance is determined by its instance class. The DB instance class you need depends on your processing power and memory requirements.

**Supported RDS for Oracle instance classes**

The supported RDS for Oracle instance classes are a subset of the RDS DB instance classes. For the complete list of RDS instance classes, see [DB instance classes (p. 10)](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/DB-Instance-Class.html).

RDS for Oracle also offers instance classes that are optimized for workloads that require additional memory, storage, and I/O per vCPU. These instance classes use the following naming convention:

- `db.r5b. instance_size.tpcthreads_per_core.memratio`
- `db.r5. instance_size.tpcthreads_per_core.memratio`

The following is an example of a supported instance class:

- `db.r5b.4xlarge.tpc2.mem2x`

The components of the preceding instance class name are as follows:

- `db.r5b.4xlarge` – The name of the instance class.
- `tpc2` – The threads per core. A value of 2 means that multithreading is turned on. If the value is 1, multithreading is turned off.
- `mem2x` – The ratio of additional memory to the standard memory for the instance class. In this example, the optimization provides twice as much memory as a standard `db.r5.4xlarge` instance.

The following table lists all instance classes supported for Oracle Database. Oracle Database 12c Release 1 (12.1.0.2) and Oracle Database 12c Release 2 (12.2.0.2) are listed in the table, but support for these releases is deprecated. For information about the memory attributes of each type, see [RDS for Oracle instance types](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/DB-Instance-Class.html).

**Note**
We encourage all BYOL customers to consult their licensing agreement to assess the impact of Amazon RDS for Oracle deprecations. For more information on the compute capacity of DB instance classes supported by RDS for Oracle, see [DB instance classes (p. 10)]() and [Configuring the processor for a DB instance class (p. 48)]().

**Note**
If you have DB snapshots of DB instances that were using deprecated DB instance classes, you can choose a DB instance class that is not deprecated when you restore the DB snapshots. For more information, see [Restoring from a DB snapshot (p. 487)]().

### Deprecated Oracle DB instance classes

The following DB instance classes are deprecated for RDS for Oracle:

- db.m1, db.m2, db.m3
- db.t3.micro (supported only on 12.1.0.2, which is deprecated)
- db.t1, db.t2
- db.r1, db.r2, db.r3

The preceding DB instance classes have been replaced by better performing DB instance classes that are generally available at a lower cost. RDS for Oracle automatically scales DB instances to DB instance classes that are not deprecated.

If you have DB instances that use deprecated DB instance classes, Amazon RDS will modify each one automatically to use a comparable DB instance class that is not deprecated. You can change the DB instance class for a DB instance yourself by modifying the DB instance. For more information, see [Modifying an Amazon RDS DB instance (p. 333)]().

If you have DB snapshots of DB instances that were using deprecated DB instance classes, you can choose a DB instance class that is not deprecated when you restore the DB snapshots. For more information, see [Restoring from a DB snapshot (p. 487)]().
RDS for Oracle architecture

The multitenant architecture enables an Oracle database to function as a multitenant container database (CDB). A CDB can include customer-created pluggable databases (PDBs). A non-CDB is an Oracle database that uses the traditional architecture, which can't contain PDBs. For more information about the multitenant architecture, see Oracle Multitenant Administrator's Guide.

The architecture is a permanent characteristic that you can't change later. The architecture requirements are as follows:

Oracle Database 21c
   You must create the instance as a CDB.
Oracle Database 19c
   You can create the instance as either a CDB or non-CDB.
Oracle Database 12c
   You must create the instance as a non-CDB.

For more information, see Creating an Amazon RDS DB instance (p. 236).

Currently, Amazon RDS supports a subset of multitenant architecture called the single-tenant architecture. In this case, your CDB contains only one PDB. The single-tenant architecture uses the same RDS APIs as the non-CDB architecture. Your experience with a non-CDB is mostly identical to your experience with a PDB. You can't access the CDB itself.

The following sections explain the principal differences between the non-multitenant and single-tenant architectures. For more information, see Limitations of a single-tenant CDB (p. 1539).

Topics
• Database creation and connections in a single-tenant architecture (p. 1533)
• Database upgrades in a single-tenant architecture (p. 1534)
• User accounts and privileges in a single-tenant architecture (p. 1534)
• Parameters in a single-tenant architecture (p. 1534)
• Snapshots in a single-tenant architecture (p. 1534)
• Data migration in a single-tenant architecture (p. 1534)

Database creation and connections in a single-tenant architecture

When you create a CDB, specify the DB instance identifier just as for a non-CDB. The instance identifier forms the first part of your endpoint. The system identifier (SID) is the name of the CDB. The SID of every CDB is RDSCDB. You can't choose a different value.

In the single-tenant architecture, you always connect to the PDB rather than the CDB. Specify the endpoint for the PDB just as for a non-CDB. The only difference is that you specify pdb_name for the database name, where pdb_name is the name you chose for your PDB. The following example shows the format for the connection string in SQL*Plus.

```
sqlplus 'dbuser@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=endpoint)(PORT=port))
(CONNECT_DATA=(SID=pdb_name)))'
```
Database upgrades in a single-tenant architecture

You can upgrade a CDB to a different Oracle Database release. For example, you can upgrade a DB instance from Oracle Database 19c to Oracle Database 21c. You can't upgrade a non-CDB to a CDB.

User accounts and privileges in a single-tenant architecture

In the Oracle multitenant architecture, all users accounts are either common users or local users. A CDB common user is a database user whose single identity and password are known in the CDB root and in every existing and future PDB. In contrast, a local user exists only in a single PDB.

The RDS master user is a local user account in the PDB. If you create new user accounts, these users will also be local users residing in the PDB. You can't use any user accounts to create new PDBs or modify the state of the existing PDB.

The rdsadmin user is a common user account. You can run Oracle for RDS packages that exist in this account, but you can't log in as rdsadmin. For more information, see About Common Users and Local Users in the Oracle documentation.

Parameters in a single-tenant architecture

CDBs have their own parameter classes and different default parameter values. The CDB parameter classes are as follows:

- oracle-ee-cdb-21
- oracle-se2-cdb-21
- oracle-ee-cdb-19
- oracle-se2-cdb-19

You specify parameters at the CDB level rather than the PDB level. The PDB inherits parameter settings from the CDB. For more information about setting parameters, see Working with DB parameter groups (p. 233).

Snapshots in a single-tenant architecture

Snapshots work the same in a single-tenant and non-multitenant architecture. The only difference is that when you restore a snapshot, you can only rename the PDB, not the CDB. The CDB is always named RDSCDB. For more information, see Oracle Database considerations (p. 489).

Data migration in a single-tenant architecture

RDS for Oracle doesn't support unplugging and plugging in PDBs. For more information about migrating data, see Importing data into Oracle on Amazon RDS (p. 1667).

RDS for Oracle parameters

In Amazon RDS, you manage parameters using parameter groups. For more information, see Working with parameter groups (p. 295). To view the supported parameters for a specific Oracle Database edition and version, run the AWS CLI command describe-engine-default-parameters.

For example, to view the supported parameters for the Enterprise Edition of Oracle Database 19c, run the following command.
RDS for Oracle character sets

RDS for Oracle supports two types of character sets: the DB character set and national character set.

DB character set

The Oracle database character set is used in the CHAR, VARCHAR2, and CLOB data types. The database also uses this character set for metadata such as table names, column names, and SQL statements. The Oracle database character set is typically referred to as the DB character set.

You set the character set when you create a DB instance. You can't change the DB character set after you create the database.

Supported DB character sets

The following table lists the Oracle DB character sets that are supported in Amazon RDS. You can use a value from this table with the --character-set-name parameter of the AWS CLI `create-db-instance` command or with the `CharacterSetName` parameter of the Amazon RDS API `CreateDBInstance` operation.

**Note**

The character set for a CDB is always AL32UTF8. You can set a different character set for the PDB only.

**NLS_LANG environment variable**

A *locale* is a set of information addressing linguistic and cultural requirements that corresponds to a given language and country. Setting the NLS_LANG environment variable in your client's environment is the simplest way to specify locale behavior for Oracle. This variable sets the language and territory used by the client application and the database server. It also indicates the client's character set, which corresponds to the character set for data entered or displayed by a client application. For more...
information on NLS_LANG and character sets, see What is a character set or code page? in the Oracle documentation.

**NLS initialization parameters**

You can also set the following National Language Support (NLS) initialization parameters at the instance level for an Oracle DB instance in Amazon RDS:

- NLS_DATE_FORMAT
- NLS_LENGTH_SEMANTICS
- NLS_NCHAR_CONV_EXCP
- NLS_TIME_FORMAT
- NLS_TIME_TZ_FORMAT
- NLS_TIMESTAMP_FORMAT
- NLS_TIMESTAMP_TZ_FORMAT

For information about modifying instance parameters, see Working with parameter groups (p. 295).

You can set other NLS initialization parameters in your SQL client. For example, the following statement sets the NLS_LANGUAGE initialization parameter to GERMAN in a SQL client that is connected to an Oracle DB instance:

```
ALTER SESSION SET NLS_LANGUAGE=GERMAN;
```

For information about connecting to an Oracle DB instance with a SQL client, see Connecting to your Oracle DB instance (p. 1540).

**National character set**

The national character set is used in the NCHAR, NVARCHAR2, and NCL0B data types. The national character set is typically referred to as the **NCHAR character set**. Unlike the DB character set, the NCHAR character set doesn't affect database metadata.

The NCHAR character set supports the following character sets:

- AL16UTF16 (default)
- UTF8

You can specify either value with the `--nchar-character-set-name` parameter of the `create-db-instance` command (AWS CLI version 2 only). If you use the Amazon RDS API, specify the `NcharCharacterSetName` parameter of `CreateDBInstance` operation. You can't change the national character set after you create the database.

For more information about Unicode in Oracle databases, see Supporting multilingual databases with unicode in the Oracle documentation.

**RDS for Oracle limitations**

Following are important limitations of using RDS for Oracle.

**Note**

This list is not exhaustive.
Oracle file size limits in Amazon RDS

The maximum size of a single file on RDS for Oracle DB instances is 16 TiB (tebibytes). If you try to resize a data file in a bigfile tablespace to a value over the limit, you receive an error such as the following.

```
ORA-01237: cannot extend datafile 6
ORA-01110: data file 6: '/rdsdbdata/db/mydir/datafile/myfile.dbf'
ORA-27059: could not reduce file size
Linux-x86_64 Error: 27: File too large
Additional information: 2
```

Public synonyms for Oracle-supplied schemas

Don't create or modify public synonyms for Oracle-supplied schemas, including SYS, SYSTEM, and RDSADMIN. Such actions might result in invalidation of core database components and affect the availability of your DB instance.

You can create public synonyms referencing objects in your own schemas.

Schemas for unsupported features

In general, Amazon RDS doesn't prevent you from creating schemas for unsupported features. However, if you create schemas for Oracle features and components that require SYS privileges, you can damage the data dictionary and affect your instance availability. Use only supported features and schemas that are available in Adding options to Oracle DB instances (p. 1698).

Limitations for Oracle DBA privileges

In the database, a role is a collection of privileges that you can grant to or revoke from a user. An Oracle database uses roles to provide security.

The predefined role DBA normally allows all administrative privileges on an Oracle database. When you create a DB instance, your master user account gets DBA privileges (with some limitations). To deliver a managed experience, an RDS for Oracle database doesn't provide the following privileges for the DBA role:

- ALTER DATABASE
- ALTER SYSTEM
- CREATE ANY DIRECTORY
- DROP ANY DIRECTORY
- GRANT ANY PRIVILEGE
- GRANT ANY ROLE

Use the master user account for administrative tasks such as creating additional user accounts in the database. You can't use SYS, SYSTEM, and other Oracle-supplied administrative accounts.
Limitations of a single-tenant CDB

The following options aren't supported for the single-tenant architecture:

- Database Activity Streams
- Oracle Data Guard
- Oracle Enterprise Manager
- Oracle Enterprise Manager Agent
- Oracle Label Security

The following operations work in a single-tenant CDB, but no customer-visible mechanism can detect the current status of the operations:

- Enabling and disabling block change tracking (p. 1626)
- Enabling auditing for the SYS.AUD$ table (p. 1605)

Note
Auditing information isn't available from within the PDB.

Deprecation of TLS 1.0 and 1.1 Transport Layer Security

Transport Layer Security protocol versions 1.0 and 1.1 (TLS 1.0 and TLS 1.1) are deprecated. In accordance with security best practices, Oracle has deprecated the use of TLS 1.0 and TLS 1.1. To meet your security requirements, RDS for Oracle strongly recommends that you use TLS 1.2 instead.
Connecting to your Oracle DB instance

After Amazon RDS provisions your Oracle DB instance, you can use any standard SQL client application to connect to the DB instance. In this topic, you connect to a DB instance that is running the Oracle database engine by using Oracle SQL Developer or SQL*Plus.

For an example that walks you through the process of creating and connecting to a sample DB instance, see Creating an Oracle DB instance and connecting to a database on an Oracle DB instance (p. 186).

Topics

- Finding the endpoint of your Oracle DB instance (p. 1540)
- Connecting to your DB instance using Oracle SQL developer (p. 1542)
- Connecting to your DB instance using SQL*Plus (p. 1544)
- Considerations for security groups (p. 1545)
- Considerations for process architecture (p. 1545)
- Troubleshooting connections to your Oracle DB instance (p. 1545)
- Modifying connection properties using sqlnet.ora parameters (p. 1546)

Finding the endpoint of your Oracle DB instance

Each Amazon RDS DB instance has an endpoint, and each endpoint has the DNS name and port number for the DB instance. To connect to your DB instance using a SQL client application, you need the DNS name and port number for your DB instance.

You can find the endpoint for a DB instance using the Amazon RDS console or the AWS CLI.

**Note**
If you are using Kerberos authentication, see Connecting to Oracle with Kerberos authentication (p. 1564).

Console

**To find the endpoint using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the console, choose the AWS Region of your DB instance.
3. Find the DNS name and port number for your DB Instance.
   a. Choose Databases to display a list of your DB instances.
   b. Choose the Oracle DB instance name to display the instance details.
   c. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
To find the endpoint of an Oracle DB instance by using the AWS CLI, call the `describe-db-instances` command.

**Example To find the endpoint using the AWS CLI**

```
aws rds describe-db-instances
```

Search for `Endpoint` in the output to find the DNS name and port number for your DB instance. The `Address` line in the output contains the DNS name. The following is an example of the JSON endpoint output.

```
"Endpoint": {
    "HostedZoneId": "Z1PVIF0B656C1W",
    "Port": 3306,
    "Address": "myinstance.123456789012.us-west-2.rds.amazonaws.com"
},
```
Connecting to your DB instance using Oracle SQL developer

In this procedure, you connect to your DB instance by using Oracle SQL Developer. To download a standalone version of this utility, see the Oracle SQL developer downloads page.

To connect to your DB instance, you need its DNS name and port number. For information about finding the DNS name and port number for a DB instance, see Finding the endpoint of your Oracle DB instance (p. 1540).

To connect to a DB instance using SQL developer

1. Start Oracle SQL Developer.
2. On the Connections tab, choose the add (+) icon.
3. In the New/Select Database Connection dialog box, provide the information for your DB instance:
   - For Connection Name, enter a name that describes the connection, such as Oracle-RDS.
   - For Username, enter the name of the database administrator for the DB instance.
   - For Password, enter the password for the database administrator.
   - For Hostname, enter the DNS name of the DB instance.
   - For Port, enter the port number.
   - For SID, enter the Oracle database SID.
The completed dialog box should look similar to the following.

4. Choose Connect.

5. You can now start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your DB instance, do the following:

   a. In the Worksheet tab for your connection, enter the following SQL query.

   ```sql
   SELECT NAME FROM V$DATABASE;
   ```

   b. Choose the execute icon to run the query.

   SQL Developer returns the database name.
Connecting to your DB instance using SQL*Plus

You can use a utility like SQL*Plus to connect to an Amazon RDS DB instance running Oracle. To download Oracle Instant Client, which includes a standalone version of SQL*Plus, see Oracle Instant Client Downloads.

To connect to your DB instance, you need its DNS name and port number. For information about finding the DNS name and port number for a DB instance, see Finding the endpoint of your Oracle DB instance (p. 1540).

Example To connect to an Oracle DB instance using SQL*Plus

In the following examples, substitute the user name of your DB instance administrator. Also, substitute the DNS name for your DB instance, and then include the port number and the Oracle SID. The SID value is the name of the DB instance's database that you specified when you created the DB instance, and not the name of the DB instance.

For Linux, macOS, or Unix:

```
sqlplus 'user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))(CONNECT_DATA=(SID=database_name)))'
```

For Windows:

```
sqlplus user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))(CONNECT_DATA=(SID=database_name)))
```

You should see output similar to the following.
After you enter the password for the user, the SQL prompt appears.

```
SQL>
```

**Note**

The shorter format connection string (Easy connect or EZCONNECT), such as `sqlplus USER/PASSWORD@LONGER-TAN-63-CHARS-RDS-ENDPOINT-HERE:1521/DATABASE_IDENTIFIER`, might encounter a maximum character limit and should not be used to connect.

### Considerations for security groups

For you to connect to your DB instance, it must be associated with a security group that contains the necessary IP addresses and network configuration. Your DB instance might use the default security group. If you assigned a default, nonconfigured security group when you created the DB instance, the firewall prevents connections. For information about creating a new security group, see [*Controlling access with security groups*](#).

After you create the new security group, you modify your DB instance to associate it with the security group. For more information, see [*Modifying an Amazon RDS DB instance*](#).

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see [*Oracle Secure Sockets Layer*](#).

### Considerations for process architecture

Server processes handle user connections to an Oracle DB instance. By default, the Oracle DB instance uses dedicated server processes. With dedicated server processes, each server process services only one user process. You can optionally configure shared server processes. With shared server processes, each server process can service multiple user processes.

You might consider using shared server processes when a high number of user sessions are using too much memory on the server. You might also consider shared server processes when sessions connect and disconnect very often, resulting in performance issues. There are also disadvantages to using shared server processes. For example, they can strain CPU resources, and they are more complicated to configure and administer.

For more information about dedicated and shared server processes, see [*About dedicated and shared server processes*](#) in the Oracle documentation. For more information about configuring shared server processes on an RDS for Oracle DB instance, see [*How do I configure Amazon RDS for Oracle database to work with shared servers?*](#) in the Knowledge Center.

### Troubleshooting connections to your Oracle DB instance

The following are issues you might encounter when you try to connect to your Oracle DB instance.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unable to connect to your DB instance.</td>
<td>For a newly created DB instance, the DB instance has a status of <em>creating</em> until it is ready to use. When the state changes to <em>available</em>,</td>
</tr>
</tbody>
</table>
## Issue | Troubleshooting suggestions

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB instance is available.</td>
<td></td>
</tr>
<tr>
<td>If you can't send or receive communications over the port that you specified when you created the DB instance, you can't connect to the DB instance. Check with your network administrator to verify that the port you specified for your DB instance allows inbound and outbound communication.</td>
<td></td>
</tr>
<tr>
<td>The access rules enforced by your local firewall and the IP addresses you authorized to access your DB instance in the security group for the DB instance might not match. The problem is most likely the inbound or outbound rules on your firewall.</td>
<td></td>
</tr>
<tr>
<td>Make sure that you specified the server name and port number correctly. For <strong>Server name</strong>, enter the DNS name from the console. For information about finding the DNS name and port number for a DB instance, see <strong>Finding the endpoint of your Oracle DB instance</strong> (p. 1540).</td>
<td></td>
</tr>
<tr>
<td>You were able to reach the DB instance, but the connection was refused. This is usually caused by providing an incorrect user name or password. Verify the user name and password, and then retry.</td>
<td></td>
</tr>
<tr>
<td>Ensure the correct SID is entered. The SID is the same as your DB name. Find the DB name in the Configuration tab of the Databases page for your instance. You can also find the DB name using the AWS CLI: <code>aws rds describe-db-instances --query 'DBInstances[*].DBInstanceIdentifier,DBName'</code> --output text.</td>
<td></td>
</tr>
</tbody>
</table>

For more information on connection issues, see **Can't connect to Amazon RDS DB instance** (p. 2289).

### Modifying connection properties using sqlnet.ora parameters

The sqlnet.ora file includes parameters that configure Oracle Net features on Oracle database servers and clients. Using the parameters in the sqlnet.ora file, you can modify properties for connections in and out of the database.

For more information about why you might set sqlnet.ora parameters, see **Configuring profile parameters** in the Oracle documentation.
Setting sqlnet.ora parameters

Amazon RDS for Oracle parameter groups include a subset of sqlnet.ora parameters. You set them in the same way that you set other Oracle parameters. The `sqlnetora.` prefix identifies which parameters are sqlnet.ora parameters. For example, in an Oracle parameter group in Amazon RDS, the `default_sdu_size` sqlnet.ora parameter is `sqlnetora.default_sdu_size`.

For information about managing parameter groups and setting parameter values, see Working with parameter groups (p. 295).

Supported sqlnet.ora parameters

Amazon RDS supports the following sqlnet.ora parameters. Changes to dynamic sqlnet.ora parameters take effect immediately.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid values</th>
<th>Static/Dynamic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sqlnetora.default_sdu_size</code></td>
<td>Oracle 12c – 512 to 2097152</td>
<td>Dynamic</td>
<td>The session data unit (SDU) size, in bytes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The SDU is the amount of data that is put in a buffer and sent across the network at one time.</td>
</tr>
<tr>
<td><code>sqlnetora.diag_adr_enabled</code></td>
<td>ON, OFF</td>
<td>Dynamic</td>
<td>A value that enables or disables Automatic Diagnostic Repository (ADR) tracing.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>ON specifies that ADR file tracing is used.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>OFF specifies that non-ADR file tracing is used.</td>
</tr>
<tr>
<td><code>sqlnetora.recv_buf_size</code></td>
<td>8192 to 268435456</td>
<td>Dynamic</td>
<td>The buffer space limit for receive operations of sessions, supported by the TCP/IP, TCP/IP with SSL, and SDP protocols.</td>
</tr>
<tr>
<td><code>sqlnetora.send_buf_size</code></td>
<td>8192 to 268435456</td>
<td>Dynamic</td>
<td>The buffer space limit for send operations of sessions, supported by the TCP/IP, TCP/IP with SSL, and SDP protocols.</td>
</tr>
<tr>
<td><code>sqlnetora.sqlnet.allowed_logon_version_client</code></td>
<td>8, 10, 11, 12</td>
<td>Dynamic</td>
<td>Minimum authentication protocol version allowed for clients, and servers acting as clients, to establish a connection to Oracle DB instances.</td>
</tr>
<tr>
<td><code>sqlnetora.sqlnet.allowed_logon_version_server</code></td>
<td>8r9, 10, 11, 12, 12a</td>
<td>Dynamic</td>
<td>Minimum authentication protocol version allowed to establish a connection to Oracle DB instances.</td>
</tr>
<tr>
<td><code>sqlnetora.sqlnet.expire_time</code></td>
<td>0 to 1440</td>
<td>Dynamic</td>
<td>Time interval, in minutes, to send a check to verify that client-server connections are active.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Valid values</td>
<td>Static/Dynamic</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>--------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.inbound_connect_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a client to connect with the database server and provide the necessary authentication information.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.outbound_connect_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a client to establish an Oracle Net connection to the DB instance.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.recv_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a database server to wait for client data after establishing a connection.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.send_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a database server to complete a send operation to clients after establishing a connection.</td>
</tr>
<tr>
<td>sqlnetora.tcp.connect_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a client to establish a TCP connection to the database server.</td>
</tr>
<tr>
<td>sqlnetora.trace_level_server</td>
<td>0, 4, 10, 16, OFF, USER, ADMIN, SUPPORT</td>
<td>Dynamic</td>
<td>For non-ADR tracing, turns server tracing on at a specified level or turns it off.</td>
</tr>
</tbody>
</table>

The default value for each supported sqlnet.ora parameter is the Oracle default for the release. For information about default values for Oracle Database 12c, see Parameters for the sqlnet.ora file in the Oracle Database 12c documentation.

**Viewing sqlnet.ora parameters**

You can view sqlnet.ora parameters and their settings using the AWS Management Console, the AWS CLI, or a SQL client.

**Viewing sqlnet.ora parameters using the console**

For information about viewing parameters in a parameter group, see Working with parameter groups (p. 295).

In Oracle parameter groups, the sqlnetora . prefix identifies which parameters are sqlnet.ora parameters.

**Viewing sqlnet.ora parameters using the AWS CLI**

To view the sqlnet.ora parameters that were configured in an Oracle parameter group, use the AWS CLI describe-db-parameters command.

To view the all of the sqlnet.ora parameters for an Oracle DB instance, call the AWS CLI download-db-log-file-portion command. Specify the DB instance identifier, the log file name, and the type of output.
Example

The following code lists all of the sqlnet.ora parameters for mydbinstance.

For Linux, macOS, or Unix:

```
aws rds download-db-log-file-portion \
   --db-instance-identifier mydbinstance \
   --log-file-name trace/sqlnet-parameters \
   --output text
```

For Windows:

```
aws rds download-db-log-file-portion ^^ \
   --db-instance-identifier mydbinstance ^^ \
   --log-file-name trace/sqlnet-parameters ^^ \
   --output text
```

Viewing sqlnet.ora parameters using a SQL client

After you connect to the Oracle DB instance in a SQL client, the following query lists the sqlnet.ora parameters.

```
SELECT * FROM TABLE 
    (rdsadmin.rds_file_util.read_text_file( 
        p_directory => 'BDUMP', 
        p_filename  => 'sqlnet-parameters'));
```

For information about connecting to an Oracle DB instance in a SQL client, see Connecting to your Oracle DB instance (p. 1540).
Securing Oracle DB instance connections

Amazon RDS for Oracle supports SSL/TLS encrypted connections and also the Oracle Native Network Encryption (NNE) option to encrypt connections between your application and your Oracle DB instance. For more information about the Oracle Native Network Encryption option, see Oracle native network encryption (p. 1763).

Topics
- Using SSL with an RDS for Oracle DB instance (p. 1550)
- Updating applications to use new SSL/TLS certificates (p. 1550)
- Configuring Kerberos authentication for Amazon RDS for Oracle (p. 1553)
- Configuring UTL_HTTP access using certificates and an Oracle wallet (p. 1565)

Using SSL with an RDS for Oracle DB instance

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS), but we still often refer to the protocol as SSL. Amazon RDS supports SSL encryption for Oracle DB instances. Using SSL, you can encrypt a connection between your application client and your Oracle DB instance. SSL support is available in all AWS Regions for Oracle.

To enable SSL encryption for an Oracle DB instance, add the Oracle SSL option to the option group associated with the DB instance. Amazon RDS uses a second port, as required by Oracle, for SSL connections. Doing this allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and an Oracle client. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

For more information, see Oracle Secure Sockets Layer (p. 1774).

Note
You can't use both SSL and Oracle native network encryption (NNE) on the same DB instance. Before you can use SSL encryption, you must disable any other connection encryption.

Updating applications to use new SSL/TLS certificates

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances.

Important
When you change the certificate for an Amazon RDS for Oracle DB instance, only the database listener is restarted. The DB instance isn't restarted. Existing database connections are unaffected, but new connections will encounter errors for a brief period while the listener is restarted.

Note
For client applications that use SSL/TLS to connect to your DB instances, you must update your client application trust stores to include the new CA certificates.
After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 2154). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152). For information about using SSL/TLS with Oracle DB instances, see Oracle Secure Sockets Layer (p. 1774).

Topics
- Finding out whether applications connect using SSL (p. 1551)
- Updating your application trust store (p. 1551)
- Example Java code for establishing SSL connections (p. 1552)

Finding out whether applications connect using SSL

If your Oracle DB instance uses an option group with the SSL option added, you might be using SSL. Check this by following the instructions in Listing the options and option settings for an option group (p. 287). For information about the SSL option, see Oracle Secure Sockets Layer (p. 1774).

Check the listener log to determine whether there are SSL connections. The following is sample output in a listener log.

```
date time * (CONNECT_DATA=(CID=(PROGRAM=program) (HOST=host)(USER=user))(SID=sid)) * (ADDRESS=(PROTOCOL=tcps)(HOST=host)(PORT=port)) * establish * ORCL * 0
```

When PROTOCOL has the value tcps for an entry, it shows an SSL connection. However, when HOST is 127.0.0.1, you can ignore the entry. Connections from 127.0.0.1 are a local management agent on the DB instance. These connections aren’t external SSL connections. Therefore, you have applications connecting using SSL if you see listener log entries where PROTOCOL is tcps and HOST is not 127.0.0.1.

To check the listener log, you can publish the log to Amazon CloudWatch Logs. For more information, see Publishing Oracle logs to Amazon CloudWatch Logs (p. 748).

Updating your application trust store

You can update the trust store for applications that use SQL*Plus or JDBC for SSL/TLS connections.

Updating your application trust store for SQL*Plus

You can update the trust store for applications that use SQL*Plus for SSL/TLS connections.

Note
When you update the trust store, you can retain older certificates in addition to adding the new certificates.

To update the trust store for SQL*Plus applications

1. Download the 2019 root certificate that works for all AWS Regions and put the file in the ssl_wallet directory.

   For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).
2. Run the following command to update the Oracle wallet.

```
prompt>orapki wallet add -wallet $ORACLE_HOME/ssl_wallet -trusted_cert -cert $ORACLE_HOME/ssl_wallet/rds-ca-2019-root.pem -auto_login_only
```

Replace the file name with the one that you downloaded.

3. Run the following command to confirm that the wallet was updated successfully.

```
prompt>orapki wallet display -wallet $ORACLE_HOME/ssl_wallet
```

Your output should contain the following.

```
Trusted Certificates:
Subject: CN=Amazon RDS Root 2019 CA,OU=Amazon RDS,O=Amazon Web Services, Inc.,L=Seattle,ST=Washington,C=US
```

### Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).

For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 2160).

### Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection using JDBC.

```java
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.util.Properties;

public class OracleSslConnectionTest {
    private static final String DB_SERVER_NAME = "<dns-name-provided-by-amazon-rds>";
    private static final Integer SSL_PORT = "<ssl-option-port-configured-in-option-group>";
    private static final String DB_SID = "<oracle-sid>";
    private static final String DB_USER = "<user name>";
    private static final String DB_PASSWORD = "<password>";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "<file-path-to-keystore>";
    private static final String KEY_STORE_PASS = "<keystore-password>";

    public static void main(String[] args) throws SQLException {
        final Properties properties = new Properties();
        final String connectionString = String.format(
            "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))(CONNECT_DATA=(SID=%s)))",
            DB_SERVER_NAME, SSL_PORT, DB_SID);
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);
        properties.put("oracle.jdbc.2EE13Compliant", "true");
        properties.put("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        properties.put("javax.net.ssl.trustStoreType", "JKS");
        properties.put("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
    }
}
```
final Connection connection = DriverManager.getConnection(connectionString, properties);
// If no exception, that means handshake has passed, and an SSL connection can be opened
}

**Important**

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance (p. 2154).

### Configuring Kerberos authentication for Amazon RDS for Oracle

You can use Kerberos authentication to authenticate users when they connect to your Amazon RDS for Oracle DB instance. In this configuration, your DB instance works with AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD. When users authenticate with an RDS for Oracle DB instance joined to the trusting domain, authentication requests are forwarded to the directory that you create with AWS Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized place for storing and managing credentials for multiple database instances. A directory can also improve your overall security profile.

### Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS for Oracle with Kerberos authentication, see Kerberos authentication (p. 105).

**Note**

Kerberos authentication isn't supported for DB instance classes that are deprecated for RDS for Oracle DB instances. For more information, see RDS for Oracle instance classes (p. 1529).

**Topics**

- Setting up Kerberos authentication for Oracle DB instances (p. 1553)
- Managing a DB instance in a domain (p. 1562)
- Connecting to Oracle with Kerberos authentication (p. 1564)

### Setting up Kerberos authentication for Oracle DB instances

Use AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to set up Kerberos authentication for an Oracle DB instance. To set up Kerberos authentication, complete the following steps:

- Step 1: Create a directory using the AWS Managed Microsoft AD (p. 1554)
- Step 2: Create a trust (p. 1557)
- Step 3: Configure IAM permissions for Amazon RDS (p. 1557)
- Step 4: Create and configure users (p. 1559)
- Step 5: Enable cross-VPC traffic between the directory and the DB instance (p. 1559)
- Step 6: Create or modify an Oracle DB instance (p. 1559)
- Step 7: Create Kerberos authentication Oracle logins (p. 1561)
• **Step 8: Configure an Oracle client (p. 1562)**

  **Note**
  During the setup, RDS creates an Oracle database user named `managed_service_user@example.com` with the `CREATE SESSION` privilege, where `example.com` is your domain name. This user corresponds to the user that Directory Service creates inside your Managed Active Directory. Periodically, RDS uses the credentials provided by the Directory Service to log in to your Oracle database. Afterwards, RDS immediately destroys the ticket cache.

**Step 1: Create a directory using the AWS Managed Microsoft AD**

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.
  
  **Note**
  Be sure to save this password. AWS Directory Service doesn't store it. You can reset it, but you can't retrieve it.
- Creates a security group for the directory controllers.

When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you created your directory and is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

To create the directory, use the AWS Management Console, the AWS CLI, or the AWS Directory Service API. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the Oracle DB instance.
To create a directory with AWS Managed Microsoft AD

2. In the navigation pane, choose Directories and choose Set up Directory.
3. Choose AWS Managed Microsoft AD. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:
   
   **Directory DNS name**
   
   The fully qualified name for the directory, such as corp.example.com.
   
   **Directory NetBIOS name**
   
   The short name for the directory, such as CORP.
   
   **Directory description**
   
   (Optional) A description for the directory.
   
   **Admin password**
   
   The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

   The directory administrator password and can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:
   
   - Lowercase letters (a–z)
   - Uppercase letters (A–Z)
   - Numbers (0–9)
   - Non-alphanumeric characters (~!@#$%^&*_-+=`|(){}[\]:;"'<,.?/)
   
   **Confirm password**
   
   The administrator password retyped.
5. Choose Next.
6. Enter the following information in the Networking section and then choose Next:
   
   **VPC**
   
   The VPC for the directory. Create the Oracle DB instance in this same VPC.
   
   **Subnets**
   
   Subnets for the directory servers. The two subnets must be in different Availability Zones.
7. Review the directory information and make any necessary changes. When the information is correct, choose Create directory.
It takes several minutes for the directory to be created. When it has been successfully created, the Status value changes to **Active**.

To see information about your directory, choose the directory name in the directory listing. Note the **Directory ID** value because you need this value when you create or modify your Oracle DB instance.
Step 2: Create a trust

If you plan to use AWS Managed Microsoft AD only, move on to Step 3: Configure IAM permissions for Amazon RDS (p. 1557).

To get Kerberos authentication using an on-premises or self-hosted Microsoft Active Directory, create a forest trust or external trust. The trust can be one-way or two-way. For more information about setting up forest trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.

Step 3: Configure IAM permissions for Amazon RDS

To call AWS Directory Service for you, Amazon RDS requires an IAM role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess. This role allows Amazon RDS to make calls to the AWS Directory Service.

**Note**

For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

Creating an IAM role

When you create a DB instance using the AWS Management Console, and the console user has the **iam:CreateRole** permission, the console creates `rds-directoryservice-kerberos-`
access-role automatically. Otherwise, you must create the IAM role manually. When you create an IAM role manually, choose Directory Service, and attach the AWS managed policy AmazonRDSDirectoryServiceAccess to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

**Note**
The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for RDS for Oracle.

### Creating an IAM trust policy manually

Optionally, you can create resource policies with the required permissions instead of using the managed IAM policy AmazonRDSDirectoryServiceAccess. Specify both directoryservice.rds.amazonaws.com and rds.amazonaws.com as principals.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the aws:SourceArn and aws:SourceAccount global condition context keys in resource policies. The most effective way to protect against the confused deputy problem is to use the aws:SourceArn global condition context key with the full ARN of an Amazon RDS resource. For more information, see Preventing cross-service confused deputy problems (p. 2193).

The following example shows how you can use the aws:SourceArn and aws:SourceAccount global condition context keys in Amazon RDS to prevent the confused deputy problem.

```
{
 "Version": "2012-10-17",
 "Statement": [
  {
   "Sid": "",
   "Effect": "Allow",
   "Principal": {
     "Service": [
       "directoryservice.rds.amazonaws.com",
       "rds.amazonaws.com"
     ],
   },
   "Action": "sts:AssumeRole",
   "Condition": {
     "ArnLike": {
       "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"
     },
     "StringEquals": {
       "aws:SourceAccount": "123456789012"
     }
   }
  }
 ]
}
```

The role must also have the following IAM policy.

```
{
 "Version": "2012-10-17",
 "Statement": [
  {
   "Action": [
     "ds:DescribeDirectories",
     "ds:AuthorizeApplication",
     "ds:UnauthorizeApplication",
     "ds:GetAuthorizedApplicationDetails"
   ],
   "Effect": "Allow",
   "Principal": {
     "Service": "directoryservice.rds.amazonaws.com"
   }
  }
 ]
}
```
Configuring Kerberos authentication

Step 4: Create and configure users

You can create users with the Active Directory Users and Computers tool, which is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. In this case, users are individual people or entities that have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that is a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information about creating users in your Microsoft Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 6: Create or modify an Oracle DB instance (p. 1559).

If you plan to locate the directory and the DB instance in different AWS accounts or VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway. The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the Amazon Virtual Private Cloud Peering Guide.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance's security group can receive inbound traffic from the directory's security group. For more information, see Best practices for AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join in the AWS Directory Service Administration Guide.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the Directory ID value. You use this directory ID to join the DB instance to the domain.

Step 6: Create or modify an Oracle DB instance

Create or modify an Oracle DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new Oracle DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.

For instructions, see Creating an Amazon RDS DB instance (p. 236).
• Modify an existing Oracle DB instance using the console, the `modify-db-instance` CLI command, or the `ModifyDBInstance` RDS API operation.

For instructions, see Modifying an Amazon RDS DB instance (p. 333).

• Restore an Oracle DB instance from a DB snapshot using the console, the `restore-db-instance-from-db-snapshot` CLI command, or the `RestoreDBInstanceFromDBSnapshot` RDS API operation.

For instructions, see Restoring from a DB snapshot (p. 487).

• Restore an Oracle DB instance to a point-in-time using the console, the `restore-db-instance-to-point-in-time` CLI command, or the `RestoreDBInstanceToPointInTime` RDS API operation.

For instructions, see Restoring a DB instance to a specified time (p. 534).

Kerberos authentication is only supported for Oracle DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. When you create or modify the DB instance, do the following:

• Provide the domain identifier (d-* identifier) that was generated when you created your directory.
• Provide the name of the IAM role that you created.
• Ensure that the DB instance security group can receive inbound traffic from the directory security group and send outbound traffic to the directory.

When you use the console to create a DB instance, choose Password and Kerberos authentication in the Database authentication section. Choose Browse Directory and then select the directory, or choose Create a new directory.

When you use the console to modify or restore a DB instance, choose the directory in the Kerberos authentication section, or choose Create a new directory.
When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --domain d-ID \
  --domain-iam-role-name role-name
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --domain d-ID ^
  --domain-iam-role-name role-name
```

**Important**
If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

**Note**
MANAGED_SERVICE_USER is a service account whose name is randomly generated by Directory Service for RDS. During the Kerberos authentication setup, RDS for Oracle creates a user with the same name and assigns it the CREATE SESSION privilege. The Oracle DB user is identified externally as MANAGED_SERVICE_USER@EXAMPLE.COM, where EXAMPLE.COM is the name of your domain. Periodically, RDS uses the credentials provided by the Directory Service to log in to your Oracle database. Afterward, RDS immediately destroys the ticket cache.

**Step 7: Create Kerberos authentication Oracle logins**

Use the Amazon RDS master user credentials to connect to the Oracle DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision Oracle logins and users from the Microsoft Active Directory users and groups in your domain. To manage database permissions, you grant and revoke standard Oracle permissions to these logins.

**To allow a Microsoft Active Directory user to authenticate with Oracle**

1. Connect to the Oracle DB instance using your Amazon RDS master user credentials.
2. Create an externally authenticated user in Oracle database.

In the following example, replace KRUSER@CORP.EXAMPLE.COM with the user name and domain name.

```sql
CREATE USER "KRUSER@CORP.EXAMPLE.COM" IDENTIFIED EXTERNALLY;
GRANT CREATE SESSION TO "KRUSER@CORP.EXAMPLE.COM";
```

Users (both humans and applications) from your domain can now connect to the Oracle DB instance from a domain joined client machine using Kerberos authentication.
Step 8: Configure an Oracle client

To configure an Oracle client, meet the following requirements:

- Create a configuration file named krb5.conf (Linux) or krb5.ini (Windows) to point to the domain. Configure the Oracle client to use this configuration file.
- Verify that traffic can flow between the client host and AWS Directory Service over DNS port 53 over TCP/UDP, Kerberos ports (88 and 464 for managed AWS Directory Service) over TCP, and LDAP port 389 over TCP.
- Verify that traffic can flow between the client host and the DB instance over the database port.

Following is sample content for AWS Managed Microsoft AD.

```plaintext
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
    kdc = example.com
    admin_server = example.com
}
[domain_realm]
.example.com = CORP.EXAMPLE.COM
corp.com = CORP.EXAMPLE.COM
```

Following is sample content for on-premise Microsoft AD. In your krb5.conf or krb5.ini file, replace `on-prem-ad-server-name` with the name of your on-premises AD server.

```plaintext
[libdefaults]
default_realm = ONPREM.COM
[realms]
AWSAD.COM = {
    kdc = awsad.com
    admin_server = awsad.com
}
ONPREM.COM = {
    kdc = `on-prem-ad-server-name`
    admin_server = `on-prem-ad-server-name`
}
[domain_realm]
.awsad.com = AWSAD.COM
awsad.com = AWSAD.COM
.onprem.com = ONPREM.COM
onprem.com = ONPREM.COM
```

Note

After you configure your krb5.ini or krb5.conf file, we recommend that you reboot the server.

The following is sample sqlnet.ora content for a SQL*Plus configuration:

```plaintext
SQLNET.AUTHENTICATION_SERVICES=(KERBEROS5PRE,KERBEROS5)
SQLNET.KERBEROS5_CONF=path_to_krb5.conf_file
```

For an example of a SQL Developer configuration, see Document 1609359.1 from Oracle Support.

Managing a DB instance in a domain

You can use the console, the CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate a Microsoft Active Directory to enable Kerberos authentication. You can also disassociate a Microsoft Active Directory to disable Kerberos authentication.
authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the `modify-db-instance` CLI command and specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the `modify-db-instance` CLI command and specify `none` for the `--domain` option.
- To move a DB instance from one domain to another, use the `modify-db-instance` CLI command and specify the domain identifier of the new domain for the `--domain` option.

**Viewing the status of domain membership**

After you create or modify your DB instance, the DB instance becomes a member of the domain. You can view the status of the domain membership for the DB instance in the console or by running the `describe-db-instances` CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. If the attempt to enable Kerberos authentication fails when you create or modify a DB instance, make sure that you're using the correct IAM role. Then modify the DB instance to join the domain.

**Note**

Only Kerberos authentication with Amazon RDS for Oracle sends traffic to the domain's DNS servers. All other DNS requests are treated as outbound network access on your DB instances running Oracle. For more information about outbound network access with Amazon RDS for Oracle, see Setting up a custom DNS server (p. 1591).

**Force-rotating Kerberos keys**

A secret key is shared between AWS Managed Microsoft AD and Amazon RDS for Oracle DB instance. This key is rotated automatically every 45 days. You can use the following Amazon RDS procedure to force the rotation of this key.

```
SELECT rdsadmin.rdsadmin_kerberos_auth_tasks.rotate_kerberos_keytab AS TASK_ID FROM DUAL;
```

**Note**

In a read replica configuration, this procedure is available only on the source DB instance and not on the read replica.
The SELECT statement returns the ID of the task in a VARCHAR2 data type. You can view the status of an ongoing task in a bdump file. The bdump files are located in the /rdsdbdata/log/trace directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure.

**Note**
Tasks are executed asynchronously.

## Connecting to Oracle with Kerberos authentication

This section assumes that you have set up your Oracle client as described in [Step 8: Configure an Oracle client (p. 1562)](#). To connect to the Oracle DB with Kerberos authentication, log in using the Kerberos authentication type. For example, after launching Oracle SQL Developer, choose **Kerberos Authentication** as the authentication type, as shown following.

To connect to Oracle with Kerberos authentication with SQL*Plus:

1. At a command prompt, run the following command:

```
kinit username
```

   Replace `username` with the user name and, at the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. Open SQL*Plus and connect using the DNS name and port number for the Oracle DB instance.

   For more information about connecting to an Oracle DB instance in SQL*Plus, see [Connecting to your DB instance using SQL*Plus (p. 1544)](#).
Configuring UTL_HTTP access using certificates and an Oracle wallet

Amazon RDS supports outbound network access on your Oracle DB instances. To connect your DB instance to the network, you can use the following PL/SQL packages:

**UTL_HTTP**

This package makes HTTP calls from SQL and PL/SQL. You can use it to access data on the Internet over HTTP. For more information, see [UTL_HTTP](https://docs.oracle.com) in the Oracle documentation.

**UTL_TCP**

This package provides TCP/IP client-side access functionality in PL/SQL. This package is useful to PL/SQL applications that use Internet protocols and email. For more information, see [UTL_TCP](https://docs.oracle.com) in the Oracle documentation.

**UTL_SMTP**

This package provides interfaces to the SMTP commands that enable a client to dispatch emails to an SMTP server. For more information, see [UTL_SMTP](https://docs.oracle.com) in the Oracle documentation.

Before configuring your instance for network access, review the following requirements and considerations:

- To use SMTP with the UTL_MAIL option, see Oracle UTL_MAIL (p. 1805).
- The Domain Name Server (DNS) name of the remote host can be any of the following:
  - Publicly resolvable.
  - The endpoint of an Amazon RDS DB instance.
  - Resolvable through a custom DNS server. For more information, see Setting up a custom DNS server (p. 1591).
  - The private DNS name of an Amazon EC2 instance in the same VPC or a peered VPC. In this case, make sure that the name is resolvable through a custom DNS server. Alternatively, to use the DNS provided by Amazon, you can enable the enableDnsSupport attribute in the VPC settings and enable DNS resolution support for the VPC peering connection. For more information, see DNS support in your VPC and Modifying your VPC peering connection.
  - To connect securely to remote SSL/TLS resources, we recommend that you create and upload customized Oracle wallets. By using the Amazon S3 integration with Amazon RDS for Oracle feature, you can download a wallet from Amazon S3 into Oracle DB instances. For information about Amazon S3 integration for Oracle, see Amazon S3 integration (p. 1700).
  - You can establish database links between Oracle DB instances over an SSL/TLS endpoint if the Oracle SSL option is configured for each instance. No further configuration is required. For more information, see Oracle Secure Sockets Layer (p. 1774).

By completing the following tasks, you can configure UTL_HTTP.REQUEST to work with websites that require client authentication certificates during the SSL handshake. You can also configure password authentication for UTL_HTTP access to websites by modifying the Oracle wallet generation commands and the DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACE procedure. For more information, see DBMS_NETWORK_ACL_ADMIN in the Oracle Database documentation.

**Note**

You can adapt the following tasks for UTL_SMTP, which enables you to send emails over SSL/TLS (including Amazon Simple Email Service).
• Step 1: Get the root certificate for a website (p. 1566)
• Step 2: Create an Oracle wallet (p. 1566)
• Step 3: Download your Oracle wallet to your RDS for Oracle instance (p. 1567)
• Step 4: Grant user permissions for the Oracle wallet (p. 1568)
• Step 5: Configure access to a website from your DB instance (p. 1569)
• Step 6: Test connections from your DB instance to a website (p. 1571)

Step 1: Get the root certificate for a website

For the RDS for Oracle instance to make secure connections to a website, add the root CA certificate. Amazon RDS uses the root certificate to sign the website certificate to the Oracle wallet.

You can get the root certificate in various ways. For example, you can do the following:

1. Use a web server to visit the website secured by the certificate.
2. Download the root certificate that was used for signing.

For AWS services, root certificates typically reside in the Amazon trust services repository.

Step 2: Create an Oracle wallet

Create an Oracle wallet that contains both the web server certificates and the client authentication certificates. The RDS Oracle instance uses the web server certificate to establish a secure connection to the website. The website needs the client certificate to authenticate the Oracle database user.

You might want to configure secure connections without using client certificates for authentication. In this case, you can skip the Java keystore steps in the following procedure.

To create an Oracle wallet

1. Place the root and client certificates in a single directory, and then change into this directory.
2. Convert the .p12 client certificate to the Java keystore.

   Note
   If you're not using client certificates for authentication, you can skip this step.

   The following example converts the client certificate named client_certificate.p12 to the Java keystore named client_keystore.jks. The keystore is then included in the Oracle wallet. The keystore password is P12PASSWORD.

   ```
   orapki wallet pkcs12_to_jks -wallet ./ -jksKeyStoreLoc ./client_keystore.jks -jksKeyStorepwd P12PASSWORD
   ```

3. Create a directory for your Oracle wallet that is different from the certificate directory.

   The following example creates the directory /tmp/wallet.

   ```
   mkdir -p /tmp/wallet
   ```

4. Create an Oracle wallet in your wallet directory.

   The following example sets the Oracle wallet password to P12PASSWORD, which is the same password used by the Java keystore in a previous step. Using the same password is convenient, but not necessary. The -auto_login parameter turns on the automatic login feature, so that you don't need to specify a password every time you want to access it.
5. Add the Java keystore to your Oracle wallet.

   **Note**
   If you're not using client certificates for authentication, you can skip this step.

   The following example adds the keystore `client_keystore.jks` to the Oracle wallet named `/tmp/wallet`. In this example, you specify the same password for the Java keystore and the Oracle wallet.

   ```bash
   orapki wallet jks_to_pkcs12 -wallet /tmp/wallet -pwd P12PASSWORD -keystore ./client_keystore.jks -jkspwd P12PASSWORD
   ```

6. Add the root certificate for your target website to the Oracle wallet.

   The following example adds a certificate named `Root_CA.cer`.

   ```bash
   orapki wallet add -wallet /tmp/wallet -trusted_cert -cert ./Root_CA.cer -pwd P12PASSWORD
   ```

7. Add any intermediate certificates.

   The following example adds a certificate named `Intermediate.cer`. Repeat this step as many times as need to load all intermediate certificates.

   ```bash
   orapki wallet add -wallet /tmp/wallet -trusted_cert -cert ./Intermediate.cer -pwd P12PASSWORD
   ```

8. Confirm that your newly created Oracle wallet has the required certificates.

   ```bash
   orapki wallet display -wallet /tmp/wallet -pwd P12PASSWORD
   ```

**Step 3: Download your Oracle wallet to your RDS for Oracle instance**

In this step, you upload your Oracle wallet to Amazon S3, and then download the wallet from Amazon S3 to your RDS for Oracle instance.

**To download your Oracle wallet to your RDS for Oracle DB instance**

1. Complete the prerequisites for Amazon S3 integration with Oracle, and add the S3_INTEGRATION option to your Oracle DB instance. Ensure that the IAM role for the option has access to the Amazon S3 bucket you are using.

   For more information, see Amazon S3 integration (p. 1700).

2. Log in to your DB instance as the master user, and then create an Oracle directory to hold the Oracle wallet.

   The following example creates an Oracle directory named `WALLET_DIR`.

   ```bash
   EXEC rdsadmin.rdsadmin_util.create_directory('WALLET_DIR');
   ```

   For more information, see Creating and dropping directories in the main data storage space (p. 1649).
3. Upload the Oracle wallet to your Amazon S3 bucket.
   
   You can use any supported upload technique.

4. If you're re-uploading an Oracle wallet, delete the existing wallet. Otherwise, skip to the next step.

   The following example removes the existing wallet, which is named `cwallet.sso`.
   
   ```sql
   EXEC UTL_FILE.FREMOVE ('WALLET_DIR', 'cwallet.sso');
   ```

5. Download the Oracle wallet from your Amazon S3 bucket to the Oracle DB instance.

   The following example downloads the wallet named `cwallet.sso` from the Amazon S3 bucket named `my_s3_bucket` to the DB instance directory named `WALLET_DIR`.
   
   ```sql
   SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
       p_bucket_name    => 'my_s3_bucket',
       p_s3_prefix      => 'cwallet.sso',
       p_directory_name => 'WALLET_DIR')
   AS TASK_ID FROM DUAL;
   ```

6. (Optional) Download a password-protected Oracle wallet.

   Download this wallet only if you want to require a password for every use of the wallet. The following example downloads password-protected wallet `ewallet.p12`.
   
   ```sql
   SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
       p_bucket_name    => 'my_s3_bucket',
       p_s3_prefix      => 'ewallet.p12',
       p_directory_name => 'WALLET_DIR')
   AS TASK_ID FROM DUAL;
   ```

7. Check the status of your DB task.

   Substitute the task ID returned from the preceding steps for `dbtask-1234567890123-4567.log` in the following example.
   
   ```sql
   SELECT TEXT FROM
   TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-1234567890123-4567.log'));
   ```

8. Check the contents of the directory that you're using to store the Oracle wallet.

   ```sql
   SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'WALLET_DIR'));
   ```

For more information, see Listing files in a DB instance directory (p. 1650).

**Step 4: Grant user permissions for the Oracle wallet**

You can either create a new database user or configure an existing user. In either case, you must configure the user to access the Oracle wallet for secure connections and client authentication using certificates.

**To grant user permissions for the Oracle wallet**

1. Log in your RDS for Oracle DB instance as the master user.

2. If you don't want to configure an existing database user, create a new user. Otherwise, skip to the next step.
The following example creates a database user named *my-user*.

```sql
CREATE USER my-user IDENTIFIED BY my-user-pwd;
GRANT CONNECT TO my-user;
```

3. Grant permission to your database user on the directory containing your Oracle wallet.

The following example grants read access to user *my-user* on directory *WALLET_DIR*.

```sql
GRANT READ ON DIRECTORY WALLET_DIR TO my-user;
```

4. Grant permission to your database user to use the UTL_HTTP package.

The following PL/SQL program grants UTL_HTTP access to user *my-user*.

```sql
BEGIN
    rdsadmin.rdsadmin_util.grant_sys_object('UTL_HTTP', UPPER('my-user'));
END;
/
```

5. Grant permission to your database user to use the UTL_FILE package.

The following PL/SQL program grants UTL_FILE access to user *my-user*.

```sql
BEGIN
    rdsadmin.rdsadmin_util.grant_sys_object('UTL_FILE', UPPER('my-user'));
END;
/
```

**Step 5: Configure access to a website from your DB instance**

In this step, you configure your Oracle database user so that it can connect to your target website using UTL_HTTP, your uploaded Oracle Wallet, and the client certificate. For more information, see Configuring Access Control to an Oracle Wallet in the Oracle Database documentation.

**To configure access to a website from your RDS for Oracle DB instance**

1. Log into your RDS for Oracle DB instance as the master user.
2. Create a Host Access Control Entry (ACE) for your user and the target website on a secure port.

The following example configures *my-user* to access *secret.encrypted-website.com* on secure port 443.

```sql
BEGIN
    DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
        host       => 'secret.encrypted-website.com',
        lower_port => 443,
        upper_port => 443,
        ace        => xs$ace_type(privilege_list => xs$name_list('http'),
                                   principal_name => 'my-user',
                                   principal_type => xs_acl.ptype_db));
END;
/
```

For more information, see Configuring Access Control for External Network Services in the Oracle Database documentation.
3. (Optional) Create an ACE for your user and target website on the standard port.

You might need to use the standard port if some web pages are served from the standard web server port (80) instead of the secure port (443).

BEGIN
  DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
    host       => 'secret.encrypted-website.com',
    lower_port => 80,
    upper_port => 80,
    ace        => xs$ace_type(privilege_list => xs$name_list('http'),
                               principal_name => 'my-user',
                               principal_type => xs_acl.ptype_db));
END;
/

4. Confirm that the access control entries exist.

SET LINESIZE 150
COLUMN HOST FORMAT A40
COLUMN ACL FORMAT A50

SELECT HOST, LOWER_PORT, UPPER_PORT, ACL
  FROM DBA_NETWORK_ACLS
ORDER BY HOST;

5. Grant permission to your database user to use the UTL_HTTP package.

The following PL/SQL program grants UTL_HTTP access to user my-user.

BEGIN
  rdsadmin.rdsadmin_util.grant_sys_object('UTL_HTTP', UPPER('my-user'));
END;
/

6. Confirm that related access control lists exist.

SET LINESIZE 150
COLUMN ACL FORMAT A50
COLUMN PRINCIPAL FORMAT A20
COLUMN PRIVILEGE FORMAT A10

SELECT ACL, PRINCIPAL, PRIVILEGE, IS_GRANT,
  TO_CHAR(START_DATE, 'DD-MON-YYYY') AS START_DATE,
  TO_CHAR(END_DATE, 'DD-MON-YYYY') AS END_DATE
  FROM DBA_NETWORK_ACL_PRIVILEGES
ORDER BY ACL, PRINCIPAL, PRIVILEGE;

7. Grant permission to your database user to use certificates for client authentication and your Oracle wallet for connections.

Note
If you're not using client certificates for authentication, you can skip this step.

DECLARE
  l_wallet_path all_directories.directory_path%type;
BEGIN
  SELECT DIRECTORY_PATH
    INTO l_wallet_path
    FROM ALL_DIRECTORIES
    WHERE UPPER(DIRECTORY_NAME)= 'WALLET_DIR';
  DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACE(
Step 6: Test connections from your DB instance to a website

In this step, you configure your database user so that it can connect to the website using UTL_HTTP, your uploaded Oracle Wallet, and the client certificate.

To configure access to a website from your RDS for Oracle DB instance

1. Log in your RDS for Oracle DB instance as a database user with UTL_HTTP permissions.
2. Confirm that a connection to your target website can resolve the host address.

   The following example gets the host address from secret.encrypted-website.com.

   ```sql
   SELECT UTL_INADDR.GET_HOST_ADDRESS(host => 'secret.encrypted-website.com')
   FROM DUAL;
   ```

3. Test a failed connection.

   The following query fails because UTL_HTTP requires the location of the Oracle wallet with the certificates.

   ```sql
   SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
   ```

4. Test website access by using UTL_HTTP.SET_WALLET and selecting from DUAL.

   ```sql
   DECLARE
   l_wallet_path all_directories.directory_path%type;
   BEGIN
   SELECT DIRECTORY_PATH
   INTO l_wallet_path
   FROM ALL_DIRECTORIES
   WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
   UTL_HTTP.SET_WALLET('file:/'||l_wallet_path);
   END;
   /
   SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
   ```

5. (Optional) Test website access by storing your query in a variable and using EXECUTE IMMEDIATE.

   ```sql
   DECLARE
   l_wallet_path all_directories.directory_path%type;
   v_webpage_sql VARCHAR2(1000);
   v_results VARCHAR2(32767);
   BEGIN
   SELECT DIRECTORY_PATH
   INTO l_wallet_path
   FROM ALL_DIRECTORIES
   WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
   END;
   /
   DECLARE
   l_wallet_path all_directories.directory_path%type;
   v_webpage_sql VARCHAR2(1000);
   v_results VARCHAR2(32767);
   BEGIN
   SELECT DIRECTORY_PATH
   INTO l_wallet_path
   FROM ALL_DIRECTORIES
   WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
   END;
   /
   SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
   ```
6. (Optional) Find the file system location of your Oracle wallet directory.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'WALLET_DIR'));
```

Use the output from the previous command to make an HTTP request. For example, if the directory is `rdsdbdata/userdirs/01`, run the following query.

```
SELECT UTL_HTTP.REQUEST('https://secret.encrypted-website.com/', '', 'file://rdsdbdata/userdirs/01')
FROM DUAL;
```
Administering your Oracle DB instance

Following are the common management tasks that you perform with an Amazon RDS DB instance. Some tasks are the same for all RDS DB instances. Other tasks are specific to RDS for Oracle.

The following tasks are common to all RDS databases, but Oracle has special considerations. For example, connect to an Oracle Database using the Oracle clients SQL*Plus and SQL Developer.

<table>

</table>
Following, you can find a description for Amazon RDS–specific implementations of common DBA tasks for RDS Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Also, RDS restricts access to certain system procedures and tables that require advanced privileges. In many of the tasks, you run the rdsadmin package, which is an Amazon RDS–specific tool that enables you to administer your database.

The following are common DBA tasks for DB instances running Oracle:

- **System tasks (p. 1581)**

Oracle method: `—` |
| Accessing Opatch files (p. 1651)    | Amazon RDS method: `rdsadmin.rds_file_util.read_text_file` or `rdsadmin.tracefile_listing`  
Oracle method: `opatch` |
| Setting parameters for advisor tasks (p. 1653) | Amazon RDS method: `rdsadmin.rdsadmin_util.advisor_task_set_parameter`  
Oracle method: Various stored package procedures |
| Disabling AUTO_STATS_ADVISOR_TASK (p. 1654) | Amazon RDS method: `rdsadmin.rdsadmin_util.advisor_task_drop`  
Oracle method: `—` |
You can also use Amazon RDS procedures for Amazon S3 integration with Oracle and for running OEM Management Agent database tasks. For more information, see Amazon S3 integration (p. 1700) and Performing database tasks with the Management Agent (p. 1751).

Performing common system tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to the system on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

Topics
- Disconnecting a session (p. 1581)
- Terminating a session (p. 1582)
- Canceling a SQL statement in a session (p. 1583)
- Enabling and disabling restricted sessions (p. 1584)
- Flushing the shared pool (p. 1584)
- Flushing the buffer cache (p. 1585)
- Flushing the database smart flash cache (p. 1585)
- Granting SELECT or EXECUTE privileges to SYS objects (p. 1585)
- Revoking SELECT or EXECUTE privileges on SYS objects (p. 1586)
- Granting privileges to non-master users (p. 1587)
- Creating custom functions to verify passwords (p. 1588)
- Setting up a custom DNS server (p. 1591)
- Setting and unsetting system diagnostic events (p. 1592)

Disconnecting a session

To disconnect the current session by ending the dedicated server process, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.disconnect`. The `disconnect` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sid</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The session identifier.</td>
</tr>
<tr>
<td>serial</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The serial number of the session.</td>
</tr>
<tr>
<td>method</td>
<td>varchar</td>
<td>'IMMEDIATE'</td>
<td>No</td>
<td>Valid values are 'IMMEDIATE' or 'POST_TRANSACTION'.</td>
</tr>
</tbody>
</table>
The following example disconnects a session.

```
begin
    rdsadmin.rdsadmin_util.disconnect(
        sid    => sid,
        serial => serial_number);
end;
/
```

To get the session identifier and the session serial number, query the V$SESSION view. The following example gets all sessions for the user AWSUSER.

```
SELECT SID, SERIAL#, STATUS FROM V$SESSION WHERE USERNAME = 'AWSUSER';
```

The database must be open to use this method. For more information about disconnecting a session, see ALTER SYSTEM in the Oracle documentation.

### Terminating a session

To terminate a session, use the Amazon RDS procedure rdsadmin.rdsadmin_util.kill. The kill procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sid</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The session identifier.</td>
</tr>
<tr>
<td>serial</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The serial number of the session.</td>
</tr>
<tr>
<td>method</td>
<td>varchar</td>
<td>null</td>
<td>No</td>
<td>Valid values are 'IMMEDIATE' or 'PROCESS'. If you specify IMMEDIATE, it has the same effect as running the following statement: ALTER SYSTEM KILL SESSION 'sid,serial#' IMMEDIATE.</td>
</tr>
</tbody>
</table>

If you specify PROCESS, you terminate the processes associated with a session. Only specify PROCESS if terminating the session using IMMEDIATE was unsuccessful.

To get the session identifier and the session serial number, query the V$SESSION view. The following example gets all sessions for the user AWSUSER.

```
SELECT SID, SERIAL#, STATUS FROM V$SESSION WHERE USERNAME = 'AWSUSER';
```

The following example terminates a session.

```
begin
    rdsadmin.rdsadmin_util.kill(
        sid    => sid,
        serial => serial_number,
        method => 'IMMEDIATE');
end;
/
```
The following example terminates the processes associated with a session.

```
BEGIN
    rdsadmin.rdsadmin_util.kill(
        sid => sid,
        serial => serial_number,
        method => 'IMMEDIATE');
END;
/
```

The following example terminates the processes associated with a session.

```
BEGIN
    rdsadmin.rdsadmin_util.kill(
        sid => sid,
        serial => serial_number,
        method => 'PROCESS');
END;
/
```

**Canceling a SQL statement in a session**

To cancel a SQL statement in a session, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.cancel`.

**Note**

This procedure is supported for Oracle Database 19c (19.0.0) and all higher major and minor versions of RDS for Oracle.

The `cancel` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sid</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The session identifier.</td>
</tr>
<tr>
<td>serial</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The serial number of the session.</td>
</tr>
<tr>
<td>sql_id</td>
<td>varchar2</td>
<td>null</td>
<td>No</td>
<td>The SQL identifier of the SQL statement.</td>
</tr>
</tbody>
</table>

The following example cancels a SQL statement in a session.

```
begin
    rdsadmin.rdsadmin_util.cancel(
        sid => sid,
        serial => serial_number,
        sql_id => sql_id);
end;
/
```

To get the session identifier, the session serial number, and the SQL identifier of a SQL statement, query the V$SESSION view. The following example gets all sessions and SQL identifiers for the user AWSUSER.

```
select SID, SERIAL#, SQL_ID, STATUS from V$SESSION where USERNAME = 'AWSUSER';
```
Enabling and disabling restricted sessions

To enable and disable restricted sessions, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.restricted_session`. The `restricted_session` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Yes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_enable</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to enable restricted sessions, false to disable restricted sessions.</td>
</tr>
</tbody>
</table>

The following example shows how to enable and disable restricted sessions.

```sql
/* Verify that the database is currently unrestricted. */
SELECT LOGINS FROM V$INSTANCE;
LOGINS
-------
ALLOWED

/* Enable restricted sessions */
EXEC rdsadmin.rdsadmin_util.restricted_session(p_enable => true);

/* Verify that the database is now restricted. */
SELECT LOGINS FROM V$INSTANCE;
LOGINS
--------
RESTRICTED

/* Disable restricted sessions */
EXEC rdsadmin.rdsadmin_util.restricted_session(p_enable => false);

/* Verify that the database is now unrestricted again. */
SELECT LOGINS FROM V$INSTANCE;
LOGINS
-------
ALLOWED
```

Flushing the shared pool

To flush the shared pool, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_shared_pool`. The `flush_shared_pool` procedure has no parameters.

The following example flushes the shared pool.

```sql
EXEC rdsadmin.rdsadmin_util.flush_shared_pool;
```
Flushing the buffer cache

To flush the buffer cache, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_buffer_cache`. The `flush_buffer_cache` procedure has no parameters.

The following example flushes the buffer cache.

```
EXEC rdsadmin.rdsadmin_util.flush_buffer_cache;
```

Flushing the database smart flash cache

To flush the database smart flash cache, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_flash_cache`. The `flush_flash_cache` procedure has no parameters. The following example flushes the database smart flash cache.

```
EXEC rdsadmin.rdsadmin_util.flush_flash_cache;
```

For more information about using the database smart flash cache with RDS for Oracle, see Storing temporary data in an RDS for Oracle instance store (p. 1656).

Granting SELECT or EXECUTE privileges to SYS objects

Usually you transfer privileges by using roles, which can contain many objects. To grant privileges to a single object, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.grant_sys_object`. The procedure grants only privileges that the master user has already been granted through a role or direct grant.

The `grant_sys_object` procedure has the following parameters.

**Important**
For all parameter values, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run `CREATE USER myuser` or `CREATE USER MYUSER`, the data dictionary stores `MYUSER`. However, if you use double quotes in `CREATE USER "MyUser"`, the data dictionary stores `MyUser`.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_obj_name</code></td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the object to grant privileges for. The object can be a directory, function, package, procedure, sequence, table, or view. Object names must be spelled exactly as they appear in <code>DBA_OBJECTS</code>. Most system objects are defined in uppercase, so we recommend that you try that first.</td>
</tr>
<tr>
<td><code>p_grantee</code></td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the object to grant privileges to. The object can be a schema or a role.</td>
</tr>
</tbody>
</table>
### Parameter table

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_privilege</td>
<td>varchar2</td>
<td>null</td>
<td>Yes</td>
<td>—</td>
</tr>
<tr>
<td>p_grant_option</td>
<td>boolean</td>
<td>false</td>
<td>No</td>
<td>Set to true to use the with grant option. The p_grant_option parameter is supported for 12.1.0.2.v4 and later, all 12.2.0.1 versions, and all 19.0.0 versions.</td>
</tr>
</tbody>
</table>

The following example grants select privileges on an object named V_$SESSION to a user named USER1.

```sql
begin
  rdsadmin.rdsadmin_util.grant_sys_object(
    p_obj_name  => 'V_$SESSION',
    p_grantee   => 'USER1',
    p_privilege => 'SELECT');
end;
/
```

The following example grants select privileges on an object named V_$SESSION to a user named USER1 with the grant option.

```sql
begin
  rdsadmin.rdsadmin_util.grant_sys_object(
    p_obj_name     => 'V_$SESSION',
    p_grantee      => 'USER1',
    p_privilege    => 'SELECT',
    p_grant_option => true);
end;
/
```

To be able to grant privileges on an object, your account must have those privileges granted to it directly with the grant option, or via a role granted using with admin option. In the most common case, you may want to grant SELECT on a DBA view that has been granted to the SELECT_CATALOG_ROLE role. If that role isn't already directly granted to your user using with admin option, then you can't transfer the privilege. If you have the DBA privilege, then you can grant the role directly to another user.

The following example grants the SELECT_CATALOG_ROLE and EXECUTE_CATALOG_ROLE to USER1. Since the with admin option is used, USER1 can now grant access to SYS objects that have been granted to SELECT_CATALOG_ROLE.

```sql
GRANT SELECT_CATALOG_ROLE TO USER1 WITH ADMIN OPTION;
GRANT EXECUTE_CATALOG_ROLE to USER1 WITH ADMIN OPTION;
```

Objects already granted to PUBLIC do not need to be re-granted. If you use the grant_sys_object procedure to re-grant access, the procedure call succeeds.

### Revoking SELECT or EXECUTE privileges on SYS objects

To revoke privileges on a single object, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.revoke_sys_object`. The procedure only revokes privileges that the master account has already been granted through a role or direct grant.

The revoke_sys_object procedure has the following parameters.
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_obj_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the object to revoke privileges for. The object can be a directory, function, package, procedure, sequence, table, or view. Object names must be spelled exactly as they appear in DBA_OBJECTS. Most system objects are defined in upper case, so we recommend you try that first.</td>
</tr>
<tr>
<td>p_revokee</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the object to revoke privileges for. The object can be a schema or a role.</td>
</tr>
<tr>
<td>p_privilege</td>
<td>varchar2</td>
<td>null</td>
<td>Yes</td>
<td>—</td>
</tr>
</tbody>
</table>

The following example revokes select privileges on an object named `V_$SESSION` from a user named `USER1`.

```sql
begin
  rdsadmin.rdsadmin_util.revoke_sys_object(
    p_obj_name  => 'V_$SESSION',
    p_revokee   => 'USER1',
    p_privilege => 'SELECT');
end;
/
```

**Granting privileges to non-master users**

You can grant select privileges for many objects in the SYS schema by using the `SELECT_CATALOG_ROLE` role. The `SELECT_CATALOG_ROLE` role gives users `SELECT` privileges on data dictionary views. The following example grants the role `SELECT_CATALOG_ROLE` to a user named `user1`.

```sql
GRANT SELECT_CATALOG_ROLE TO user1;
```

You can grant `EXECUTE` privileges for many objects in the SYS schema by using the `EXECUTE_CATALOG_ROLE` role. The `EXECUTE_CATALOG_ROLE` role gives users `EXECUTE` privileges for packages and procedures in the data dictionary. The following example grants the role `EXECUTE_CATALOG_ROLE` to a user named `user1`.

```sql
GRANT EXECUTE_CATALOG_ROLE TO user1;
```

The following example gets the permissions that the roles `SELECT_CATALOG_ROLE` and `EXECUTE_CATALOG_ROLE` allow.

```sql
SELECT *
  FROM ROLE_TAB_PRIVS
```
WHERE ROLE IN ('SELECT_CATALOG_ROLE','EXECUTE_CATALOG_ROLE')
ORDER BY ROLE, TABLE_NAME ASC;

The following example creates a non-master user named user1, grants the CREATE SESSION privilege, and grants the SELECT privilege on a database named sh.sales.

```
CREATE USER user1 IDENTIFIED BY PASSWORD;
GRANT CREATE SESSION TO user1;
GRANT SELECT ON sh.sales TO user1;
```

Creating custom functions to verify passwords

You can create a custom password verification function in the following ways:

- To use standard verification logic, and to store your function in the SYS schema, use the `create_verify_function` procedure.
- To use custom verification logic, or to avoid storing your function in the SYS schema, use the `create_passthrough_verify_fcn` procedure.

**The create_verify_function procedure**

You can create a custom function to verify passwords by using the Amazon RDS procedure `rdsadmin.rdsadmin_password_verify.create_verify_function`. The `create_verify_function` procedure is supported for version 12.1.0.2.v5 and all higher major and minor versions of RDS for Oracle.

The `create_verify_function` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_verify_function_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name for your custom function. This function is created for you in the SYS schema. You assign this function to user profiles.</td>
</tr>
<tr>
<td>p_min_length</td>
<td>number</td>
<td>8</td>
<td>No</td>
<td>The minimum number of characters required.</td>
</tr>
<tr>
<td>p_max_length</td>
<td>number</td>
<td>256</td>
<td>No</td>
<td>The maximum number of characters allowed.</td>
</tr>
<tr>
<td>p_min_letters</td>
<td>number</td>
<td>1</td>
<td>No</td>
<td>The minimum number of letters required.</td>
</tr>
<tr>
<td>p_min_uppercase</td>
<td>number</td>
<td>0</td>
<td>No</td>
<td>The minimum number of uppercase letters required.</td>
</tr>
<tr>
<td>p_min_lowercase</td>
<td>number</td>
<td>0</td>
<td>No</td>
<td>The minimum number of lowercase letters required.</td>
</tr>
<tr>
<td>p_min_digits</td>
<td>number</td>
<td>1</td>
<td>No</td>
<td>The minimum number of digits required.</td>
</tr>
<tr>
<td>p_min_special</td>
<td>number</td>
<td>0</td>
<td>No</td>
<td>The minimum number of special characters required.</td>
</tr>
</tbody>
</table>
### Parameter name | Data type | Default | Required | Description
--- | --- | --- | --- | ---
p_min_different_chars | number | 3 | No | The minimum number of different characters required between the old and new password.
p_disallow_username | boolean | true | No | Set to true to disallow the user name in the password.
p_disallow_reverse | boolean | true | No | Set to true to disallow the reverse of the user name in the password.
p_disallow_db_name | boolean | true | No | Set to true to disallow the database or server name in the password.
p_disallow_simple_strings | boolean | true | No | Set to true to disallow simple strings as the password.
p_disallow_whitespace | boolean | false | No | Set to true to disallow white space characters in the password.
p_disallow_at_sign | boolean | false | No | Set to true to disallow the @ character in the password.

You can create multiple password verification functions.

There are restrictions on the name of your custom function. Your custom function can't have the same name as an existing system object. The name can be no more than 30 characters long. Also, the name must include one of the following strings: PASSWORD, VERIFY, COMPLEXITY, ENFORCE, or STRENGTH.

The following example creates a function named `CUSTOM_PASSWORD_FUNCTION`. The function requires that a password has at least 12 characters, 2 uppercase characters, 1 digit, and 1 special character, and that the password disallows the @ character.

```
begin
  rdsadmin.rdsadmin_password_verify.create_verify_function(
    p_verify_function_name => 'CUSTOM_PASSWORD_FUNCTION',
    p_min_length           => 12,
    p_min_uppercase        => 2,
    p_min_digits           => 1,
    p_min_special          => 1,
    p_disallow_at_sign     => true);
end;
/
```

To see the text of your verification function, query DBA_SOURCE. The following example gets the text of a custom password function named `CUSTOM_PASSWORD_FUNCTION`.

```sql
COL TEXT FORMAT a150
SELECT TEXT
  FROM DBA_SOURCE
WHERE OWNER = 'SYS'
```
To associate your verification function with a user profile, use `alter profile`. The following example associates a verification function with the `DEFAULT` user profile.

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_VERIFY_FUNCTION CUSTOM_PASSWORD_FUNCTION;
```

To see what user profiles are associated with what verification functions, query `DBA_PROFILES`. The following example gets the profiles that are associated with the custom verification function named `CUSTOM_PASSWORD_FUNCTION`.

```
SELECT * FROM DBA_PROFILES WHERE RESOURCE_NAME = 'PASSWORD' AND LIMIT = 'CUSTOM_PASSWORD_FUNCTION';
```

```
PROFILE                    RESOURCE_NAME                     RESOURCE  LIMIT
-------------------------  --------------------------------  --------
DEFAULT                    PASSWORD_VERIFY_FUNCTION          PASSWORD
CUSTOM_PASSWORD_FUNCTION
```

The following example gets all profiles and the password verification functions that they are associated with.

```
SELECT * FROM DBA_PROFILES WHERE RESOURCE_NAME = 'PASSWORD_VERIFY_FUNCTION';
```

```
PROFILE                    RESOURCE_NAME                     RESOURCE  LIMIT
-------------------------  --------------------------------  --------
DEFAULT                    PASSWORD_VERIFY_FUNCTION          PASSWORD
CUSTOM_PASSWORD_FUNCTION
RDSADMIN                   PASSWORD_VERIFY_FUNCTION          PASSWORD  NULL
```

**The create_passthrough_verify_fcn procedure**

The `create_passthrough_verify_fcn` procedure is supported for version 12.1.0.2.v7 and all higher major and minor versions of RDS for Oracle.

You can create a custom function to verify passwords by using the Amazon RDS procedure `rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn`. The `create_passthrough_verify_fcn` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_verify_function_name</code></td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name for your custom verification function. This is a wrapper function that is created for you in the SYS schema, and it doesn't contain any verification logic. You assign this function to user profiles.</td>
</tr>
<tr>
<td><code>p_target_owner</code></td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The schema owner for your custom verification function.</td>
</tr>
</tbody>
</table>
### System tasks

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_target_function_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of your existing custom function that contains the verification logic. Your custom function must return a boolean. Your function should return <code>true</code> if the password is valid and <code>false</code> if the password is invalid.</td>
</tr>
</tbody>
</table>

The following example creates a password verification function that uses the logic from the function named `PASSWORD_LOGIC_EXTRA_STRONG`.

```sql
begin
   rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn(
      p_verify_function_name => 'CUSTOM_PASSWORD_FUNCTION',
      p_target_owner => 'TEST_USER',
      p_target_function_name => 'PASSWORD_LOGIC_EXTRA_STRONG');
end;
/
```

To associate the verification function with a user profile, use `alter profile`. The following example associates the verification function with the DEFAULT user profile.

```sql
ALTER PROFILE DEFAULT LIMIT PASSWORD_VERIFY_FUNCTION CUSTOM_PASSWORD_FUNCTION;
```

### Setting up a custom DNS server

Amazon RDS supports outbound network access on your DB instances running Oracle. For more information about outbound network access, including prerequisites, see Configuring UTL_HTTP access using certificates and an Oracle wallet (p. 1565).

Amazon RDS Oracle allows Domain Name Service (DNS) resolution from a custom DNS server owned by the customer. You can resolve only fully qualified domain names from your Amazon RDS DB instance through your custom DNS server.

After you set up your custom DNS name server, it takes up to 30 minutes to propagate the changes to your DB instance. After the changes are propagated to your DB instance, all outbound network traffic requiring a DNS lookup queries your DNS server over port 53.

To set up a custom DNS server for your Amazon RDS for Oracle DB instance, do the following:

- From the DHCP options set attached to your virtual private cloud (VPC), set the `domain-name-servers` option to the IP address of your DNS name server. For more information, see DHCP options sets.

  **Note**
  The `domain-name-servers` option accepts up to four values, but your Amazon RDS DB instance uses only the first value.

- Ensure that your DNS server can resolve all lookup queries, including public DNS names, Amazon EC2 private DNS names, and customer-specific DNS names. If the outbound network traffic contains any DNS lookups that your DNS server can't handle, your DNS server must have appropriate upstream DNS providers configured.

- Configure your DNS server to produce User Datagram Protocol (UDP) responses of 512 bytes or less.
• Configure your DNS server to produce Transmission Control Protocol (TCP) responses of 1024 bytes or less.

• Configure your DNS server to allow inbound traffic from your Amazon RDS DB instances over port 53. If your DNS server is in an Amazon VPC, the VPC must have a security group that contains inbound rules that permit UDP and TCP traffic on port 53. If your DNS server is not in an Amazon VPC, it must have appropriate firewall allow-listing to permit UDP and TCP inbound traffic on port 53.

For more information, see Security groups for your VPC and Adding and removing rules.

• Configure the VPC of your Amazon RDS DB instance to allow outbound traffic over port 53. Your VPC must have a security group that contains outbound rules that allow UDP and TCP traffic on port 53.

For more information, see Security groups for your VPC and Adding and removing rules.

• The routing path between the Amazon RDS DB instance and the DNS server has to be configured correctly to allow DNS traffic.

• If the Amazon RDS DB instance and the DNS server are not in the same VPC, a peering connection has to be set up between them. For more information, see What is VPC peering?

Setting and unsetting system diagnostic events

To set and unset diagnostic events at the session level, you can use the Oracle SQL statement ALTER SESSION SET EVENTS. However, to set events at the system level you can't use Oracle SQL. Instead, use the system event procedures in the rdsadmin.rdsadmin_util package. The system event procedures are available in the following engine versions:

• All Oracle Database 21c versions
• 19.0.0.0.ru-2020-10.rur-2020-10.r1 and higher Oracle Database 19c versions

For more information, see Version 19.0.0.0.ru-2020-10.rur-2020-10.r1 in the Amazon RDS for Oracle Release Notes.

• 12.2.0.1.ru-2020-10.rur-2020-10.r1 and higher Oracle Database 12c Release 2 (12.2.0.1) versions

For more information, see Version 12.2.0.1.ru-2020-10.rur-2020-10.r1 in the Amazon RDS for Oracle Release Notes.

• 12.1.0.2.V22 and higher Oracle Database 12c Release 1 (12.1.0.2) versions

For more information, see Version 12.1.0.2.v22 in the Amazon RDS for Oracle Release Notes.

Important

Internally, the rdsadmin.rdsadmin_util package sets events by using the ALTER SYSTEM SET EVENTS statement. This ALTER SYSTEM statement isn't documented in the Oracle Database documentation. Some system diagnostic events can generate large amounts of tracing information, cause contention, or affect database availability. We recommend that you test specific diagnostic events in your nonproduction database, and only set events in your production database under guidance of Oracle Support.

Listing allowed system diagnostic events

To list the system events that you can set, use the Amazon RDS procedure rdsadmin.rdsadmin_util.list_allowed_system_events. This procedure accepts no parameters.

The following example lists all system events that you can set.

```sql
SET SERVEROUTPUT ON
```
EXEC rdsadmin.rdsadmin_util.list_allowed_system_events;

The following sample output lists event numbers and their descriptions. Use the Amazon RDS procedures `set_system_event` to set these events and `unset_system_event` to unset them.

<table>
<thead>
<tr>
<th>Event Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>604</td>
<td>- error occurred at recursive SQL level</td>
</tr>
<tr>
<td>942</td>
<td>- table or view does not exist</td>
</tr>
<tr>
<td>1401</td>
<td>- inserted value too large for column</td>
</tr>
<tr>
<td>1403</td>
<td>- no data found</td>
</tr>
<tr>
<td>1410</td>
<td>- invalid ROWID</td>
</tr>
<tr>
<td>1422</td>
<td>- exact fetch returns more than requested number of rows</td>
</tr>
<tr>
<td>1426</td>
<td>- numeric overflow</td>
</tr>
<tr>
<td>1427</td>
<td>- single-row subquery returns more than one row</td>
</tr>
<tr>
<td>1476</td>
<td>- divisor is equal to zero</td>
</tr>
<tr>
<td>1483</td>
<td>- invalid length for DATE or NUMBER bind variable</td>
</tr>
<tr>
<td>1489</td>
<td>- result of string concatenation is too long</td>
</tr>
<tr>
<td>1562</td>
<td>- unable to extend temp segment by in tablespace</td>
</tr>
<tr>
<td>1585</td>
<td>- a non-numeric character was found where a numeric was expected</td>
</tr>
<tr>
<td>4031</td>
<td>- unable to allocate bytes of shared memory (&quot;,&quot;&quot;,&quot;&quot;,&quot;&quot;&quot;)</td>
</tr>
<tr>
<td>6592</td>
<td>- PL/SQL: numeric or value error</td>
</tr>
<tr>
<td>10027</td>
<td>- Specify Deadlock Trace Information to be Dumped</td>
</tr>
<tr>
<td>10046</td>
<td>- enable SQL statement timing</td>
</tr>
<tr>
<td>10053</td>
<td>- CBO Enable optimizer trace</td>
</tr>
<tr>
<td>10173</td>
<td>- Dynamic Sampling time-out error</td>
</tr>
<tr>
<td>10442</td>
<td>- enable trace of kst for ORA-01555 diagnostics</td>
</tr>
<tr>
<td>12008</td>
<td>- error in materialized view refresh path</td>
</tr>
<tr>
<td>12012</td>
<td>- error on auto execute of job</td>
</tr>
<tr>
<td>12504</td>
<td>- TNS:listener was not given the SERVICE_NAME in CONNECT_DATA</td>
</tr>
<tr>
<td>14400</td>
<td>- inserted partition key does not map to any partition</td>
</tr>
<tr>
<td>51693</td>
<td>- Table data object failed to load/unload and is being skipped due to error:</td>
</tr>
</tbody>
</table>

**Note**

The list of the allowed system events can change over time. To make sure that you have the most recent list of eligible events, use `rdsadmin.rdsadmin_util.list_allowed_system_events`.

### Setting system diagnostic events

To set a system event, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.set_system_event`. You can only set events listed in the output of `rdsadmin.rdsadmin_util.list_allowed_system_events`. The `set_system_event` procedure accepts the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_event</code></td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The system event number. The value must be one of the event numbers reported by <code>list_allowed_system_events</code>.</td>
</tr>
<tr>
<td><code>p_level</code></td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The event level. See the Oracle Database documentation or Oracle Support for descriptions of different level values.</td>
</tr>
</tbody>
</table>

The procedure `set_system_event` constructs and runs the required ALTER SYSTEM SET EVENTS statements according to the following principles:
The event type (context or errorstack) is determined automatically.

A statement in the form `ALTER SYSTEM SET EVENTS 'event LEVEL event_level'` sets the context events. This notation is equivalent to `ALTER SYSTEM SET EVENTS 'event TRACE NAME CONTEXT FOREVER, LEVEL event_level'`.

A statement in the form `ALTER SYSTEM SET EVENTS 'event ERRORSTACK (event_level)'` sets the error stack events. This notation is equivalent to `ALTER SYSTEM SET EVENTS 'event TRACE NAME ERRORSTACK LEVEL event_level'`.

The following example sets event 942 at level 3, and event 10442 at level 10. Sample output is included.

```sql
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.set_system_event(942,3);
Setting system event 942 with: alter system set events '942 errorstack (3)'
PL/SQL procedure successfully completed.

SQL> EXEC rdsadmin.rdsadmin_util.set_system_event(10442,10);
Setting system event 10442 with: alter system set events '10442 level 10'
PL/SQL procedure successfully completed.
```

### Listing system diagnostic events that are set

To list the system events that are currently set, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.list_set_system_events`. This procedure reports only events set at system level by `set_system_event`.

The following example lists the active system events.

```sql
SET SERVEROUTPUT ON
EXEC rdsadmin.rdsadmin_util.list_set_system_events;
```

The following sample output shows the list of events, the event type, the level at which the events are currently set, and the time when the event was set.

```
942 errorstack (3) - set at 2020-11-03 11:42:27
10442 level 10 - set at 2020-11-03 11:42:41
PL/SQL procedure successfully completed.
```

### Unsetting system diagnostic events

To unset a system event, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.unset_system_event`. You can only unset events listed in the output of `rdsadmin.rdsadmin_util.list_allowed_system_events`. The `unset_system_event` procedure accepts the following parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_event</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The system event number. The value must be one of the event numbers reported by <code>list_allowed_system_events</code>.</td>
</tr>
</tbody>
</table>
The following example unsets events 942 and 10442. Sample output is included.

SQL> SET SERVEROUTPUT ON
 SQL> EXEC rdsadmin.rdsadmin_util.unset_system_event(942);
 Unsetting system event 942 with: alter system set events '942 off'
 PL/SQL procedure successfully completed.

SQL> EXEC rdsadmin.rdsadmin_util.unset_system_event(10442);
 Unsetting system event 10442 with: alter system set events '10442 off'
 PL/SQL procedure successfully completed.

Performing common database tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to databases on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Amazon RDS also restricts access to some system procedures and tables that require advanced privileges.

Topics

- Changing the global name of a database (p. 1595)
- Creating and sizing tablespaces (p. 1596)
- Setting the default tablespace (p. 1596)
- Setting the default temporary tablespace (p. 1597)
- Creating a temporary tablespace on the instance store (p. 1597)
- Adding a tempfile to the instance store on a read replica (p. 1597)
- Dropping tempfiles on a read replica (p. 1598)
- Checkpointing a database (p. 1599)
- Setting distributed recovery (p. 1599)
- Setting the database time zone (p. 1599)
- Working with Oracle external tables (p. 1600)
- Generating performance reports with Automatic Workload Repository (AWR) (p. 1601)
- Adjusting database links for use with DB instances in a VPC (p. 1605)
- Setting the default edition for a DB instance (p. 1605)
- Enabling auditing for the SYS.AUD$ table (p. 1605)
- Disabling auditing for the SYS.AUD$ table (p. 1606)
- Cleaning up interrupted online index builds (p. 1606)
- Skipping corrupt blocks (p. 1607)
- Resizing the temporary tablespace in a read replica (p. 1609)
- Purging the recycle bin (p. 1610)
- Setting the Data Redaction policy for full redaction (p. 1610)

Changing the global name of a database

To change the global name of a database, use the Amazon RDS procedure rdsadmin.rdsadmin_util.rename_global_name. The rename_global_name procedure has the following parameters.
Amazon Relational Database Service User Guide
Database tasks

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_new_global_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The new global name for the database.</td>
</tr>
</tbody>
</table>

The database must be open for the name change to occur. For more information about changing the global name of a database, see ALTER DATABASE in the Oracle documentation.

The following example changes the global name of a database to new_global_name.

EXEC rdsadmin.rdsadmin_util.rename_global_name(p_new_global_name => 'new_global_name');

---

Creating and sizing tablespaces

Amazon RDS only supports Oracle Managed Files (OMF) for data files, log files, and control files. When you create data files and log files, you can't specify the physical file names.

By default, tablespaces are created with auto-extend enabled, and no maximum size. Because of these default settings, tablespaces can grow to consume all allocated storage. We recommend that you specify an appropriate maximum size on permanent and temporary tablespaces, and that you carefully monitor space usage.

The following example creates a tablespace named users2 with a starting size of 1 gigabyte and a maximum size of 10 gigabytes:

CREATE TABLESPACE users2 DATAFILE SIZE 1G AUTOEXTEND ON MAXSIZE 10G;

The following example creates temporary tablespace named temp01:

CREATE TEMPORARY TABLESPACE temp01;

We recommend that you don't use smallfile tablespaces because you can't resize smallfile tablespaces with Amazon RDS for Oracle. However, you can add a datafile to a smallfile tablespace.

You can resize a bigfile tablespace by using ALTER TABLESPACE. You can specify the size in kilobytes (K), megabytes (M), gigabytes (G), or terabytes (T).

The following example resizes a bigfile tablespace named users2 to 200 MB.

ALTER TABLESPACE users2 RESIZE 200M;

The following example adds an additional datafile to a smallfile tablespace named users2.

ALTER TABLESPACE users2 ADD DATAFILE SIZE 100000M AUTOEXTEND ON NEXT 250m MAXSIZE UNLIMITED;

---

Setting the default tablescape

To set the default tablespace, use the Amazon RDS procedure rdsadmin.rdsadmin_util.alter_default_tablespace. The alter_default_tablespace procedure has the following parameters.
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tablespace_name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the default tablespace.</td>
</tr>
</tbody>
</table>

The following example sets the default tablespace to users2:

```sql
EXEC rdsadmin.rdsadmin_util.alter_default_tablespace(tablespace_name => 'users2');
```

### Setting the default temporary tablespace

To set the default temporary tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_temp_tablespace`. The `alter_default_temp_tablespace` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tablespace_name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the default temporary tablespace.</td>
</tr>
</tbody>
</table>

The following example sets the default temporary tablespace to temp01:

```sql
EXEC rdsadmin.rdsadmin_util.alter_default_temp_tablespace(tablespace_name => 'temp01');
```

### Creating a temporary tablespace on the instance store

To create a temporary tablespace on the instance store, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace`. The `create_inst_store_tmp_tblspace` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tablespace_name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the temporary tablespace.</td>
</tr>
</tbody>
</table>

The following example creates the temporary tablespace temp01 in the instance store.

```sql
EXEC rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace(p_tablespace_name => 'temp01');
```

**Important**

When you run `rdsadmin_util.create_inst_store_tmp_tblspace`, the newly created temporary tablespace is not automatically set as the default temporary tablespace. To set it as the default, see [Setting the default temporary tablespace](p. 1597).

For more information, see [Storing temporary data in an RDS for Oracle instance store](p. 1656).

### Adding a tempfile to the instance store on a read replica

When you create a temporary tablespace on a primary DB instance, the read replica doesn't create tempfiles. Assume that an empty temporary tablespace exists on your read replica for either of the following reasons:
You dropped a tempfile from the tablespace on your read replica. For more information, see Dropping tempfiles on a read replica (p. 1598).

You created a new temporary tablespace on the primary DB instance. In this case, RDS for Oracle synchronizes the metadata to the read replica.

You can add a tempfile to the empty temporary tablespace, and store the tempfile in the instance store. To create a tempfile in the instance store, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_inst_store_tempfile`. You can use this procedure only on a read replica. The procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_tablespace_name</code></td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the temporary tablespace on your read replica.</td>
</tr>
</tbody>
</table>

In the following example, the empty temporary tablespace `temp01` exists on your read replica. Run the following command to create a tempfile for this tablespace, and store it in the instance store.

```sql
EXEC rdsadmin.rdsadmin_util.add_inst_store_tempfile(p_tablespace_name => 'temp01');
```

For more information, see Storing temporary data in an RDS for Oracle instance store (p. 1656).

**Dropping tempfiles on a read replica**

You can't drop an existing temporary tablespace on a read replica. You can change the tempfile storage on a read replica from Amazon EBS to the instance store, or from the instance store to Amazon EBS. To achieve these goals, do the following:

1. Drop the current tempfiles in the temporary tablespace on the read replica.
2. Create new tempfiles on different storage.

To drop the tempfiles, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_replica_tempfiles`. You can use this procedure only on read replicas. The `drop_replica_tempfiles` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_tablespace_name</code></td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the temporary tablespace on your read replica.</td>
</tr>
</tbody>
</table>

Assume that a temporary tablespace named `temp01` resides in the instance store on your read replica. Drop all tempfiles in this tablespace by running the following command.

```sql
EXEC rdsadmin.rdsadmin_util.drop_replica_tempfiles(p_tablespace_name => 'temp01');
```

For more information, see Storing temporary data in an RDS for Oracle instance store (p. 1656).
Checkpointing a database

To checkpoint the database, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.checkpoint`. The checkpoint procedure has no parameters.

The following example checkpoints the database.

```
EXEC rdsadmin.rdsadmin_util.checkpoint;
```

Setting distributed recovery

To set distributed recovery, use the Amazon RDS procedures `rdsadmin.rdsadmin_util.enable_distr_recovery` and `disable_distr_recovery`. The procedures have no parameters.

The following example enables distributed recovery.

```
EXEC rdsadmin.rdsadmin_util.enable_distr_recovery;
```

The following example disables distributed recovery.

```
EXEC rdsadmin.rdsadmin_util.disable_distr_recovery;
```

Setting the database time zone

You can set the time zone of your Amazon RDS Oracle database in the following ways:

- The Timezone option

  The Timezone option changes the time zone at the host level and affects all date columns and values such as `SYSDATE`. For more information, see Oracle time zone (p. 1794).

- The Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_db_time_zone`

  The `alter_db_time_zone` procedure changes the time zone for only certain data types, and doesn't change `SYSDATE`. There are additional restrictions on setting the time zone listed in the Oracle documentation.

  **Note**

  You can also set the default time zone for Oracle Scheduler. For more information, see Setting the time zone for Oracle Scheduler jobs (p. 1639).

The `alter_db_time_zone` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_new_tz</code></td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The new time zone as a named region or an absolute offset from Coordinated Universal Time (UTC). Valid offsets range from -12:00 to +14:00.</td>
</tr>
</tbody>
</table>

The following example changes the time zone to UTC plus three hours.
EXEC rdsadmin.rdsadmin_util.alter_db_time_zone(p_new_tz => '+3:00');

The following example changes the time zone to the Africa/Algiers time zone.

EXEC rdsadmin.rdsadmin_util.alter_db_time_zone(p_new_tz => 'Africa/Algiers');

After you alter the time zone by using the alter_db_time_zone procedure, reboot your DB instance for the change to take effect. For more information, see Rebooting a DB instance (p. 378). For information about upgrading time zones, see Time zone considerations (p. 1814).

Working with Oracle external tables

Oracle external tables are tables with data that is not in the database. Instead, the data is in external files that the database can access. By using external tables, you can access data without loading it into the database. For more information about external tables, see Managing external tables in the Oracle documentation.

With Amazon RDS, you can store external table files in directory objects. You can create a directory object, or you can use one that is predefined in the Oracle database, such as the DATA_PUMP_DIR directory. For information about creating directory objects, see Creating and dropping directories in the main data storage space (p. 1649). You can query the ALL_DIRECTORIES view to list the directory objects for your Amazon RDS Oracle DB instance.

Note
Directory objects point to the main data storage space (Amazon EBS volume) used by your instance. The space used—along with data files, redo logs, audit, trace, and other files—counts against allocated storage.

You can move an external data file from one Oracle database to another by using the DBMS_FILE_TRANSFER package or the UTL_FILE package. The external data file is moved from a directory on the source database to the specified directory on the destination database. For information about using DBMS_FILE_TRANSFER, see Importing using Oracle Data Pump (p. 1668).

After you move the external data file, you can create an external table with it. The following example creates an external table that uses the emp_xt_file1.txt file in the USER_DIR1 directory.

```
CREATE TABLE emp_xt (  
  emp_id NUMBER,  
  first_name VARCHAR2(50),  
  last_name VARCHAR2(50),  
  user_name VARCHAR2(20)  
)  
ORGANIZATION EXTERNAL (  
  TYPE ORACLE_LOADER  
  DEFAULT DIRECTORY USER_DIR1  
  ACCESS PARAMETERS (  
    RECORDS DELIMITED BY NEWLINE  
    FIELDS TERMINATED BY ','  
    MISSING FIELD VALUES ARE NULL  
    (emp_id,first_name,last_name,user_name)  
  )  
  LOCATION ('emp_xt_file1.txt')  
)  
PARALLEL  
REJECT LIMIT UNLIMITED;
```

Suppose that you want to move data that is in an Amazon RDS Oracle DB instance into an external data file. In this case, you can populate the external data file by creating an external table and selecting the
data from the table in the database. For example, the following SQL statement creates the `orders_xt` external table by querying the `orders` table in the database.

```sql
CREATE TABLE orders_xt
ORGANIZATION EXTERNAL
(
    TYPE ORACLE_DATAPUMP
    DEFAULT DIRECTORY DATA_PUMP_DIR
    LOCATION ('orders_xt.dmp')
)
AS SELECT * FROM orders;
```

In this example, the data is populated in the `orders_xt.dmp` file in the `DATA_PUMP_DIR` directory.

### Generating performance reports with Automatic Workload Repository (AWR)

To gather performance data and generate reports, Oracle recommends Automatic Workload Repository (AWR). AWR requires Oracle Database Enterprise Edition and a license for the Diagnostics and Tuning packs. To enable AWR, set the `CONTROL_MANAGEMENT_PACK_ACCESS` initialization parameter to either `DIAGNOSTIC` or `DIAGNOSTIC+TUNING`.

### Working with AWR reports in RDS

To generate AWR reports, you can run scripts such as `awrrpt.sql`. These scripts are installed on the database host server. In Amazon RDS, you don't have direct access to the host. However, you can get copies of SQL scripts from another installation of Oracle Database.

You can also use AWR by running procedures in the `SYS.DBMS_WORKLOAD_REPOSITORY` PL/SQL package. You can use this package to manage baselines and snapshots, and also to display ASH and AWR reports. For example, to generate an AWR report in text format run the `DBMS_WORKLOAD_REPOSITORY.AWR_REPORT_TEXT` procedure. However, you can't reach these AWR reports from the AWS Management Console.

When working with AWR, we recommend using the `rdsadmin.rdsadmin_diagnostic_util` procedures. You can use these procedures to generate the following:

- AWR reports
- Active Session History (ASH) reports
- Automatic Database Diagnostic Monitor (ADDM) reports
- Oracle Data Pump Export dump files of AWR data

The `rdsadmin_diagnostic_util` procedures save the reports to the DB instance file system. You can access these reports from the console. You can also access reports using the `rdsadmin.rds_file_util` procedures, and you can access reports that are copied to Amazon S3 using the S3 Integration option. For more information, see `Reading files in a DB instance directory (p. 1650)` and `Amazon S3 integration (p. 1700)`.

You can use the `rdsadmin_diagnostic_util` procedures in the following Amazon RDS for Oracle DB engine versions:

- All Oracle Database 21c versions
- 19.0.0.0.ru-2020-04.rur-2020-04.r1 and higher Oracle Database 19c versions
- 12.2.0.1.ru-2020-04.rur-2020-04.r1 and higher Oracle Database 12c Release 2 (12.2) versions
- 12.1.0.2.v20 and higher Oracle Database 12c Release 1 (12.1) versions
## Common parameters for the diagnostic utility package

You typically use the following parameters when managing AWR and ADDM with the `rdsadmin_diagnostic_util` package.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>begin_snap_id</td>
<td>NUMBER</td>
<td>—</td>
<td>Yes</td>
<td>The ID of the beginning snapshot.</td>
</tr>
<tr>
<td>end_snap_id</td>
<td>NUMBER</td>
<td>—</td>
<td>Yes</td>
<td>The ID of the ending snapshot.</td>
</tr>
<tr>
<td>dump_directory</td>
<td>VARCHAR2</td>
<td>BDUMP</td>
<td>No</td>
<td>The directory to write the report or export file to. If you specify a nondefault directory, the user that runs the <code>rdsadmin_diagnostic_util</code> procedures must have write permissions for the directory.</td>
</tr>
<tr>
<td>p_tag</td>
<td>VARCHAR2</td>
<td>—</td>
<td>No</td>
<td>A string that can be used to distinguish between backups to indicate the purpose or usage of backups, such as incremental or daily. You can specify up to 30 characters. Valid characters are a-z, A-Z, 0-9, an underscore (_), a dash (-), and a period (.). The tag is not case-sensitive. RMAN always stores tags in uppercase, regardless of the case used when entering them. Tags don't need to be unique, so multiple backups can have the same tag. If you don't specify a tag, RMAN assigns a default tag automatically using the format TAGYYYYMMDDTHHMMSS, where YYYY is the year, MM is the month, DD is the day, HH is the hour (in 24-hour format), MM is the minutes, and SS is the seconds. The date and time indicate when RMAN started the backup. For example, a backup with the default tag TAG20190927T214517 indicates a backup that started on 2019-09-27 at 21:45:17. The p_tag parameter is supported for the following RDS for Oracle DB engine versions: • Oracle Database 21c (21.0.0) • Oracle Database 19c (19.0.0), using 19.0.0.0.ru-2021-10.rur-2021-10.r1 and higher • Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2021-10.rur-2021-10.r1 and higher • Oracle Database 12c Release 1 (12.1), using 12.1.0.2.V26 and higher</td>
</tr>
<tr>
<td>report_type</td>
<td>VARCHAR2</td>
<td>HTML</td>
<td>No</td>
<td>The format of the report. Valid values are TEXT and HTML.</td>
</tr>
<tr>
<td>dbid</td>
<td>NUMBER</td>
<td>—</td>
<td>No</td>
<td>A valid database identifier (DBID) shown in the DBA_HIST_DATABASE_INSTANCE view for Oracle. If this parameter is not specified, RDS uses the current DBID, which is shown in the V$DATABASE.DBID view.</td>
</tr>
</tbody>
</table>

You typically use the following parameters when managing ASH with the `rdsadmin_diagnostic_util` package.
### Generating an AWR report

To generate an AWR report, use the `rdsadmin.rdsadmin_diagnostic_util.awr_report` procedure.

The following example generates a AWR report for the snapshot range 101–106. The output text file is named `awrrpt_101_106.txt`. You can access this report from the AWS Management Console.

```sql
exec rdsadmin.rdsadmin_diagnostic_util.awr_report(101,106,'TEXT');
```

The following example generates an HTML report for the snapshot range 63–65. The output HTML file is named `awrrpt_63_65.html`. The procedure writes the report to the nondefault database directory named `AWR_RPT_DUMP`.

```sql
exec rdsadmin.rdsadmin_diagnostic_util.awr_report(63,65,'HTML','AWR_RPT_DUMP');
```

### Extracting AWR data into a dump file

To extract AWR data into a dump file, use the `rdsadmin.rdsadmin_diagnostic_util.awr_extract` procedure.

The following example extracts the snapshot range 101–106. The output dump file is named `awrextract_101_106.dmp`. You can access this file through the console.

```sql
exec rdsadmin.rdsadmin_diagnostic_util.awr_extract(101,106);
```

The following example extracts the snapshot range 63–65. The output dump file is named `awrextract_63_65.dmp`. The file is stored in the nondefault database directory named `AWR_RPT_DUMP`. 

---

**Parameter** | **Data type** | **Default** | **Required** | **Description**
--- | --- | --- | --- | ---
`begin_time` | DATE | — | Yes | The beginning time of the ASH analysis.
`end_time` | DATE | — | Yes | The ending time of the ASH analysis.
`slot_width` | NUMBER | 0 | No | The duration of the slots (in seconds) used in the "Top Activity" section of the ASH report. If this parameter isn't specified, the time interval between `begin_time` and `end_time` uses no more than 10 slots.
`sid` | NUMBER | Null | No | The session ID.
`sql_id` | VARCHAR2 | Null | No | The SQL ID.
`wait_class` | VARCHAR2 | Null | No | The wait class name.
`service_hash` | NUMBER | Null | No | The service name hash.
`module_name` | VARCHAR2 | Null | No | The module name.
`action_name` | VARCHAR2 | Null | No | The action name.
`client_id` | VARCHAR2 | Null | No | The application-specific ID of the database session.
`plsql_entry` | VARCHAR2 | Null | No | The PL/SQL entry point.
Generating an ADDM report

To generate an ADDM report, use the `rdsadmin.rdsadmin_diagnostic_util.addm_report` procedure.

The following example generates an ADDM report for the snapshot range 101–106. The output text file is named `addmrpt_101_106.txt`. You can access the report through the console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.addm_report(101,106);
```

The following example generates an ADDM report for the snapshot range 63–65. The output text file is named `addmrpt_63_65.txt`. The file is stored in the nondefault database directory named `ADDM_RPT_DUMP`.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.addm_report(63,65,'ADDM_RPT_DUMP');
```

Generating an ASH report

To generate an ASH report, use the `rdsadmin.rdsadmin_diagnostic_util.ash_report` procedure.

The following example generates an ASH report that includes the data from 14 minutes ago until the current time. The name of the output file uses the format `ashrpt_begin_timeend_time.txt`, where `begin_time` and `end_time` use the format `YYYYMMDDHH24MISS`. You can access the file through the console.

```
BEGIN
    rdsadmin.rdsadmin_diagnostic_util.ash_report(
        begin_time     =>     SYSDATE-14/1440,
        end_time       =>     SYSDATE,
        report_type    =>     'TEXT');
END;
/
```

The following example generates an ASH report that includes the data from November 18, 2019, at 6:07 PM through November 18, 2019, at 6:15 PM. The name of the output HTML report is `ashrpt_20190918180700_20190918181500.html`. The report is stored in the nondefault database directory named `AWR_RPT_DUMP`.

```
BEGIN
    rdsadmin.rdsadmin_diagnostic_util.ash_report(
        begin_time     =>    TO_DATE('2019-09-18 18:07:00', 'YYYY-MM-DD HH24:MI:SS'),
        end_time       =>    TO_DATE('2019-09-18 18:15:00', 'YYYY-MM-DD HH24:MI:SS'),
        report_type    =>    'html',
        dump_directory =>    'AWR_RPT_DUMP');
END;
/
```

Accessing AWR reports from the console or CLI

To access AWR reports or export dump files, you can use the AWS Management Console or AWS CLI. For more information, see Downloading a database log file (p. 717).
Adjusting database links for use with DB instances in a VPC

To use Oracle database links with Amazon RDS DB instances inside the same virtual private cloud (VPC) or peered VPCs, the two DB instances should have a valid route between them. Verify the valid route between the DB instances by using your VPC routing tables and network access control list (ACL).

The security group of each DB instance must allow ingress to and egress from the other DB instance. The inbound and outbound rules can refer to security groups from the same VPC or a peered VPC. For more information, see Updating your security groups to reference peered VPC security groups.

If you have configured a custom DNS server using the DHCP Option Sets in your VPC, your custom DNS server must be able to resolve the name of the database link target. For more information, see Setting up a custom DNS server (p. 1591).

For more information about using database links with Oracle Data Pump, see Importing using Oracle Data Pump (p. 1668).

Setting the default edition for a DB instance

You can redefine database objects in a private environment called an edition. You can use edition-based redefinition to upgrade an application's database objects with minimal downtime.

You can set the default edition of an Amazon RDS Oracle DB instance using the Amazon RDS procedure rdsadmin.rdsadmin_util.alter_default_edition.

The following example sets the default edition for the Amazon RDS Oracle DB instance to RELEASE_V1.

EXEC rdsadmin.rdsadmin_util.alter_default_edition('RELEASE_V1');

The following example sets the default edition for the Amazon RDS Oracle DB instance back to the Oracle default.

EXEC rdsadmin.rdsadmin_util.alter_default_edition('ORA$BASE');

For more information about Oracle edition-based redefinition, see About editions and edition-based redefinition in the Oracle documentation.

Enabling auditing for the SYS.AUD$ table

To enable auditing on the database audit trail table SYS.AUD$, use the Amazon RDS procedure rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table. The only supported audit property is ALL. You can't audit or not audit individual statements or operations.

Enabling auditing is supported for Oracle DB instances running the following versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1.0.2.v14) and later

The audit_all_sys_aud_table procedure has the following parameters.
Parameter name | Data type | Default | Required | Description
---|---|---|---|---
p_by_access | boolean | true | No | Set to true to audit BY ACCESS. Set to false to audit BY SESSION.

**Note**
In a single-tenant CDB, the following operations work, but no customer-visible mechanism can detect the current status of the operations. Auditing information isn't available from within the PDB. For more information, see [Limitations of a single-tenant CDB](p. 1539).

The following query returns the current audit configuration for SYS.AUD$ for a database.

```
SELECT * FROM DBA_OBJ_AUDIT_OPTS WHERE OWNER='SYS' AND OBJECT_NAME='AUD$';
```

The following commands enable audit of ALL on SYS.AUD$ BY ACCESS.

```
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table;
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table(p_by_access => true);
```

The following command enables audit of ALL on SYS.AUD$ BY SESSION.

```
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table(p_by_access => false);
```

For more information, see [AUDIT (traditional auditing)] in the Oracle documentation.

### Disabling auditing for the SYS.AUD$ table

To disable auditing on the database audit trail table SYS.AUD$, use the Amazon RDS procedure `rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table`. This procedure takes no parameters.

The following query returns the current audit configuration for SYS.AUD$ for a database:

```
SELECT * FROM DBA_OBJ_AUDIT_OPTS WHERE OWNER='SYS' AND OBJECT_NAME='AUD$';
```

The following command disables audit of ALL on SYS.AUD$.

```
EXEC rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table;
```

For more information, see [NOAUDIT (traditional auditing)] in the Oracle documentation.

### Cleaning up interrupted online index builds

To clean up failed online index builds, use the Amazon RDS procedure `rdsadmin.rdsadmin_dbms_repair.online_index_clean`.

The `online_index_clean` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_id</td>
<td>binary_integer</td>
<td>ALL_INDEX_ID</td>
<td>No</td>
<td>The object ID of the index. Typically, you can use</td>
</tr>
</tbody>
</table>
### Parameter name

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait_for_lock</td>
<td>binary_integer</td>
<td>rdsadmin.rdsadmin_dbms_repair.lock_wait</td>
<td>No</td>
<td>Specify rdsadmin.rdsadmin_dbms_repair.lock_wait, the default, to try to get a lock on the underlying object and retry until an internal limit is reached if the lock fails. Specify rdsadmin.rdsadmin_dbms_repair.lock_nowait to try to get a lock on the underlying object but not retry if the lock fails.</td>
</tr>
</tbody>
</table>

The following example cleans up a failed online index build:

```sql
declare
  is_clean boolean;
begin
  is_clean := rdsadmin.rdsadmin_dbms_repair.online_index_clean(
    object_id => 1234567890,
    wait_for_lock => rdsadmin.rdsadmin_dbms_repair.lock_nowait
  );
end;
/```

For more information, see [ONLINE_INDEX_CLEAN function](https://docs.oracle.com) in the Oracle documentation.

### Skipping corrupt blocks

To skip corrupt blocks during index and table scans, use the rdsadmin.rdsadmin_dbms_repair package.

The following procedures wrap the functionality of the sys.dbms_repair.admin_table procedure and take no parameters:

- rdsadmin.rdsadmin_dbms_repair.create_repair_table
- rdsadmin.rdsadmin_dbms_repair.create_orphan_keys_table
- rdsadmin.rdsadmin_dbms_repair.drop_repair_table
- rdsadmin.rdsadmin_dbms_repair.drop_orphan_keys_table
- rdsadmin.rdsadmin_dbms_repair.purge_repair_table
- rdsadmin.rdsadmin_dbms_repair.purge_orphan_keys_table

The following procedures take the same parameters as their counterparts in the DBMS_REPAIR package for Oracle databases:

- rdsadmin.rdsadmin_dbms_repair.check_object
- rdsadmin.rdsadmin_dbms_repair.dump_orphan_keys
- rdsadmin.rdsadmin_dbms_repair.fix_corrupt_blocks
- rdsadmin.rdsadmin_dbms_repair.rebuild_freelists

1607
Database tasks

• rdsadmin.rdsadmin_dbms_repair.segment.fix_status
• rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks

For more information about handling database corruption, see DBMS_REPAIR in the Oracle documentation.

**Example Responding to corrupt blocks**

This example shows the basic workflow for responding to corrupt blocks. Your steps will depend on the location and nature of your block corruption.

**Important**
Before attempting to repair corrupt blocks, review the DBMS_REPAIR documentation carefully.

**To skip corrupt blocks during index and table scans**

1. Run the following procedures to create repair tables if they don’t already exist.

   ```sql
   EXEC rdsadmin.rdsadmin_dbms_repair.create_repair_table;
   EXEC rdsadmin.rdsadmin_dbms_repair.create_orphan_keys_table;
   ```

2. Run the following procedures to check for existing records and purge them if appropriate.

   ```sql
   SELECT COUNT(*) FROM SYS.REPAIR_TABLE;
   SELECT COUNT(*) FROM SYS.ORPHAN_KEY_TABLE;
   SELECT COUNT(*) FROM SYS.DBA_REPAIR_TABLE;
   SELECT COUNT(*) FROM SYS.DBA_ORPHAN_KEY_TABLE;
   EXEC rdsadmin.rdsadmin_dbms_repair.purge_repair_table;
   EXEC rdsadmin.rdsadmin_dbms_repair.purge_orphan_keys_table;
   ```

3. Run the following procedure to check for corrupt blocks.

   ```sql
   SET SERVEROUTPUT ON
   DECLARE v_num_corrupt INT;
   BEGIN
     v_num_corrupt := 0;
     rdsadmin.rdsadmin_dbms_repair.check_object (
       schema_name => '&corruptionOwner',
       object_name => '&corruptionTable',
       corrupt_count => v_num_corrupt
     );
     dbms_output.put_line('number corrupt: '||to_char(v_num_corrupt));
   END;
   /
   COL CORRUPT_DESCRIPTION FORMAT A30
   COL REPAIR_DESCRIPTION FORMAT A30
   SELECT OBJECT_NAME, BLOCK_ID, CORRUPT_TYPE, MARKED_CORRUPT,
       CORRUPT_DESCRIPTION, REPAIR_DESCRIPTION
   FROM   SYS.REPAIR_TABLE;
   SELECT SKIP_CORRUPT
   FROM   DBA_TABLES
   WHERE  OWNER = '&corruptionOwner'
   AND    TABLE_NAME = '&corruptionTable';
   ```

4. Use the `skip_corrupt_blocks` procedure to enable or disable corruption skipping for affected tables. Depending on the situation, you may also need to extract data to a new table, and then drop the table containing the corrupt block.
Run the following procedure to enable corruption skipping for affected tables.

```
begin
    rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks (  
        schema_name => '&corruptionOwner',   
        object_name => '&corruptionTable',   
        object_type => rdsadmin.rdsadmin_dbms_repair.table_object,   
        flags => rdsadmin.rdsadmin_dbms_repair.skip_flag);
end;
/
select skip_corrupt from dba_tables where owner = '&corruptionOwner' and table_name = '&corruptionTable';
```

Run the following procedure to disable corruption skipping.

```
begin
    rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks (  
        schema_name => '&corruptionOwner',   
        object_name => '&corruptionTable',   
        object_type => rdsadmin.rdsadmin_dbms_repair.table_object,   
        flags => rdsadmin.rdsadmin_dbms_repair.noskip_flag);
end;
/
select skip_corrupt from dba_tables where owner = '&corruptionOwner' and table_name = '&corruptionTable';
```

5. When you have completed all repair work, run the following procedures to drop the repair tables.

```
EXEC rdsadmin.rdsadmin_dbms_repair.drop_repair_table;
EXEC rdsadmin.rdsadmin_dbms_repair.drop_orphan_keys_table;
```

**Resizing the temporary tablespace in a read replica**

By default, Oracle tablespaces are created with auto-extend enabled and no maximum size. Because of these default settings, tablespaces can grow too large in some cases. We recommend that you specify an appropriate maximum size on permanent and temporary tablespaces, and that you carefully monitor space usage.

To resize the temporary space in a read replica for an Oracle DB instance, use either the `rdsadmin.rdsadmin_util.resize_temp_tablespace` or the `rdsadmin.rdsadmin_util.resize_tempfile` Amazon RDS procedure.

The `resize_temp_tablespace` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>temp_tbs</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the temporary tablespace to resize.</td>
</tr>
</tbody>
</table>

The `resize_tempfile` procedure has the following parameters.
Database tasks

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_id</td>
<td>binary_integer</td>
<td>—</td>
<td>Yes</td>
<td>The file identifier of the temporary tablespace to resize.</td>
</tr>
<tr>
<td>size</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>You can specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
</tbody>
</table>

The following examples resize a temporary tablespace named TEMP to the size of 4 gigabytes on a read replica.

EXEC rdsadmin.rdsadmin_util.resize_temp_tablespace('TEMP','4G');

EXEC rdsadmin.rdsadmin_util.resize_temp_tablespace('TEMP','4096000000');

The following example resizes a temporary tablespace based on the tempfile with the file identifier 1 to the size of 2 megabytes on a read replica.

EXEC rdsadmin.rdsadmin_util.resize_tempfile(1,'2M');

For more information about read replicas for Oracle DB instances, see Working with read replicas for Amazon RDS for Oracle (p. 1682).

Purging the recycle bin

When you drop a table, your Oracle database doesn't immediately remove its storage space. The database renames the table and places it and any associated objects in a recycle bin. Purging the recycle bin removes these items and releases their storage space.

To purge the entire recycle bin, use the Amazon RDS procedure rdsadmin.rdsadmin_util.purge_dba_recyclebin. However, this procedure can't purge the recycle bin of SYS and RDSADMIN objects. If you need to purge these objects, contact AWS Support.

The following example purges the entire recycle bin.

EXEC rdsadmin.rdsadmin_util.purge_dba_recyclebin;

Setting the Data Redaction policy for full redaction

To change the default displayed values for a Data Redaction policy for full redaction on your Amazon RDS Oracle instance, use the Amazon RDS procedure rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val.

The dbms_redact_upd_full_rdct_val procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_number_val</td>
<td>number</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NUMBER datatype.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------</td>
<td>-------------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>p_binfloat_val</td>
<td>binary_float</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the BINARY_FLOAT datatype.</td>
</tr>
<tr>
<td>p_bindouble_val</td>
<td>binary_double</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the BINARY_DOUBLE datatype.</td>
</tr>
<tr>
<td>p_char_val</td>
<td>char</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the CHAR datatype.</td>
</tr>
<tr>
<td>p_varchar_val</td>
<td>varchar2</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the VARCHAR2 datatype.</td>
</tr>
<tr>
<td>p_nchar_val</td>
<td>nchar</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NCHAR datatype.</td>
</tr>
<tr>
<td>pnvarchar_val</td>
<td>nvarchar2</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NVARCHAR2 datatype.</td>
</tr>
<tr>
<td>p_date_val</td>
<td>date</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the DATE datatype.</td>
</tr>
<tr>
<td>p_ts_val</td>
<td>timestamp</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the TIMESTAMP datatype.</td>
</tr>
<tr>
<td>p_tswtz_val</td>
<td>timestamp with time zone</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the TIMESTAMP WITH TIME ZONE datatype.</td>
</tr>
<tr>
<td>p_blob_val</td>
<td>blob</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the BLOB datatype.</td>
</tr>
<tr>
<td>p_clob_val</td>
<td>clob</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the CLOB datatype.</td>
</tr>
<tr>
<td>p_nclob_val</td>
<td>nclob</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NCLOB datatype.</td>
</tr>
</tbody>
</table>

The following example changes the default redacted value to * for char datatype:

```sql
EXEC rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val(p_char_val => '*');
```

The following example changes the default redacted values for number, date and char datatypes:

```sql
begin
```
After you alter the default values for full redaction with the `dbms_redact_upd_full_rdct_val` procedure, reboot your DB instance for the change to take effect. For more information, see Rebooting a DB instance (p. 378).

### Performing common log-related tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to logging on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

For more information, see Oracle database log files (p. 745).

#### Topics
- Setting force logging (p. 1612)
- Setting supplemental logging (p. 1613)
- Switching online log files (p. 1613)
- Adding online redo logs (p. 1614)
- Dropping online redo logs (p. 1614)
- Resizing online redo logs (p. 1615)
- Retaining archived redo logs (p. 1616)
- Accessing online and archived redo logs (p. 1618)
- Downloading archived redo logs from Amazon S3 (p. 1618)

### Setting force logging

In force logging mode, Oracle logs all changes to the database except changes in temporary tablespaces and temporary segments (`NOLOGGING` clauses are ignored). For more information, see Specifying FORCE LOGGING mode in the Oracle documentation.

To set force logging, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.force_logging`. The `force_logging` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Yes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_enable</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to put the database in force logging mode, false to remove the database from force logging mode.</td>
</tr>
</tbody>
</table>

The following example puts the database in force logging mode.

```
EXEC rdsadmin.rdsadmin_util.force_logging(p_enable => true);
```
Setting supplemental logging

If you enable supplemental logging, LogMiner has the necessary information to support chained rows and clustered tables. For more information, see Supplemental logging in the Oracle documentation.

Oracle Database doesn’t enable supplemental logging by default. To enable and disable supplemental logging, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_supplemental_logging`. For more information about how Amazon RDS manages the retention of archived redo logs for Oracle DB instances, see Retaining archived redo logs (p. 1616).

The `alter_supplemental_logging` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_action</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>'ADD' to add supplemental logging, 'DROP' to drop supplemental logging.</td>
</tr>
<tr>
<td>p_type</td>
<td>varchar2</td>
<td>null</td>
<td>No</td>
<td>The type of supplemental logging. Valid values are 'ALL', 'FOREIGN KEY', 'PRIMARY KEY', 'UNIQUE', or PROCEDURAL.</td>
</tr>
</tbody>
</table>

The following example enables supplemental logging.

```
begin
    rdsadmin.rdsadmin_util.alter_supplemental_logging(
        p_action => 'ADD');
end;
/
```

The following example enables supplemental logging for all fixed-length maximum size columns.

```
begin
    rdsadmin.rdsadmin_util.alter_supplemental_logging(
        p_action => 'ADD',
        p_type   => 'ALL');
end;
/
```

The following example enables supplemental logging for primary key columns.

```
begin
    rdsadmin.rdsadmin_util.alter_supplemental_logging(
        p_action => 'ADD',
        p_type   => 'PRIMARY KEY');
end;
/
```

Switching online log files

To switch log files, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.switch_logfile`. The `switch_logfile` procedure has no parameters.
The following example switches log files.

```sql
EXEC rdsadmin.rdsadmin_util.switch_logfile;
```

## Adding online redo logs

An Amazon RDS DB instance running Oracle starts with four online redo logs, 128 MB each. To add additional redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_logfile`.

The `add_logfile` procedure has the following parameters.

**Note**
The parameters are mutually exclusive.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bytes</td>
<td>positive</td>
<td>null</td>
<td>No</td>
<td>The size of the log file in bytes.</td>
</tr>
<tr>
<td>p_size</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The size of the log file. You can specify the size in kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
</tbody>
</table>

The following command adds a 100 MB log file.

```sql
EXEC rdsadmin.rdsadmin_util.add_logfile(p_size => '100M');
```

## Dropping online redo logs

To drop redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_logfile`. The `drop_logfile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grp</td>
<td>positive</td>
<td>—</td>
<td>Yes</td>
<td>The group number of the log.</td>
</tr>
</tbody>
</table>

The following example drops the log with group number 3.

```sql
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 3);
```

You can only drop logs that have a status of unused or inactive. The following example gets the statuses of the logs.

```sql
SELECT GROUP#, STATUS FROM V$LOG;
```

<table>
<thead>
<tr>
<th>GROUP#</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>CURRENT</td>
</tr>
<tr>
<td>2</td>
<td>INACTIVE</td>
</tr>
<tr>
<td>3</td>
<td>INACTIVE</td>
</tr>
</tbody>
</table>
Resizing online redo logs

An Amazon RDS DB instance running Oracle starts with four online redo logs, 128 MB each. The following example shows how you can use Amazon RDS procedures to resize your logs from 128 MB each to 512 MB each.

```sql
/* Query V$LOG to see the logs. */
/* You start with 4 logs of 128 MB each. */
SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#       BYTES       STATUS
----------       ---------       ------------
1             134217728     INACTIVE
2             134217728     CURRENT
3             134217728     INACTIVE
4             134217728     INACTIVE

/* Add four new logs that are each 512 MB */
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);

/* Query V$LOG to see the logs. */
/* Now there are 8 logs. */
SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#       BYTES       STATUS
----------       ---------       ------------
1             134217728     INACTIVE
2             134217728     CURRENT
3             134217728     INACTIVE
4             134217728     INACTIVE
5             536870912     UNUSED
6             536870912     UNUSED
7             536870912     UNUSED
8             536870912     UNUSED

/* Drop each inactive log using the group number. */
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 1);
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 3);
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 4);

/* Query V$LOG to see the logs. */
/* Now there are 5 logs. */
SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#       BYTES       STATUS
----------       ---------       ------------
2             134217728     CURRENT
5             536870912     UNUSED
6             536870912     UNUSED
7             536870912     UNUSED
```
/* Switch logs so that group 2 is no longer current. */
EXEC rdsadmin.rdsadmin_util.switch_logfile;

/* Query V$LOG to see the logs. */
/* Now one of the new logs is current. */
SQL> SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
 2          134217728  ACTIVE
 5          536870912  CURRENT
 6          536870912  UNUSED
 7          536870912  UNUSED
 8          536870912  UNUSED

/* If the status of log 2 is still "ACTIVE", issue a checkpoint to clear it to "INACTIVE". */
EXEC rdsadmin.rdsadmin_util.checkpoint;

/* Query V$LOG to see the logs. */
/* Now the final original log is inactive. */
select GROUP#, BYTES, STATUS from V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
 2          134217728  INACTIVE
 5          536870912  CURRENT
 6          536870912  UNUSED
 7          536870912  UNUSED
 8          536870912  UNUSED

# Drop the final inactive log.
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 2);

/* Query V$LOG to see the logs. */
/* Now there are four 512 MB logs. */
SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
 5          536870912  CURRENT
 6          536870912  UNUSED
 7          536870912  UNUSED
 8          536870912  UNUSED

Retaining archived redo logs

You can retain archived redo logs locally on your DB instance for use with products like Oracle LogMiner (DBMS_LOGMNR). After you have retained the redo logs, you can use LogMiner to analyze the logs. For more information, see Using LogMiner to analyze redo log files in the Oracle documentation.
To retain archived redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.set_configuration`. The `set_configuration` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the configuration to update.</td>
</tr>
<tr>
<td>value</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The value for the configuration.</td>
</tr>
</tbody>
</table>

The following example retains 24 hours of redo logs.

```sql
begin
    rdsadmin.rdsadmin_util.set_configuration(
        name  => 'archivelog retention hours',
        value => '24');
end;
/
commit;
```

**Note**

The commit is required for the change to take effect.

To view how long archived redo logs are kept for your DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.show_configuration`.

The following example shows the log retention time.

```sql
set serveroutput on
EXEC rdsadmin.rdsadmin_util.show_configuration;
```

The output shows the current setting for `archivelog retention hours`. The following output shows that archived redo logs are kept for 48 hours.

```
NAME:archivelog retention hours
VALUE:48
DESCRIPTION:ArchiveLog expiration specifies the duration in hours before archive/redo log files are automatically deleted.
```

Because the archived redo logs are retained on your DB instance, ensure that your DB instance has enough allocated storage for the retained logs. To determine how much space your DB instance has used in the last X hours, you can run the following query, replacing X with the number of hours.

```sql
SELECT SUM(BLOCKS * BLOCK_SIZE) bytes
FROM V$ARCHIVED_LOG
WHERE FIRST_TIME >= SYSDATE-(X/24) AND DEST_ID=1;
```

RDS for Oracle only generates archived redo logs when the backup retention period of your DB instance is greater than zero. By default the backup retention period is greater than zero.

When the archived log retention period expires, RDS for Oracle removes the archived redo logs from your DB instance. To support restoring your DB instance to a point in time, Amazon RDS retains the archived redo logs outside of your DB instance based on the backup retention period. To modify the backup retention period, see [Modifying an Amazon RDS DB instance](p. 333).
**Note**
In some cases, you might be using JDBC on Linux to download archived redo logs and experience long latency times and connection resets. In such cases, the issues might be caused by the default random number generator setting on your Java client. We recommend setting your JDBC drivers to use a nonblocking random number generator.

## Accessing online and archived redo logs

You might want to access your online and archived redo log files for mining with external tools such as GoldenGate, Attunity, Informatica, and others. To access these files, do the following:

1. Create directory objects that provide read-only access to the physical file paths.

   ```
   USE rdsadmin.rdsadmin_master_util.create_archivelog_dir
   AND rdsadmin.rdsadmin_master_util.create_onlinelog_dir.
   ```

2. Read the files using PL/SQL.

   You can read the files by using PL/SQL. For more information about reading files from directory objects, see [Listing files in a DB instance directory](p. 1650) and [Reading files in a DB instance directory](p. 1650).

Accessing transaction logs is supported for the following releases:

- Oracle Database 21c
- Oracle Database 19c
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1)

The following code creates directories that provide read-only access to your online and archived redo log files:

**Important**
This code also revokes the DROP ANY DIRECTORY privilege.

```sql
EXEC rdsadmin.rdsadmin_master_util.create_archivelog_dir;
EXEC rdsadmin.rdsadmin_master_util.create_onlinelog_dir;
```

The following code drops the directories for your online and archived redo log files.

```sql
EXEC rdsadmin.rdsadmin_master_util.drop_archivelog_dir;
EXEC rdsadmin.rdsadmin_master_util.drop_onlinelog_dir;
```

The following code grants and revokes the DROP ANY DIRECTORY privilege.

```sql
EXEC rdsadmin.rdsadmin_master_util.revoke_drop_any_directory;
EXEC rdsadmin.rdsadmin_master_util.grant_drop_any_directory;
```

## Downloading archived redo logs from Amazon S3

You can download archived redo logs on your DB instance using the `rdsadmin.rdsadmin_archive_log_download` package. If archived redo logs are no longer on your DB instance, you might want to download them again from Amazon S3. Then you can mine the logs or use them to recover or replicate your database.
Note
You can't download archived redo logs on read replica instances.

Downloading archived redo logs: basic steps

The availability of your archived redo logs depends on the following retention policies:

- Backup retention policy – Logs inside of this policy are available in Amazon S3. Logs outside of this policy are removed.
- Archived log retention policy – Logs inside of this policy are available on your DB instance. Logs outside of this policy are removed.

If logs aren't on your instance but are protected by your backup retention period, use rdsadmin.rdsadmin_archive_log_download to download them again. RDS for Oracle saves the logs to the /rdsdbdata/log/arch directory on your DB instance.

To download archived redo logs from Amazon S3

1. Increase your archived redo log retention period so that RDS won't delete the logs that you download. Make sure to COMMIT your change.
   To learn how to set the retention policy, see Retaining archived redo logs (p. 1616).
2. Wait up to 5 minutes for the archived log retention policy change to take effect.
3. Download the archived redo logs from Amazon S3 using rdsadmin.rdsadmin_archive_log_download.

   For more information, see Downloading a single archived redo log (p. 1619) and Downloading a series of archived redo logs (p. 1620).

   Note
   RDS automatically checks the available storage before downloading. If the requested logs consume a high percentage of space, you receive an alert.
4. Confirm that the logs were downloaded from Amazon S3 successfully.
   You can view the status of your download task in a bdump file. The bdump files have the path name /rdsdbdata/log/trace/dbtask-task-id.log. In the preceding download step, you run a SELECT statement that returns the task ID in a VARCHAR2 data type. For more information, see similar examples in Monitoring the status of a file transfer (p. 1714).

Downloading a single archived redo log

To download a single archived redo log to the /rdsdbdata/log/arch directory, use rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum. This procedure has the following parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seqnum</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The sequence number of the archived redo log.</td>
</tr>
</tbody>
</table>

The following example downloads the log with sequence number 20.

```sql
SELECT rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum(seqnum => 20) AS TASK_ID
FROM DUAL;
```
**Downloading a series of archived redo logs**

To download a series of archived redo logs to the `/rdsdbdata/log/arch` directory, use `download_logs_in_seqnum_range`. Your download is limited to 300 logs per request. The `download_logs_in_seqnum_range` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start_seq</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The starting sequence number for the series.</td>
</tr>
<tr>
<td>end_seq</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The ending sequence number for the series.</td>
</tr>
</tbody>
</table>

The following example downloads the logs from sequence 50 to 100.

```sql
SELECT rdsadmin.rdsadmin_archive_log_download.download_logs_in_seqnum_range(start_seq => 50, end_seq => 100)
AS TASK_ID
FROM   DUAL;
```

**Performing common RMAN tasks for Oracle DB instances**

In the following section, you can find how you can perform Oracle Recovery Manager (RMAN) DBA tasks on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges.

You can use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to perform RMAN backups of your Amazon RDS for Oracle database to disk. The `rdsadmin.rdsadmin_rman_util` package supports full and incremental database file backups, tablespace backups, and archive log backups.

RMAN backups consume storage space on the Amazon RDS DB instance host. When you perform a backup, you specify an Oracle directory object as a parameter in the procedure call. The backup files are placed in the specified directory. You can use default directories, such as `DATA_PUMP_DIR`, or create a new directory. For more information, see Creating and dropping directories in the main data storage space (p. 1649).

After an RMAN backup has finished, you can copy the backup files off the Amazon RDS for Oracle DB instance host. You might do this for the purpose of restoring to a non-RDS host or for long-term storage of backups. For example, you can copy the backup files to an Amazon S3 bucket. For more information, see using Amazon S3 integration (p. 1700).

The backup files for RMAN backups remain on the Amazon RDS DB instance host until you remove them manually. You can use the `UTL_FILE.UTL_FILE` Oracle procedure to remove files from a directory. For more information, see FREMOVE procedure in the Oracle documentation.

When backing up archived redo logs or performing a full or incremental backup that includes archived redo logs, redo log retention must be set to a nonzero value. For more information, see Retaining archived redo logs (p. 1616).

**Note**

For backing up and restoring to another Amazon RDS for Oracle DB instance, you can continue to use the Amazon RDS backup and restore features. For more information, see Backing up and restoring an Amazon RDS DB instance (p. 461).

Currently, RMAN restore isn't supported for Amazon RDS for Oracle DB instances.
Common parameters for RMAN procedures

You can use procedures in the Amazon RDS package rdsadmin.rdsadmin_rman_util to perform tasks with RMAN. Several parameters are common to the procedures in the package. The package has the following common parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory_name</td>
<td>varchar2</td>
<td>A valid database directory name.</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory to contain the backup files.</td>
</tr>
<tr>
<td>p_label</td>
<td>varchar2</td>
<td>a-z, A-Z, 0-9, ' ', ',', '-'</td>
<td>—</td>
<td>No</td>
<td>A unique string that is included in the backup file names.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Note: The limit is 30 characters.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>p_owner</td>
<td>varchar2</td>
<td>A valid owner of the directory specified in p_directory_name.</td>
<td>—</td>
<td>Yes</td>
<td>The owner of the directory to contain the backup files.</td>
</tr>
<tr>
<td>p_tag</td>
<td>varchar2</td>
<td>a-z, A-Z, 0-9, ' ', ',', '-'</td>
<td>NULL</td>
<td>No</td>
<td>A string that can be used to distinguish between backups to indicate the purpose or usage of backups, such as daily, weekly, or incremental-level backups.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Note: The limit is 30 characters. The tag is not case-sensitive. Tags are always stored in uppercase, regardless of the case used when entering them.</td>
<td></td>
<td></td>
<td>Tags don't need to be unique, so multiple backups can have the same tag.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>If you don't specify a tag, then RMAN assigns a default tag automatically using the format TAGYYYYMMDDTHHMMSS, where YYYY is the year, MM is the month, DD is the day, HH is the hour (in 24-hour format), MM is the minutes,</td>
</tr>
</tbody>
</table>
### p_tag

Parameter name | Data type | Valid values | Default | Required | Description |
---|---|---|---|---|---|
**p_tag** | string | | | | and **SS** is the seconds. The date and time refer to when RMAN started the backup. For example, a backup might receive a tag TAG20190927T214517 for a backup that started on 2019-09-27 at 21:45:17. The **p_tag** parameter is supported for the following Amazon RDS for Oracle DB engine versions:
- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0), using 19.0.0.0.ru-2021-10.rur-2021-10.r1 or higher
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2021-10.rur-2021-10.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.V26 or higher

### p_compress

Parameter name | Data type | Valid values | Default | Required | Description |
---|---|---|---|---|---|
**p_compress** | boolean | TRUE, FALSE | FALSE | No | Specify TRUE to enable BASIC backup compression. Specify FALSE to disable BASIC backup compression. |

### p_include_archive_logs

Parameter name | Data type | Valid values | Default | Required | Description |
---|---|---|---|---|---|
**p_include_archive_logs** | boolean | TRUE, FALSE | FALSE | No | Specify TRUE to include archived redo logs in the backup. Specify FALSE to exclude archived redo logs from the backup. If you include archived redo logs in the backup, set retention to one hour or greater using the ```rdsadmin.rdsadmin_util.set_configuration``` procedure. Also, call the ```rdsadmin.rdsadmin_rman_util.crosscheck_archivelog``` procedure immediately before running the backup. Otherwise, the backup might fail due to missing archived redo log files that have been deleted by Amazon RDS management procedures. |

### p_include_controlfile

Parameter name | Data type | Valid values | Default | Required | Description |
---|---|---|---|---|---|
**p_include_controlfile** | boolean | TRUE, FALSE | FALSE | No | Specify TRUE to include the control file in the backup. Specify FALSE to exclude the control file from the backup. |

### p_optimize

Parameter name | Data type | Valid values | Default | Required | Description |
---|---|---|---|---|---|
**p_optimize** | boolean | TRUE, FALSE | TRUE | No | Specify TRUE to enable backup optimization, if archived redo logs are included, to reduce backup size. Specify FALSE to disable backup optimization. |
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_parallel</td>
<td>number</td>
<td>A valid integer between 1 and 254 for Oracle Database Enterprise Edition (EE) 1 for other Oracle Database editions</td>
<td>1</td>
<td>No</td>
<td>Number of channels.</td>
</tr>
<tr>
<td>p_rman_to_dbms_output</td>
<td>boolean</td>
<td>TRUE, FALSE</td>
<td>FALSE</td>
<td>No</td>
<td>When TRUE, the RMAN output is sent to the DBMS_OUTPUT package in addition to a file in the BDUMP directory. In SQL*Plus, use SET SERVEROUTPUT ON to see the output. When FALSE, the RMAN output is only sent to a file in the BDUMP directory.</td>
</tr>
<tr>
<td>p_section_size_mb</td>
<td>number</td>
<td>A valid integer</td>
<td>NULL</td>
<td>No</td>
<td>The section size in megabytes (MB). Validates in parallel by dividing each file into the specified section size. When NULL, the parameter is ignored.</td>
</tr>
<tr>
<td>p_validation_type</td>
<td>varchar2</td>
<td>'PHYSICAL', 'PHYSICAL +LOGICAL'</td>
<td>'PHYSICAL'</td>
<td></td>
<td>The level of corruption detection. Specify 'PHYSICAL' to check for physical corruption. An example of physical corruption is a block with a mismatch in the header and footer. Specify 'PHYSICAL+LOGICAL' to check for logical inconsistencies in addition to physical corruption. An example of logical corruption is a corrupt block.</td>
</tr>
</tbody>
</table>

### Validating DB instance files

You can use the Amazon RDS package rdsadmin.rdsadmin_rman_util to validate Amazon RDS for Oracle DB instance files, such as data files, tablespaces, control files, or server parameter files (SPFILES).

For more information about RMAN validation, see Validating database files and backups and VALIDATE in the Oracle documentation.

**Topics**

- Validating a DB instance (p. 1624)
- Validating a tablespace (p. 1624)
- Validating a control file (p. 1625)
- Validating an SPFILE (p. 1625)
Validating a DB instance

To validate all of the relevant files used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_database`.

This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures (p. 1621).

The following example validates the DB instance using the default values for the parameters.

```sql
EXEC rdsadmin.rdsadmin_rman_util.validate_database;
```

The following example validates the DB instance using the specified values for the parameters.

```sql
BEGIN
    rdsadmin.rdsadmin_rman_util.validate_database(
        p_validation_type     => 'PHYSICAL+LOGICAL',
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_rman_to_dbms_output => FALSE);
END;
```

When the `p_rman_to_dbms_output` parameter is set to FALSE, the RMAN output is written to a file in the BDUMP directory.

To view the files in the BDUMP directory, run the following SELECT statement.

```sql
SELECT * FROM table(rdsadmin.rds_file_util.listdir('BDUMP')) order by mtime;
```

To view the contents of a file in the BDUMP directory, run the following SELECT statement.

```sql
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','rds-rman-validate-nnn.txt'));
```

Replace the file name with the name of the file you want to view.

Validating a tablespace

To validate the files associated with a tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`.

This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
• `p_section_size_mb`
• `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures (p. 1621).

This procedure also uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_tablespace_name</code></td>
<td>varchar2</td>
<td>A valid tablespace name</td>
<td>—</td>
<td>Yes</td>
<td>The name of the tablespace.</td>
</tr>
</tbody>
</table>

Validating a control file

To validate only the control file used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_current_controlfile`.

This procedure uses the following common parameter for RMAN tasks:

• `p_validation_type`
• `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures (p. 1621).

Validating an SPFILE

To validate only the server parameter file (SPFILE) used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_spfile`.

This procedure uses the following common parameter for RMAN tasks:

• `p_validation_type`
• `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures (p. 1621).

Validating a data file

To validate a data file, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_datafile`.

This procedure uses the following common parameters for RMAN tasks:

• `p_validation_type`
• `p_parallel`
• `p_section_size_mb`
• `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures (p. 1621).

This procedure also uses the following additional parameters.
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_datafile</td>
<td>varchar2</td>
<td>A valid datafile ID number or a valid datafile name including complete path</td>
<td></td>
<td>Yes</td>
<td>The datafile ID number (from v $datafile.file#) or the full datafile name including the path (from v $datafile.name).</td>
</tr>
<tr>
<td>p_from_block</td>
<td>number</td>
<td>A valid integer</td>
<td>NULL</td>
<td>No</td>
<td>The number of the block where the validation starts within the data file. When this is NULL, 1 is used.</td>
</tr>
<tr>
<td>p_to_block</td>
<td>number</td>
<td>A valid integer</td>
<td>NULL</td>
<td>No</td>
<td>The number of the block where the validation ends within the data file. When this is NULL, the maximum block in the data file is used.</td>
</tr>
</tbody>
</table>

**Enabling and disabling block change tracking**

Block change tracking records changed blocks in a tracking file. This technique can improve the performance of RMAN incremental backups. For more information, see Using Block Change Tracking to Improve Incremental Backup Performance in the Oracle Database documentation.

To enable block change tracking for a DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.enable_block_change_tracking`. To disable block change tracking, use `disable_block_change_tracking`. These procedures take no parameters.

Read-only replicas support block change tracking. If you create a read-only replica from a source DB that uses block change tracking, the replica uses block change tracking. You can't enable block change tracking on a mounted replica. If you place a mounted replica in read-only mode, block change tracking isn't enabled, but you can enable it using `enable_block_change_tracking`. If you promote an Oracle replica to a source DB, you can use block change tracking just as for any other Oracle DB instance.

Block change tracking procedures are supported for the following DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

**Note**
In a single-tenant CDB, the following operations work, but no customer-visible mechanism can detect the current status of the operations. See also Limitations of a single-tenant CDB (p. 1539).
To determine whether block change tracking is enabled for your DB instance, run the following query.

```
SELECT STATUS, FILENAME FROM V$BLOCK_CHANGE_TRACKING;
```

The following example enables block change tracking for a DB instance.

```
EXEC rdsadmin.rdsadmin_rman_util.enable_block_change_tracking;
```

The following example disables block change tracking for a DB instance.

```
EXEC rdsadmin.rdsadmin_rman_util.disable_block_change_tracking;
```

### Crosschecking archived redo logs

You can crosscheck archived redo logs using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.crosscheck_archivelog`.

You can use this procedure to crosscheck the archived redo logs registered in the control file and optionally delete the expired logs records. When RMAN makes a backup, it creates a record in the control file. Over time, these records increase the size of the control file. We recommend that you remove expired records periodically.

**Note**
Standard Amazon RDS backups don't use RMAN and therefore don't create records in the control file.

This procedure uses the common parameter `p_rman_to_dbms_output` for RMAN tasks.

For more information, see [Common parameters for RMAN procedures (p. 1621)](#).

This procedure also uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_delete_expired</code></td>
<td>boolean</td>
<td>TRUE, FALSE</td>
<td>TRUE</td>
<td>No</td>
<td>When TRUE, delete expired archived redo log records from the control file.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>When FALSE, retain the expired archived redo log records in the control file.</td>
</tr>
</tbody>
</table>

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

The following example marks archived redo log records in the control file as expired, but does not delete the records.
The following example deletes expired archived redo log records from the control file.

```
BEGIN
rdsadmin.rdsadmin_rman_util.crosscheck_archivelog(
    p_delete_expired      => FALSE,
    p_rman_to_dbms_output => FALSE);
END;
/
```

### Backing up archived redo logs

You can use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to back up archived redo logs for an Amazon RDS Oracle DB instance.

The procedures for backing up archived redo logs are supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

### Topics

- Backing up all archived redo logs (p. 1628)
- Backing up an archived redo log from a date range (p. 1629)
- Backing up an archived redo log from an SCN range (p. 1630)
- Backing up an archived redo log from a sequence number range (p. 1632)

### Backing up all archived redo logs

To back up all of the archived redo logs for an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_all`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures (p. 1621)](#).
The following example backs up all archived redo logs for the DB instance.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_archivelog_all(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_parallel            => 4,
        p_tag                 => 'MY_LOG_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

**Backing up an archived redo log from a date range**

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a date range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_date`. The date range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures (p. 1621).

This procedure also uses the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_from_date</code></td>
<td>date</td>
<td>A date that is between the <code>start_date</code> and <code>next_date</code> of an archived redo log that exists on disk. The value must be less than or equal to the value</td>
<td>—</td>
<td>Yes</td>
<td>The starting date for the archived log backups.</td>
</tr>
</tbody>
</table>
### Parameter name | Data type | Valid values | Default | Required | Description
---|---|---|---|---|---
p_to_date | date | A date that is between the start_date and next_date of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_date. | — | Yes | The ending date for the archived log backups.

The following example backs up archived redo logs in the date range for the DB instance.

```sql
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_archivelog_date(
    p_owner => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_from_date => '03/01/2019 00:00:00',
    p_to_date => '03/02/2019 00:00:00',
    p_parallel => 4,
    p_tag => 'MY_LOG_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

### Backing up an archived redo log from an SCN range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a system change number (SCN) range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_scn`. The SCN range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
• p_parallel
• p_compress
• p_rman_to_dbms_output
• p_tag

For more information, see Common parameters for RMAN procedures (p. 1621).

This procedure also uses the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_from_scn</td>
<td>number</td>
<td>An SCN of an archived redo log that exists on disk. The value must be less than or equal to the value specified for p_to_scn.</td>
<td>—</td>
<td>Yes</td>
<td>The starting SCN for the archived log backups.</td>
</tr>
<tr>
<td>p_to_scn</td>
<td>number</td>
<td>An SCN of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_scn.</td>
<td>—</td>
<td>Yes</td>
<td>The ending SCN for the archived log backups.</td>
</tr>
</tbody>
</table>

The following example backs up archived redo logs in the SCN range for the DB instance.

```
BEGIN
   rdsadmin.rdsadmin_rman_util.backup_archivelog_scn(
      p_owner => 'SYS',
      p_directory_name => 'MYDIRECTORY',
      p_from_scn => 1533835,
      p_to_scn => 1892447,
      p_parallel => 4,
      p_tag => 'MY_LOG_BACKUP',
      p_rman_to_dbms_output => FALSE);
```
Back up an archived redo log from a sequence number range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a sequence number range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_sequence`. The sequence number range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures (p. 1621).

This procedure also uses the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_from_sequence</code></td>
<td>number</td>
<td>A sequence number an archived redo log that exists on disk. The value must be less than or equal to the value specified for <code>p_to_sequence</code>.</td>
<td>—</td>
<td>Yes</td>
<td>The starting sequence number for the archived log backups.</td>
</tr>
<tr>
<td><code>p_to_sequence</code></td>
<td>number</td>
<td>A sequence number of an archived redo log that exists on disk. The value must be</td>
<td>—</td>
<td>Yes</td>
<td>The ending sequence number for the archived log backups.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Valid values</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>--------------</td>
<td>---------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>p_owner</td>
<td></td>
<td>greater than or equal to the value specified for p_from_sequence.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>p_directory_name</td>
<td></td>
<td>'MYDIRECTORY',</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>p_from_sequence</td>
<td></td>
<td>11160,</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>p_to_sequence</td>
<td></td>
<td>11160,</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>p_parallel</td>
<td></td>
<td>4,</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>p_tag</td>
<td></td>
<td>'MY_LOG_BACKUP',</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>p_rman_to_dbms_output</td>
<td></td>
<td>FALSE</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following example backs up archived redo logs in the sequence number range for the DB instance.

BEGIN
  rdsadmin.rdsadmin_rman_util.backup_archivelog_sequence(
    p_owner => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_from_sequence => 11160,
    p_to_sequence => 11160,
    p_parallel => 4,
    p_tag => 'MY_LOG_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/

Performing a full database backup

You can perform a backup of all blocks of data files included in the backup using Amazon RDS procedure rdsadmin.rdsadmin_rman_util.backup_database_full.

This procedure uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
- p_parallel
- p_section_size_mb
- p_include_archive_logs
- p_optimize
- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures (p. 1621).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher
The following example performs a full backup of the DB instance using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_database_full(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_tag                 => 'FULL_DB_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Performing an incremental database backup

You can perform an incremental backup of your DB instance using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_database_incremental`

For more information about incremental backups, see Incremental backups in the Oracle documentation.

This procedure uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
- p_parallel
- p_section_size_mb
- p_include_archive_logs
- p_include_controlfile
- p_optimize
- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures (p. 1621).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

This procedure also uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_level</td>
<td>number</td>
<td>0, 1</td>
<td>0</td>
<td>No</td>
<td>Specify 0 to enable a full incremental backup.</td>
</tr>
</tbody>
</table>
The following example performs an incremental backup of the DB instance using the specified values for the parameters.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_database_incremental(
    p_owner => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_level => 1,
    p_parallel => 4,
    p_section_size_mb => 10,
    p_tag => 'MY_INCREMENTAL_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

## Backing up a tablespace

You can back up a tablespace using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_tablespace`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_tablespace`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures (p. 1621).

This procedure also uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_tablespace_name</code></td>
<td>varchar2</td>
<td>A valid tablespace name.</td>
<td>—</td>
<td>Yes</td>
<td>The name of the tablespace to back up.</td>
</tr>
</tbody>
</table>
This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

The following example performs a tablespace backup using the specified values for the parameters.

```sql
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_tablespace(
    p_owner               => 'SYS',
    p_directory_name      => 'MYDIRECTORY',
    p_tablespace_name     => 'MYTABLESPACE',
    p_parallel            => 4,
    p_section_size_mb     => 10,
    p_tag                 => 'MYTABLESPACE_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

### Backing up a control file

You can back up a control file using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_current_controlfile`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](p. 1621).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

The following example backs up a control file using the specified values for the parameters.

```sql
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_current_controlfile(
    p_owner               => 'SYS',
    p_directory_name      => 'MYDIRECTORY',
    p_tag                 => 'CONTROL_FILE_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
## Performing common scheduling tasks for Oracle DB instances

Some scheduler jobs owned by SYS can interfere with normal database operations. Oracle Support recommends you disable these jobs or modify the schedule. To perform tasks for Oracle Scheduler jobs owned by SYS, use the Amazon RDS package `rdsadmin.rdsadmin_dbms_scheduler`.

The `rdsadmin.rdsadmin_dbms_scheduler` procedures are supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c
- Oracle Database 12c Release 2 (12.2) on 12.2.0.2.ru-2019-07.rur-2019-07.r1 or higher 12.2 versions
- Oracle Database 12c Release 1 (12.1) on 12.1.0.2.v17 or higher 12.1 versions

## Common parameters for Oracle Scheduler procedures

To perform tasks with Oracle Scheduler, use procedures in the Amazon RDS package `rdsadmin.rdsadmin_dbms_scheduler`. Several parameters are common to the procedures in the package. The package has the following common parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>varchar2</td>
<td>'SYS.BSLN_MAINTAIN_STATS_JOB', 'SYS.CLEANUP_ONLINE_IND_BUILD'</td>
<td>-</td>
<td>Yes</td>
<td>The name of the job to modify. <strong>Note</strong> Currently, you can only modify SYS.CLEANUP_ONLINE_IND_BUILD and SYS.BSLN_MAINTAIN_STATS_JOB jobs.</td>
</tr>
<tr>
<td>attribute</td>
<td>varchar2</td>
<td>'REPEAT_INTERVAL', 'SCHEDULE_NAME'</td>
<td>-</td>
<td>Yes</td>
<td>Attribute to modify. To modify the repeat interval for the job, specify 'REPEAT_INTERVAL'. To modify the schedule name for the job, specify 'SCHEDULE_NAME'.</td>
</tr>
<tr>
<td>value</td>
<td>varchar2</td>
<td>A valid schedule interval or schedule name, depending on</td>
<td>-</td>
<td>Yes</td>
<td>The new value of the attribute.</td>
</tr>
</tbody>
</table>
Modifying DBMS_SCHEDULER jobs

To modify certain components of Oracle Scheduler, use the Oracle procedure 
dbms_scheduler.set_attribute. For more information, see DBMS_SCHEDULER and 
SET_ATTRIBUTE procedure in the Oracle documentation.

When working with Amazon RDS DB instances, prepend the schema name SYS to the object name. The 
following example sets the resource plan attribute for the Monday window object.

```
BEGIN
  DBMS_SCHEDULER.SET_ATTRIBUTE(
    name      => 'SYS.MONDAY_WINDOW',
    attribute => 'RESOURCE_PLAN',
    value     => 'resource_plan_1');
END;
/
```

Modifying AutoTask maintenance windows

Amazon RDS for Oracle instances are created with default settings for maintenance windows. Automated 
maintenance tasks such as optimizer statistics collection run during these windows. By default, the 
maintenance windows turn on Oracle Database Resource Manager.

To modify the window, use the DBMS_SCHEDULER package. You might need to modify the maintenance 
window settings for the following reasons:

- You want maintenance jobs to run at a different time, with different settings, or not at all. For 
  example, might want to modify the window duration, or change the repeat time and interval.
- You want to avoid the performance impact of enabling Resource Manager during maintenance. For 
  example, if the default maintenance plan is specified, and if the maintenance window opens while the 
database is under load, you might see wait events such as resmgr:cpu quantum. This wait event is 
related to Database Resource Manager. You have the following options:
  - Ensure that maintenance windows are active during off-peak times for your DB instance.
  - Disable the default maintenance plan by setting the resource_plan attribute to an empty string.
  - Set the resource_manager_plan parameter to FORCE: in your parameter group. If your instance 
uses Enterprise Edition, this setting prevents Database Resource Manager plans from activating.

To modify your maintenance window settings

1. Connect to your database using an Oracle SQL client.
2. Query the current configuration for a scheduler window.

The following example queries the configuration for MONDAY_WINDOW.

```
SELECT ENABLED, RESOURCE_PLAN, DURATION, REPEAT_INTERVAL
FROM   DBA_SCHEDULER_WINDOWS
WHERE  WINDOW_NAME='MONDAY_WINDOW';
```

The following output shows that the window is using the default values.
3. Modify the window using the DBMS_SCHEDULER package.

The following example sets the resource plan to null so that the Resource Manager won't run during the maintenance window.

```sql
BEGIN
  -- disable the window to make changes
  DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"', force=>TRUE);

  -- specify the empty string to use no plan
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"', attribute=>'RESOURCE_PLAN', value=>'');

  -- re-enable the window
  DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/
```

The following example sets the maximum duration of the window to 2 hours.

```sql
BEGIN
  DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"', force=>TRUE);
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"', attribute=>'DURATION',
  value=>'0 2:00:00');
  DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/
```

The following example sets the repeat interval to every Monday at 10 AM.

```sql
BEGIN
  DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"', force=>TRUE);
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"', attribute=>'REPEAT_INTERVAL',
  value=>'freq=daily;byday=MON;byhour=10;byminute=0;bysecond=0');
  DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/
```

**Setting the time zone for Oracle Scheduler jobs**

To modify the time zone for Oracle Scheduler, you can use the Oracle procedure `dbms_scheduler.set_scheduler_attribute`. For more information about the `dbms_scheduler` package, see `DBMS_SCHEDULER` and `SET_SCHEDULER_ATTRIBUTE` in the Oracle documentation.

**To modify the current time zone setting**

1. Connect to the database using a client such as SQL Developer. For more information, see [Connecting to your DB instance using Oracle SQL developer](p. 1542).
2. Set the default time zone as following, substituting your time zone for `time_zone_name`. 

---

1639
BEGIN
    DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE(
        attribute => 'default_timezone',
        value => 'time_zone_name'
    );
END;
/

In the following example, you change the time zone to Asia/Shanghai.

Start by querying the current time zone, as shown following.

```
SELECT VALUE FROM DBA_SCHEDULER_GLOBAL_ATTRIBUTE WHERE ATTRIBUTE_NAME='DEFAULT_TIMEZONE';
```

The output shows that the current time zone is ETC/UTC.

```
VALUE
--------
Etc/UTC
```

Then you set the time zone to Asia/Shanghai.

```
BEGIN
    DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE(
        attribute => 'default_timezone',
        value => 'Asia/Shanghai'
    );
END;
/
```

For more information about changing the system time zone, see Oracle time zone (p. 1794).

## Turning off Oracle Scheduler jobs owned by SYS

To disable an Oracle Scheduler job owned by the SYS user, use the `rdsadmin.rdsadmin_dbms_scheduler.disable` procedure.

This procedure uses the name common parameter for Oracle Scheduler tasks. For more information, see Common parameters for Oracle Scheduler procedures (p. 1637).

The following example disables the `SYS.CLEANUP_ONLINE_IND_BUILD` Oracle Scheduler job.

```
BEGIN
    rdsadmin.rdsadmin_dbms_scheduler.disable('SYS.CLEANUP_ONLINE_IND_BUILD');
END;
/
```

## Turning on Oracle Scheduler jobs owned by SYS

To turn on an Oracle Scheduler job owned by SYS, use the `rdsadmin.rdsadmin_dbms_scheduler.enable` procedure.

This procedure uses the name common parameter for Oracle Scheduler tasks. For more information, see Common parameters for Oracle Scheduler procedures (p. 1637).

The following example enables the `SYS.CLEANUP_ONLINE_IND_BUILD` Oracle Scheduler job.
BEGIN
    rdsadmin.rdsadmin_dbms_scheduler.enable('SYS.CLEANUP_ONLINE_IND_BUILD');
END;
/

Modifying the Oracle Scheduler repeat interval for jobs of CALENDAR type

To modify the repeat interval to modify a SYS-owned Oracle Scheduler job of CALENDAR type, use the rdsadmin.rdsadmin_dbms_scheduler.disable procedure.

This procedure uses the following common parameters for Oracle Scheduler tasks:

- name
- attribute
- value

For more information, see Common parameters for Oracle Scheduler procedures (p. 1637).

The following example modifies the repeat interval of the SYS.CLEANUP_ONLINE_IND_BUILD Oracle Scheduler job.

BEGIN
    rdsadmin.rdsadmin_dbms_scheduler.set_attribute(
        name => 'SYS.CLEANUP_ONLINE_IND_BUILD',
        attribute => 'repeat_interval',
        value => 'freq=daily;byday=FRI,SAT;byhour=20;byminute=0;bysecond=0');
END;
/

Modifying the Oracle Scheduler repeat interval for jobs of NAMED type

Some Oracle Scheduler jobs use a schedule name instead of an interval. For this type of jobs, you must create a new named schedule in the master user schema. Use the standard Oracle sys.dbms_scheduler.create_schedule procedure to do this. Also, use the rdsadmin.rdsadmin_dbms_scheduler.set_attribute procedure to assign the new named schedule to the job.

This procedure uses the following common parameter for Oracle Scheduler tasks:

- name
- attribute
- value

For more information, see Common parameters for Oracle Scheduler procedures (p. 1637).

The following example modifies the repeat interval of the SYS.BSLN_MAINTAIN_STATS_JOB Oracle Scheduler job.

BEGIN
    DBMS_SCHEDULER.CREATE_SCHEDULE (
        schedule_name => 'rds_master_user.new_schedule',
        start_date => SYSTIMESTAMP,
    )
END;
performing common diagnostic tasks for Oracle DB instances

Oracle Database includes a fault diagnosability infrastructure that you can use to investigate database problems. In Oracle terminology, a problem is a critical error such as a code bug or data corruption. An incident is the occurrence of a problem. If the same error occurs three times, then the infrastructure
shows three incidents of this problem. For more information, see Diagnosing and resolving problems in the Oracle Database documentation.

The Automatic Diagnostic Repository Command Interpreter (ADRCI) utility is an Oracle command-line tool that you use to manage diagnostic data. For example, you can use this tool to investigate problems and package diagnostic data. An incident package includes diagnostic data for an incident or all incidents that reference a specific problem. You can upload an incident package, which is implemented as a .zip file, to Oracle Support.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to ADRCI. To perform diagnostic tasks for your Oracle instance, instead use the Amazon RDS package rdsadmin.rdsadmin_adrci_util.

By using the functions in rdsadmin_adrci_util, you can list and package problems and incidents, and also show trace files. All functions return a task ID. This ID forms part of the name of log file that contains the ADRCI output, as in dbtask-<task_id>.log. The log file resides in the BDUMP directory.

**Common parameters for diagnostic procedures**

To perform diagnostic tasks, use functions in the Amazon RDS package rdsadmin.rdsadmin_adrci_util. The package has the following common parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>incident_id</td>
<td>number</td>
<td>A valid incident ID or null</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, the function shows all incidents. If the value isn't null and represents a valid incident ID, the function shows the specified incident.</td>
</tr>
<tr>
<td>problem_id</td>
<td>number</td>
<td>A valid problem ID or null</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, the function shows all problems. If the value isn't null and represents a valid problem ID, the function shows the specified problem.</td>
</tr>
<tr>
<td>last</td>
<td>number</td>
<td>A valid integer greater than 0 or null</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, then the function displays at most 50 items. If the value isn't null, the function displays the specified number.</td>
</tr>
</tbody>
</table>

**Listing incidents**

To list diagnostic incidents for Oracle, use the Amazon RDS function rdsadmin.rdsadmin_adrci_util.list_adrci_incidents. You can list incidents in either basic or detailed mode. By default, the function lists the 50 most recent incidents.

This function uses the following common parameters:

- incident_id
• **problem_id**

If you specify both of the preceding parameters, **incident_id** overrides **problem_id**. For more information, see [Common parameters for diagnostic procedures](p. 1643).

This function uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>detail</td>
<td>boolean</td>
<td>TRUE or FALSE</td>
<td>FALSE</td>
<td>No</td>
<td>If TRUE, the function lists incidents in detail mode. If FALSE, the function lists incidents in basic mode.</td>
</tr>
</tbody>
</table>

To list all incidents, query the **rdsadmin.rdsadmin_adrci_util.list_adrci_incidents** function without any arguments. The query returns the task ID.

```
SQL> SELECT rdsadmin.rdsadmin_adrci_util.list_adrci_incidents AS task_id FROM DUAL;

+---------------+----------------------------------+
<table>
<thead>
<tr>
<th>TASK_ID</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>159076706158-3126</td>
<td></td>
</tr>
</tbody>
</table>
```

Or call the **rdsadmin.rdsadmin_adrci_util.list_adrci_incidents** function without any arguments and store the output in a SQL client variable. You can use the variable in other statements.

```
SQL> VAR task_id VARCHAR2(80);
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_incidents;

PL/SQL procedure successfully completed.
```

To read the log file, call the Amazon RDS procedure **rdsadmin.rds_file_util.read_text_file**. Supply the task ID as part of the file name. The following output shows three incidents: 53523, 53522, and 53521.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-'||:task_id||'.log'));

<table>
<thead>
<tr>
<th>TEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-05-29 21:11:46.256 UTC [INFO ] ADR Home = /rdsdbdata/log/diag/rdbms/orcl_a/ORCL:</td>
</tr>
<tr>
<td>***********************************************</td>
</tr>
<tr>
<td>INCIDENT_ID</td>
</tr>
<tr>

</tr>
</tbody>
</table>

3 rows fetched |
To list a particular incident, specify its ID using the incident_id parameter. In the following example, you query the log file for incident 53523 only.

```sql
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_incidents(incident_id=>53523);
PL/SQL procedure successfully completed.

SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-'||:task_id||'.log'));
```

---

## Listing problems

To list diagnostic problems for Oracle, use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.list_adrci_problems`. By default, the function lists the 50 most recent problems. This function uses the common parameter `problem_id`. For more information, see Common parameters for diagnostic procedures (p. 1643).

To get the task ID for all problems, call the `rdsadmin.rdsadmin_adrci_util.list_adrci_problems` function without any arguments, and store the output in a SQL client variable.

```sql
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_problems;
PL/SQL procedure successfully completed.
```

To read the log file, call the `rdsadmin.rds_file_util.read_text_file` function, supplying the task ID as part of the file name. In the following output, the log file shows three problems: 1, 2, and 3.

```sql
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-'||:task_id||'.log'));
```

Listing problems

To list diagnostic problems for Oracle, use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.list_adrci_problems`. By default, the function lists the 50 most recent problems. This function uses the common parameter `problem_id`. For more information, see Common parameters for diagnostic procedures (p. 1643).

To get the task ID for all problems, call the `rdsadmin.rdsadmin_adrci_util.list_adrci_problems` function without any arguments, and store the output in a SQL client variable.

```sql
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_problems;
PL/SQL procedure successfully completed.

SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-'||:task_id||'.log'));
```
In the following example, you list problem 3 only.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_problems(problem_id=>3);
PL/SQL procedure successfully completed.
```

To read the log file for problem 3, call rdsadmin.rds_file_util.read_text_file. Supply the task ID as part of the file name.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-'||:task_id||'.log'));
```

Creating incident packages

You can create incident packages using the Amazon RDS function rdsadmin.rdsadmin_adrci_util.create_adrci_package. The output is a .zip file that you can supply to Oracle Support.

This function uses the following common parameters:
• problem_id
• incident_id

Make sure to specify one of the preceding parameters. If you specify both parameters, incident_id overrides problem_id. For more information, see Common parameters for diagnostic procedures (p. 1643).

To create a package for a specific incident, call the Amazon RDS function rdsadmin.rdsadmin_adrci_util.create_adrci_package with the incident_id parameter. The following example creates a package for incident 53523.

```
SQL> EXEC :task_id :=
rdsadmin.rdsadmin_adrci_util.create_adrci_package(incident_id=>53523);
PL/SQL procedure successfully completed.
```

To read the log file, call the rdsadmin.rds_file_util.read_text_file. You can supply the task ID as part of the file name. The output shows that you generated incident package ORA700EVE_20200529212043_COM_1.zip.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
'/dbtask-':''||:task_id||'.log'));
```

```
TEXT
------------------------------------------------------------------------------------------------------------------------------------------------------------
2020-05-29 21:20:43.031 UTC [INFO ] The ADRCI package is being created.
ORA700EVE_20200529212043_COM_1.zip, mode complete
2020-05-29 21:20:47.642 UTC [INFO ] The ADRCI package was successfully created.
```

To package diagnostic data for a particular problem, specify its ID using the problem_id parameter. In the following example, you package data for problem 3 only.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.create_adrci_package(problem_id=>3);
PL/SQL procedure successfully completed.
```

To read the task output, call rdsadmin.rds_file_util.read_text_file, supplying the task ID as part of the file name. The output shows that you generated incident package ORA700EVE_20200529212111_COM_1.zip.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
'/dbtask-':''||:task_id||'.log'));
```

```
TEXT
------------------------------------------------------------------------------------------------------------------------------------------------------------
ORA700EVE_20200529212111_COM_1.zip, mode complete
2020-05-29 21:21:15.646 UTC [INFO ] The ADRCI package was successfully created.
```

**Showing trace files**

You can show trace files using the Amazon RDS function rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile.
This function uses the following parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename</td>
<td>varchar2</td>
<td>A valid trace file name</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, the function shows all trace files. If it isn't null, the function shows the specified file.</td>
</tr>
</tbody>
</table>

To show the trace file, call the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile` with the `incident_id` parameter.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile;
PL/SQL procedure successfully completed.
```

To list the trace file names, call the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, supplying the task ID as part of the file name.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-'||:task_id||'.log')) WHERE TEXT LIKE '%/alert_%';
TEXT
-----------------------------------------------
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-28
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-27
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-26
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-25
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-24
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-23
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-22
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-21
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log
9 rows selected.
```

In the following example, you generate output for alert_ORCL.log.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile('diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log');
PL/SQL procedure successfully completed.
```

To read the log file, call `rdsadmin.rds_file_util.read_text_file`. Supply the task ID as part of the file name. The output shows the first 10 lines of alert_ORCL.log.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-'||:task_id||'.log')) WHERE ROWNUM <= 10;
TEXT
-----------------------------------------------------------------------------------------
2020-05-29 21:24:02.083 UTC [INFO ] The trace files are being displayed.

```
Performing miscellaneous tasks for Oracle DB instances

Following, you can find how to perform miscellaneous DBA tasks on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn’t provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

Topics

• Creating and dropping directories in the main data storage space (p. 1649)
• Listing files in a DB instance directory (p. 1650)
• Reading files in a DB instance directory (p. 1650)
• Accessing Opatch files (p. 1651)
• Managing advisor tasks (p. 1653)

Creating and dropping directories in the main data storage space

To create directories, use the Amazon RDS procedure 
rdsadmin.rdsadmin_util.create_directory. You can create up to 10,000 directories, all located in your main data storage space. To drop directories, use the Amazon RDS procedure rdsadmin.rdsadmin_util.drop_directory.

The create_directory and drop_directory procedures have the following required parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory.</td>
</tr>
</tbody>
</table>

The following example creates a new directory named PRODUCT_DESCRIPTIONS.

EXEC rdsadmin.rdsadmin_util.create_directory(p_directory_name => 'product_descriptions');

The data dictionary stores the directory name in uppercase. You can list the directories by querying DBA_DIRECTORIES. The system chooses the actual host pathname automatically. The following example gets the directory path for the directory named PRODUCT_DESCRIPTIONS:

```
SELECT DIRECTORY_PATH
FROM DBA_DIRECTORIES
WHERE DIRECTORY_NAME='PRODUCT_DESCRIPTIONS';
```

---

1649
The master user name for the DB instance has read and write privileges in the new directory, and can grant access to other users. EXECUTE privileges are not available for directories on a DB instance. Directories are created in your main data storage space and will consume space and I/O bandwidth.

The following example drops the directory named PRODUCT_DESCRIPTIONS.

```sql
EXEC rdsadmin.rdsadmin_util.drop_directory(p_directory_name => 'product_descriptions');
```

**Note**
You can also drop a directory by using the Oracle SQL command `DROP DIRECTORY`.

Dropping a directory doesn't remove its contents. Because the `rdsadmin.rdsadmin_util.create_directory` procedure can reuse pathnames, files in dropped directories can appear in a newly created directory. Before you drop a directory, we recommend that you use `UTL_FILE.FREMOVE` to remove files from the directory. For more information, see `FREMOVE procedure` in the Oracle documentation.

### Listing files in a DB instance directory

To list the files in a directory, use the Amazon RDS procedure `rdsadmin.rds_file_util.listdir`. The `listdir` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory to list.</td>
</tr>
</tbody>
</table>

The following example grants read/write privileges on the directory PRODUCT_DESCRIPTIONS to user `rdsadmin`, and then lists the files in this directory.

```sql
GRANT READ,WRITE ON DIRECTORY PRODUCT_DESCRIPTIONS TO rdsadmin;
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'PRODUCT_DESCRIPTIONS'));
```

### Reading files in a DB instance directory

To read a text file, use the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. The `read_text_file` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory that contains the file.</td>
</tr>
<tr>
<td>p_filename</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the file to read.</td>
</tr>
</tbody>
</table>

The following example creates the file `rice.txt` in the directory PRODUCT_DESCRIPTIONS.

```sql
declare
  fh sys.utl_file.file_type;
```
begin
  fh := utl_file.fopen(location=>'PRODUCT_DESCRIPTIONS', filename=>'rice.txt',
    open_mode=>'w');
  utl_file.put(file=>fh, buffer=>'AnyCompany brown rice, 15 lbs');
  utl_file.fclose(file=>fh);
end;
/

The following example reads the file rice.txt from the directory PRODUCT_DESCRIPTIONS.

```
SELECT * FROM TABLE
  (rdsadmin.rds_file_util.read_text_file(
    p_directory => 'PRODUCT_DESCRIPTIONS',
    p_filename  => 'rice.txt'));
```

## Accessing Opatch files

Opatch is an Oracle utility that enables the application and rollback of patches to Oracle software. The Oracle mechanism for determining which patches have been applied to a database is the opatch lsinventory command. To open service requests for Bring Your Own Licence (BYOL) customers, Oracle Support requests the lsinventory file and sometimes the lsinventory_detail file generated by Opatch.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to Opatch. Instead, the lsinventory-dbv.txt in the BDUMP directory contains the patch information related to your current engine version. When you perform a minor or major upgrade, Amazon RDS updates lsinventory-dbv.txt within an hour of applying the patch. To verify the applied patches, read lsinventory-dbv.txt. This action is similar to running the opatch lsinventory command.

### Note

The examples in this section assume that the BDUMP directory is named BDUMP. On a read replica, the BDUMP directory name is different. To learn how to get the BDUMP name by querying V$DATABASE_DB_UNIQUE_NAME on a read replica, see Listing files (p. 746).

The inventory files use the Amazon RDS naming convention lsinventory-dbv.txt and lsinventory_detail-dbv.txt, where dbv is the full name of your DB version. The lsinventory-dbv.txt file is available on all DB versions. The corresponding lsinventory_detail-dbv.txt is available on the following DB versions:

- 19.0.0.0, ru-2020-01.rur-2020-01.r1 or later
- 12.2.0.1, ru-2020-01.rur-2020-01.r1 or later
- 12.1.0.2, v19 or later

For example, if your DB version is 19.0.0.0.ru-2021-07.ru-2021-07.r1, then your inventory files have the following names.

```
lsinventory-19.0.0.0.ru-2021-07.ru-2021-07.r1.txt
lsinventory_detail-19.0.0.0.ru-2021-07.ru-2021-07.r1.txt
```

Ensure that you download the files that match the current version of your DB engine.

### Console

**To download an inventory file using the console**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. In the **Logs** section, search for `lsinventory`.
7. Select the file that you want to access, and then choose **Download**.

**SQL**

To read the `lsinventory-<dbv>.txt` in a SQL client, you can use a SELECT statement. For this technique, use either of the following rdsadmin functions: `rdsadmin.rds_file_util.read_text_file` or `rdsadmin.tracefile_listing`.

In the following sample query, replace `<dbv>` with your Oracle DB version. For example, your DB version might be `19.0.0.0.ru-2020-04.rur-2020-04.r1`.

```sql
SELECT text
FROM   TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'lsinventory-<dbv>.txt'));
```

**PL/SQL**

To read the `lsinventory-<dbv>.txt` in a SQL client, you can write a PL/SQL program. This program uses `utl_file` to read the file, and `dbms_output` to print it. These are Oracle-supplied packages.

In the following sample program, replace `<dbv>` with your Oracle DB version. For example, your DB version might be `19.0.0.0.ru-2020-04.rur-2020-04.r1`.

```sql
SET SERVEROUTPUT ON
DECLARE
  v_file              SYS.UTL_FILE.FILE_TYPE;
  v_line              VARCHAR2(1000);
  v_oracle_home_type  VARCHAR2(1000);
  c_directory         VARCHAR2(30) := 'BDUMP';
  c_output_file       VARCHAR2(30) := 'lsinventory-<dbv>.txt';
BEGIN
  v_file := SYS.UTL_FILE.FOPEN(c_directory, c_output_file, 'r');
  LOOP
    BEGIN
      SYS.UTL_FILE.GET_LINE(v_file, v_line, 1000);
      DBMS_OUTPUT.PUT_LINE(v_line);
      EXCEPTION
        WHEN no_data_found THEN
          EXIT;
      END;
    END LOOP;
END;
/
```

Or query `rdsadmin.tracefile_listing`, and spool the output to a file. The following example spools the output to `/tmp/tracefile.txt`.

```sql
SPOOL /tmp/tracefile.txt
SELECT *
FROM   rdsadmin.tracefile_listing
WHERE  FILENAME LIKE 'lsinventory%';
SPOOL OFF;
```
Managing advisor tasks

Oracle Database includes a number of advisors. Each advisor supports automated and manual tasks. You can use procedures in the rdsadmin.rdsadmin_util package to manage some advisor tasks.

The advisor task procedures are available in the following engine versions:

- Oracle Database 21c (21.0.0)
- Version 19.0.0.0.ru-2021-01.rur-2021-01.r1 and higher Oracle Database 19c versions

For more information, see Version 19.0.0.0.ru-2021-01.rur-2021-01.r1 in the Amazon RDS for Oracle Release Notes.

- Version 12.2.0.1.ru-2021-01.rur-2021-01.r1 and higher Oracle Database 12c (Release 2) 12.2.0.1 versions

For more information, see Version 12.2.0.1.ru-2021-01.rur-2021-01.r1 in the Amazon RDS for Oracle Release Notes.

Topics

- Setting parameters for advisor tasks (p. 1653)
- Disabling AUTO_STATS_ADVISOR_TASK (p. 1654)
- Re-enabling AUTO_STATS_ADVISOR_TASK (p. 1655)

Setting parameters for advisor tasks

To set parameters for some advisor tasks, use the Amazon RDS procedure rdsadmin.rdsadmin_util.advisor_task_set_parameter. The advisor_task_set_parameter procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_task_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the advisor task whose parameters you want to change. The following values are valid:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• AUTO_STATS_ADVISOR_TASK</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• INDIVIDUAL_STATS_ADVISOR_TASK</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• SYS_AUTO_SPM_EVOLVE_TASK</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• SYS_AUTO_SQL_TUNING_TASK</td>
</tr>
<tr>
<td>p_parameter</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the task parameter. To find valid parameters for an advisor task, run the following query. Substitute p_task_name with a valid value for p_task_name:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>COL PARAMETER_NAME FORMAT a30</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>COL PARAMETER_VALUE FORMAT a30</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>SELECT PARAMETER_NAME, PARAMETER_VALUE</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>FROM DBA_ADVISOR_PARAMETERS</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>WHERE TASK_NAME='p_task_name'</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>AND PARAMETER_VALUE != 'UNUSED'</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>ORDER BY PARAMETER_NAME;</td>
</tr>
</tbody>
</table>
The following PL/SQL program sets ACCEPT_PLANS to FALSE for SYS_AUTO_SPM_EVOLVE_TASK. The SQL Plan Management automated task verifies the plans and generates a report of its findings, but does not evolve the plans automatically. You can use a report to identify new SQL plan baselines and accept them manually.

```sql
BEGIN
    rdsadmin.rdsadmin_util.advisor_task_set_parameter(
        p_task_name => 'SYS_AUTO_SPM_EVOLVE_TASK',
        p_parameter => 'ACCEPT_PLANS',
        p_value => 'FALSE');
END;
```

The following PL/SQL program sets EXECUTION_DAYS_TO_EXPIRE to 10 for AUTO_STATS_ADVISOR_TASK. The predefined task AUTO_STATS_ADVISOR_TASK runs automatically in the maintenance window once per day. The example sets the retention period for the task execution to 10 days.

```sql
BEGIN
    rdsadmin.rdsadmin_util.advisor_task_set_parameter(
        p_task_name => 'AUTO_STATS_ADVISOR_TASK',
        p_parameter => 'EXECUTION_DAYS_TO_EXPIRE',
        p_value => '10');
END;
```

Disabling AUTO_STATS_ADVISOR_TASK

To disable AUTO_STATS_ADVISOR_TASK, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.advisor_task_drop`. The advisor_task_drop procedure accepts the following parameter.

**Note**

This procedure is available in Oracle Database 12c Release 2 (12.2.0.1) and later.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_task_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the advisor task to be disabled. The only valid value is AUTO_STATS_ADVISOR_TASK.</td>
</tr>
</tbody>
</table>

The following command drops AUTO_STATS_ADVISOR_TASK.
You can re-enabling AUTO_STATS_ADVISOR_TASK using
rdsadmin.rdsadmin_util.dbms_stats_init.

Re-enabling AUTO_STATS_ADVISOR_TASK

To re-enable AUTO_STATS_ADVISOR_TASK, use the Amazon RDS procedure
rdsadmin.rdsadmin_util.dbms_stats_init. The dbms_stats_init procedure takes no
parameters.

The following command re-enables AUTO_STATS_ADVISOR_TASK.

EXEC rdsadmin.rdsadmin_util.dbms_stats_init()
Configuring advanced RDS for Oracle features

RDS for Oracle supports various advanced features, including HugePages, an instance store, and extended data types.

Topics
- Storing temporary data in an RDS for Oracle instance store (p. 1656)
- Turning on HugePages for an RDS for Oracle instance (p. 1662)
- Turning on extended data types in RDS for Oracle (p. 1665)

Storing temporary data in an RDS for Oracle instance store

Use an instance store for the temporary tablespaces and the Database Smart Flash Cache (the flash cache) on supported RDS for Oracle DB instance classes.

Topics
- Overview of the RDS for Oracle instance store (p. 1656)
- Turning on an RDS for Oracle instance store (p. 1658)
- Configuring an RDS for Oracle instance store (p. 1658)
- Considerations when changing the DB instance type (p. 1660)
- Working with an instance store on an Oracle read replica (p. 1661)
- Configuring a temporary tablespace group on an instance store and Amazon EBS (p. 1661)
- Removing an RDS for Oracle instance store (p. 1662)

Overview of the RDS for Oracle instance store

An instance store provides temporary block-level storage for an RDS for Oracle DB instance. You can use an instance store for temporary storage of information that changes frequently.

An instance store is based on Non-Volatile Memory Express (NVMe) devices that are physically attached to the host computer. The storage is optimized for low latency, random I/O performance, and sequential read throughput.

The size of the instance store varies by DB instance type. For more information about the instance store, see Amazon EC2 instance store in the Amazon Elastic Compute Cloud User Guide for Linux Instances.

Topics
- Types of data in the RDS for Oracle instance store (p. 1656)
- Benefits of the RDS for Oracle instance store (p. 1657)
- Supported instance classes for the RDS for Oracle instance store (p. 1657)
- Supported engine versions for the RDS for Oracle instance store (p. 1658)
- Supported AWS Regions for the RDS for Oracle instance store (p. 1658)
- Cost of the RDS for Oracle instance store (p. 1658)

Types of data in the RDS for Oracle instance store

You can place the following types of RDS for Oracle temporary data in an instance store:
A temporary tablespace

Oracle Database uses temporary tablespaces to store intermediate query results that don't fit in memory. Larger queries can generate large amounts of intermediate data that needs to be cached temporarily, but doesn't need to persist. In particular, a temporary tablespace is useful for sorts, hash aggregations, and joins. If your RDS for Oracle DB instance uses the Enterprise Edition or Standard Edition 2, you can place a temporary tablespace in an instance store.

The flash cache

The flash cache improves the performance of single-block random reads in the conventional path. A best practice is to size the cache to accommodate most of your active data set. If your RDS for Oracle DB instance uses the Enterprise Edition, you can place the flash cache in an instance store.

By default, an instance store is configured for a temporary tablespace but not for the flash cache. You can't place Oracle data files and database log files in an instance store.

Benefits of the RDS for Oracle instance store

You might consider using an instance store to store temporary files and caches that you can afford to lose. If you want to improve DB performance, or if an increasing workload is causing performance problems for your Amazon EBS storage, consider scaling to an instance class that supports an instance store.

By placing your temporary tablespace and flash cache on an instance store, you get the following benefits:

- Lower read latencies
- Higher throughput
- Reduced load on your Amazon EBS volumes
- Lower storage and snapshot costs because of reduced Amazon EBS load
- Less need to provision high IOPS, possibly lowering your overall cost

By placing your temporary tablespace on the instance store, you deliver an immediate performance boost to queries that use temporary space. When you place the flash cache on the instance store, cached block reads typically have much lower latency than Amazon EBS reads. The flash cache needs to be "warmed up" before it delivers performance benefits. The cache warms up by itself because the database writes blocks to the flash cache as they age out of the database buffer cache.

**Note**

In some cases, the flash cache causes performance overhead because of cache management. Before you turn on the flash cache in a production environment, we recommend that you analyze your workload and test the cache in a test environment.

Supported instance classes for the RDS for Oracle instance store

Amazon RDS supports the instance store for the following DB instance classes:

- db.m5d
- db.r5d
- db.x2idn
- db.x2iedn

RDS for Oracle supports the preceding DB instance classes for the BYOL licensing model only. For more information, see [Supported RDS for Oracle instance classes](p. 1529) and [Bring Your Own License (BYOL)](p. 1526).
To see the total instance storage for the supported DB instance types, run the following command in the AWS CLI.

**Example**

```bash
aws ec2 describe-instance-types \
  --filters "Name=instance-type,Values=*5d.*large*" \
  --query "InstanceTypes[?contains(InstanceType,'m5d')||contains(InstanceType,'r5d')]
  [InstanceType, InstanceStorageInfo.TotalSizeInGB]" \
  --output table
```

The preceding command returns the raw device size for the instance store. RDS for Oracle uses a small portion of this space for configuration. The space in the instance store that is available for temporary tablespaces or the flash cache is slightly smaller.

**Supported engine versions for the RDS for Oracle instance store**

The instance store is supported for the following RDS for Oracle engine versions:

- 21.0.0.0.ru-2022-01.rur-2022-01.r1 or higher Oracle Database 21c versions
- 19.0.0.0.ru-2021-10.rur-2021-10.r1 or higher Oracle Database 19c versions

**Supported AWS Regions for the RDS for Oracle instance store**

The instance store is available in all AWS Regions where one or more of these instance types are supported. For more information on the db.m5d and db.r5d instance classes, see [DB instance classes](p. 10). For more information on the instance classes supported by Amazon RDS for Oracle, see [RDS for Oracle instance classes](p. 1529).

**Cost of the RDS for Oracle instance store**

The cost of the instance store is built into the cost of the instance-store turned on instances. You don't incur additional costs by enabling an instance store on an RDS for Oracle DB instance. For more information about instance-store turned on instances, see [Supported instance classes for the RDS for Oracle instance store](p. 1657).

**Turning on an RDS for Oracle instance store**

To turn on the instance store for RDS for Oracle temporary data, do one of the following:

- Create an RDS for Oracle DB instance using a supported instance class. For more information, see [Creating an Amazon RDS DB instance](p. 236).
- Modify an existing RDS for Oracle DB instance to use a supported instance class. For more information, see [Modifying an Amazon RDS DB instance](p. 333).

**Configuring an RDS for Oracle instance store**

By default, 100% of instance store space is allocated to the temporary tablespace. To configure the instance store to allocate space to the flash cache and temporary tablespace, set the following parameters in the parameter group for your instance:

\[
\text{db\_flash\_cache\_size}=\left\{(\text{DBInstanceStore} \times \{0,2,4,6,8,10\})/10\right\}
\]

This parameter specifies the amount of storage space allocated for the flash cache. This parameter is valid only for Oracle Database Enterprise Edition. The default value is \(\text{DBInstanceStore} \times 0/10\). If you set a nonzero value for \text{db\_flash\_cache\_size}, your RDS for Oracle instance enables the flash cache after you restart the instance.
rds.instance_store_temp_size={DBInstanceStore*{0,2,4,6,8,10}/10}

This parameter specifies the amount of storage space allocated for the temporary tablespace. The default value is {DBInstanceStore*10/10}. This parameter is modifiable for Oracle Database Enterprise Edition and read-only for Standard Edition 2. If you set a nonzero value for rds.instance_store_temp_size, Amazon RDS allocates space in the instance store for the temporary tablespace.

You can set the db_flash_cache_size and rds.instance_store_temp_size parameters for DB instances that don't use an instance store. In this case, both settings evaluate to 0, which turns off the feature. In this case, you can use the same parameter group for different instance sizes and for instances that don't use an instance store. If you modify these parameters, make sure to reboot the associated instances so that the changes can take effect.

**Important**

If you allocate space for a temporary tablespace, Amazon RDS doesn't create the temporary tablespace automatically. To learn how to create the temporary tablespace on the instance store, see Creating a temporary tablespace on the instance store (p. 1597).

The combined value of the preceding parameters must not exceed 10/10, or 100%. The following table illustrates valid and invalid parameter settings.

<table>
<thead>
<tr>
<th>db_flash_cache_size setting</th>
<th>rds.instance_store_temp_size setting</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>db_flash_cache_size={DBInstanceStore*0/10}</td>
<td>rds.instance_store_temp_size={DBInstanceStore*10/10}</td>
<td>This is a valid configuration for all editions of Oracle Database. Amazon RDS allocates 100% of instance store space to the temporary tablespace. This is the default.</td>
</tr>
<tr>
<td>db_flash_cache_size={DBInstanceStore*10/10}</td>
<td>rds.instance_store_temp_size={DBInstanceStore*0/10}</td>
<td>This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 100% of instance store space to the flash cache.</td>
</tr>
<tr>
<td>db_flash_cache_size={DBInstanceStore*2/10}</td>
<td>rds.instance_store_temp_size={DBInstanceStore*8/10}</td>
<td>This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 20% of instance store space to the flash cache, and 80% of instance store space to the temporary tablespace.</td>
</tr>
</tbody>
</table>
Configuring the instance store

<table>
<thead>
<tr>
<th>db_flash_cache_size setting</th>
<th>rds.instance_store_temp_size setting</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>db_flash_cache_size={DBInstanceStore*6/10}</td>
<td>rds.instance_store_temp_size={DBInstanceStore*4/10}</td>
<td>This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 60% of instance store space to the flash cache, and 40% of instance store space to the temporary tablespace.</td>
</tr>
<tr>
<td>db_flash_cache_size={DBInstanceStore*2/10}</td>
<td>rds.instance_store_temp_size={DBInstanceStore*4/10}</td>
<td>This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 20% of instance store space to the flash cache, and 40% of instance store space to the temporary tablespace.</td>
</tr>
<tr>
<td>db_flash_cache_size={DBInstanceStore*8/10}</td>
<td>rds.instance_store_temp_size={DBInstanceStore*8/10}</td>
<td>This is an invalid configuration because the combined percentage of instance store space exceeds 100%. In such cases, Amazon RDS fails the attempt.</td>
</tr>
</tbody>
</table>

Considerations when changing the DB instance type

If you change your DB instance type, it can affect the configuration of the flash cache or the temporary tablespace on the instance store. Consider the following modifications and their effects:

You scale up or scale down the DB instance that supports the instance store.

The following values increase or decrease proportionally to the new size of the instance store:

- The new size of the flash cache.
- The space allocated to the temporary tablespaces that reside in the instance store.

For example, the setting db_flash_cache_size={DBInstanceStore*6/10} on a db.m5d.4xlarge instance provides around 340 GB of flash cache space. If you scale up the instance type to db.m5d.8xlarge, the flash cache space increases to around 680 GB.
You modify a DB instance that doesn't use an instance store to an instance that does use an instance store.

If `db_flash_cache_size` is set to a value larger than 0, the flash cache is configured. If `rds.instance_store_temp_size` is set to a value larger than 0, the instance store space is allocated for use by a temporary tablespace. RDS for Oracle doesn't move tempfiles to the instance store automatically. For information about using the allocated space, see Creating a temporary tablespace on the instance store (p. 1597) or Adding a tempfile to the instance store on a read replica (p. 1597).

You modify a DB instance that uses an instance store to an instance that doesn't use an instance store.

In this case, RDS for Oracle removes the flash cache. RDS re-creates the tempfile that is currently located on the instance store on an Amazon EBS volume. The maximum size of the new tempfile is the former size of the `rds.instance_store_temp_size` parameter.

### Working with an instance store on an Oracle read replica

Read replicas support the flash cache and temporary tablespaces on an instance store. While the flash cache works the same way as on the primary DB instance, note the following differences for temporary tablespaces:

- You can't create a temporary tablespace on a read replica. If you create a new temporary tablespace on the primary instance, RDS for Oracle replicates the tablespace information without tempfiles. To add a new tempfile, use either of the following techniques:
  - Use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_inst_store_tempfile`. RDS for Oracle creates a tempfile in the instance store on your read replica, and adds it to the specified temporary tablespace.
  - Run the `ALTER TABLESPACE ... ADD TEMPFILE` command. RDS for Oracle places the tempfile on Amazon EBS storage.

  **Note**
  The tempfile sizes and storage types can be different on the primary DB instance and the read replica.

- You can manage the default temporary tablespace setting only on the primary DB instance. RDS for Oracle replicates the setting to all read replicas.

- You can configure the temporary tablespace groups only on the primary DB instance. RDS for Oracle replicates the setting to all read replicas.

### Configuring a temporary tablespace group on an instance store and Amazon EBS

You can configure a temporary tablespace group to include temporary tablespaces on both an instance store and Amazon EBS. This technique is useful when you want more temporary storage than is allowed by the maximum setting of `rds.instance_store_temp_size`.

When you configure a temporary tablespace group on both an instance store and Amazon EBS, the two tablespaces have significantly different performance characteristics. Oracle Database chooses the tablespace to serve queries based on an internal algorithm. Therefore, similar queries can vary in performance.

Typically, you create a temporary tablespace in the instance store as follows:

1. Create a temporary tablespace in the instance store.
2. Set the new tablespace as the database default temporary tablespace.
If the tablespace size in the instance store is insufficient, you can create additional temporary storage as follows:

1. Assign the temporary tablespace in the instance store to a temporary tablespace group.
2. Create a new temporary tablespace in Amazon EBS if one doesn’t exist.
3. Assign the temporary tablespace in Amazon EBS to the same tablespace group that includes the instance store tablespace.
4. Set the tablespace group as the default temporary tablespace.

The following example assumes that the size of the temporary tablespace in the instance store doesn’t meet your application requirements. The example creates the temporary tablespace temp_in_inst_store in the instance store, assigns it to tablespace group temp_group, adds the existing Amazon EBS tablespace named temp_in_ebs to this group, and sets this group as the default temporary tablespace.

```
SQL> EXEC rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace('temp_in_inst_store');
PL/SQL procedure successfully completed.

SQL> ALTER TABLESPACE temp_in_inst_store TABLESPACE GROUP temp_group;
Tablespace altered.

SQL> ALTER TABLESPACE temp_in_ebs TABLESPACE GROUP temp_group;
Tablespace altered.

SQL> EXEC rdsadmin.rdsadmin_util.alter_default_temp_tablespace('temp_group');
PL/SQL procedure successfully completed.

SQL> SELECT * FROM DBA_TABLESPACE_GROUPS;
GROUP_NAME                     TABLESPACE_NAME
------------------------------ ------------------------------
TEMP_GROUP                     TEMP_IN_EBS                    ------------------------------
TEMP_GROUP                     TEMP_IN_INST_STORE

SQL> SELECT PROPERTY_VALUE FROM DATABASE_PROPERTIES WHERE PROPERTY_NAME='DEFAULT_TEMP_TABLESPACE';
PROPERTY_VALUE
--------------
TEMP_GROUP
```

Removing an RDS for Oracle instance store

To remove the instance store, modify your RDS for Oracle DB instance to use an instance type that doesn’t support instance store, such as db.m5 or db.r5.

**Turning on HugePages for an RDS for Oracle instance**

Amazon RDS for Oracle supports Linux kernel HugePages for increased database scalability. HugePages results in smaller page tables and less CPU time spent on memory management, increasing the performance of large database instances. For more information, see Overview of HugePages in the Oracle documentation.

You can use HugePages with all supported versions and editions of RDS for Oracle.
The `use_large_pages` parameter controls whether HugePages are turned on for a DB instance. The possible settings for this parameter are ONLY, FALSE, and `{DBInstanceClassHugePagesDefault}`. The `use_large_pages` parameter is set to `{DBInstanceClassHugePagesDefault}` in the default DB parameter group for Oracle.

To control whether HugePages are turned on for a DB instance automatically, you can use the `DBInstanceClassHugePagesDefault` formula variable in parameter groups. The value is determined as follows:

- For the DB instance classes mentioned in the table following, `DBInstanceClassHugePagesDefault` always evaluates to FALSE by default, and `use_large_pages` evaluates to FALSE. You can turn on HugePages manually for these DB instance classes if the DB instance class has at least 14 GiB of memory.
- For DB instance classes not mentioned in the table following, if the DB instance class has less than 14 GiB of memory, `DBInstanceClassHugePagesDefault` always evaluates to FALSE. Also, `use_large_pages` evaluates to FALSE.
- For DB instance classes not mentioned in the table following, if the instance class has at least 14 GiB of memory and less than 100 GiB of memory, `DBInstanceClassHugePagesDefault` evaluates to TRUE by default. Also, `use_large_pages` evaluates to ONLY. You can turn off HugePages manually by setting `use_large_pages` to FALSE.
- For DB instance classes not mentioned in the table following, if the instance class has at least 100 GiB of memory, `DBInstanceClassHugePagesDefault` always evaluates to TRUE. Also, `use_large_pages` evaluates to ONLY and HugePages can't be disabled.

HugePages are not turned on by default for the following DB instance classes.

<table>
<thead>
<tr>
<th>DB instance class family</th>
<th>DB instance classes with HugePages not turned on by default</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.m5</td>
<td>db.m5.large</td>
</tr>
<tr>
<td>db.m4</td>
<td>db.m4.large, db.m4.xlarge, db.m4.2xlarge, db.m4.4xlarge, db.m4.10xlarge</td>
</tr>
<tr>
<td>db.t3</td>
<td>db.t3.micro, db.t3.small, db.t3.medium, db.t3.large</td>
</tr>
</tbody>
</table>

For more information about DB instance classes, see [Hardware specifications for DB instance classes](p. 62).

To turn on HugePages for new or existing DB instances manually, set the `use_large_pages` parameter to ONLY. You can't use HugePages with Oracle Automatic Memory Management (AMM). If you set the parameter `use_large_pages` to ONLY, then you must also set both `memory_target` and `memory_max_target` to 0. For more information about setting DB parameters for your DB instance, see [Working with parameter groups](p. 295).

You can also set the `sga_target`, `sga_max_size`, and `pga_aggregate_target` parameters. When you set system global area (SGA) and program global area (PGA) memory parameters, add the values together. Subtract this total from your available instance memory (`DBInstanceClassMemory`) to determine the free memory beyond the HugePages allocation. You must leave free memory of at least 2 GiB, or 10 percent of the total available instance memory, whichever is smaller.

After you configure your parameters, you must reboot your DB instance for the changes to take effect. For more information, see [Rebooting a DB instance](p. 378).

**Note**

The Oracle DB instance defers changes to SGA-related initialization parameters until you reboot the instance without failover. In the Amazon RDS console, choose **Reboot** but do not choose...
**Reboot with failover.** In the AWS CLI, call the `reboot-db-instance` command with the `--no-force-failover` parameter. The DB instance does not process the SGA-related parameters during failover or during other maintenance operations that cause the instance to restart.

The following is a sample parameter configuration for HugePages that enables HugePages manually. You should set the values to meet your needs.

```plaintext
memory_target            = 0
memory_max_target        = 0
pga_aggregate_target     = {DBInstanceClassMemory*1/8}
sga_target               = {DBInstanceClassMemory*3/4}
sga_max_size             = {DBInstanceClassMemory*3/4}
use_large_pages          = ONLY
```

Assume the following parameters values are set in a parameter group.

```plaintext
memory_target            = IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})
memory_max_target        = IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})
pga_aggregate_target     = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*1/8}, 0)
sga_target               = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*3/4}, 0)
sga_max_size             = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*3/4}, 0)
use_large_pages          = {DBInstanceClassHugePagesDefault}
```

The parameter group is used by a db.r4 DB instance class with less than 100 GiB of memory. With these parameter settings and `use_large_pages` set to `{DBInstanceClassHugePagesDefault}`, HugePages are turned on for the db.r4 instance.

Consider another example with following parameters values set in a parameter group.

```plaintext
memory_target            = IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})
memory_max_target        = IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})
pga_aggregate_target     = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*1/8}, 0)
sga_target               = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*3/4}, 0)
sga_max_size             = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*3/4}, 0)
use_large_pages          = FALSE
```

The parameter group is used by a db.r4 DB instance class and a db.r5 DB instance class, both with less than 100 GiB of memory. With these parameter settings, HugePages are turned off on the db.r4 and db.r5 instance.

**Note**

If this parameter group is used by a db.r4 DB instance class or db.r5 DB instance class with at least 100 GiB of memory, the FALSE setting for `use_large_pages` is overridden and set to ONLY. In this case, a customer notification regarding the override is sent.

After HugePages are active on your DB instance, you can view HugePages information by enabling enhanced monitoring. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 635).
Turning on extended data types in RDS for Oracle

Amazon RDS Oracle Database 12c supports extended data types. With extended data types, the maximum size is 32,767 bytes for the VARCHAR2, NVARCHAR2, and RAW data types. To use extended data types, set the MAX_STRING_SIZE parameter to EXTENDED. For more information, see Extended data types in the Oracle documentation.

If you don't want to use extended data types, keep the MAX_STRING_SIZE parameter set to STANDARD (the default). In this case, the size limits are 4,000 bytes for the VARCHAR2 and NVARCHAR2 data types, and 2,000 bytes for the RAW data type.

You can turn on extended data types on a new or existing DB instance. For new DB instances, DB instance creation time is typically longer when you turn on extended data types. For existing DB instances, the DB instance is unavailable during the conversion process.

The following are considerations for a DB instance with extended data types enabled:

- **When you turn on extended data types for a DB instance, you can't change the DB instance back to use the standard size for data types. After a DB instance is converted to use extended data types, if you set the MAX_STRING_SIZE parameter back to STANDARD it results in the incompatible-parameters status.**

- **When you restore a DB instance that uses extended data types, you must specify a parameter group with the MAX_STRING_SIZE parameter set to EXTENDED. During restore, if you specify the default parameter group or any other parameter group with MAX_STRING_SIZE set to STANDARD it results in the incompatible-parameters status.**

- **We recommend that you don't turn on extended data types for Oracle DB instances running on the t2.micro DB instance class.**

When the DB instance status is incompatible-parameters because of the MAX_STRING_SIZE setting, the DB instance remains unavailable until you set the MAX_STRING_SIZE parameter to EXTENDED and reboot the DB instance.

### Turning on extended data types for a new DB instance

**To turn on extended data types for a new DB instance**

1. Set the MAX_STRING_SIZE parameter to EXTENDED in a parameter group.

   To set the parameter, you can either create a new parameter group or modify an existing parameter group.

   For more information, see Working with parameter groups (p. 295).

2. Create a new Amazon RDS Oracle DB instance, and associate the parameter group with MAX_STRING_SIZE set to EXTENDED with the DB instance.

   For more information, see Creating an Amazon RDS DB instance (p. 236).

### Turning on extended data types for an existing DB instance

When you modify a DB instance to turn on extended data types, the data in the database is converted to use the extended sizes. The DB instance is unavailable during the conversion. The amount of time it takes to convert the data depends on the DB instance class used by the DB instance and the size of the database.
Note
After you turn on extended data types, you can't perform a point-in-time restore to a time during the conversion. You can restore to the time immediately before the conversion or after the conversion.

To turn on extended data types for an existing DB instance

1. Take a snapshot of the database.
   
   If there are invalid objects in the database, Amazon RDS tries to recompile them. The conversion to extended data types can fail if Amazon RDS can't recompile an invalid object. The snapshot enables you to restore the database if there is a problem with the conversion. Always check for invalid objects before conversion and fix or drop those invalid objects. For production databases, we recommend testing the conversion process on a copy of your DB instance first.

   For more information, see Creating a DB snapshot (p. 483).

2. Set the MAX_STRING_SIZE parameter to EXTENDED in a parameter group.
   
   To set the parameter, you can either create a new parameter group or modify an existing parameter group.

   For more information, see Working with parameter groups (p. 295).

3. Modify the DB instance to associate it with the parameter group with MAX_STRING_SIZE set to EXTENDED.

   For more information, see Modifying an Amazon RDS DB instance (p. 333).

4. Reboot the DB instance for the parameter change to take effect.

   For more information, see Rebooting a DB instance (p. 378).
Importing data into Oracle on Amazon RDS

How you import data into an Amazon RDS for Oracle DB instance depends on the following:

- The amount of data you have
- The number of database objects in your database
- The variety of database objects in your database

For example, you can use the following tools, depending on your requirements:

- Oracle SQL Developer – Import a simple, 20 MB database.
- Oracle Data Pump – Import complex databases, or databases that are several hundred megabytes or several terabytes in size. You can use Amazon S3 in this task. For example, download Data Pump files from Amazon S3 to the DB instance. For more information, see Amazon S3 integration (p. 1700).
- AWS Database Migration Service (AWS DMS) – Migrate databases without downtime. For more information about AWS DMS, see What is AWS Database Migration Service and the blog post Migrating Oracle databases with near-zero downtime using AWS DMS.

**Important**

Before you use the preceding migration techniques, we recommend that you back up your database. After you import the data, you can back up your RDS for Oracle DB instances by creating snapshots. Later, you can restore the snapshots. For more information, see Backing up and restoring an Amazon RDS DB instance (p. 461).

For many database engines, ongoing replication can continue until you are ready to switch over to the target database. You can use AWS DMS to migrate to RDS for Oracle from either the same database engine or a different engine. If you migrate from a different database engine, you can use the AWS Schema Conversion Tool to migrate schema objects that AWS DMS doesn’t migrate.

**Topics**

- Importing using Oracle SQL Developer (p. 1667)
- Importing using Oracle Data Pump (p. 1668)
- Importing using Oracle Export/Import (p. 1678)
- Importing using Oracle SQL*Loader (p. 1679)
- Migrating with Oracle materialized views (p. 1680)

Importing using Oracle SQL Developer

For small databases, you can use Oracle SQL Developer, a graphical Java tool distributed without cost by Oracle. You can install this tool on your desktop computer (Windows, Linux, or Mac) or on one of your servers. SQL Developer provides options for migrating data between two Oracle databases, or for migrating data from other databases, such as MySQL, to an Oracle database. SQL Developer is best suited for migrating small databases. We recommend that you read the Oracle SQL Developer product documentation before you begin migrating your data.

After you install SQL Developer, you can use it to connect to your source and target databases. Use the Database Copy command on the Tools menu to copy your data to your Amazon RDS instance.

Oracle also has documentation on how to migrate from other databases, including MySQL and SQL Server. For more information, see http://www.oracle.com/technetwork/database/migration in the Oracle documentation.
Importing using Oracle Data Pump

Oracle Data Pump is a utility that allows you to export Oracle data to a dump file and import it into another Oracle database. It is a long-term replacement for the Oracle Export/Import utilities. Oracle Data Pump is the recommended way to move large amounts of data from an Oracle database to an Amazon RDS DB instance.

The examples in this section show one way to import data into an Oracle database, but Oracle Data Pump supports other techniques. For more information, see the Oracle Database documentation.

The examples in this section use the DBMS_DATAPUMP package. You can accomplish the same tasks using the Oracle Data Pump command line utilities impdp and expdp. You can install these utilities on a remote host as part of an Oracle Client installation, including Oracle Instant Client. For more information, see How do I use Oracle Instant Client to run Data Pump Import or Export for my Amazon RDS for Oracle DB instance?

Topics

- Overview of Oracle Data Pump (p. 1668)
- Importing data with Oracle Data Pump and an Amazon S3 bucket (p. 1670)
- Importing data with Oracle Data Pump and a database link (p. 1674)

Overview of Oracle Data Pump

Oracle Data Pump is made up of the following components:

- Command-line clients expdp and impdp
- The DBMS_DATAPUMP PL/SQL package
- The DBMS_METADATA PL/SQL package

You can use Oracle Data Pump for the following scenarios:

- Import data from an Oracle database, either on-premises or on an Amazon EC2 instance, to an RDS for Oracle DB instance.
- Import data from an RDS for Oracle DB instance to an Oracle database, either on-premises or on an Amazon EC2 instance.
- Import data between RDS for Oracle DB instances, for example, to migrate data from EC2-Classic to VPC.

To download Oracle Data Pump utilities, see Oracle database software downloads on the Oracle Technology Network website. For compatibility considerations when migrating between versions of Oracle Database, see the Oracle Database documentation.

Oracle Data Pump workflow

Typically, you use Oracle Data Pump in the following stages:

1. Export your data into a dump file on the source database.
2. Upload your dump file to your destination RDS for Oracle DB instance. You can transfer using an Amazon S3 bucket or by using a database link between the two databases.
3. Import the data from your dump file into your RDS for Oracle DB instance.
Oracle Data Pump best practices

When you use Oracle Data Pump to import data into an RDS for Oracle instance, we recommend the following best practices:

- Perform imports in schema or table mode to import specific schemas and objects.
- Limit the schemas you import to those required by your application.
- Don't import in full mode or import schemas for system-maintained components.

Because RDS for Oracle doesn't allow access to SYS or SYSDBA administrative users, these actions might damage the Oracle data dictionary and affect the stability of your database.

- When loading large amounts of data, do the following:
  1. Transfer the dump file to the target RDS for Oracle DB instance.
  2. Take a DB snapshot of your instance.
  3. Test the import to verify that it succeeds.

If database components are invalidated, you can delete the DB instance and re-create it from the DB snapshot. The restored DB instance includes any dump files staged on the DB instance when you took the DB snapshot.

- Don't import dump files that were created using the Oracle Data Pump export parameters TRANSPORT_TABLESPACES, TRANSPORTABLE, or TRANSPORT_FULL_CHECK. RDS for Oracle DB instances don't support importing these dump files.

- Don't import dump files that contain Oracle Scheduler objects in SYS, SYSTEM, RDSADMIN, RDSSEC, and RDS_DATAGUARD, and belong to the following categories:
  - Jobs
  - Programs
  - Schedules
  - Chains
  - Rules
  - Evaluation contexts
  - Rule sets

RDS for Oracle DB instances don't support importing these dump files.

- To exclude unsupported Oracle Scheduler objects, use additional directives during the Data Pump export. If you use DBMS_DATAPUMP, you can add an additional METADATA_FILTER before the DBMS_METADATA.START_JOB:

```sql
DBMS_DATAPUMP.METADATA_FILTER(  
v_hdn1,  
'EXCLUDE_NAME_EXPR',  
q'[IN (SELECT NAME FROM SYS.OBJ$  
   WHERE TYPE# IN (66,67,74,79,59,62,46)  
   AND OWNER# IN  
   (SELECT USER# FROM SYS.USER$  
   WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')  
   ))]'  
)'PROCJOB');
```

If you use expdp, create a parameter file that contains the exclude directive shown in the following example. Then use PARFILE=parameter_file with your expdp command.
**Importing data with Oracle Data Pump and an Amazon S3 bucket**

The following import process uses Oracle Data Pump and an Amazon S3 bucket. The steps are as follows:

1. Export data on the source database using the Oracle `DBMS_DATAPUMP` package.
2. Place the dump file in an Amazon S3 bucket.
3. Download the dump file from the Amazon S3 bucket to the `DATA_PUMP_DIR` directory on the target RDS for Oracle DB instance.
4. Import the data from the copied dump file into the RDS for Oracle DB instance using the package `DBMS_DATAPUMP`.

**Topics**

- Requirements for Importing data with Oracle Data Pump and an Amazon S3 bucket (p. 1670)
- Step 1: Grant privileges to the database user on the RDS for Oracle target DB instance (p. 1671)
- Step 2: Export data into a dump file using `DBMS_DATAPUMP` (p. 1671)
- Step 3: Upload the dump file to your Amazon S3 bucket (p. 1672)
- Step 4: Download the dump file from your Amazon S3 bucket to your target DB instance (p. 1672)
- Step 5: Import your dump file into your target DB instance using `DBMS_DATAPUMP` (p. 1673)
- Step 6: Clean up (p. 1674)

**Requirements for Importing data with Oracle Data Pump and an Amazon S3 bucket**

The process has the following requirements:

- Make sure that an Amazon S3 bucket is available for file transfers, and that the Amazon S3 bucket is in the same AWS Region as the DB instance. For instructions, see Create a bucket in the Amazon Simple Storage Service Getting Started Guide.
- The object that you upload into the Amazon S3 bucket must be 5 TB or less. For more information about working with objects in Amazon S3, see Amazon Simple Storage Service User Guide.

  **Note**
  
  If your dump file exceeds 5 TB, you can run the Oracle Data Pump export with the parallel option. This operation spreads the data into multiple dump files so that you do not exceed the 5 TB limit for individual files.

- You must prepare the Amazon S3 bucket for Amazon RDS integration by following the instructions in Configuring IAM permissions for RDS for Oracle integration with Amazon S3 (p. 1700).
- You must ensure that you have enough storage space to store the dump file on the source instance and the target DB instance.
Importing using Oracle Data Pump

Note
This process imports a dump file into the DATA_PUMP_DIR directory, a preconfigured directory on all Oracle DB instances. This directory is located on the same storage volume as your data files. When you import the dump file, the existing Oracle data files use more space. Thus, you should make sure that your DB instance can accommodate that additional use of space. The imported dump file is not automatically deleted or purged from the DATA_PUMP_DIR directory. To remove the imported dump file, use UTL_FILE.FREMOVE, found on the Oracle website.

Step 1: Grant privileges to the database user on the RDS for Oracle target DB instance

In this step, you create the schemas into which you plan to import data and grant the users necessary privileges.

To create users and grant necessary privileges on the RDS for Oracle target instance

1. Use SQL*Plus or Oracle SQL Developer to log in as the master user to the RDS for Oracle DB instance into which the data will be imported. For information about connecting to a DB instance, see Connecting to your Oracle DB instance (p. 1540).
2. Create the required tablespaces before you import the data. For more information, see Creating and sizing tablespaces (p. 1596).
3. Create the user account and grant the necessary permissions and roles if the user account into which the data is imported doesn't exist. If you plan to import data into multiple user schemas, create each user account and grant the necessary privileges and roles to it.

For example, the following SQL statements create a new user and grant the necessary permissions and roles to import the data into the schema owned by this user. Replace schema_1 with the name of your schema in this step and in the following steps.

```sql
CREATE USER schema_1 IDENTIFIED BY my_password;
GRANT CREATE SESSION, RESOURCE TO schema_1;
ALTER USER schema_1 QUOTA 100M ON users;
```

The preceding statements grant the new user the CREATE SESSION privilege and the RESOURCE role. You might need additional privileges and roles depending on the database objects that you import.

Step 2: Export data into a dump file using DBMS_DATAPUMP

To create a dump file, use the DBMS_DATAPUMP package.

To export Oracle data into a dump file

1. Use SQL Plus or Oracle SQL Developer to connect to the source RDS for Oracle DB instance with an administrative user. If the source database is an RDS for Oracle DB instance, connect with the Amazon RDS master user.
2. Export the data by calling DBMS_DATAPUMP procedures.

The following script exports the SCHEMA_1 schema into a dump file named sample.dmp in the DATA_PUMP_DIR directory. Replace SCHEMA_1 with the name of the schema that you want to export.

```sql
DECLARE
    v_hdl NUMBER;
BEGIN
    v_hdl := DBMS_DATAPUMP.OPEN(1671
```
operation => 'EXPORT',
job_mode => 'SCHEMA',
job_name => null
);
DBMS_DATAPUMP.ADD_FILE(
handle => v_hdnl,
filename => 'sample.dmp',
directory => 'DATA_PUMP_DIR',
filetype => dbms_datapump.ku$_file_type_dump_file
);
DBMS_DATAPUMP.ADD_FILE(
handle => v_hdnl,
filename => 'sample_exp.log',
directory => 'DATA_PUMP_DIR',
filetype => dbms_datapump.ku$_file_type_log_file
);
DBMS_DATAPUMP.METADATA_FILTER(v_hdnl, 'SCHEMA_EXPR', 'IN (''
SCHEMA_1''')');
DBMS_DATAPUMP.METADATA_FILTER(v_hdnl, 'EXCLUDE_NAME_EXPR',
q'IN (SELECT NAME FROM SYS.OBJ$
WHERE TYPE# IN (66,67,74,79,59,62,46)
AND OWNER# IN
(SELECT USER# FROM SYS.USER$
WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
)
)',
'PROC_OBJ')
);
DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/

Note
Data Pump starts jobs asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation.

3. (Optional) View the contents of the export log by calling the rdsadmin.rds_file_util.read_text_file procedure. For more information, see Reading files in a DB instance directory (p. 1650).

Step 3: Upload the dump file to your Amazon S3 bucket

Use the Amazon RDS procedure rdsadmin.rdsadmin_s3_tasks.upload_to_s3 to copy the dump file to the Amazon S3 bucket. The following example uploads all of the files from the DATA_PUMP_DIR directory to an Amazon S3 bucket named myS3bucket.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
p_bucket_name => 'myS3bucket',
p_directory_name => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket (p. 1709).

Step 4: Download the dump file from your Amazon S3 bucket to your target DB instance

Perform this step using the Amazon RDS procedure rdsadmin.rdsadmin_s3_tasks.download_from_s3. When you download a file to a directory, the
procedure download_from_s3 skips the download if an identically named file already exists in the
directory. To remove a file from the download directory, use UTL_FILE.FREMOVE, found on the Oracle
website.

To download your dump file

1. Start SQL*Plus or Oracle SQL Developer and log in as the master on your Amazon RDS target Oracle
   DB instance
2. Download the dump file using the Amazon RDS procedure
   rdsadmin.rdsadmin_s3_tasks.download_from_s3

   The following example downloads all files from an Amazon S3 bucket named myS3bucket to the
directory DATA_PUMP_DIR.

   ```sql
   SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3( 
       p_bucket_name => 'myS3bucket', 
       p_directory_name => 'DATA_PUMP_DIR') 
   AS TASK_ID FROM DUAL;
   ```

   The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information,
see Downloading files from an Amazon S3 bucket to an Oracle DB instance (p. 1712).

Step 5: Import your dump file into your target DB instance using
DBMS_DATAPUMP

Use DBMS_DATAPUMP to import the schema into your RDS for Oracle DB instance. Additional options
such as METADATA_REMAP might be required.

To import data into your target DB instance

1. Start SQL*Plus or SQL Developer and log in as the master user to your RDS for Oracle DB instance.
2. Export the data by calling DBMS_DATAPUMP procedures.

   The following example imports the SCHEMA_1 data from sample_copied.dmp into your target DB
instance.

   ```sql
   DECLARE
   v_hdnl NUMBER;
   BEGIN
   v_hdnl := DBMS_DATAPUMP.OPEN( 
       operation => 'IMPORT', 
       job_mode  => 'SCHEMA', 
       job_name  => null);
   DBMS_DATAPUMP.ADD_FILE( 
       handle => v_hdnl, 
       filename => 'sample_copied.dmp', 
       directory => 'DATA_PUMP_DIR', 
       filetype => dbms_datapump.ku$_file_type_dump_file);
   DBMS_DATAPUMP.ADD_FILE( 
       handle => v_hdnl, 
       filename => 'sample_imp.log', 
       directory => 'DATA_PUMP_DIR', 
       filetype => dbms_datapump.ku$_file_type_log_file);
   DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN (''SCHEMA_1'')');
   DBMS_DATAPUMP.START_JOB(v_hdnl);
   END;
   ```
Note
Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the import log by using the rdsadmin.rds_file_util.read_text_file procedure. For more information, see Reading files in a DB instance directory (p. 1650).

3. Verify the data import by listing the schema tables on your target DB instance.

For example, the following query returns the number of tables for `SCHEMA_1`.

```sql
SELECT COUNT(*) FROM DBA_TABLES WHERE OWNER='SCHEMA_1';
```

Step 6: Clean up

After the data has been imported, you can delete the files that you don't want to keep.

To remove unneeded files

1. Start SQL*Plus or SQL Developer and log in as the master user to your RDS for Oracle DB instance.
2. List the files in DATA_PUMP_DIR using the following command.

```sql
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('DATA_PUMP_DIR')) ORDER BY MTIME;
```
3. Delete files in DATA_PUMP_DIR that you no longer require, use the following command.

```sql
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','filename');
```

For example, the following command deletes the file named `sample_copied.dmp`.

```sql
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','sample_copied.dmp');
```

Importing data with Oracle Data Pump and a database link

The following import process uses Oracle Data Pump and the Oracle DBMS_FILE_TRANSFER package. The steps are as follows:

1. Connect to a source Oracle database, which can be an on-premises database, Amazon EC2 instance, or an RDS for Oracle DB instance.
2. Export data using the DBMS_DATAPUMP package.
3. Use DBMS_FILE_TRANSFER.PUT_FILE to copy the dump file from the Oracle database to the DATA_PUMP_DIR directory on the target RDS for Oracle DB instance that is connected using a database link.
4. Import the data from the copied dump file into the RDS for Oracle DB instance using the DBMS_DATAPUMP package.

The import process using Oracle Data Pump and the DBMS_FILE_TRANSFER package has the following steps.

Topics
- Requirements for importing data with Oracle Data Pump and a database link (p. 1675)
- Step 1: Grant privileges to the user on the RDS for Oracle target DB instance (p. 1675)
• Step 2: Grant privileges to the user on the source database (p. 1676)
• Step 3: Create a dump file using DBMS_DATAPUMP (p. 1676)
• Step 4: Create a database link to the target DB instance (p. 1677)
• Step 5: Copy the exported dump file to the target DB instance using DBMS_FILE_TRANSFER (p. 1677)
• Step 6: Import the data file to the target DB instance using DBMS_DATAPUMP (p. 1677)
• Step 7: Clean up (p. 1678)

Requirements for importing data with Oracle Data Pump and a database link

The process has the following requirements:

• You must have execute privileges on the DBMS_FILE_TRANSFER and DBMS_DATAPUMP packages.
• You must have write privileges to the DATA_PUMP_DIR directory on the source DB instance.
• You must ensure that you have enough storage space to store the dump file on the source instance and the target DB instance.

Note
This process imports a dump file into the DATA_PUMP_DIR directory, a preconfigured directory on all Oracle DB instances. This directory is located on the same storage volume as your data files. When you import the dump file, the existing Oracle data files use more space. Thus, you should make sure that your DB instance can accommodate that additional use of space. The imported dump file is not automatically deleted or purged from the DATA_PUMP_DIR directory. To remove the imported dump file, use UTL_FILE.FREMOVE, found on the Oracle website.

Step 1: Grant privileges to the user on the RDS for Oracle target DB instance

To grant privileges to the user on the RDS for Oracle target DB instance, take the following steps:

1. Use SQL Plus or Oracle SQL Developer to connect to the RDS for Oracle DB instance into which you intend to import the data. Connect as the Amazon RDS master user. For information about connecting to the DB instance, see Connecting to your Oracle DB instance (p. 1540).
2. Create the required tablespaces before you import the data. For more information, see Creating and sizing tablespaces (p. 1596).
3. If the user account into which the data is imported doesn't exist, create the user account and grant the necessary permissions and roles. If you plan to import data into multiple user schemas, create each user account and grant the necessary privileges and roles to it.

For example, the following commands create a new user named schema_1 and grant the necessary permissions and roles to import the data into the schema for this user.

```
CREATE USER schema_1 IDENTIFIED BY my-password;
GRANT CREATE SESSION, RESOURCE TO schema_1;
ALTER USER schema_1 QUOTA 100M ON users;
```

The preceding example grants the new user the CREATE SESSION privilege and the RESOURCE role. Additional privileges and roles might be required depending on the database objects that you import.

Note
Replace schema_1 with the name of your schema in this step and in the following steps.
**Step 2: Grant privileges to the user on the source database**

Use SQL*Plus or Oracle SQL Developer to connect to the RDS for Oracle DB instance that contains the data to be imported. If necessary, create a user account and grant the necessary permissions.

**Note**

If the source database is an Amazon RDS instance, you can skip this step. You use your Amazon RDS master user account to perform the export.

The following commands create a new user and grant the necessary permissions.

```sql
CREATE USER export_user IDENTIFIED BY my-password;
GRANT CREATE SESSION, CREATE TABLE, CREATE DATABASE LINK TO export_user;
ALTER USER export_user QUOTA 100M ON users;
GRANT READ, WRITE ON DIRECTORY data_pump_dir TO export_user;
GRANT SELECT_CATALOG_ROLE TO export_user;
GRANT EXECUTE ON DBMS_DATAPUMP TO export_user;
GRANT EXECUTE ON DBMS_FILE_TRANSFER TO export_user;
```

**Step 3: Create a dump file using DBMS_DATAPUMP**

To create a dump file, do the following:

1. Use SQL*Plus or Oracle SQL Developer to connect to the source Oracle instance with an administrative user or with the user you created in step 2. If the source database is an Amazon RDS for Oracle DB instance, connect with the Amazon RDS master user.
2. Create a dump file using the Oracle Data Pump utility.

The following script creates a dump file named `sample.dmp` in the `DATA_PUMP_DIR` directory.

```sql
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'EXPORT',
    job_mode  => 'SCHEMA',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample.dmp',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_dump_file);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample_exp.log',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(
    v_hdnl, 'SCHEMA_EXPR', 'IN ('"SCHEMA_1"')');
  DBMS_DATAPUMP.METADATA_FILTER(
    v_hdnl, 'EXCLUDE_NAME_EXPR',
    q'[IN (SELECT NAME FROM sys.OBJ$
      WHERE TYPE# IN (66,67,74,79,59,62,46)
      AND OWNER# IN
      (SELECT USER# FROM SYS.USER$)');
END;
```

1676
WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
)
);
DBMS_DATAPUMP.START_JOB(v_hdn1);
END;
/

Note
Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the export log by using the rdsadmin.rds_file_util.read_text_file procedure. For more information, see Reading files in a DB instance directory (p. 1650).

Step 4: Create a database link to the target DB instance

Create a database link between your source DB instance and your target DB instance. Your local Oracle instance must have network connectivity to the DB instance in order to create a database link and to transfer your export dump file.

Perform this step connected with the same user account as the previous step.

If you are creating a database link between two DB instances inside the same VPC or peered VPCs, the two DB instances should have a valid route between them. The security group of each DB instance must allow ingress to and egress from the other DB instance. The security group inbound and outbound rules can refer to security groups from the same VPC or a peered VPC. For more information, see Adjusting database links for use with DB instances in a VPC (p. 1605).

The following command creates a database link named to_rds that connects to the Amazon RDS master user at the target DB instance.

```
CREATE DATABASE LINK to_rds
CONNECT TO <master_user_account> IDENTIFIED BY <password>
USING '(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=<dns or ip address of remote db>)(PORT=<listener port>))(CONNECT_DATA=(SID=<remote SID>)))';
```

Step 5: Copy the exported dump file to the target DB instance using DBMS_FILE_TRANSFER

Use DBMS_FILE_TRANSFER to copy the dump file from the source database instance to the target DB instance. The following script copies a dump file named sample.dmp from the source instance to a target database link named to_rds (created in the previous step).

```
BEGIN
DBMS_FILE_TRANSFER.PUT_FILE(
    source_directory_object       => 'DATA_PUMP_DIR',
    source_file_name              => 'sample.dmp',
    destination_directory_object  => 'DATA_PUMP_DIR',
    destination_file_name         => 'sample_copied.dmp',
    destination_database          => 'to_rds' );
END;
/
```

Step 6: Import the data file to the target DB instance using DBMS_DATAPUMP

Use Oracle Data Pump to import the schema in the DB instance. Additional options such as METADATA_REMAP might be required.
Connect to the DB instance with the Amazon RDS master user account to perform the import.

```sql
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode  => 'SCHEMA',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdnl,
    filename => 'sample_copied.dmp',
    directory => 'DATA_PUMP_DIR',
    filetype => dbms_datapump.ku$_file_type_dump_file );
  DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdnl,
    filename => 'sample_imp.log',
    directory => 'DATA_PUMP_DIR',
    filetype => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN (' Schema_1 ')');
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

**Note**

Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the import log by using the rdsadmin.rds_file_util.read_text_file procedure. For more information, see Reading files in a DB instance directory (p. 1650).

You can verify the data import by viewing the user's tables on the DB instance. For example, the following query returns the number of tables for `schema_1`.

```sql
SELECT COUNT(*) FROM DBA_TABLES WHERE OWNER='Schema_1';
```

**Step 7: Clean up**

After the data has been imported, you can delete the files that you don't want to keep. You can list the files in `DATA_PUMP_DIR` using the following command.

```sql
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('DATA_PUMP_DIR')) ORDER BY MTIME;
```

To delete files in `DATA_PUMP_DIR` that you no longer require, use the following command.

```sql
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','<file name>');</sql```

For example, the following command deletes the file named "sample_copied.dmp".

```sql
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','sample_copied.dmp');
```

**Importing using Oracle Export/Import**

You might consider Oracle Export/Import utilities for migrations in the following conditions:

- Your data size is small.
- Data types such as binary float and double aren't required.

**To export tables and then import them**

1. Export the tables from the source database using the `exp` command.

   The following command exports the tables named `tab1`, `tab2`, and `tab3`. The dump file is `exp_file.dmp`.

   ```
   exp cust_dba@ORCL FILE=exp_file.dmp TABLES=(tab1,tab2,tab3) LOG=exp_file.log
   ```

   The export creates a binary dump file that contains both the schema and data for the specified tables.

2. Import the schema and data into a target database using the `imp` command.

   The following command imports the tables `tab1`, `tab2`, and `tab3` from dump file `exp_file.dmp`.

   ```
   imp cust_dba@targetdb FROMUSER=cust_schema TOUSER=cust_schema \
   TABLES=(tab1,tab2,tab3) FILE=exp_file.dmp LOG=imp_file.log
   ```

Export and Import have other variations that might be better suited to your requirements. See the Oracle Database documentation for full details.

**Importing using Oracle SQL*Loader**

You might consider Oracle SQL*Loader for large databases that contain a limited number of objects. Because the process of exporting from a source database and loading to a target database is specific to the schema, the following example creates the sample schema objects, exports from a source, and then loads the data into a target database.

1. Create a sample source table using the following SQL statement.

   ```
   CREATE TABLE customer_0 TABLESPACE users 
   AS (SELECT ROWNUM id, o.* 
    FROM   ALL_OBJECTS o, ALL_OBJECTS x 
    WHERE  ROWNUM <= 1000000);
   ```

2. On the target RDS for Oracle DB instance, create a destination table for loading the data. The clause `WHERE 1=2` ensures that you copy the structure of `ALL_OBJECTS`, but don't copy any rows.

   ```
   CREATE TABLE customer_1 TABLESPACE users 
   AS (SELECT 0 AS ID, OWNER, OBJECT_NAME, CREATED 
    FROM   ALL_OBJECTS 
    WHERE  1=2);
   ```

3. Export the data from the source database to a text file. The following example uses SQL*Plus. For your data, you will likely need to generate a script that does the export for all the objects in the database.

   ```
   ALTER SESSION SET NLS_DATE_FORMAT = 'YYYY/MM/DD HH24:MI:SS'
   ```
4. Create a control file to describe the data. You might need to write a script to perform this step.

```sql
cat << EOF > sqlldr_1.ctl
load data
infile customer_0.out
into table customer_1
APPEND
fields terminated by "," optionally enclosed by ""
(id           POSITION(01:10)    INTEGER EXTERNAL,
owner        POSITION(12:41)    CHAR,
object_name  POSITION(43:72)    CHAR,
created      POSITION(74:92)    date "YYYY/MM/DD HH24:MI:SS"
)
EOF
```

If needed, copy the files generated by the preceding code to a staging area, such as an Amazon EC2 instance.

5. Import the data using SQL*Loader with the appropriate user name and password for the target database.

```
sqlldr cust_dba@targetdb CONTROL=sqlldr_1.ctl BINDSIZE=10485760 READSIZE=10485760 ROWS=1000
```

## Migrating with Oracle materialized views

To migrate large datasets efficiently, you can use Oracle materialized view replication. With replication, you can keep the target tables synchronized with the source tables. Thus, you can switch over to Amazon RDS later, if needed.

Before you can migrate using materialized views, make sure that you meet the following requirements:

- Configure access from the target database to the source database. In the following example, access rules were enabled on the source database to allow the RDS for Oracle target database to connect to the source over SQL*Net.
- Create a database link from the RDS for Oracle DB instance to the source database.

### To migrate data using materialized views

1. Create a user account on both source and RDS for Oracle target instances that can authenticate with the same password. The following example creates a user named `dblink_user`.

```
CREATE USER dblink_user IDENTIFIED BY my-password
DEFAULT TABLESPACE users
TEMPORARY TABLESPACE temp;
GRANT CREATE SESSION TO dblink_user;
```
GRANT SELECT ANY TABLE TO dblink_user;
GRANT SELECT ANY DICTIONARY TO dblink_user;

2. Create a database link from the RDS for Oracle target instance to the source instance using your newly created user.

```sql
CREATE DATABASE LINK remote_site
CONNECT TO dblink_user IDENTIFIED BY my-password
USING '(description=(address=(protocol=tcp) (host=my-host) (port=my-listener-port)) (connect_data=(sid=my-source-db-sid)))';
```

3. Test the link:

```sql
SELECT * FROM V$INSTANCE@remote_site;
```

4. Create a sample table with primary key and materialized view log on the source instance.

```sql
CREATE TABLE customer_0 TABLESPACE users
AS (SELECT ROWNUM id, o.*
    FROM   ALL_OBJECTS o, ALL_OBJECTS x
    WHERE  ROWNUM <= 1000000);
ALTER TABLE customer_0 ADD CONSTRAINT pk_customer_0 PRIMARY KEY (id) USING INDEX;
CREATE MATERIALIZED VIEW LOG ON customer_0;
```

5. On the target RDS for Oracle DB instance, create a materialized view.

```sql
CREATE MATERIALIZED VIEW customer_0
BUILD IMMEDIATE REFRESH FAST
AS (SELECT *
    FROM   cust_dba.customer_0@remote_site);
```

6. On the target RDS for Oracle DB instance, refresh the materialized view.

```sql
EXEC DBMS_MV.REFRESH('CUSTOMER_0', 'f');
```

7. Drop the materialized view and include the PRESERVE TABLE clause to retain the materialized view container table and its contents.

```sql
DROP MATERIALIZED VIEW customer_0 PRESERVE TABLE;
```

The retained table has the same name as the dropped materialized view.
Working with read replicas for Amazon RDS for Oracle

To configure replication between Oracle DB instances, you can create replica databases. For an overview of Amazon RDS read replicas, see Overview of Amazon RDS read replicas (p. 384). For a summary of the differences between Oracle replicas and other DB engines, see Differences between read replicas for different DB engines (p. 385).

Topics
- Overview of RDS for Oracle replicas (p. 1682)
- Considerations for RDS for Oracle replicas (p. 1683)
- Preparing to create an Oracle replica (p. 1685)
- Creating an RDS for Oracle replica in mounted mode (p. 1686)
- Modifying the RDS for Oracle replica mode (p. 1688)
- Working with RDS for Oracle replica backups (p. 1688)
- Performing an Oracle Data Guard switchover (p. 1690)
- Troubleshooting RDS for Oracle replicas (p. 1696)

Overview of RDS for Oracle replicas

An Oracle replica database is a physical copy of your primary database. An Oracle replica in read-only mode is called a read replica. An Oracle replica in mounted mode is called a mounted replica. Oracle Database doesn't permit writes in a replica, but you can promote a replica to make it writable. The promoted read replica has the replicated data to the point when the request was made to promote it.

The following video provides a helpful overview of RDS for Oracle disaster recovery.

For more information, see the blog post Managed disaster recovery with Amazon RDS for Oracle cross-Region automated backups - Part 1 and Managed disaster recovery with Amazon RDS for Oracle cross-Region automated backups - Part 2.

Topics
- Read-only and mounted replicas (p. 1682)
- Archived redo log retention (p. 1683)
- Outages during replication (p. 1683)

Read-only and mounted replicas

When creating or modifying an Oracle replica, you can place it in either of the following modes:

Read-only

This is the default. Active Data Guard transmits and applies changes from the source database to all read replica databases.

You can create up to five read replicas from one source DB instance. For general information about read replicas that applies to all DB engines, see Working with read replicas (p. 382). For information about Oracle Data Guard, see Oracle Data Guard concepts and administration in the Oracle documentation.
Mounted

In this case, replication uses Oracle Data Guard, but the replica database doesn't accept user connections. The primary use for mounted replicas is cross-Region disaster recovery.

A mounted replica can't serve a read-only workload. The mounted replica deletes archived redo log files after it applies them, regardless of the archived log retention policy.

You can create a combination of mounted and read-only DB replicas for the same source DB instance. You can change a read-only replica to mounted mode, or change a mounted replica to read-only mode. In either case, the Oracle database preserves the archived log retention setting.

Archived redo log retention

If a primary DB instance has no cross-Region read replicas, Amazon RDS for Oracle keeps a minimum of two hours of archived redo logs on the source DB instance. This is true regardless of the setting for.archivelog retention hours in rdsadmin.rdsadmin_util.set_configuration.

RDS purges logs from the source DB instance after two hours or after the archive log retention hours setting has passed, whichever is longer. RDS purges logs from the read replica after the archive log retention hours setting has passed only if they have been successfully applied to the database.

In some cases, a primary DB instance might have one or more cross-Region read replicas. If so, Amazon RDS for Oracle keeps the transaction logs on the source DB instance until they have been transmitted and applied to all cross-Region read replicas. For information about rdsadmin.rdsadmin_util.set_configuration, see Retaining archived redo logs (p. 1616).

Outages during replication

When you create an Oracle replica, no outage occurs for the source DB instance. Amazon RDS takes a snapshot of the source DB instance. This snapshot becomes the replica. Amazon RDS sets the necessary parameters and permissions for the source DB and replica without service interruption. Similarly, if you delete a replica, no outage occurs.

Considerations for RDS for Oracle replicas

Before creating an Oracle replica, consider the following requirements, restrictions, and recommendations.

Topics

- Version and licensing considerations for RDS for Oracle replicas (p. 1683)
- Option considerations for RDS for Oracle replicas (p. 1684)
- Backup and restore considerations for RDS for Oracle replicas (p. 1684)
- Miscellaneous considerations for RDS for Oracle replicas (p. 1685)

Version and licensing considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following requirements, restrictions, and recommendations:

- If the replica is in read-only mode, make sure that you have an Active Data Guard license. If you place the replica in mounted mode, you don't need an Active Data Guard license. Only the Oracle DB engine supports mounted replicas.
- Oracle replicas are supported for the Oracle Enterprise Edition (EE) engine only.
Considerations for Oracle replicas

- Oracle replicas are available for instances created using version Oracle Database 12c Release 1 (12.1.0.2.v10) and higher 12c releases, and for non-CDB instances of Oracle Database 19c. Replicas of CDBs aren't supported.

- Oracle replicas are available for DB instances running only on DB instance classes with two or more vCPUs. A source DB instance can't use the db.t3.micro or db.t3.small instance classes.

- The Oracle DB engine version of the source DB instance and all of its replicas must be the same. Amazon RDS upgrades the replicas immediately after upgrading the source DB instance, regardless of a replica's maintenance window. For major version upgrades of cross-Region replicas, Amazon RDS automatically does the following:
  - Generates an option group for the target version.
  - Copies all options and option settings from the original option group to the new option group.
  - Associates the upgraded cross-Region replica with the new option group.

  For more information about upgrading the DB engine version, see Upgrading the RDS for Oracle DB engine (p. 1809).

Option considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following requirements, restrictions, and recommendations:

- If your Oracle replica is in the same AWS Region as its source DB instance, make sure that it belongs to the same option group as the source DB instance. Modifications to the source option group or source option group membership propagate to replicas. These changes are applied to the replicas immediately after they are applied to the source DB instance, regardless of the replica's maintenance window.

  For more information about option groups, see Working with option groups (p. 279).

- When you create an Oracle cross-Region replica, Amazon RDS creates a dedicated option group for it.

  You can't remove an Oracle cross-Region replica from its dedicated option group. No other DB instances can use the dedicated option group for an Oracle cross-Region replica.

  You can only add or remove the following nonreplicated options from a dedicated option group:
  - NATIVE_NETWORK_ENCRYPTION
  - OEM
  - OEM_AGENT
  - SSL

  To add other options to an Oracle cross-Region replica, add them to the source DB instance's option group. The option is also installed on all of the source DB instance's replicas. For licensed options, make sure that there are sufficient licenses for the replicas.

  When you promote an Oracle cross-Region replica, the promoted replica behaves the same as other Oracle DB instances, including the management of its options. You can promote a replica explicitly or implicitly by deleting its source DB instance.

  For more information about option groups, see Working with option groups (p. 279).

Backup and restore considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following requirements, restrictions, and recommendations:
To create snapshots of RDS for Oracle replicas or turn on automatic backups, make sure to set the backup retention period manually. Automatic backups aren't turned on by default.

The database time refers to the latest applied transaction time of the data in the backup. When you restore a replica backup, you restore to the database time, not the time that the backup was taken. The difference is significant because a replica can lag behind the primary for minutes or hours.

To find the difference, use the describe-db-snapshots command. Compare the snapshotDatabaseTime, which is the database time of the replica backup, and the OriginalSnapshotCreateTime field, which is the latest applied transaction on the primary database.

Miscellaneous considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following requirements, restrictions, and recommendations:

• If a DB instance is a source for one or more cross-Region replicas, the source DB retains its archived redo logs until they are applied on all cross-Region replicas. The archived redo logs might result in increased storage consumption.

• A logon trigger on a primary instance must permit access to the RDS_DATAGUARD user and to any user whose AUTHENTICATED_IDENTITY value is RDS_DATAGUARD or rdsdb. Also, the trigger must not set the current schema for the RDS_DATAGUARD user.

• To avoid disrupting RDS automation, system triggers must permit specific users to log on to the primary and replica database. System triggers include DDL, logon, and database role triggers. We recommend that you add code to your triggers to exclude the users listed in the following sample code:

```sql
-- Determine who the user is
SELECT SYS_CONTEXT('USERENV','AUTHENTICATED_IDENTITY') INTO CURRENT_USER FROM DUAL;
-- The following users should always be able to login to either the Primary or Replica
IF CURRENT_USER IN ('master_user', 'SYS', 'SYSTEM', 'RDS_DATAGUARD', 'rdsdb') THEN
  RETURN;
END IF;
```

• To avoid blocking connections from the Data Guard broker process, don't enable restricted sessions. For more information about restricted sessions, see Enabling and disabling restricted sessions (p. 1584).

• Block change tracking is supported for read-only replicas, but not for mounted replicas. You can change a mounted replica to a read-only replica, and then enable block change tracking. For more information, see Enabling and disabling block change tracking (p. 1626).

Preparing to create an Oracle replica

Before you can begin using your replica, perform the following tasks.

Topics

• Enabling automatic backups (p. 1686)
• Enabling force logging mode (p. 1686)
• Changing your logging configuration (p. 1686)
• Setting the MAX_STRING_SIZE parameter (p. 1686)
• Planning compute and storage resources (p. 1686)
Enabling automatic backups

Before a DB instance can serve as a source DB instance, make sure to enable automatic backups on the source DB instance. To learn how to perform this procedure, see Enabling automated backups (p. 464).

Enabling force logging mode

We recommend that you enable force logging mode. In force logging mode, the Oracle database writes redo records even when NOLOGGING is used with data definition language (DDL) statements.

To enable force logging mode

1. Log in to your Oracle database using a client tool such as SQL Developer.
2. Enable force logging mode by running the following procedure.

```
exec rdsadmin.rdsadmin_util.force_logging(p_enable => true);
```

For more information about this procedure, see Setting force logging (p. 1612).

Changing your logging configuration

If you want to change your logging configuration, we recommend that you complete the changes before making a DB instance the source for replicas. Also, we recommend that you not modify the logging configuration after you create the replicas. Modifications can cause the online redo logging configuration to get out of sync with the standby logging configuration.

Modify the logging configuration for a DB instance by using the Amazon RDS procedures rdsadmin.rdsadmin_util.add_logfile and rdsadmin.rdsadmin_util.drop_logfile. For more information, see Adding online redo logs (p. 1614) and Dropping online redo logs (p. 1614).

Setting the MAX_STRING_SIZE parameter

Before you create an Oracle replica, ensure that the setting of the MAX_STRING_SIZE parameter is the same on the source DB instance and the replica. You can do this by associating them with the same parameter group. If you have different parameter groups for the source and the replica, you can set MAX_STRING_SIZE to the same value. For more information about setting this parameter, see Turning on extended data types for a new DB instance (p. 1665).

Planning compute and storage resources

Ensure that the source DB instance and its replicas are sized properly, in terms of compute and storage, to suit their operational load. If a replica reaches compute, network, or storage resource capacity, the replica stops receiving or applying changes from its source. Amazon RDS for Oracle doesn't intervene to mitigate high replica lag between a source DB instance and its replicas. You can modify the storage and CPU resources of a replica independently from its source and other replicas.

Creating an RDS for Oracle replica in mounted mode

By default, Oracle replicas are read-only. To create a replica in mounted mode, use the console, the AWS CLI, or the RDS API.
### Console

**To create a mounted replica from a source Oracle DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the Oracle DB instance that you want to use as the source for a mounted replica.
4. For **Actions**, choose **Create replica**.
5. For **Replica mode**, choose **Mounted**.
6. Choose the settings that you want to use. For **DB instance identifier**, enter a name for the read replica. Adjust other settings as needed.
7. For **Regions**, choose the Region where the mounted replica will be launched.
8. Choose your instance size and storage type. We recommend that you use the same DB instance class and storage type as the source DB instance for the read replica.
9. For **Multi-AZ deployment**, choose **Create a standby instance** to create a standby of your replica in another Availability Zone for failover support for the mounted replica. Creating your mounted replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.
10. Choose the other settings that you want to use.
11. Choose **Create replica**.

In the **Databases** page, the mounted replica has the role Replica.

### AWS CLI

To create an Oracle replica in mounted mode, set `--replica-mode` to `mounted` in the AWS CLI command `create-db-instance-read-replica`.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
  --db-instance-identifier myreadreplica \
  --source-db-instance-identifier mydbinstance \
  --replica-mode mounted
```

For Windows:

```
aws rds create-db-instance-read-replica ^
  --db-instance-identifier myreadreplica ^
  --source-db-instance-identifier mydbinstance ^
  --replica-mode mounted
```

To change a read-only replica to a mounted state, set `--replica-mode` to `mounted` in the AWS CLI command `modify-db-instance`. To place a mounted replica in read-only mode, set `--replica-mode` to `open-read-only`.

### RDS API

To create an Oracle replica in mounted mode, specify `ReplicaMode=mounted` in the RDS API operation `CreateDBInstanceReadReplica`.
Modifying the RDS for Oracle replica mode

To change the replica mode of an existing replica, use the console, AWS CLI, or RDS API. When you change to mounted mode, the replica disconnects all active connections. When you change to read-only mode, Amazon RDS initializes Active Data Guard.

The change operation can take a few minutes. During the operation, the DB instance status changes to **modifying**. For more information about status changes, see Viewing Amazon RDS DB instance status (p. 551).

**Console**

**To change the replica mode of an Oracle replica from mounted to read-only**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the mounted replica database.
4. Choose **Modify**.
5. For **Replica mode**, choose **Read-only**.
6. Choose the other settings that you want to change.
7. Choose **Continue**.
8. For **Scheduling of modifications**, choose **Apply immediately**.
9. Choose **Modify DB instance**.

**AWS CLI**

To change a read replica to mounted mode, set `--replica-mode` to `mounted` in the AWS CLI command `modify-db-instance`. To change a mounted replica to read-only mode, set `--replica-mode` to `open-read-only`.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier myreadreplica \
  --replica-mode mode
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier myreadreplica ^
  --replica-mode mode
```

**RDS API**

To change a read-only replica to mounted mode, set `ReplicaMode=mounted` in `ModifyDBInstance`. To change a mounted replica to read-only mode, set `ReplicaMode=read-only`.

**Working with RDS for Oracle replica backups**

You can create and restore backups of an RDS for Oracle replica. Both automatic backups and manual snapshots are supported. For more information, see Backing up and restoring an Amazon RDS DB
instance (p. 461). The following sections describe the key differences between managing backups of a primary and an RDS for Oracle replica.

**Turning on RDS for Oracle replica backups**

An Oracle replica doesn't have automated backups turned on by default. You turn on automated backups by setting the backup retention period to a positive nonzero value.

**Console**

**To enable automated backups immediately**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.
4. For Backup retention period, choose a positive nonzero value, for example 3 days.
5. Choose Continue.
6. Choose Apply immediately.
7. On the confirmation page, choose Modify DB instance to save your changes and enable automated backups.

**AWS CLI**

To enable automated backups, use the AWS CLI modify-db-instance command.

Include the following parameters:

- --db-instance-identifier
- --backup-retention-period
- --apply-immediately or --no-apply-immediately

In the following example, we enable automated backups by setting the backup retention period to three days. The changes are applied immediately.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --backup-retention-period 3 \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --backup-retention-period 3 ^
  --apply-immediately
```
RDS API

To enable automated backups, use the RDS API ModifyDBInstance operation with the following required parameters:

- DBInstanceIdentifier
- BackupRetentionPeriod

Restoring an RDS for Oracle replica backup

You can restore an Oracle replica backup just as you can restore a backup of the primary instance. For more information, see the following:

- Restoring from a DB snapshot (p. 487)
- Restoring a DB instance to a specified time (p. 534)

The main consideration when you restore a replica backup is determining the point in time to which you are restoring. The database time refers to the latest applied transaction time of the data in the backup. When you restore a replica backup, you restore to the database time, not the time when the backup completed. The difference is significant because an RDS for Oracle replica can lag behind the primary by minutes or hours. Thus, the database time of a replica backup, and thus the point in time to which you restore it, might be much earlier than the backup creation time.

To find the difference between database time and creation time, use the describe-db-snapshots command. Compare the SnapshotDatabaseTime, which is the database time of the replica backup, and the OriginalSnapshotCreateTime field, which is the latest applied transaction on the primary database. The following example shows the difference between the two times:

```bash
aws rds describe-db-snapshots
  --db-instance-identifier my-oracle-replica
  --db-snapshot-identifier my-replica-snapshot

{
  "DBSnapshots": [
    {
      "DBSnapshotIdentifier": "my-replica-snapshot",
      "DBInstanceIdentifier": "my-oracle-replica",
      "SnapshotDatabaseTime": "2022-07-26T17:49:44Z",
      ...,
      "OriginalSnapshotCreateTime": "2021-07-26T19:49:44Z"
    }
  ]
}
```

Performing an Oracle Data Guard switchover

In an Oracle Data Guard environment, a primary database supports one or more standby databases. You can perform a managed, switchover-based role transition from a primary database to a standby database.

Topics

- Overview of Oracle Data Guard switchover (p. 1691)
- Preparing for the Oracle Data Guard switchover (p. 1694)
- Initiating the Oracle Data Guard switchover (p. 1694)
- Monitoring the Oracle Data Guard switchover (p. 1696)
Overview of Oracle Data Guard switchover

A switchover is a role reversal between a primary database and a standby database. During a switchover, the original primary database transitions to a standby role, while the original standby database transitions to the primary role.

Amazon RDS supports a fully managed, switchover-based role transition for Oracle Database replicas. The replicas can reside in separate AWS Regions or in different Availability Zones (AZs) of a single Region. You can only initiate a switchover to a standby database that is mounted or open read-only.

Topics
- Benefits of Oracle Data Guard switchover (p. 1692)
- Supported Oracle Database versions (p. 1692)
- AWS Region support (p. 1692)
- Cost of Oracle Data Guard switchover (p. 1692)
• How Oracle Data Guard switchover works (p. 1693)

Benefits of Oracle Data Guard switchover

Just as for RDS for Oracle read replicas, a managed switchover relies on Oracle Data Guard. The operation is designed to have zero data loss. Amazon RDS automates the following aspects of the switchover:

• Reverses the roles of your primary database and specified standby database, putting the new standby database in the same state (mounted or read-only) as the original standby
• Ensures data consistency
• Maintains your replication configuration after the transition
• Supports repeated reversals, allowing your new standby database to return to its original primary role

Supported Oracle Database versions

Oracle Data Guard switchover is supported for the following releases:

• Oracle Database 19c
• Oracle Database 12c Release 2 (12.2)
• Oracle Database 12c Release 1 (12.1) using PSU 12.1.0.2.v10 or higher

AWS Region support

Oracle Data Guard switchover is available in the following AWS Regions:

• Asia Pacific (Mumbai)
• Asia Pacific (Osaka)
• Asia Pacific (Seoul)
• Asia Pacific (Singapore)
• Asia Pacific (Sydney)
• Asia Pacific (Tokyo)
• Canada (Central)
• Europe (Frankfurt)
• Europe (Ireland)
• Europe (London)
• Europe (Paris)
• Europe (Stockholm)
• South America (São Paulo)
• US East (N. Virginia)
• US East (Ohio)
• US West (N. California)
• US West (Oregon)

Cost of Oracle Data Guard switchover

The Oracle Data Guard switchover feature doesn't incur additional costs. You need an Oracle Data Guard license to use read replicas in mounted mode, and an Oracle Active Data Guard license to use read replicas in read-only mode.
How Oracle Data Guard switchover works

Oracle Data Guard switchover is a fully managed operation. You initiate the switchover for a standby database by issuing the CLI command `switchover-read-replica`. Then Amazon RDS modifies the primary and standby roles in your replication configuration.

The original standby and original primary are the roles that exist before the switchover. The new standby and new primary are the roles that exist after the switchover. A bystander replica is a replica database that serves as a standby database in the Oracle Data Guard environment but is not switching roles.

Topics

• Stages of the Oracle Data Guard switchover (p. 1693)
• After the Oracle Data Guard switchover (p. 1693)

Stages of the Oracle Data Guard switchover

To perform the switchover, Amazon RDS must take the following steps:

1. Block new transactions on the original primary database. During the switchover, Amazon RDS interrupts replication for all databases in your Oracle Data Guard configuration. During the switchover, the original primary database can't process write requests.
2. Ship unapplied transactions to the original standby database, and apply them.
3. Restart the new standby database in read-only or mounted mode. The mode depends on the open state of the original standby database before the switchover.
4. Open the new primary database in read/write mode.

After the Oracle Data Guard switchover

Amazon RDS switches the roles of the primary and standby database. You are responsible for reconnecting your application and performing any other desired configuration.

Topics

• Success criteria (p. 1693)
• Connection to the new primary database (p. 1693)
• Configuration of the new primary database (p. 1694)

Success criteria

The Oracle Data Guard switchover is successful when the original standby database does the following:

• Transitions to its role as new primary database
• Completes its reconfiguration

To limit downtime, your new primary database becomes active as soon as possible. Because Amazon RDS configures bystander replicas asynchronously, these replicas might become active after the original primary database.

Connection to the new primary database

Amazon RDS won't propagate your current database connections to the new primary database after the switchover. After the Oracle Data Guard switchover completes, reconnect your application to the new primary database.
Configuration of the new primary database

To perform a switchover to the new primary database, Amazon RDS changes the mode of the original standby database to open. The change in role is the only change to the database. Amazon RDS doesn't set up features such as Multi-AZ replication.

If you perform a switchover to a cross-Region replica with different options, the new primary database keeps its own options. Amazon RDS won't migrate the options on the original primary database. If the original primary database had options such as SSL, NNE, OEM, and OEM_AGENT, Amazon RDS doesn't propagate them to the new primary database.

Preparing for the Oracle Data Guard switchover

Before initiating the Oracle Data Guard switchover, make sure that your replication environment meets the following requirements:

- The original standby database is mounted or open read-only.
- Automatic backups are enabled on the original standby database.
- The original primary database and the original standby database are in an available state.
- The original primary database and the original standby database have no pending maintenance actions.
- The original standby database is in the replicating state.
- You aren't attempting to initiate a switchover when either the primary database or standby database is currently in a switchover lifecycle. If a replica database is reconfiguring after a switchover, Amazon RDS prevents you from initiating another switchover.

**Note**

A *bystander replica* is a replica in the Oracle Data Guard configuration that isn't the target of the switchover. Bystander replicas can be in any state during the switchover.

- The original standby database has a configuration that is as close as desired to the original primary database. Assume a scenario where the original primary and original standby databases have different options. After the switchover completes, Amazon RDS doesn't automatically reconfigure the new primary database to have the same options as the original primary database.
- You configure your desired Multi-AZ deployment before initiating a switchover. Amazon RDS doesn't manage Multi-AZ as part of the switchover. The Multi-AZ deployment remains as it is.

Assume that db_maz is the primary database in a Multi-AZ deployment, and db_saz is a Single-AZ replica. You initiate a switchover from db_maz to db_saz. Afterward, db_maz is a Multi-AZ replica database, and db_saz is a Single-AZ primary database. The new primary database is now unprotected by a Multi-AZ deployment.

- In preparation for a cross-Region switchover, the primary database doesn't use the same option group as a DB instance outside of the replication configuration. For a cross-Region switchover to succeed, the current primary database and its read replicas must be the only DB instances to use the option group of the current primary database. Otherwise, Amazon RDS prevents the switchover.

Initiating the Oracle Data Guard switchover

You can switch over an RDS for Oracle read replica to the primary role, and the former primary DB instance to a replica role.

Console

**To switch over an Oracle read replica to the primary DB role**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
Performing an Oracle Data Guard switchover

2. In the Amazon RDS console, choose **Databases**.

   The **Databases** pane appears. Each read replica shows **Replica** in the **Role** column.

3. Choose the read replica that you want to switch over to the primary role.

4. For **Actions**, choose **Switch over replica**.

5. Choose **I acknowledge**. Then choose **Switch over replica**.

6. On the **Databases** page, monitor the progress of the switchover.

   When the switchover completes, the role of the switchover target changes from **Replica** to **Source**.

**AWS CLI**

To switch over an Oracle replica to the primary DB role, use the AWS CLI `switchover-read-replica` command. The following examples make the Oracle replica named `replica-to-be-made-primary` into the new primary database.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds switchover-read-replica \
  --db-instance-identifier replica-to-be-made-primary
```

For Windows:

```bash
aws rds switchover-read-replica ^
  --db-instance-identifier replica-to-be-made-primary
```

**RDS API**

To switch over an Oracle replica to the primary DB role, call the Amazon RDS API `SwitchoverReadReplica` operation with the required parameter `DBInstanceIdentifier`. This parameter specifies the name of the Oracle replica that you want to assume the primary DB role.
Monitoring the Oracle Data Guard switchover

To check the status of your instances, use the AWS CLI command `describe-db-instances`. The following command checks the status of the DB instance `orcl2`. This database was a standby database before the switchover, but is the new primary database after the switchover.

```
aws rds describe-db-instances \
  --db-instance-identifier orcl2
```

To confirm that the switchover completed successfully, query `V$DATABASE.OPEN_MODE`. Check that the value for the new primary database is `READ WRITE`.

```
SELECT OPEN_MODE FROM V$DATABASE;
```

To look for switchover-related events, use the AWS CLI command `describe-events`. The following example looks for events on the `orcl2` instance.

```
aws rds describe-events \
  --source-identifier orcl2 \
  --source-type db-instance
```

Troubleshooting RDS for Oracle replicas

This section describes possible replication problems and solutions.

Topics

- Monitoring Oracle replication lag (p. 1696)
- Troubleshooting Oracle replication failure after adding or modifying triggers (p. 1697)

Monitoring Oracle replication lag

To monitor replication lag in Amazon CloudWatch, view the Amazon RDS ReplicaLag metric. For more information about replication lag time, see Monitoring read replication (p. 392) and Amazon CloudWatch metrics for Amazon RDS (p. 644).

For a read replica, if the lag time is too long, query the following views:

- `V$ARCHIVED_LOG` – Shows which commits have been applied to the read replica.
- `V$DATAGUARD_STATS` – Shows a detailed breakdown of the components that make up the ReplicaLag metric.
- `V$DATAGUARD_STATUS` – Shows the log output from Oracle's internal replication processes.

For a mounted replica, if the lag time is too long, you can't query the V$ views. Instead, do the following:

- Check the ReplicaLag metric in CloudWatch.
- Check the alert log file for the replica in the console. Look for errors in the recovery messages. The messages include the log sequence number, which you can compare to the primary sequence number. For more information, see Oracle database log files (p. 745).
Troubleshooting Oracle replication failure after adding or modifying triggers

If you add or modify any triggers, and if replication fails afterward, the problem may be the triggers. Ensure that the trigger excludes the following user accounts, which are required by RDS for replication:

- User accounts with administrator privileges
- SYS
- SYSTEM
- RDS_DATAGUARD
- rdsdb

For more information, see Miscellaneous considerations for RDS for Oracle replicas (p. 1685).
Adding options to Oracle DB instances

In Amazon RDS, an option is an additional feature. Following, you can find a description of options that you can add to Amazon RDS instances running the Oracle DB engine.

Topics
- Overview of Oracle DB options (p. 1698)
- Amazon S3 integration (p. 1700)
- Oracle Application Express (APEX) (p. 1716)
- Amazon EFS integration (p. 1727)
- Oracle Java virtual machine (p. 1737)
- Oracle Enterprise Manager (p. 1740)
- Oracle Label Security (p. 1755)
- Oracle Locator (p. 1758)
- Oracle Multimedia (p. 1761)
- Oracle native network encryption (p. 1763)
- Oracle OLAP (p. 1771)
- Oracle Secure Sockets Layer (p. 1774)
- Oracle Spatial (p. 1782)
- Oracle SQLT (p. 1785)
- Oracle Statspack (p. 1791)
- Oracle time zone (p. 1794)
- Oracle time zone file autoupgrade (p. 1798)
- Oracle Transparent Data Encryption (p. 1803)
- Oracle UTL_MAIL (p. 1805)
- Oracle XML DB (p. 1808)

Overview of Oracle DB options

To enable options for your Oracle database, add them to an option group, and then associate the option group with your DB instance. For more information, see Working with option groups (p. 279).

Topics
- Summary of Oracle Database options (p. 1698)
- Options supported for different editions (p. 1699)
- Memory requirements for specific options (p. 1699)

Summary of Oracle Database options

You can add the following options for Oracle DB instances.

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon S3 integration (p. 1700)</td>
<td>S3_INTEGRATION</td>
</tr>
<tr>
<td>Oracle Application Express (APEX) (p. 1716)</td>
<td>APEX</td>
</tr>
<tr>
<td></td>
<td>APEX-DEV</td>
</tr>
<tr>
<td>Option</td>
<td>Option ID</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>------------------------------------------</td>
</tr>
<tr>
<td>Oracle Enterprise Manager (p. 1740)</td>
<td>OEM</td>
</tr>
<tr>
<td></td>
<td>OEM_AGENT</td>
</tr>
<tr>
<td>Oracle Java virtual machine (p. 1737)</td>
<td>JVM</td>
</tr>
<tr>
<td>Oracle Label Security (p. 1755)</td>
<td>OLS</td>
</tr>
<tr>
<td>Oracle Locator (p. 1758)</td>
<td>LOCATOR</td>
</tr>
<tr>
<td>Oracle Multimedia (p. 1761)</td>
<td>MULTIMEDIA</td>
</tr>
<tr>
<td>Oracle native network encryption (p. 1763)</td>
<td>NATIVE_NETWORK_ENCRYPTION</td>
</tr>
<tr>
<td>Oracle OLAP (p. 1771)</td>
<td>OLAP</td>
</tr>
<tr>
<td>Oracle Secure Sockets Layer (p. 1774)</td>
<td>SSL</td>
</tr>
<tr>
<td>Oracle Spatial (p. 1782)</td>
<td>SPATIAL</td>
</tr>
<tr>
<td>Oracle SQLT (p. 1785)</td>
<td>SQLT</td>
</tr>

<td>TIMEZONE_FILE_AUTOPGRADE</td>
</tr>
<tr>
<td>Oracle Transparent Data Encryption (p. 1803)</td>
<td>TDE</td>
</tr>
<tr>
<td>Oracle UTL_MAIL (p. 1805)</td>
<td>UTL_MAIL</td>
</tr>
<tr>
<td>Oracle XML DB (p. 1808)</td>
<td>XMLDB</td>
</tr>
</tbody>
</table>

### Options supported for different editions

RDS for Oracle prevents you from adding options to an edition if they aren't supported. To find out which RDS options are supported in different Oracle Database editions, use the command `aws rds describe-option-group-options`. The following example lists supported options for Oracle Database 19c Enterprise Edition.

```
aws rds describe-option-group-options \
  --engine-name oracle-ee \
  --major-engine-version 19
```

For more information, see `describe-option-group-options` in the AWS CLI Command Reference.

### Memory requirements for specific options

Some options require additional memory to run on your DB instance. For example, Oracle Enterprise Manager Database Control uses about 300 MB of RAM. If you enable this option for a small DB instance, you might encounter performance problems due to memory constraints. You can adjust the Oracle parameters so that the database requires less RAM. Alternatively, you can scale up to a larger DB instance.
Amazon S3 integration

You can transfer files between your RDS for Oracle DB instance and an Amazon S3 bucket. You can use Amazon S3 integration with Oracle Database features such as Oracle Data Pump. For example, you can download Data Pump files from Amazon S3 to your RDS for Oracle DB instance. For more information, see Importing data into Oracle on Amazon RDS (p. 1667).

**Note**
Your DB instance and your Amazon S3 bucket must be in the same AWS Region.

**Topics**
- Configuring IAM permissions for RDS for Oracle integration with Amazon S3 (p. 1700)
- Adding the Amazon S3 integration option (p. 1708)
- Transferring files between Amazon RDS for Oracle and an Amazon S3 bucket (p. 1709)
- Removing the Amazon S3 integration option (p. 1715)

Configuring IAM permissions for RDS for Oracle integration with Amazon S3

For RDS for Oracle to integrate with Amazon S3, your DB instance must have access to an Amazon S3 bucket. The Amazon VPC used by your DB instance doesn't need to provide access to the Amazon S3 endpoints.

RDS for Oracle supports uploading files from a DB instance in one account to an Amazon S3 bucket in a different account. Where additional steps are required, they are noted in the following sections.

**Topics**
- Step 1: Create an IAM policy for your Amazon RDS role (p. 1700)
- Step 2: (Optional) Create an IAM policy for your Amazon S3 bucket (p. 1703)
- Step 3: Create an IAM role for your DB instance and attach your policy (p. 1705)
- Step 4: Associate your IAM role with your RDS for Oracle DB instance (p. 1707)

Step 1: Create an IAM policy for your Amazon RDS role

In this step, you create an AWS Identity and Access Management (IAM) policy with the permissions required to transfer files from your Amazon S3 bucket to your RDS DB instance.

To create the policy, make sure you have the following:

- The Amazon Resource Name (ARN) for your bucket
- The ARN for your AWS KMS key, if your bucket uses SSE-KMS or SSE-S3 encryption

**Note**
An Oracle DB instance can't access Amazon S3 buckets encrypted with SSE-C.

For more information, see Protecting data using server-side encryption in the Amazon Simple Storage Service User Guide.

**Console**

**To create an IAM policy to allow Amazon RDS access to an Amazon S3 bucket**

1. Open the IAM Management Console.
Choose **Create Policy**.

4. On the **Visual editor** tab, choose **Choose a service**, and then choose **S3**.

5. For **Actions**, choose **Expand all**, and then choose the bucket permissions and object permissions required to transfer files from an Amazon S3 bucket to Amazon RDS. For example, do the following:

   - Expand **List**, and then select **ListBucket**.
   - Expand **Read**, and then select **GetObject**.
   - Expand **Write**, and then select **PutObject** and **DeleteObject**.
   - Expand **Permissions management**, and then select **PutObjectAcl**. This permission is necessary if you plan to upload files to a bucket owned by a different account, and this account needs full control of the bucket contents.

   **Object permissions** are permissions for object operations in Amazon S3. You must grant them for objects in a bucket, not the bucket itself. For more information, see Permissions for object operations.

6. Choose **Resources**, and choose **Add ARN for bucket**.

7. In the **Add ARN(s)** dialog box, provide the details about your resource, and choose **Add**.

   Specify the Amazon S3 bucket to allow access to. For instance, to allow Amazon RDS to access the Amazon S3 bucket named example-bucket, set the ARN value to `arn:aws:s3:::example-bucket`.

8. If the **object** resource is listed, choose **Add ARN for object**.

9. In the **Add ARN(s)** dialog box, provide the details about your resource.

   For the Amazon S3 bucket, specify the Amazon S3 bucket to allow access to. For the object, you can choose **Any** to grant permissions to any object in the bucket.

   **Note**
   You can set **Amazon Resource Name (ARN)** to a more specific ARN value to allow Amazon RDS to access only specific files or folders in an Amazon S3 bucket. For more information about how to define an access policy for Amazon S3, see Managing access permissions to your Amazon S3 resources.

10. (Optional) Choose **Add additional permissions** to add resources to the policy. For example, do the following:

    - If your bucket is encrypted with a custom KMS key, select **KMS** for the service. Select **Encrypt**, **ReEncrypt**, **Decrypt**, **DescribeKey**, and **GenerateDataKey** for actions. Enter the ARN of your custom key as the resource. For more information, see Protecting Data Using Server-Side Encryption with KMS keys Stored in AWS Key Management Service (SSE-KMS) in the Amazon Simple Storage Service User Guide.
    - If you want Amazon RDS to access to access other buckets, add the ARNs for these buckets. Optionally, you can also grant access to all buckets and objects in Amazon S3.

11. Choose **Next: Tags** and then **Next: Review**.

12. For **Name**, enter a name for your IAM policy, for example `rds-s3-integration-policy`. You use this name when you create an IAM role to associate with your DB instance. You can also add an optional **Description** value.

13. Choose **Create policy**.

**AWS CLI**

Create an AWS Identity and Access Management (IAM) policy that grants Amazon RDS access to an Amazon S3 bucket. After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step.
Include the appropriate actions in the policy based on the type of access required:

- **GetObject** – Required to transfer files from an Amazon S3 bucket to Amazon RDS.
- **ListBucket** – Required to transfer files from an Amazon S3 bucket to Amazon RDS.
- **PutObject** – Required to transfer files from Amazon RDS to an Amazon S3 bucket.

The following AWS CLI command creates an IAM policy named `rds-s3-integration-policy` with these options. It grants access to a bucket named `your-s3-bucket-arn`.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam create-policy
--policy-name rds-s3-integration-policy
--policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "s3integration",
      "Action": ["s3:GetObject", "s3:ListBucket", "s3:PutObject"],
      "Effect": "Allow",
      "Resource": ["arn:aws:s3:::your-s3-bucket-arn", "arn:aws:s3:::your-s3-bucket-arn/*"]
    }
  ]
}
```

The following example includes permissions for custom KMS keys.

```bash
aws iam create-policy
--policy-name rds-s3-integration-policy
--policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "s3integration",
      "Effect": "Allow",
      "Resource": ["arn:aws:s3:::your-s3-bucket-arn", "arn:aws:s3:::your-s3-bucket-arn/*", "arn:aws:kms:::your-kms-arn"]
    }
  ]
}
```
For Windows:

```bash
aws iam create-policy
   --policy-name rds-s3-integration-policy
   --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
     {
       "Sid": "s3integration",
       "Action": [
         "s3:GetObject",
         "s3:ListBucket",
         "s3:PutObject"
       ],
       "Effect": "Allow",
       "Resource": [
         "arn:aws:s3:::your-s3-bucket-arn",
         "arn:aws:s3:::your-s3-bucket-arn/*"
       ]
     }
   ]
}
}
```

The following example includes permissions for custom KMS keys.

```bash
aws iam create-policy
   --policy-name rds-s3-integration-policy
   --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
     {
       "Sid": "s3integration",
       "Action": [
         "s3:GetObject",
         "s3:ListBucket",
         "s3:PutObject",
         "kms:Decrypt",
         "kms:Encrypt",
         "kms:ReEncrypt",
         "kms:GenerateDataKey",
         "kms:DescribeKey",
       ],
       "Effect": "Allow",
       "Resource": [
         "arn:aws:s3:::your-s3-bucket-arn",
         "arn:aws:s3:::your-s3-bucket-arn/*",
         "arn:aws:kms:::your-kms-arn"
       ]
     }
   ]
}
```

**Step 2: (Optional) Create an IAM policy for your Amazon S3 bucket**

This step is necessary only in the following conditions:

- You plan to upload files to an Amazon S3 bucket from one account (account A) and access them from a different account (account B).
- Account B owns the bucket.
• Account B needs full control of objects loaded into the bucket.

If the preceding conditions don’t apply to you, skip to Step 3: Create an IAM role for your DB instance and attach your policy (p. 1705).

To create your bucket policy, make sure you have the following:

• The account ID for account A
• The user name for account A
• The ARN value for the Amazon S3 bucket in account B

Console

To create or edit a bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the Buckets list, choose the name of the bucket that you want to create a bucket policy for or whose bucket policy you want to edit.
3. Choose Permissions.
4. Under Bucket policy, choose Edit. This opens the Edit bucket policy page.
5. On the Edit bucket policy page, explore Policy examples in the Amazon S3 User Guide, choose Policy generator to generate a policy automatically, or edit the JSON in the Policy section.

If you choose Policy generator, the AWS Policy Generator opens in a new window:

a. On the AWS Policy Generator page, in Select Type of Policy, choose S3 Bucket Policy.
b. Add a statement by entering the information in the provided fields, and then choose Add Statement. Repeat for as many statements as you would like to add. For more information about these fields, see the IAM JSON policy elements reference in the IAM User Guide.

   Note
   For convenience, the Edit bucket policy page displays the Bucket ARN (Amazon Resource Name) of the current bucket above the Policy text field. You can copy this ARN for use in the statements on the AWS Policy Generator page.

c. After you finish adding statements, choose Generate Policy.
d. Copy the generated policy text, choose Close, and return to the Edit bucket policy page in the Amazon S3 console.
6. In the Policy box, edit the existing policy or paste the bucket policy from the Policy generator. Make sure to resolve security warnings, errors, general warnings, and suggestions before you save your policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Example permissions",
      "Effect": "Allow",
      "Principal": {
      },
      "Action": [
        "s3:PutObject",
        "s3:PutObjectAcl"
      ],
      "Resource": [
```
7. Choose Save changes, which returns you to the Bucket Permissions page.

**Step 3: Create an IAM role for your DB instance and attach your policy**

This step assumes that you have created the IAM policy in Step 1: Create an IAM policy for your Amazon RDS role (p. 1700). In this step, you create a role for your RDS for Oracle DB instance and then attach your policy to the role.

**Console**

**To create an IAM role to allow Amazon RDS access to an Amazon S3 bucket**

1. Open the IAM Management Console.
2. In the navigation pane, choose Roles.
3. Choose Create role.
4. For AWS service, choose RDS.
5. For Select your use case, choose RDS – Add Role to Database.
6. Choose Next.
7. For Search under Permissions policies, enter the name of the IAM policy you created, and choose the policy when it appears in the list.
8. Choose Next.
9. Set Role name to a name for your IAM role, for example rds-s3-integration-role. You can also add an optional Description value.
10. Choose Create role.

**AWS CLI**

**To create a role and attach your policy to it**

1. Create an IAM role that Amazon RDS can assume on your behalf to access your Amazon S3 buckets.

   We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

   You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

   - Use `aws:SourceArn` if you want cross-service access for a single resource.
   - Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

   In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role.

   The following AWS CLI command creates the role named `rds-s3-integration-role` for this purpose.
Example

For Linux, macOS, or Unix:

```bash
aws iam create-role \
  --role-name rds-s3-integration-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": my_account_ID,
            "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
          }
        }
      }
    ]
  }
```

For Windows:

```bash
aws iam create-role ^
  --role-name rds-s3-integration-role ^
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": my_account_ID,
            "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
          }
        }
      }
    ]
  }
```

For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

2. After the role is created, note the ARN of the role. You need the ARN for a subsequent step.

3. Attach the policy you created to the role you created.

The following AWS CLI command attaches the policy to the role named rds-s3-integration-role.

Example

For Linux, macOS, or Unix:
aws iam attach-role-policy \
   --policy-arn your-policy-arn \
   --role-name rds-s3-integration-role

For Windows:

aws iam attach-role-policy ^
   --policy-arn your-policy-arn ^
   --role-name rds-s3-integration-role

Replace *your-policy-arn* with the policy ARN that you noted in a previous step.

**Step 4: Associate your IAM role with your RDS for Oracle DB instance**

The last step in configuring permissions for Amazon S3 integration is associating your IAM role with your DB instance. Note the following requirements:

- You must have access to an IAM role with the required Amazon S3 permissions policy attached to it.
- You can only associate one IAM role with your RDS for Oracle DB instance at a time.
- The status of your instance must be available.

**Console**

**To associate your IAM role with your RDS for Oracle DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose *Databases* from the navigation pane.
3. If your database instance is unavailable, choose *Actions* and then *Start*. When the instance status shows *Started*, go to the next step.
4. Choose the Oracle DB instance name to display its details.
5. On the *Connectivity & security* tab, scroll down to the *Manage IAM roles* section at the bottom of the page.
6. Choose the role to add in the *Add IAM roles to this instance* section.
7. For *Feature*, choose *S3_INTEGRATION*.
8. Choose *Add role*. 
AWS CLI

The following AWS CLI command adds the role to an Oracle DB instance named mydbinstance.

Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance
   --db-instance-identifier mydbinstance
   --feature-name S3_INTEGRATION
   --role-arn your-role-arn
```

For Windows:

```
aws rds add-role-to-db-instance ^
   --db-instance-identifier mydbinstance ^
   --feature-name S3_INTEGRATION ^
   --role-arn your-role-arn
```

Replace your-role-arn with the role ARN that you noted in a previous step. S3_INTEGRATION must be specified for the --feature-name option.

Adding the Amazon S3 integration option

To use Amazon RDS for Oracle Integration with Amazon S3, your Amazon RDS for Oracle DB instance must be associated with an option group that includes the S3_INTEGRATION option.

Console

To configure an option group for Amazon S3 integration

1. Create a new option group or identify an existing option group to which you can add the S3_INTEGRATION option.

   For information about creating an option group, see Creating an option group (p. 280).

2. Add the S3_INTEGRATION option to the option group.

   For information about adding an option to an option group, see Adding an option to an option group (p. 283).

3. Create a new Oracle DB instance and associate the option group with it, or modify an Oracle DB instance to associate the option group with it.

   For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 236).

   For information about modifying an Oracle DB instance, see Modifying an Amazon RDS DB instance (p. 333).

AWS CLI

To configure an option group for Amazon S3 integration

1. Create a new option group or identify an existing option group to which you can add the S3_INTEGRATION option.

   For information about creating an option group, see Creating an option group (p. 280).
2. Add the S3_INTEGRATION option to the option group.

For example, the following AWS CLI command adds the S3_INTEGRATION option to an option group named `myoptiongroup`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group
    --option-group-name myoptiongroup
    --options OptionName=S3_INTEGRATION,OptionVersion=1.0
```

For Windows:

```bash
aws rds add-option-to-option-group
    --option-group-name myoptiongroup
    --options OptionName=S3_INTEGRATION,OptionVersion=1.0
```

3. Create a new Oracle DB instance and associate the option group with it, or modify an Oracle DB instance to associate the option group with it.

For information about creating a DB instance, see *Creating an Amazon RDS DB instance* (p. 236).

For information about modifying an Oracle DB instance, see *Modifying an Amazon RDS DB instance* (p. 333).

**Transferring files between Amazon RDS for Oracle and an Amazon S3 bucket**

To transfer files between an Oracle DB instance and an Amazon S3 bucket, you can use the Amazon RDS package `rdsadmin_s3_tasks`. You can compress files with GZIP when uploading them, and decompress them when downloading.

**Note**

The procedures in `rdsadmin_s3_tasks` upload or download the files in a single directory. You can't include subdirectories in these operations.

**Topics**

- Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket (p. 1709)
- Downloading files from an Amazon S3 bucket to an Oracle DB instance (p. 1712)
- Monitoring the status of a file transfer (p. 1714)

**Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket**

To upload files from your DB instance to an Amazon S3 bucket, use the procedure `rdsadmin.rdsadmin_s3_tasks.upload_to_s3`. For example, you can upload Oracle Recovery Manager (RMAN) backup files or Oracle Data Pump files. The maximum object size in an Amazon S3 bucket is 5 TB. For more information about working with objects, see *Amazon Simple Storage Service User Guide*. For more information about performing RMAN backups, see *Performing common RMAN tasks for Oracle DB instances* (p. 1620).

The `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` procedure has the following parameters.
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_bucket_name</td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>The name of the Amazon S3 bucket to upload files to.</td>
</tr>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>The name of the Oracle directory object to upload files from. The directory can be any user-created directory object or the Data Pump directory, such as DATA_PUMP_DIR. Note You can only upload files from the specified directory. You can't upload files in subdirectories in the specified directory.</td>
</tr>
<tr>
<td>p_s3_prefix</td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>An Amazon S3 file name prefix that files are uploaded to. An empty prefix uploads all files to the top level in the specified Amazon S3 bucket and doesn't add a prefix to the file names. For example, if the prefix is folder_1/oradb, files are uploaded to folder_1. In this case, the oradb prefix is added to each file.</td>
</tr>
<tr>
<td>p_prefix</td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>A file name prefix that file names must match to be uploaded. An empty prefix uploads all files in the specified directory.</td>
</tr>
<tr>
<td>p_compression_level</td>
<td>NUMBER</td>
<td>0</td>
<td>optional</td>
<td>The level of GZIP compression. Valid values range from 0 to 9: • 0 – No compression • 1 – Fastest compression • 9 – Highest compression</td>
</tr>
<tr>
<td>p_bucket_owner_full_control</td>
<td>VARCHAR2</td>
<td>–</td>
<td>optional</td>
<td>The access control setting for the bucket. The only valid values are null or FULL_CONTROL. This setting is required only.</td>
</tr>
</tbody>
</table>
The return value for the `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` procedure is a task ID.

The following example uploads all of the files in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`. The files aren't compressed.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name => 'mys3bucket',
    p_prefix => '',
    p_s3_prefix => '',
    p_directory_name => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The following example uploads all of the files with the prefix `db` in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`. Amazon RDS applies the highest level of GZIP compression to the files.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name => 'mys3bucket',
    p_prefix => 'db',
    p_s3_prefix => '',
    p_directory_name => 'DATA_PUMP_DIR',
    p_compression_level => 9)
AS TASK_ID FROM DUAL;
```

The following example uploads all of the files in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`. The files are uploaded to a `dbfiles` folder. In this example, the GZIP compression level is 1, which is the fastest level of compression.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name => 'mys3bucket',
    p_prefix => '',
    p_s3_prefix => 'dbfiles/',
    p_directory_name => 'DATA_PUMP_DIR',
    p_compression_level => 1)
AS TASK_ID FROM DUAL;
```

The following example uploads all of the files in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`. The files are uploaded to a `dbfiles` folder and `ora` is added to the beginning of each file name. No compression is applied.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name => 'mys3bucket',
    p_prefix => '',
    p_s3_prefix => 'dbfiles/ora',
    p_directory_name => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The following example assumes that the command is run in account A, but account B requires full control of the bucket contents. The command `rdsadmin_s3_tasks.upload_to_s3` transfers all files in the

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>if you upload files from one account (account A) into a bucket owned by a different account (account B), and account B needs full control of the files.</td>
</tr>
</tbody>
</table>
DATA_PUMP_DIR directory to the bucket named s3bucketOwnedByAccountB. Access control is set to FULL_CONTROL so that account B can access the files in the bucket. The GZIP compression level is 6, which balances speed and file size.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name => 's3bucketOwnedByAccountB',
    p_prefix => '',
    p_s3_prefix => '',
    p_directory_name => 'DATA_PUMP_DIR',
    p_bucket_owner_full_control => 'FULL_CONTROL',
    p_compression_level => 6
) AS TASK_ID FROM DUAL;
```

In each example, the SELECT statement returns the ID of the task in a VARCHAR2 data type.

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace task-id with the task ID returned by the procedure.

**Note**

Tasks are executed asynchronously.

**Downloading files from an Amazon S3 bucket to an Oracle DB instance**

To download files from an Amazon S3 bucket to an RDS for Oracle instance, use the Amazon RDS procedure rdsadmin.rdsadmin_s3_tasks.download_from_s3.

When you download files using the procedure download_from_s3, consider the following:

- The download limit is 2000 files per procedure call. If you need to download more than 2000 files from Amazon S3, split your download into separate actions, with no more than 2000 files per procedure call.
- If a file exists in your download folder, and you attempt to download a file with the same name, download_from_s3 skips the download. To remove a file from the download directory, use UTL_FILE.FREMOVE, found on the Oracle website.

The download_from_s3 procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_bucket_name</td>
<td>VARCHAR2</td>
<td>–</td>
<td>Required</td>
<td>The name of the Amazon S3 bucket to download files from.</td>
</tr>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>–</td>
<td>Required</td>
<td>The name of the Oracle directory object to download files to. The directory can be any user-created directory object or the Data Pump directory, such as DATA_PUMP_DIR.</td>
</tr>
<tr>
<td>p_error_on_zero_downloads</td>
<td>VARCHAR2</td>
<td>FALSE</td>
<td>Optional</td>
<td>A flag that determines whether the task raises an error when no objects in the Amazon S3 bucket match the prefix. If this parameter is not set or set to FALSE.</td>
</tr>
</tbody>
</table>
The return value for the `rdsadmin.rdsadmin_s3_tasks.download_from_s3` procedure is a task ID.

The following example downloads all files in the Amazon S3 bucket named `mys3bucket` to the `DATA_PUMP_DIR` directory. The files aren't compressed, so no decompression is applied.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name => 'mys3bucket',
    p_directory_name => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The following example downloads all of the files with the prefix `db` in the Amazon S3 bucket named `mys3bucket` to the `DATA_PUMP_DIR` directory. The files are compressed with GZIP, so decompression is...
applied. The parameter `p_error_on_zero_downloads` turns on prefix error checking, so if the prefix
doesn't match any files in the bucket, the task raises an exception and fails.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name => 'mys3bucket',
    p_s3_prefix => 'db',
    p_directory_name => 'DATA_PUMP_DIR',
    p_decompression_format => 'GZIP',
    p_error_on_zero_downloads => 'TRUE')
AS TASK_ID FROM DUAL;
```

The following example downloads all of the files in the folder `myfolder/` in the Amazon S3 bucket
named `mys3bucket` to the `DATA_PUMP_DIR` directory. Use the `p_s3_prefix` parameter to specify the
Amazon S3 folder. The uploaded files are compressed with GZIP, but aren't decompressed during the
download.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name          =>  'mys3bucket',
    p_s3_prefix            =>  'myfolder/',
    p_directory_name       =>  'DATA_PUMP_DIR',
    p_decompression_format =>  'NONE')
AS TASK_ID FROM DUAL;
```

The following example downloads the file `mydumpfile.dmp` in the Amazon S3 bucket named
`mys3bucket` to the `DATA_PUMP_DIR` directory. No decompression is applied.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name    =>  'mys3bucket',
    p_s3_prefix      =>  'mydumpfile.dmp',
    p_directory_name =>  'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

In each example, the SELECT statement returns the ID of the task in a VARCHAR2 data type.

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-
    task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure.

**Note**

Tasks are executed asynchronously.

You can use the UTL_FILE. FREMOVE Oracle procedure to remove files from a directory. For more information, see FREMOVE procedure in the Oracle documentation.

**Monitoring the status of a file transfer**

File transfer tasks publish Amazon RDS events when they start and when they complete. For information
about viewing events, see Viewing Amazon RDS events (p. 682).

You can view the status of an ongoing task in a bdump file. The bdump files are located in the /
`rdsdbdata/log/trace` directory. Each bdump file name is in the following format.

`dbtask-task-id.log`

Replace `task-id` with the ID of the task that you want to monitor.
Note
Tasks are executed asynchronously.

You can use the `rdsadmin.rds_file_util.read_text_file` stored procedure to view the contents of bdump files. For example, the following query returns the contents of the `dbtask-154698886389-2444.log` bdump file.

```sql
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-154698886389-2444.log'));
```

Removing the Amazon S3 integration option

You can remove Amazon S3 integration option from a DB instance.

To remove the Amazon S3 integration option from a DB instance, do one of the following:

- To remove the Amazon S3 integration option from multiple DB instances, remove the `S3_INTEGRATION` option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 291).

- To remove the Amazon S3 integration option from a single DB instance, modify the instance and specify a different option group that doesn't include the `S3_INTEGRATION` option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).
Oracle Application Express (APEX)

Amazon RDS supports Oracle Application Express (APEX) through the use of the APEX and APEX-DEV options. Oracle APEX can be deployed as a run-time environment or as a full development environment for web-based applications. Using Oracle APEX, developers can build applications entirely within the web browser. For more information, see Oracle application Express in the Oracle documentation.

Topics

• APEX components (p. 1716)
• APEX version requirements (p. 1716)
• Prerequisites for Oracle APEX and ORDS (p. 1717)
• Adding the Amazon RDS APEX options (p. 1718)
• Unlocking the public user account (p. 1718)
• Configuring RESTful services for Oracle APEX (p. 1719)
• Setting up ORDS for Oracle APEX (p. 1719)
• Setting up Oracle APEX listener (p. 1723)
• Upgrading the APEX version (p. 1725)
• Removing the APEX option (p. 1725)

APEX components

Oracle APEX consists of the following main components:

• A repository that stores the metadata for APEX applications and components. The repository consists of tables, indexes, and other objects that are installed in your Amazon RDS DB instance.

• A listener that manages HTTP communications with Oracle APEX clients. The listener accepts incoming connections from web browsers, forwards them to the Amazon RDS DB instance for processing, and then sends results from the repository back to the browsers. Amazon RDS for Oracle supports the following types of listeners:
  • For APEX version 5.0 and later, use Oracle Rest Data Services (ORDS) version 19.1 and higher. We recommend that you use the latest supported version of Oracle APEX and ORDS. This documentation describes older versions for backwards compatibility only.
  • For APEX version 4.1.1, you can use Oracle APEX Listener version 1.1.4.
  • You can use Oracle HTTP Server and mod_plsql listeners.

  Note
  Amazon RDS doesn't support the Oracle XML DB HTTP server with the embedded PL/SQL gateway; you can't use this as a listener for APEX. In general, Oracle recommends against using the embedded PL/SQL gateway for applications that run on the internet.

For more information about these listener types, see About choosing a web listener in the Oracle documentation.

When you add the Amazon RDS APEX options to your DB instance, Amazon RDS installs the Oracle APEX repository only. Install your listener on a separate host, such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer.

APEX version requirements

The APEX option uses storage on the DB instance class for your DB instance. Following are the supported versions and approximate storage requirements for Oracle APEX.
<table>
<thead>
<tr>
<th>APEX version</th>
<th>Storage requirements</th>
<th>Supported Oracle Database versions</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle APEX version 22.1.v1</td>
<td>124 MiB</td>
<td>All</td>
<td>This version includes patch 34020981: PSE BUNDLE FOR APEX 22.1 (PSES ON TOP OF 22.1.0), PATCH_VERSION 6.</td>
</tr>
<tr>
<td>Oracle APEX version 21.2.v1</td>
<td>125 MiB</td>
<td>All</td>
<td>This version includes patch 33420059: PSE BUNDLE FOR APEX 21.2 (PSES ON TOP OF 21.2.0), PATCH_VERSION 8.</td>
</tr>
<tr>
<td>Oracle APEX version 21.1.v1</td>
<td>125 MiB</td>
<td>All</td>
<td>This version includes patch 32598392: PSE BUNDLE FOR APEX 21.1, PATCH_VERSION 3.</td>
</tr>
<tr>
<td>Oracle APEX version 20.2.v1</td>
<td>148 MiB</td>
<td>All except 21c</td>
<td>This version includes patch 32006852: PSE BUNDLE FOR APEX 20.2, PATCH_VERSION 2020.11.12. You can see the patch number and date by running the following query: SELECT PATCH_VERSION, PATCH_NUMBER FROM APEX_PATCHES;</td>
</tr>
<tr>
<td>Oracle APEX version 20.1.v1</td>
<td>173 MiB</td>

<td></td>
</tr>
</tbody>
</table>

**Prerequisites for Oracle APEX and ORDS**

To use Oracle APEX and ORDS, make sure you have the following:

- The Java Runtime Environment (JRE)
- An Oracle client installation that includes the following:
• SQL*Plus or SQL Developer for administration tasks
• Oracle Net Services for configuring connections to your Oracle instance

Adding the Amazon RDS APEX options

To add the Amazon RDS APEX options to a DB instance, do the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the options to the option group.
3. Associate the option group with the DB instance.

When you add the Amazon RDS APEX options, a brief outage occurs while your DB instance is automatically restarted.

To add the APEX options to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For Engine, choose the Oracle edition that you want to use. The APEX options are supported on all editions.
   b. For Major engine version, choose the version of your DB instance.

   For more information, see Creating an option group (p. 280).

2. Add the options to the option group. If you want to deploy only the Oracle APEX run-time environment, add only the APEX option. If you want to deploy the full development environment, add both the APEX and APEX-DEV options. For Oracle Database 12c, add the APEX and APEX-DEV options.

   For Version, choose the version of APEX that you want to use. If you don’t choose a version, version 4.2.6.v1 is the default for Oracle Database 12c.

   **Important**
   If you add the APEX options to an existing option group that is already attached to one or more DB instances, a brief outage occurs. During this outage, all the DB instances are automatically restarted.

   For more information about adding options, see Adding an option to an option group (p. 283).

3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the APEX options to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance (p. 333).

Unlocking the public user account

After the Amazon RDS APEX options are installed, make sure to do the following:

1. Change the password for the APEX public user account.
2. Unlock the account.

You can do this by using the Oracle SQL*Plus command line utility. Connect to your DB instance as the master user, and issue the following commands. Replace new_password with a password of your choice.

```sql
ALTER USER APEX_PUBLIC_USER IDENTIFIED BY new_password;
ALTER USER APEX_PUBLIC_USER ACCOUNT UNLOCK;
```

### Configuring RESTful services for Oracle APEX

To configure RESTful services in APEX (not needed for APEX 4.1.1.V1), use SQL*Plus to connect to your DB instance as the master user. After you do this, run the `rdsadmin.rdsadmin_run_apex_rest_config` stored procedure. When you run the stored procedure, you provide passwords for the following users:

- APEX_LISTENER
- APEX_REST_PUBLIC_USER

The stored procedure runs the `apex_rest_config.sql` script, which creates new database accounts for these users.

**Note**

Configuration isn't required for Oracle APEX version 4.1.1.v1. For this Oracle APEX version only, you don't need to run the stored procedure.

The following command runs the stored procedure.

```sql
EXEC rdsadmin.rdsadmin_run_apex_rest_config('apex_listener_password', 'apex_rest_public_user_password');
```

### Setting up ORDS for Oracle APEX

You are now ready to install and configure Oracle Rest Data Services (ORDS) for use with Oracle APEX. For APEX version 5.0 and later, use Oracle Rest Data Services (ORDS) version 19.1 and higher.

Install the listener on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. For the examples in this section, we assume that the name of your host is `myapexhost.example.com`, and that your host is running Linux.

#### Preparing to install ORDS

Before you can install ORDS, you need to create a nonprivileged OS user, and then download and unzip the APEX installation file.

**To prepare for ORDS installation**

1. Log in to `myapexhost.example.com` as root.
2. Create a nonprivileged OS user to own the listener installation. The following command creates a new user named `apexuser`.

   ```
   useradd -d /home/apexuser apexuser
   ```

   The following command assigns a password to the new user.

   ```
   passwd apexuser;
   ```
3. Log in to myapexhost.example.com as apexuser, and download the APEX installation file from Oracle to your /home/apexuser directory:
   - Oracle application Express prior release archives
4. Unzip the file in the /home/apexuser directory.

```
unzip apex_<version>.zip
```

After you unzip the file, there is an apex directory in the /home/apexuser directory.
5. While you are still logged into myapexhost.example.com as apexuser, download the Oracle REST Data Services file from Oracle to your /home/apexuser directory: http://www.oracle.com/technetwork/developer-tools/apex-listener/downloads/index.html.

### Installing and configuring ORDS

Before you can use APEX, you need to download the ords.war file, use Java to install ORDS, and then start the listener.

#### To install and configure ORDS for use with Oracle APEX

1. Create a new directory based on ORDS, and then unzip the listener file.

   ```
   mkdir /home/apexuser/ORDS
   cd /home/apexuser/ORDS
   ```

2. Download the file `ords.version.number.zip` from Oracle REST data services.
3. Unzip the file into the /home/apexuser/ORDS directory.
4. If you're installing ORDS in a multitenant database, add the following line to the file /home/apexuser/ORDS/params/ords_params.properties:

   ```
   pdb.disable.lockdown=false
   ```
5. Grant the master user the required privileges to install ORDS.

   After the Amazon RDS APEX option is installed, give the master user the required privileges to install the ORDS schema. You can do this by connecting to the database and running the following commands. Replace `MASTER_USER` with the uppercase name of your master user.

   **Important**

   When you enter the user name, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run `CREATE USER myuser` or `CREATE USER MYUSER`, the data dictionary stores MYUSER. However, if you use double quotes in `CREATE USER "MyUser"`, the data dictionary stores MyUser. For more information, see [Granting SELECT or EXECUTE privileges to SYS objects](p. 1585).

   ```
   exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_OBJECTS', 'MASTER_USER', 'SELECT', true);
   exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_ROLE_PRIVS', 'MASTER_USER', 'SELECT', true);
   exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_TAB_COLUMNS', 'MASTER_USER', 'SELECT', true);
   exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONS_COLUMNS', 'MASTER_USER', 'SELECT', true);
   exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONSTRAINTS', 'MASTER_USER', 'SELECT', true);
   ```
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_OBJECTS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_PROCEDURES', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TAB_COLUMNS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TABLES', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_VIEWS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('WPIUTL', 'MASTER_USER', 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SESSION', 'MASTER_USER', 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_UTILITY', 'MASTER_USER', 'EXECUTE', true);

Note
These commands apply to ORDS version 19.1 and later.

6. Install the ORDS schema using the downloaded ords.war file.

```
java -jar ords.war install advanced
```

The program prompts you for the following information. The default values are in brackets. For more information, see Introduction to Oracle REST data services in the Oracle documentation.

- Enter the location to store configuration data:

  Enter `/home/apexuser/ORDS`. This is the location of the ORDS configuration files.

  Choose the desired connection type.

- Enter the name of the database server [localhost]: DB_instance_endpoint

  Choose the default or enter the correct value.

- Enter the database listener port [1521]: DB_instance_port

  Choose the default or enter the correct value.

- Enter 1 to specify the database service name, or 2 to specify the database SID [1]:

  Choose 2 to specify the database SID.

- Database SID [xe]

  Choose the default or enter the correct value.

- Enter 1 if you want to verify/install Oracle REST Data Services schema or 2 to skip this step [1]:

  Choose 1. This step creates the Oracle REST Data Services proxy user named ORDS_PUBLIC_USER.

- Enter the database password for ORDS_PUBLIC_USER:

  Enter the password, and then confirm it.

- Requires to login with administrator privileges to verify Oracle REST Data Services schema.

Enter the administrator user name: master_user

Enter the database password for master_user: master_user_password

Confirm the password: master_user_password
• Enter the default tablespace for ORDS_METADATA [SYSAUX].

Enter the temporary tablespace for ORDS_METADATA [TEMP].

Enter the default tablespace for ORDS_PUBLIC_USER [USERS].

Enter the temporary tablespace for ORDS_PUBLIC_USER [TEMP].

• Enter 1 if you want to use PL/SQL Gateway or 2 to skip this step. If you're using Oracle Application Express or migrating from mod_plsql, you must enter 1 [1].

Choose the default.

• Enter the PL/SQL Gateway database user name [APEX_PUBLIC_USER]

Choose the default.

• Enter the database password for APEX_PUBLIC_USER:

Enter the password, and then confirm it.

• Enter 1 to specify passwords for Application Express RESTful Services database users (APEX_LISTENER, APEX_REST_PUBLIC_USER) or 2 to skip this step [1]:

Choose 2 for APEX 4.1.1.V1; choose 1 for all other APEX versions.

• [Not needed for APEX 4.1.1.v1] Database password for APEX_LISTENER

Enter the password (if required), and then confirm it.

• [Not needed for APEX 4.1.1.v1] Database password for APEX_REST_PUBLIC_USER

Enter the password (if required), and then confirm it.

• Enter a number to select a feature to enable:

Enter 1 to enable all features: SQL Developer Web, REST Enabled SQL, and Database API.

• Enter 1 if you wish to start in standalone mode or 2 to exit [1]:

Enter 1.

• Enter the APEX static resources location:

If you unzipped APEX installation files into /home/apexuser, enter /home/apexuser/apex/images. Otherwise, enter unzip_path/apex/images, where unzip_path is the directory where you unzipped the file.

• Enter 1 if using HTTP or 2 if using HTTPS [1]:

If you enter 1, specify the HTTP port. If you enter 2, specify the HTTPS port and the SSL host name. The HTTPS option prompts you to specify how you will provide the certificate:

• Enter 1 to use the self-signed certificate.

• Enter 2 to provide your own certificate. If you enter 2, specify the path for the SSL certificate and the path for the SSL certificate private key.

7. Set a password for the APEX admin user. To do this, use SQL*Plus to connect to your DB instance as the master user, and then run the following commands.

```
EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
grant APEX_ADMINISTRATOR_ROLE to master;
@/home/apexuser/apex/apxchpwd.sql
```

Replace master with your master user name. When the apxchpwd.sql script prompts you, enter a new admin password.

8. Start the ORDS listener. Run the following code.
java -jar ords.war

The first time you start ORDS, you are prompted to provide the location of the APEX Static resources. This images folder is located in the /apex/images directory in the installation directory for APEX.

9. Return to the APEX administration window in your browser and choose Administration. Next, choose Application Express Internal Administration. When you are prompted for credentials, enter the following information:

- **User name** – admin
- **Password** – the password you set using the apxchpwd.sql script

Choose Login, and then set a new password for the admin user.

Your listener is now ready for use.

**Setting up Oracle APEX listener**

**Note**

Oracle APEX Listener is deprecated.

Amazon RDS for Oracle continues to support APEX version 4.1.1 and Oracle APEX Listener version 1.1.4. We recommend that you use the latest supported versions of Oracle APEX and ORDS.

Install Oracle APEX Listener on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. We assume that the name of your host is myapexhost.example.com, and that your host is running Linux.

**Preparing to install Oracle APEX listener**

Before you can install Oracle APEX Listener, you need to create a nonprivileged OS user, and then download and unzip the APEX installation file.

**To prepare for Oracle APEX listener installation**

1. Log in to myapexhost.example.com as root.
2. Create a nonprivileged OS user to own the listener installation. The following command creates a new user named apexuser.

```
useradd -d /home/apexuser apexuser
```

The following command assigns a password to the new user.

```
pwdp apexuser;
```

3. Log in to myapexhost.example.com as apexuser, and download the APEX installation file from Oracle to your /home/apexuser directory:

- Oracle application Express prior release archives

4. Unzip the file in the /home/apexuser directory.

```
unzip apex_<version>.zip
```
After you unzip the file, there is an apex directory in the /home/apexuser directory.

5. While you are still logged into myapexhost.example.com as apexuser, download the Oracle APEX Listener file from Oracle to your /home/apexuser directory.

### Installing and configuring Oracle APEX listener

Before you can use APEX, you need to download the apex.war file, use Java to install Oracle APEX Listener, and then start the listener.

**To install and configure Oracle APEX listener**

1. Create a new directory based on Oracle APEX Listener and open the listener file.

   ```bash
   mkdir /home/apexuser/apexlistener
   cd /home/apexuser/apexlistener
   unzip ..../apex_listener.version.zip
   ```

2. Run the following code.

   ```bash
   java -Dapex.home=./apex -Dapex.images=/home/apexuser/apex/images -Dapex.erase -jar ./apex.war
   ```

3. Enter information for the program prompts following:
   - The APEX Listener Administrator user name. The default is adminlistener.
   - A password for the APEX Listener Administrator.
   - The APEX Listener Manager user name. The default is managerlistener.
   - A password for the APEX Listener Administrator.

   The program prints a URL that you need to complete the configuration, as follows.

   ```bash
   INFO: Please complete configuration at: http://localhost:8080/apex/listenerConfigure
   Database is not yet configured
   ```

4. Leave Oracle APEX Listener running so that you can use Oracle Application Express. When you have finished this configuration procedure, you can run the listener in the background.

5. From your web browser, go to the URL provided by the APEX Listener program. The Oracle Application Express Listener administration window appears. Enter the following information:

   - **Username** – APEX_PUBLIC_USER
   - **Password** – the password for APEX_PUBLIC_USER. This password is the one that you specified earlier when you configured the APEX repository. For more information, see Unlocking the public user account (p. 1718).
   - **Connection type** – Basic
   - **Hostname** – the endpoint of your Amazon RDS DB instance, such as mydb.f9bfa893tft.us-east-1.rds.amazonaws.com.
   - **Port** – 1521
   - **SID** – the name of the database on your Amazon RDS DB instance, such as mydb.

6. Choose **Apply**. The APEX administration window appears.

7. Set a password for the APEX admin user. To do this, use SQL*Plus to connect to your DB instance as the master user, and then run the following commands.
EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
grant APEX_ADMINISTRATOR_ROLE to master;
@/home/apexuser/apex/apxchpwd.sql

Replace `master` with your master user name. When the `apxchpwd.sql` script prompts you, enter a new admin password.

8. Return to the APEX administration window in your browser and choose Application Express. Next, choose Application Express Internal Administration. When you are prompted for credentials, enter the following information:

- **User name** – admin
- **Password** – the password you set using the `apxchpwd.sql` script

Choose Login, and then set a new password for the admin user.

Your listener is now ready for use.

### Upgrading the APEX version

**Important**

Back up your DB instance before you upgrade APEX. For more information, see Creating a DB snapshot (p. 483) and Testing an Oracle DB upgrade (p. 1815).

To upgrade APEX with your DB instance, do the following:

- Create a new option group for the upgraded version of your DB instance.
- Add the upgraded versions of APEX and APEX-DEV to the new option group. Be sure to include any other options that your DB instance uses. For more information, see Option group considerations (p. 1813).
- When you upgrade your DB instance, specify the new option group for your upgraded DB instance.

After you upgrade your version of APEX, the APEX schema for the previous version might still exist in your database. If you don't need it anymore, you can drop the old APEX schema from your database after you upgrade.

If you upgrade the APEX version and RESTful services were not configured in the previous APEX version, we recommend that you configure RESTful services. For more information, see Configuring RESTful services for Oracle APEX (p. 1719).

In some cases when you plan to do a major version upgrade of your DB instance, you might find that you're using an APEX version that isn't compatible with your target database version. In these cases, you can upgrade your version of APEX before you upgrade your DB instance. Upgrading APEX first can reduce the amount of time that it takes to upgrade your DB instance.

**Note**

After upgrading APEX, install and configure a listener for use with the upgraded version. For instructions, see Setting up Oracle APEX listener (p. 1723).

### Removing the APEX option

You can remove the Amazon RDS APEX options from a DB instance. To remove the APEX options from a DB instance, do one of the following:

- To remove the APEX options from multiple DB instances, remove the APEX options from the option group they belong to. This change affects all DB instances that use the option group. When you
remove the APEX options from an option group that is attached to multiple DB instances, a brief outage occurs while all the DB instances are restarted.

For more information, see Removing an option from an option group (p. 291).

• To remove the APEX options from a single DB instance, modify the DB instance and specify a different option group that doesn't include the APEX options. You can specify the default (empty) option group, or a different custom option group. When you remove the APEX options, a brief outage occurs while your DB instance is automatically restarted.

For more information, see Modifying an Amazon RDS DB instance (p. 333).

When you remove the APEX options from a DB instance, the APEX schema is removed from your database.
Amazon EFS integration

You can transfer files between your RDS for Oracle DB instance and an Amazon EFS file system. You can use Amazon EFS integration with Oracle Database features such as Oracle Data Pump. For example, you can import Data Pump files from Amazon EFS to your RDS for Oracle DB instance. You don't need to copy these files locally because Data Pump imports directly from the EFS file system. For more information, see Importing data into Oracle on Amazon RDS (p. 1667).

Note the following requirements and restrictions:

• Amazon EFS integration is supported only for Oracle Database 19c - July 2022 Patch Set Update (PSU) 19.0.0.0.ru-2022-07.rur-2022-07.r1 or later.
• Your DB instance and your EFS file system must be in the same AWS Region and the same VPC.
• Your VPC must have the enableDnsSupport attribute enabled. For more information, see DNS attributes in your VPC in the Amazon Virtual Private Cloud User Guide.
• Your EFS file system must use the Standard or Standard-IA storage class.
• RDS for Oracle doesn't support automated backups or manual DB snapshots of an EFS file system. Instead, you must use AWS Backup or other solutions to back up your EFS file system. For more information, see Backing up your Amazon EFS file systems.

Topics

• Configuring network permissions for RDS for Oracle integration with Amazon EFS (p. 1727)
• Configuring IAM permissions for RDS for Oracle integration with Amazon EFS (p. 1728)
• Adding the EFS_INTEGRATION option (p. 1731)
• Configuring Amazon EFS file system permissions (p. 1732)
• Transferring files between RDS for Oracle and an Amazon EFS file system (p. 1733)
• Removing the EFS_INTEGRATION option (p. 1734)
• Troubleshooting Amazon EFS integration (p. 1734)

Configuring network permissions for RDS for Oracle integration with Amazon EFS

For RDS for Oracle to integrate with Amazon EFS, make sure that your DB instance has network access to an EFS file system. For more information, see Controlling network access to Amazon EFS file systems for NFS clients in the Amazon Elastic File System User Guide.

Topics

• Controlling network access with security groups (p. 1727)
• Controlling network access with file system policies (p. 1728)

Controlling network access with security groups

You can control your DB instance access to EFS file systems using network layer security mechanisms such as VPC security groups. To allow access to an EFS file system for your DB instance, make sure that your EFS file system meets the following requirements:

• A mount target exists in every Availability Zone.
• A security group is attached to the mount target.
• The security group has an inbound rule to allow the network subnet or security group of the RDS for Oracle DB instance on TCP/2049 (Type NFS).

1727
Controlling network access with file system policies

Amazon EFS integration with RDS for Oracle works with the default (empty) EFS file system policy. The default policy doesn’t use IAM to authenticate. Instead, it grants full access to any anonymous client that can connect to the file system using a mount target. The default policy is in effect whenever a user-configured file system policy isn’t in effect, including at file system creation. For more information, see Default EFS file system policy in the Amazon Elastic File System User Guide.

To strengthen access to your EFS file system for all clients, including RDS for Oracle, you can configure IAM permissions. In this approach, you create a file system policy. For more information, see Creating file system policies in the Amazon Elastic File System User Guide.

Configuring IAM permissions for RDS for Oracle integration with Amazon EFS

For RDS for Oracle to integrate with Amazon EFS, your DB instance must have IAM permissions to access to an Amazon EFS file system.

Step 1: Create an IAM role for your DB instance and attach your policy

In this step, you create a role for your RDS for Oracle DB instance to allow Amazon RDS to access your EFS file system.

Console

To create an IAM role to allow Amazon RDS access to an EFS file system

1. Open the IAM Management Console.
2. In the navigation pane, choose Roles.
3. Choose Create role.
4. For AWS service, choose RDS.
5. For Select your use case, choose RDS – Add Role to Database.
6. Choose Next.
7. Don’t add any permissions policies. Choose Next.
8. Set Role name to a name for your IAM role, for example rds-efs-integration-role. You can also add an optional Description value.
9. Choose Create role.

AWS CLI

To limit the service’s permissions to a specific resource, we recommend using the aws:SourceArn and aws:SourceAccount global condition context keys in resource-based trust relationships. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the aws:SourceArn value contain the account ID. In this case, the aws:SourceAccount value and the account in the aws:SourceArn value must use the same account ID when used in the same statement.

• Use aws:SourceArn if you want cross-service access for a single resource.
• Use aws:SourceAccount if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the aws:SourceArn global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role.

The following AWS CLI command creates the role named rds-efs-integration-role for this purpose.

Example

For Linux, macOS, or Unix:

```bash
aws iam create-role
  --role-name rds-efs-integration-role
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": "my_account_ID",
            "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
          }
        }
      }
    ]
  }'
```

For Windows:

```bash
aws iam create-role ^
  --role-name rds-efs-integration-role ^
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": "my_account_ID",
            "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
          }
        }
      }
    ]
  }'
```

For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

Step 2: Create a file system policy for your Amazon EFS file system

In this step, you create a file system policy for your EFS file system.
To create or edit an EFS file system policy

1. Open the EFS Management Console.
3. On the File systems page, choose the file system that you want to edit or create a file system policy for. The details page for that file system is displayed.
4. Choose the File system policy tab.

If the policy is empty, then the default EFS file system policy is in use. For more information, see Default EFS file system policy in the Amazon Elastic File System User Guide.
5. Choose Edit. The File system policy page appears.
6. In Policy editor, enter a policy such as the following, and then choose Save.

```json
{
"Version": "2012-10-17",
"Id": "ExamplePolicy01",
"Statement": [
{
"Sid": "ExampleStatement01",
"Effect": "Allow",
"Principal": {
"AWS": "arn:aws:iam::123456789012:role/rds-efs-integration-role"
},
"Action": [
"elasticfilesystem:ClientMount",
"elasticfilesystem:ClientWrite",
"elasticfilesystem:ClientRootAccess"
],
"Resource": "arn:aws:elasticfilesystem:Region:123456789012:file-system/fs-1234567890abcdef0"
}
}
```

Step 3: Associate your IAM role with your RDS for Oracle DB instance

In this step, you associate your IAM role with your DB instance. Be aware of the following requirements:

- You must have access to an IAM role with the required Amazon EFS permissions policy attached to it.
- You can associate only one IAM role with your RDS for Oracle DB instance at a time.
- The status of your instance must be Available.

For more information, see Identity and access management for Amazon EFS in the Amazon Elastic File System User Guide.

Console

To associate your IAM role with your RDS for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases.
3. If your database instance is unavailable, choose Actions and then Start. When the instance status shows Started, go to the next step.
4. Choose the Oracle DB instance name to display its details.
5. On the **Connectivity & security** tab, scroll down to the **Manage IAM roles** section at the bottom of the page.
6. Choose the role to add in the **Add IAM roles to this instance** section.
7. For **Feature**, choose **EFS_INTEGRATION**.
8. Choose **Add role**.

**AWS CLI**

The following AWS CLI command adds the role to an Oracle DB instance named *mydbinstance*.

**Example**

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
  --db-instance-identifier mydbinstance \ 
  --feature-name EFS_INTEGRATION \ 
  --role-arn your-role-arn
```

For Windows:

```
aws rds add-role-to-db-instance ^
  --db-instance-identifier mydbinstance ^
  --feature-name EFS_INTEGRATION ^
  --role-arn your-role-arn
```

Replace `your-role-arn` with the role ARN that you noted in a previous step. **EFS_INTEGRATION** must be specified for the --feature-name option.

**Adding the EFS_INTEGRATION option**

To integrate Amazon RDS for Oracle with Amazon EFS, your DB instance must be associated with an option group that includes the **EFS_INTEGRATION** option.

Multiple Oracle DB instances that belong to the same option group share the same EFS file system. Different DB instances can access the same data, but access can be divided by using different Oracle directories. For more information see Transferring files between RDS for Oracle and an Amazon EFS file system (p. 1733).

**Console**

**To configure an option group for Amazon EFS integration**

1. Create a new option group or identify an existing option group to which you can add the **EFS_INTEGRATION** option.

   For information about creating an option group, see Creating an option group (p. 280).

2. Add the **EFS_INTEGRATION** option to the option group. You need to specify the **EFS_ID** file system ID and set the **USE_IAM_ROLE** flag.

   For more information, see Adding an option to an option group (p. 283).

3. Associate the option group with your DB instance in either of the following ways:

   * Create a new Oracle DB instance and associate the option group with it. For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 236).
• Modify an Oracle DB instance to associate the option group with it. For information about modifying an Oracle DB instance, see Modifying an Amazon RDS DB instance (p. 333).

AWS CLI

To configure an option group for EFS integration

1. Create a new option group or identify an existing option group to which you can add the EFS_INTEGRATION option.
   
   For information about creating an option group, see Creating an option group (p. 280).

2. Add the EFS_INTEGRATION option to the option group.
   
   For example, the following AWS CLI command adds the EFS_INTEGRATION option to an option group named myoptiongroup.

   Example

   For Linux, macOS, or Unix:

   ```bash
   aws rds add-option-to-option-group \
   --option-group-name myoptiongroup \
   --options "OptionName=EFS_INTEGRATION,OptionSettings="[
   {Name=EFS_ID,Value=fs-1234567890abcdef0},{Name=USE_IAM_ROLE,Value=TRUE}]
   ```

   For Windows:

   ```bash
   aws rds add-option-to-option-group ^
   --option-group-name myoptiongroup ^
   --options "OptionName=EFS_INTEGRATION,OptionSettings=^
   [{Name=EFS_ID,Value=fs-1234567890abcdef0},{Name=USE_IAM_ROLE,Value=TRUE}]"
   ```

3. Associate the option group with your DB instance in either of the following ways:

   • Create a new Oracle DB instance and associate the option group with it. For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 236).
   
   • Modify an Oracle DB instance to associate the option group with it. For information about modifying an Oracle DB instance, see Modifying an Amazon RDS DB instance (p. 333).

Configuring Amazon EFS file system permissions

By default, only the root user (UID 0) has read, write, and execute permissions for a newly created EFS file system. For other users to modify the file system, the root user must explicitly grant them access. The user for the RDS for Oracle DB instance is in the others category. For more information, see Working with users, groups, and permissions at the Network File System (NFS) Level in the Amazon Elastic File System User Guide.

To allow your RDS for Oracle DB instance to read and write files on an EFS file system, do the following:

• Mount an EFS file system locally on your Amazon EC2 instance.

• Configure fine grain permissions.

For example, to grant other users permissions to write to the EFS file system root, run chmod 777 on this directory. For more information, see Example Amazon EFS file system use cases and permissions in the Amazon Elastic File System User Guide.
Transferring files between RDS for Oracle and an Amazon EFS file system

To transfer files between an RDS for Oracle instance and an Amazon EFS file system, create at least one Oracle directory and configure EFS file system permissions to control DB instance access.

Topics
- Creating an Oracle directory (p. 1733)
- Transferring data to and from an EFS file system: examples (p. 1733)

Creating an Oracle directory

To create an Oracle directory, use the procedure `rdsadmin.rdsadmin_util.create_directory_efs`. The procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>-</td>
<td>Yes</td>
<td>The name of the Oracle directory.</td>
</tr>
</tbody>
</table>
| p_path_on_efs           | VARCHAR2   | -       | Yes      | The path on the EFS file system. The prefix of the path name uses the pattern `/rdsefs-fsid/`, where `fsid` is a placeholder for your EFS file system ID. For example, if your EFS file system is named `fs-1234567890abcdef0`, and you create a subdirectory on this file system named `mydir`, you could specify the following value: `/rdsefs-fs-1234567890abcdef0/mydir`

Assume that you create a subdirectory named `/datapump1` on the EFS file system `fs-1234567890abcdef0`. The following example creates an Oracle directory `DATA_PUMP_DIR_EFS` that points to the `/datapump1` directory on the EFS file system. The file system path value for the `p_path_on_efs` parameter is prefixed with the string `/rdsefs-`.

```
BEGIN
  rdsadmin.rdsadmin_util.create_directory_efs(
    p_directory_name => 'DATA_PUMP_DIR_EFS',
    p_path_on_efs    => '/rdsefs-fs-1234567890abcdef0/datapump1');
END;
/
```

Transferring data to and from an EFS file system: examples

The following example uses Oracle Data Pump to export the table named `MY_TABLE` to file `datapump.dmp`. This file resides on an EFS file system.

```
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(operation => 'EXPORT', job_mode => 'SCHEMA',
                              job_name=>null);
  DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdnl,
    ...
```

1733
The following example uses Oracle Data Pump to import the table named `MY_TABLE` from file `datapump.dmp`. This file resides on an EFS file system.

```sql
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
      operation => 'IMPORT',
      job_mode  => 'SCHEMA',
      job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
      handle    => v_hdnl,
      filename  => 'datapump.dmp',
      directory => 'DATA_PUMP_DIR_EFS',
      filetype  => dbms_datapump.ku$_file_type_dump_file);
  DBMS_DATAPUMP.ADD_FILE(
      handle    => v_hdnl,
      filename  => 'datapump-imp.log',
      directory => 'DATA_PUMP_DIR_EFS',
      filetype  => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN (''MY_TABLE'')');
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

For more information, see Importing data into Oracle on Amazon RDS (p. 1667).

**Removing the EFS_INTEGRATION option**

To remove the EFS_INTEGRATION option from an RDS for Oracle DB instance, do one of the following:

- To remove the EFS_INTEGRATION option from multiple DB instances, remove the EFS_INTEGRATION option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 291).

- To remove the EFS_INTEGRATION option from a single DB instance, modify the instance and specify a different option group that doesn't include the EFS_INTEGRATION option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).

**Troubleshooting Amazon EFS integration**

Your RDS for Oracle DB instance monitors the connectivity to an Amazon EFS file system. When monitoring detects an issue, it might try to correct the issue and publish an event in the RDS console. For more information, see Viewing Amazon RDS events.
Use the information in this section to help you diagnose and fix common issues when you work with Amazon EFS integration.

<table>
<thead>
<tr>
<th>Notification</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
</table>
| The EFS for RDS Oracle instance *instance_name* isn't available on the primary host. NFS port 2049 of your EFS isn't reachable. | The DB instance can't communicate with the EFS file system. | Make sure of the following:  
• The EFS file system exists.  
• The security group that is attached to the EFS mount target has an inbound rule to allow the security group or network subnet of the RDS for Oracle DB instance on TCP/2049 (Type NFS). |
| The EFS isn't reachable. | An error occurred during the installation of the EFS_INTEGRATION option. | Make sure of the following:  
• The EFS file system exists.  
• The security group that is attached to the EFS mount target has an inbound rule to allow the security group or network subnet of the RDS for Oracle DB instance on TCP/2049 (Type NFS).  
• The enableDnsSupport attribute is turned on for your VPC. |
| The associated role with your DB instance wasn't found. | An error occurred during the installation of the EFS_INTEGRATION option. | Make sure that you associated an IAM role with your RDS for Oracle DB instance. |
| N/A | You might see the following error: PLS-00302: component 'CREATE_DIRECTORY_EFS' must be declared. This error can occur when you're using a version of RDS for Oracle that doesn't support Amazon EFS. | Make sure that you are using RDS for Oracle DB instance version 19.0.0.0.ru-2022-07.rur-2022-07.r1 or higher. |
| Read access of your EFS is denied. Check your file system policy. | Your DB instance can't read the EFS file system. | Make sure that your EFS file system allows read access through the IAM role or on the EFS file system level. |
| N/A | Your DB instance can't write to the EFS file system. | Take the following steps:  
1. Make sure that your EFS file system is mounted on an Amazon EC2 instance.  
2. Give the others group write access to your RDS user. The simplest technique is to run the `chmod 777` command on |
<table>

</table>
Oracle Java virtual machine

Amazon RDS supports Oracle Java Virtual Machine (JVM) through the use of the JVM option. Oracle Java provides a SQL schema and functions that facilitate Oracle Java features in an Oracle database. For more information, see Introduction to Java in Oracle database in the Oracle documentation.

You can use Oracle JVM with the following Oracle Database versions:

- Oracle Database 21c (21.0.0), all versions
- Oracle Database 19c (19.0.0), all versions
- Oracle Database 12c Release 2 (12.2), all versions
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v13 and higher

Java implementation in Amazon RDS has a limited set of permissions. The master user is granted the RDS_JAVA_ADMIN role, which grants a subset of the privileges granted by the JAVA_ADMIN role. To list the privileges granted to the RDS_JAVA_ADMIN role, run the following query on your DB instance:

```sql
SELECT * FROM dba_java_policy
WHERE grantee IN ('RDS_JAVA_ADMIN', 'PUBLIC')
AND enabled = 'ENABLED'
ORDER BY type_name, name, grantee;
```

Prerequisites for Oracle JVM

The following are prerequisites for using Oracle Java:

- Your DB instance must be of a large enough class. Oracle Java isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see DB instance classes (p. 10).
- Your DB instance must have Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available. Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 333).

Best practices for Oracle JVM

The following are best practices for using Oracle Java:

- For maximum security, use the JVM option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 1774).
- Configure your DB instance to restrict network access. For more information, see Scenarios for accessing a DB instance in a VPC (p. 2263) and Working with a DB instance in a VPC (p. 2251).
- Update the configuration of your HTTPS endpoints to support TLSv1.2 if you meet the following conditions:
  - You use Oracle Java Virtual Machine (JVM) to connect an HTTPS endpoint over TLSv1 or TLSv1.1 protocols.
  - Your endpoint doesn't support the TLSv1.2 protocol.
  - You haven't applied the April 2021 release update to your Oracle DB.

By updating your endpoint configuration, you ensure that the connectivity of the JVM to the HTTPS endpoint will continue to work. For more information about TLS changes in the Oracle JRE and JDK, see Oracle JRE and JDK Cryptographic Roadmap.
Adding the Oracle JVM option

The following is the general process for adding the JVM option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

There is a brief outage while the JVM option is added. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Java is available.

**Note**
During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

To add the JVM option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   - For *Engine*, choose the DB engine used by the DB instance (oracle-ee, oracle-se, oracle-se1, or oracle-se2).
   - For *Major engine version*, choose the version of your DB instance.

For more information, see Creating an option group (p. 280).

2. Add the JVM option to the option group. For more information about adding options, see Adding an option to an option group (p. 283).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).

4. Grant the required permissions to users.

The Amazon RDS master user has the permissions to use the JVM option by default. If other users require these permissions, connect to the DB instance as the master user in a SQL client and grant the permissions to the users.

The following example grants the permissions to use the JVM option to the test_proc user.

```sql
create user test_proc identified by password;
CALL dbms_java.grant_permission('TEST_PROC', 'oracle.aurora.security.JServerPermission', 'LoadClassInPackage.*', '');
```

After the user is granted the permissions, the following query should return output.

```sql
select * from dba_java_policy where grantee='TEST_PROC';
```

**Note**
The Oracle user name is case-sensitive, and it usually has all uppercase characters.
Removing the Oracle JVM option

You can remove the JVM option from a DB instance. There is a brief outage while the option is removed. After you remove the JVM option, you don't need to restart your DB instance.

**Warning**
Removing the JVM option can result in data loss if the DB instance is using data types that were enabled as part of the option. Back up your data before proceeding. For more information, see Backing up and restoring an Amazon RDS DB instance (p. 461).

To remove the JVM option from a DB instance, do one of the following:

- Remove the JVM option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 291).
- Modify the DB instance and specify a different option group that doesn't include the JVM option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).
Oracle Enterprise Manager

Amazon RDS supports Oracle Enterprise Manager (OEM). OEM is the Oracle product line for integrated management of enterprise information technology.

Amazon RDS supports OEM through the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>
<th>Supported OEM releases</th>
<th>Supported Oracle Database releases</th>
</tr>
</thead>
<tbody>
<tr>
<td>OEM Database Express (p. 1741)</td>
<td>OEM</td>
<td>OEM Database Express 12c</td>
<td>Oracle Database 19c (non-CDB only) and Oracle Database 12c</td>
</tr>
<tr>
<td>OEM Management Agent (p. 1745)</td>
<td>OEM_AGENT</td>
<td>OEM Cloud Control for 13c</td>
<td>Oracle Database 19c (non-CDB only) and Oracle Database 12c</td>
</tr>
</tbody>
</table>

**Note**

You can use OEM Database or OEM Management Agent, but not both.

**Note**

These options aren't supported for the single-tenant architecture.
Oracle Enterprise Manager Database Express

Amazon RDS supports Oracle Enterprise Manager (OEM) Database Express through the use of the OEM option. Amazon RDS supports Oracle Enterprise Manager Database Express for the following releases:

- Oracle Database 19c (non-CDB only)
- Oracle Database 12c

OEM Database Express and Database Control are similar tools that have a web-based interface for Oracle database administration. For more information about these tools, see Accessing Enterprise Manager database Express 18c and Accessing Enterprise Manager Database Express 12c in the Oracle documentation.

The following is a limitation for OEM Database Express:

- OEM Database Express isn't supported on the db.t3.micro or db.t3.small DB instance classes.

For more information about DB instance classes, see RDS for Oracle instance classes (p. 1529).

OEM Database option settings

Amazon RDS supports the following settings for the OEM option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>An integer value</td>
<td>The port on the DB instance that listens for OEM Database. The default for OEM Database Express is 5500.</td>
</tr>
<tr>
<td>Security Groups</td>
<td>—</td>
<td>A security group that has access to Port.</td>
</tr>
</tbody>
</table>

Adding the OEM Database option

The general process for adding the OEM option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When you add the OEM option for an Oracle Database 12c or later DB instance, a brief outage occurs while your DB instance is automatically restarted.

To add the OEM option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine** choose the oracle edition for your DB instance.
   b. For **Major engine version** choose the version of your DB instance.
For more information, see Creating an option group (p. 280).

2. Add the OEM option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group (p. 283). For more information about each setting, see OEM Database option settings (p. 1741).

   **Note**
   If you add the OEM option to an existing option group that is already attached to one or more Oracle Database 19c (non-CDB only) or Oracle Database 12c DB instances, a brief outage occurs while all the DB instances are automatically restarted.

3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).

   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the OEM option for an Oracle Database 19c (non-CDB only) or Oracle Database 12c DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance (p. 333).

   **Note**
   You can also use the AWS CLI to add the OEM option. For examples, see Adding an option to an option group (p. 283).

**Accessing OEM through your browser**

After you enable the OEM option, you can begin using the OEM Database tool from your web browser.

You can access either OEM Database Control or OEM Database Express from your web browser. For example, if the endpoint for your Amazon RDS DB instance is mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com, and your OEM port is 1158, then the URL to access the OEM Database Control is as follows.

https://mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com:1158/em

When you access either tool from your web browser, a login window appears that prompts you for a user name and password. Type the master user name and master password for your DB instance. You are now ready to manage your Oracle databases.

**Modifying OEM Database settings**

After you enable OEM Database, you can modify the Security Groups setting for the option.

You can’t modify the OEM port number after you have associated the option group with a DB instance. To change the OEM port number for a DB instance, do the following:

1. Create a new option group.
2. Add the OEM option with the new port number to the new option group.
3. Remove the existing option group from the DB instance.
4. Add the new option group to the DB instance.

For more information about how to modify option settings, see Modifying an option setting (p. 288). For more information about each setting, see OEM Database option settings (p. 1741).
Running OEM Database Express tasks

You can use Amazon RDS procedures to run certain OEM Database Express tasks. By running these procedures, you can do the tasks listed following.

**Note**
OEM Database Express tasks run asynchronously.

**Tasks**
- Switching the website front end for OEM Database Express to Adobe Flash (p. 1743)
- Switching the website front end for OEM Database Express to Oracle JET (p. 1744)

Switching the website front end for OEM Database Express to Adobe Flash

**Note**
This task is available only for Oracle Database 19c non-CDBs.

Starting with Oracle Database 19c, Oracle has deprecated the former OEM Database Express user interface, which was based on Adobe Flash. Instead, OEM Database Express now uses an interface built with Oracle JET. If you experience difficulties with the new interface, you can switch back to the deprecated Flash-based interface. Difficulties you might experience with the new interface include being stuck on a Loading screen after logging in to OEM Database Express. You might also miss certain features that were present in the Flash-based version of OEM Database Express.

To switch the OEM Database Express website front end to Adobe Flash, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash`. This procedure is equivalent to the `execemx` `emx` SQL command.

Security best practices discourage the use of Adobe Flash. Although you can revert to the Flash-based OEM Database Express, we recommend the use of the JET-based OEM Database Express websites if possible. If you revert to using Adobe Flash and want to switch back to using Oracle JET, use the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet` procedure. After an Oracle database upgrade, a newer version of Oracle JET might resolve JET-related issues in OEM Database Express. For more information about switching to Oracle JET, see Switching the website front end for OEM Database Express to Oracle JET (p. 1744).

**Note**
Running this task from the source DB instance for a read replica also causes the read replica to switch its OEM Database Express website front ends to Adobe Flash.

The following procedure invocation creates a task to switch the OEM Database Express website to Adobe Flash and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash() as TASK_ID from DUAL;
```

You can view the result by displaying the task's output file.

```sql
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure. For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory (p. 1650)

You can also view the contents of the task's output file in the AWS Management Console by searching the log entries in the Logs & events section for the task-id.
Switching the website front end for OEM Database Express to Oracle JET

**Note**
This task is available only for Oracle Database 19c non-CDBs.

To switch the OEM Database Express website front end to Oracle JET, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet`. This procedure is equivalent to the `execemx omx` SQL command.

By default, the OEM Database Express websites for Oracle DB instances running 19c or later use Oracle JET. If you used the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash` procedure to switch the OEM Database Express website front end to Adobe Flash, you can switch back to Oracle JET. To do this, use the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet` procedure. For more information about switching to Adobe Flash, see Switching the website front end for OEM Database Express to Adobe Flash (p. 1743).

**Note**
Running this task from the source DB instance for a read replica also causes the read replica to switch its OEM Database Express website front ends to Oracle JET.

The following procedure invocation creates a task to switch the OEM Database Express website to Oracle JET and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet() as TASK_ID from DUAL;
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure. For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory (p. 1650)

You can also view the contents of the task's output file in the AWS Management Console by searching the log entries in the Logs & events section for the task-id.

Removing the OEM Database option

You can remove the OEM option from a DB instance. When you remove the OEM option for an Oracle Database 12c or later DB instance, a brief outage occurs while your instance is automatically restarted. Therefore, after you remove the OEM option, you don't need to restart your DB instance.

To remove the OEM option from a DB instance, do one of the following:

- Remove the OEM option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 291).
- Modify the DB instance and specify a different option group that doesn't include the OEM option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).
Oracle Management Agent for Enterprise Manager Cloud Control

Oracle Enterprise Manager (OEM) Management Agent is a software component that monitors targets running on hosts and communicates that information to the middle-tier Oracle Management Service (OMS). For more information, see Overview of Oracle Enterprise Manager cloud control 12c and Overview of Oracle Enterprise Manager cloud control 13c in the Oracle documentation.

Amazon RDS supports Management Agent through the use of the OEM_AGENT option. Management Agent requires an Amazon RDS DB instance running any of the following releases:

- Oracle Database 19c (19.0.0.0) using the non-CDB architecture
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1.0.2)

Amazon RDS supports Management Agent for the following versions of OEM:

- Oracle Enterprise Manager Cloud Control for 13c
- Oracle Enterprise Manager Cloud Control for 12c

Topics
- Prerequisites for Management Agent (p. 1745)
- Limitations for Management Agent (p. 1747)
- Option settings for Management Agent (p. 1747)
- Adding the Management Agent option (p. 1749)
- Using the Management Agent (p. 1750)
- Modifying Management Agent settings (p. 1751)
- Performing database tasks with the Management Agent (p. 1751)
- Removing the Management Agent option (p. 1754)

Prerequisites for Management Agent

To use Management Agent, ensure that you meet the following prerequisites.

General prerequisites

Following are general prerequisites for using Management Agent:

- You need an Oracle Management Service (OMS) that is configured to connect to your Amazon RDS DB instance.
- In most cases, you must configure your VPC to allow connections from OMS to your DB instance. If you aren't familiar with Amazon Virtual Private Cloud (Amazon VPC), we recommend that you complete the steps in Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2268) before continuing.
- Management Agent version 13.5.0.0.v1 requires OMS version 13.5.0.0 or later.
- Management Agent version 13.4.0.9.v1 requires OMS version 13.4.0.9 or later and patch 32198287.
- Ensure that you have sufficient storage space for your OEM release:
  - At least 8.5 GiB for OEM 13c Release 5
  - At least 8.5 GiB for OEM 13c Release 4
  - At least 8.5 GiB for OEM 13c Release 3
  - At least 5.5 GiB for OEM 13c Release 2
• At least 4.5 GiB OEM 13c Release 1
• At least 2.5 GiB for OEM 12c
• If you are using Management Agent versions OEM_AGENT 13.2.0.0.v3 and 13.3.0.0.v2, and if you want to use TCPS connectivity, follow the instructions in Configuring third party CA certificates for communication with target databases in the Oracle documentation. Also, update the JDK on your OMS by following the instructions in the Oracle document with the Oracle Doc ID 2241358.1. This step ensures that OMS supports all the cipher suites that the database supports.

**Note**
TCPS connectivity between the Management Agent and the DB instance is only supported for Management Agent versions OEM_AGENT 13.2.0.0.v3 and 13.3.0.0.v2.

**Oracle Database release prerequisites**

Following are the supported Oracle Database versions for each Management Agent version.

<table>
<thead>
<tr>
<th>Management Agent version</th>
<th>Oracle Database 19c using the non-CDB architecture</th>
<th>Oracle Database 12c Release 2 (12.2)</th>
<th>Oracle Database 12c Release 1 (12.1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>13.5.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.4.0.9.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.3.0.0.v2</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.3.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.2.0.0.v3</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.2.0.0.v2</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.2.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.1.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>12.1.0.5.v1</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>12.1.0.4.v1</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>

Following are prerequisites for different database versions:

• For an Amazon RDS DB instance running Oracle Database 19c (19.0.0.0), the minimum AGENT VERSION is 13.1.0.0.v1.
• For an Amazon RDS DB instance running Oracle Database Release 2 (12.2.0.1) or lower, meet the following requirements:
  • For OMS 13c Release 2 with Oracle patch 25163555 applied, use OEM Agent 13.2.0.0.v2 or later.
    Use OMSPatcher to apply the patch.
  • For unpatched OMS 13c Release 2, use OEM Agent 13.2.0.0.v1.
    Use OMSPatcher to apply patches.

**OMS host communication prerequisites**

Make sure that your OMS host and your Amazon RDS DB instance can communicate. Do the following:
• To connect from the Management Agent to your OMS, if your OMS is behind a firewall, add the IP addresses of your DB instances to your OMS.

Make sure the firewall for the OMS allows traffic from both the DB listener port (default 1521) and the OEM Agent port (default 3872), originating from the IP address of the DB instance.

• To connect from your OMS to the Management Agent, if your OMS has a publicly resolvable host name, add the OMS address to a security group. Your security group must have inbound rules that allow access to the DB listener port and the Management Agent port. For an example of creating a security and adding inbound rules, see Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2268).

• To connect from your OMS to the Management Agent, if your OMS doesn't have a publicly resolvable host name, use one of the following:
  • If your OMS is hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance in a private VPC, you can set up VPC peering to connect from OMS to Management Agent. For more information, see A DB instance in a VPC accessed by an EC2 instance in a different VPC (p. 2265).
  • If your OMS is hosted on-premises, you can set up a VPN connection to allow access from OMS to Management Agent. For more information, see A DB instance in a VPC accessed by a client application through the internet (p. 2266) or VPN connections.

Limitations for Management Agent

Following are some limitations to using Management Agent:

• Administrative tasks such as job execution and database patching, that require host credentials, aren't supported.

• Host metrics and the process list aren't guaranteed to reflect the actual system state. Thus, you shouldn't use OEM to monitor the root file system or mount point file system. For more information about monitoring the operating system, see Monitoring OS metrics with Enhanced Monitoring (p. 635).

• Autodiscovery isn't supported. You must manually add database targets.

• OMS module availability depends on your database edition. For example, the database performance diagnosis and tuning module is only available for Oracle Database Enterprise Edition.

• Management Agent consumes additional memory and computing resources. If you experience performance problems after enabling the OEM_AGENT option, we recommend that you scale up to a larger DB instance class. For more information, see DB instance classes (p. 10) and Modifying an Amazon RDS DB instance (p. 333).

• The user running the OEM_AGENT on the Amazon RDS host doesn't have operating system access to the alert log. Thus, you can't collect metrics for DB Alert Log and DB Alert Log Error Status in OEM.

Option settings for Management Agent

Amazon RDS supports the following settings for the Management Agent option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Required</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (AGENT_VERSION)</td>
<td>Yes</td>
<td>13.5.0.0.v1</td>
<td>The version of the Management Agent software.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.4.0.9.v1</td>
<td>The AWS CLI option name is OptionVersion.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.3.0.0.v2</td>
<td>Note In the AWS GovCloud (US) Regions, 12.1 and 13.1 versions aren't available.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.3.0.0.v1</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.2.0.0.v3</td>
<td></td>
</tr>
<tr>
<td>Option setting</td>
<td>Required</td>
<td>Valid values</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Port (AGENT_PORT)</td>
<td>Yes</td>
<td>13.2.0.0.v2, 13.2.0.0.v1, 13.1.0.0.v1, 12.1.0.5.v1, 12.1.0.4.v1</td>
<td>The port on the DB instance that listens for the OMS host. The default is 3872. Your OMS host must belong to a security group that has access to this port. The AWS CLI option name is Port.</td>
</tr>
<tr>
<td>Security Groups</td>
<td>Yes</td>
<td>Existing security groups</td>
<td>A security group that has access to Port. Your OMS host must belong to this security group. The AWS CLI option name is VpcSecurityGroupMemberships or DBSecurityGroupMemberships.</td>
</tr>
<tr>
<td>OMS_HOST</td>
<td>Yes</td>
<td>A string value, for example my.example.oms</td>
<td>The publicly accessible host name or IP address of the OMS. The AWS CLI option name is OMS_HOST.</td>
</tr>
<tr>
<td>OMS_PORT</td>
<td>Yes</td>
<td>An integer value</td>
<td>The HTTPS upload port on the OMS Host that listens for the Management Agent. To determine the HTTPS upload port, connect to the OMS host, and run the following command (which requires the SYSMAN password): emctl status oms -details. The AWS CLI option name is OMS_PORT.</td>
</tr>
<tr>
<td>AGENT_REGISTRATION_PASSWORD</td>
<td>String</td>
<td>A string value</td>
<td>The password that the Management Agent uses to authenticate itself with the OMS. We recommend that you create a persistent password in your OMS before enabling the OEM_AGENT option. With a persistent password you can share a single Management Agent option group among multiple Amazon RDS databases. The AWS CLI option name is AGENT_REGISTRATION_PASSWORD.</td>
</tr>
<tr>
<td>ALLOW_TLS_ONLY</td>
<td>No</td>
<td>true, false (default)</td>
<td>A value that configures the OEM Agent to support only the TLSv1 protocol while the agent listens as a server. This setting is only supported for 12.1 agent versions. Later agent versions only support Transport Layer Security (TLS) by default.</td>
</tr>
</tbody>
</table>
### Option settings

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Required</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MINIMUM_TLS_VERSION</td>
<td>No</td>
<td>TLSv1 (default), TLSv1.2</td>
<td>A value that specifies the minimum TLS version supported by the OEM Agent while the agent listens as a server. This setting is only supported for agent versions 13.1.0.0.v1 and higher. Earlier agent versions only support the TLSv1 setting.</td>
</tr>
<tr>
<td>TLS_CIPHER_SUITE</td>
<td>No</td>
<td>TLS_RSA_WITH_AES_128_CBC_SHA (Default supported by all agent versions)</td>
<td>A value that specifies the TLS cipher suite used by the OEM Agent while the agent listens as a server.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>TLS_RSA_WITH_AES_128_CBC_SHA256 (Requires version 13.1.0.0.v1 or above)</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>TLS_RSA_WITH_AES_256_CBC_SHA (Requires version 13.2.0.0.v3 or above)</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>TLS_RSA_WITH_AES_256_CBC_SHA256 (Requires version 13.2.0.0.v3 or above)</td>
<td></td>
</tr>
</tbody>
</table>

### Adding the Management Agent option

The general process for adding the Management Agent option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If you encounter errors, check My Oracle Support documents for information about resolving specific problems.

After you add the Management Agent option, you don't need to restart your DB instance. As soon as the option group is active, the OEM Agent is active.

If your OMS host is using an untrusted third-party certificate, Amazon RDS returns the following error.

```
You successfully installed the OEM_AGENT option. Your OMS host is using an untrusted third party certificate. Configure your OMS host with the trusted certificates from your third party.
```

If this error is returned, the Management Agent option isn't enabled until the problem is corrected. For information about correcting the problem, see the My Oracle Support document 2202569.1.
To add the Management Agent option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine** choose the oracle edition for your DB instance.
   b. For **Major engine version** choose the version of your DB instance.

   For more information, see Creating an option group (p. 280).

2. Add the **OEM_AGENT** option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group (p. 283). For more information about each setting, see Option settings for Management Agent (p. 1747).

3. Apply the option group to a new or existing DB instance:

   • For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
   • For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).

AWS CLI

The following example uses the AWS CLI **add-option-to-option-group** command to add the OEM_AGENT option to an option group called myoptiongroup.

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group
  --option-group-name "myoptiongroup"
  --options
    OptionName=OEM_AGENT,OptionVersion=13.1.0.0.v1,Port=3872,VpcSecurityGroupMemberships=sg-1234567890,Opt
    [Name=OMS_HOST,Value=my.example.oms],{Name=OMS_PORT,Value=4903},{Name=AGENT_REGISTRATION_PASSWORD,Value=password}\n    --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^
  --option-group-name "myoptiongroup" ^
  --options
    OptionName=OEM_AGENT,OptionVersion=13.1.0.0.v1,Port=3872,VpcSecurityGroupMemberships=sg-1234567890,Opt
    [Name=OMS_PORT,Value=4903],{Name=AGENT_REGISTRATION_PASSWORD,Value=password} ^
    --apply-immediately
```

Using the Management Agent

After you enable the Management Agent option, take the following steps to begin using it.

To use the Management Agent

1. Unlock and reset the DBSNMP account credential. Do this by running the following code on your target database on your DB instance and using your master user account.

   ```sql
   ALTER USER dbsnmp IDENTIFIED BY new_password ACCOUNT UNLOCK;
   ```
2. Add your targets to the OMS console manually:
   a. In your OMS console, choose **Setup, Add Target, Add Targets Manually**.
   b. Choose **Add Targets Declaratively by Specifying Target Monitoring Properties**.
   c. For **Target Type**, choose **Database Instance**.
   d. For **Monitoring Agent**, choose the agent with the identifier that is the same as your RDS DB instance identifier.
   e. Choose **Add Manually**.
   f. Enter the endpoint for the Amazon RDS DB instance, or choose it from the host name list. Make sure that the specified host name matches the endpoint of the Amazon RDS DB instance.
      For information about finding the endpoint for your Amazon RDS DB instance, see Finding the endpoint of your Oracle DB instance (p. 1540).
   g. Specify the following database properties:
      • For **Target name**, enter a name.
      • For **Database system name**, enter a name.
      • For **Monitor username**, enter **dbsnmp**.
      • For **Monitor password**, enter the password from step 1.
      • For **Role**, enter **normal**.
      • For **Oracle home path**, enter **/oracle**.
      • For **Listener Machine name**, the agent identifier already appears.
      • For **Port**, enter the database port. The RDS default port is 1521.
      • For **Database name**, enter the name of your database.
   h. Choose **Test Connection**.
   i. Choose **Next**. The target database appears in your list of monitored resources.

**Modifying Management Agent settings**

After you enable the Management Agent, you can modify settings for the option. For more information about how to modify option settings, see Modifying an option setting (p. 288). For more information about each setting, see Option settings for Management Agent (p. 1747).

**Performing database tasks with the Management Agent**

You can use Amazon RDS procedures to run certain EMCTL commands on the Management Agent. By running these procedures, you can do the tasks listed following.

**Note**
Tasks are executed asynchronously.

**Tasks**

- Getting the status of the Management Agent (p. 1752)
-Restarting the Management Agent (p. 1752)
- Listing the targets monitored by the Management Agent (p. 1752)
- Listing the collection threads monitored by the Management Agent (p. 1752)
- Clearing the Management Agent state (p. 1753)
- Making the Management Agent upload its OMS (p. 1753)
- Pinging the OMS (p. 1753)
- Viewing the status of an ongoing task (p. 1753)
Getting the status of the Management Agent

To get the status of the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.get_status_oem_agent`. This procedure is equivalent to the `emctl status agent` command.

The following procedure creates a task to get the Management Agent's status and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.get_status_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task (p. 1753).

Restarting the Management Agent

To restart the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.restart_oem_agent`. This procedure is equivalent to running the `emctl stop agent` and `emctl start agent` commands.

The following procedure creates a task to restart the Management Agent and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.restart_oem_agent as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task (p. 1753).

Listing the targets monitored by the Management Agent

To list the targets monitored by the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.list_targets_oem_agent`. This procedure is equivalent to running the `emctl config agent listtargets` command.

The following procedure creates a task to list the targets monitored by the Management Agent and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.list_targets_oem_agent as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task (p. 1753).

Listing the collection threads monitored by the Management Agent

To list all of the running, ready, and scheduled collection threads monitored by the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.list_clxn_threads_oem_agent`. This procedure is equivalent to the `emctl status agent scheduler` command.

The following procedure creates a task to list the collection threads and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.list_clxn_threads_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task (p. 1753).
Clearing the Management Agent state

To clear the Management Agent's state, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.clearstate_oem_agent`. This procedure is equivalent to running the `emctl clearstate agent` command.

The following procedure creates a task that clears the Management Agent's state and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.clearstate_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task (p. 1753).

Making the Management Agent upload its OMS

To make the Management Agent upload the Oracle Management Server (OMS) associated with it, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.upload_oem_agent`. This procedure is equivalent to running the `emctl upload agent` command.

The following procedure creates a task that makes the Management Agent upload its associated OMS and return the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.upload_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task (p. 1753).

Pinging the OMS

To ping the Management Agent's OMS, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent`. This procedure is equivalent to running the `emctl pingOMS` command.

The following procedure creates a task that pings the Management Agent's OMS and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task (p. 1753).

Viewing the status of an ongoing task

You can view the status of an ongoing task in a bdump file. The bdump files are located in the `/rdsdbdata/log/trace` directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

When you want to monitor a task, replace `task-id` with the ID of the task that you want to monitor.

To view the contents of bdump files, run the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. The following query returns the contents of the `dbtask-1546988886389-2444.log` bdump file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-1546988886389-2444.log'));
```
For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory (p. 1650).

Removing the Management Agent option

You can remove the OEM Agent from a DB instance. After you remove the OEM Agent, you don't need to restart your DB instance.

To remove the OEM Agent from a DB instance, do one of the following:

- Remove the OEM Agent option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 291).
- Modify the DB instance and specify a different option group that doesn't include the OEM Agent option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).
Oracle Label Security

Amazon RDS supports Oracle Label Security for the Enterprise Edition of Oracle Database through the use of the OLS option.

Most database security controls access at the object level. Oracle Label Security provides fine-grained control of access to individual table rows. For example, you can use Label Security to enforce regulatory compliance with a policy-based administration model. You can use Label Security policies to control access to sensitive data, and restrict access to only users with the appropriate clearance level. For more information, see Introduction to Oracle Label Security in the Oracle documentation.

Topics
- Prerequisites for Oracle Label Security (p. 1755)
- Adding the Oracle Label Security option (p. 1755)
- Using Oracle Label Security (p. 1756)
- Removing the Oracle Label Security option (p. 1756)
- Troubleshooting (p. 1757)

Prerequisites for Oracle Label Security

Familiarize yourself with the following prerequisites for Oracle Label Security:

- Your DB instance must use the Bring Your Own License model. For more information, see RDS for Oracle licensing options (p. 1526).
- You must have a valid license for Oracle Enterprise Edition with Software Update License and Support.
- Your Oracle license must include the Label Security option.
- You must be using the non-multitenant database architecture rather than the single-tenant architecture. For more information, see RDS for Oracle architecture (p. 1533).

Adding the Oracle Label Security option

The general process for adding the Oracle Label Security option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
   
   **Important**
   Oracle Label Security is a permanent and persistent option.
3. Associate the option group with the DB instance.

After you add the Label Security option, as soon as the option group is active, Label Security is active.

To add the label security option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   
   a. For **Engine**, choose **oracle-ee**.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group (p. 280).
2. Add the **OLS** option to the option group. For more information about adding options, see *Adding an option to an option group* (p. 283).

   **Important**
   If you add Label Security to an existing option group that is already attached to one or more DB instances, all the DB instances are restarted.

3. Apply the option group to a new or existing DB instance:

   • For a new DB instance, you apply the option group when you launch the instance. For more information, see *Creating an Amazon RDS DB instance* (p. 236).

   • For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the Label Security option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see *Modifying an Amazon RDS DB instance* (p. 333).

**Using Oracle Label Security**

To use Oracle Label Security, you create policies that control access to specific rows in your tables. For more information, see *Creating an Oracle Label Security policy* in the Oracle documentation.

When you work with Label Security, you perform all actions as the LBAC_DBA role. The master user for your DB instance is granted the LBAC_DBA role. You can grant the LBAC_DBA role to other users so that they can administer Label Security policies.

For the following releases, make sure to grant access to the **OLS_ENFORCEMENT** package to any new users who require access to Oracle Label Security:

- Oracle Database 19c using the non-CDB architecture
- Oracle Database 12c Release 2 (12.2)

To grant access to the **OLS_ENFORCEMENT** package, connect to the DB instance as the master user and run the following SQL statement:

```sql
GRANT ALL ON LBACSYS.OLS_ENFORCEMENT TO username;
```

You can configure Label Security through the Oracle Enterprise Manager (OEM) Cloud Control. Amazon RDS supports the OEM Cloud Control through the Management Agent option. For more information, see *Oracle Management Agent for Enterprise Manager Cloud Control* (p. 1745).

**Removing the Oracle Label Security option**

You can remove Oracle Label Security from a DB instance.

To remove Label Security from a DB instance, do one of the following:

• To remove Label Security from multiple DB instances, remove the Label Security option from the option group they belong to. This change affects all DB instances that use the option group. When you remove Label Security from an option group that is attached to multiple DB instances, all the DB instances are restarted. For more information, see *Removing an option from an option group* (p. 291).

• To remove Label Security from a single DB instance, modify the DB instance and specify a different option group that doesn't include the Label Security option. You can specify the default (empty) option group, or a different custom option group. When you remove the Label Security option, a brief outage occurs while your DB instance is automatically restarted. For more information, see *Modifying an Amazon RDS DB instance* (p. 333).
## Troubleshooting

The following are issues you might encounter when you use Oracle Label Security.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you try to create a policy, you see an error message similar to</td>
<td>A known issue with Oracle's Label Security feature prevents users with usernames of 16</td>
</tr>
<tr>
<td>the following: <strong>insufficient authorization for the</strong></td>
<td>or 24 characters from running Label Security commands. You can create a new user with a</td>
</tr>
<tr>
<td><strong>SYSDBA</strong> package.</td>
<td>different number of characters, grant LBAC_DBA to the new user, log in as the new user,</td>
</tr>
<tr>
<td></td>
<td>and run the OLS commands as the new user. For additional information, please contact</td>
</tr>
<tr>

</table>
Oracle Locator

Amazon RDS supports Oracle Locator through the use of the LOCATOR option. Oracle Locator provides capabilities that are typically required to support internet and wireless service-based applications and partner-based GIS solutions. Oracle Locator is a limited subset of Oracle Spatial. For more information, see Oracle Locator in the Oracle documentation.

Important
If you use Oracle Locator, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle Locator for the following releases of Oracle Database:

- Oracle Database 19c (19.0.0.0)
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v13 or later

Oracle Locator isn't supported for Oracle Database 21c, but its functionality is available in the Oracle Spatial option. Formerly, the Spatial option required additional licenses. Oracle Locator represented a subset of Oracle Spatial features and didn't require additional licenses. In 2019, Oracle announced that all Oracle Spatial features were included in the Enterprise Edition and Standard Edition Two licenses without additional cost. Consequently, the Oracle Spatial option no longer required additional licensing.

Starting with Oracle Database 21c, the Oracle Locator option is no longer supported. To use the Oracle Locator features in Oracle Database 21c, install the Oracle Spatial option instead. For more information, see Machine Learning, Spatial and Graph - No License Required! in the Oracle Database Insider blog.

Prerequisites for Oracle Locator

The following are prerequisites for using Oracle Locator:

- Your DB instance must be of sufficient class. Oracle Locator is not supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes (p. 1529).
- Your DB instance must have Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 333).

Best practices for Oracle Locator

The following are best practices for using Oracle Locator:

- For maximum security, use the LOCATOR option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 1774).
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC (p. 2263) and Working with a DB instance in a VPC (p. 2251).

Adding the Oracle Locator option

The following is the general process for adding the LOCATOR option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the LOCATOR option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Locator is available.

**Note**
During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

**To add the LOCATOR option to a DB instance**

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the oracle edition for your DB instance.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group (p. 280).

2. Add the **LOCATOR** option to the option group. For more information about adding options, see Adding an option to an option group (p. 283).

3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).

**Using Oracle Locator**

After you enable the Oracle Locator option, you can begin using it. You should only use Oracle Locator features. Don't use any Oracle Spatial features unless you have a license for Oracle Spatial.

For a list of features that are supported for Oracle Locator, see **Features Included with Locator** in the Oracle documentation.

For a list of features that are not supported for Oracle Locator, see **Features Not Included with Locator** in the Oracle documentation.

**Removing the Oracle Locator option**

After you drop all objects that use data types provided by the LOCATOR option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the LOCATOR option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the LOCATOR option, you don't need to restart your DB instance.

**To drop the LOCATOR option**

1. Back up your data.
**Warning**
If the instance uses data types that were enabled as part of the option, and if you remove the LOCATOR option, you can lose data. For more information, see *Backing up and restoring an Amazon RDS DB instance* (p. 461).

2. **Check whether any existing objects reference data types or features of the LOCATOR option.**

   If LOCATOR options exist, the instance can get stuck when applying the new option group that doesn't have the LOCATOR option. You can identify the objects by using the following queries:

   ```sql
   SELECT OWNER, SEGMENT_NAME, TABLESPACE_NAME, BYTES/1024/1024 mbytes
   FROM   DBA_SEGMENTS
   WHERE  SEGMENT_TYPE LIKE '%TABLE%
   AND    (OWNER, SEGMENT_NAME) IN
       (SELECT DISTINCT OWNER, TABLE_NAME
        FROM   DBA_TAB_COLUMNS
        WHERE  DATA_TYPE='SDO_GEOMETRY'
        AND    OWNER <> 'MDSYS')
   ORDER BY 1,2,3,4;

   SELECT OWNER, TABLE_NAME, COLUMN_NAME
   FROM   DBA_TAB_COLUMNS
   WHERE  DATA_TYPE = 'SDO_GEOMETRY'
   AND    OWNER <> 'MDSYS'
   ORDER BY 1,2,3;
   ```

3. **Drop any objects that reference data types or features of the LOCATOR option.**

4. **Do one of the following:**

   - Remove the LOCATOR option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see *Removing an option from an option group* (p. 291).
   - Modify the DB instance and specify a different option group that doesn't include the LOCATOR option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see *Modifying an Amazon RDS DB instance* (p. 333).
Amazon Relational Database Service User Guide
Multimedia

Oracle Multimedia

Amazon RDS supports Oracle Multimedia through the use of the MULTIMEDIA option. You can use Oracle Multimedia to store, manage, and retrieve images, audio, video, and other heterogeneous media data. For more information, see Oracle Multimedia in the Oracle documentation.

**Important**
If you use Oracle Multimedia, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle Multimedia for all editions of the following versions:

- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v13 or higher

**Note**
Oracle desupported Oracle Multimedia in Oracle Database 19c. So, Oracle Multimedia isn't supported for Oracle Database 19c DB instances. For more information, see Desupport of Oracle Multimedia in the Oracle documentation.

Prerequisites for Oracle Multimedia

The following are prerequisites for using Oracle Multimedia:

- Your DB instance must be of sufficient class. Oracle Multimedia is not supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes (p. 1529).
- Your DB instance must have **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 333).

Best practices for Oracle Multimedia

The following are best practices for using Oracle Multimedia:

- For maximum security, use the MULTIMEDIA option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 1774).
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC (p. 2263) and Working with a DB instance in a VPC (p. 2251).

Adding the Oracle Multimedia option

The following is the general process for adding the MULTIMEDIA option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the MULTIMEDIA option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed.
on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Multimedia is available.

**Note**
During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

**To add the MULTIMEDIA option to a DB instance**

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the edition for your Oracle DB instance.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see *Creating an option group* (p. 280).

2. Add the **MULTIMEDIA** option to the option group. For more information about adding options, see *Adding an option to an option group* (p. 283).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see *Creating an Amazon RDS DB instance* (p. 236).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see *Modifying an Amazon RDS DB instance* (p. 333).

**Removing the Oracle Multimedia option**

After you drop all objects that use data types provided by the MULTIMEDIA option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the MULTIMEDIA option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the MULTIMEDIA option, you don't need to restart your DB instance.

**To drop the MULTIMEDIA option**

1. Back up your data.

   **Warning**
   If the instance uses data types that were enabled as part of the option, and if you remove the MULTIMEDIA option, you can lose data. For more information, see *Backing up and restoring an Amazon RDS DB instance* (p. 461).

2. Check whether any existing objects reference data types or features of the MULTIMEDIA option.

3. Drop any objects that reference data types or features of the MULTIMEDIA option.

4. Do one of the following:
   - Remove the MULTIMEDIA option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see *Removing an option from an option group* (p. 291).
   - Modify the DB instance and specify a different option group that doesn't include the MULTIMEDIA option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see *Modifying an Amazon RDS DB instance* (p. 333).
Oracle native network encryption

Amazon RDS supports Oracle native network encryption (NNE). With native network encryption, you can encrypt data as it moves to and from a DB instance. Amazon RDS supports NNE for all editions of Oracle Database.

A detailed discussion of Oracle native network encryption is beyond the scope of this guide, but you should understand the strengths and weaknesses of each algorithm and key before you decide on a solution for your deployment. For information about the algorithms and keys that are available through Oracle native network encryption, see Configuring network data encryption in the Oracle documentation. For more information about AWS security, see the AWS security center.

Note
You can use Native Network Encryption or Secure Sockets Layer, but not both. For more information, see Oracle Secure Sockets Layer (p. 1774).

NNE option settings

You can specify encryption requirements on both the server and the client. The DB instance can act as a client when, for example, it uses a database link to connect to another database. You might want to avoid forcing encryption on the server side. For example, you might not want to force all client communications to use encryption because the server requires it. In this case, you can force encryption on the client side using the SQLNET.*CLIENT options.

Amazon RDS supports the following settings for the NNE option.

Note
When you use commas to separate values for an option setting, don't put a space after the comma.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default values</th>
<th>Description</th>
</tr>
</thead>
</table>
| SQLNET.ALLOW_WEAK_CRYPTO_CLIENT         | TRUE, FALSE  | TRUE           | The behavior of the server when a client using a non-secure cipher attempts to connect to the database. If TRUE, clients can connect even if they aren't patched with the July 2021 PSU. If the setting is FALSE, clients can connect to the database only when they are patched with the July 2021 PSU. Before you set SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS to FALSE, make sure that the following conditions are met:
  - SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT have one matching encryption method that is not DES, 3DES, or RC4 (all key lengths).
  - SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method that is not MD5.
  - The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error. |
<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default values</th>
<th>Description</th>
</tr>
</thead>
</table>
| SQLNET.ALLOW_WEAK_CRYPTO | TRUE, FALSE | TRUE | The behavior of the server when a client using a non-secure cipher attempts to connect to the database. The following ciphers are considered not secure:  
  - DES encryption method (all key lengths)  
  - 3DES encryption method (all key lengths)  
  - RC4 encryption method (all key lengths)  
  - MD5 checksumming method  
  If the setting is TRUE, clients can connect when they use the preceding non-secure ciphers.  
  If the setting is FALSE, the database prevents clients from connecting when they use the preceding non-secure ciphers. Before you set SQLNET.ALLOW_WEAK_CRYPTO to FALSE, make sure that the following conditions are met:  
  - SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT have one matching encryption method that is not DES, 3DES, or RC4 (all key lengths).  
  - SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method that is not MD5.  
  - The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error. |
| SQLNET.CRYPTO_CHECKSUM_CLIENT | Accepted, Rejected, Requested, Required | | The data integrity behavior when a DB instance connects to the client, or a server acting as a client. When a DB instance uses a database link, it acts as a client.  
  Requested indicates that the client doesn't require the DB instance to perform a checksum. |
| SQLNET.CRYPTO_CHECKSUM_SERVER | Accepted, Rejected, Requested, Required | | The data integrity behavior when a client, or a server acting as a client, connects to the DB instance. When a DB instance uses a database link, it acts as a client.  
  Requested indicates that the DB instance doesn't require the client to perform a checksum. |

</tr>
</tbody>
</table>
Option setting | Valid values | Default values | Description
--- | --- | --- | ---
SQLNET.ENCRYPTION_TYPES_SERVER | RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40 | RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40 | A list of encryption algorithms used by the DB instance. The DB instance uses each algorithm, in order, to attempt to decrypt the client input until an algorithm succeeds or until the end of the list is reached.

Amazon RDS uses the following default list from Oracle. You can change the order or limit the algorithms that the client will accept.

1. RC4_256: RSA RC4 (256-bit key size)
2. AES256: AES (256-bit key size)
3. AES192: AES (192-bit key size)
4. 3DES168: 3-key Triple-DES (112-bit effective key size)
5. RC4_128: RSA RC4 (128-bit key size)
6. AES128: AES (128-bit key size)
7. 3DES112: 2-key Triple-DES (80-bit effective key size)
8. RC4_56: RSA RC4 (56-bit key size)
9. DES: Standard DES (56-bit key size)
10. RC4_40: RSA RC4 (40-bit key size)
11. DES40: DES40 (40-bit key size)

You can specify either one value or a comma-separated list of values. If you comma, don't insert a space after the comma; otherwise, you receive an InvalidParameterValue error.

This parameter and SQLNET.SQLNET.ENCRYPTION_TYPES_SERVER must have a common cipher.

### Adding the NNE option

The general process for adding the NNE option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When the option group is active, NNE is active.

**To add the NNE option to a DB instance using the AWS Management Console**

1. For **Engine**, choose the Oracle edition that you want to use. NNE is supported on all editions.
2. For **Major engine version**, choose the version of your DB instance.

For more information, see Creating an option group (p. 280).
3. Add the NNE option to the option group. For more information about adding options, see Adding an option to an option group (p. 283).

   **Note**
   After you add the NNE option, you don't need to restart your DB instances. As soon as the option group is active, NNE is active.

4. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. After you add the NNE option, you don't need to restart your DB instance. As soon as the option group is active, NNE is active. For more information, see Modifying an Amazon RDS DB instance (p. 333).

### Setting NNE values in the sqlnet.ora

With Oracle native network encryption, you can set network encryption on the server side and client side. The client is the computer used to connect to the DB instance. You can specify the following client settings in the sqlnet.ora:

- SQLNET.ALLOW_WEAK_CRYPTO
- SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS
- SQLNET.CRYPTO_CHECKSUM_CLIENT
- SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT
- SQLNET.ENCRYPTION_CLIENT
- SQLNET.ENCRYPTION_TYPES_CLIENT

For information, see Configuring network data encryption and integrity for Oracle servers and clients in the Oracle documentation.

Sometimes, the DB instance rejects a connection request from an application. For example, a rejection can occur when the encryption algorithms on the client and on the server don't match. To test Oracle native network encryption, add the following lines to the sqlnet.ora file on the client:

```plaintext
DIAG_ADR_ENABLED=off
TRACE_DIRECTORY_CLIENT=/tmp
TRACE_FILE_CLIENT=nettrace
TRACE_LEVEL_CLIENT=16
```

When a connection is attempted, the preceding lines generate a trace file on the client called `/tmp/nettrace*`. The trace file contains information about the connection. For more information about connection-related issues when you are using Oracle Native Network Encryption, see About negotiating encryption and integrity in the Oracle Database documentation.

### Modifying NNE option settings

After you enable NNE, you can modify settings for the option. For more information about how to modify option settings, see Modifying an option setting (p. 288). For more information about each setting, see NNE option settings (p. 1763).

**Topics**
- Modifying CRYPTO_CHECKSUM_* values (p. 1769)
- Modifying ALLOW_WEAK_CRYPTO* settings (p. 1769)
Modifying CRYPTO_CHECKSUM_* values

If you modify NNE option settings, make sure that the following option settings have at least one common cipher:

- SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER
- SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT

The following example shows a scenario in which you modify SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER. The configuration is valid because the CRYPTO_CHECKSUM_TYPES_CLIENT and CRYPTO_CHECKSUM_TYPES_SERVER both use SHA256.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Values before modification</th>
<th>Values after modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT</td>
<td>SHA256, SHA384, SHA512</td>
<td>No change</td>
</tr>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER</td>
<td>SHA256, SHA384, SHA512, SHA1, MD5</td>
<td>SHA1, MD5, SHA256</td>
</tr>
</tbody>
</table>

For another example, assume that you want to modify SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER from its default setting to SHA1, MD5. In this case, make sure you set SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT to SHA1 or MD5. These algorithms aren't included in the default values for SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT.

Modifying ALLOW_WEAK_CRYPTO* settings

To set the SQLNET.ALLOW_WEAK_CRYPTO* options from the default value to FALSE, make sure that the following conditions are met:

- SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT have one matching secure encryption method. A method is considered secure if it's not DES, 3DES, or RC4 (all key lengths).
- SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method. A method is considered secure if it's not MD5.
- The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error.

The following example shows sample NNE settings. Assume that you want to set SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT to FALSE, thereby blocking non-secure connections. The checksum option settings meet the prerequisites because they both have SHA256. However, SQLNET.ENCRYPTION_TYPES_CLIENT and SQLNET.ENCRYPTION_TYPES_SERVER use the DES, 3DES, and RC4 encryption methods, which are non-secure. Therefore, to set the SQLNET.ALLOW_WEAK_CRYPTO* options to FALSE, first set SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT to a secure encryption method such as AES256.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT</td>
<td>SHA256, SHA384, SHA512</td>
</tr>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER</td>
<td>SHA1, MD5, SHA256</td>
</tr>
<tr>
<td>SQLNET.ENCRYPTION_TYPES_CLIENT</td>
<td>RC4_256, 3DES168, DES40</td>
</tr>
</tbody>
</table>
Option setting | Values
---|---
SQLNET.ENCRIPTION_TYPES_SERVER | RC4_256, 3DES168, DES40

Removing the NNE option

You can remove NNE from a DB instance.

To remove NNE from a DB instance, do one of the following:

- To remove NNE from multiple DB instances, remove the NNE option from the option group they belong to. This change affects all DB instances that use the option group. After you remove the NNE option, you don't need to restart your DB instances. For more information, see Removing an option from an option group (p. 291).

- To remove NNE from a single DB instance, modify the DB instance and specify a different option group that doesn’t include the NNE option. You can specify the default (empty) option group, or a different custom option group. After you remove the NNE option, you don't need to restart your DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 333).
Oracle OLAP

Amazon RDS supports Oracle OLAP through the use of the OLAP option. This option provides On-line Analytical Processing (OLAP) for Oracle DB instances. You can use Oracle OLAP to analyze large amounts of data by creating dimensional objects and cubes in accordance with the OLAP standard. For more information, see the Oracle documentation.

**Important**

If you use Oracle OLAP, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle OLAP for the following editions and versions of Oracle:

- Oracle Database 21c Enterprise Edition, all versions
- Oracle Database 19c Enterprise Edition, all versions
- Oracle Database 12c Release 2 (12.2.0.1) Enterprise Edition, all versions
- Oracle Database 12c Release 1 (12.1.0.2) Enterprise Edition, version 12.1.0.2.v13 or later

**Prerequisites for Oracle OLAP**

The following are prerequisites for using Oracle OLAP:

- You must have an Oracle OLAP license from Oracle. For more information, see Licensing Information in the Oracle documentation.
- Your DB instance must be of a sufficient instance class. Oracle OLAP isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes (p. 1529).
- Your DB instance must have **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 333).
- Your DB instance must not have a user named OLAPSYS. If it does, the OLAP option installation fails.

**Best practices for Oracle OLAP**

The following are best practices for using Oracle OLAP:

- For maximum security, use the OLAP option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 1774).
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC (p. 2263) and Working with a DB instance in a VPC (p. 2251).

**Adding the Oracle OLAP option**

The following is the general process for adding the OLAP option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.
If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the OLAP option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle OLAP is available.

**To add the OLAP option to a DB instance**

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   - For **Engine**, choose the Oracle edition for your DB instance.
   - For **Major engine version**, choose the version of your DB instance.

   For more information, see *Creating an option group* (p. 280).

2. Add the **OLAP** option to the option group. For more information about adding options, see *Adding an option to an option group* (p. 283).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, apply the option group when you launch the instance. For more information, see *Creating an Amazon RDS DB instance* (p. 236).
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see *Modifying an Amazon RDS DB instance* (p. 333).

**Using Oracle OLAP**

After you enable the Oracle OLAP option, you can begin using it. For a list of features that are supported for Oracle OLAP, see the Oracle documentation.

**Removing the Oracle OLAP option**

After you drop all objects that use data types provided by the OLAP option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the OLAP option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the OLAP option, you don't need to restart your DB instance.

**To drop the OLAP option**

1. Back up your data.
   **Warning**
   If the instance uses data types that were enabled as part of the option, and if you remove the OLAP option, you can lose data. For more information, see *Backing up and restoring an Amazon RDS DB instance* (p. 461).

2. Check whether any existing objects reference data types or features of the OLAP option.

3. Drop any objects that reference data types or features of the OLAP option.

4. Do one of the following:
   - Remove the OLAP option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see *Removing an option from an option group* (p. 291).
   - Modify the DB instance and specify a different option group that doesn't include the OLAP option. This change affects a single DB instance. You can specify the default (empty) option group,
or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).
Oracle Secure Sockets Layer

You enable Secure Sockets Layer (SSL) encryption for an RDS for Oracle DB instance by adding the Oracle SSL option to the option group associated with an RDS for Oracle DB instance. You specify the port you want to communicate over using SSL. You must configure SQL*Plus as shown in this following section.

You enable SSL encryption for an RDS for Oracle DB instance by adding the Oracle SSL option to the option group associated with the DB instance. Amazon RDS uses a second port, as required by Oracle, for SSL connections. This approach allows both clear text and SSL-encrypted communication to occur at the same time between an DB instance and SQL*Plus. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

**Note**
You can use SSL or Native Network Encryption (NNE) on the same RDS for Oracle DB instance, but not both. If you use SSL encryption, make sure to turn off any other connection encryption.
For more information, see Oracle native network encryption (p. 1763).

SSL/TLS and NNE and are no longer part of Oracle Advanced Security. In RDS for Oracle, you can use SSL encryption with all licensed editions of the following database versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2) – no longer supported
- Oracle Database 12c Release 1 (12.1) – no longer supported

TLS versions for the Oracle SSL option

Amazon RDS for Oracle supports Transport Layer Security (TLS) versions 1.0 and 1.2. To use the Oracle SSL option, use the SQLNET.SSL_VERSION option setting. The following values are allowed for this option setting:

- "1.0" – Clients can connect to the DB instance using TLS 1.0 only.
- "1.2" – Clients can connect to the DB instance using TLS 1.2 only.
- "1.2 or 1.0" – Clients can connect to the DB instance using either TLS 1.2 or 1.0.

To use the Oracle SSL option, the SQLNET.SSL_VERSION option setting is also required:

- For existing Oracle SSL options, SQLNET.SSL_VERSION is set to "1.0" automatically. You can change the setting if necessary.
- When you add a new Oracle SSL option, you must set SQLNET.SSL_VERSION explicitly to a valid value.

The following table shows the TLS option settings that are supported for different Oracle engine versions and editions.

<table>
<thead>
<tr>
<th>Oracle engine version</th>
<th>SQLNET.SSL_VERSION = &quot;1.0&quot;</th>
<th>SQLNET.SSL_VERSION = &quot;1.2&quot;</th>
<th>SQLNET.SSL_VERSION = &quot;1.2 or 1.0&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>21.0.0.0 (All editions)</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>
Secure Sockets Layer (SSL)

Oracle engine version | SQLNET.SSL_VERSION = "1.0" | SQLNET.SSL_VERSION = "1.2" | SQLNET.SSL_VERSION = "1.2 or 1.0"
---|---|---|---
19.0.0.0 (All editions) | Supported | Supported | Supported
12.2.0.1 (All editions) | Supported | Supported | Supported
12.1.0.2 (All editions) | Supported | Supported | Supported

Cipher suites for the Oracle SSL option

Amazon RDS for Oracle supports multiple SSL cipher suites. By default, the Oracle SSL option is configured to use the SSL_RSA_WITH_AES_256_CBC_SHA cipher suite. To specify a different cipher suite to use over SSL connections, use the SQLNET.CIPHER_SUITE option setting. Following are the allowed values for this option setting:

- "SSL_RSA_WITH_AES_256_CBC_SHA" – The default setting, which is compatible with TLS 1.0 and TLS 1.2
- "SSL_RSA_WITH_AES_256_CBC_SHA256" – Only compatible with TLS 1.2
- "SSL_RSA_WITH_AES_256_GCM_SHA384" – Only compatible with TLS 1.2

For existing Oracle SSL options, SQLNET.CIPHER_SUITE is set to "SSL_RSA_WITH_AES_256_CBC_SHA" automatically. You can change the setting if necessary.

The following table shows the cipher suite option settings that are supported for different Oracle engine versions and editions.

FIPS support

RDS for Oracle allows you to use the Federal Information Processing Standard (FIPS) standard for 140-2. FIPS 140-2 is a United States government standard that defines cryptographic module security requirements. You turn on the FIPS standard by setting FIPS.SSLFIPS_140 to TRUE for the Oracle SSL option. When FIPS 140-2 is configured for SSL, the cryptographic libraries encrypt data between the client and the RDS for Oracle DB instance.

You can turn on the FIPS setting with the following Oracle database versions and editions:

- 19.0.0.0: All versions, all editions including Standard Edition Two
- 12.2.0.1: All versions, all editions including Standard Edition Two
- 12.1.0.2: Version 2 and later, all editions including Standard Edition Two
Clients must use the cipher suite that is FIPS-compliant. When establishing a connection, the client and RDS for Oracle DB instance negotiate which cipher suite to use when transmitting messages back and forth. The following table shows the FIPS-compliant SSL cipher suites for each TLS version.

<table>
<thead>
<tr>
<th>SQLNET.SSL_VERSION</th>
<th>Supported cipher suites</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0</td>
<td>SSL_RSA_WITH_AES_256_CBC_SHA</td>
</tr>
<tr>
<td>1.2</td>
<td>SSL_RSA_WITH_AES_256_CBC_SHA</td>
</tr>
<tr>
<td></td>
<td>SSL_RSA_WITH_AES_256_GCM_SHA384</td>
</tr>
</tbody>
</table>

For more information, see Oracle database FIPS 140-2 settings in the Oracle documentation.

**Adding the SSL option**

To use SSL, your RDS for Oracle DB instance must be associated with an option group that includes the SSL option.

**Console**

**To add the SSL option to an option group**

1. Create a new option group or identify an existing option group to which you can add the SSL option.
   
   For information about creating an option group, see Creating an option group (p. 280).
2. Add the SSL option to the option group.
   
   If you want to use only FIPS-verified cipher suites for SSL connections, set the option FIPS.SSLFIPS_140 to TRUE. For information about the FIPS standard, see FIPS support (p. 1775).
   
   For information about adding an option to an option group, see Adding an option to an option group (p. 283).
3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.
   
   For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 236).
   
   For information about modifying an DB instance, see Modifying an Amazon RDS DB instance (p. 333).

**AWS CLI**

**To add the SSL option to an option group**

1. Create a new option group or identify an existing option group to which you can add the SSL option.
   
   For information about creating an option group, see Creating an option group (p. 280).
2. Add the SSL option to the option group.
   
   Specify the following option settings:
   
   • Port – The SSL port number
   • VpcSecurityGroupMemberships – The VPC security group for which the option is enabled
Secure Sockets Layer (SSL)

• SQLNET.SSL_VERSION – The TLS version that client can use to connect to the DB instance

For example, the following AWS CLI command adds the SSL option to an option group named ora-option-group.

Example

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group --option-group-name ora-option-group --options 'OptionName=SSL,Port=2484,VpcSecurityGroupMemberships="sg-68184619",OptionSettings=[{Name=SQLNET.SSL_VERSION,Value=1.0}]
```

For Windows:

```bash
aws rds add-option-to-option-group --option-group-name ora-option-group --options 'OptionName=SSL,Port=2484,VpcSecurityGroupMemberships="sg-68184619",OptionSettings=[{Name=SQLNET.SSL_VERSION,Value=1.0}]
```

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

For information about creating an DB instance, see Creating an Amazon RDS DB instance (p. 236).

For information about modifying an DB instance, see Modifying an Amazon RDS DB instance (p. 333).

Configuring SQL*Plus to use SSL with an RDS for Oracle DB instance

You must configure SQL*Plus before connecting to an RDS for Oracle DB instance that uses the Oracle SSL option.

**Note**

To allow access to the DB instance from the appropriate clients, ensure that your security groups are configured correctly. For more information, see Controlling access with security groups (p. 2232). Also, these instructions are for SQL*Plus and other clients that directly use an Oracle home. For JDBC connections, see Setting up an SSL connection over JDBC (p. 1779).

To configure SQL*Plus to use SSL to connect to an RDS for Oracle DB instance

1. Set the ORACLE_HOME environment variable to the location of your Oracle home directory.

   The path to your Oracle home directory depends on your installation. The following example sets the ORACLE_HOME environment variable.

   ```bash
   prompt>export ORACLE_HOME=/home/user/app/user/product/12.1.0/dbhome_1
   ```

   For information about setting Oracle environment variables, see SQL*Plus environment variables in the Oracle documentation, and also see the Oracle installation guide for your operating system.

2. Append $ORACLE_HOME/lib to the LD_LIBRARY_PATH environment variable.

   The following is an example that sets the LD_LIBRARY_PATH environment variable.
3. Create a directory for the Oracle wallet at $ORACLE_HOME/ssl_wallet.

   The following is an example that creates the Oracle wallet directory.

   ```bash
   prompt>mkdir $ORACLE_HOME/ssl_wallet
   ```

4. Download the root certificate that works for all AWS Regions and put the file in the ssl_wallet directory.

   For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).

5. In the $ORACLE_HOME/network/admin directory, modify or create the tnsnames.ora file and include the following entry.

   ```
   <net_service_name> = (DESCRIPTION = (ADDRESS_LIST = (ADDRESS = (PROTOCOL = TCPS)
   (HOST = <endpoint>) (PORT = <ssl port number>)))(CONNECT_DATA = (SID = <database name>))
   (SECURITY = (SSL_SERVER_CERT_DN = "C=US,ST=Washington,L=Seattle,O=Amazon.com,OU=RDS,CN=<endpoint>")))
   ```

6. In the same directory, modify or create the sqlnet.ora file and include the following parameters.

   **Note**
   To communicate with entities over a TLS secured connection, Oracle requires a wallet with the necessary certificates for authentication. You can use Oracle's ORAPKI utility to create and maintain Oracle wallets, as shown in step 7. For more information, see Setting up Oracle wallet using ORAPKI in the Oracle documentation.

   ```
   WALLET_LOCATION = (SOURCE = (METHOD = FILE) (METHOD_DATA = (DIRECTORY = $ORACLE_HOME/ssl_wallet)))
   SSL_CLIENT_AUTHENTICATION = FALSE
   SSL_VERSION = 1.0
   SSL_CIPHER_SUITES = (SSL_RSA_WITH_AES_256_CBC_SHA)
   SSL_SERVER_DN_MATCH = ON
   ```

   **Note**
   You can set SSL_VERSION to a higher value if your DB instance supports it.

7. Run the following commands to create the Oracle wallet.

   ```bash
   prompt>orapki wallet create -wallet $ORACLE_HOME/ssl_wallet -auto_login_only
   prompt>orapki wallet add -wallet $ORACLE_HOME/ssl_wallet -trusted_cert -cert $ORACLE_HOME/ssl_wallet/rds-ca-2019-root.pem -auto_login_only
   ```

   Replace the file name with the one you downloaded.

---

**Connecting to an RDS for Oracle DB instance using SSL**

After you configure SQL*Plus to use SSL as described previously, you can connect to the RDS for Oracle DB instance with the SSL option. Optionally, you can first export the TNS_ADMIN value that points to the directory that contains the tnsnames.ora and sqlnet.ora files. Doing so ensures that SQL*Plus can find these files consistently. The following example exports the TNS_ADMIN value.
Connect to the DB instance. For example, you can connect using SQL*Plus and a `<net_service_name>` in a tnsnames.ora file.

```
sqlplus <mydbuser>@<net_service_name>
```

You can also connect to the DB instance using SQL*Plus without using a tnsnames.ora file by using the following command.

```
sqlplus '<mydbuser>@(DESCRIPTION = (ADDRESS = (PROTOCOL = TCPS)(HOST = <endpoint>) (PORT = <ssl port number>))(CONNECT_DATA = (SID = <database name>)))'
```

You can also connect to the RDS for Oracle DB instance without using SSL. For example, the following command connects to the DB instance through the clear text port without SSL encryption.

```
sqlplus '<mydbuser>@(DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(HOST = <endpoint>) (PORT = <port number>))(CONNECT_DATA = (SID = <database name>)))'
```

If you want to close Transmission Control Protocol (TCP) port access, create a security group with no IP address ingresses and add it to the instance. This addition closes connections over the TCP port, while still allowing connections over the SSL port that are specified from IP addresses within the range permitted by the SSL option security group.

### Setting up an SSL connection over JDBC

To use an SSL connection over JDBC, you must create a keystore, trust the Amazon RDS root CA certificate, and use the code snippet specified following.

To create the keystore in JKS format, use the following command. For more information about creating the keystore, see the [Oracle documentation](#).

```
keytool -keystore clientkeystore -genkey -alias client
```

Next, take the following steps to trust the Amazon RDS root CA certificate.

#### To trust the Amazon RDS root CA certificate

1. Download the root certificate that works for all AWS Regions and put the file in the ssl_wallet directory.

   For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance](#).

2. Convert the certificate to .der format using the following command.

   ```
   ```

   Replace the file name with the one you downloaded.

3. Import the certificate into the keystore using the following command.

   ```
   ```

4. Confirm that the key store was created successfully.
Enter the keystore password when you are prompted for it.

The following code example shows how to set up the SSL connection using JDBC.

```java
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.util.Properties;

public class OracleSslConnectionTest {
    private static final String DB_SERVER_NAME = "<dns-name-provided-by-amazon-rds>";
    private static final Integer SSL_PORT = "<ssl-option-port-configured-in-option-group>";
    private static final String DB_SID = "<oracle-sid>";
    private static final String DB_USER = "<user name>";
    private static final String DB_PASSWORD = "<password>";
    private static final String KEY_STORE_FILE_PATH = "<file-path-to-keystore>";
    private static final String KEY_STORE_PASS = "<keystore-password>";

    public static void main(String[] args) throws SQLException {
        final Properties properties = new Properties();
        final String connectionString = String.format(
            "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))
(CONNECT_DATA=(SID=%s)))",
            DB_SERVER_NAME, SSL_PORT, DB_SID);
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);
        properties.put("oracle.jdbc.J2EE13Compliant", "true");
        properties.put("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        properties.put("javax.net.ssl.trustStoreType", "JKS");
        properties.put("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
        final Connection connection = DriverManager.getConnection(connectionString, properties);
        // If no exception, that means handshake has passed, and an SSL connection can be opened
    }
}
```

Enforcing a DN match with an SSL connection

You can use the Oracle parameter SSL_SERVER_DN_MATCH to enforce that the distinguished name (DN) for the database server matches its service name. If you enforce the match verifications, then SSL ensures that the certificate is from the server. If you don't enforce the match verification, then SSL performs the check but allows the connection, regardless if there is a match. If you do not enforce the match, you allow the server to potentially fake its identify.

To enforce DN matching, add the DN match property and use the connection string specified below.

Add the property to the client connection to enforce DN matching.

```java
properties.put("oracle.net.ssl_server_dn_match", "TRUE");
```

Use the following connection string to enforce DN matching when using SSL.

```java
final String connectionString = String.format(
    "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))
(CONNECT_DATA=(SID=%s)))",
    DB_SERVER_NAME, SSL_PORT, DB_SID);
```
"jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=%s)(PORT=%d))" +
"(CONNECT_DATA=(SID=%s))" +
"(SECURITY = (SSL_SERVER_CERT_DN =
"C=US,ST=Washington,L=Seattle,O=Amazon.com,OU=RDS,CN=%s")))",
DB_SERVER_NAME, SSL_PORT, DB_SID, DB_SERVER_NAME);}
Oracle Spatial

Amazon RDS supports Oracle Spatial through the use of the SPATIAL option. Oracle Spatial provides a SQL schema and functions that facilitate the storage, retrieval, update, and query of collections of spatial data in an Oracle database. For more information, see Spatial Concepts in the Oracle documentation.

**Important**

If you use Oracle Spatial, Amazon RDS automatically updates your DB instance to the latest Oracle PSU when any of the following exist:

- Security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+
- Other announced security vulnerabilities

Amazon RDS supports Oracle Spatial only in Oracle Enterprise Edition (EE) and Oracle Standard Edition 2 (SE2). The following table shows the versions of the DB engine that support EE and SE2.

<table>
<thead>
<tr>
<th>Oracle DB Version</th>
<th>EE</th>
<th>SE2</th>
</tr>
</thead>
<tbody>
<tr>
<td>21.0.0.0, all versions</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>19.0.0.0, all versions</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>12.2.0.1, all versions</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>12.1.0.2.v13 or later</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

**Prerequisites for Oracle Spatial**

The following are prerequisites for using Oracle Spatial:

- Make sure that your DB instance is of a sufficient instance class. Oracle Spatial isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes (p. 1529).
- Make sure that your DB instance has Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 333).

**Best practices for Oracle Spatial**

The following are best practices for using Oracle Spatial:

- For maximum security, use the SPATIAL option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 1774).
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC (p. 2263) and Working with a DB instance in a VPC (p. 2251).

**Adding the Oracle Spatial option**

The following is the general process for adding the SPATIAL option to a DB instance:
1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the SPATIAL option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Spatial is available.

**Note**
During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

### To add the SPATIAL option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the Oracle edition for your DB instance.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group (p. 280).

2. Add the SPATIAL option to the option group. For more information about adding options, see Adding an option to an option group (p. 283).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).

### Removing the Oracle Spatial option

After you drop all objects that use data types provided by the SPATIAL option, you can drop the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the SPATIAL option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the SPATIAL option, you don't need to restart your DB instance.

### To drop the SPATIAL option

1. Back up your data.
   **Warning**
   If the instance uses data types that were enabled as part of the option, and if you remove the SPATIAL option, you can lose data. For more information, see Backing up and restoring an Amazon RDS DB instance (p. 461).

2. Check whether any existing objects reference data types or features of the SPATIAL option.

   If SPATIAL options exist, the instance can get stuck when applying the new option group that doesn't have the SPATIAL option. You can identify the objects by using the following queries:

   ```sql
   SELECT OWNER, SEGMENT_NAME, TABLESPACE_NAME, BYTES/1024/1024 mbytes
   ```
FROM DBA_SEGMENTS
WHERE SEGMENT_TYPE LIKE '%TABLE%'
AND (OWNER, SEGMENT_NAME) IN
(SELECT DISTINCT OWNER, TABLE_NAME
  FROM DBA_TAB_COLUMNS
  WHERE DATA_TYPE='SDO_GEOMETRY'
  AND OWNER <> 'MDSYS')
ORDER BY 1,2,3,4;

SELECT OWNER, TABLE_NAME, COLUMN_NAME
FROM DBA_TAB_COLUMNS
WHERE DATA_TYPE = 'SDO_GEOMETRY'
AND OWNER <> 'MDSYS'
ORDER BY 1,2,3;

3. Drop any objects that reference data types or features of the SPATIAL option.
4. Do one of the following:

  • Remove the SPATIAL option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 291).

  • Modify the DB instance and specify a different option group that doesn't include the SPATIAL option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).
Oracle SQLT

Amazon RDS supports Oracle SQLTXPLAIN (SQLT) through the use of the SQLT option.

The Oracle EXPLAIN PLAN statement can determine the execution plan of a SQL statement. It can verify whether the Oracle optimizer chooses a certain execution plan, such as a nested loops join. It also helps you understand the optimizer's decisions, such as why it chose a nested loops join over a hash join. So EXPLAIN PLAN helps you understand the statement's performance.

SQLT is an Oracle utility that produces a report. The report includes object statistics, object metadata, optimizer-related initialization parameters, and other information that a database administrator can use to tune a SQL statement for optimal performance. SQLT produces an HTML report with hyperlinks to all of the sections in the report.

Unlike Automatic Workload Repository or Statspack reports, SQLT works on individual SQL statements. SQLT is a collection of SQL, PL/SQL, and SQL*Plus files that collect, store, and display performance data.

Following are the supported Oracle versions for each SQLT version.

<table>
<thead>
<tr>
<th>SQLT version</th>
<th>Oracle Database 21c</th>
<th>Oracle Database 19c</th>
<th>Oracle Database 12c Release 2 (12.2)</th>
<th>Oracle Database 12c Release 1 (12.1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2018-07-25.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>2018-03-31.v1</td>
<td>Not supported</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>2016-04-29.v1</td>
<td>Not supported</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>

To download SQLT and access instructions for using it:

- Log in to your My Oracle Support account, and open the following documents:
- To download SQLT: Document 215187.1
- For SQLT usage instructions: Document 1614107.1
- For frequently asked questions about SQLT: Document 1454160.1
- For information about reading SQLT output: Document 1456176.1
- For interpreting the Main report: Document 1922234.1

You can use SQLT with any edition of the following Oracle Database versions:

- Oracle Database 21c (21.0.0.0)
- Oracle Database 19c (19.0.0.0)
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1.0.2)

Amazon RDS does not support the following SQLT methods:

- XPLORE
- XHUME

Prerequisites for SQLT

The following are prerequisites for using SQLT:
You must remove users and roles that are required by SQLT, if they exist.

The SQLT option creates the following users and roles on a DB instance:
- SQLTXPLAIN user
- SQLTXADMIN user
- SQLT_USER_ROLE role

If your DB instance has any of these users or roles, log in to the DB instance using a SQL client, and drop them using the following statements:

```
DROP USER SQLTXPLAIN CASCADE;
DROP USER SQLTXADMIN CASCADE;
DROP ROLE SQLT_USER_ROLE CASCADE;
```

You must remove tablespaces that are required by SQLT, if they exist.

The SQLT option creates the following tablespaces on a DB instance:
- RDS_SQLT_TS
- RDS_TEMP_SQLT_TS

If your DB instance has these tablespaces, log in to the DB instance using a SQL client, and drop them.

### SQLT option settings

SQLT can work with licensed features that are provided by the Oracle Tuning Pack and the Oracle Diagnostics Pack. The Oracle Tuning Pack includes the SQL Tuning Advisor, and the Oracle Diagnostics Pack includes the Automatic Workload Repository. The SQLT settings enable or disable access to these features from SQLT.

Amazon RDS supports the following settings for the SQLT option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LICENSE_PACK</td>
<td>T, D, N</td>
<td>N</td>
<td>The Oracle Management Packs that you want to access with SQLT. Enter one of the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- T indicates that you have a license for the Oracle Tuning Pack and the Oracle Diagnostics Pack, and you want to access the SQL Tuning Advisor and Automatic Workload Repository from SQLT.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- D indicates that you have a license for the Oracle Diagnostics Pack, and you want to access the Automatic Workload Repository from SQLT.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- N indicates that you don't have a license for the Oracle Tuning Pack and the Oracle Diagnostics Pack, or that you have a license for one or both of them, but you don't want SQLT to access them.</td>
</tr>
<tr>
<td>Option setting</td>
<td>Valid values</td>
<td>Default value</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>--------------</td>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td>VERSION</td>
<td>2016-04-29.v1</td>
<td></td>
<td>The version of SQLT that you want to install.</td>
</tr>
<tr>
<td></td>
<td>2018-03-31.v1</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>2018-07-25.v1</td>
<td>2016-04-29.v1</td>
<td></td>
</tr>
</tbody>
</table>

The version of SQLT that you want to install.

**Note**

For Oracle Database 19c and 21c, the only supported version is 2018-07-25.v1. This version is the default for these releases.

**Adding the SQLT option**

The following is the general process for adding the SQLT option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the SQLT option to the option group.
3. Associate the option group with the DB instance.

After you add the SQLT option, as soon as the option group is active, SQLT is active.

**To add the SQLT option to a DB instance**

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the Oracle edition that you want to use. The SQLT option is supported on all editions.
   b. For **Major engine version**, choose the version of your DB instance.

For more information, see Creating an option group (p. 280).

2. Add the **SQLT** option to the option group. For more information about adding options, see Adding an option to an option group (p. 283).

3. Apply the option group to a new or existing DB instance:
   a. For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
• For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).
4. (Optional) Verify the SQLT installation on each DB instance with the SQLT option.
   a. Use a SQL client to connect to the DB instance as the master user.
      For information about connecting to an Oracle DB instance using a SQL client, see Connecting to your Oracle DB instance (p. 1540).
   b. Run the following query:

      ```sql
      SELECT sqltxplain.sqlt$a.get_param('tool_version') sqlt_version FROM DUAL;
      ```

      The query returns the current version of the SQLT option on Amazon RDS. 12.1.160429 is an example of a version of SQLT that is available on Amazon RDS.
5. Change the passwords of the users that are created by the SQLT option.
   a. Use a SQL client to connect to the DB instance as the master user.
   b. Run the following SQL statement to change the password for the SQLTXADMIN user:

      ```sql
      ALTER USER SQLTXADMIN IDENTIFIED BY new_password ACCOUNT UNLOCK;
      ```
   c. Run the following SQL statement to change the password for the SQLTXPLAIN user:

      ```sql
      ALTER USER SQLTXPLAIN IDENTIFIED BY new_password ACCOUNT UNLOCK;
      ```

      **Note**
      Upgrading SQLT requires uninstalling an older version of SQLT and then installing the new version. So, all SQLT metadata can be lost when you upgrade SQLT. A major version upgrade of a database also uninstalls and re-installs SQLT. An example of a major version upgrade is an upgrade from Oracle Database 12c Release 2 (12.2) to Oracle Database 19c.

**Using SQLT**

SQLT works with the Oracle SQL*Plus utility.

**To use SQLT**

1. Download the SQLT .zip file from Document 215187.1 on the My Oracle Support site.
   **Note**
   You can't download SQLT 12.1.160429 from the My Oracle Support site. Oracle has deprecated this older version.
2. Unzip the SQLT .zip file.
3. From a command prompt, change to the sqlt/run directory on your file system.
4. From the command prompt, open SQL*Plus, and connect to the DB instance as the master user.
For information about connecting to a DB instance using SQL*Plus, see Connecting to your Oracle DB instance (p. 1540).

5. Get the SQL ID of a SQL statement:

```
SELECT SQL_ID FROM V$SQL WHERE SQL_TEXT='sql_statement';
```

Your output is similar to the following:

```
SQL_ID
--------
chvsmttqjzjkn
```

6. Analyze a SQL statement with SQLT:

```
START sqltxtract.sql sql_id sqltxplain_user_password
```

For example, for the SQL ID chvsmttqjzjkn, enter the following:

```
START sqltxtract.sql chvsmttqjzjkn sqltxplain_user_password
```

SQLT generates the HTML report and related resources as a .zip file in the directory from which the SQLT command was run.

7. (Optional) To enable application users to diagnose SQL statements with SQLT, grant SQLT_USER_ROLE to each application user with the following statement:

```
GRANT SQLT_USER_ROLE TO application_user_name;
```

**Note**

Oracle does not recommend running SQLT with the SYS user or with users that have the DBA role. It is a best practice to run SQLT diagnostics using the application user’s account, by granting SQLT_USER_ROLE to the application user.

### Upgrading the SQLT option

With Amazon RDS for Oracle, you can upgrade the SQLT option from your existing version to a higher version. To upgrade the SQLT option, complete steps 1–3 in Using SQLT (p. 1788) for the new version of SQLT. Also, if you granted privileges for the previous version of SQLT in step 7 of that section, grant the privileges again for the new SQLT version.

Upgrading the SQLT option results in the loss of the older SQLT version's metadata. The older SQLT version's schema and related objects are dropped, and the newer version of SQLT is installed. For more information about the changes in the latest SQLT version, see Document 1614201.1 on the My Oracle Support site.
Note
Version downgrades are not supported.

Modifying SQLT settings

After you enable SQLT, you can modify the LICENSE_PACK and VERSION settings for the option.

For more information about how to modify option settings, see Modifying an option setting (p. 288). For more information about each setting, see SQLT option settings (p. 1786).

Removing the SQLT option

You can remove SQLT from a DB instance.

To remove SQLT from a DB instance, do one of the following:

- To remove SQLT from multiple DB instances, remove the SQLT option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 291).

- To remove SQLT from a single DB instance, modify the DB instance and specify a different option group that doesn't include the SQLT option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).
Oracle Statspack

The Oracle Statspack option installs and enables the Oracle Statspack performance statistics feature. Oracle Statspack is a collection of SQL, PL/SQL, and SQL*Plus scripts that collect, store, and display performance data. For information about using Oracle Statspack, see Oracle Statspack in the Oracle documentation.

**Note**
Oracle Statspack is no longer supported by Oracle and has been replaced by the more advanced Automatic Workload Repository (AWR). AWR is available only for Oracle Enterprise Edition customers who have purchased the Diagnostics Pack. You can use Oracle Statspack with any Oracle DB engine on Amazon RDS. You can't run Oracle Statspack on Amazon RDS read replicas.

Setting up Oracle Statspack

To run Statspack scripts, you must add the Statspack option.

**To set up Oracle Statspack**

1. In a SQL client, log in to the Oracle DB with an administrative account.
2. Do either of the following actions, depending on whether Statspack is installed:
   - If Statspack is installed, and the PERFSTAT account is associated with Statspack, skip to Step 4.
   - If Statspack is not installed, and the PERFSTAT account exists, drop the account as follows:
     ```sql
     DROP USER PERFSTAT CASCADE;
     ```
     Otherwise, attempting to add the Statspack option generates an error and RDS-Event-0058.
3. Add the Statspack option to an option group. See Adding an option to an option group (p. 283).
   Amazon RDS automatically installs the Statspack scripts on the DB instance and then sets up the PERFSTAT account.
4. Reset the password using the following SQL statement, replacing `pwd` with your new password:
   ```sql
   ALTER USER PERFSTAT IDENTIFIED BY pwd ACCOUNT UNLOCK;
   ```
   You can log in using the PERFSTAT user account and run the Statspack scripts.
5. Do either of the following actions, depending on your DB engine version:
   - If you are using Oracle Database 12c Release 2 (12.2) or lower, skip this step.
   - If you are using Oracle Database 19c or higher, grant the CREATE JOB privilege to the PERFSTAT account using the following statement:
     ```sql
     GRANT CREATE JOB TO PERFSTAT;
     ```
6. Ensure that idle wait events in the PERFSTAT.STATS$IDLE_EVENT table are populated.

Because of Oracle Bug 28523746, the idle wait events in PERFSTAT.STATS$IDLE_EVENT may not be populated. To ensure all idle events are available, run the following statement:

```sql
INSERT INTO PERFSTAT.STATS$IDLE_EVENT (EVENT)
SELECT NAME FROM V$EVENT_NAME WHERE WAIT_CLASS='Idle'
MINUS
SELECT EVENT FROM PERFSTAT.STATS$IDLE_EVENT;
```
Generating Statspack reports

A Statspack report compares two snapshots.

To generate Statspack reports

1. In a SQL client, log in to the Oracle DB with the PERFSTAT account.
2. Create a snapshot using either of the following techniques:
   - Create a Statspack snapshot manually.
   - Create a job that takes a Statspack snapshot after a given time interval. For example, the following job creates a Statspack snapshot every hour:

   ```sql
   VARIABLE jn NUMBER;
   exec dbms_job.submit(:jn, 'statspack.snap;', SYSDATE, 'TRUNC(SYSDATE+1/24, ''HH24'')');
   COMMIT;
   ```
3. View the snapshots using the following query:

   ```sql
   SELECT SNAP_ID, SNAP_TIME FROM STATS$SNAPSHOT ORDER BY 1;
   ```
4. Run the Amazon RDS procedure `rdsadmin.rds_run_spreport`, replacing `begin_snap` and `end_snap` with the snapshot IDs:

   ```sql
   exec rdsadmin.rds_run_spreport(begin_snap, end_snap);
   ```
   For example, the following command creates a report based on the interval between Statspack snapshots 1 and 2:

   ```sql
   exec rdsadmin.rds_run_spreport(1,2);
   ```
   The file name of the Statspack report includes the number of the two snapshots. For example, a report file created using Statspack snapshots 1 and 2 would be named `ORCL_spreport_1_2.lst`.
5. Monitor the output for errors.

   Oracle Statspack performs checks before running the report. Therefore, you could also see error messages in the command output. For example, you might try to generate a report based on an invalid range, where the beginning Statspack snapshot value is larger than the ending value. In this case, the output shows the error message, but the DB engine does not generate an error file.

   ```sql
   exec rdsadmin.rds_run_spreport(2,1);
   * ERROR at line 1:
   ORA-20000: Invalid snapshot IDs. Find valid ones in perfstat.stats$snapshot.
   ```
   If you use an invalid number a Statspack snapshot, the output shows an error. For example, if you try to generate a report for snapshots 1 and 50, but snapshot 50 doesn't exist, the output shows an error.

   ```sql
   exec rdsadmin.rds_run_spreport(1,50);
   * ERROR at line 1:
   ```
ORA-20000: Could not find both snapshot IDs

6. (Optional)

To retrieve the report, call the trace file procedures, as explained in Working with Oracle trace files (p. 745).

Alternatively, download the Statspack report from the RDS console. Go to the Log section of the DB instance details and choose Download:

If an error occurs while generating a report, the DB engine uses the same naming conventions as for a report but with an extension of .err. For example, if an error occurred while creating a report using Statspack snapshots 1 and 7, the report file would be named ORCL_spreport_1_7.err. You can download the error report using the same techniques as for a standard Snapshot report.

Removing Statspack files

To remove Oracle Statspack files, use the following command:

```
exec statspack.purge(begin snap, end snap);
```
Oracle time zone

To change the system time zone used by your Oracle DB instance, use the time zone option. For example, you might change the time zone of a DB instance to be compatible with an on-premises environment, or a legacy application. The time zone option changes the time zone at the host level. Changing the time zone impacts all date columns and values, including SYSDATE and SYSTIMESTAMP.

The time zone option differs from the rdsadmin_util.alter_db_time_zone command. The alter_db_time_zone command changes the time zone only for certain data types. The time zone option changes the time zone for all date columns and values. For more information about alter_db_time_zone, see Setting the database time zone (p. 1599). For more information about upgrade considerations, see Time zone considerations (p. 1814).

Considerations for setting the time zone

The time zone option is a permanent and persistent option. Therefore, you can't do the following:

- Remove the option from an option group after you add the option.
- Remove the option group from a DB instance after you add the group.
- Modify the time zone setting of the option to a different time zone.

If you accidentally set the time zone incorrectly, you need to recover the DB instance to its previous time zone setting. We strongly urge you to use one of the following strategies, depending on your situation:

- Your DB instance currently uses the default option group.
  Take a snapshot of your DB instance, and then add the time zone option to your DB instance. For more information, see Creating a DB snapshot (p. 483).
- Your DB instance currently uses a nondefault option group.
  Take a snapshot of your DB instance, create a new option group with the time zone option, and then add the option group to your instance.

We strongly urge you to test the time zone option on a test DB instance before you add it to a production DB instance. Adding the time zone option can cause problems with tables that use system date to add dates or times. We recommend that you analyze your data and applications to determine the impact of changing the time zone.

Time zone option settings

Amazon RDS supports the following settings for the time zone option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIME_ZONE</td>
<td>One of the available time zones. For the full list, see Available time zones (p. 1796).</td>
<td>The new time zone for your DB instance.</td>
</tr>
</tbody>
</table>

Adding the time zone option

The general process for adding the time zone option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When you add the time zone option, a brief outage occurs while your DB instance is automatically restarted.

**Console**

**To add the time zone option to a DB instance**

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine** choose the oracle edition for your DB instance.
   b. For **Major engine version** choose the version of your DB instance.

   For more information, see Creating an option group (p. 280).

2. Add the **Timezone** option to the option group, and configure the option settings.

   **Important**
   If you add the time zone option to an existing option group that is already attached to one or more DB instances, a brief outage occurs while all the DB instances are automatically restarted.

   For more information about adding options, see Adding an option to an option group (p. 283). For more information about each setting, see Time zone option settings (p. 1794).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the time zone option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance (p. 333).

**AWS CLI**

The following example uses the AWS CLI `add-option-to-option-group` command to add the Timezone option and the TIME_ZONE option setting to an option group called `myoptiongroup`. The time zone is set to Africa/Cairo.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
  --option-group-name "myoptiongroup" \
  --options "OptionName=Timezone,OptionSettings=[[Name=TIME_ZONE,Value=Africa/Cairo]]" \
  --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
  --option-group-name "myoptiongroup" ^
  --options "OptionName=Timezone,OptionSettings=[[Name=TIME_ZONE,Value=Africa/Cairo]]" ^
  --apply-immediately
```
Modifying time zone settings

The time zone option is a permanent and persistent option. You can't remove the option from an option group after you add it. You can't remove the option group from a DB instance after you add it. You can't modify the time zone setting of the option to a different time zone. If you set the time zone incorrectly, restore a snapshot of your DB instance from before you added the time zone option.

Removing the time zone option

The time zone option is a permanent and persistent option. You can't remove the option from an option group after you add it. You can't remove the option group from a DB instance after you add it. To remove the time zone option, restore a snapshot of your DB instance from before you added the time zone option.

Available time zones

You can use the following values for the time zone option.

<table>
<thead>
<tr>
<th>Zone</th>
<th>Time zone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Africa</td>
<td>Africa/Cairo, Africa/Casablanca, Africa/Harare, Africa/Lagos, Africa/Luanda,</td>
</tr>
<tr>
<td></td>
<td>Africa/Monrovia, Africa/Nairobi, Africa/Tripoli, Africa/Windhoek</td>
</tr>
<tr>
<td></td>
<td>America/Araguaina, America/Argentina/Buenos_Aires, America/Asuncion,</td>
</tr>

</tbody>
</table>
Oracle time zone file autoupgrade

With the TIMEZONE_FILE_AUTOPGRADE option, you can upgrade the current time zone file to the latest version on your DB instance.

Topics

- Purpose of time zone files (p. 1798)
- Considerations for updating your time zone file (p. 1798)
- Strategies for updating your time zone file (p. 1799)
- Preparing to update the time zone file (p. 1800)
- Adding the time zone file autoupgrade option (p. 1801)
- Checking your data after the update of the time zone file (p. 1802)

Purpose of time zone files

In Oracle Database, the TIMESTAMP WITH TIME ZONE data type stores time stamp and time zone data. This data type is useful for preserving local time zone information.

Oracle Database stores transition rules and UTC offsets in *time zone files*. The offset is the difference between local time and UTC. When you create an Oracle database in an on-premises environment, you choose the time zone file version. Data with the TIMESTAMP WITH TIME ZONE data type uses the rules in the associated time zone file version. The time zone files reside in $ORACLE_HOME/oracore/zoneinfo/.

If a government changes the rules for Daylight Savings Time (DST), Oracle publishes new time zone files. Oracle releases time zone files separately from PSUs and RUs. The time zone file names use the format DSTvversion, as in DSTv35. When you add the TIMEZONE_FILE_AUTOPGRADE option in Amazon RDS for Oracle, you can update your time zone files.

The TIMEZONE_FILE_AUTOPGRADE option is useful when you move data between different environments. If you try to import data from a source database with a higher time zone file version than the target database, you receive the ORA-39405 error. Previously, you had to work around the error by using either of the following techniques:

- Create an RDS for Oracle instance with the desired time zone file, export data from your source database, and then import it into the new database.
- Use AWS DMS or logical replication to migrate your data.

With the TIMEZONE_FILE_AUTOPGRADE option, you can upgrade the time zone file on the source database without using the preceding cumbersome techniques.

Considerations for updating your time zone file

When you update your time zone file, data that uses TIMESTAMP WITH TIME ZONE might change. Your primary consideration is downtime.

**Warning**

If you add the TIMEZONE_FILE_AUTOPGRADE, your engine upgrade might have prolonged downtime. Updating time zone data for a large database might take hours or even days.

The length of the update depends on factors such as the following:

- The amount of TIMESTAMP WITH TIME ZONE data in your database
• The instance configuration
• The DB instance class
• The storage configuration
• The database configuration
• The database parameter settings

Additional downtime can occur when you do the following:

• Add the option to the option group when the instance uses an outdated time zone file
• Upgrade the Oracle database engine when the new engine version contains a new version of the time zone file

**Note**
During the time zone file update, RDS for Oracle calls `PURGE_DBA_RECYCLEBIN`.

**Strategies for updating your time zone file**

You can upgrade your engine and update your time zone file independently. Thus, you must choose among different update strategies.

The examples in this section assume that your instance uses database version 19.0.0.0.ru-2019-07.rur-2019-07.r1 and time zone file DSTv33. Your DB instance file system includes file DSTv34. Also assume that release update 19.0.0.0.ru-2021-01.rur-2021-01.r1 includes DSTv35. To update your time zone file, you can use the following strategies:

• Update the time zone file used by your database without upgrading the DB engine version.

  Update the time zone file used by your instance from DSTv33 to DSTv34. In your modify instance operation, do the following:
  • Add `TIMEZONE_FILE_AUTOUPGRADE` to the option group used by your instance.
  • Don't change your engine version.

• Upgrade your DB engine version and the time zone file in the same operation.

  Upgrade your engine to version 19.0.0.0.ru-2021-01.rur-2021-01.r1 and update your time zone file to DSTv35 in the same operation. In your modify instance operation, do the following:
  • Add `TIMEZONE_FILE_AUTOUPGRADE` to the option group used by your instance.
  • Change your engine version.

• Upgrade your DB engine version without updating the time zone file.

  Upgrade your database to version 19.0.0.0.ru-2021-01.rur-2021-01.r1 but retain time zone file DSTv33. In this case, the possibilities are as follows:
  • Your instance isn't associated with an option group that includes `TIMEZONE_FILE_AUTOUPGRADE`. Leave the option group as it is.
  • Your instance is associated with an option group that includes `TIMEZONE_FILE_AUTOUPGRADE`. Associate your instance with an option group that doesn't have `TIMEZONE_FILE_AUTOUPGRADE`. Then modify the engine version.

You might choose this strategy for the following reasons:

• Your data doesn't use the `TIMESTAMP WITH TIME ZONE` data type.
• Your data uses the `TIMESTAMP WITH TIME ZONE` data type, but your data is not affected by the time zone changes.
• You want to postpone updating the time zone file because you can't tolerate the extra downtime.
Preparing to update the time zone file

A time zone file upgrade has two separate phases: prepare and upgrade. While not required, we strongly recommend that you perform the prepare step. In this step, you find out which data will be affected by running the PL/SQL procedure `DBMS_DST.FIND_AFFECTED_TABLES`. For more information about the prepare window, see Upgrading the Time Zone File and Timestamp with Time Zone Data in the Oracle Database documentation.

To prepare to update the time zone file

1. Connect to your Oracle database using a SQL client.
2. Determine the current timezone file version used.

   ```sql
   SELECT * FROM V$TIMEZONE_FILE;
   ```

3. Determine the latest timezone file version available on your DB instance. This step is only applicable if you use Oracle Database 12c Release 2 (12.2) or higher.

   ```sql
   SELECT DBMS_DST.GET_LATEST_TIMEZONE_VERSION FROM DUAL;
   ```

4. Determine the total size of tables that have columns of type `TIMESTAMP WITH LOCAL TIME ZONE` or `TIMESTAMP WITH TIME ZONE`.

   ```sql
   SELECT SUM(BYTES)/1024/1024/1024 "Total_size_w_TSTZ_columns_GB"
   FROM DBA_SEGMENTS
   WHERE SEGMENT_TYPE LIKE 'TABLE'
   AND (SELECT OWNER, TABLE_NAME
        FROM DBA_TAB_COLUMNS
        WHERE DATA_TYPE LIKE 'TIMESTAMP%TIME ZONE')
   GROUP BY OWNER, SEGMENT_NAME;
   ```

5. Determine the names and sizes of segments that have columns of type `TIMESTAMP WITH LOCAL TIME ZONE` or `TIMESTAMP WITH TIME ZONE`.

   ```sql
   SELECT OWNER, SEGMENT_NAME, SUM(BYTES)/1024/1024/1024 "SEGMENT_SIZE_W_TSTZ_COLUMNS_GB"
   FROM DBA_SEGMENTS
   WHERE SEGMENT_TYPE LIKE 'TABLE'
   AND (SELECT OWNER, TABLE_NAME
        FROM DBA_TAB_COLUMNS
        WHERE DATA_TYPE LIKE 'TIMESTAMP%TIME ZONE')
   GROUP BY OWNER, SEGMENT_NAME;
   ```

6. Run the prepare step.

   - The procedure `DBMS_DST.CREATE_AFFECTED_TABLE` creates a table to store any affected data. You pass the name of this table to the `DBMS_DST.FIND_AFFECTED_TABLES` procedure. For more information, see CREATE_AFFECTED_TABLE Procedure in the Oracle Database documentation.
   - This procedure `CREATE_ERROR_TABLE` creates a table to log errors. For more information, see CREATE_ERROR_TABLE Procedure in the Oracle Database documentation.

The following example creates the affected data and error tables, and finds all affected tables.

```sql
EXEC DBMS_DST.CREATE_ERROR_TABLE('my_error_table')
EXEC DBMS_DST.CREATE_AFFECTED_TABLE('my_affected_table')
EXEC DBMS_DST.BEGIN_PREPARE(new_version);
EXEC DBMS_DST.FIND_AFFECTED_TABLES('my_affected_table', TRUE, 'my_error_table');
```
Adding the time zone file autoupgrade option

The procedure for adding the time zone autoupgrade option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When you add the option, a brief outage occurs while your DB instance is automatically restarted.

**Console**

**To add the time zone file autoupgrade option to a DB instance**

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine** choose the oracle edition for your DB instance.
   b. For **Major engine version** choose the version of your DB instance.

   For more information, see Creating an option group (p. 280).

2. Add the **TIMEZONE_FILE_AUToupgrade** option to the option group.

   **Important**
   
   If you add the option to an existing option group that is already attached to one or more DB instances, a brief outage occurs while all the DB instances are automatically restarted.

3. Apply the option group to a new or existing DB instance:

   • For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 236).
   • For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the time zone option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance (p. 333).

**AWS CLI**

The following example uses the AWS CLI `add-option-to-option-group` command to add the **TIMEZONE_FILE_AUToupgrade** option to an option group called `myoptiongroup`.

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group
```
Checking your data after the update of the time zone file

We recommend that you check your data after you update the time zone file. During the prepare step, RDS for Oracle automatically creates the following tables:

- `rdsadmin.rds_dst_affected_tables` – Lists the tables that contain data affected by the update
- `rdsadmin.rds_dst_error_table` – Lists the errors generated during the update

These tables are independent of any tables that you create in the prepare window. To see the results of the update, query the tables as follows.

```
SELECT * FROM rdsadmin.rds_dst_affected_tables;
SELECT * FROM rdsadmin.rds_dst_error_table;
```

For more information about the schema for the affected data and error tables, see `FIND_AFFECTED_TABLES Procedure` in the Oracle documentation.
Oracle Transparent Data Encryption

Amazon RDS supports Oracle Transparent Data Encryption (TDE), a feature of the Oracle Advanced Security option available in Oracle Enterprise Edition. This feature automatically encrypts data before it is written to storage and automatically decrypts data when the data is read from storage.

Oracle Transparent Data Encryption is used in scenarios where you need to encrypt sensitive data in case data files and backups are obtained by a third party or when you need to address security-related regulatory compliance issues.

The TDE option is a permanent option that can't be removed from an option group. You can't disable TDE from a DB instance once that instance is associated with an option group with the Oracle TDE option. You can change the option group of a DB instance that is using the TDE option, but the option group associated with the DB instance must include the TDE option. You can also modify an option group that includes the TDE option by adding or removing other options.

A detailed explanation about Oracle Transparent Data Encryption is beyond the scope of this guide. For information about using Oracle Transparent Data Encryption, see Securing stored data using Transparent Data Encryption. For more information about Oracle Advanced Security, see Oracle advanced security in the Oracle documentation. For more information on AWS security, see the AWS security center.

Note
You can't share a DB snapshot that uses this option. For more information about sharing DB snapshots, see Sharing a DB snapshot (p. 507).

TDE encryption modes

Oracle Transparent Data Encryption supports two encryption modes: TDE tablespace encryption and TDE column encryption. TDE tablespace encryption is used to encrypt entire application tables. TDE column encryption is used to encrypt individual data elements that contain sensitive data. You can also apply a hybrid encryption solution that uses both TDE tablespace and column encryption.

Note
Amazon RDS manages the Oracle Wallet and TDE master key for the DB instance. You do not need to set the encryption key using the command ALTER SYSTEM set encryption key.

For information about TDE best practices, see Oracle advanced security Transparent Data Encryption best practices.

Once the option is enabled, you can check the status of the Oracle Wallet by using the following command:

```sql
SELECT * FROM v$encryption_wallet;
```

To create an encrypted tablespace, use the following command:

```sql
CREATE TABLESPACE encrypt_ts ENCRYPTION DEFAULT STORAGE (ENCRYPT);
```

To specify the encryption algorithm, use the following command:

```sql
CREATE TABLESPACE encrypt_ts ENCRYPTION USING 'AES256' DEFAULT STORAGE (ENCRYPT);
```

Note that the previous commands for encrypting a tablespace are the same as the commands you would use with an Oracle installation not on Amazon RDS, and the ALTER TABLE syntax to encrypt a column is also the same as the commands you would use for an Oracle installation not on Amazon RDS.
You should determine if your DB instance is associated with an option group that has the **TDE** option. To view the option group that a DB instance is associated with, you can use the RDS console, the `describe-db-instance` AWS CLI command, or the API operation `DescribeDBInstances`.

To comply with several security standards, Amazon RDS is working to implement automatic periodic master key rotation.

### Adding the TDE option

The process for using Oracle Transparent Data Encryption (TDE) with Amazon RDS is as follows:

1. If the DB instance is not associated with an option group that has the **TDE** option enabled, you must either create an option group and add the **TDE** option or modify the associated option group to add the **TDE** option. For information about creating or modifying an option group, see Working with option groups (p. 279). For information about adding an option to an option group, see Adding an option to an option group (p. 283).
2. Associate the DB instance with the option group with the **TDE** option. For information about associating a DB instance with an option group, see Modifying an Amazon RDS DB instance (p. 333).

### Removing the TDE option

To remove the **TDE** option with a DB instance, complete the following steps:

1. Decrypt all your data on the DB instance.
2. Copy the data to a new DB instance that is not associated with an option group with **TDE** enabled.
3. Delete the original instance.

You can name the new instance the same name as the previous DB instance.

### Using TDE with Oracle Data Pump

You can use Oracle Data Pump to import or export encrypted dump files. Amazon RDS supports the password encryption mode (`ENCRYPTION_MODE=PASSWORD`) for Oracle Data Pump. Amazon RDS does not support transparent encryption mode (`ENCRYPTION_MODE=TRANSPARENT`) for Oracle Data Pump. For more information about using Oracle Data Pump with Amazon RDS, see Importing using Oracle Data Pump (p. 1668).
Oracle UTL_MAIL

Amazon RDS supports Oracle UTL_MAIL through the use of the UTL_MAIL option and SMTP servers. You can send email directly from your database by using the UTL_MAIL package. Amazon RDS supports UTL_MAIL for the following versions of Oracle:

- Oracle Database 21c (21.0.0.0), all versions
- Oracle Database 19c (19.0.0.0), all versions
- Oracle Database 12c Release 2 (12.2), all versions
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v5 and later

The following are some limitations to using UTL_MAIL:

- UTL_MAIL does not support Transport Layer Security (TLS) and therefore emails are not encrypted.
  To connect securely to remote SSL/TLS resources by creating and uploading custom Oracle wallets, follow the instructions in Configuring UTL_HTTP access using certificates and an Oracle wallet (p. 1565).

  The specific certificates that are required for your wallet vary by service. For AWS services, these can typically be found in the Amazon trust services repository.

- UTL_MAIL does not support authentication with SMTP servers.
- You can only send a single attachment in an email.
- You can't send attachments larger than 32 K.
- You can only use ASCII and Extended Binary Coded Decimal Interchange Code (EBCDIC) character encodings.
- SMTP port (25) is throttled based on the elastic network interface owner's policies.

When you enable UTL_MAIL, only the master user for your DB instance is granted the execute privilege. If necessary, the master user can grant the execute privilege to other users so that they can use UTL_MAIL.

Important
We recommend that you enable Oracle's built-in auditing feature to track the use of UTL_MAIL procedures.

Prerequisites for Oracle UTL_MAIL

The following are prerequisites for using Oracle UTL_MAIL:

- One or more SMTP servers, and the corresponding IP addresses or public or private Domain Name Server (DNS) names. For more information about private DNS names resolved through a custom DNS server, see Setting up a custom DNS server (p. 1591).
- For Oracle versions prior to 12c, your DB instance must also use the XML DB option. For more information, see Oracle XML DB (p. 1808).

Adding the Oracle UTL_MAIL option

The general process for adding the Oracle UTL_MAIL option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

After you add the UTL_MAIL option, as soon as the option group is active, UTL_MAIL is active.

**To add the UTL_MAIL option to a DB instance**

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the edition of Oracle you want to use.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see *Creating an option group* (p. 280).

2. Add the **UTL_MAIL** option to the option group. For more information about adding options, see *Adding an option to an option group* (p. 283).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see *Creating an Amazon RDS DB instance* (p. 236).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see *Modifying an Amazon RDS DB instance* (p. 333).

**Using Oracle UTL_MAIL**

After you enable the UTL_MAIL option, you must configure the SMTP server before you can begin using it.

You configure the SMTP server by setting the SMTP_OUT_SERVER parameter to a valid IP address or public DNS name. For the SMTP_OUT_SERVER parameter, you can specify a comma-separated list of the addresses of multiple servers. If the first server is unavailable, UTL_MAIL tries the next server, and so on.

You can set the default SMTP_OUT_SERVER for a DB instance by using a **DB parameter group**. You can set the SMTP_OUT_SERVER parameter for a session by running the following code on your database on your DB instance.

```sql
ALTER SESSION SET smtp_out_server = mailserver.domain.com:25;
```

After the UTL_MAIL option is enabled, and your SMTP_OUT_SERVER is configured, you can send mail by using the **SEND** procedure. For more information, see **UTL_MAIL** in the Oracle documentation.

**Removing the Oracle UTL_MAIL option**

You can remove Oracle UTL_MAIL from a DB instance.

To remove UTL_MAIL from a DB instance, do one of the following:

- To remove UTL_MAIL from multiple DB instances, remove the UTL_MAIL option from the option group they belong to. This change affects all DB instances that use the option group. For more information, see *Removing an option from an option group* (p. 291).
- To remove UTL_MAIL from a single DB instance, modify the DB instance and specify a different option group that doesn't include the UTL_MAIL option. You can specify the default (empty) option group.
group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 333).

Troubleshooting

The following are issues you might encounter when you use UTL_MAIL with Amazon RDS.

- Throttling. SMTP port (25) is throttled based on the elastic network interface owner's policies. If you can successfully send email by using UTL_MAIL, and you see the error ORA-29278: SMTP transient error: 421 Service not available, you are possibly being throttled. If you experience throttling with email delivery, we recommend that you implement a backoff algorithm. For more information about backoff algorithms, see Error retries and exponential backoff in AWS and How to handle a “throttling – Maximum sending rate exceeded” error.

You can request that this throttle be removed. For more information, see How do I remove the throttle on port 25 from my EC2 instance?
Oracle XML DB

Oracle XML DB adds native XML support to your DB instance. With XML DB, you can store and retrieve structured or unstructured XML, in addition to relational data. XML DB is preinstalled on Oracle version 12c and later.
Upgrading the RDS for Oracle DB engine

When Amazon RDS supports a new version of Oracle, you can upgrade your DB instances to the new version. For information about which Oracle versions are available on Amazon RDS, see Amazon RDS for Oracle Release Notes.

Important
RDS for Oracle Database 11g is deprecated. If you maintain Oracle Database 11g snapshots, you can upgrade them to a later release. For more information, see Upgrading an Oracle DB snapshot (p. 1816).

Topics
- Overview of RDS for Oracle engine upgrades (p. 1809)
- Oracle major version upgrades (p. 1811)
- Oracle minor version upgrades (p. 1812)
- Considerations for Oracle DB upgrades (p. 1813)
- Testing an Oracle DB upgrade (p. 1815)
- Upgrading an Oracle DB instance (p. 1816)
- Upgrading an Oracle DB snapshot (p. 1816)

Overview of RDS for Oracle engine upgrades

Before upgrading your RDS for Oracle DB instance, familiarize yourself with the following concepts.

Topics
- Major and minor version upgrades (p. 1809)
- Expected support dates for RDS for Oracle major releases (p. 1810)
- Oracle engine version management (p. 1810)
- Automatic snapshots during engine upgrades (p. 1810)
- Oracle upgrades in a Multi-AZ deployment (p. 1811)
- Oracle upgrades of read replicas (p. 1811)
- Oracle upgrades of micro DB instances (p. 1811)

Major and minor version upgrades

Amazon RDS supports the following upgrades to an Oracle DB instance:

- Major version upgrades
  
  In general, a major version upgrade for a database engine can introduce changes that aren't compatible with existing applications. To upgrade your DB instance to a major version, you must perform the action manually.

- Minor version upgrades

  A minor version upgrade includes only changes that are backward-compatible with existing applications. If you enable auto minor version upgrades on your DB instance, minor version upgrades occur automatically. In all other cases, you upgrade the DB instance manually.

When you upgrade the DB engine, an outage occurs. The duration of the outage depends on your engine version and instance size.
Expected support dates for RDS for Oracle major releases

RDS for Oracle major versions remain available at least until the end of support date for the corresponding Oracle Database release version. You can use the following dates to plan your testing and upgrade cycles. These dates represent the earliest date that an upgrade to a newer version might be required. If Amazon extends support for an RDS for Oracle version for longer than originally stated, we plan to update this table to reflect the later date.

<table>
<thead>
<tr>
<th>Oracle Database major release version</th>
<th>Expected date for upgrading to a newer version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Database 19c</td>
<td>April 30, 2024 without Extended Support or an Unlimited License Agreement</td>
</tr>
<tr>
<td></td>
<td>April 30, 2027 with Extended Support or an Unlimited License Agreement</td>
</tr>
<tr>
<td>Oracle Database 21c</td>
<td>April 30, 2024</td>
</tr>
</tbody>
</table>

Before we ask that you upgrade to a newer major version and to help you plan, we provide a reminder at least 12 months in advance. We do so to communicate the detailed upgrade process. Details include the timing of certain milestones, the impact on your DB instances, and the actions that we recommend that you take. We recommend that you thoroughly test your applications with new RDS for Oracle versions before performing a major version upgrade.

After this advance notification period, an automatic upgrade to the subsequent major version might be applied to any RDS for Oracle DB instance still running the older version. If so, the upgrade is started during scheduled maintenance windows.

Oracle engine version management

With DB engine version management, you control when and how the database engine is patched and upgraded. You get the flexibility to maintain compatibility with database engine patch versions. You can also test new patch versions of RDS for Oracle to ensure they work with your application before deploying them in production. In addition, you upgrade the versions on your own terms and timelines.

Note
Amazon RDS periodically aggregates official Oracle database patches using an Amazon RDS-specific DB engine version. To see a list of which Oracle patches are contained in an Amazon RDS Oracle-specific engine version, go to Amazon RDS for Oracle Release Notes.

Automatic snapshots during engine upgrades

During upgrades of an Oracle DB instance, snapshots offer protection against upgrade issues. If the backup retention period for your DB instance is greater than 0, Amazon RDS takes the following DB snapshots during the upgrade:

1. A snapshot of the DB instance before any upgrade changes have been made. If the upgrade fails, you can restore this snapshot to create a DB instance running the old version.
2. A snapshot of the DB instance after the upgrade completes.

Note
To change your backup retention period, see Modifying an Amazon RDS DB instance (p. 333).

After an upgrade, you can't revert to the previous engine version. However, you can create a new Oracle DB instance by restoring the pre-upgrade snapshot.
Oracle upgrades in a Multi-AZ deployment

If your DB instance is in a Multi-AZ deployment, Amazon RDS upgrades both the primary and standby replicas. If no operating system updates are required, the primary and standby upgrades occur simultaneously. The instances are not available until the upgrade completes.

If operating system updates are required in a Multi-AZ deployment, Amazon RDS applies the updates when you request the DB upgrade. Amazon RDS performs the following steps:

1. Updates the operating system on the standby DB instance.
2. Upgrades the standby DB instance.
3. Fails over the primary instance to the standby DB instance.
4. Upgrades the operating system on the new standby DB instance, which was formerly the primary instance.
5. Upgrades the new standby DB instance.

Oracle upgrades of read replicas

The Oracle DB engine version of the source DB instance and all of its read replicas must be the same. Amazon RDS performs the upgrade in the following stages:

1. Upgrades the source DB instance. The read replicas are available during this stage.
2. Upgrades the read replicas in parallel, regardless of the replica maintenance windows. The source DB is available during this stage.

For major version upgrades of cross-Region read replicas, Amazon RDS performs additional actions:

- Generates an option group for the target version automatically
- Copies all options and option settings from the original option group to the new option group
- Associates the upgraded cross-Region read replica with the new option group

Oracle upgrades of micro DB instances

We don't recommend upgrading databases running on micro DB instances. Because these instances have limited CPU, the upgrade can take hours to complete.

You can upgrade micro DB instances with small amounts of storage (10–20 GiB) by copying your data using Data Pump. Before you migrate your production DB instances, we recommend that you test by copying data using Data Pump.

Oracle major version upgrades

To perform a major version upgrade, modify the DB instance manually. Major version upgrades don't occur automatically.

Supported versions for major upgrades

Amazon RDS supports the following major version upgrades.

<table>
<thead>
<tr>
<th>Current version</th>
<th>Upgrade supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>19.0.0.0 using the CDB architecture</td>
<td>21.0.0.0</td>
</tr>
</tbody>
</table>
A major version upgrade of Oracle Database must upgrade to a Release Update (RU) that was released in the same month or later. Major version downgrades aren't supported for any Oracle Database versions.

**Supported instance classes for major upgrades**

Your current Oracle DB instance might run on a DB instance class that isn't supported for the version to which you are upgrading. In this case, before you upgrade, migrate the DB instance to a supported DB instance class. For more information about the supported DB instance classes for each version and edition of Amazon RDS for Oracle, see [DB instance classes](p. 10).

**Gathering statistics before major upgrades**

Before you perform a major version upgrade, Oracle recommends that you gather optimizer statistics on the DB instance that you are upgrading. This action can reduce DB instance downtime during the upgrade.

To gather optimizer statistics, connect to the DB instance as the master user, and run the `DBMS_STATS.GATHER_DICTIONARY_STATS` procedure, as in the following example.

```
EXEC DBMS_STATS.GATHER_DICTIONARY_STATS;
```

For more information, see [Gathering optimizer statistics to decrease Oracle database downtime](p. 369) in the Oracle documentation.

**Allowing major upgrades**

A major engine version upgrade might be incompatible with your application. The upgrade is irreversible. If you specify a major version for the `EngineVersion` parameter that is different from the current major version, you must allow major version upgrades.

If you upgrade a major version using the CLI command `modify-db-instance`, specify `--allow-major-version-upgrade`. This setting isn't persistent, so you must specify `--allow-major-version-upgrade` whenever you perform a major upgrade. This parameter has no impact on upgrades of minor engine versions. For more information, see [Upgrading a DB instance engine version](p. 369).

If you upgrade a major version using the console, you don't need to choose an option to allow the upgrade. Instead, the console displays a warning that major upgrades are irreversible.

**Oracle minor version upgrades**

A minor version upgrade applies an Oracle Database Patch Set Update (PSU) or Release Update (RU) in a major version.

An Amazon RDS for Oracle DB instance is scheduled to be upgraded automatically during its next maintenance window when it meets the following conditions:

- The DB instance has the **Auto minor version upgrade** option enabled.
- The DB instance is not running the latest minor DB engine version.

Amazon RDS for Oracle upgrades your DB instance to the latest quarterly RU or RUR four to six weeks after it is made available. For more information about RUs and RURs, see [Amazon RDS for Oracle Release Notes](p. 10).

**Note**

RDS for Oracle doesn't support minor version downgrades.
Considerations for Oracle DB upgrades

Before you upgrade your Oracle instance, review the following information.

Topics

• Oracle Multitenant considerations (p. 1813)
• Option group considerations (p. 1813)
• Parameter group considerations (p. 1814)
• Time zone considerations (p. 1814)
• Oracle Database 12c upgrade considerations (p. 1814)

Oracle Multitenant considerations

The following table describes the architectures supported in different releases.

<table>
<thead>
<tr>
<th>Oracle Database release</th>
<th>Architecture</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Database 21c</td>
<td>CDB only</td>
</tr>
<tr>
<td>Oracle Database 19c</td>
<td>CDB or non-CDB</td>
</tr>
<tr>
<td>Oracle Database 12c Release 2 (12.2)</td>
<td>Non-CDB only</td>
</tr>
<tr>
<td>Oracle Database 12c Release 1 (12.1)</td>
<td>Non-CDB only</td>
</tr>
</tbody>
</table>

The following table describes supported and unsupported upgrade paths.

<table>
<thead>
<tr>
<th>Upgrade path</th>
<th>Supported?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-CDB to non-CDB</td>
<td>Yes</td>
</tr>
<tr>
<td>CDB to CDB</td>
<td>Yes</td>
</tr>
<tr>
<td>Non-CDB to CDB</td>
<td>No</td>
</tr>
<tr>
<td>CDB to non-CDB</td>
<td>No</td>
</tr>
</tbody>
</table>

For more information about Oracle Multitenant in RDS for Oracle, see RDS for Oracle architecture (p. 1533).

Option group considerations

If your DB instance uses a custom option group, sometimes Amazon RDS can't automatically assign a new option group. For example, this situation occurs when you upgrade to a new major version. In such cases, specify a new option group when you upgrade. We recommend that you create a new option group, and add the same options to it as in your existing custom option group.

For more information, see Creating an option group (p. 280) or Copying an option group (p. 282).

If your DB instance uses a custom option group that contains the APEX option, you can sometimes reduce the upgrade time. To do this, upgrade your version of APEX at the same time as your DB instance. For more information, see Upgrading the APEX version (p. 1725).
Parameter group considerations

If your DB instance uses a custom parameter group, sometimes Amazon RDS can't automatically assign your DB instance a new parameter group. For example, this situation occurs when you upgrade to a new major version. In such cases, make sure to specify a new parameter group when you upgrade. We recommend that you create a new parameter group, and configure the parameters as in your existing custom parameter group.

For more information, see Creating a DB parameter group (p. 297) or Copying a DB parameter group (p. 304).

Time zone considerations

You can use the time zone option to change the system time zone used by your Oracle DB instance. For example, you might change the time zone of a DB instance to be compatible with an on-premises environment, or a legacy application. The time zone option changes the time zone at the host level. Amazon RDS for Oracle updates the system time zone automatically throughout the year. For more information about the system time zone, see Oracle time zone (p. 1794).

When you create an Oracle DB instance, the database automatically sets the database time zone. The database time zone is also known as the Daylight Saving Time (DST) time zone. The database time zone is distinct from the system time zone.

Between Oracle Database releases, patch sets or individual patches may include new DST versions. These patches reflect the changes in transition rules for various time zone regions. For example, a government might change when DST takes effect. Changes to DST rules may affect existing data of the TIMESTAMP WITH TIME ZONE data type.

If you upgrade an RDS for Oracle DB instance, Amazon RDS doesn't upgrade the database time zone file automatically. To upgrade the time zone file automatically, you can include the TIMEZONE_FILE_AUTOUPGRADE option in the option group associated with your DB instance during or after the engine version upgrade. For more information, see Oracle time zone file autoupgrade (p. 1798).

Alternatively, to upgrade the database time zone file manually, create a new Oracle DB instance that has the desired DST patch. However, we recommend that you upgrade the database time zone file using the TIMEZONE_FILE_AUTOUPGRADE option.

After upgrading the time zone file, migrate the data from your current instance to the new instance. You can migrate data using several techniques, including the following:

- AWS Database Migration Service
- Oracle GoldenGate
- Oracle Data Pump
- Original Export/Import (desupported for general use)

**Note**

When you migrate data using Oracle Data Pump, the utility raises the error ORA-39405 when the target time zone version is lower than the source time zone version.

For more information, see TIMESTAMP WITH TIMEZONE restrictions in the Oracle documentation.

Oracle Database 12c upgrade considerations

Amazon RDS has deprecated support for Oracle Database 12c on both Oracle Enterprise Edition and Oracle Standard Edition 2. As explained in Oracle Database 12c with Amazon RDS (p. 1525), Amazon RDS
began automatically upgrading Oracle Database 12c DB instances to Oracle Database 19c. You can no longer upgrade manually. The automatic upgrades began on the following dates:

- April 1, 2022 for Oracle Database 12c Release 2 (12.2.0.1)
- August 1, 2022 for Oracle Database 12c Release 1 (12.1.0.2)

The automatic upgrades are not guaranteed to occur in your maintenance window. All Oracle Database 12c DB instances, including reserved instances, will move to the latest available Release Update (RU).

After your Oracle Database 12c DB instance is upgraded to Oracle Database 19c, consider the following:

- Your SQL statements might perform differently after the upgrade. If so, you can use the OPTIMIZER_FEATURES_ENABLE parameter to retain the behavior of the Oracle Database 12c optimizer. For more information, see Influencing the Optimizer in the Oracle Database documentation.
- If you have Extended Support for Oracle Database 12c on the BYOL model, consider the implications. In this case, you must have Extended Support agreements from Oracle Support for Oracle Database 19c. For details on licensing and support requirements for BYOL, see Amazon RDS for Oracle FAQs.

**Testing an Oracle DB upgrade**

Before you upgrade your DB instance to a major version, thoroughly test your database and all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.

**To test a major version upgrade**

1. Review the Oracle upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications. For more information, see Database Upgrade Guide in the Oracle documentation.
2. If your DB instance uses a custom option group, create a new option group compatible with the new version you are upgrading to. For more information, see Option group considerations (p. 1813).
3. If your DB instance uses a custom parameter group, create a new parameter group compatible with the new version you are upgrading to. For more information, see Parameter group considerations (p. 1814).
4. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot (p. 483).
5. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring from a DB snapshot (p. 487).
6. Modify this new test DB instance to upgrade it to the new version, by using one of the following methods:
   - Console (p. 369)
   - AWS CLI (p. 370)
   - RDS API (p. 370)
7. Perform testing:
   - Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version.
   - Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1.
   - Test all stored procedures, functions, and triggers.
   - Direct test versions of your applications to the upgraded DB instance. Verify that the applications work correctly with the new version.
• Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage. You might need to choose a larger instance class to support the new version in production. For more information, see DB instance classes (p. 10).

8. If all tests pass, upgrade your production DB instance. We recommend that you confirm that the DB instance working correctly before allowing write operations to the DB instance.

Upgrading an Oracle DB instance

To learn how to upgrade an Oracle DB instance, see Upgrading a DB instance engine version (p. 369).

Upgrading an Oracle DB snapshot

If you have existing manual DB snapshots, you can upgrade them to a later version of the Oracle database engine.

When Oracle stops providing patches for a version, and Amazon RDS deprecates the version, you can upgrade your snapshots that correspond to the deprecated version. For more information, see Oracle engine version management (p. 1810).

Amazon RDS supports upgrading snapshots in all AWS Regions.

Console

To upgrade an Oracle DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose Snapshots, and then select the DB snapshot that you want to upgrade.

3. For Actions, choose Upgrade snapshot. The Upgrade snapshot page appears.

4. Choose the New engine version to upgrade the snapshot to.

5. (Optional) For Option group, choose the option group for the upgraded DB snapshot. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations (p. 1813).

6. Choose Save changes to save your changes.

During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from available to upgrading, and then changes to active upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to unavailable. You can't recover the snapshot from this state.

Note
If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade an Oracle DB snapshot by using the AWS CLI, call the modify-db-snapshot command with the following parameters:

• --db-snapshot-identifier – The name of the DB snapshot.
• --engine-version – The version to upgrade the snapshot to.
You might also need to include the following parameter. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations (p. 1813).

- `--option-group-name` – The option group for the upgraded DB snapshot.

**Example**

The following example upgrades a DB snapshot.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \
    --db-snapshot-identifier mydbsnapshot \
    --engine-version 19.0.0.0.ru-2020-10.rur-2020-10.r1 \
    --option-group-name default:oracle-se2-19
```

For Windows:

```
aws rds modify-db-snapshot ^
    --db-snapshot-identifier mydbsnapshot ^
    --engine-version 19.0.0.0.ru-2020-10.rur-2020-10.r1 ^
    --option-group-name default:oracle-se2-19
```

**RDS API**

To upgrade an Oracle DB snapshot by using the Amazon RDS API, call the `ModifyDBSnapshot` operation with the following parameters:

- `DBSnapshotIdentifier` – The name of the DB snapshot.
- `EngineVersion` – The version to upgrade the snapshot to.

You might also need to include the `OptionGroupName` parameter. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations (p. 1813).
Using third-party software with your RDS for Oracle DB instance

To use tools and third-party software with RDS for Oracle DB instances, review the information in the following sections.

Topics
- Setting up Amazon RDS to host tools and third-party software for Oracle (p. 1819)
- Using Oracle GoldenGate with Amazon RDS for Oracle (p. 1825)
- Using the Oracle Repository Creation Utility on RDS for Oracle (p. 1838)
- Configuring Oracle Connection Manager on an Amazon EC2 instance (p. 1844)
- Installing a Siebel database on Oracle on Amazon RDS (p. 1846)
Setting up Amazon RDS to host tools and third-party software for Oracle

You can use Amazon RDS to host an Oracle DB instance that supports software and components such as the following:

- Siebel Customer Relationship Management (CRM)
- Oracle Fusion Middleware Metadata — installed by the Repository Creation Utility (RCU)

The following procedures help you create an Oracle DB instance on Amazon RDS that you can use to host additional software and components for Oracle.

Topics
- Creating a VPC for use with an Oracle database (p. 1819)
- Creating an Oracle DB instance (p. 1824)
- Additional Amazon RDS interfaces (p. 1824)

Creating a VPC for use with an Oracle database

In the following procedure, you create a virtual private cloud (VPC) based on the Amazon VPC service, a private subnet, and a security group. Your Amazon RDS DB instance needs to be available only to your middle-tier components, and not to the public internet. Thus, your Amazon RDS DB instance is hosted in a private subnet, providing greater security.

To create a VPC based on Amazon VPC

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region for your VPC. This example uses the US West (Oregon) region.
3. In the upper-left corner, choose VPC Dashboard, and then choose Start VPC Wizard.
4. On the page Step 1: Select a VPC Configuration, choose VPC with Public and Private Subnets, and then choose Select.
5. On the page Step 2: VPC with Public and Private Subnets, shown following, set the following values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv4 CIDR block</td>
<td>10.0.0.0/16</td>
</tr>
<tr>
<td></td>
<td>For more information about selecting CIDR blocks for your VPC, see VPC sizing.</td>
</tr>
<tr>
<td>IPv6 CIDR block</td>
<td>No IPv6 CIDR Block</td>
</tr>
<tr>
<td>VPC name</td>
<td>The name for your VPC, for example vpc-1.</td>
</tr>
<tr>
<td>Public subnet's IPv4 CIDR</td>
<td>10.0.0.0/24</td>
</tr>
<tr>
<td></td>
<td>For more information about subnet sizing, see Subnet sizing.</td>
</tr>
<tr>
<td>Availability Zone</td>
<td>An Availability Zone for your AWS Region.</td>
</tr>
</tbody>
</table>
### Setting up

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Public subnet name</strong></td>
<td>The name for your public subnet, for example <code>subnet-public-1</code>.</td>
</tr>
<tr>
<td><strong>Private subnet's IPv4 CIDR</strong></td>
<td>10.0.1.0/24</td>
</tr>
<tr>
<td></td>
<td>For more information about subnet sizing, see <a href="#">Subnet sizing</a>.</td>
</tr>
<tr>
<td><strong>Availability Zone</strong></td>
<td>An Availability Zone for your AWS Region.</td>
</tr>
<tr>
<td><strong>Private subnet name</strong></td>
<td>The name for your private subnet, for example <code>subnet-private-1</code>.</td>
</tr>
<tr>
<td><strong>Instance type</strong></td>
<td>An instance type for your NAT instance, for example <code>t2.small</code>.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td>If you don't see <strong>Instance type</strong> in the console, choose <strong>Use a NAT instance instead</strong>.</td>
</tr>
<tr>
<td><strong>Key pair name</strong></td>
<td>No key pair</td>
</tr>
<tr>
<td><strong>Service endpoints</strong></td>
<td>None</td>
</tr>
<tr>
<td><strong>Enable DNS hostnames</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Hardware tenancy</strong></td>
<td>Default</td>
</tr>
</tbody>
</table>
6. Choose **Create VPC**.

An Amazon RDS DB instance in a VPC requires at least two private subnets or at least two public subnets, to support Multi-AZ deployment. For more information about working with multiple Availability Zones, see *Regions, Availability Zones, and Local Zones* (p. 79). Because your database is private, add a second private subnet to your VPC.

**To create an additional subnet**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose **VPC Dashboard**, choose **Subnets**, and then choose **Create Subnet**.
4. On the **Create Subnet** page, set the following values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name tag</strong></td>
<td>The name for your second private subnet, for example <strong>subnet-private-2</strong>.</td>
</tr>
<tr>
<td><strong>VPC</strong></td>
<td>Your VPC, for example <strong>vpc-1</strong>.</td>
</tr>
</tbody>
</table>
| **Availability Zone** | An Availability Zone for your AWS Region.  
  **Note**  
  Choose an Availability Zone different from the one that you chose for the first private subnet. |
| **CIDR block**     | 10.0.2.0/24                                                            |

5. Choose **Yes, Create**.

Both private subnets must use the same route table. In the following procedure, you check to make sure the route tables match, and if not you edit one of them.

**To ensure the subnets use the same route table.**

1. Sign in to the AWS Management Console and open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose **VPC Dashboard**, choose **Subnets**, and then choose your first private subnet, for example **subnet-private-1**.
4. At the bottom of the console, choose the **Route Table** tab, shown following.

![Route Table Screenshot](image)

5. Make a note of the route table, for example **rtb-0d9fc668**.
6. In the list of subnets, choose the second private subnet, for example **subnet-private-2**.
7. At the bottom of the console, choose the **Route Table** tab.
8. If the route table for the second subnet is not the same as the route table for the first subnet, edit it to match:
   a. Choose **Edit**.
   b. For **Change to**, choose the route table that matches your first subnet.
   c. Choose **Save**.
A security group acts as a virtual firewall for your DB instance to control inbound and outbound traffic. In the following procedure, you create a security group for your DB instance. For more information about security groups, see Security groups for your VPC.

**To create a VPC security group for a private Amazon RDS DB instance**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose VPC Dashboard, choose Security Groups, and then choose Create Security Group.
4. On the page Create Security Group, set the following values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name tag</td>
<td>The name for your security group, for example sgdb-1.</td>
</tr>
<tr>
<td>Group name</td>
<td>The name for your security group, for example sgdb-1.</td>
</tr>
<tr>
<td>Description</td>
<td>A description for your security group.</td>
</tr>
<tr>
<td>VPC</td>
<td>Your VPC, for example vpc-1.</td>
</tr>
</tbody>
</table>

5. Choose Yes, Create.

In the following procedure, you add rules to your security group to control inbound traffic to your DB instance. For more information about inbound rules, see Security group rules.

**To add inbound rules to the security group**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose VPC Dashboard, choose Security Groups, and then choose your security group, for example sgdb-1.
4. At the bottom of the console, choose the Inbound Rules tab, and then choose Edit.
5. Set these values, as shown following.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Oracle (1521)</td>
</tr>
<tr>
<td>Protocol</td>
<td>TCP (6)</td>
</tr>
<tr>
<td>Port Range</td>
<td>1521</td>
</tr>
<tr>
<td>Source</td>
<td>The identifier of your security group. When you choose the box, you see the name of your security group, for example sgdb-1.</td>
</tr>
</tbody>
</table>
6. Choose Save.

**Creating an Oracle DB instance**

You can use Amazon RDS to host an Oracle DB instance. When you create the new DB instance, specify the VPC and security group you created previously using the instructions in Creating a VPC for use with an Oracle database (p. 1819). Also, choose No for Publicly accessible.

For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 236).

**Additional Amazon RDS interfaces**

In the preceding tasks, you use the AWS Management Console to perform tasks. Amazon Web Services also provides the AWS Command Line Interface (AWS CLI), and an application programming interface (API). You can use the AWS CLI or the API to automate many of the tasks for managing Amazon RDS, including tasks to manage an Oracle DB instance with Amazon RDS.

For more information, see AWS Command Line Interface reference for Amazon RDS and Amazon RDS API Reference.
Using Oracle GoldenGate with Amazon RDS for Oracle

Oracle GoldenGate collects, replicates, and manages transactional data between databases. It is a log-based change data capture (CDC) and replication software package used with databases for online transaction processing (OLTP) systems. Oracle GoldenGate creates trail files that contain the most recent changed data from the source database. It then pushes these files to the server, where a process converts the trail file into standard SQL to be applied to the target database.

Oracle GoldenGate with RDS for Oracle supports the following features:

- Active-Active database replication
- Disaster recovery
- Data protection
- In-Region and cross-Region replication
- Zero-downtime migration and upgrades
- Data replication between an RDS for Oracle DB instance and a non-Oracle database

Note
For a list of supported databases, see Oracle Fusion Middleware Supported System Configurations in the Oracle documentation.

You can use Oracle GoldenGate with RDS for Oracle to upgrade to major versions of Oracle Database. For example, you can use Oracle GoldenGate to upgrade from an Oracle Database 11g on-premises database to Oracle Database 19c on an Amazon RDS DB instance.

Topics
- Supported versions and licensing options for Oracle GoldenGate (p. 1825)
- Requirements and limitations for Oracle GoldenGate (p. 1826)
- Oracle GoldenGate architecture (p. 1826)
- Setting up Oracle GoldenGate (p. 1829)
- Working with the EXTRACT and REPLICAT utilities of Oracle GoldenGate (p. 1834)
- Troubleshooting Oracle GoldenGate (p. 1836)

Supported versions and licensing options for Oracle GoldenGate

You can use Standard Edition Two (SE2) or Enterprise Edition (EE) of RDS for Oracle with Oracle GoldenGate version 12c and higher. You can use the following Oracle GoldenGate features:

- Oracle GoldenGate Remote Capture (extract) is supported.
- Capture (extract) is supported on RDS for Oracle DB instances that use the traditional non-CDB database architecture. Oracle GoldenGate Remote PDB capture is supported on Oracle Database 21c container databases (CDBs).
- Oracle GoldenGate Remote Delivery (replicat) is supported on RDS for Oracle DB instances that use either the non-CDB or CDB architectures. Remote Delivery supports Integrated Replicat, Parallel Replicat, Coordinated Replicat, and classic Replicat.
- RDS for Oracle supports the Classic and Microservices architectures of Oracle GoldenGate.
- Oracle GoldenGate DDL and Sequence value replication is supported when using Integrated capture mode.
You are responsible for managing Oracle GoldenGate licensing (BYOL) for use with Amazon RDS in all AWS Regions. For more information, see RDS for Oracle licensing options (p. 1526).

Requirements and limitations for Oracle GoldenGate

When you're working with Oracle GoldenGate and RDS for Oracle, consider the following requirements and limitations:

- You're responsible for setting up and managing Oracle GoldenGate for use with RDS for Oracle.
- You're responsible for setting up an Oracle GoldenGate version that is certified with the source and the target databases. For more information, see Oracle Fusion Middleware Supported System Configurations in the Oracle documentation.
- You can use Oracle GoldenGate on many different AWS environments for many different use cases. If you have a support-related issue relating to Oracle GoldenGate, contact Oracle Support Services.
- You can use Oracle GoldenGate on RDS for Oracle DB instances that use Oracle Transparent Data Encryption (TDE). To maintain the integrity of replicated data, configure encryption on the Oracle GoldenGate hub using Amazon EBS encrypted volumes or trail file encryption. Also configure encryption for data sent between the Oracle GoldenGate hub and the source and target database instances. RDS for Oracle DB instances support encryption with Oracle Secure Sockets Layer (p. 1774) or Oracle native network encryption (p. 1763).

Oracle GoldenGate architecture

The Oracle GoldenGate architecture for use with Amazon RDS consists of the following decoupled modules:

Source database

Your source database can be either an on-premises Oracle database, an Oracle database on an Amazon EC2 instance, or an Oracle database on an Amazon RDS DB instance.

Oracle GoldenGate hub

An Oracle GoldenGate hub moves transaction information from the source database to the target database. Your hub can be either of the following:

- An Amazon EC2 instance with Oracle Database and Oracle GoldenGate installed
- An on-premises Oracle installation

You can have more than one Amazon EC2 hub. We recommend that you use two hubs if you use Oracle GoldenGate for cross-Region replication.

Target database

Your target database can be on either an Amazon RDS DB instance, an Amazon EC2 instance, or an on-premises location.

The following sections describe common scenarios for Oracle GoldenGate on Amazon RDS.

Topics

- On-premises source database and Oracle GoldenGate hub (p. 1827)
- On-premises source database and Amazon EC2 hub (p. 1827)
- Amazon RDS source database and Amazon EC2 hub (p. 1827)
- Amazon EC2 source database and Amazon EC2 hub (p. 1828)
- Amazon EC2 hubs in different AWS Regions (p. 1828)
On-premises source database and Oracle GoldenGate hub

In this scenario, an on-premises Oracle source database and on-premises Oracle GoldenGate hub provides data to a target Amazon RDS DB instance.

On-premises source database and Amazon EC2 hub

In this scenario, an on-premises Oracle database acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.

Amazon RDS source database and Amazon EC2 hub

In this scenario, an RDS for Oracle DB instance acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.
Amazon EC2 source database and Amazon EC2 hub

In this scenario, an Oracle database on an Amazon EC2 instance acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.

Amazon EC2 hubs in different AWS Regions

In this scenario, an Oracle database on an Amazon RDS DB instance is connected to an Amazon EC2 instance hub in the same AWS Region. The hub is connected to an Amazon EC2 instance hub in a different AWS Region. This second hub provides data to the target RDS for Oracle DB instance in the same AWS Region as the second Amazon EC2 instance hub.
Note
Any issues that affect running Oracle GoldenGate on an on-premises environment also affect running Oracle GoldenGate on AWS. We strongly recommend that you monitor the Oracle GoldenGate hub to ensure that EXTRACT and REPLICAT are resumed if a failover occurs. Because the Oracle GoldenGate hub is run on an Amazon EC2 instance, Amazon RDS does not manage the Oracle GoldenGate hub and cannot ensure that it is running.

Setting up Oracle GoldenGate

To set up Oracle GoldenGate using Amazon RDS, configure the hub on an Amazon EC2 instance, and then configure the source and target databases. The following sections give an example of how to set up Oracle GoldenGate for use with Amazon RDS for Oracle.

Topics
- Setting up an Oracle GoldenGate hub on Amazon EC2 (p. 1829)
- Setting up a source database for use with Oracle GoldenGate on Amazon RDS (p. 1830)
- Setting up a target database for use with Oracle GoldenGate on Amazon RDS (p. 1832)

Setting up an Oracle GoldenGate hub on Amazon EC2

To create an Oracle GoldenGate hub on an Amazon EC2 instance, you first create an Amazon EC2 instance with a full client installation of Oracle RDBMS. The Amazon EC2 instance must also have Oracle GoldenGate software installed. The Oracle GoldenGate software versions depend on the source and target database versions. For more information about installing Oracle GoldenGate, see the Oracle GoldenGate documentation.

The Amazon EC2 instance that serves as the Oracle GoldenGate hub stores and processes the transaction information from the source database into trail files. To support this process, make sure that you meet the following requirements:

- You have allocated enough storage for the trail files.
- The Amazon EC2 instance has enough processing power to manage the amount of data.
- The EC2 instance has enough memory to store the transaction information before it's written to the trail file.
To set up an Oracle GoldenGate classic architecture hub on an Amazon EC2 instance

1. Create subdirectories in the Oracle GoldenGate directory.
   
   In the Amazon EC2 command line shell, start ggsci, the Oracle GoldenGate command interpreter. The CREATE SUBDIRS command creates subdirectories under the /gg directory for parameter, report, and checkpoint files.

   ```
   prompt$ cd /gg
   prompt$ ./ggsci
   GGSCI> CREATE SUBDIRS
   ```

2. Configure the mgr.prm file.

   The following example adds lines to the $GGHOME/dirprm/mgr.prm file.

   ```
   PORT 8199
   PurgeOldExtracts ./dirdat/*, UseCheckpoints, MINKEEPDAYS 5
   ```

3. Start the manager.

   The following example starts ggsci and runs the start mgr command.

   ```
   GGSCI> start mgr
   ```

The Oracle GoldenGate hub is now ready for use.

**Setting up a source database for use with Oracle GoldenGate on Amazon RDS**

When your source database is running Oracle Database 12c or later, complete the following tasks to set up a source database for use with Oracle GoldenGate.

**Setup steps**
- Step 1: Turn on supplemental logging on the source database (p. 1830)
- Step 2: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true (p. 1830)
- Step 3: Set the log retention period on the source database (p. 1831)
- Step 4: Create an Oracle GoldenGate user account on the source database (p. 1831)
- Step 5: Grant user account privileges on the source database (p. 1831)
- Step 6: Add a TNS alias for the source database (p. 1832)

**Step 1: Turn on supplemental logging on the source database**

To turn on the minimum database-level supplemental logging, run the following PL/SQL procedure:

```sql
EXEC rdsadmin.rdsadmin_util.alter_supplemental_logging(p_action => 'ADD')
```

**Step 2: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true**

When you set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true, it allows database services to support logical replication. If your source database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with the ENABLE_GOLDENGATE_REPLICATION initialization parameter set to true. For more information about the ENABLE_GOLDENGATE_REPLICATION initialization parameter, see the Oracle Database documentation.
Step 3: Set the log retention period on the source database

Make sure that you configure the source database to retain archived redo logs. Consider the following guidelines:

- Specify the duration for log retention in hours. The minimum value is one hour.
- Set the duration to exceed any potential downtime of the source DB instance, any potential period of communication, and any potential period of networking issues for the source instance. Such a duration lets Oracle GoldenGate recover logs from the source instance as needed.
- Ensure that you have sufficient storage on your instance for the files.

For example, set the retention period for archived redo logs to 24 hours.

```sql
EXEC rdsadmin.rdsadmin_util.set_configuration('archivelog retention hours',24)
```

If you don’t have log retention enabled, or if the retention value is too small, you receive an error message similar to the following.

```
2022-03-06 06:17:27  ERROR   OGG-00446  error 2 (No such file or directory)
opening redo log /rdsdbdata/db/GGTEST3_A/onlinelog/o1_mf_2_9k4bp1n6_.log for sequence 1306
Not able to establish initial position for begin time 2022-03-06 06:16:55.
```

Because your DB instance retains your archived redo logs, make sure that you have sufficient space for the files. To see how much space you have used in the last `num_hours` hours, run the following query, replacing `num_hours` with the number of hours.

```sql
SELECT SUM(BLOCKS * BLOCK_SIZE) BYTES FROM V$ARCHIVED_LOG
WHERE NEXT_TIME>=SYSDATE-`num_hours`/24 AND DEST_ID=1;
```

Step 4: Create an Oracle GoldenGate user account on the source database

Oracle GoldenGate runs as a database user and requires the appropriate database privileges to access the redo and archived redo logs for the source database. To provide these, create a user account on the source database. For more information about the permissions for an Oracle GoldenGate user account, see the Oracle documentation.

The following statements create a user account named `oggadm1`.

```sql
CREATE TABLESPACE administrator;
CREATE USER oggadm1 IDENTIFIED BY "password"
DEFAULT TABLESPACE ADMINISTRATOR TEMPORARY TABLESPACE TEMP;
ALTER USER oggadm1 QUOTA UNLIMITED ON administrator;
```

Step 5: Grant user account privileges on the source database

In this task, you grant necessary account privileges for database users on your source database.

To grant account privileges on the source database

1. Grant the necessary privileges to the Oracle GoldenGate user account using the SQL command grants and the `rdsadmin.rdsadmin_util` procedure `grant_sys_object`. The following statements grant privileges to a user named `oggadm1`.

```sql
GRANT CREATE SESSION, ALTER SESSION TO oggadm1;
GRANT RESOURCE TO oggadm1;
GRANT SELECT ANY DICTIONARY TO oggadm1;
```
GRANT FLASHBACK ANY TABLE TO oggadm1;
GRANT SELECT ANY TABLE TO oggadm1;
GRANT SELECT_CATALOG_ROLE TO rds_master_user_name WITH ADMIN OPTION;
EXEC rdsadmin.rdsadmin_util.grant_sys_object ('DBA_CLUSTERS', 'OGGADM1');
GRANT EXECUTE ON DBMS_FLASHBACK TO oggadm1;
GRANT SELECT ON SYS.V_$DATABASE TO oggadm1;
GRANT ALTER ANY TABLE TO oggadm1;

2. Grant the privileges needed by a user account to be an Oracle GoldenGate administrator. The package that you use to perform the grant, dbms_goldengate_auth or rdsadmin_dbms_goldengate_auth, depends on the Oracle DB engine version.

- For Oracle DB versions that are later than or equal to Oracle Database 12c Release 2 (12.2), which requires patch level 12.2.0.1.ru-2019-04.rur-2019-04.r1 or later, run the following PL/SQL program.

```sql
EXEC rdsadmin.rdsadmin_dbms_goldengate_auth.grant_admin_privilege (
    grantee => 'OGGADM1',
    privilege_type => 'capture',
    grant_select_privileges => true,
    do_grants => TRUE);
```

- For Oracle database versions that are earlier than Oracle Database 12c Release 2 (12.2), run the following PL/SQL program.

```sql
EXEC dbms_goldengate_auth.grant_admin_privilege (
    grantee => 'OGGADM1',
    privilege_type => 'capture',
    grant_select_privileges => true,
    do_grants => TRUE);
```

To revoke privileges, use the procedure revoke_admin_privilege in the same package.

**Step 6: Add a TNS alias for the source database**

Add the following entry to $ORACLE_HOME/network/admin/tnsnames.ora in the Oracle home to be used by the EXTRACT process. For more information on the tnsnames.ora file, see the Oracle documentation.

```sql
OGGSOURCE=
    (DESCRIPTION=
        (ENABLE=BROKEN)
        (ADDRESS_LIST=
            (ADDRESS=(PROTOCOL=TCP)(HOST=goldengate-source.abcdef12345.us-west-2.rds.amazonaws.com)(PORT=8200)))
            (CONNECT_DATA=(SERVICE_NAME=ORCL))
    )
```

**Setting up a target database for use with Oracle GoldenGate on Amazon RDS**

In this task, you set up a target DB instance for use with Oracle GoldenGate.

**Setup steps**

- **Step 1:** Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true (p. 1833)
- **Step 2:** Create an Oracle GoldenGate user account on the target database (p. 1833)
- **Step 3:** Grant account privileges on the target database (p. 1833)
- **Step 4:** Add a TNS alias for the target database (p. 1834)
Step 1: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true

When you set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true, it allows database services to support logical replication. If your source database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with the ENABLE_GOLDENGATE_REPLICATION initialization parameter set to true. For more information about the ENABLE_GOLDENGATE_REPLICATION initialization parameter, see the Oracle Database documentation.

Step 2: Create an Oracle GoldenGate user account on the target database

Oracle GoldenGate runs as a database user and requires the appropriate database privileges. To make sure it has these privileges, create a user account on the target database.

The following statement creates a user named oggadm1.

```sql
CREATE TABLESPACE administrator;
CREATE USER oggadm1 IDENTIFIED BY "password"
    DEFAULT TABLESPACE administrator
    TEMPORARY TABLESPACE temp;
ALTER USER oggadm1 QUOTA UNLIMITED ON administrator;
```

Step 3: Grant account privileges on the target database

In this task, you grant necessary account privileges for database users on your target database.

**To grant account privileges on the target database**

1. Grant necessary privileges to the Oracle GoldenGate user account on the target database. In the following example, you grant privileges to oggadm1.

   ```sql
   GRANT CREATE SESSION TO oggadm1;
   GRANT ALTER SESSION TO oggadm1;
   GRANT CREATE CLUSTER TO oggadm1;
   GRANT CREATE INDEXTYPE TO oggadm1;
   GRANT CREATE OPERATOR TO oggadm1;
   GRANT CREATE PROCEDURE TO oggadm1;
   GRANT CREATE SEQUENCE TO oggadm1;
   GRANT CREATE TABLE TO oggadm1;
   GRANT CREATE TRIGGER TO oggadm1;
   GRANT CREATE TYPE TO oggadm1;
   GRANT SELECT ANY DICTIONARY TO oggadm1;
   GRANT CREATE ANY TABLE TO oggadm1;
   GRANT ALTER ANY TABLE TO oggadm1;
   GRANT LOCK ANY TABLE TO oggadm1;
   GRANT SELECT ANY TABLE TO oggadm1;
   GRANT INSERT ANY TABLE TO oggadm1;
   GRANT UPDATE ANY TABLE TO oggadm1;
   GRANT DELETE ANY TABLE TO oggadm1;
   ```

2. Grant the privileges needed by a user account to be an Oracle GoldenGate administrator. The package that you use to perform the grant, dbms_goldengate_auth or rdsadmin_dbms_goldengate_auth, depends on the Oracle DB engine version.

   For Oracle database versions that are later than or equal to Oracle Database 12c Release 2 (12.2), which requires patch level 12.2.0.1.ru-2019-04.rur-2019-04.r1 or later, run the following PL/SQL program.

   ```sql
   EXEC rdsadmin.rdsadmin_dbms_goldengate_auth.grant_admin_privilege (grantee => 'OGGADM1',);
   ```
privilege_type          => 'apply',
grant_select_privileges => true,
do_grants               => TRUE);

• For Oracle database versions that are lower than Oracle Database 12c Release 2 (12.2), run the following PL/SQL program.

EXEC dbms_goldengate_auth.grant_admin_privilege (
grantee                 => 'OGGADM1',
privilege_type          => 'apply',
grant_select_privileges => true,
do_grants               => TRUE);

To revoke privileges, use the procedure revoke_admin_privilege in the same package.

Step 4: Add a TNS alias for the target database

Add the following entry to $ORACLE_HOME/network/admin/tnsnames.ora in the Oracle home to be used by the REPLICAT process. For Oracle Multitenant databases, make sure that the TNS alias points to the service name of the PDB. For more information on the tnsnames.ora file, see the Oracle documentation.

OGGTARGET=
  (DESCRIPTION=
    (ENABLE=BROKEN)
    (ADDRESS_LIST=
      (ADDRESS=(PROTOCOL=TCP)(HOST=goldengate-target.abcdef12345.us-west-2.rds.amazonaws.com)(PORT=8200))
      (CONNECT_DATA=(SERVICE_NAME=ORCL))
    )
  )

Working with the EXTRACT and REPLICAT utilities of Oracle GoldenGate

The Oracle GoldenGate utilities EXTRACT and REPLICAT work together to keep the source and target databases in sync via incremental transaction replication using trail files. All changes that occur on the source database are automatically detected by EXTRACT, then formatted and transferred to trail files on the Oracle GoldenGate on-premises or EC2-instance hub. After initial load is completed, the data is read from these files and replicated to the target database by the REPLICAT utility.

Running the Oracle GoldenGate EXTRACT utility

The EXTRACT utility retrieves, converts, and outputs data from the source database to trail files. EXTRACT queues transaction details to memory or to temporary disk storage. When the transaction is committed to the source database, EXTRACT flushes all of the transaction details to a trail file. The trail file routes these details to the Oracle GoldenGate on-premises or the Amazon EC2 instance hub and then to the target database.

The following steps start the EXTRACT utility, capture the data from EXAMPLE.TABLE in source database OGGSOURCE, and create the trail files.

To run the EXTRACT utility

1. Configure the EXTRACT parameter file on the Oracle GoldenGate hub (on-premises or Amazon EC2 instance). The following listing shows an example EXTRACT parameter file named $GGHOME/dirprm/eabc prm.
EXTRACT EABC
USERID oggadm1@OGGSOURCE, PASSWORD "my-password"
EXTRAIL /path/to/goldengate/dirdat/ab
IGNOREREPLICATES
GETAPPLOPS
TRANLOGOPTIONS EXCLUDEUSER OGGADM1
TABLE EXAMPLE.TABLE;

2. On the Oracle GoldenGate hub, log in to the source database and launch the Oracle GoldenGate command line interface `ggsci`. The following example shows the format for logging in.

dblogin oggadm1@OGGSOURCE

3. Add transaction data to turn on supplemental logging for the database table.

add trandata EXAMPLE.TABLE

4. Using the `ggsci` command line, enable the EXTRACT utility using the following commands.

add extract EABC tranlog, INTEGRATED tranlog, begin now
add exttrail /path/to/goldengate/dirdat/ab
extract EABC,
MEGABYTES 100

5. Register the EXTRACT utility with the database so that the archive logs are not deleted. This task allows you to recover old, uncommitted transactions if necessary. To register the EXTRACT utility with the database, use the following command.

register EXTRACT EABC, DATABASE

6. Start the EXTRACT utility with the following command.

start EABC

Running the Oracle GoldenGate REPLICAT utility

The REPLICAT utility "pushes" transaction information in the trail files to the target database.

The following steps enable and start the REPLICAT utility so that it can replicate the captured data to the table EXAMPLE.TABLE in target database OGGTARGET.

To run the REPLICATE utility

1. Configure the REPLICAT parameter file on the Oracle GoldenGate hub (on-premises or EC2 instance). The following listing shows an example REPLICAT parameter file named $GGHOME/dirprm/rabc.prm.

REPLICAT RABC
USERID oggadm1@OGGTARGET, password "my-password"
ASSUMETARGETDEFS
MAP EXAMPLE.TABLE, TARGET EXAMPLE.TABLE;
2. Log in to the target database and launch the Oracle GoldenGate command line interface (ggsci). The following example shows the format for logging in.

   ```
   dblogin userid oggadm1@OGGTARGET
   ```

3. Using the ggsci command line, add a checkpoint table. The user indicated should be the Oracle GoldenGate user account, not the target table schema owner. The following example creates a checkpoint table named gg_checkpoint.

   ```
   add checkpointtable oggadm1.oggchkpt
   ```

4. To enable the REPLICAT utility, use the following command.

   ```
   add replicat RABC EXTTRAIL /path/to/goldengate/dirdat/ab CHECKPOINTTABLE oggadm1.oggchkpt
   ```

5. Start the REPLICAT utility by using the following command.

   ```
   start RABC
   ```

**Troubleshooting Oracle GoldenGate**

This section explains the most common issues when using Oracle GoldenGate with Amazon RDS for Oracle.

**Topics**

- Error opening an online redo log (p. 1836)
- Oracle GoldenGate appears to be properly configured but replication is not working (p. 1836)
- Integrated REPLICAT slow due to query on SYS."_DBA_APPLY_CDR_INFO" (p. 1837)

**Error opening an online redo log**

Make sure that you configure your databases to retain archived redo logs. Consider the following guidelines:

- Specify the duration for log retention in hours. The minimum value is one hour.
- Set the duration to exceed any potential downtime of the source DB instance, any potential period of communication, and any potential period of networking issues for the source DB instance. Such a duration lets Oracle GoldenGate recover logs from the source DB instance as needed.
- Ensure that you have sufficient storage on your instance for the files.

If you don't have log retention enabled, or if the retention value is too small, you receive an error message similar to the following.

```
2022-03-06 06:17:27  ERROR   OGG-00446  error 2 (No such file or directory)
opening redo log /rdsdbdata/db/GGTEST3_A/onlinelog/o1_mf_2_9k4bp1n6_.log for sequence 1306
Not able to establish initial position for begin time 2022-03-06 06:16:55.
```

**Oracle GoldenGate appears to be properly configured but replication is not working**

For pre-existing tables, you must specify the SCN that Oracle GoldenGate works from.
To fix this issue

1. Log in to the source database and launch the Oracle GoldenGate command line interface (ggsci). The following example shows the format for logging in.

   ```
   dblogin userid oggadm1@OGGSOURCE
   ```

2. Using the ggsci command line, set up the start SCN for the EXTRACT process. The following example sets the SCN to 223274 for the EXTRACT.

   ```
   ALTER EXTRACT EABC SCN 223274
   ```

3. Log in to the target database. The following example shows the format for logging in.

   ```
   dblogin userid oggadm1@OGGTARGET
   ```

4. Using the ggsci command line, set up the start SCN for the REPLICAT process. The following example sets the SCN to 223274 for the REPLICAT.

   ```
   start RABC atcsn 223274
   ```

Integrated REPLICAT slow due to query on SYS."_DBA_APPLY_CDR_INFO"

Oracle GoldenGate Conflict Detection and Resolution (CDR) provides basic conflict resolution routines. For example, CDR can resolve a unique conflict for an INSERT statement.

When CDR resolves a collision, it can insert records into the exception table `_DBA_APPLY_CDR_INFO` temporarily. Integrated REPLICAT deletes these records later. In a rare scenario, the integrated REPLICAT can process a large number of collisions, but a new integrated REPLICAT does not replace it. Instead of being removed, the existing rows in `_DBA_APPLY_CDR_INFO` are orphaned. Any new integrated REPLICAT processes slow down because they are querying orphaned rows in `_DBA_APPLY_CDR_INFO`.

To remove all rows from `_DBA_APPLY_CDR_INFO`, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.truncate_apply$._cdr_info`. This procedure is released as part of the October 2020 release and patch update. The procedure is available in the following database versions:

- Version 21.0.0.0.ru-2022-01.rur-2022-01.r1 and higher
- Version 19.0.0.0.ru-2020-10.rur-2020-10.r1 and higher

The following example truncates the table `_DBA_APPLY_CDR_INFO`.

```
SET SERVEROUTPUT ON SIZE 2000
EXEC rdsadmin.rdsadmin_util.truncate_apply$._cdr_info;
```
Using the Oracle Repository Creation Utility on RDS for Oracle

You can use Amazon RDS to host an RDS for Oracle DB instance that holds the schemas to support your Oracle Fusion Middleware components. Before you can use Fusion Middleware components, create and populate schemas for them in your database. You create and populate the schemas by using the Oracle Repository Creation Utility (RCU).

Supported versions and licensing options for RCU

Amazon RDS supports Oracle Repository Creation Utility (RCU) version 12c only. You can use the RCU in the following configurations:

- RCU 12c with Oracle Database 21c
- RCU 12c with Oracle Database 19c
- RCU 12c with Oracle Database 12c Release 2 (12.2)
- RCU 12c with Oracle Database 12c Release 1 (12.1) using 12.1.0.2.v4 or higher

Before you can use RCU, make sure that you do the following:

- Obtain a license for Oracle Fusion Middleware.
- Follow the Oracle licensing guidelines for the Oracle database that hosts the repository. For more information, see Oracle Fusion Middleware Licensing Information User Manual in the Oracle documentation.

Fusion MiddleWare supports repositories on Oracle Database Enterprise Edition and Standard Edition Two. Oracle recommends Enterprise Edition for production installations that require partitioning and installations that require online index rebuild.

Before you create your RDS for Oracle instance, confirm the Oracle database version that you need to support the components that you want to deploy. To find the requirements for the Fusion Middleware components and versions you want to deploy, use the Certification Matrix. For more information, see Oracle Fusion Middleware Supported System Configurations in the Oracle documentation.

Amazon RDS supports Oracle database version upgrades as needed. For more information, see Upgrading a DB instance engine version (p. 369).

Requirements and limitations for RCU

To use RCU, you need an Amazon VPC. Your Amazon RDS DB instance must be available only to your Fusion Middleware components, and not to the public Internet. Thus, host your Amazon RDS DB instance in a private subnet, which provides greater security. For information about how to create an Amazon VPC for use with an RDS for Oracle instance, see Creating a VPC for use with an Oracle database (p. 1819).

You also need an RDS for Oracle DB instance. For information about how to create an RDS for Oracle DB instance for use with Fusion Middleware metadata, see Creating an Oracle DB instance (p. 1824).

You can store the schemas for any Fusion Middleware components in your Amazon RDS DB instance. The following schemas have been verified to install correctly:

- Analytics (ACTIVITIES)
- Audit Services (IAU)
• Audit Services Append (IAU_APPEND)
• Audit Services Viewer (IAU_VIEWER)
• Discussions (DISCUSSIONS)
• Metadata Services (MDS)
• Oracle Business Intelligence (BIPLATFORM)
• Oracle Platform Security Services (OPSS)
• Portal and Services (WEBCENTER)
• Portlet Producers (PORTLET)
• Service Table (STB)
• SOA Infrastructure (SOAINFRA)
• User Messaging Service (UCSUMS)
• WebLogic Services (WLS)

Guidelines for using RCU

The following are some recommendations for working with your DB instance in this scenario:

• We recommend that you use Multi-AZ for production workloads. For more information about working with multiple Availability Zones, see Regions, Availability Zones, and Local Zones (p. 79).
• For additional security, Oracle recommends that you use Transparent Data Encryption (TDE) to encrypt your data at rest. If you have an Enterprise Edition license that includes the Advanced Security Option, you can enable encryption at rest by using the TDE option. For more information, see Oracle Transparent Data Encryption (p. 1803).

Amazon RDS also provides an encryption at rest option for all database editions. For more information, see Encrypting Amazon RDS resources (p. 2147).
• Configure your VPC Security Groups to allow communication between your application servers and your Amazon RDS DB instance. The application servers that host the Fusion Middleware components can be on Amazon EC2 or on-premises.

Running RCU

To create and populate the schemas to support your Fusion Middleware components, use the Oracle Repository Creation Utility (RCU). You can run RCU in different ways.

Topics
• Running RCU using the command line in one step (p. 1839)
• Running RCU using the command line in multiple steps (p. 1840)
• Running RCU in interactive mode (p. 1841)

Running RCU using the command line in one step

If you don't need to edit any of your schemas before populating them, you can run RCU in a single step. Otherwise, see the following section for running RCU in multiple steps.

You can run the RCU in silent mode by using the command-line parameter -silent. When you run RCU in silent mode, you can avoid typing passwords on the command line by creating a text file containing the passwords. Create a text file with the password for dbUser on the first line, and the password for each component on subsequent lines. You specify the name of the password file as the last parameter to the RCU command.
Example

The following example creates and populates schemas for the SOA Infrastructure component (and its dependencies) in a single step.

For Linux, macOS, or Unix:

```bash
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
    -silent \ 
    -createRepository \ 
    -connectString $({dbhost}:${dbport}:${dbname} \ 
    -dbUser $({dbuser}) \ 
    -dbRole Normal \ 
    -honorOMF \ 
    -schemaPrefix $({SCHEMA_PREFIX}) \ 
    -component MDS \ 
    -component STB \ 
    -component OPSS \ 
    -component IAU \ 
    -component IAU_APPEND \ 
    -component IAU_VIEWER \ 
    -component UCSUMS \ 
    -component WLS \ 
    -component SOAINFRA \ 
    -f < /tmp/passwordfile.txt
```

For more information, see Running Repository Creation Utility from the command line in the Oracle documentation.

Running RCU using the command line in multiple steps

To manually edit your schema scripts, run RCU in multiple steps:

1. Run RCU in Prepare Scripts for System Load mode by using the -generateScript command-line parameter to create the scripts for your schemas.
2. Manually edit and run the generated script `script_systemLoad.sql`.
3. Run RCU again in Perform Product Load mode by using the -dataLoad command-line parameter to populate the schemas.
4. Run the generated cleanup script `script_postDataLoad.sql`.

To run RCU in silent mode, specify the command-line parameter -silent. When you run RCU in silent mode, you can avoid typing passwords on the command line by creating a text file containing the passwords. Create a text file with the password for dbUser on the first line, and the password for each component on subsequent lines. Specify the name of the password file as the last parameter to the RCU command.

Example

The following example creates schema scripts for the SOA Infrastructure component and its dependencies.

For Linux, macOS, or Unix:

```bash
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
    -silent \ 
    -generateScript \ 
```
Now you can edit the generated script, connect to your Oracle DB instance, and run the script. The generated script is named `script_systemLoad.sql`. For information about connecting to your Oracle DB instance, see Connecting to your sample Oracle DB instance (p. 190).

The following example populates the schemas for the SOA Infrastructure component (and its dependencies).

For Linux, macOS, or Unix:

```bash
export JAVA_HOME=/usr/java/jdk1.8.0_65
$(ORACLE_HOME)/oracle_common/bin/rcu \
-silent \
-dataLoad \
-connectString ${dbhost}:${dbport}:${dbname} \n-dbUser ${dbuser} \n-dbRole Normal \n-honorOMF \n[/-encryptTablespace true] \n-schemaPrefix ${SCHEMA_PREFIX} \n-component MDS \n-component STB \n-component OPSS \n-component IAU \n-component IAU_APPEND \n-component IAU_VIEWER \n-component UCSUMS \n-component WLS \n-component SOAINFRA \n-scriptLocation /tmp/rcuscripts \n-f < /tmp/passwordfile.txt
```

To finish, you connect to your Oracle DB instance, and run the clean-up script. The script is named `script_postDataLoad.sql`. For more information, see Running Repository Creation Utility from the command line in the Oracle documentation.

**Running RCU in interactive mode**

To use the RCU graphical user interface, run RCU in interactive mode. Include the `-interactive` parameter and omit the `-silent` parameter. For more information, see Understanding Repository Creation Utility screens in the Oracle documentation.

**Example**

The following example starts RCU in interactive mode and pre-populates the connection information.
Troubleshooting RCU

Be mindful of the following issues.

**Topics**
- Oracle Managed Files (OMF) (p. 1842)
- Object privileges (p. 1842)
- Enterprise Scheduler Service (p. 1843)

**Oracle Managed Files (OMF)**

Amazon RDS uses OMF data files to simplify storage management. You can customize tablespace attributes, such as size and extent management. However, if you specify a data file name when you run RCU, the tablespace code fails with ORA-20900. You can use RCU with OMF in the following ways:

- In RCU 12.2.1.0 and later, use the `-honorOMF` command-line parameter.
- In RCU 12.1.0.3 and later, use multiple steps and edit the generated script. For more information, see Running RCU using the command line in multiple steps (p. 1840).

**Object privileges**

Because Amazon RDS is a managed service, you don't have full SYSDBA access to your RDS for Oracle DB instance. However, RCU 12c supports users with lower privileges. In most cases, the master user privilege is sufficient to create repositories.

The master account can directly grant privileges that it has already been granted WITH GRANT OPTION. In some cases, when you attempt to grant SYS object privileges, the RCU might fail with ORA-01031. You can retry and run the rdsadmin_util.grant_sys_object stored procedure, as shown in the following example:

```sql
BEGIN
    rdsadmin.rdsadmin_util.grant_sys_object('GV_${SESSION}','MY_DBA','SELECT');
END;
/
```

If you attempt to grant SYS privileges on the object SCHEMA_VERSION_REGISTRY, the operation might fail with ORA-20199: Error in rdsadmin_util.grant_sys_object. You can qualify the table SCHEMA_VERSION_REGISTRY$ and the view SCHEMA_VERSION_REGISTRY with the schema owner name, which is SYSTEM, and retry the operation. Or, you can create a synonym. Log in as the master user and run the following statements:

```sql
CREATE OR REPLACE VIEW SYSTEM.SCHEMA_VERSION_REGISTRY
AS SELECT * FROM SYSTEM.SCHEMA_VERSION_REGISTRY$;
```
CREATE OR REPLACE PUBLIC SYNONYM SCHEMA_VERSION_REGISTGY FOR SYSTEM.SCHEMA_VERSION_REGISTGY;
CREATE OR REPLACE PUBLIC SYNONYM SCHEMA_VERSION_REGISTGY$ FOR SCHEMA_VERSION_REGISTGY;

Enterprise Scheduler Service

When you use the RCU to drop an Enterprise Scheduler Service repository, the RCU might fail with Error: Component drop check failed.
Configuring Oracle Connection Manager on an Amazon EC2 instance

Oracle Connection Manager (CMAN) is a proxy server that forwards connection requests to database servers or other proxy servers. You can use CMAN to configure the following:

**Access control**

You can create rules that filter out user-specified client requests and accept others.

**Session multiplexing**

You can funnel multiple client sessions through a network connection to a shared server destination.

Typically, CMAN resides on a host separate from the database server and client hosts. For more information, see Configuring Oracle Connection Manager in the Oracle Database documentation.

**Topics**

- Supported versions and licensing options for CMAN (p. 1844)
- Requirements and limitations for CMAN (p. 1844)
- Configuring CMAN (p. 1844)

**Supported versions and licensing options for CMAN**

CMAN supports the Enterprise Edition of all versions of Oracle Database that Amazon RDS supports. For more information, see RDS for Oracle releases (p. 1522).

You can install Oracle Connection Manager on a separate host from the host where Oracle Database is installed. You don't need a separate license for the host that runs CMAN.

**Requirements and limitations for CMAN**

To provide a fully managed experience, Amazon RDS restricts access to the operating system. You can't modify database parameters that require operating system access. Thus, Amazon RDS doesn't support features of CMAN that require you to log in to the operating system.

**Configuring CMAN**

When you configure CMAN, you perform most of the work outside of your RDS for Oracle database.

**Topics**

- Step 1: Configure CMAN on an Amazon EC2 instance in the same VPC as the RDS for Oracle instance (p. 1844)
- Step 2: Configure database parameters for CMAN (p. 1845)
- Step 3: Associate your DB instance with the parameter group (p. 1845)

**Step 1: Configure CMAN on an Amazon EC2 instance in the same VPC as the RDS for Oracle instance**

To learn how to set up CMAN, follow the detailed instructions in the blog post Configuring and using Oracle Connection Manager on Amazon EC2 for Amazon RDS for Oracle.
Step 2: Configure database parameters for CMAN

For CMAN features such as Traffic Director Mode and session multiplexing, set REMOTE_LISTENER parameter to the address of CMAN instance in a DB parameter group. Consider the following scenario:

- The CMAN instance resides on a host with IP address 10.0.159.100 and uses port 1521.
- The databases orcla, orclb, and orclc reside on separate RDS for Oracle DB instances.

The following table shows how to set the REMOTE_LISTENER value. The LOCAL_LISTENER value is set automatically by Amazon RDS.

<table>
<thead>
<tr>
<th>DB instance name</th>
<th>DB instance IP</th>
<th>Local listener value (set automatically)</th>
<th>Remote listener value (set by user)</th>
</tr>
</thead>
<tbody>
<tr>
<td>orcla</td>
<td>10.0.159.200</td>
<td>(address= (protocol=tcp) (host=10.0.159.200) (port=1521) )</td>
<td>10.0.159.100:1521</td>
</tr>
<tr>
<td>orclb</td>
<td>10.0.159.300</td>
<td>(address= (protocol=tcp) (host=10.0.159.300) (port=1521) )</td>
<td>10.0.159.100:1521</td>
</tr>
<tr>
<td>orclc</td>
<td>10.0.159.400</td>
<td>(address= (protocol=tcp) (host=10.0.159.400) (port=1521) )</td>
<td>10.0.159.100:1521</td>
</tr>
</tbody>
</table>

Step 3: Associate your DB instance with the parameter group

Create or modify your DB instance to use the parameter group that you configured in Step 2: Configure database parameters for CMAN (p. 1845). For more information, see Associating a DB parameter group with a DB instance (p. 299).
Installing a Siebel database on Oracle on Amazon RDS

You can use Amazon RDS to host a Siebel Database on an Oracle DB instance. The Siebel Database is part of the Siebel Customer Relationship Management (CRM) application architecture. For an illustration, see Generic architecture of Siebel business application.

Use the following topic to help set up a Siebel Database on an Oracle DB instance on Amazon RDS. You can also find out how to use Amazon Web Services to support the other components required by the Siebel CRM application architecture.

Note
To install a Siebel Database on Oracle on Amazon RDS, you need to use the master user account. You don't need SYSDBA privilege; master user privilege is sufficient. For more information, see Master user account privileges (p. 2234).

Licensing and versions
To install a Siebel Database on Amazon RDS, you must use your own Oracle Database license, and your own Siebel license. You must have the appropriate Oracle Database license (with Software Update License and Support) for the DB instance class and Oracle Database edition. For more information, see RDS for Oracle licensing options (p. 1526).

Oracle Database Enterprise Edition is the only edition certified by Siebel for this scenario. Amazon RDS supports Siebel CRM version 15.0 or 16.0. Use Oracle Database 12c Release 1 (12.1.0.2.0). For the procedures following, we use Siebel CRM version 15.0 and Oracle Database Release 1 (12.1.0.2) or Oracle Database Release 2 (12.2.0.1). For more information, see Oracle Database 12c with Amazon RDS (p. 1525).

Amazon RDS supports database version upgrades. For more information, see Upgrading a DB instance engine version (p. 369).

Before you begin
Before you begin, you need an Amazon VPC. Because your Amazon RDS DB instance needs to be available only to your Siebel Enterprise Server, and not to the public Internet, your Amazon RDS DB instance is hosted in a private subnet, providing greater security. For information about how to create an Amazon VPC for use with Siebel CRM, see Creating a VPC for use with an Oracle database (p. 1819).

Before you begin, you also need an Oracle DB instance. For information about how to create an Oracle DB instance for use with Siebel CRM, see Creating an Oracle DB instance (p. 1824).

Installing and configuring a Siebel database
After you create your Oracle DB instance, you can install your Siebel Database. You install the database by creating table owner and administrator accounts, installing stored procedures and functions, and then running the Siebel Database Configuration Wizard. For more information, see Installing the Siebel database on the RDBMS.

To run the Siebel Database Configuration Wizard, you need to use the master user account. You don't need SYSDBA privilege; master user privilege is sufficient. For more information, see Master user account privileges (p. 2234).

Using other Amazon RDS features with a Siebel database
After you create your Oracle DB instance, you can use additional Amazon RDS features to help you customize your Siebel Database.
Collecting statistics with the Oracle Statspack option

You can add features to your DB instance through the use of options in DB option groups. When you created your Oracle DB instance, you used the default DB option group. If you want to add features to your database, you can create a new option group for your DB instance.

If you want to collect performance statistics on your Siebel Database, you can add the Oracle Statspack feature. For more information, see Oracle Statspack (p. 1791).

Some option changes are applied immediately, and some option changes are applied during the next maintenance window for the DB instance. For more information, see Working with option groups (p. 279). After you create a customized option group, modify your DB instance to attach it. For more information, see Modifying an Amazon RDS DB instance (p. 333).

Performance tuning with parameters

You manage your DB engine configuration through the use of parameters in a DB parameter group. When you created your Oracle DB instance, you used the default DB parameter group. If you want to customize your database configuration, you can create a new parameter group for your DB instance.

When you change a parameter, depending on the type of the parameter, the changes are applied either immediately or after you manually reboot the DB instance. For more information, see Working with parameter groups (p. 295). After you create a customized parameter group, modify your DB instance to attach it. For more information, see Modifying an Amazon RDS DB instance (p. 333).

To optimize your Oracle DB instance for Siebel CRM, you can customize certain parameters. The following table shows some recommended parameter settings. For more information about performance tuning Siebel CRM, see Siebel CRM Performance Tuning Guide.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Default value</th>
<th>Guidance for optimal Siebel CRM performance</th>
</tr>
</thead>
<tbody>
<tr>
<td>_always_semi_join</td>
<td>CHOOSE</td>
<td>OFF</td>
</tr>
<tr>
<td>_b_tree_bitmap_plans</td>
<td>TRUE</td>
<td>FALSE</td>
</tr>
<tr>
<td>_like_with_bind</td>
<td>FALSE</td>
<td>TRUE</td>
</tr>
<tr>
<td>_no_or_expansion</td>
<td>FALSE</td>
<td>FALSE</td>
</tr>
<tr>
<td>_optimizer_max_permutations</td>
<td>2000</td>
<td>100</td>
</tr>
<tr>
<td>_optimizer_sortmerge</td>
<td>TRUE</td>
<td>FALSE</td>
</tr>
<tr>
<td>_partition_view</td>
<td>TRUE</td>
<td>FALSE</td>
</tr>
<tr>
<td>open_cursors</td>
<td>300</td>
<td>At least 2000</td>
</tr>
</tbody>
</table>

Creating snapshots

After you create your Siebel Database, you can copy the database by using the snapshot features of Amazon RDS. For more information, see Creating a DB snapshot (p. 483) and Restoring from a DB snapshot (p. 487).
Support for other Siebel CRM components

In addition to your Siebel Database, you can also use Amazon Web Services to support the other components of your Siebel CRM application architecture. You can find more information about the support provided by Amazon AWS for additional Siebel CRM components in the following table.

<table>
<thead>
<tr>
<th>Siebel CRM component</th>
<th>Amazon AWS Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Siebel Enterprise (with one or more Siebel Servers)</td>
<td>You can host your Siebel Servers on Amazon Elastic Compute Cloud (Amazon EC2) instances. You can use Amazon EC2 to launch as many or as few virtual servers as you need. Using Amazon EC2, you can scale up or down easily to handle changes in requirements. For more information, see What is Amazon EC2? You can put your servers in the same VPC with your DB instance and use the VPC security group to access the database. For more information, see Working with a DB instance in a VPC (p. 2251).</td>
</tr>
<tr>
<td>Web Servers (with Siebel Web Server Extensions)</td>
<td>You can install multiple Web Servers on multiple EC2 instances. You can then use Elastic Load Balancing to distribute incoming traffic among the instances. For more information, see What is Elastic Load Balancing?</td>
</tr>
<tr>
<td>Siebel Gateway Name Server</td>
<td>You can host your Siebel Gateway Name Server on an EC2 instance. You can then put your server in the same VPC with the DB instance and use the VPC security group to access the database. For more information, see Working with a DB instance in a VPC (p. 2251).</td>
</tr>
</tbody>
</table>
Oracle Database engine release notes

Updates to your Amazon RDS for Oracle DB instances keep them current. If you apply updates, you can be confident that your DB instance is running a version of the database software that has been tested by both Oracle and Amazon. We don't support applying one-off patches to individual RDS for Oracle DB instances.

You can specify any currently supported Oracle Database version when you create a new DB instance. You can specify the major version, such as Oracle Database 19c, and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version that you have specified. To see a list of supported versions and defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

For details about the Oracle Database versions that Amazon RDS supports, see the Amazon RDS for Oracle Release Notes.
Amazon RDS for PostgreSQL

Amazon RDS supports DB instances running several versions of PostgreSQL. For a list of available versions, see Available PostgreSQL database versions (p. 1857).

Note
Deprecation of PostgreSQL 9.6 is scheduled for April 26, 2022. For more information, see Deprecation of PostgreSQL version 10 (p. 1858).

You can create DB instances and DB snapshots, point-in-time restores and backups. DB instances running PostgreSQL support Multi-AZ deployments, read replicas, Provisioned IOPS, and can be created inside a virtual private cloud (VPC). You can also use Secure Socket Layer (SSL) to connect to a DB instance running PostgreSQL.

Before creating a DB instance, make sure to complete the steps in Setting up for Amazon RDS (p. 153).

You can use any standard SQL client application to run commands for the instance from your client computer. Such applications include pgAdmin, a popular Open Source administration and development tool for PostgreSQL, or psql, a command line utility that is part of a PostgreSQL installation. To deliver a managed service experience, Amazon RDS doesn’t provide host access to DB instances. Also, it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn’t allow direct host access to a DB instance by using Telnet or Secure Shell (SSH).

Amazon RDS for PostgreSQL is compliant with many industry standards. For example, you can use Amazon RDS for PostgreSQL databases to build HIPAA-compliant applications and to store healthcare-related information. This includes storage for protected health information (PHI) under a completed Business Associate Agreement (BAA) with AWS. Amazon RDS for PostgreSQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements. Amazon RDS for PostgreSQL has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see AWS cloud compliance.

To import PostgreSQL data into a DB instance, follow the information in the Importing data into PostgreSQL on Amazon RDS (p. 1912) section.

Following is a list of other sections in this guide that can help you understand and use important features of RDS for PostgreSQL:

- Understanding PostgreSQL roles and permissions (p. 1967)
- Controlling user access to the PostgreSQL database (p. 1969)
- Working with parameters on your RDS for PostgreSQL DB instance (p. 1986)
- Understanding logging mechanisms supported by RDS for PostgreSQL (p. 1985)
- Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL (p. 1977)
- Using a custom DNS server for outbound network access (p. 1889)
Working with the database preview environment

The PostgreSQL community continuously releases new PostgreSQL version and extensions, including beta versions. This gives PostgreSQL users the opportunity to try out a new PostgreSQL version early. To learn more about the PostgreSQL community beta release process, see Beta Information in the PostgreSQL documentation. Similarly, Amazon RDS makes certain PostgreSQL beta versions available as Preview releases. This allows you to create DB instances using the Preview version and test out its features in the Database Preview Environment.

RDS for PostgreSQL DB instances in the Database Preview Environment are functionally similar to other RDS for PostgreSQL instances. However, you can't use a Preview version for production.

Keep in mind the following important limitations:

• All DB instances are deleted 60 days after you create them, along with any backups and snapshots.
• You can only create a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service.
• You can only use General Purpose SSD and Provisioned IOPS SSD storage.
• You can't get help from AWS Support with DB instances. Instead, you can post your questions to the AWS-managed Q&A community, AWS re:Post.
• You can't copy a snapshot of a DB instance to a production environment.

The following options are supported by the Preview.

• You can create DB instances using M6i, R6i, M6g, M5, T3, R6g, and R5 instance types only. For more information about RDS instance classes, see DB instance classes (p. 10).
• You can use both single-AZ and multi-AZ deployments.
• You can use standard PostgreSQL dump and load functions to export databases from or import databases to the Database Preview Environment.

Features not supported in the preview environment

The following features aren't available in the preview environment:

• Cross-Region snapshot copy
• Cross-Region read replicas

Creating a new DB instance in the preview environment

Use the following procedure to create a DB instance in the preview environment.

To create a DB instance in the preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Dashboard from the navigation pane.
3. In the Dashboard page, locate the Database Preview Environment section on the Dashboard page, as shown in the following image.
You can navigate directly to the Database preview environment. Before you can proceed, you must acknowledge and accept the limitations.

4. To create the RDS for PostgreSQL DB instance, follow the same process as that for creating any Amazon RDS DB instance. For more information, see the Console (p. 239) procedure in Creating a DB instance (p. 239).

To create an instance in the Database Preview Environment using the RDS API or the AWS CLI, use the following endpoint.

rds-preview.us-east-2.amazonaws.com
PostgreSQL version 15 in the database preview environment

PostgreSQL version 15 is now available in the Amazon RDS Database Preview Environment. PostgreSQL version 15 contains several improvements that are described in the following PostgreSQL documentation:

- PostgreSQL 15
- PostgreSQL 15 Beta 3 Released!

For information on the Database Preview Environment, see the section called "The database preview environment" (p. 1854). To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.
Available PostgreSQL database versions

Amazon RDS supports DB instances running several editions of PostgreSQL. You can specify any currently available PostgreSQL version when creating a new DB instance. You can specify the major version (such as PostgreSQL 14), and any available minor version for the specified major version. If no version is specified, Amazon RDS defaults to an available version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified.

To see a list of available versions, as well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command. For example, to display the default PostgreSQL engine version, use the following command:

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

For details about the PostgreSQL versions that are supported on Amazon RDS, see the Amazon RDS for PostgreSQL Release Notes.

Deprecation of PostgreSQL version 10

On April 17, 2023, Amazon RDS plans to deprecate PostgreSQL 10 using the following schedule. We recommend that you take action and upgrade your PostgreSQL databases running on major version 10 to a later version, such as PostgreSQL version 14. To upgrade your RDS for PostgreSQL major version 10 DB instance from a PostgreSQL version older than 10.19, we recommend that you first upgrade to version 10.19 and then upgrade to version 14. For more information, see Upgrading the PostgreSQL DB engine for Amazon RDS (p. 1891).

<table>
<thead>
<tr>
<th>Action or recommendation</th>
<th>Dates</th>
</tr>
</thead>
<tbody>
<tr>
<td>The PostgreSQL community plans to deprecate PostgreSQL 10 and won't provide any security patches after this date.</td>
<td>November 10, 2022</td>
</tr>
<tr>
<td>Start upgrading RDS for PostgreSQL 10 DB instances to a later major version, such as PostgreSQL 14. Although you can continue to restore PostgreSQL 10 snapshots and create read replicas with version 10, be aware of the other critical dates in this deprecation schedule and their impact.</td>
<td>Now – February 14, 2023</td>
</tr>
<tr>
<td>After this date, you can't create new Amazon RDS instances with PostgreSQL major version 10 from either the AWS Management Console or the AWS CLI.</td>
<td>February 14, 2023</td>
</tr>
<tr>
<td>After this date, Amazon RDS automatically upgrades PostgreSQL 10 instances to version 14. If you restore a PostgreSQL 10 database snapshot, Amazon RDS automatically upgrades the restored database to PostgreSQL 14.</td>
<td>April 17, 2023</td>
</tr>
</tbody>
</table>

For more information about RDS for PostgreSQL version 10 deprecation, see [Announcement]: RDS for PostgreSQL 10 deprecation in AWS re:Post.
Deprecation of PostgreSQL version 9.6

On March 31, 2022, Amazon RDS plans to deprecate PostgreSQL 9.6 using the following schedule. This extends the previously announced date of January 18, 2022 to April 26, 2022. You should upgrade all your PostgreSQL 9.6 DB instances to PostgreSQL 12 or higher as soon as possible. We recommend that you first upgrade to minor version 9.6.20 or higher and then upgrade directly to PostgreSQL 12 rather than upgrading to an intermediate major version. For more information, see Upgrading the PostgreSQL DB engine for Amazon RDS (p. 1891).

<table>
<thead>

<td>Start upgrading RDS for PostgreSQL 9.6 DB instances to PostgreSQL 12 or higher as soon as possible. Although you can continue to restore PostgreSQL 9.6 snapshots and create read replicas with version 9.6, be aware of the other critical dates in this deprecation schedule and their impact.</td>
<td>Now – March 31, 2022</td>
</tr>
<tr>
<td>After this date, you can’t create new Amazon RDS instances with PostgreSQL major version 9.6 from either the AWS Management Console or the AWS CLI.</td>
<td>March 31, 2022</td>
</tr>
<tr>
<td>After this date, Amazon RDS automatically upgrades PostgreSQL 9.6 instances to version 12. If you restore a PostgreSQL 9.6 database snapshot, Amazon RDS automatically upgrades the restored database to PostgreSQL 12.</td>
<td>April 26, 2022</td>
</tr>
</tbody>
</table>

Deprecated versions for Amazon RDS for PostgreSQL

RDS for PostgreSQL 9.5 is deprecated as of March, 2021. For more information about RDS for PostgreSQL 9.5 deprecation, see Upgrading from Amazon RDS for PostgreSQL version 9.5.

To learn more about deprecation policy for RDS for PostgreSQL, see Amazon RDS FAQs. For more information about PostgreSQL versions, see Versioning Policy in the PostgreSQL documentation.
Supported PostgreSQL extension versions

RDS for PostgreSQL supports many PostgreSQL extensions. The PostgreSQL community sometimes refers to these as modules. Extensions expand on the functionality provided by the PostgreSQL engine. You can find a list of extensions supported by Amazon RDS in the default DB parameter group for that PostgreSQL version. You can also see the current extensions list using `psql` by showing the `rds.extensions` parameter as in the following example.

```
SHOW rds.extensions;
```

**Note**
Parameters added in a minor version release might display inaccurately when using the `rds.extensions` parameter in `psql`.

As of RDS for PostgreSQL 13, certain extensions can be installed by database users other than the `rds_superuser`. These are known as trusted extensions. To learn more, see PostgreSQL trusted extensions (p. 1860).

Certain versions of RDS for PostgreSQL support the `rds.allowed_extensions` parameter. This parameter lets an `rds_superuser` limit the extensions that can be installed in the RDS for PostgreSQL DB instance. For more information, see Restricting installation of PostgreSQL extensions (p. 1859).

For lists of PostgreSQL extensions and versions that are supported by each available RDS for PostgreSQL version, see PostgreSQL extensions supported on Amazon RDS in Amazon RDS for PostgreSQL Release Notes.

Restricting installation of PostgreSQL extensions

You can restrict which extensions can be installed on a PostgreSQL DB instance. To do so, set the `rds.allowed_extensions` parameter to a string of comma-separated extension names. Only these extensions can then be installed in the PostgreSQL DB instance.

The default string for the `rds.allowed_extensions` parameter is `'*'`, which means that any extension available for the engine version can be installed. Changing the `rds.allowed_extensions` parameter does not require a database restart because it's a dynamic parameter.

The PostgreSQL DB instance engine must be one of the following versions for you to use the `rds.allowed_extensions` parameter:

- PostgreSQL 14.1 or a higher minor version
- PostgreSQL 13.2 or a higher minor version
- PostgreSQL 12.6 or a higher minor version

To see which extension installations are allowed, use the following `psql` command.

```
postgres=> SHOW rds.allowed_extensions;

rds.allowed_extensions
------------------------
*
```

If an extension was installed prior to it being left out of the list in the `rds.allowed_extensions` parameter, the extension can still be used normally, and commands such as `ALTER EXTENSION` and `DROP EXTENSION` will continue to work. However, after an extension is restricted, `CREATE EXTENSION` commands for the restricted extension will fail.
Installation of extension dependencies with `CREATE EXTENSION CASCADE` are also restricted. The extension and its dependencies must be specified in `rds.allowed_extensions`. If an extension dependency installation fails, the entire `CREATE EXTENSION CASCADE` statement will fail.

If an extension is not included with the `rds.allowed_extensions` parameter, you will see an error such as the following if you try to install it.

```
ERROR: permission denied to create extension "extension-name"
HINT: This extension is not specified in "rds.allowed_extensions".
```

### PostgreSQL trusted extensions

To install most PostgreSQL extensions requires `rds_superuser` privileges. PostgreSQL 13 introduced trusted extensions, which reduce the need to grant `rds_superuser` privileges to regular users. With this feature, users can install many extensions if they have the `CREATE` privilege on the current database instead of requiring the `rds_superuser` role. For more information, see the SQL `CREATE EXTENSION` command in the PostgreSQL documentation.

The following lists the extensions that can be installed by a user who has the `CREATE` privilege on the current database and do not require the `rds_superuser` role:

- `bool_plperl`
- `btree_gin`
- `btree_gist`
- `citext`
- `cube`
- `dict_int`
- `fuzzystrmatch`
- `hstore`
- `intarray`
- `isn`
- `jsonb_plperl`
- `ltree`
- `pg_trgm`
- `pgcrypto`
- `plperl`
- `plpgsql`
- `pltcl`
- `tablefunc`
- `tsm_system_rows`
- `tsm_system_time`
- `unaccent`
- `uuid-ossp`

For lists of PostgreSQL extensions and versions that are supported by each available RDS for PostgreSQL version, see [PostgreSQL extensions supported on Amazon RDS](https://docs.aws.amazon.com/rds/latest/infrastructure-guides/postgresql-support.html) in *Amazon RDS for PostgreSQL Release Notes*. 
Connecting to a DB instance running the PostgreSQL database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the instance. Before you can connect, the DB instance must be available and accessible. Whether you can connect to the instance from outside the VPC depends on how you created the Amazon RDS DB instance:

- If you created your DB instance as *public*, devices and Amazon EC2 instances outside the VPC can connect to your database.
- If you created your DB instance as *private*, only Amazon EC2 instances and devices inside the Amazon VPC can connect to your database.

To check whether your DB instance is public or private, use the AWS Management Console to view the Connectivity & security tab for your instance. Under Security, you can find the "Publicly accessible" value, with No for private, Yes for public.

To learn more about different Amazon RDS and Amazon VPC configurations and how they affect accessibility, see Scenarios for accessing a DB instance in a VPC (p. 2263).

If the DB instance is available and accessible, you can connect by providing the following information to the SQL client application:

- The DB instance endpoint, which serves as the host name (DNS name) for the instance.
- The port on which the DB instance is listening. For PostgreSQL, the default port is 5432.
- The user name and password for the DB instance. The default 'master username' for PostgreSQL is postgres.
- The name and password of the database (DB name).

You can obtain these details by using the AWS Management Console, the AWS CLI describe-db-instances command, or the Amazon RDS API DescribeDBInstances operation.

**To find the endpoint, port number, and DB name using the AWS Management Console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Open the RDS console and then choose Databases to display a list of your DB instances.
3. Choose the PostgreSQL DB instance name to display its details.
4. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
5. On the **Configuration** tab, note the DB name. If you created a database when you created the RDS for PostgreSQL instance, you see the name listed under DB name. If you didn't create a database, the DB name displays a dash (-).
Using pgAdmin to connect to a RDS for PostgreSQL DB instance

You can use the open-source tool pgAdmin to connect to your RDS for PostgreSQL DB instance. You can download and install pgAdmin from http://www.pgadmin.org/ without having a local instance of PostgreSQL on your client computer.

To connect to your RDS for PostgreSQL DB instance using pgAdmin

1. Launch the pgAdmin application on your client computer.
3. In the Create - Server dialog box, type a name on the General tab to identify the server in pgAdmin.
4. On the Connection tab, type the following information from your DB instance:
   - For Host, type the endpoint, for example mypostgresql.c6c8dntfzzhgv0.us-east-2.rds.amazonaws.com.
   - For Port, type the assigned port.
   - For Username, type the user name that you entered when you created the DB instance (if you changed the 'master username' from the default, postgres).
   - For Password, type the password that you entered when you created the DB instance.
5. Choose Save.

If you have any problems connecting, see Troubleshooting connections to your RDS for PostgreSQL instance (p. 1866).

6. To access a database in the pgAdmin browser, expand Servers, the DB instance, and Databases. Choose the DB instance’s database name.

7. To open a panel where you can enter SQL commands, choose Tools, Query Tool.
Using psql to connect to your RDS for PostgreSQL DB instance

You can use a local instance of the psql command line utility to connect to a RDS for PostgreSQL DB instance. You need either PostgreSQL or the psql client installed on your client computer.

To connect to your RDS for PostgreSQL DB instance using psql, you need to provide host (DNS) information, access credentials, and the name of the database.

Use one of the following formats to connect to your RDS for PostgreSQL DB instance. When you connect, you're prompted for a password. For batch jobs or scripts, use the --no-password option. This option is set for the entire session.

**Note**
A connection attempt with --no-password fails when the server requires password authentication and a password is not available from other sources. For more information, see the psql documentation.

If this is the first time you are connecting to this DB instance, or if you didn't yet create a database for this RDS for PostgreSQL instance, you can connect to the postgres database using the 'master username' and password.

For Unix, use the following format.

```
psql \
  --host=<DB instance endpoint> \
  --port=<port> \
  --username=<master username> \
  --password \
  --dbname=<database name>
```

For Windows, use the following format.

```
psql ^
  --host=<DB instance endpoint> ^
  --port=<port> ^
  --username=<master username> ^
  --password ^
  --dbname=<database name>
```

For example, the following command connects to a database called mypgdb on a PostgreSQL DB instance called mypostgresql using fictitious credentials.

```
psql --host=mypostgresql.c6c8mwvfdfv0.us-west-2.rds.amazonaws.com --port=5432 --username=awsuser --password --dbname=mypgdb
```

Connecting with the AWS JDBC Driver for PostgreSQL

The AWS JDBC Driver for PostgreSQL is a client wrapper designed for use with RDS for PostgreSQL. The AWS JDBC Driver for PostgreSQL extends the functionality of the community pgJDBC driver by enabling AWS features such as authentication. For more information about the AWS JDBC Driver for PostgreSQL and complete instructions for using it, see the AWS JDBC Driver for PostgreSQL GitHub repository.

The AWS JDBC Driver for PostgreSQL supports AWS Identity and Access Management (IAM) database authentication and AWS Secrets Manager. For more information on using these authentication...
mechanisms with the driver, see AWS IAM Authentication Plugin and AWS Secrets Manager Plugin in the AWS JDBC Driver for PostgreSQL GitHub repository.

For more information about IAM database authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2195). For more information about Secrets Manager, see the AWS Secrets Manager User Guide.

Troubleshooting connections to your RDS for PostgreSQL instance

Topics

• Error – FATAL: database name does not exist (p. 1866)
• Error – Could not connect to server: Connection timed out (p. 1866)
• Errors with security group access rules (p. 1866)

Error – FATAL: database name does not exist

If when trying to connect you receive an error like FATAL: database name does not exist, try using the default database name postgres for the --dbname option.

Error – Could not connect to server: Connection timed out

If you can't connect to the DB instance, the most common error is Could not connect to server: Connection timed out. If you receive this error, check the following:

• Check that the host name used is the DB instance endpoint and that the port number used is correct.
• Make sure that the DB instance's public accessibility is set to Yes to allow external connections. To modify the Public access setting, see Modifying an Amazon RDS DB instance (p. 333).
• Check that the security group assigned to the DB instance has rules to allow access through any firewall your connection might go through. For example, if the DB instance was created using the default port of 5432, your company might have firewall rules blocking connections to that port from external company devices.

To fix this, modify the DB instance to use a different port. Also, make sure that the security group applied to the DB instance allows connections to the new port. To modify the Database port setting, see Modifying an Amazon RDS DB instance (p. 333).
• See also Errors with security group access rules (p. 1866).

Errors with security group access rules

By far the most common connection problem is with the security group's access rules assigned to the DB instance. If you used the default security group when you created the DB instance, the security group likely didn't have access rules that allow you to access the instance.

For the connection to work, the security group you assigned to the DB instance at its creation must allow access to the DB instance. For example, if the DB instance was created in a VPC, it must have a VPC security group that authorizes connections. Check if the DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the application is running.

You can add or edit an inbound rule in the security group. For Source, choosing My IP allows access to the DB instance from the IP address detected in your browser. For more information, see Provide access to your DB instance in your VPC by creating a security group (p. 156).
Alternatively, if the DB instance was created outside of a VPC, it must have a database security group that authorizes those connections.

For more information about Amazon RDS security groups, see Controlling access with security groups (p. 2232).
Securing connections to RDS for PostgreSQL with SSL/TLS

RDS for PostgreSQL supports Secure Socket Layer (SSL) encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your PostgreSQL DB instances. You can also force all connections to your PostgreSQL DB instance to use SSL. RDS for PostgreSQL also supports Transport Layer Security (TLS), the successor protocol to SSL.

To learn more about Amazon RDS and data protection, including encrypting connections using SSL/TLS, see Data protection in Amazon RDS (p. 2146).

Topics
- Using SSL with a PostgreSQL DB instance (p. 1868)
- Updating applications to use new SSL/TLS certificates (p. 1871)

Using SSL with a PostgreSQL DB instance

Amazon RDS supports Secure Socket Layer (SSL) encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your PostgreSQL DB instances. By default, RDS for PostgreSQL uses and expects all clients to connect using SSL/TLS, but you can also require it. RDS for PostgreSQL supports Transport Layer Security (TLS) versions 1.1 and 1.2.

For general information about SSL support and PostgreSQL databases, see SSL support in the PostgreSQL documentation. For information about using an SSL connection over JDBC, see Configuring the client in the PostgreSQL documentation.

SSL support is available in all AWS Regions for PostgreSQL. Amazon RDS creates an SSL certificate for your PostgreSQL DB instance when the instance is created. If you enable SSL certificate verification, then the SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

Topics
- Connecting to a PostgreSQL DB instance over SSL (p. 1868)
- Requiring an SSL connection to a PostgreSQL DB instance (p. 1869)
- Determining the SSL connection status (p. 1869)
- SSL cipher suites in RDS for PostgreSQL (p. 1871)

Connecting to a PostgreSQL DB instance over SSL

To connect to a PostgreSQL DB instance over SSL

1. Download the certificate.

   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).

2. Import the certificate into your operating system.

   For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 2160).

3. Connect to your PostgreSQL DB instance over SSL.
When you connect using SSL, your client can choose whether to verify the certificate chain. If your connection parameters specify `sslmode=verify-ca` or `sslmode=verify-full`, then your client requires the RDS CA certificates to be in their trust store or referenced in the connection URL. This requirement is to verify the certificate chain that signs your database certificate.

When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used is different between libpq-based clients (such as psql) and JDBC. The libpq-based clients default to `prefer`, and JDBC clients default to `verify-full`.

Use the `sslrootcert` parameter to reference the certificate, for example `sslrootcert=rds-ca-2019-root.pem`.

The following is an example of using `psql` to connect to a PostgreSQL DB instance using SSL with certificate verification.

```
$ psql -h db-name.555555555555.ap-southeast-1.rds.amazonaws.com
     -p 5432 dbname=testDB user=testuser sslrootcert=rds-ca-2019-root.pem sslmode=verify-full
```

### Requiring an SSL connection to a PostgreSQL DB instance

You can require that connections to your PostgreSQL DB instance use SSL by using the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). You can set the `rds.force_ssl` parameter to 1 (on) to require SSL for connections to your DB instance.

To change the value of this parameter, you need to create a custom DB parameter group. You then change the value for `rds.force_ssl` in your custom DB parameter group to 1 to turn on this feature. If you prepare the custom DB parameter group before creating your RDS for PostgreSQL DB instance you can choose it (instead of a default parameter group) during the creation process. If you do this after your RDS for PostgreSQL DB instance is already running, you need to reboot the instance so that your instance uses the custom parameter group. For more information, see Working with parameter groups (p. 295).

When the `rds.force_ssl` feature is active on your DB instance, connection attempts that aren't using SSL are rejected with the following message:

```
$ psql -h db-name.555555555555.ap-southeast-1.rds.amazonaws.com -p 5432 dbname=testDB
     user=testuser sslmode=verify-full
psql: error: FATAL: no pg_hba.conf entry for host "w.x.y.z", user "testuser", database "testDB", SSL off
```

### Determining the SSL connection status

The encrypted status of your connection is shown in the logon banner when you connect to the DB instance:

```
Password for user master:
psql (10.3)
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.
postgres=>
```

You can also load the `sslinfo` extension and then call the `ssl_is_used()` function to determine if SSL is being used. The function returns `t` if the connection is using SSL, otherwise it returns `f`. 1869
postgres=> CREATE EXTENSION sslinfo;
CREATE EXTENSION
postgres=> SELECT ssl_is_used();
ssl_is_used
--------
t
(1 row)

For more detailed information, you can use the following query to get information from pg_settings:

```
SELECT name as "Parameter name", setting as value, short_desc FROM pg_settings WHERE name LIKE '%ssl%';
```

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>value</th>
<th>short_desc</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssl</td>

</tr>
</tbody>
</table>

(14 rows)

You can also collect all the information about your RDS for PostgreSQL DB instance's SSL usage by process, client, and application by using the following query:

```
SELECT datname as "Database name", usename as "User name", ssl, client_addr, application_name, backend_type
FROM pg_stat_ssl
JOIN pg_stat_activity
ON pg_stat_ssl.pid = pg_stat_activity.pid
ORDER BY ssl;
```

<table>
<thead>
<tr>
<th>Database name</th>
<th>User name</th>
<th>ssl</th>
<th>client_addr</th>
<th>application_name</th>
<th>backend_type</th>
</tr>

Updating applications to use new SSL/TLS certificates

Certificates used for Secure Socket Layer or Transport Layer Security (SSL/TLS) typically have a set lifetime. When service providers update their Certificate Authority (CA) certificates, clients must update their applications to use the new certificates. Following, you can find information about how to determine if your client applications use SSL/TLS to connect to your Amazon RDS for PostgreSQL DB instance. You also find information about how to check if those applications verify the server certificate when they connect.

Note
A client application that's configured to verify the server certificate before SSL/TLS connection must have a valid CA certificate in the client's trust store. Update the client trust store when necessary for new certificates.
After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a nonproduction environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 2154). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152). For information about using SSL/TLS with PostgreSQL DB instances, see Using SSL with a PostgreSQL DB instance (p. 1868).

**Topics**
- Determining whether applications are connecting to PostgreSQL DB instances using SSL (p. 1872)
- Determining whether a client requires certificate verification in order to connect (p. 1872)
- Updating your application trust store (p. 1873)
- Using SSL/TLS connections for different types of applications (p. 1873)

### Determining whether applications are connecting to PostgreSQL DB instances using SSL

Check the DB instance configuration for the value of the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). If the `rds.force_ssl` parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see Working with parameter groups (p. 295).

If you are using RDS PostgreSQL version 9.5 or later major version and `rds.force_ssl` is not set to 1 (on), query the `pg_stat_ssl` view to check connections using SSL. For example, the following query returns only SSL connections and information about the clients using SSL.

```
SELECT datname, usename, ssl, client_addr
FROM pg_stat_ssl INNER JOIN pg_stat_activity ON pg_stat_ssl.pid = pg_stat_activity.pid
WHERE ssl is true and usename<>'rdsadmin';
```

Only rows using SSL/TLS connections are displayed with information about the connection. The following is sample output.

<table>
<thead>
<tr>
<th>datname</th>
<th>usename</th>
<th>ssl</th>
<th>client_addr</th>
</tr>
</thead>
<tbody>
<tr>
<td>benchdb</td>
<td>pgadmin</td>
<td>t</td>
<td>53.95.6.13</td>
</tr>
<tr>
<td>postgres</td>
<td>pgadmin</td>
<td>t</td>
<td>53.95.6.13</td>
</tr>
</tbody>
</table>

(2 rows)

This query displays only the current connections at the time of the query. The absence of results doesn't indicate that no applications are using SSL connections. Other SSL connections might be established at a different time.

### Determining whether a client requires certificate verification in order to connect

When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used is different between libpq-based clients (such as psql) and JDBC. The libpq-based clients default to `prefer`, where JDBC clients default to `verify-full`. The certificate on the server is verified only when `sslrootcert` is provided with `sslmode` set to `require`, `verify-ca`, or `verify-full`. An error is thrown if the certificate is invalid.
Use PGSSLROOTCERT to verify the certificate with the PGSSLMODE environment variable, with PGSSLMODE set to require, verify-ca, or verify-full.

```bash
```

Use the sslrootcert argument to verify the certificate with sslmode in connection string format, with sslmode set to require, verify-ca, or verify-full to verify the certificate.

```bash
psql "host=pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com sslmode=require sslrootcert=/fullpath/rds-ca-2019-root.pem user=masteruser dbname=postgres"
```

For example, in the preceding case, if you are using an invalid root certificate, then you see an error similar to the following on your client.

```
psql: SSL error: certificate verify failed
```

### Updating your application trust store

For information about updating the trust store for PostgreSQL applications, see [Secure TCP/IP connections with SSL](https://www.postgresql.org/docs/13/ssl-configuration.html) in the PostgreSQL documentation.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_ManagingYourDBInstanceSDC.html#rds-ssl-root-certificate) (p. 2152).

For sample scripts that import certificates, see [Sample script for importing certificates into your trust store](https://github.com/aws/aws-rds-db-library/blob/master/samples/scale-out-ssl.sh) (p. 2160).

**Note**

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

### Using SSL/TLS connections for different types of applications

The following provides information about using SSL/TLS connections for different types of applications:

- **psql**

  The client is invoked from the command line by specifying options either as a connection string or as environment variables. For SSL/TLS connections, the relevant options are sslmode (environment variable PGSSLMODE), sslrootcert (environment variable PGSSLROOTCERT).

  For the complete list of options, see [Parameter key words](https://www.postgresql.org/docs/13/ssl-configuration.html#Parameter-key-words) in the PostgreSQL documentation. For the complete list of environment variables, see [Environment variables](https://www.postgresql.org/docs/13/libpq-environment.html) in the PostgreSQL documentation.

- **pgAdmin**

  This browser-based client is a more user-friendly interface for connecting to a PostgreSQL database.

  For information about configuring connections, see the [pgAdmin documentation](https://www.pgadmin.org/docs/).

- **JDBC**

  JDBC enables database connections with Java applications.

  For general information about connecting to a PostgreSQL database with JDBC, see [Connecting to the database](https://jdbc.postgresql.org/) in the PostgreSQL JDBC driver documentation. For information about connecting with SSL/TLS, see [Configuring the client](https://jdbc.postgresql.org/manual/security.html) in the PostgreSQL JDBC driver documentation.
• **Python**

A popular Python library for connecting to PostgreSQL databases is **psycopg2**.

For information about using psycopg2, see the [psycopg2 documentation](#). For a short tutorial on how to connect to a PostgreSQL database, see [Psycopg2 tutorial](#). You can find information about the options the connect command accepts in [The psycopg2 module content](#).

**Important**

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance](#).
Using Kerberos authentication with Amazon RDS for PostgreSQL

You can use Kerberos to authenticate users when they connect to your DB instance running PostgreSQL. To do so, you configure your DB instance to use AWS Directory Service for Microsoft Active Directory for Kerberos authentication. AWS Directory Service for Microsoft Active Directory is also called AWS Managed Microsoft AD. It's a feature available with AWS Directory Service. To learn more, see What is AWS Directory Service? in the AWS Directory Service Administration Guide.

You create an AWS Managed Microsoft AD directory to store user credentials. You then provide to your PostgreSQL DB instance the Active Directory's domain and other information. When users authenticate with the PostgreSQL DB instance, authentication requests are forwarded to the AWS Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized place for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

You can also access credentials from your own on-premises Microsoft Active Directory. To do so you create a trusting domain relationship so that the AWS Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your PostgreSQL instances with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

Topics

- Region and version availability (p. 1875)
- Overview of Kerberos authentication for PostgreSQL DB instances (p. 1875)
- Setting up Kerberos authentication for PostgreSQL DB instances (p. 1876)
- Managing a DB instance in a Domain (p. 1885)
- Connecting to PostgreSQL with Kerberos authentication (p. 1886)

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS for PostgreSQL with Kerberos authentication, see Kerberos authentication (p. 105).

Overview of Kerberos authentication for PostgreSQL DB instances

To set up Kerberos authentication for a PostgreSQL DB instance, take the following steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service API to create the directory. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the instance.

2. Create a role that provides Amazon RDS access to make calls to your AWS Managed Microsoft AD directory. To do so, create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.
For the IAM role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

4. If you plan to locate the directory and the DB instance in different AWS accounts or virtual private clouds (VPCs), configure VPC peering. For more information, see What is VPC peering? in the Amazon VPC Peering Guide.

5. Create or modify a PostgreSQL DB instance either from the console, CLI, or RDS API using one of the following methods:
   - Creating an Amazon RDS DB instance (p. 236)
   - Modifying an Amazon RDS DB instance (p. 333)
   - Restoring from a DB snapshot (p. 487)
   - Restoring a DB instance to a specified time (p. 534)

   You can locate the instance in the same Amazon Virtual Private Cloud (VPC) as the directory or in a different AWS account or VPC. When you create or modify the PostgreSQL DB instance, do the following:
   - Provide the domain identifier (d-* identifier) that was generated when you created your directory.
   - Provide the name of the IAM role that you created.
   - Ensure that the DB instance security group can receive inbound traffic from the directory security group.

6. Use the RDS master user credentials to connect to the PostgreSQL DB instance. Create the user in PostgreSQL to be identified externally. Externally identified users can log in to the PostgreSQL DB instance using Kerberos authentication.

### Setting up Kerberos authentication for PostgreSQL DB instances

You use AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to set up Kerberos authentication for a PostgreSQL DB instance. To set up Kerberos authentication, take the following steps.

#### Topics
- Step 1: Create a directory using AWS Managed Microsoft AD (p. 1877)
- Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and AWS Directory Service (p. 1880)
- Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service (p. 1881)
- Step 4: Create and configure users (p. 1882)
- Step 5: Enable cross-VPC traffic between the directory and the DB instance (p. 1882)
- Step 6: Create or modify a PostgreSQL DB instance (p. 1883)
- Step 7: Create PostgreSQL users for your Kerberos principals (p. 1884)
- Step 8: Configure a PostgreSQL client (p. 1885)
Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and DNS servers for you. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within your VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

  **Important**
  Make sure to save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

- Creates a security group for the directory controllers. The security group must permit communication with the PostgreSQL DB instance.

When you launch AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU, which has the NetBIOS name that you entered when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run Active Directory and Domain Name Service (DNS) modules for Windows PowerShell on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

**To create a directory with AWS Managed Microsoft AD**

1. In the AWS Directory Service console navigation pane, choose Directories, and then choose Set up directory.
2. Choose AWS Managed Microsoft AD. AWS Managed Microsoft AD is the only option currently supported for use with Amazon RDS.
3. Choose Next.
4. On the Enter directory information page, provide the following information:
Edition

Choose the edition that meets your requirements.

Directory DNS name

The fully qualified name for the directory, such as corp.example.com.

Directory NetBIOS name

An optional short name for the directory, such as CORP.

Directory description

An optional description for the directory.

Admin password

The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Nonalphanumeric characters (~!#$%^&*_+-=\|(){}[]:;"'<>?,./)

Confirm password

Retype the administrator password.

Important
Make sure that you save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

5. Choose Next.

6. On the Choose VPC and subnets page, provide the following information:

VPC

Choose the VPC for the directory. You can create the PostgreSQL DB instance in this same VPC or in a different VPC.

Subnets

Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose Next.

8. Review the directory information. If changes are needed, choose Previous and make the changes. When the information is correct, choose Create directory.
It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID** value. You need this value when you create or modify your PostgreSQL DB instance.
Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and AWS Directory Service

If you don’t plan to use your own on-premises Microsoft Active Directory, skip to Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service (p. 1881).

To get Kerberos authentication using your on-premises Active Directory, you need to create a trusting domain relationship using a forest trust between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD directory (created in Step 1: Create a directory using AWS Managed Microsoft AD (p. 1877)). The trust can be one-way, where the AWS Managed Microsoft AD directory trusts the on-premises Microsoft Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.

Note
If you use an on-premises Microsoft Active Directory, Windows clients connect using the domain name of the AWS Directory Service in the endpoint rather than rds.amazonaws.com. To learn more, see Connecting to PostgreSQL with Kerberos authentication (p. 1886).
Make sure that your on-premises Microsoft Active Directory domain name includes a DNS suffix routing that corresponds to the newly created trust relationship. The following screenshot shows an example.

Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service

For Amazon RDS to call AWS Directory Service for you, your AWS account needs an IAM role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess. This role allows Amazon RDS to make calls to AWS Directory Service.

When you create a DB instance using the AWS Management Console and your console user account has the iam:CreateRole permission, the console creates the needed IAM role automatically. In this case, the role name is rds-directoryservice-kerberos-access-role. Otherwise, you must create the IAM role manually. When you create this IAM role, choose Directory Service, and attach the AWS managed policy AmazonRDSDirectoryServiceAccess to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

Note

The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for Amazon RDS for PostgreSQL.

As an alternative to using the AmazonRDSDirectoryServiceAccess managed policy, you can create policies with the required permissions. In this case, the IAM role must have the following IAM trust policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": ['directoryservice.rds.amazonaws.com'],
        "Service": ['directoryservice.rds.amazonaws.com']
      }
    }
  ]
}
```
The role must also have the following IAM role policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ds:DescribeDirectories",
                "ds:AuthorizeApplication",
                "ds:UnauthorizeApplication",
                "ds:GetAuthorizedApplicationDetails"
            ],
            "Effect": "Allow",
            "Resource": "*"
        }
    ]
}
```

**Step 4: Create and configure users**

You can create users by using the Active Directory Users and Computers tool. This is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. For more information, see [Add Users and Computers to the Active Directory domain](https://docs.microsoft.com/en-us/windows-server/administration/add-users-and-computers) in the Microsoft documentation. In this case, users are individuals or other entities, such as their computers that are part of the domain and whose identities are being maintained in the directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that's a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information, see [Create a user](https://docs.aws.amazon.com DIRECTORY-SERVICES/latest/admin-guide/ds-create-user.html) in the *[AWS Directory Service Administration Guide](https://docs.aws.amazon.com/ Directory-Services/latest/admin-guide/ds-create-user.html)*.

**Step 5: Enable cross-VPC traffic between the directory and the DB instance**

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 6: [Create or modify a PostgreSQL DB instance](#). If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or [AWS Transit Gateway](https://docs.aws.amazon.com/ transit-gateway/latest/userguide/what-is.html).

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in [What is VPC peering?](https://docs.aws.amazon.com/ virtual-private-cloud/latest/vpc/what-is-vpc-peering.html) in the *Amazon Virtual Private Cloud Peering Guide*.

**To enable cross-VPC traffic using VPC peering**

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance security group can receive inbound traffic from the directory security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.
If a different AWS account owns the directory, you must share the directory.

**To share the directory between AWS accounts**

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in *Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join* in the *AWS Directory Service Administration Guide*.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the Directory ID value. You use this directory ID to join the DB instance to the domain.

**Step 6: Create or modify a PostgreSQL DB instance**

Create or modify a PostgreSQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new PostgreSQL DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation. For instructions, see *Creating an Amazon RDS DB instance* (p. 236).
- Modify an existing PostgreSQL DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation. For instructions, see *Modifying an Amazon RDS DB instance* (p. 333).
- Restore a PostgreSQL DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation. For instructions, see *Restoring from a DB snapshot* (p. 487).
- Restore a PostgreSQL DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation. For instructions, see *Restoring a DB instance to a specified time* (p. 534).

Kerberos authentication is only supported for PostgreSQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows ingress and egress within the directory's VPC so the DB instance can communicate with the directory.

**Console**

When you use the console to create, modify, or restore a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Then choose **Browse Directory**. Select the directory or choose **Create a new directory** to use the Directory Service.
AWS CLI

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

For example, the following CLI command modifies a DB instance to use a directory.

```
aws rds modify-db-instance --db-instance-identifier mydbinstance --domain d-Directory-ID --domain-iam-role-name role-name
```

Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Step 7: Create PostgreSQL users for your Kerberos principals

At this point, your RDS for PostgreSQL DB instance is joined to the AWS Managed Microsoft AD domain. The users that you created in the directory in Step 4: Create and configure users (p. 1882) need to be set up as PostgreSQL database users and granted privileges to login to the database. You do that by signing in as the database user with rds_superuser privileges. For example, if you accepted the defaults when you created your RDS for PostgreSQL DB instance, you use postgres, as shown in the following steps.

To create PostgreSQL database users for Kerberos principals

1. Use psql to connect to your RDS for PostgreSQL DB instance endpoint using psql. The following example uses the default postgres account for the rds_superuser role.

   ```
   psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Create a database user name for each Kerberos principal (Active Directory username) that you want to have access to the database. Use the canonical username (identity) as defined in the Active Directory instance, that is, a lower-case alias (username in Active Directory) and the upper-case name of the Active Directory domain for that user name. The Active Directory user name is an externally authenticated user, so use quotes around the name as shown following.

   ```
   postgres=> CREATE USER "username@CORP.EXAMPLE.COM" WITH LOGIN;
   CREATE ROLE
   ```

3. Grant the rds_ad role to the database user.

   ```
   postgres=> GRANT rds_ad TO "username@CORP.EXAMPLE.COM";
   GRANT ROLE
   ```

After you finish creating all the PostgreSQL users for your Active Directory user identities, users can access the RDS for PostgreSQL DB instance by using their Kerberos credentials.

It's assumed that the database users who authenticate using Kerberos are doing so from client machines that are members of the Active Directory domain.
Managing a DB instance in a Domain

You can use the console, the CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate an Active Directory to enable Kerberos authentication. You can also remove the association for an Active Directory to disable Kerberos.
authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the `modify-db-instance` CLI command. Specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the `modify-db-instance` CLI command. Specify none for the `--domain` option.
- To move a DB instance from one domain to another, use the `modify-db-instance` CLI command. Specify the domain identifier of the new domain for the `--domain` option.

**Understanding Domain membership**

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership in the console or by running the `describe-db-instances` CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. In some cases, the attempt to enable Kerberos authentication might fail when you create or modify a DB instance. If so, make sure that you are using the correct IAM role, then modify the DB instance to join the domain.

**Note**

Only Kerberos authentication with RDS for PostgreSQL sends traffic to the domain's DNS servers. All other DNS requests are treated as outbound network access on your DB instances running PostgreSQL. For more information about outbound network access with RDS for PostgreSQL, see Using a custom DNS server for outbound network access (p. 1889).

**Connecting to PostgreSQL with Kerberos authentication**

You can connect to PostgreSQL with Kerberos authentication with the pgAdmin interface or with a command-line interface such as psql. For more information about connecting, see Connecting to a DB instance running the PostgreSQL database engine (p. 1861). For information about obtaining the endpoint, port number, and other details needed for connection, see Using pgAdmin to connect to a PostgreSQL DB instance (p. 198).
pgAdmin

To use pgAdmin to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. Launch the pgAdmin application on your client computer.
3. In the Create - Server dialog box, enter a name on the General tab to identify the server in pgAdmin.
4. On the Connection tab, enter the following information from your RDS for PostgreSQL database.
   - For **Host**, enter the endpoint for the RDS for PostgreSQL DB instance. An endpoint looks similar to the following:

   ```
   RDS-DB-instance.111122223333.aws-region.rds.amazonaws.com
   ```

   To connect to an on-premises Microsoft Active Directory from a Windows client, you use the domain name of the AWS Managed Active Directory instead of `rds.amazonaws.com` in the host endpoint. For example, suppose that the domain name for the AWS Managed Active Directory is `corp.example.com`. Then for **Host**, the endpoint would be specified as follows:

   ```
   RDS-DB-instance.111122223333.aws-region.corp.example.com
   ```

   - For **Port**, enter the assigned port.
   - For **Maintenance database**, enter the name of the initial database to which the client will connect.
   - For **Username**, enter the user name that you entered for Kerberos authentication in `Step 7: Create PostgreSQL users for your Kerberos principals` (p. 1884).

5. Choose Save.

Psql

To use psql to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. At a command prompt, run the following command.

   ```
   kinit username
   ```

   Replace `username` with the user name. At the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. If the PostgreSQL DB instance is using a publicly accessible VPC, put a private IP address for your DB instance endpoint in your `/etc/hosts` file on the EC2 client. For example, the following commands obtain the private IP address and then put it in the `/etc/hosts` file.

   ```
   % dig +short PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com
   ;; Truncated, retrying in TCP mode.
   34.210.197.118
   % echo "34.210.197.118 PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com" >> /etc/hosts
   ```

   If you're using an on-premises Microsoft Active Directory from a Windows client, then you need to connect using a specialized endpoint. Instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint, use the domain name of the AWS Managed Active Directory.
For example, suppose that the domain name for your AWS Managed Active Directory is corp.example.com. Then use the format `PostgreSQL-endpoint.AWS-Region.corp.example.com` for the endpoint and put it in the `/etc/hosts` file.

```bash
% echo " 34.210.197.118 PostgreSQL-endpoint.AWS-Region.corp.example.com" >> /etc/hosts
```

3. Use the following `psql` command to log in to a PostgreSQL DB instance that is integrated with Active Directory.

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com postgres
```

To log in to the PostgreSQL DB cluster from a Windows client using an on-premises Active Directory, use the following `psql` command with the domain name from the previous step (corp.example.com):

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.corp.example.com postgres
```
Using a custom DNS server for outbound network access

RDS for PostgreSQL supports outbound network access on your DB instances and allows Domain Name Service (DNS) resolution from a custom DNS server owned by the customer. You can resolve only fully qualified domain names from your RDS for PostgreSQL DB instance through your custom DNS server.

Topics
- Turning on custom DNS resolution (p. 1889)
- Turning off custom DNS resolution (p. 1889)
- Setting up a custom DNS server (p. 1889)

Turning on custom DNS resolution

To turn on DNS resolution in your customer VPC, first associate a custom DB parameter group to your RDS for PostgreSQL instance. Then turn on the rds.custom_dns_resolution parameter by setting it to 1, and then restart the DB instance for the changes to take place.

Turning off custom DNS resolution

To turn off DNS resolution in your customer VPC, first turn off the rds.custom_dns_resolution parameter of your custom DB parameter group by setting it to 0. Then restart the DB instance for the changes to take place.

Setting up a custom DNS server

After you set up your custom DNS name server, it takes up to 30 minutes to propagate the changes to your DB instance. After the changes are propagated to your DB instance, all outbound network traffic requiring a DNS lookup queries your DNS server over port 53.

Note
If you don't set up a custom DNS server and rds.custom_dns_resolution is set to 1, hosts are resolved using an Amazon Route 53 private zone. For more information, see Working with private hosted zones.

To set up a custom DNS server for your RDS for PostgreSQL DB instance

1. From the Dynamic Host Configuration Protocol (DHCP) options set attached to your VPC, set the domain-name-servers option to the IP address of your DNS name server. For more information, see DHCP options sets.
   
   Note
   The domain-name-servers option accepts up to four values, but your Amazon RDS DB instance uses only the first value.

2. Ensure that your DNS server can resolve all lookup queries, including public DNS names, Amazon EC2 private DNS names, and customer-specific DNS names. If the outbound network traffic contains any DNS lookups that your DNS server can't handle, your DNS server must have appropriate upstream DNS providers configured.

3. Configure your DNS server to produce User Datagram Protocol (UDP) responses of 512 bytes or less.

4. Configure your DNS server to produce Transmission Control Protocol (TCP) responses of 1,024 bytes or less.
5. Configure your DNS server to allow inbound traffic from your Amazon RDS DB instances over port 53. If your DNS server is in an Amazon VPC, the VPC must have a security group that contains inbound rules that allow UDP and TCP traffic on port 53. If your DNS server is not in an Amazon VPC, it must have appropriate firewall settings to allow UDP and TCP inbound traffic on port 53.

For more information, see Security groups for your VPC and Adding and removing rules.

6. Configure the VPC of your Amazon RDS DB instance to allow outbound traffic over port 53. Your VPC must have a security group that contains outbound rules that allow UDP and TCP traffic on port 53.

For more information, see Security groups for your VPC and Adding and removing rules in the Amazon VPC User Guide.

7. Make sure that the routing path between the Amazon RDS DB instance and the DNS server is configured correctly to allow DNS traffic.

Also, if the Amazon RDS DB instance and the DNS server are not in the same VPC, make sure that a peering connection is set up between them. For more information, see What is VPC peering? in Amazon VPC Peering Guide.
Upgrading the PostgreSQL DB engine for Amazon RDS

There are two types of upgrades you can manage for your PostgreSQL DB instance:

- Operating system updates – Occasionally, Amazon RDS might need to update the underlying operating system of your DB instance to apply security fixes or OS changes. You can decide when Amazon RDS applies OS updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API. For more information about OS updates, see Applying updates for a DB instance (p. 361).

- Database engine upgrades – When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version.

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for PostgreSQL DB instances: major version upgrades and minor version upgrades.

**Major version upgrades**

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you follow the steps described in Choosing a major version upgrade for PostgreSQL (p. 1893). During a major version upgrade, Amazon RDS also upgrades all of your in-Region read replicas along with the primary DB instance.

**Minor version upgrades**

In contrast, minor version upgrades include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or you can enable the Auto minor version upgrade option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. If your PostgreSQL DB instance is using read replicas, you must first upgrade all of the read replicas before upgrading the primary instance. If your DB instance is in a Multi-AZ deployment, then the writer and any standby replicas are upgraded simultaneously. Therefore, your DB instance might not be available until the upgrade is complete. For more details, see Automatic minor version upgrades for PostgreSQL (p. 1899). For information about manually performing a minor version upgrade, see Manually upgrading the engine version (p. 369).

For more information about database engine versions, and the policy for deprecating database engine versions, see Database Engine Versions in the Amazon RDS FAQs.

- Overview of upgrading PostgreSQL (p. 1892)
- PostgreSQL version numbers (p. 1893)
- Choosing a major version upgrade for PostgreSQL (p. 1893)
- How to perform a major version upgrade (p. 1895)
- Automatic minor version upgrades for PostgreSQL (p. 1899)
- Upgrading PostgreSQL extensions (p. 1901)
Overview of upgrading PostgreSQL

To safely upgrade your DB instances, Amazon RDS uses the pg_upgrade utility described in the PostgreSQL documentation.

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
  --engine postgres
  --engine-version version-number
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}"
  --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions
  --engine postgres
  --engine-version version-number
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}"
  --output text
```

For example, to identify the valid upgrade targets for a PostgreSQL version 10.11 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
  --engine postgres
  --engine-version 10.11
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}"
  --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions
  --engine postgres
  --engine-version 10.11
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}"
  --output text
```

If your backup retention period is greater than 0, Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. If the upgrade doesn't work for your databases, you can restore this snapshot to create a DB instance running the old version. The second DB snapshot is taken after the upgrade completes.

**Note**

Amazon RDS takes DB snapshots during the upgrade process only if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see Modifying an Amazon RDS DB instance (p. 333).

When you perform a major version upgrade of the primary DB instance, all the in-Region read replicas are also automatically upgraded. After the upgrade workflow starts, the read replicas wait for the pg_upgrade to complete successfully on the primary DB instance. Then the primary DB instance upgrade waits for the read replica upgrades to complete. You experience an outage until the upgrade is complete.
If your DB instance is in a Multi-AZ deployment, both the primary writer DB instance and standby DB instances are upgraded. The writer and standby DB instances are upgraded at the same time.

After an upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the DB snapshot that was taken before the upgrade to create a new DB instance.

**PostgreSQL version numbers**

The version numbering sequence for the PostgreSQL database engine is as follows:

- For PostgreSQL versions 10 and later, the engine version number is in the form `major.minor`. The major version number is the integer part of the version number. The minor version number is the fractional part of the version number.

  A major version upgrade increases the integer part of the version number, such as upgrading from `10.minor` to `11.minor`.

- For PostgreSQL versions earlier than 10, the engine version number is in the form `major.major.minor`. The major engine version number is both the integer and the first fractional part of the version number. For example, 9.6 is a major version. The minor version number is the third part of the version number. For example, for version 9.6.12, the 12 is the minor version number.

  A major version upgrade increases the major part of the version number. For example, an upgrade from `9.6.12` to `10.11` is a major version upgrade, where 9.6 and 10 are the major version numbers.

**Choosing a major version upgrade for PostgreSQL**

Major version upgrades can contain changes that are not backward-compatible with previous versions of the database. New functionality can cause your existing applications to stop working correctly. For this reason, Amazon RDS doesn't apply major version upgrades automatically. To perform a major version upgrade, you modify your DB instance manually. Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production DB instances. When you do a PostgreSQL major version upgrade, we recommend that you follow the steps described in [How to perform a major version upgrade](p. 1895).

When you upgrade a PostgreSQL DB instance to its next major version, any read replicas associated with the DB instance are also upgraded to that next major version. In some cases, you can skip to a higher major version when upgrading. If your upgrade skips a major version, the read replicas are also upgraded to that target major version. Upgrades to version 11 that skip other major versions have certain limitations. You can find the details in the steps described in [How to perform a major version upgrade](p. 1895).

Most PostgreSQL extensions aren't upgraded during a PostgreSQL engine upgrade. These must be upgraded separately. For more information, see [Upgrading PostgreSQL extensions](p. 1901).

You can find out which major versions are available for your RDS for PostgreSQL DB instance by running the following AWS CLI query:

```bash
aws rds describe-db-engine-versions --engine postgres --engine-version your-version --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

The following table summarizes the results of this query for all available versions. An asterisk (*) on the version number means that version is deprecated. If your current version is deprecated, we recommend that you upgrade to the newest minor version upgrade target or to one of the other
Choosing a major version upgrade

available upgrade targets for that version. For more information about RDS for PostgreSQL 9.6 deprecation, see Deprecation of PostgreSQL version 10 (p. 1858).

</tr>
</tbody>
</table>
How to perform a major version upgrade

We recommend the following process when upgrading an Amazon RDS PostgreSQL DB instance:

1. **Have a version-compatible parameter group ready** – If you are using a custom parameter group, you have two options. You can specify a default parameter group for the new DB engine version. Or you can create your own custom parameter group for the new DB engine version. For more information, see [Working with parameter groups](#).

2. **Check for unsupported DB instance classes** – Check that your database's instance class is compatible with the PostgreSQL version you are upgrading to. For more information, see [Supported DB engines for DB instance classes](#).

3. **Check for unsupported usage:**
   - **Prepared transactions** – Commit or roll back all open prepared transactions before attempting an upgrade.

   You can use the following query to verify that there are no open prepared transactions on your instance.

---

<table>
<thead>
<tr>
<th>Current source version (<em>deprecated</em>)</th>
<th>Newest minor version upgrade target</th>
<th>Newest major version upgrade target</th>
<th>Other available upgrade targets</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.22</td>
<td>14.5</td>
<td>13.8</td>
<td></td>
</tr>
<tr>
<td>10.21</td>
<td>14.4</td>
<td>13.7</td>
<td>12.11</td>
</tr>
<tr>
<td>10.20</td>
<td>14.2</td>
<td>13.6</td>
<td>12.10</td>
</tr>
<tr>
<td>10.19</td>
<td>14.1</td>
<td>13.5</td>
<td>12.9</td>
</tr>
<tr>
<td>9.6.24</td>
<td>14.1</td>
<td>13.5</td>
<td>12.9</td>
</tr>
</tbody>
</table>
SELECT count(*) FROM pg_catalog.pg_prepared_xacts;

- **Reg* data types** – Remove all uses of the reg* data types before attempting an upgrade. Except for regtype and regclass, you can't upgrade the reg* data types. The pg_upgrade utility can't persist this data type, which is used by Amazon RDS to do the upgrade.

To verify that there are no uses of unsupported reg* data types, use the following query for each database.

```
SELECT count(*) FROM pg_catalog.pg_class c, pg_catalog.pg_namespace n,
    pg_catalog.pg_attribute a
WHERE c.oid = a.attrelid
AND NOT a.attisdropped
    AND a.atttypid IN ('pg_catalog.regproc'::pg_catalog.regtype,
        'pg_catalog.regprocedure'::pg_catalog.regtype,
        'pg_catalog.regoper'::pg_catalog.regtype,
        'pg_catalog.regoperator'::pg_catalog.regtype,
        'pg_catalog.regconfig'::pg_catalog.regtype,
        'pg_catalog.regdictionary'::pg_catalog.regtype)
    AND c.relnamespace = n.oid
    AND n.nspname NOT IN ('pg_catalog', 'information_schema');
```

4. **Handle logical replication slots** – An upgrade can't occur if the instance has any logical replication slots. Logical replication slots are typically used for AWS DMS migration and for replicating tables from the database to data lakes, BI tools, and other targets. Before upgrading, make sure that you know the purpose of any logical replication slots that are in use, and confirm that it's okay to delete them. If the logical replication slots are still being used, you shouldn't delete them, and you can't proceed with the upgrade.

If the logical replication slots aren't needed, you can delete them using the following SQL:

```
SELECT * FROM pg_replication_slots;
SELECT pg_drop_replication_slot(slot_name);
```

Logical replication setups that use the pglogical extension also need to have slots dropped for a successful major version upgrade. For information about how to identify and drop slots created using the pglogical extension, see Managing logical replication slots for RDS for PostgreSQL (p. 2075).

5. **Handle read replicas** – An upgrade also upgrades the in-Region read replicas along with the primary DB instance.

You can't upgrade read replicas separately. If you could, it could lead to situations where the primary and replica DB instances have different PostgreSQL major versions. However, read replica upgrades might increase downtime on the primary DB instance. To prevent a read replica upgrade, promote the replica to a standalone instance or delete it before starting the upgrade process.

The upgrade process recreates the read replica's parameter group based on the read replica's current parameter group. You can apply a custom parameter group to a read replica only after the upgrade completes by modifying the read replica. For more information about read replicas, see Working with read replicas for Amazon RDS for PostgreSQL (p. 1904).

6. **Perform a backup** – We recommend that you perform a backup before performing the major version upgrade so that you have a known restore point for your database. If your backup retention period is greater than 0, the upgrade process creates DB snapshots of your DB instance before and after upgrading. To change your backup retention period, see Modifying an Amazon RDS DB instance (p. 333). To perform a backup manually, see Creating a DB snapshot (p. 483).
7. **Upgrade certain extensions before a major version upgrade** – If you plan to skip a major version with the upgrade, you need to update certain extensions before performing the major version upgrade. For example, upgrading from versions 9.5.x or 9.6.x to version 11.x skips a major version. The extensions to update include PostGIS and related extensions for processing spatial data.

- address_standardizer
- address_standardizer_data_us
- postgis
- postgis_tiger_geocoder
- postgis_topology

Run the following command for each extension that you're using:

```
ALTER EXTENSION PostgreSQL-extension UPDATE TO 'new-version'
```

For more information, see Upgrading PostgreSQL extensions (p. 1901). To learn more about upgrading PostGIS, see Step 6: Upgrade the PostGIS extension (p. 2084).

8. **Drop certain extensions before the major version upgrade** – An upgrade that skips a major version to version 11.x doesn't support updating the pgRouting extension. Upgrading from versions 9.4.x, 9.5.x, or 9.6.x to versions 11.x skip a major version. It's safe to drop the pgRouting extension and then reinstall it to a compatible version after the upgrade. For the extension versions you can update to, see Supported PostgreSQL extension versions (p. 1859).

The tsearch2 and chkpass extensions are no longer supported for PostgreSQL versions 11 or later. If you are upgrading to version 11.x, drop the tsearch2, and chkpass extensions before the upgrade.

9. **Drop unknown data types** – Drop unknown data types depending on the target version.

PostgreSQL version 10 stopped supporting the unknown data type. If a version 9.6 database uses the unknown data type, an upgrade to a version 10 shows an error message such as the following:

```
Database instance is in a state that cannot be upgraded: PreUpgrade checks failed: The instance could not be upgraded because the 'unknown' data type is used in user tables. Please remove all usages of the 'unknown' data type and try again."
```

To find the unknown data type in your database so you can remove the offending column or change it to a supported data type, use the following SQL:

```
SELECT DISTINCT data_type FROM information_schema.columns WHERE data_type ILIKE 'unknown';
```

10. **Perform an upgrade dry run** – We highly recommend testing a major version upgrade on a duplicate of your production database before attempting the upgrade on your production database. To create a duplicate test instance, you can either restore your database from a recent snapshot or do a point-in-time restore of your database to its latest restorable time. For more information, see Restoring from a snapshot (p. 489) or Restoring a DB instance to a specified time (p. 534). For details on performing the upgrade, see Manually upgrading the engine version (p. 369).

In upgrading a version 9.6 DB instance to version 10, be aware that PostgreSQL 10 enables parallel queries by default. You can test the impact of parallelism before the upgrade by changing the `max_parallel_workers_per_gather` parameter on your test DB instance to 2.

**Note**

The default value for `max_parallel_workers_per_gather` parameter in the default.postgresql10 DB parameter group is 2.
For more information, see Parallel Query in the PostgreSQL documentation. To disable parallelism on version 10, set the max_parallel_workers_per_gather parameter to 0.

During the major version upgrade, the public and template1 databases and the public schema in every database on the instance are temporarily renamed. These objects appear in the logs with their original name and a random string appended. The string is appended so that custom settings such as locale and owner are preserved during the major version upgrade. After the upgrade completes, the objects are renamed back to their original names.

**Note**
During the major version upgrade process, you can’t do a point-in-time restore of your instance. After Amazon RDS performs the upgrade, it takes an automatic backup of the instance. You can perform a point-in-time restore to times before the upgrade began and after the automatic backup of your instance has completed.

If an upgrade fails with precheck procedure errors, resolve the issues – During the major version upgrade process, Amazon RDS for PostgreSQL first runs a precheck procedure to identify any issues that might cause the upgrade to fail. The precheck procedure checks all potential incompatible conditions across all databases in the instance.

If the precheck encounters an issue, it creates a log event indicating the upgrade precheck failed. The precheck process details are in an upgrade log named pg_upgrade_precheck.log for all the databases of a DB instance. Amazon RDS appends a timestamp to the file name. For more information about viewing logs, see Monitoring Amazon RDS log files (p. 716).

If a read replica upgrade fails at precheck, replication on the failed read replica is broken and the read replica is put in the terminated state. Delete the read replica and recreate a new read replica based on the upgraded primary DB instance.

Resolve all of the issues identified in the precheck log and then retry the major version upgrade. The following is an example of a precheck log.

```
Upgrade could not be run on Wed Apr 4 18:30:52 2018
The instance could not be upgraded from 9.6.11 to 10.6 for the following reasons.
Please take appropriate action on databases that have usage incompatible with the requested major engine version upgrade and try the upgrade again.

* There are uncommitted prepared transactions. Please commit or rollback all prepared transactions.* One or more role names start with 'pg_'. Rename all role names that start with 'pg_'.

* The following issues in the database 'my"million$"db' need to be corrected before upgrading:** The ['"line","reg*"] data types are used in user tables. Remove all usage of these data types.
** The database name contains characters that are not supported by RDS for PostgreSQL. Rename the database.
** The database has extensions installed that are not supported on the target database version. Drop the following extensions from your database: ['"tsearch2"].

* The following issues in the database 'mydb' need to be corrected before upgrading:** The database has views or materialized views that depend on 'pg_stat_activity'. Drop the views.
```

If a read replica upgrade fails while upgrading the database, resolve the issue – A failed read replica is placed in the incompatible-restore state and replication is terminated on the DB instance. Delete the read replica and recreate a new read replica based on the upgraded primary DB instance.

A read replica upgrade might fail for the following reasons:
- It was unable to catch up with the primary DB instance even after a wait time.
It was in a terminal or incompatible lifecycle state such as storage-full, incompatible-restore, and so on.

When the primary DB instance upgrade started, there was a separate minor version upgrade running on the read replica.

The read replica used incompatible parameters.

The read replica was unable to communicate with the primary DB instance to synchronize the data folder.

13 **Upgrade your production instance** – When the dry-run major version upgrade is successful, you should be able to upgrade your production database with confidence. For more information, see *Manually upgrading the engine version* (p. 369).

14 Run the `ANALYZE` operation to refresh the `pg_statistic` table. You should do this for every database on all your PostgreSQL DB instances. Optimizer statistics aren't transferred during a major version upgrade, so you need to regenerate all statistics to avoid performance issues. Run the command without any parameters to generate statistics for all regular tables in the current database, as follows:

```
ANALYZE VERBOSE
```

The `VERBOSE` flag is optional, but using it shows you the progress. For more information, see `ANALYZE` in the PostgreSQL documentation.

**Note**

Run `ANALYZE` on your system after the upgrade to avoid performance issues.

After the major version upgrade is complete, we recommend the following:

- A PostgreSQL upgrade doesn't upgrade any PostgreSQL extensions. To upgrade extensions, see *Upgrading PostgreSQL extensions* (p. 1901).

- Optionally, use Amazon RDS to view two logs that the `pg_upgrade` utility produces. These are `pg_upgrade_internal.log` and `pg_upgrade_server.log`. Amazon RDS appends a timestamp to the file name for these logs. You can view these logs as you can any other log. For more information, see *Monitoring Amazon RDS log files* (p. 716).

  You can also upload the upgrade logs to Amazon CloudWatch Logs. For more information, see *Publishing PostgreSQL logs to Amazon CloudWatch Logs* (p. 757).

- To verify that everything works as expected, test your application on the upgraded database with a similar workload. After the upgrade is verified, you can delete this test instance.

## Automatic minor version upgrades for PostgreSQL

If you enable the **Auto minor version upgrade** option when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

For each RDS for PostgreSQL major version, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the PostgreSQL community version
- Overall fleet stability since the minor version was released
You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified PostgreSQL minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions
  --engine postgres
  --engine-version minor-version
  --region region
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
  --output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine postgres ^
  --engine-version minor-version ^
  --region region ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
  --output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for PostgreSQL minor version 10.11 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions
  --engine postgres
  --engine-version 10.11
  --region us-east-2
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
  --output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine postgres ^
  --engine-version 10.11 ^
  --region us-east-2 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
  --output table
```

Your output is similar to the following.

```
----------------------------------
|    DescribeDBEngineVersions     |
+--------------+-----------------+|
|  AutoUpgrade |  EngineVersion  ||
+--------------+-----------------+|
|  False       |  10.12          ||
|  False       |  10.13          ||
|  False       |  10.14          ||
|  False       |  10.15          ||
|  False       |  10.16          ||
|  True        |  10.17          ||
|  False       |  10.18          ||
```
In this example, the AutoUpgrade value is **True** for PostgreSQL version 10.17. So, the automatic minor upgrade target is PostgreSQL version 10.17, which is highlighted in the output.

A PostgreSQL DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The DB instance has the **Auto minor version upgrade** option enabled.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see [Automatically upgrading the minor engine version](p. 371).

**Note**

A PostgreSQL upgrade doesn't upgrade PostgreSQL extensions. To upgrade extensions, see [Upgrading PostgreSQL extensions](p. 1901).

### Upgrading PostgreSQL extensions

A PostgreSQL engine upgrade doesn't upgrade most PostgreSQL extensions. To update an extension after a version upgrade, use the `ALTER EXTENSION UPDATE` command.

**Note**

For information about updating the PostGIS extension, see [Managing spatial data with the PostGIS extension](p. 2081) (Step 6: Upgrade the PostGIS extension (p. 2084)).

To update the `pg_repack` extension, drop the extension and then create the new version in the upgraded DB instance. For more information, see [pg_repack installation](p. 2081) in the pg_repack documentation.

To upgrade an extension, use the following command.

```
ALTER EXTENSION extension_name UPDATE TO 'new_version'
```

For the list of supported versions of PostgreSQL extensions, see [Supported PostgreSQL extension versions](p. 1859).

To list your currently installed extensions, use the PostgreSQL `pg_extension` catalog in the following command.

```
SELECT * FROM pg_extension;
```

To view a list of the specific extension versions that are available for your installation, use the PostgreSQL `pg_available_extension_versions` view in the following command.

```
SELECT * FROM pg_available_extension_versions;
```
Upgrading a PostgreSQL DB snapshot engine version

With Amazon RDS, you can create a storage volume DB snapshot of your PostgreSQL DB instance. When you create a DB snapshot, the snapshot is based on the engine version used by your Amazon RDS instance. In addition to upgrading the DB engine version of your DB instance, you can also upgrade the engine version for your DB snapshots.

After restoring a DB snapshot upgraded to a new engine version, make sure to test that the upgrade was successful. For more information about a major version upgrade, see Upgrading the PostgreSQL DB engine for Amazon RDS (p. 1891). To learn how to restore a DB snapshot, see Restoring from a DB snapshot (p. 487).

You can upgrade manual DB snapshots that are either encrypted or not encrypted.

For the list of engine versions that are available for upgrading a DB snapshot, see Upgrading the PostgreSQL DB engine for Amazon RDS.

Note
You can't upgrade automated DB snapshots that are created during the automated backup process.

Console

To upgrade a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the snapshot that you want to upgrade.
4. For Actions, choose Upgrade snapshot. The Upgrade snapshot page appears.
5. Choose the New engine version to upgrade to.
6. Choose Save changes to upgrade the snapshot.

During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from available to upgrading, and then changes to active upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to unavailable. You can't recover the snapshot from this state.

Note
If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade a DB snapshot to a new database engine version, use the AWS CLI modify-db-snapshot command.

Parameters

• --db-snapshot-identifier – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 414).
• --engine-version – The engine version to upgrade the DB snapshot to.
Example

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \
  --db-snapshot-identifier my_db_snapshot \
  --engine-version new_version
```

For Windows:

```
aws rds modify-db-snapshot ^
  --db-snapshot-identifier my_db_snapshot ^
  --engine-version new_version
```

RDS API

To upgrade a DB snapshot to a new database engine version, call the Amazon RDS API ModifyDBSnapshot operation.

- **DBSnapshotIdentifier** – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 414).
- **EngineVersion** – The engine version to upgrade the DB snapshot to.
Working with read replicas for Amazon RDS for PostgreSQL

You can scale reads for your Amazon RDS for PostgreSQL DB instance by adding read replicas to the instance. As with other Amazon RDS database engines, RDS for PostgreSQL uses the native replication mechanisms of PostgreSQL to keep read replicas up to date with changes on the source DB. For general information about read replicas and Amazon RDS, see Working with read replicas (p. 382).

Following, you can find information specific to working with read replicas with RDS for PostgreSQL.

Contents

- Read replica limitations with PostgreSQL (p. 1904)

  - Using RDS for PostgreSQL read replicas with Multi-AZ configurations (p. 1906)
  - Using cascading read replicas with RDS for PostgreSQL (p. 1906)
- How streaming replication works for different RDS for PostgreSQL versions (p. 1907)
  - Understanding the parameters that control PostgreSQL replication (p. 1908)
    - Example: How a read replica recovers from replication interruptions (p. 1909)
- Monitoring and tuning the replication process (p. 1909)
- Monitoring replication slots for your RDS for PostgreSQL DB instance (p. 1910)

Read replica limitations with PostgreSQL

The following are limitations for PostgreSQL read replicas:

- PostgreSQL read replicas are read-only. Although a read replica isn't a writable DB instance, you can promote it to become a standalone RDS for PostgreSQL DB instance. However, the process isn't reversible.

- You can't create a read replica from another read replica if your RDS for PostgreSQL DB instance is running a PostgreSQL version earlier than 14.1. RDS for PostgreSQL supports cascading read replicas on RDS for PostgreSQL version 14.1 and higher releases only. For more information, see Using cascading read replicas with RDS for PostgreSQL (p. 1906).

- If you promote a PostgreSQL read replica, it becomes a writable DB instance. It stops receiving write-ahead log (WAL) files from a source DB instance, and it's no longer a read-only instance. You can create new read replicas from the promoted DB instance as you do for any RDS for PostgreSQL DB instance. For more information, see Promoting a read replica to be a standalone DB instance (p. 389).

- If you promote a PostgreSQL read replica from within a replication chain (a series of cascading read replicas), any existing downstream read replicas continue receiving WAL files from the promoted instance, automatically. For more information, see Using cascading read replicas with RDS for PostgreSQL (p. 1906).

- If no user transactions are running on the source DB instance, the associated PostgreSQL read replica reports a replication lag of up to five minutes. The replica lag is calculated as \( \text{currentTime} - \text{lastCommittedTransactionTimestamp} \), which means that when no transactions are being processed, the value of replica lag increases for a period of time until the write-ahead log (WAL) segment switches. By default RDS for PostgreSQL switches the WAL segment every 5 minutes, which results in a transaction record and a decrease in the reported lag.

- You can't turn on automated backups for PostgreSQL read replicas for RDS for PostgreSQL versions earlier than 14.1. Automated backups for read replicas are supported for RDS for PostgreSQL 14.1 and higher versions only. For RDS for PostgreSQL 13 and earlier versions, create a snapshot from a read replica if you want a backup of it.
Read replica configuration with PostgreSQL

RDS for PostgreSQL uses PostgreSQL native streaming replication to create a read-only copy of a source DB instance. This read replica DB instance is an asynchronously created physical replica of the source DB instance. It’s created by a special connection that transmits write ahead log (WAL) data from the source DB instance to the read replica. For more information, see Streaming Replication in the PostgreSQL documentation.

PostgreSQL asynchronously streams database changes to this secure connection as they’re made on the source DB instance. You can encrypt communications from your client applications to the source DB instance or any read replicas by setting the `ssl` parameter to 1. For more information, see Using SSL with a PostgreSQL DB instance (p. 1868).

PostgreSQL uses a replication role to perform streaming replication. The role is privileged, but you can’t use it to modify any data. PostgreSQL uses a single process for handling replication.

You can create a PostgreSQL read replica without affecting operations or users of the source DB instance. Amazon RDS sets the necessary parameters and permissions for you, on the source DB instance and the read replica, without affecting the service. A snapshot is taken of the source DB instance, and this snapshot is used to create the read replica. If you delete the read replica at some point in the future, no outage occurs.

You can create up to 15 read replicas from one source DB instance within the same Region. As of RDS for PostgreSQL 14.1, you can also create up to three levels of read replica in a chain (cascade) from a source DB instance. For more information, see Using cascading read replicas with RDS for PostgreSQL (p. 1906). In all cases, the source DB instance needs to have automated backups configured. You do this by setting the backup retention period on your DB instance to any value other than 0. For more information, see Creating a read replica (p. 387).

You can create read replicas for your RDS for PostgreSQL DB instance in the same AWS Region as your source DB instance. This is known as in-Region replication. You can also create read replicas in different AWS Regions than the source DB instance. This is known as cross-Region replication. For more information about setting up cross-Region read replicas, see Creating a read replica in a different AWS Region (p. 395). The various mechanisms supporting the replication process for in-Region and cross-Region differ slightly depending on the RDS for PostgreSQL version as explained in How streaming replication works for different RDS for PostgreSQL versions (p. 1907).

For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, be sure to also scale the read replicas.

Amazon RDS overrides any incompatible parameters on a read replica if they prevent the read replica from starting. For example, suppose that the `max_connections` parameter value is higher on the source DB instance than on the read replica. In that case, Amazon RDS updates the parameter on the read replica to be the same value as that on the source DB instance.

RDS for PostgreSQL read replicas have access to external databases that are available through foreign data wrappers (FDWs) on the source DB instance. For example, suppose that your RDS for PostgreSQL DB instance is using the `mysql_fdw` wrapper to access data from RDS for MySQL. If so, your read replicas can also access that data. Other supported FDWs include `oracle_fdw`, `postgres_fdw`, and `tds_fdw`. For more information, see Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL (p. 2088).
Using RDS for PostgreSQL read replicas with Multi-AZ configurations

You can create a read replica from a single-AZ or Multi-AZ DB instance. You can use Multi-AZ deployments to improve the durability and availability of critical data, with a standby replica. A standby replica is a dedicated read replica that can assume the workload if the source DB fails over. You can't use your standby replica to serve read traffic. However, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. To learn more about Multi-AZ deployments, see Multi-AZ DB instance deployments (p. 126).

If the source DB instance of a Multi-AZ deployment fails over to a standby, the associated read replicas switch to using the standby (now primary) as their replication source. The read replicas might need to restart, depending on the RDS for PostgreSQL version, as follows:

- **PostgreSQL 13 and higher versions** – Restarting isn't required. The read replicas are automatically synchronized with the new primary. However, in some cases your client application might cache Domain Name Service (DNS) details for your read replicas. If so, set the time-to-live (TTL) value to less than 30 seconds. Doing this prevents the read replica from holding on to a stale IP address (and thus, prevents it from synchronizing with the new primary). To learn more about this and other best practices, see Amazon RDS basic operational guidelines (p. 222).

- **PostgreSQL 12 and all earlier versions** – The read replicas restart automatically after a fail over to the standby replica because the standby (now primary) has a different IP address and a different instance name. Restarting synchronizes the read replica with the new primary.

To learn more about failover, see Failover process for Amazon RDS (p. 128). To learn more about how read replicas work in a Multi-AZ deployment, see Working with read replicas (p. 382).

To provide failover support for a read replica, you can create the read replica as a Multi-AZ DB instance so that Amazon RDS creates a standby of your replica in another Availability Zone (AZ). Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

Using cascading read replicas with RDS for PostgreSQL

As of version 14.1, RDS for PostgreSQL supports cascading read replicas. With cascading read replicas, you can scale reads without adding overhead to your source RDS for PostgreSQL DB instance. Updates to the WAL log aren't sent by the source DB instance to each read replica. Instead, each read replica in a cascading series sends WAL log updates to the next read replica in the series. This reduces the burden on the source DB instance.

With cascading read replicas, your RDS for PostgreSQL DB instance sends WAL data to the first read replica in the chain. That read replica then sends WAL data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for PostgreSQL DB instance, but without the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for PostgreSQL DB instance. For example, suppose that you have an RDS for PostgreSQL 14.1 DB instance, rpg-db-main. You can do the following:

- Starting with rpg-db-main, create the first read replica in the chain, read-replica-1.
- Next, from read-replica-1, create the next read replica in the chain, read-replica-2.
- Finally, from read-replica-2, create the third read replica in the chain, read-replica-3.
You can't create another read replica beyond this third cascading read replica in the series for rpg-db-main. A complete series of instances from an RDS for PostgreSQL source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, turn on automatic backups on your RDS for PostgreSQL. Create the read replica first and then turn on automatic backups on the RDS for PostgreSQL DB instance. The process is the same as for other Amazon RDS DB engines. For more information, see Creating a read replica (p. 387).

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload off of your rpg-db-main DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote read-replica-2. The chain is affected as follows:

- Promoting read-replica-2 removes it from the replication chain.
- It is now a full read/write DB instance.
- It continues replicating to read-replica-3, just as it was doing before promotion.
- Your rpg-db-main continues replicating to read-replica-1.

For more information about promoting read replicas, see Promoting a read replica to be a standalone DB instance (p. 389).

Note
For cascading read replicas, RDS for PostgreSQL supports 15 read replicas for each source DB instance at first level of replication, and 5 read replicas for each source DB instance at the second and third level of replication.

How streaming replication works for different RDS for PostgreSQL versions

As discussed in Read replica configuration with PostgreSQL (p. 1905), RDS for PostgreSQL uses PostgreSQL's native streaming replication protocol to send WAL data from the source DB instance. It sends source WAL data to read replicas for both in-Region and cross-Region read replicas. With version 9.4, PostgreSQL introduced physical replication slots as a supporting mechanism for the replication process.

A physical replication slot prevents a source DB instance from removing WAL data before it's consumed by all read replicas. Each read replica has its own physical slot on the source DB instance. The slot keeps track of the oldest WAL (by logical sequence number, LSN) that might be needed by the replica. After all slots and DB connections have progressed beyond a given WAL (LSN), that LSN becomes a candidate for removal at the next checkpoint.

Amazon RDS uses Amazon S3 to archive WAL data. For in-Region read replicas, you can use this archived data to recover the read replica when necessary. An example of when you might do so is if the connection between source DB and read replica is interrupted for any reason.

In the following table, you can find a summary of differences between PostgreSQL versions and the supporting mechanisms for in-Region and cross-Region used by RDS for PostgreSQL.

<table>
<thead>
<tr>
<th>In-Region</th>
<th>Cross-Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>PostgreSQL 14.1 and higher versions</td>
<td>Replication slots</td>
</tr>
<tr>
<td>• Replication slots</td>
<td>• Amazon S3 archive</td>
</tr>
</tbody>
</table>
How replication works for different RDS for PostgreSQL versions

### In-Region

<table>
<thead>
<tr>
<th>PostgreSQL 13 and lower versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Amazon S3 archive</td>
</tr>
</tbody>
</table>

### Cross-Region

<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>- Replication slots</td>
</tr>
</tbody>
</table>

For more information, see Monitoring and tuning the replication process (p. 1909).

## Understanding the parameters that control PostgreSQL replication

The following parameters affect the replication process and determine how well read replicas stay up to date with the source DB instance:

### max_wal_senders

The `max_wal_senders` parameter specifies the maximum number of connections that the source DB instance can support at the same time over the streaming replication protocol. The default for RDS for PostgreSQL 13 and higher releases is 20. This parameter should be set to slightly higher than the actual number of read replicas. If this parameter is set too low for the number of read replicas, replication stops.

For more information, see `max_wal_senders` in the PostgreSQL documentation.

### wal_keep_segments

The `wal_keep_segments` parameter specifies the number of write-ahead log (WAL) files that the source DB instance keeps in the `pg_wal` directory. The default setting is 32.

If `wal_keep_segments` isn't set to a large enough value for your deployment, a read replica can fall so far behind that streaming replication stops. If that happens, Amazon RDS generates a replication error and begins recovery on the read replica. It does so by replaying the source DB instance’s archived WAL data from Amazon S3. This recovery process continues until the read replica has caught up enough to continue streaming replication. You can see this process in action as captured by the PostgreSQL log in Example: How a read replica recovers from replication interruptions (p. 1909).

**Note**

In PostgreSQL version 13, the `wal_keep_segments` parameter is named `wal_keep_size`. It serves the same purpose as `wal_keep_segments`, but its default value is in megabytes (MB) (2048 MB) rather than the number of files. For more information, see `wal_keep_segments` and `wal_keep_size` in the PostgreSQL documentation.

### max_slot_wal_keep_size

The `max_slot_wal_keep_size` parameter controls the quantity of WAL data that the RDS for PostgreSQL DB instance retains in the `pg_wal` directory to serve slots. This parameter is used for configurations that use replication slots. The default value for this parameter is -1, meaning that there's no limit to how much WAL data is kept on the source DB instance. For information about monitoring your replication slots, see Monitoring replication slots for your RDS for PostgreSQL DB instance (p. 1910).

For more information about this parameter, see `max_slot_wal_keep_size` in the PostgreSQL documentation.

Whenever the stream that provides WAL data to a read replica is interrupted, PostgreSQL switches into recovery mode. It restores the read replica by using archived WAL data from Amazon S3 or by using
Monitoring and tuning the replication process

Example: How a read replica recovers from replication interruptions

In the following example, you find the log details that demonstrate the recovery process for a read replica. The example is from an RDS for PostgreSQL DB instance running PostgreSQL version 12.9 in the same AWS Region as the source DB, so replication slots aren’t used. The recovery process is the same for other RDS for PostgreSQL DB instances running PostgreSQL earlier than version 14.1 with in-Region read replicas.

When the read replica lost contact with the source DB instance, Amazon RDS records the issue in the log as 

```
FATAL: could not receive data from WAL stream
ERROR: requested WAL segment ... has already been removed
```

As shown in the bold line, Amazon RDS recovers the replica by replaying an archived WAL file.

```
2014-11-07 19:01:10 UTC::@:\[23180\]:DEBUG: switched WAL source from archive to stream after failure
2014-11-07 19:01:10 UTC::@:\[11575\]:LOG: started streaming WAL from primary at 1A/D3000000 on timeline 1
2014-11-07 19:01:10 UTC::@:\[11575\]:FATAL: could not receive data from WAL stream:
ERROR: requested WAL segment 0000001000001A000000D3 has already been removed
2014-11-07 19:01:10 UTC::@:\[23180\]:DEBUG: could not restore file "00000002.history" from archive: return code 0
2014-11-07 19:01:15 UTC::@:\[23180\]:DEBUG: switched WAL source from stream to archive after failure recovering 000000010000001A000000D3
2014-11-07 19:01:16 UTC::@:\[23180\]:LOG: restored log file "000000010000001A000000D3" from archive
```

When Amazon RDS replays enough archived WAL data on the replica to catch up, streaming to the read replica begins again. When streaming resumes, Amazon RDS writes an entry to the log file similar to the following.

```
2014-11-07 19:41:36 UTC::@:\[24714\]:LOG: started streaming WAL from primary at 1B/B6000000 on timeline 1
```

Monitoring and tuning the replication process

We strongly recommend that you routinely monitor your RDS for PostgreSQL DB instance and read replicas. You need to ensure that your read replicas are keeping up with changes on the source DB instance. Amazon RDS transparently recovers your read replicas when interruptions to the replication process occur. However, it’s best to avoid needing to recover at all. Recovering using replication slots is faster than using the Amazon S3 archive, but any recovery process can affect read performance.

To determine how well your read replicas are keeping up with the source DB instance, you can do the following:

- **Check the amount of ReplicaLag between source DB instance and replicas.** 
  
  Replica lag is the amount of time, in milliseconds, that a read replica lags behind its source DB instance. This metric reports the result of the following query.

  ```sql
  SELECT extract(epoch from now() - pg_last_xact_replay_timestamp()) AS replica_lag
  ```

  Replica lag is an indication of how well a read replica is keeping up with the source DB instance. It’s the amount of latency between the source DB instance and a specific read instance. A high value for replica lag can indicate a mismatch between the DB instance classes or storage types (or both) used by the source DB instance and its read replicas. The DB instance class and storage types for DB source instance and all read replicas should be the same.
Replica lag can also be the result of intermittent connection issues. You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric. To learn more about ReplicaLag and other metrics for Amazon RDS, see Amazon CloudWatch metrics for Amazon RDS (p. 644).

- **Check the PostgreSQL log for information you can use to adjust your settings.** At every checkpoint, the PostgreSQL log captures the number of recycled transaction log files, as shown in the following example.

```
2014-11-07 19:59:35 UTC::@:[26820]:LOG: checkpoint complete: wrote 376 buffers (0.2%);
0 transaction log file(s) added, 0 removed, 1 recycled; write=35.681 s, sync=0.013 s,
total=35.703 s;
sync files=10, longest=0.013 s, average=0.001 s
```

You can use this information to figure out how many transaction files are being recycled in a given time period. You can then change the setting for wal_keep_segments if necessary. For example, suppose that the PostgreSQL log at checkpoint complete shows 35 recycled for a 5-minute interval. In this case, the wal_keep_segments default value of 32 isn't sufficient to keep pace with the streaming activity, so you should increase the value of this parameter.

- **Use Amazon CloudWatch to monitor metrics that can predict replication issues.** Rather than analyzing the PostgreSQL log directly, you can use Amazon CloudWatch to check metrics that have been collected. For example, you can check the value of the TransactionLogsGeneration metric to see how much WAL data is being generated by the source DB instance. In some cases, the workload on your DB instance might generate a large amount of WAL data. If so, you might need to change the DB instance class for your source DB instance and read replicas. Using an instance class with high (10 Gbps) network performance can reduce replica lag.

### Monitoring replication slots for your RDS for PostgreSQL DB instance

All versions of RDS for PostgreSQL use replication slots for cross-Region read replicas. RDS for PostgreSQL 14.1 and higher versions use replication slots for in-Region read replicas. In-region read replicas also use Amazon S3 to archive WAL data. In other words, if your DB instance and read replicas are running PostgreSQL 14.1 or higher, replication slots and Amazon S3 archives are both available for recovering the read replica. Recovering a read replica using its replication slot is faster than recovering from Amazon S3 archive. So, we recommend that you monitor the replication slots and related metrics.

You can view the replication slots on your RDS for PostgreSQL DB instances by querying the `pg_replication_slots` view, as follows.

```
postgres=> SELECT * FROM pg_replication_slots;
slot_name                  | plugin | slot_type | datoid | database | temporary | active
| active_pid | xmin | catalog_xmin | restart_lsn | confirmed_flush_lsn | wal_status | safe_wal_size | two_phase
---------------------------+--------+-----------+--------+----------+-----------+--------
| f | 13194 | 23/D80000060 | | reserved | f |
(1 row)
```

The `wal_status` of reserved value means that the amount of WAL data held by the slot is within the bounds of the `max_wal_size` parameter. In other words, the replication slot is properly sized. Other possible status values are as follows:
- **extended** – The slot exceeds the `max_wal_size` setting, but the WAL data is retained.
- **unreserved** – The slot no longer has the all required WAL data. Some of it will be removed at the next checkpoint.
- **lost** – Some required WAL data has been removed. The slot is no longer usable.

The `pg_replication_slots` view shows you the current state of your replication slots. To assess the performance of your replication slots, you can use Amazon CloudWatch and monitor the following metrics:

- **OldestReplicationSlotLag** – Lists the slot that has the most lag, that is the one that's furthest behind the primary. This lag can be associated with the read replica but also the connection.
- **TransactionLogsDiskUsage** – Shows how much storage is being used for WAL data. When a read replica lags significantly, the value of this metric can increase substantially.

To learn more about using Amazon CloudWatch and its metrics for RDS for PostgreSQL, see *Monitoring Amazon RDS metrics with Amazon CloudWatch* (p. 563). For more information about monitoring streaming replication on your RDS for PostgreSQL DB instances, see *Best practices for Amazon RDS PostgreSQL replication* on the *AWS Database Blog*. 
Importing data into PostgreSQL on Amazon RDS

Suppose that you have an existing PostgreSQL deployment that you want to move to Amazon RDS. The complexity of your task depends on the size of your database and the types of database objects that you're transferring. For example, consider a database that contains datasets on the order of gigabytes, along with stored procedures and triggers. Such a database is going to be more complicated than a simple database with only a few megabytes of test data and no triggers or stored procedures.

We recommend that you use native PostgreSQL database migration tools under the following conditions:

- You have a homogeneous migration, where you are migrating from a database with the same database engine as the target database.
- You are migrating an entire database.
- The native tools allow you to migrate your system with minimal downtime.

In most other cases, performing a database migration using AWS Database Migration Service (AWS DMS) is the best approach. AWS DMS can migrate databases without downtime and, for many database engines, continue ongoing replication until you are ready to switch over to the target database. You can migrate to either the same database engine or a different database engine using AWS DMS. If you are migrating to a different database engine than your source database, you can use the AWS Schema Conversion Tool (AWS SCT). You use AWS SCT to migrate schema objects that are not migrated by AWS DMS. For more information about AWS DMS, see What is AWS Database Migration Service?

Modify your DB parameter group to include the following settings for your import only. You should test the parameter settings to find the most efficient settings for your DB instance size. You also need to revert back to production values for these parameters after your import completes.

Modify your DB instance settings to the following:

- Disable DB instance backups (set backup_retention to 0).
- Disable Multi-AZ.

Modify your DB parameter group to include the following settings. You should only use these settings when importing data. You should test the parameter settings to find the most efficient settings for your DB instance size. You also need to revert back to production values for these parameters after your import completes.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Recommended value when importing</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maintenance_work_mem</td>
<td>524288, 1048576, 2097152, or 4194304 (in KB)</td>
<td>The value for this setting depends on the size of your host. This parameter is used during CREATE INDEX statements and each parallel command can use this much memory. Calculate the best value so that you don't set this value so high that you run out of memory.</td>
</tr>
<tr>
<td>max_wal_size</td>
<td>256 (for version 9.6), 4096 (for versions 10 and higher)</td>
<td>Maximum size to let the WAL grow during automatic checkpoints. Increasing this parameter can increase the amount of time needed for crash recovery. This parameter replaces checkpoint_segments for PostgreSQL 9.6 and later.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Recommended value when importing</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>----------------------------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For PostgreSQL version 9.6, this value is in 16 MB units. For later versions, the value is in 1 MB units. For example, in version 9.6, 128 means 128 chunks that are each 16 MB in size. In version 12.4, 2048 means 2048 chunks that are each 1 MB in size.</td>
</tr>
<tr>
<td>checkpoint_timeout</td>
<td>1800</td>
<td>The value for this setting allows for less frequent WAL rotation.</td>
</tr>
<tr>
<td>synchronous_commit</td>
<td>Off</td>
<td>Disable this setting to speed up writes. Turning this parameter off can increase the risk of data loss in the event of a server crash (do not turn off FSYNC).</td>
</tr>
<tr>
<td>wal_buffers</td>
<td>8192</td>
<td>This is value is in 8 KB units. This again helps your WAL generation speed</td>
</tr>
<tr>
<td>autovacuum</td>
<td>Off</td>
<td>Disable the PostgreSQL auto vacuum parameter while you are loading data so that it doesn't use resources</td>
</tr>
</tbody>
</table>

Use the `pg_dump -Fc` (compressed) or `pg_restore -j` (parallel) commands with these settings.

**Note**

The PostgreSQL command `pg_dumpall` requires `super_user` permissions that are not granted when you create a DB instance, so it cannot be used for importing data.

**Topics**

- Importing a PostgreSQL database from an Amazon EC2 instance (p. 1913)
- Using the `\copy` command to import data to a table on a PostgreSQL DB instance (p. 1915)
- Importing data from Amazon S3 into an RDS for PostgreSQL DB instance (p. 1916)
- Transporting PostgreSQL databases between DB instances (p. 1929)

### Importing a PostgreSQL database from an Amazon EC2 instance

If you have data in a PostgreSQL server on an Amazon EC2 instance and want to move it to a PostgreSQL DB instance, you can use the following process. The following list shows the steps to take. Each step is discussed in more detail in the following sections.

1. Create a file using `pg_dump` that contains the data to be loaded
2. Create the target DB instance
3. Use `psql` to create the database on the DB instance and load the data
4. Create a DB snapshot of the DB instance
Step 1: Create a file using `pg_dump` that contains the data to load

The `pg_dump` utility uses the `COPY` command to create a schema and data dump of a PostgreSQL database. The dump script generated by `pg_dump` loads data into a database with the same name and recreates the tables, indexes, and foreign keys. You can use the `pg_restore` command and the `-d` parameter to restore the data to a database with a different name.

Before you create the data dump, you should query the tables to be dumped to get a row count so you can confirm the count on the target DB instance.

The following command creates a dump file called `mydb2dump.sql` for a database called `mydb2`.

```
prompt>pg_dump dbname=mydb2 -f mydb2dump.sql
```

Step 2: Create the target DB instance

Create the target PostgreSQL DB instance using either the Amazon RDS console, AWS CLI, or API. Create the instance with the backup retention setting set to 0 and disable Multi-AZ. Doing so allows faster data import. You must create a database on the instance before you can dump the data. The database can have the same name as the database that contains the dumped data. Alternatively, you can create a database with a different name. In this case, you use the `pg_restore` command and the `-d` parameter to restore the data into the newly named database.

For example, the following commands can be used to dump, restore, and rename a database.

```
pg_dump -Fc -v -h [endpoint of instance] -U [master username] [database] > [database].dump
createdb [new database name]
pg_restore -v -h [endpoint of instance] -U [master username] -d [new database name] [database].dump
```

Step 3: Use `psql` to create the database on the DB instance and load data

You can use the same connection you used to run the `pg_dump` command to connect to the target DB instance and recreate the database. Using `psql`, you can use the master user name and master password to create the database on the DB instance.

The following example uses `psql` and a dump file named `mydb2dump.sql` to create a database called `mydb2` on a PostgreSQL DB instance called `mypginstance`:

For Linux, macOS, or Unix:

```
psql -f mydb2dump.sql
```

For Windows:

```
psql -f mydb2dump.sql
```

1914
Using the \copy command to import data to a table on a PostgreSQL DB instance

The PostgreSQL \copy command is a meta-command available from the psql interactive client tool. You can use \copy to import data into a table on your RDS for PostgreSQL DB instance. To use the \copy command, you need to first create the table structure on the target DB instance so that \copy has a destination for the data being copied.

You can use \copy to load data from a comma-separated values (CSV) file, such as one that's been exported and saved to your client workstation.

To import the CSV data to the target RDS for PostgreSQL DB instance, first connect to the target DB instance using psql.

```bash
psql --host=host.mypginstance.55555555555555.aws-region.rds.amazonaws.com --port=8199 --username=myawsuser --password --dbname=mydb2
```

You then run \copy command with the following parameters to identify the target for the data and its format.

- **target_table** – The name of the table that should receive the data being copied from the CSV file.
- **column_list** – Column specifications for the table.
- **'filename'** – The complete path to the CSV file on your local workstation.

```bash
\copy target_table from '/path/to/local/filename.csv' WITH DELIMITER ',' CSV;
```

If your CSV file has column heading information, you can use this version of the command and parameters.

```bash
\copy target_table (column-1, column-2, column-3, ...) from '/path/to/local/filename.csv' WITH DELIMITER ',' CSV HEADER;
```

If the \copy command fails, PostgreSQL outputs error messages.

You can also combine the psql command with the \copy meta-command as shown in the following examples. This example uses source-table as the source table name, source-table.csv as the .csv file, and target-db as the target database:

For Linux, macOS, or Unix:
Importing data from Amazon S3 into an RDS for PostgreSQL DB instance

You can import data that's been stored using Amazon Simple Storage Service into a table on an RDS for PostgreSQL DB instance. To do this, you first install the RDS for PostgreSQL aws_s3 extension. This extension provides the functions that you use to import data from an Amazon S3 bucket. A bucket is an Amazon S3 container for objects and files. The data can be in a comma-separate value (CSV) file, a text file, or a compressed (gzip) file. Following, you can learn how to install the extension and how to import data from Amazon S3 into a table.

Your database must be running PostgreSQL version 10.7 or higher to import from Amazon S3 into RDS for PostgreSQL.

If you don't have data stored on Amazon S3, you need to first create a bucket and store the data. For more information, see the following topics in the Amazon Simple Storage Service User Guide.

• Create a bucket
• Add an object to a bucket

Note
Importing data from Amazon S3 isn't supported for Aurora Serverless v1. It is supported for Aurora Serverless v2.

Topics
• Installing the aws_s3 extension (p. 1916)
• Overview of importing data from Amazon S3 data (p. 1917)
• Setting up access to an Amazon S3 bucket (p. 1918)
• Importing data from Amazon S3 to your RDS for PostgreSQL DB instance (p. 1923)
• Function reference (p. 1925)

Installing the aws_s3 extension

Before you can use Amazon S3 with your RDS for PostgreSQL DB instance, you need to install the aws_s3 extension. This extension provides functions for importing data from an Amazon S3. It also provides functions for exporting data from an RDS for PostgreSQL DB instance to an Amazon S3.
bucket. For more information, see Exporting data from an RDS for PostgreSQL DB instance to Amazon S3 (p. 1935). The aws_s3 extension depends on some of the helper functions in the aws_commons extension, which is installed automatically when needed.

**To install the aws_s3 extension**

1. Use psql (or pgAdmin) to connect to the RDS for PostgreSQL DB instance as a user that has rds_superuser privileges. If you kept the default name during the setup process, you connect as postgres.

   ```bash
   psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ``

2. To install the extension, run the following command.

   ```bash
   postgres=> CREATE EXTENSION aws_s3 CASCADE;
   NOTICE: installing required extension "aws_commons"
   CREATE EXTENSION
   ``

3. To verify that the extension is installed, you can use the psql `\dx` metacommand.

   ```bash
   postgres=> \dx
   List of installed extensions
     Name     | Version |   Schema   |                 Description
     -------------+---------+------------+---------------------------------------------
     aws_commons  | 1.2     | public     | Common data types across AWS services
     aws_s3       | 1.1     | public     | AWS S3 extension for importing data from S3
     plpgsql      | 1.0     | pg_catalog | PL/pgSQL procedural language
   (3 rows)
   ``

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

**Overview of importing data from Amazon S3 data**

**To import S3 data into Amazon RDS**

First, gather the details that you need to supply to the function. These include the name of the table on your RDS for PostgreSQL DB instance, and the bucket name, file path, file type, and AWS Region where the Amazon S3 data is stored. For more information, see View an object in the Amazon Simple Storage Service User Guide.

1. Get the name of the table into which the aws_s3.table_import_from_s3 function is to import the data. As an example, the following command creates a table `t1` that can be used in later steps.

   ```bash
   postgres=> CREATE TABLE t1
             (col1 varchar(80),
              col2 varchar(80),
              col3 varchar(80));
   ``

2. Get the details about the Amazon S3 bucket and the data to import. To do this, open the Amazon S3 console at https://console.aws.amazon.com/s3/, and choose Buckets. Find the bucket containing your data in the list. Choose the bucket, open its Object overview page, and then choose Properties.

   Make a note of the bucket name, path, the AWS Region, and file type. You need the Amazon Resource Name (ARN) later, to set up access to Amazon S3 through an IAM role. For more information, see Setting up access to an Amazon S3 bucket (p. 1918). The image following shows an example.
3. You can verify the path to the data on the Amazon S3 bucket by using the AWS CLI command `aws s3 cp`. If the information is correct, this command downloads a copy of the Amazon S3 file.

4. Set up permissions on your RDS for PostgreSQL DB instance to allow access to the file on the Amazon S3 bucket. To do so, you use either an AWS Identity and Access Management (IAM) role or security credentials. For more information, see Setting up access to an Amazon S3 bucket (p. 1918).

5. Supply the path and other Amazon S3 object details gathered (see step 2) to the `create_s3_uri` function to construct an Amazon S3 URI object. To learn more about this function, see `aws_commons.create_s3_uri` (p. 1928). The following is an example of constructing this object during a psql session.

```sql
postgres=> SELECT aws_commons.create_s3_uri(
    'docs-lab-store-for-rpg',
    'versions_and_jdks_listing.csv',
    'us-west-1'
) AS s3_uri \
  \gset
```

In the next step, you pass this object (`aws_commons._s3_uri_1`) to the `aws_s3.table_import_from_s3` function to import the data to the table.

6. Invoke the `aws_s3.table_import_from_s3` function to import the data from Amazon S3 into your table. For reference information, see `aws_s3.table_import_from_s3` (p. 1925). For examples, see Importing data from Amazon S3 to your RDS for PostgreSQL DB instance (p. 1923).

### Setting up access to an Amazon S3 bucket

To import data from an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket containing the file. You provide access to an Amazon S3 bucket in one of two ways, as described in the following topics.

#### Topics
- Using an IAM role to access an Amazon S3 bucket (p. 1919)
Using an IAM role to access an Amazon S3 bucket

Before you load data from an Amazon S3 file, give your RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket the file is in. This way, you don't have to manage additional credential information or provide it in the `aws_s3.table_import_from_s3` (p. 1925) function call.

To do this, create an IAM policy that provides access to the Amazon S3 bucket. Create an IAM role and attach the policy to the role. Then assign the IAM role to your DB instance.

*Note*
You can't associate an IAM role with an Aurora Serverless v1 DB cluster, so the following steps don't apply.

**To give an RDS for PostgreSQL DB instance access to Amazon S3 through an IAM role**

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your RDS for PostgreSQL DB instance to access Amazon S3.

   Include in the policy the following required actions to allow the transfer of files from an Amazon S3 bucket to Amazon RDS:
   - `s3:GetObject`
   - `s3:ListBucket`

   Include in the policy the following resources to identify the Amazon S3 bucket and objects in the bucket. This shows the Amazon Resource Name (ARN) format for accessing Amazon S3.
   - `arn:aws:s3:::your-s3-bucket`
   - `arn:aws:s3:::your-s3-bucket/*`

   For more information on creating an IAM policy for RDS for PostgreSQL, see Creating and using an IAM policy for IAM database access (p. 2198). See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

   The following AWS CLI command creates an IAM policy named `rds-s3-import-policy` with these options. It grants access to a bucket named `your-s3-bucket`.

   *Note*
   Make a note of the Amazon Resource Name (ARN) of the policy returned by this command. You need the ARN in a subsequent step when you attach the policy to an IAM role.

   **Example**

   For Linux, macOS, or Unix:

   ```bash
   aws iam create-policy
   --policy-name rds-s3-import-policy
   --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   {
       "Sid": "s3import",
       "Action": ["s3:GetObject", "s3:ListBucket"]
   ]
   }'
   ```
For Windows:

```bash
aws iam create-policy ^
--policy-name rds-s3-import-policy ^
--policy-document '{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "s3import",
         "Action": ["s3:GetObject","s3:ListBucket"],
         "Effect": "Allow",
         "Resource": ["arn:aws:s3:::your-s3-bucket","arn:aws:s3:::your-s3-bucket/*"]
      }
   ]
}'
```

2. Create an IAM role.

You do this so Amazon RDS can assume this IAM role to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-import-role`.

**Example**

For Linux, macOS, or Unix:

```
aws iam create-role \
```
For Windows:

```bash
aws iam create-role ^
--role-name rds-s3-import-role ^
--assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "111122223333",
        }
      }
    }
  ]
}

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created in the previous step to the role named `rds-s3-import-role` Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam attach-role-policy ^
--policy-arn your-policy-arn ^
--role-name rds-s3-import-role
```

For Windows:

```bash
aws iam attach-role-policy ^
--policy-arn your-policy-arn ^
```
4. Add the IAM role to the DB instance.
   You do so by using the AWS Management Console or AWS CLI, as described following.

**Console**

**To add an IAM role for a PostgreSQL DB instance using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the PostgreSQL DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this instance**.
4. Under **Feature**, choose **s3Import**.
5. Choose **Add role**.

**AWS CLI**

**To add an IAM role for a PostgreSQL DB instance using the CLI**

- Use the following command to add the role to the PostgreSQL DB instance named **my-db-instance**. Replace **your-role-arn** with the role ARN that you noted in a previous step. Use **s3Import** for the value of the --feature-name option.

**Example**

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
    --db-instance-identifier my-db-instance \
    --feature-name s3Import \
    --role-arn your-role-arn \
    --region your-region
```

For Windows:

```
aws rds add-role-to-db-instance ^
    --db-instance-identifier my-db-instance ^
    --feature-name s3Import ^
    --role-arn your-role-arn ^
    --region your-region
```

**RDS API**

To add an IAM role for a PostgreSQL DB instance using the Amazon RDS API, call the **AddRoleToDBInstance** operation.

**Using security credentials to access an Amazon S3 bucket**

If you prefer, you can use security credentials to provide access to an Amazon S3 bucket instead of providing access with an IAM role. You do so by specifying the **credentials** parameter in the **aws_s3.table_import_from_s3 (p. 1925)** function call.
The credentials parameter is a structure of type `aws_commons._aws_credentials_1`, which contains AWS credentials. Use the `aws_commons.create_aws_credentials` function to set the access key and secret key in an `aws_commons._aws_credentials_1` structure, as shown following.

```
postgres=> SELECT aws_commons.create_aws_credentials(
    'sample_access_key', 'sample_secret_key', '')
AS creds \gset
```

After creating the `aws_commons._aws_credentials_1` structure, use the `aws_s3.table_import_from_s3` function with the credentials parameter to import the data, as shown following.

```
postgres=> SELECT aws_s3.table_import_from_s3(
    't', '', '(format csv)',
    's3_uri',
    'creds'
);
```

Or you can include the `aws_commons.create_aws_credentials` function call inline within the `aws_s3.table_import_from_s3` function call.

```
postgres=> SELECT aws_s3.table_import_from_s3(
    't', '', '(format csv)',
    's3_uri',
    aws_commons.create_aws_credentials('sample_access_key', 'sample_secret_key', '')
);
```

### Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to import data from Amazon S3, see the following for recommendations:

- Troubleshooting Amazon RDS identity and access (p. 2222)
- Troubleshooting Amazon S3 in the *Amazon Simple Storage Service User Guide*
- Troubleshooting Amazon S3 and IAM in the *IAM User Guide*

### Importing data from Amazon S3 to your RDS for PostgreSQL DB instance

You import data from your Amazon S3 bucket by using the `table_import_from_s3` function of the `aws_s3` extension. For reference information, see `aws_s3.table_import_from_s3` (p. 1925).

#### Note

The following examples use the IAM role method to allow access to the Amazon S3 bucket. Thus, the `aws_s3.table_import_from_s3` function calls don't include credential parameters.

The following shows a typical example.

```
postgres=> SELECT aws_s3.table_import_from_s3(
    't1',
    '',
    '(format csv)',
    's3_uri'
);
```

The parameters are the following:
• t1 – The name for the table in the PostgreSQL DB instance to copy the data into.
• ' ' – An optional list of columns in the database table. You can use this parameter to indicate which columns of the S3 data go in which table columns. If no columns are specified, all the columns are copied to the table. For an example of using a column list, see Importing an Amazon S3 file that uses a custom delimiter (p. 1924).
• (format csv) – PostgreSQL COPY arguments. The copy process uses the arguments and format of the PostgreSQL COPY command to import the data. Choices for format include comma-separated value (CSV) as shown in this example, text, and binary. The default is text.
• s3_uri – A structure that contains the information identifying the Amazon S3 file. For an example of using the aws_commons.create_s3_uri (p. 1928) function to create an s3_uri structure, see Overview of importing data from Amazon S3 data (p. 1917).

For more information about this function, see aws_s3.table_import_from_s3 (p. 1925).

The aws_s3.table_import_from_s3 function returns text. To specify other kinds of files for import from an Amazon S3 bucket, see one of the following examples.

**Topics**

- Importing an Amazon S3 file that uses a custom delimiter (p. 1924)
- Importing an Amazon S3 compressed (gzip) file (p. 1925)
- Importing an encoded Amazon S3 file (p. 1925)

**Importing an Amazon S3 file that uses a custom delimiter**

The following example shows how to import a file that uses a custom delimiter. It also shows how to control where to put the data in the database table using the column_list parameter of the aws_s3.table_import_from_s3 (p. 1925) function.

For this example, assume that the following information is organized into pipe-delimited columns in the Amazon S3 file.

```
1|foo1|bar1|elephant1
2|foo2|bar2|elephant2
3|foo3|bar3|elephant3
4|foo4|bar4|elephant4
...```

To import a file that uses a custom delimiter

1. Create a table in the database for the imported data.

```sql
postgres=> CREATE TABLE test (a text, b text, c text, d text, e text);
```

2. Use the following form of the aws_s3.table_import_from_s3 (p. 1925) function to import data from the Amazon S3 file.

You can include the aws_commons.create_s3_uri (p. 1928) function call inline within the aws_s3.table_import_from_s3 function call to specify the file.

```sql
postgres=> SELECT aws_s3.table_import_from_s3(
    'test',
    'a,b,d,e',
    'DELIMITER '''',
    aws_commons.create_s3_uri('sampleBucket', 'pipeDelimitedSampleFile', 'us-east-2'))
```
The data is now in the table in the following columns.

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
<th>e</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>foo1</td>
<td></td>
<td>bar1</td>
<td>elephant1</td>
</tr>
<tr>
<td>2</td>
<td>foo2</td>
<td></td>
<td>bar2</td>
<td>elephant2</td>
</tr>
<tr>
<td>3</td>
<td>foo3</td>
<td></td>
<td>bar3</td>
<td>elephant3</td>
</tr>
<tr>
<td>4</td>
<td>foo4</td>
<td></td>
<td>bar4</td>
<td>elephant4</td>
</tr>
</tbody>
</table>

**Importing an Amazon S3 compressed (gzip) file**

The following example shows how to import a file from Amazon S3 that is compressed with gzip. The file that you import needs to have the following Amazon S3 metadata:

- Key: Content-Encoding
- Value: gzip

If you upload the file using the AWS Management Console, the metadata is typically applied by the system. For information about uploading files to Amazon S3 using the AWS Management Console, the AWS CLI, or the API, see [Uploading objects](#) in the Amazon Simple Storage Service User Guide.

For more information about Amazon S3 metadata and details about system-provided metadata, see [Editing object metadata in the Amazon S3 console](#) in the Amazon Simple Storage Service User Guide.

Import the gzip file into your RDS for PostgreSQL DB instance as shown following.

```sql
postgres=> CREATE TABLE test_gzip(id int, a text, b text, c text, d text);
postgres=> SELECT aws_s3.table_import_from_s3('test_gzip', '', '(format csv)', 'myS3Bucket', 'test-data.gz', 'us-east-2');
```

**Importing an encoded Amazon S3 file**

The following example shows how to import a file from Amazon S3 that has Windows-1252 encoding.

```sql
postgres=> SELECT aws_s3.table_import_from_s3('test_table', '', 'encoding "WIN1252"', aws_commons.create_s3_uri('sampleBucket', 'SampleFile', 'us-east-2'));
```

**Function reference**

**Functions**

- `aws_s3.table_import_from_s3` (p. 1925)
- `aws_commons.create_s3_uri` (p. 1928)
- `aws_commons.create_aws_credentials` (p. 1928)

`aws_s3.table_import_from_s3`

Imports Amazon S3 data into an Amazon RDS table. The `aws_s3` extension provides the `aws_s3.table_import_from_s3` function. The return value is text.
Syntax

The required parameters are `table_name`, `column_list` and `options`. These identify the database table and specify how the data is copied into the table.

You can also use the following parameters:

• The `s3_info` parameter specifies the Amazon S3 file to import. When you use this parameter, access to Amazon S3 is provided by an IAM role for the PostgreSQL DB instance.

```python
aws_s3.table_import_from_s3 (
    table_name text,
    column_list text,
    options text,
    s3_info aws_commons._s3_uri_1
)
```

• The `credentials` parameter specifies the credentials to access Amazon S3. When you use this parameter, you don't use an IAM role.

```python
aws_s3.table_import_from_s3 (
    table_name text,
    column_list text,
    options text,
    s3_info aws_commons._s3_uri_1,
    credentials aws_commons._aws_credentials_1
)
```

Parameters

table_name

A required text string containing the name of the PostgreSQL database table to import the data into.

column_list

A required text string containing an optional list of the PostgreSQL database table columns in which to copy the data. If the string is empty, all columns of the table are used. For an example, see Importing an Amazon S3 file that uses a custom delimiter (p. 1924).

options

A required text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied into the PostgreSQL table. For more details, see the PostgreSQL COPY documentation.

s3_info

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

• `bucket` – The name of the Amazon S3 bucket containing the file.
• `file_path` – The Amazon S3 file name including the path of the file.
• `region` – The AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 79).

credentials

An `aws_commons._aws_credentials_1` composite type containing the following credentials to use for the import operation:
• Access key
• Secret key
• Session token

For information about creating an `aws_commons._aws_credentials_1` composite structure, see `aws_commons.create_aws_credentials` (p. 1928).

Alternate syntax

To help with testing, you can use an expanded set of parameters instead of the `s3_info` and `credentials` parameters. Following are additional syntax variations for the `aws_s3.table_import_from_s3` function:

• Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters. With this form of the function, access to Amazon S3 is provided by an IAM role on the PostgreSQL DB instance.

```sql
aws_s3.table_import_from_s3 (  
  table_name text,  
  column_list text,  
  options text,  
  bucket text,  
  file_path text,  
  region text
)
```

• Instead of using the `credentials` parameter to specify Amazon S3 access, use the combination of the `access_key`, `session_key`, and `session_token` parameters.

```sql
aws_s3.table_import_from_s3 (  
  table_name text,  
  column_list text,  
  options text,  
  bucket text,  
  file_path text,  
  region text,  
  access_key text,  
  secret_key text,  
  session_token text
)
```

Alternate parameters

`bucket`

A text string containing the name of the Amazon S3 bucket that contains the file.

`file_path`

A text string containing the Amazon S3 file name including the path of the file.

`region`

A text string identifying the AWS Region location of the file. For a listing of AWS Region names and associated values, see `Regions, Availability Zones, and Local Zones` (p. 79).

`access_key`

A text string containing the access key to use for the import operation. The default is NULL.
**secret_key**

A text string containing the secret key to use for the import operation. The default is NULL.

**session_token**

(Optional) A text string containing the session key to use for the import operation. The default is NULL.

**aws_commons.create_s3_uri**

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. Use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the `aws_s3.table_import_from_s3` function.

**Syntax**

```python
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
    region text
)
```

**Parameters**

**bucket**

A required text string containing the Amazon S3 bucket name for the file.

**file_path**

A required text string containing the Amazon S3 file name including the path of the file.

**region**

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 79).

**aws_commons.create_aws_credentials**

Sets an access key and secret key in an `aws_commons._aws_credentials_1` structure. Use the results of the `aws_commons.create_aws_credentials` function in the `credentials` parameter of the `aws_s3.table_import_from_s3` function.

**Syntax**

```python
aws_commons.create_aws_credentials(
    access_key text,
    secret_key text,
    session_token text
)
```

**Parameters**

**access_key**

A required text string containing the access key to use for importing an Amazon S3 file. The default is NULL.
Transporting PostgreSQL databases between DB instances

By using PostgreSQL transportable databases for Amazon RDS, you can move a PostgreSQL database between two DB instances. This is a very fast way to migrate large databases between different DB instances. To use this approach, your DB instances must both run the same major version of PostgreSQL.

This capability requires that you install the pg_transport extension on both the source and the destination DB instance. The pg_transport extension provides a physical transport mechanism that moves the database files with minimal processing. This mechanism moves data much faster than traditional dump and load processes, with less downtime.

**Note**
PostgreSQL transportable databases are available in RDS for PostgreSQL 11.5 and higher, and RDS for PostgreSQL version 10.10 and higher.

To transport a PostgreSQL DB instance from one RDS for PostgreSQL DB instance to another, you first set up the source and destination instances as detailed in Setting up a DB instance for transport (p. 1930). You can then transport the database by using the function described in Transporting a PostgreSQL database (p. 1931).

**Topics**
- Limitations for using PostgreSQL transportable databases (p. 1929)
- Setting up to transport a PostgreSQL database (p. 1930)
- Transporting a PostgreSQL database to the destination from the source (p. 1931)
- What happens during database transport (p. 1932)
- Transportable databases function reference (p. 1933)
- Transportable databases parameter reference (p. 1934)

**Limitations for using PostgreSQL transportable databases**

Transportable databases have the following limitations:

- **Read replicas** – You can’t use transportable databases on read replicas or parent instances of read replicas.
- **Unsupported column types** – You can’t use the reg data types in any database tables that you plan to transport with this method. These types depend on system catalog object IDs (OIDs), which often change during transport.
- **Tablespaces** – All source database objects must be in the default pg_default tablespace.
- **Compatibility** – Both the source and destination DB instances must run the same major version of PostgreSQL.
- **Extensions** – The source DB instance can have only the pg_transport installed.
• **Roles and ACLs** – The source database's access privileges and ownership information aren't carried over to the destination database. All database objects are created and owned by the local destination user of the transport.

• **Concurrent transports** – A single DB instance can support up to 32 concurrent transports, including both imports and exports, if worker processes have been configured properly.

• **RDS for PostgreSQL DB instances only** – PostgreSQL transportable databases are supported on RDS for PostgreSQL DB instances only. You can't use it with on-premises databases or databases running on Amazon EC2.

**Setting up to transport a PostgreSQL database**

Before you begin, make sure that your RDS for PostgreSQL DB instances meet the following requirements:

• The RDS for PostgreSQL DB instances for source and destination must run the same version of PostgreSQL.

• The destination DB can't have a database of the same name as the source DB that you want to transport.

• The account you use to run the transport needs `rds_superuser` privileges on both the source DB and the destination DB.

• The security group for the source DB instance must allow inbound access from the destination DB instance. This might already be the case if your source and destination DB instances are located in the VPC. For more information about security groups, see Controlling access with security groups (p. 2232).

Transporting databases from a source DB instance to a destination DB instance requires several changes to the DB parameter group associated with each instance. That means that you must create a custom DB parameter group for the source DB instance and create a custom DB parameter group for the destination DB instance.

**Note**

If your DB instances are already configured using custom DB parameter groups, you can start with step 2 in the following procedure.

**To configure the custom DB group parameters for transporting databases**

For the following steps, use an account that has `rds_superuser` privileges.
