# Table of Contents

What is Amazon RDS? ........................................................................................................... 1
Overview ................................................................................................................................... 1
  - Amazon EC2 and on-premises databases ........................................................................ 1
  - Amazon RDS and Amazon EC2 ...................................................................................... 2
  - Amazon RDS Custom for Oracle and Microsoft SQL Server ........................................ 3
  - Amazon RDS on AWS Outposts ....................................................................................... 3
DB instances ................................................................................................................................ 3
DB engines .................................................................................................................................. 4
DB instance classes .................................................................................................................. 4
DB instance storage .................................................................................................................. 4
  - Amazon Virtual Private Cloud (Amazon VPC) .............................................................. 5
AWS Regions and Availability Zones ....................................................................................... 5
Security ...................................................................................................................................... 5
Amazon RDS monitoring .......................................................................................................... 5
How to work with Amazon RDS .............................................................................................. 5
  - AWS Management Console ............................................................................................ 6
  - Command line interface .................................................................................................... 6
  - Amazon RDS APIs ........................................................................................................... 6
How you are charged for Amazon RDS .................................................................................... 6
What's next? .............................................................................................................................. 6
  - Getting started ................................................................................................................ 6
  - Topics specific to database engines ................................................................................. 6
Amazon RDS shared responsibility model ............................................................................. 8
DB instances ................................................................................................................................ 9
DB instance classes .................................................................................................................. 11
  - DB instance class types ................................................................................................ 11
  - Supported DB engines ................................................................................................. 14
  - Determining DB instance class support in AWS Regions ............................................... 68
  - Changing your DB instance class .................................................................................. 71
  - Configuring the processor for RDS for Oracle .............................................................. 71
  - Hardware specifications .................................................................................................. 87
DB instance storage .................................................................................................................. 101
  - Storage types ............................................................................................................... 101
  - General Purpose SSD storage ...................................................................................... 102
  - Provisioned IOPS storage ............................................................................................. 104
  - Comparing SSD storage types ...................................................................................... 106
  - Magnetic storage .......................................................................................................... 107
  - Monitoring storage performance .................................................................................. 107
  - Factors that affect storage performance ..................................................................... 108
Regions, Availability Zones, and Local Zones ...................................................................... 110
  - AWS Regions ............................................................................................................... 111
  - Availability Zones ......................................................................................................... 113
  - Local Zones .................................................................................................................. 114
Supported Amazon RDS features by Region and engine ...................................................... 116
  - Table conventions ........................................................................................................ 116
  - Feature quick reference ............................................................................................... 116
  - Blue/Green Deployments ............................................................................................. 118
  - Cross-Region automated backups ................................................................................. 118
  - Cross-Region read replicas ........................................................................................... 119
  - Database activity streams ............................................................................................. 121
  - Dual-stack mode .......................................................................................................... 125
  - Export snapshots to S3 .................................................................................................. 133
  - IAM database authentication ....................................................................................... 138
  - Kerberos authentication ............................................................................................... 141
Multi-AZ DB clusters .......................................................... 147
Performance Insights ........................................................ 150
RDS Custom ...................................................................... 151
Amazon RDS Proxy .......................................................... 155
Secrets Manager integration ............................................... 161
Engine-native features ...................................................... 162
DB instance billing for Amazon RDS .................................... 163
On-Demand DB instances .................................................. 164
Reserved DB instances ...................................................... 165
Setting up .......................................................................... 174
Sign up for an AWS account ................................................ 174
Create an administrative user ............................................. 174
Grant programmatic access ................................................ 175
Determine requirements .................................................... 176
Provide access to your DB instance ..................................... 177
Getting started .................................................................. 180
Creating and connecting to a MariaDB DB instance .............. 181
Prerequisites ................................................................. 182
Step 1: Create an EC2 instance .......................................... 182
Step 2: Create a MariaDB DB instance ................................. 185
Step 3: Connect to a MariaDB DB instance ........................... 190
Step 4: Delete the EC2 instance and DB instance ................. 193
(Optional) Connect your DB instance to a Lambda function ... 193
Creating and connecting to a Microsoft SQL Server DB instance .......................................................... 194
Prerequisites ................................................................. 195
Step 1: Create an EC2 instance .......................................... 195
Step 2: Create a SQL Server DB instance ............................ 199
Step 3: Connecting to your SQL Server DB instance ............ 204
Step 4: Exploring your sample DB instance ........................ 206
Step 5: Delete the EC2 instance and DB instance ............... 208
(Optional) Connect your DB instance to a Lambda function ... 208
Creating and connecting to a MySQL DB instance ............... 209
Prerequisites ................................................................. 210
Step 1: Create an EC2 instance .......................................... 210
Step 2: Create a MySQL DB instance ................................. 213
Step 3: Connect to a MySQL DB instance ............................ 218
Step 4: Delete the EC2 instance and DB instance ............... 221
(Optional) Connect your DB instance to a Lambda function ... 221
Creating and connecting to an Oracle DB instance ............... 222
Prerequisites ................................................................. 223
Step 1: Create an EC2 instance .......................................... 223
Step 2: Create an Oracle DB instance ................................. 226
Step 3: Connect your SQL client to an Oracle DB instance ... 231
Step 4: Delete the EC2 instance and DB instance ............... 234
(Optional) Connect your DB instance to a Lambda function ... 234
Creating and connecting to a PostgreSQL DB instance ...... 235
Prerequisites ................................................................. 236
Step 1: Create an EC2 instance .......................................... 236
Step 2: Create a PostgreSQL DB instance .......................... 240
Step 3: Connect to a PostgreSQL DB instance .................... 245
Step 4: Delete the EC2 instance and DB instance ............... 248
(Optional) Connect your DB instance to a Lambda function ... 248
Tutorial: Create a web server and an Amazon RDS DB instance .......................................................... 249
Launch an EC2 instance ................................................... 250
Create a DB instance ....................................................... 255
Install a web server ......................................................... 264
Tutorial: Create a Lambda function to access your Amazon RDS DB instance .......................................... 273
Prerequisites .......................................................................................................................... 274
Create an Amazon RDS DB instance .................................................................................. 274
Create Lambda function and proxy .................................................................................... 275
Create a function execution role .......................................................................................... 275
Create a Lambda deployment package ................................................................................. 276
Update the Lambda function ............................................................................................... 278
Test your Lambda function in the console ........................................................................... 279
Create an Amazon SQS queue .............................................................................................. 280
Create an event source mapping to invoke your Lambda function .................................... 280
Test and monitor your setup ................................................................................................. 281
Clean up your resources ...................................................................................................... 282

What is Amazon Relational Database Service (Amazon RDS)?

Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for an industry-standard relational database and manages common database administration tasks.

**Note**
This guide covers Amazon RDS database engines other than Amazon Aurora. For information about using Amazon Aurora, see the Amazon Aurora User Guide.

If you are new to AWS products and services, begin learning more with the following resources:

- For an overview of all AWS products, see What is cloud computing?
- Amazon Web Services provides a number of database services. To learn more about the variety of database options available on AWS, see Choosing an AWS database service and Running databases on AWS.

Overview of Amazon RDS

Why do you want to run a relational database in the AWS Cloud? Because AWS takes over many of the difficult and tedious management tasks of a relational database.

**Topics**
- Amazon EC2 and on-premises databases (p. 1)
- Amazon RDS and Amazon EC2 (p. 2)
- Amazon RDS Custom for Oracle and Microsoft SQL Server (p. 3)
- Amazon RDS on AWS Outposts (p. 3)

Amazon EC2 and on-premises databases

Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. Amazon EC2 eliminates your need to invest in hardware up front, so you can develop and deploy applications faster.

When you buy an on-premises server, you get CPU, memory, storage, and IOPS, all bundled together. With Amazon EC2, these are split apart so that you can scale them independently. If you need more CPU, less IOPS, or more storage, you can easily allocate them.

For a relational database in an on-premises server, you assume full responsibility for the server, operating system, and software. For a database on an Amazon EC2 instance, AWS manages the layers below the operating system. In this way, Amazon EC2 eliminates some of the burden of managing an on-premises database server.

In the following table, you can find a comparison of the management models for on-premises databases and Amazon EC2.
Amazon EC2 isn't a fully managed service. Thus, when you run a database on Amazon EC2, you're more prone to user errors. For example, when you update the operating system or database software manually, you might accidentally cause application downtime. You might spend hours checking every change to identify and fix an issue.

Amazon RDS and Amazon EC2

Amazon RDS is a managed database service. It's responsible for most management tasks. By eliminating tedious manual tasks, Amazon RDS frees you to focus on your application and your users. We recommend Amazon RDS over Amazon EC2 as your default choice for most database deployments.

In the following table, you can find a comparison of the management models in Amazon EC2 and Amazon RDS.

<table>

</table>
Amazon RDS provides the following specific advantages over database deployments that aren't fully managed:

- You can use the database products you are already familiar with: MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL.
- Amazon RDS manages backups, software patching, automatic failure detection, and recovery.
- You can turn on automated backups, or manually create your own backup snapshots. You can use these backups to restore a database. The Amazon RDS restore process works reliably and efficiently.
- You can get high availability with a primary instance and a synchronous secondary instance that you can fail over to when problems occur. You can also use read replicas to increase read scaling.
- In addition to the security in your database package, you can help control who can access your RDS databases. To do so, you can use AWS Identity and Access Management (IAM) to define users and permissions. You can also help protect your databases by putting them in a virtual private cloud (VPC).

Amazon RDS Custom for Oracle and Microsoft SQL Server

Amazon RDS Custom is an RDS management type that gives you full access to your database and operating system.

You can use the control capabilities of RDS Custom to access and customize the database environment and operating system for legacy and packaged business applications. Meanwhile, Amazon RDS automates database administration tasks and operations.

In this deployment model, you can install applications and change configuration settings to suit your applications. At the same time, you can offload database administration tasks such as provisioning, scaling, upgrading, and backup to AWS. You can take advantage of the database management benefits of Amazon RDS, with more control and flexibility.

For Oracle Database and Microsoft SQL Server, RDS Custom combines the automation of Amazon RDS with the flexibility of Amazon EC2. For more information on RDS Custom, see Working with Amazon RDS Custom (p. 978).

With the shared responsibility model of RDS Custom, you get more control than in Amazon RDS, but also more responsibility. For more information, see Shared responsibility model in RDS Custom (p. 979).

Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts extends RDS for SQL Server, RDS for MySQL, and RDS for PostgreSQL databases to AWS Outposts environments. AWS Outposts uses the same hardware as in public AWS Regions to bring AWS services, infrastructure, and operation models on-premises. With RDS on Outposts, you can provision managed DB instances close to the business applications that must run on-premises. For more information, see Working with Amazon RDS on AWS Outposts (p. 1193).

DB instances

A DB instance is an isolated database environment in the AWS Cloud. The basic building block of Amazon RDS is the DB instance.
Your DB instance can contain one or more user-created databases. You can access your DB instance by using the same tools and applications that you use with a standalone database instance. You can create and modify a DB instance by using the AWS Command Line Interface (AWS CLI), the Amazon RDS API, or the AWS Management Console.

**DB engines**

A *DB engine* is the specific relational database software that runs on your DB instance. Amazon RDS currently supports the following engines:

- MariaDB
- Microsoft SQL Server
- MySQL
- Oracle
- PostgreSQL

Each DB engine has its own supported features, and each version of a DB engine can include specific features. Support for Amazon RDS features varies across AWS Regions and specific versions of each DB engine. To check feature support in different engine versions and Regions, see [Supported features in Amazon RDS by AWS Region and DB engine](p. 116).

Additionally, each DB engine has a set of parameters in a DB parameter group that control the behavior of the databases that it manages.

**DB instance classes**

A *DB instance class* determines the computation and memory capacity of a DB instance. A DB instance class consists of both the DB instance type and the size. Each instance type offers different compute, memory, and storage capabilities. For example, `db.m6g` is a general-purpose DB instance type powered by AWS Graviton2 processors. Within the `db.m6g` instance type, `db.m6g.2xlarge` is a DB instance class.

You can select the DB instance that best meets your needs. If your needs change over time, you can change DB instances. For information, see [DB instance classes](p. 11).

**Note**

For pricing information on DB instance classes, see the Pricing section of the Amazon RDS product page.

**DB instance storage**

Amazon EBS provides durable, block-level storage volumes that you can attach to a running instance. DB instance storage comes in the following types:

- General Purpose (SSD)
- Provisioned IOPS (PIOPS)
- Magnetic

The storage types differ in performance characteristics and price. You can tailor your storage performance and cost to the needs of your database.

Each DB instance has minimum and maximum storage requirements depending on the storage type and the database engine it supports. It's important to have sufficient storage so that your databases have room to grow. Also, sufficient storage makes sure that features for the DB engine have room to write content or log entries. For more information, see [Amazon RDS DB instance storage](p. 101).
Amazon Virtual Private Cloud (Amazon VPC)

You can run a DB instance on a virtual private cloud (VPC) using the Amazon Virtual Private Cloud (Amazon VPC) service. When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. The basic functionality of Amazon RDS is the same whether it's running in a VPC or not. Amazon RDS manages backups, software patching, automatic failure detection, and recovery. There's no additional cost to run your DB instance in a VPC. For more information on using Amazon VPC with RDS, see Amazon VPC VPCs and Amazon RDS (p. 2705).

Amazon RDS uses Network Time Protocol (NTP) to synchronize the time on DB instances.

AWS Regions and Availability Zones

Amazon cloud computing resources are housed in highly available data center facilities in different areas of the world (for example, North America, Europe, or Asia). Each data center location is called an AWS Region.

Each AWS Region contains multiple distinct locations called Availability Zones, or AZs. Each Availability Zone is engineered to be isolated from failures in other Availability Zones. Each is engineered to provide inexpensive, low-latency network connectivity to other Availability Zones in the same AWS Region. By launching instances in separate Availability Zones, you can protect your applications from the failure of a single location. For more information, see Regions, Availability Zones, and Local Zones (p. 110).

You can run your DB instance in several Availability Zones, an option called a Multi-AZ deployment. When you choose this option, Amazon automatically provisions and maintains one or more secondary standby DB instances in a different Availability Zone. Your primary DB instance is replicated across Availability Zones to each secondary DB instance. This approach helps provide data redundancy and failover support, eliminate I/O freezes, and minimize latency spikes during system backups. In a Multi-AZ DB clusters deployment, the secondary DB instances can also serve read traffic. For more information, see Configuring and managing a Multi-AZ deployment (p. 492).

Security

A security group controls the access to a DB instance. It does so by allowing access to IP address ranges or Amazon EC2 instances that you specify.

For more information about security groups, see Security in Amazon RDS (p. 2582).

Amazon RDS monitoring

There are several ways that you can track the performance and health of a DB instance. You can use the Amazon CloudWatch service to monitor the performance and health of a DB instance. CloudWatch performance charts are shown in the Amazon RDS console. You can also subscribe to Amazon RDS events to be notified about changes to a DB instance, DB snapshot, or DB parameter group. For more information, see Monitoring metrics in an Amazon RDS instance (p. 678).

How to work with Amazon RDS

There are several ways that you can interact with Amazon RDS.
AWS Management Console

The AWS Management Console is a simple web-based user interface. You can manage your DB instances from the console with no programming required. To access the Amazon RDS console, sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

Command line interface

You can use the AWS Command Line Interface (AWS CLI) to access the Amazon RDS API interactively. To install the AWS CLI, see Installing the AWS Command Line Interface. To begin using the AWS CLI for RDS, see AWS Command Line Interface reference for Amazon RDS.

Amazon RDS APIs

If you are a developer, you can access the Amazon RDS programmatically using APIs. For more information, see Amazon RDS API reference (p. 2759).

For application development, we recommend that you use one of the AWS Software Development Kits (SDKs). The AWS SDKs handle low-level details such as authentication, retry logic, and error handling, so that you can focus on your application logic. AWS SDKs are available for a wide variety of languages. For more information, see Tools for Amazon web services.

AWS also provides libraries, sample code, tutorials, and other resources to help you get started more easily. For more information, see Sample code & libraries.

How you are charged for Amazon RDS

When you use Amazon RDS, you can choose to use on-demand DB instances or reserved DB instances. For more information, see DB instance billing for Amazon RDS (p. 163).

For Amazon RDS pricing information, see the Amazon RDS product page.

What's next?

The preceding section introduced you to the basic infrastructure components that RDS offers. What should you do next?

Getting started

Create a DB instance using instructions in Getting started with Amazon RDS (p. 180).

Topics specific to database engines

You can review information specific to a particular DB engine in the following sections:

- Amazon RDS for MariaDB (p. 1271)
- Amazon RDS for Microsoft SQL Server (p. 1370)
- Amazon RDS for MySQL (p. 1638)
- Amazon RDS for Oracle (p. 1801)
- Amazon RDS for PostgreSQL (p. 2164)
Amazon RDS shared responsibility model

Amazon RDS is responsible for hosting the software components and infrastructure of DB instances and DB cluster. You are responsible for query tuning, which is the process of adjusting SQL queries to improve performance. Query performance is highly dependent on database design, data size, data distribution, application workload, and query patterns, which can vary greatly. Monitoring and tuning are highly individualized processes that you own for your RDS databases. You can use Amazon RDS Performance Insights and other tools to identify problematic queries.
Amazon RDS DB instances

A DB instance is an isolated database environment running in the cloud. It is the basic building block of Amazon RDS. A DB instance can contain multiple user-created databases, and can be accessed using the same client tools and applications you might use to access a standalone database instance. DB instances are simple to create and modify with the AWS command line tools, Amazon RDS API operations, or the AWS Management Console.

**Note**
Amazon RDS supports access to databases using any standard SQL client application. Amazon RDS does not allow direct host access.

You can have up to 40 Amazon RDS DB instances, with the following limitations:

- 10 for each SQL Server edition (Enterprise, Standard, Web, and Express) under the "license-included" model
- 10 for Oracle under the "license-included" model
- 40 for MySQL, MariaDB, or PostgreSQL
- 40 for Oracle under the "bring-your-own-license" (BYOL) licensing model

**Note**
If your application requires more DB instances, you can request additional DB instances by using this form.

Each DB instance has a DB instance identifier. This customer-supplied name uniquely identifies the DB instance when interacting with the Amazon RDS API and AWS CLI commands. The DB instance identifier must be unique for that customer in an AWS Region.

The DB instance identifier forms part of the DNS hostname allocated to your instance by RDS. For example, if you specify `db1` as the DB instance identifier, then RDS will automatically allocate a DNS endpoint for your instance. An example endpoint is `db1abcdefghijkl.us-east-1.rds.amazonaws.com`, where `db1` is your instance ID.

In the example endpoint `db1abcdefghijkl.us-east-1.rds.amazonaws.com`, the string `abcdefghijkl` is a unique identifier for a specific combination of AWS Region and AWS account. The identifier `abcdefghijkl` in the example is internally generated by RDS and doesn't change for the specified combination of Region and account. Thus, all your DB instances in this Region share the same fixed identifier. Consider the following features of the fixed identifier:

- If you rename your DB instance, the endpoint is different but the fixed identifier is the same. For example, if you rename `db1` to `renamed-db1`, the new instance endpoint is `renamed-db1abcdefghijkl.us-east-1.rds.amazonaws.com`.
- If you delete and re-create a DB instance with the same DB instance identifier, the endpoint is the same.
- If you use the same account to create a DB instance in a different Region, the internally generated identifier is different because the Region is different, as in `db2mnopqrstuvwxyz.us-west-1.rds.amazonaws.com`.

Each DB instance supports a database engine. Amazon RDS currently supports MySQL, MariaDB, PostgreSQL, Oracle, Microsoft SQL Server, and Amazon Aurora database engines.

When creating a DB instance, some database engines require that a database name be specified. A DB instance can host multiple databases, or a single Oracle database with multiple schemas. The database name value depends on the database engine:
• For the MySQL and MariaDB database engines, the database name is the name of a database hosted in your DB instance. Databases hosted by the same DB instance must have a unique name within that instance.
• For the Oracle database engine, database name is used to set the value of ORACLE_SID, which must be supplied when connecting to the Oracle RDS instance.
• For the Microsoft SQL Server database engine, database name is not a supported parameter.
• For the PostgreSQL database engine, the database name is the name of a database hosted in your DB instance. A database name is not required when creating a DB instance. Databases hosted by the same DB instance must have a unique name within that instance.

Amazon RDS creates a master user account for your DB instance as part of the creation process. This master user has permissions to create databases and to perform create, delete, select, update, and insert operations on tables the master user creates. You must set the master user password when you create a DB instance, but you can change it at any time using the AWS CLI, Amazon RDS API operations, or the AWS Management Console. You can also change the master user password and manage users using standard SQL commands.

**Note**
This guide covers non-Aurora Amazon RDS database engines. For information about using Amazon Aurora, see the *Amazon Aurora User Guide*. 
DB instance classes

The DB instance class determines the computation and memory capacity of an Amazon RDS DB instance. The DB instance class that you need depends on your processing power and memory requirements.

A DB instance class consists of both the DB instance class type and the size. For example, db.r6g is a memory-optimized DB instance class type powered by AWS Graviton2 processors. Within the db.r6g instance class type, db.r6g.2xlarge is a DB instance class. The size of this class is 2xlarge.

For more information about instance class pricing, see [Amazon RDS pricing](#).

### Topics
- [DB instance class types](#) (p. 11)
- [Supported DB engines for DB instance classes](#) (p. 14)
- [Determining DB instance class support in AWS Regions](#) (p. 68)
- [Changing your DB instance class](#) (p. 71)
- [Configuring the processor for a DB instance class in RDS for Oracle](#) (p. 71)
- [Hardware specifications for DB instance classes](#) (p. 87)

### DB instance class types

Amazon RDS supports DB instance classes for the following use cases:

- [General-purpose](#) (p. 11)
- [Memory-optimized](#) (p. 12)
- [Burstable-performance](#) (p. 14)

For more information about Amazon EC2 instance types, see [Instance types](#) in the Amazon EC2 documentation.

### General-purpose instance class types

The following general-purpose DB instance class types are available:

- **db.m7g** – General-purpose DB instance classes powered by AWS Graviton3 processors. These instance classes deliver balanced compute, memory, and networking for a broad range of general-purpose workloads.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton3 processors. To do so, complete the same steps as with any other DB instance modification.

- **db.m6g** – General-purpose DB instance classes powered by AWS Graviton2 processors. These instances deliver balanced compute, memory, and networking for a broad range of general-purpose workloads. The db.m6gd instance classes have local NVMe-based SSD block-level storage for applications that need high-speed, low latency local storage.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.

- **db.m6i** – General-purpose DB instance classes powered by 3rd Generation Intel Xeon Scalable processors. These instances are SAP Certified and ideal for workloads such as backend servers supporting enterprise applications, gaming servers, caching fleets, and application development
environments. The db.m6id instance classes offer up to 7.6 TB of local NVMe-based SSD storage, whereas db.m6i offers EBS-only storage.

- **db.m5** – General-purpose DB instance classes that provide a balance of compute, memory, and network resources, and are a good choice for many applications. The db.m5d instance class offers NVMe-based SSD storage that is physically connected to the host server. The db.m5 instance classes provide more computing capacity than the previous db.m4 instance classes. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.

- **db.m4** – General-purpose DB instance classes that provide more computing capacity than the previous db.m3 instance classes.

For the RDS for Oracle DB engines, Amazon RDS no longer supports db.m4 DB instance classes. If you had previously created RDS for Oracle db.m4 DB instances, Amazon RDS automatically upgrades those DB instances to equivalent db.m5 DB instance classes.

- **db.m3** – General-purpose DB instance classes that provide more computing capacity than the previous db.m1 instance classes.

For the RDS for MariaDB, RDS for MySQL, and RDS for PostgreSQL DB engines, Amazon RDS has started the end-of-life process for db.m3 DB instance classes using the following schedule, which includes upgrade recommendations. For all RDS DB instances that use db.m3 DB instance classes, we recommend that you upgrade to a db.m5 DB instance class as soon as possible.

<table>
<thead>
<tr>
<th>Action or recommendation</th>
<th>Dates</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can no longer create RDS DB instances that use db.m3 DB instance classes.</td>
<td>Now</td>
</tr>
<tr>
<td>Amazon RDS started automatic upgrades of RDS DB instances that use db.m3 DB instance classes to equivalent db.m5 DB instance classes.</td>
<td>February 1, 2023</td>
</tr>
</tbody>
</table>

**Memory-optimized instance class types**

The memory-optimized Z family supports the following instance class type:

- **db.z1d** – Instance classes optimized for memory-intensive applications. These instance classes offer both high compute capacity and a high memory footprint. High frequency z1d instances deliver a sustained all-core frequency of up to 4.0 GHz.

The memory-optimized X family supports the following instance class types:

- **db.x2g** – Instance classes optimized for memory-intensive applications and powered by AWS Graviton2 processors. These instance classes offer low cost per GiB of memory.

You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.

- **db.x2i** – Instance classes optimized for memory-intensive applications. The db.x2iedn and db.x2idn classes are powered by third-generation Intel Xeon Scalable processors (Ice Lake). They include up to 3.8 TB of local NVMe SSD storage, up to 100 Gbps of networking bandwidth, and up to 4 TiB (db.x2iden) or 2 TiB (db.x2idn) of memory. The db.x2iezn class is powered by second-generation Intel Xeon Scalable processors (Cascade Lake) with an all-core turbo frequency of up to 4.5 GHz and up to 1.5 TiB of memory.

- **db.x1** – Instance classes optimized for memory-intensive applications. These instance classes offer one of the lowest price per GiB of RAM among the DB instance classes and up to 1,952 GiB of DRAM-based instance memory. The db.x1e type offers up to 3,904 GiB of DRAM-based instance memory.
The memory-optimized R family supports the following instance class types:

- **db.r7g** – Instance classes powered by AWS Graviton3 processors. These instance classes are ideal for running memory-intensive workloads in open-source databases such as MySQL and PostgreSQL.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton3 processors. To do so, complete the same steps as with any other DB instance modification.

- **db.r6g** – Instance classes powered by AWS Graviton2 processors. These instance classes are ideal for running memory-intensive workloads in open-source databases such as MySQL and PostgreSQL. The db.r6gd type offers local NVMe-based SSD block-level storage for applications that need high-speed, low latency local storage.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.

- **db.r6i** – Instance classes powered by 3rd Generation Intel Xeon Scalable processors. These instances are SAP-Certified and are an ideal fit for memory-intensive workloads in open-source databases such as MySQL and PostgreSQL. The db.r6id instance class type has a memory-to-vCPU ratio of 8:1 and a maximum memory of 1 TiB. The db.r6id instance class type offers up to 7.6 TB of local NVMe-based SSD storage, whereas the db.r6i class type offers EBS-only storage.

- **db.r5b** – Instance classes that are memory-optimized for throughput-intensive applications. Powered by the AWS Nitro System, db.r5b instances deliver up to 60 Gbps bandwidth and 260,000 IOPS of EBS performance. This is the fastest block storage performance on EC2.

- **db.r5d** – Instance classes that are optimized for low latency, very high random I/O performance, and high sequential read throughput.

- **db.r5** – Instance classes optimized for memory-intensive applications. These instance classes offer improved networking performance. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.

- **db.r4** – Instance classes that provide improved networking over previous db.r3 instance classes.

  For the RDS for Oracle DB engines, Amazon RDS has started the end-of-life process for db.r4 DB instance classes using the following schedule, which includes upgrade recommendations. For RDS for Oracle DB instances that use db.r4 instance classes, we recommend that you upgrade to a db.r5 instance class as soon as possible.

<table>
<thead>
<tr>
<th>Action or recommendation</th>
<th>Dates</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can no longer create RDS for Oracle DB instances that use db.r4 DB instance classes.</td>
<td>Now</td>
</tr>
<tr>
<td>Amazon RDS started automatic upgrades of RDS for Oracle DB instances that use db.r4 DB instance classes.</td>
<td>April 17, 2023</td>
</tr>
</tbody>
</table>

- **db.r3** – Instance classes that provide memory optimization.

  For the RDS for MariaDB, RDS for MySQL, and RDS for PostgreSQL DB engines, Amazon RDS has started the end-of-life process for db.r3 DB instance classes using the following schedule, which includes upgrade recommendations. For all RDS DB instances that use db.r3 DB instance classes, we recommend that you upgrade to a db.r5 DB instance class as soon as possible.

<table>
<thead>
<tr>
<th>Action or recommendation</th>
<th>Dates</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can no longer create RDS DB instances that use db.r3 DB instance classes.</td>
<td>Now</td>
</tr>
</tbody>
</table>
Amazon RDS started automatic upgrades of RDS DB instances that use db.r3 DB instance classes to equivalent db.r5 DB instance classes.

<table>
<thead>
<tr>
<th>Action or recommendation</th>
<th>Dates</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon RDS started automatic upgrades of RDS DB instances that use db.r3 DB instance classes to equivalent db.r5 DB instance classes.</td>
<td>February 1, 2023</td>
</tr>
</tbody>
</table>

### Burstable-performance instance class types

The following burstable-performance DB instance class types are available:

- **db.t4g** – General-purpose instance classes powered by Arm-based AWS Graviton2 processors. These instance classes deliver better price performance than previous burstable-performance DB instance classes for a broad set of burstable general-purpose workloads. Amazon RDS db.t4g instances are configured for Unlimited mode. This means that they can burst beyond the baseline over a 24-hour window for an additional charge.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.

- **db.t3** – Instance classes that provide a baseline performance level, with the ability to burst to full CPU usage. The db.t3 instances are configured for Unlimited mode. These instance classes provide more computing capacity than the previous db.t2 instance classes. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.

- **db.t2** – Instance classes that provide a baseline performance level, with the ability to burst to full CPU usage. We recommend using these instance classes only for development and test servers, or other non-production servers.

  **Note**
  The DB instance classes that use the AWS Nitro System (db.m5, db.r5, db.t3) are throttled on combined read plus write workload.

  For DB instance class hardware specifications, see [Hardware specifications for DB instance classes](p. 87).

### Supported DB engines for DB instance classes

The following are DB engine-specific considerations for DB instance classes:

**Microsoft SQL Server**

DB instance class support varies according to the version and edition of SQL Server. For instance class support by version and edition, see [DB instance class support for Microsoft SQL Server](p. 1374).

**Oracle**

DB instance class support varies according to the Oracle Database version and edition. RDS for Oracle supports additional memory-optimized instance classes. These classes have names of the form `db.r5.instance_size.tpcthreads_per_core.memratio`. For the vCPU count and memory allocation for each optimized class, see [Supported RDS for Oracle instance classes](p. 1813).

**RDS Custom**

For information about the DB instance classes supported in RDS Custom, see [DB instance class support for RDS Custom for Oracle](p. 999) and [DB instance class support for RDS Custom for SQL Server](p. 1089).
In the following table, you can find details about supported Amazon RDS DB instance classes for each Amazon RDS DB engine. The cell for each engine contains one of the following values:

Yes

The instance class is supported for all versions of the DB engine.

No

The instance class isn't supported for the DB engine.

specific-versions

The instance class is supported only for the specified database versions of the DB engine.

Amazon RDS periodically deprecates major and minor versions. For information about current supported versions, see topics for the individual DB engines: MariaDB versions (p. 1281), Microsoft SQL Server versions (p. 1378), MySQL versions (p. 1643), Oracle versions (p. 1805), and PostgreSQL versions (p. 2171).

Determining DB instance class support in AWS Regions

To determine the DB instance classes supported by each DB engine in a specific AWS Region, you can take one of several approaches. You can use the AWS Management Console, the Amazon RDS Pricing page, or the `describe-orderable-db-instance-options` command for the AWS Command Line Interface (AWS CLI).

**Note**
When you perform operations with the AWS CLI, it automatically shows the supported DB instance classes for a specific DB engine, DB engine version, and AWS Region. Examples of the operations that you can perform include creating and modifying a DB instance.

**Contents**
- Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions (p. 68)
- Using the AWS CLI to determine DB instance class support in AWS Regions (p. 69)
  - Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region (p. 69)
  - Listing the DB engine versions that support a specific DB instance class in an AWS Region (p. 70)

**Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions**

You can use the Amazon RDS Pricing page to determine the DB instance classes supported by each DB engine in a specific AWS Region.

To use the pricing page to determine the DB instance classes supported by each engine in a Region

1. Go to Amazon RDS Pricing.
2. Choose a DB engine.
3. On the pricing page for the DB engine, choose On-Demand DB Instances or Reserved DB Instances.
4. To see the DB instance classes available in an AWS Region, choose the AWS Region in Region.

Other choices might be available for some DB engines, such as Single-AZ Deployment or Multi-AZ Deployment.

Using the AWS CLI to determine DB instance class support in AWS Regions

You can use the AWS CLI to determine which DB instance classes are supported for specific DB engines and DB engine versions in an AWS Region. The following table shows the valid DB engine values.

<table>
<thead>
<tr>
<th>Engine names</th>
<th>Engine values in CLI commands</th>
<th>More information about versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB</td>
<td>mariaadb</td>
<td>MariaDB on Amazon RDS versions (p. 1281)</td>
</tr>
<tr>
<td>Microsoft SQL Server</td>
<td>sqlserver-ee, sqlserver-se, sqlserver-ex, sqlserver-web</td>
<td>Microsoft SQL Server versions on Amazon RDS (p. 1378)</td>
</tr>
<tr>
<td>MySQL</td>
<td>mysql</td>
<td>MySQL on Amazon RDS versions (p. 1643)</td>
</tr>
<tr>
<td>Oracle</td>
<td>oracle-ee, oracle-se2</td>
<td>Amazon RDS for Oracle Release Notes</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>postgres</td>
<td>Available PostgreSQL database versions (p. 2171)</td>
</tr>
</tbody>
</table>

For information about AWS Region names, see AWS Regions (p. 111).

The following examples demonstrate how to determine DB instance class support in an AWS Region using the describe-orderable-db-instance-options AWS CLI command.

**Note**
To limit the output, these examples show results only for the General Purpose SSD (gp2) storage type. If necessary, you can change the storage type to General Purpose SSD (gp3), Provisioned IOPS (io1), or magnetic (standard) in the commands.

**Topics**
- Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region (p. 69)
- Listing the DB engine versions that support a specific DB instance class in an AWS Region (p. 70)

**Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region**

To list the DB instance classes that are supported by a specific DB engine version in an AWS Region, run the following command.
For Linux, macOS, or Unix:

```bash
aws rds describe-orderable-db-instance-options --engine engine --engine-version version \
--query "*[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}[]? StorageType=='gp2']][[].{DBInstanceClass:DBInstanceClass}"
  --output text \
  --region region
```

For Windows:

```bash
aws rds describe-orderable-db-instance-options --engine engine --engine-version version 
--query "*[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}[]? StorageType=='gp2']][[].{DBInstanceClass:DBInstanceClass}"
  --output text 
  --region region
```

For example, the following command lists the supported DB instance classes for version 13.6 of the RDS for PostgreSQL DB engine in US East (N. Virginia).

For Linux, macOS, or Unix:

```bash
aws rds describe-orderable-db-instance-options --engine postgres --engine-version 13.6 \
--query "*[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}[]? StorageType=='gp2']][[].{DBInstanceClass:DBInstanceClass}"
  --output text \
  --region us-east-1
```

For Windows:

```bash
aws rds describe-orderable-db-instance-options --engine postgres --engine-version 13.6 
--query "*[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}[]? StorageType=='gp2']][[].{DBInstanceClass:DBInstanceClass}"
  --output text 
  --region us-east-1
```

Listing the DB engine versions that support a specific DB instance class in an AWS Region

To list the DB engine versions that support a specific DB instance class in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```bash
aws rds describe-orderable-db-instance-options --engine engine --db-instance-class DB_instance_class \
--query "*[].{EngineVersion:EngineVersion,StorageType:StorageType}[]? StorageType=='gp2']][[].{EngineVersion:EngineVersion}"
  --output text \
  --region region
```

For Windows:

```bash
aws rds describe-orderable-db-instance-options --engine engine --db-instance-class DB_instance_class 
--query "*[].{EngineVersion:EngineVersion,StorageType:StorageType}[]? StorageType=='gp2']][[].{EngineVersion:EngineVersion}"
  --output text 
```
Changing your DB instance class

You can change the CPU and memory available to a DB instance by changing its DB instance class. To change the DB instance class, modify your DB instance by following the instructions in Modifying an Amazon RDS DB instance (p. 401).

Configuring the processor for a DB instance class in RDS for Oracle

Amazon RDS DB instance classes support Intel Hyper-Threading Technology, which enables multiple threads to run concurrently on a single Intel Xeon CPU core. Each thread is represented as a virtual CPU (vCPU) on the DB instance. A DB instance has a default number of CPU cores, which varies according to DB instance class. For example, a db.m4.xlarge DB instance class has two CPU cores and two threads per core by default—four vCPUs in total.

**Note**
Each vCPU is a hyperthread of an Intel Xeon CPU core.

Topics
- Overview of configuring the processor (p. 71)
- DB instance classes that support processor configuration (p. 72)
- Setting the CPU cores and threads per CPU core for a DB instance class (p. 80)

Overview of configuring the processor

When you use RDS for Oracle, you can usually find a DB instance class that has a combination of memory and number of vCPUs to suit your workloads. However, you can also specify the following processor features to optimize your RDS for Oracle DB instance for specific workloads or business needs:

- **Number of CPU cores** – You can customize the number of CPU cores for the DB instance. You might do this to potentially optimize the licensing costs of your software with a DB instance that has sufficient amounts of RAM for memory-intensive workloads but fewer CPU cores.
• **Threads per core** – You can disable Intel Hyper-Threading Technology by specifying a single thread per CPU core. You might do this for certain workloads, such as high-performance computing (HPC) workloads.

You can control the number of CPU cores and threads for each core separately. You can set one or both in a request. After a setting is associated with a DB instance, the setting persists until you change it.

The processor settings for a DB instance are associated with snapshots of the DB instance. When a snapshot is restored, its restored DB instance uses the processor feature settings used when the snapshot was taken.

If you modify the DB instance class for a DB instance with nondefault processor settings, either specify default processor settings or explicitly specify processor settings at modification. This requirement ensures that you are aware of the third-party licensing costs that might be incurred when you modify the DB instance.

There is no additional or reduced charge for specifying processor features on an RDS for Oracle DB instance. You're charged the same as for DB instances that are launched with default CPU configurations.

### DB instance classes that support processor configuration

You can configure the number of CPU cores and CPU threads per core only when the following conditions are met:

- You're configuring an RDS for Oracle DB instance. For information about the DB instance classes supported by different Oracle Database editions, see [RDS for Oracle instance classes](p. 1812).
- Your DB instance is using the Bring Your Own License (BYOL) licensing option of RDS for Oracle. For more information about Oracle licensing options, see [RDS for Oracle licensing options](p. 1809).
- Your DB instance doesn't belong to one of the db.r5 or db.r5b instance classes that have predefined processor configurations. These instance classes have names in the form `db.r5.instance_size.tpcthreads_per_core.memratio` or `db.r5b.instance_size.tpcthreads_per_core.memratio`. For example, `db.r5b.xlarge.tpc2.mem4x` is preconfigured with 2 threads per core (tpc2) and 4x as much memory as the standard `db.r5b.xlarge` instance class. You can't configure the processor features of these optimized instance classes. For more information, see [Supported RDS for Oracle instance classes](p. 1813).

In the following table, you can find the DB instance classes that support setting a number of CPU cores and CPU threads per core. You can also find the default value and the valid values for the number of CPU cores and CPU threads per core for each DB instance class.

<table>

</tbody>
</table>

**Note**
You can use AWS CloudTrail to monitor and audit changes to the process configuration of Amazon RDS for Oracle DB instances. For more information about using CloudTrail, see Monitoring Amazon RDS API calls in AWS CloudTrail (p. 940).

### Setting the CPU cores and threads per CPU core for a DB instance class

You can configure the number of CPU cores and threads per core for the DB instance class when you perform the following operations:

- Creating an Amazon RDS DB instance (p. 300)
- Modifying an Amazon RDS DB instance (p. 401)
- Restoring from a DB snapshot (p. 615)
- Restoring a DB instance to a specified time (p. 660)

**Note**
When you modify a DB instance to configure the number of CPU cores or threads per core, there is a brief DB instance outage.

You can set the CPU cores and the threads per CPU core for a DB instance class using the AWS Management Console, the AWS CLI, or the RDS API.

#### Console

When you are creating, modifying, or restoring a DB instance, you set the DB instance class in the AWS Management Console. The **Instance specifications** section shows options for the processor. The following image shows the processor features options.
Configuring the processor for RDS for Oracle

Instance specifications

DB engine
Oracle Database Enterprise Edition

License model
bring-your-own-license

DB engine version
Oracle 12.1.0.2.v12

DB instance class
db.r4.xlarge — 4 vCPU, 30.5 GiB RAM

Multi-AZ deployment
○ Create replica in different zone
  Creates a replica in a different Availability Zone (AZ) to provide data redundancy, eliminate I/O freezes, and minimize latency spikes during system backups.
  ○ No

Storage type
Provisioned IOPS (SSD)

Allocated storage
100 GiB
(Minimum: 100 GiB, Maximum: 16384 GiB)

Provisioned IOPS
1000

Additional configuration

Processor features

☑ Override default values
  You can change the number of CPU cores and threads per core on the DB instance class.

Core count
2

Threads per core
2
Set the following options to the appropriate values for your DB instance class under **Processor features**:

- **Core count** – Set the number of CPU cores using this option. The value must be equal to or less than the maximum number of CPU cores for the DB instance class.
- **Threads per core** – Specify 2 to enable multiple threads per core, or specify 1 to disable multiple threads per core.

When you modify or restore a DB instance, you can also set the CPU cores and the threads per CPU core to the defaults for the instance class.

When you view the details for a DB instance in the console, you can view the processor information for its DB instance class on the **Configuration** tab. The following image shows a DB instance class with one CPU core and multiple threads per core enabled.

```
Instance and IOPS
Instance Class
db.r4.large
Core count
1
Threads per core
2
vCPU enabled
2
Storage Type
Provisioned IOPS (SSD)
IOPS
1000
Storage
100 GiB
```

For Oracle DB instances, the processor information only appears for Bring Your Own License (BYOL) DB instances.

**AWS CLI**

You can set the processor features for a DB instance when you run one of the following AWS CLI commands:

- `create-db-instance`
To configure the processor of a DB instance class for a DB instance by using the AWS CLI, include the `--processor-features` option in the command. Specify the number of CPU cores with the `coreCount` feature name, and specify whether multiple threads per core are enabled with the `threadsPerCore` feature name.

The option has the following syntax.

```
--processor-features "Name=coreCount,Value=<value>" "Name=threadsPerCore,Value=<value>"
```

The following are examples that configure the processor:

### Examples

- Setting the number of CPU cores for a DB instance (p. 83)
- Setting the number of CPU cores and disabling multiple threads for a DB instance (p. 83)
- Viewing the valid processor values for a DB instance class (p. 84)
- Returning to default processor settings for a DB instance (p. 85)
- Returning to the default number of CPU cores for a DB instance (p. 85)
- Returning to the default number of threads per core for a DB instance (p. 86)

### Setting the number of CPU cores for a DB instance

**Example**

The following example modifies `mydbinstance` by setting the number of CPU cores to 4. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --processor-features "Name=coreCount,Value=4" \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --processor-features "Name=coreCount,Value=4" ^
  --apply-immediately
```

### Setting the number of CPU cores and disabling multiple threads for a DB instance

**Example**

The following example modifies `mydbinstance` by setting the number of CPU cores to 4 and disabling multiple threads per core. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.
For Linux, macOS, or Unix:

```
aws rds modify-db-instance --db-instance-identifier mydbinstance
--processor-features "Name=coreCount,Value=4" "Name=threadsPerCore,Value=1"
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--processor-features "Name=coreCount,Value=4" "Name=threadsPerCore,Value=1" ^
--apply-immediately
```

Viewing the valid processor values for a DB instance class

**Example**

You can view the valid processor values for a particular DB instance class by running the `describe-orderable-db-instance-options` command and specifying the instance class for the `--db-instance-class` option. For example, the output for the following command shows the processor options for the `db.r3.large` instance class.

```
aws rds describe-orderable-db-instance-options --engine oracle-ee --db-instance-class db.r3.large
```

Following is sample output for the command in JSON format.

```json
{
   "SupportsIops": true,
   "MaxIopsPerGib": 50.0,
   "LicenseModel": "bring-your-own-license",
   "DBInstanceClass": "db.r3.large",
   "SupportsIAMDatabaseAuthentication": false,
   "MinStorageSize": 100,
   "AvailabilityZones": [
      {
         "Name": "us-west-2a"
      },
      {
         "Name": "us-west-2b"
      },
      {
         "Name": "us-west-2c"
      }
   ],
   "EngineVersion": "12.1.0.2.v2",
   "MaxStorageSize": 32768,
   "MinIopsPerGib": 1.0,
   "MaxIopsPerDbInstance": 40000,
   "ReadReplicaCapable": false,
   "AvailableProcessorFeatures": [
      {
         "Name": "coreCount",
         "DefaultValue": "1",
         "AllowedValues": "1"
      },
      {
         "Name": "threadsPerCore",
         "DefaultValue": "2",
         "AllowedValues": "1,2"
      }
   ]
}```
In addition, you can run the following commands for DB instance class processor information:

- `describe-db-instances` – Shows the processor information for the specified DB instance.
- `describe-db-snapshots` – Shows the processor information for the specified DB snapshot.
- `describe-valid-db-instance-modifications` – Shows the valid modifications to the processor for the specified DB instance.

In the output of the preceding commands, the values for the processor features are not null only if the following conditions are met:

- You are using an RDS for Oracle DB instance.
- Your RDS for Oracle DB instance supports changing processor values.
- The current CPU core and thread settings are set to nondefault values.

If the preceding conditions aren't met, you can get the instance type using `describe-db-instances`. You can get the processor information for this instance type by running the EC2 operation `describe-instance-types`.

**Returning to default processor settings for a DB instance**

**Example**

The following example modifies `mydbinstance` by returning its DB instance class to the default processor values for it. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
    --db-instance-identifier mydbinstance
    --use-default-processor-features
    --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --use-default-processor-features ^
    --apply-immediately ^
```

**Returning to the default number of CPU cores for a DB instance**

**Example**

The following example modifies `mydbinstance` by returning its DB instance class to the default number of CPU cores for it. The threads per core setting isn't changed. The changes are applied immediately.
by using --apply-immediately. If you want to apply the changes during the next scheduled maintenance window, omit the --apply-immediately option.

For Linux, macOS, or Unix:

```shell
aws rds modify-db-instance
  --db-instance-identifier mydbinstance
  --processor-features "Name=coreCount,Value=DEFAULT"
  --apply-immediately
```

For Windows:

```shell
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --processor-features "Name=coreCount,Value=DEFAULT" ^
  --apply-immediately
```

Returning to the default number of threads per core for a DB instance

Example

The following example modifies mydbinstance by returning its DB instance class to the default number of threads per core for it. The number of CPU cores setting isn't changed. The changes are applied immediately by using --apply-immediately. If you want to apply the changes during the next scheduled maintenance window, omit the --apply-immediately option.

For Linux, macOS, or Unix:

```shell
aws rds modify-db-instance
  --db-instance-identifier mydbinstance
  --processor-features "Name=threadsPerCore,Value=DEFAULT"
  --apply-immediately
```

For Windows:

```shell
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --processor-features "Name=threadsPerCore,Value=DEFAULT" ^
  --apply-immediately
```

RDS API

You can set the processor features for a DB instance when you call one of the following Amazon RDS API operations:

- `CreateDBInstance`
- `ModifyDBInstance`
- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceFromS3`
- `RestoreDBInstanceToPointInTime`

To configure the processor features of a DB instance class for a DB instance by using the Amazon RDS API, include the `ProcessFeatures` parameter in the call.

The parameter has the following syntax.

```shell
ProcessFeatures "Name=coreCount,Value=<value>" "Name=threadsPerCore,Value=<value>"
```
Specify the number of CPU cores with the `coreCount` feature name, and specify whether multiple threads per core are enabled with the `threadsPerCore` feature name.

You can view the valid processor values for a particular DB instance class by running the `DescribeOrderableDBInstanceOptions` operation and specifying the instance class for the `DBInstanceClass` parameter. You can also use the following operations:

- `DescribeDBInstances` – Shows the processor information for the specified DB instance.
- `DescribeDBSnapshots` – Shows the processor information for the specified DB snapshot.
- `DescribeValidDBInstanceModifications` – Shows the valid modifications to the processor for the specified DB instance.

In the output of the preceding operations, the values for the processor features are not null only if the following conditions are met:

- You are using an RDS for Oracle DB instance.
- Your RDS for Oracle DB instance supports changing processor values.
- The current CPU core and thread settings are set to nondefault values.

If the preceding conditions aren't met, you can get the instance type using `DescribeDBInstances`. You can get the processor information for this instance type by running the EC2 operation `DescribeInstanceTypes`.

**Hardware specifications for DB instance classes**

The following terminology is used to describe hardware specifications for DB instance classes:

**vCPU**

The number of virtual central processing units (CPUs). A virtual CPU is a unit of capacity that you can use to compare DB instance classes. Instead of purchasing or leasing a particular processor to use for several months or years, you are renting capacity by the hour. Our goal is to make a consistent and specific amount of CPU capacity available, within the limits of the actual underlying hardware.

**ECU**

The relative measure of the integer processing power of an Amazon EC2 instance. To make it easy for developers to compare CPU capacity between different instance classes, we have defined an Amazon EC2 Compute Unit. The amount of CPU that is allocated to a particular instance is expressed in terms of these EC2 Compute Units. One ECU currently provides CPU capacity equivalent to a 1.0–1.2 GHz 2007 Opteron or 2007 Xeon processor.

**Memory (GiB)**

The RAM, in gibibytes, allocated to the DB instance. There is often a consistent ratio between memory and vCPU. As an example, take the db.r4 instance class, which has a memory to vCPU ratio similar to the db.r5 instance class. However, for most use cases the db.r5 instance class provides better, more consistent performance than the db.r4 instance class.

**EBS-optimized**

The DB instance uses an optimized configuration stack and provides additional, dedicated capacity for I/O. This optimization provides the best performance by minimizing contention between I/O and other traffic from your instance. For more information about Amazon EBS–optimized instances, see Amazon EBS–Optimized instances in the Amazon EC2 User Guide for Linux Instances.

EBS-optimized instances have a baseline and maximum IOPS rate. The maximum IOPS rate is enforced at the DB instance level. A set of EBS volumes that combine to have an IOPS rate that is higher than the maximum can't exceed the instance-level threshold. For example, if the maximum
IOPS for a particular DB instance class is 40,000, and you attach four 64,000 IOPS EBS volumes, the maximum IOPS is 40,000 rather than 256,000. For the IOPS maximum specific to each EC2 instance type, see Supported instance types in the Amazon EC2 User Guide for Linux Instances.

Max. EBS bandwidth (Mbps)

The maximum EBS bandwidth in megabits per second. Divide by 8 to get the expected throughput in megabytes per second.

Important
General Purpose SSD (gp2) volumes for Amazon RDS DB instances have a throughput limit of 250 MiB/s in most cases. However, the throughput limit can vary depending on volume size. For more information, see Amazon EBS volume types in the Amazon EC2 User Guide for Linux Instances.

Network bandwidth

The network speed relative to other DB instance classes.

In the following table, you can find hardware details about the Amazon RDS DB instance classes.

For information about Amazon RDS DB engine support for each DB instance class, see Supported DB engines for DB instance classes (p. 14).

* These DB instance classes can support maximum performance for 30 minutes at least once every 24 hours. For more information on baseline performance of the underlying EC2 instance types, see [Amazon EBS-optimized instances](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/instancedata-optimized-baselines.html) in the *Amazon EC2 User Guide for Linux Instances.*

** The r3.8xlarge DB instance class doesn't have dedicated EBS bandwidth and therefore doesn't offer EBS optimization. For this instance class, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.
Amazon RDS DB instance storage

DB instances for Amazon RDS for MySQL, MariaDB, PostgreSQL, Oracle, and Microsoft SQL Server use Amazon Elastic Block Store (Amazon EBS) volumes for database and log storage.

In some cases, your database workload might not be able to achieve 100 percent of the IOPS that you have provisioned. For more information, see Factors that affect storage performance (p. 108).

For more information about instance storage pricing, see Amazon RDS pricing.

Amazon RDS storage types

Amazon RDS provides three storage types: General Purpose SSD (also known as gp2 and gp3), Provisioned IOPS SSD (also known as io1), and magnetic (also known as standard). They differ in performance characteristics and price, which means that you can tailor your storage performance and cost to the needs of your database workload. You can create MySQL, MariaDB, Oracle, and PostgreSQL RDS DB instances with up to 64 tebibytes (TiB) of storage. You can create SQL Server RDS DB instances with up to 16 TiB of storage. For this amount of storage, use the Provisioned IOPS SSD and General Purpose SSD storage types.

The following list briefly describes the three storage types:

- **General Purpose SSD** – General Purpose SSD volumes offer cost-effective storage that is ideal for a broad range of workloads running on medium-sized DB instances. General Purpose storage is best suited for development and testing environments.

  For more information about General Purpose SSD storage, including the storage size ranges, see General Purpose SSD storage (p. 102).

- **Provisioned IOPS SSD** – Provisioned IOPS storage is designed to meet the needs of I/O-intensive workloads, particularly database workloads, that require low I/O latency and consistent I/O throughput. Provisioned IOPS storage is best suited for production environments.

  For more information about Provisioned IOPS storage, including the storage size ranges, see Provisioned IOPS SSD storage (p. 104).

- **Magnetic** – Amazon RDS also supports magnetic storage for backward compatibility. We recommend that you use General Purpose SSD or Provisioned IOPS SSD for any new storage needs. The maximum amount of storage allowed for DB instances on magnetic storage is less than that of the other storage types. For more information, see Magnetic storage (p. 107).

When you select General Purpose SSD or Provisioned IOPS SSD, depending on the engine selected and the amount of storage requested, Amazon RDS automatically stripes across multiple volumes to enhance performance, as shown in the following table.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Amazon RDS storage size</th>
<th>Number of volumes provisioned</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB, MySQL, and PostgreSQL</td>
<td>Less than 400 GiB</td>
<td>1</td>
</tr>
<tr>
<td>MariaDB, MySQL, and PostgreSQL</td>
<td>Between 400 and 64,000 GiB</td>
<td>4</td>
</tr>
<tr>
<td>Oracle</td>
<td>Less than 200 GiB</td>
<td>1</td>
</tr>
<tr>
<td>Oracle</td>
<td>Between 200 and 64,000 GiB</td>
<td>4</td>
</tr>
</tbody>
</table>
When you modify a General Purpose SSD or Provisioned IOPS SSD volume, it goes through a sequence of states. While the volume is in the optimizing state, your volume performance is in between the source and target configuration specifications. Transitional volume performance will be no less than the lowest of the two specifications. For more information on volume modifications, see Monitor the progress of volume modifications in the Amazon EC2 User Guide.

Important
When you modify an instance’s storage so that it goes from one volume to four volumes, or when you modify an instance using magnetic storage, Amazon RDS does not use the Elastic Volumes feature. Instead, Amazon RDS provisions new volumes and transparently moves the data from the old volume to the new volumes. This operation consumes a significant amount of IOPS and throughput of both the old and new volumes. Depending on the size of the volume and the amount of database workload present during the modification, this operation can consume a high amount of IOPS, significantly increase IO latency, and take several hours to complete, while the RDS instance remains in the Modifying state.

General Purpose SSD storage

General Purpose SSD storage offers cost-effective storage that is acceptable for most database workloads that aren’t latency sensitive.

Note
DB instances that use General Purpose SSD storage can experience much longer latency after read replica creation, Multi-AZ conversion, and DB snapshot restoration than instances that use Provisioned IOPS storage. If you need a DB instance with minimum latency after these operations, we recommend using Provisioned IOPS SSD storage (p. 104).

Amazon RDS offers two types of General Purpose SSD storage: gp2 storage (p. 102) and gp3 storage (p. 103).

gp2 storage

When your applications don’t need high storage performance, you can use General Purpose SSD gp2 storage. Baseline I/O performance for gp2 storage is 3 IOPS for each GiB, with a minimum of 100 IOPS. This relationship means that larger volumes have better performance. For example, baseline performance for one 100-GiB volume is 300 IOPS. Baseline performance for one 1,000 GiB volume is 3,000 IOPS. Maximum baseline performance for one gp2 volume (5334 GiB and greater) is 16,000 IOPS.

Individual gp2 volumes below 1,000 GiB in size also have the ability to burst to 3,000 IOPS for extended periods of time. Volume I/O credit balance determines burst performance. For more information about volume I/O credits, see I/O credits and burst performance in the Amazon EC2 User Guide. For a more detailed description of how baseline performance and I/O credit balance affect performance, see the post Understanding burst vs. baseline performance with Amazon RDS and gp2 on the AWS Database Blog.

Many workloads never deplete the burst balance. However, some workloads can exhaust the 3,000 IOPS burst storage credit balance, so you should plan your storage capacity to meet the needs of your workloads.

For gp2 volumes larger than 1,000 GiB, the baseline performance is greater than the burst performance. For such volumes, burst is irrelevant because the baseline performance is better than the 3,000 IOPS burst performance. However, for DB instances of certain engines and sizes, storage is striped across four
volumes providing four times the baseline throughput, and four times the burst IOPS of a single volume. Storage performance for gp2 volumes on Amazon RDS DB engines, including the threshold, is shown in the following table.

<table>
<thead>
<tr>
<th>DB engine</th>
<th>RDS Storage size</th>
<th>Range of Baseline IOPS</th>
<th>Range of Baseline Throughput</th>
<th>Burst IOPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB, MySQL, and PostgreSQL</td>

<tr>
<td>SQL Server</td>
<td>Between 1,000 and 16,384 GiB</td>
<td>3,000-16,000 IOPS</td>
<td>250 MiB/s</td>
<td>N/A*</td>
</tr>
</tbody>
</table>

* The baseline performance of the volume exceeds the maximum burst performance.

**gp3 storage**

By using General Purpose SSD gp3 storage volumes, you can customize storage performance independently of storage capacity. *Storage performance* is the combination of I/O operations per second (IOPS) and how fast the storage volume can perform reads and writes (storage throughput). On gp3 storage volumes, Amazon RDS provides a baseline storage performance of 3000 IOPS and 125 MiB/s.

For every RDS DB engine except RDS for SQL Server, when the storage size for gp3 volumes reaches a certain threshold, the baseline storage performance increases to 12,000 IOPS and 500 MiB/s. This is because of *volume striping*, where the storage uses four volumes instead of one. RDS for SQL Server doesn’t support volume striping, and therefore doesn’t have a threshold value.

**Note**

General Purpose SSD gp3 storage is supported on Single-AZ and Multi-AZ DB instances, but isn’t supported on Multi-AZ DB clusters. For more information, see Configuring and managing a Multi-AZ deployment (p. 492) and Multi-AZ DB cluster deployments (p. 499).
Storage performance for gp3 volumes on Amazon RDS DB engines, including the threshold, is shown in the following table.

<table>
<thead>
<tr>
<th>DB engine</th>
<th>Storage size</th>
<th>Baseline storage performance</th>
<th>Range of Provisioned IOPS</th>
<th>Range of provisioned storage throughput</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB, MySQL, and PostgreSQL</td>
<td>Less than 400 GiB</td>
<td>3,000 IOPS/125 MiB/s</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>MariaDB, MySQL, and PostgreSQL</td>
<td>400 GiB and higher</td>
<td>12,000 IOPS/500 MiB/s</td>
<td>12,000–64,000 IOPS</td>
<td>500–4,000 MiB/s</td>
</tr>
<tr>
<td>Oracle</td>
<td>Less than 200 GiB</td>
<td>3,000 IOPS/125 MiB/s</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Oracle</td>
<td>200 GiB and higher</td>
<td>12,000 IOPS/500 MiB/s</td>
<td>12,000–64,000 IOPS</td>
<td>500–4,000 MiB/s</td>
</tr>
<tr>
<td>SQL Server</td>
<td>20 GiB–16 TiB</td>
<td>3,000 IOPS/125 MiB/s</td>
<td>3,000–16,000 IOPS</td>
<td>125–1,000 MiB/s</td>
</tr>
</tbody>
</table>

For every DB engine except RDS for SQL Server, you can provision additional IOPS and storage throughput when storage size is at or above the threshold value. For RDS for SQL Server, you can provision additional IOPS and storage throughput for any available storage size. For all DB engines, you pay for only the additional provisioned storage performance. For more information, see Amazon RDS pricing.

Although the added Provisioned IOPS and storage throughput aren't dependent on the storage size, they are related to each other. When you raise the IOPS above 32,000 for MariaDB and MySQL, the storage throughput value automatically increases from 500 MiB/s. For example, when you set the IOPS to 40,000 on RDS for MySQL, the storage throughput must be at least 625 MiB/s. The automatic increase doesn't happen for Oracle, PostgreSQL, and SQL Server DB instances.

Storage performance values for gp3 volumes on RDS have the following constraints:

- The maximum ratio of storage throughput to IOPS is 0.25 for all supported DB engines.
- The minimum ratio of IOPS to allocated storage (in GiB) is 0.5 on RDS for SQL Server. There is no minimum ratio for the other supported DB engines.
- The maximum ratio of IOPS to allocated storage is 500 for all supported DB engines.
- If you're using storage autoscaling, the same ratios between IOPS and maximum storage threshold (in GiB) also apply.

For more information on storage autoscaling, see Managing capacity automatically with Amazon RDS storage autoscaling (p. 480).

**Provisioned IOPS SSD storage**

For a production application that requires fast and consistent I/O performance, we recommend Provisioned IOPS storage. Provisioned IOPS storage is a storage type that delivers predictable performance, and consistently low latency. Provisioned IOPS storage is optimized for online transaction processing (OLTP) workloads that require consistent performance. Provisioned IOPS helps performance tuning of these workloads.
When you create a DB instance, you specify the IOPS rate and the size of the volume. Amazon RDS provides that IOPS rate for the DB instance until you change it.

**io1 storage**

For I/O-intensive workloads, you can use Provisioned IOPS SSD io1 storage and achieve up to 256,000 I/O operations per second (IOPS). The throughput of io1 volumes varies based on the amount of IOPS provisioned per volume and on the size of the IO operations being executed. For more information about throughput of io1 volumes, see [Provisioned IOPS volumes](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/vpc-ebs-throughput.html) in the [Amazon EC2 User Guide](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/).  

The following table shows the range of Provisioned IOPS and and maximum throughput for each database engine and storage size range.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Range of storage size</th>
<th>Range of Provisioned IOPS</th>
<th>Maximum throughput</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB, MySQL, and PostgreSQL</td>
<td>Between 100 and 399 GiB</td>
<td>1,000–19,950 IOPS</td>
<td>500 MiB/s</td>
</tr>
<tr>
<td>MariaDB, MySQL, and PostgreSQL</td>
<td>Between 400 and 65,536 GiB</td>
<td>1,000–256,000 IOPS</td>
<td>4,000 MiB/s</td>
</tr>
<tr>
<td>Oracle</td>
<td>Between 100 and 199 GiB</td>
<td>1,000–9,950 IOPS</td>
<td>500 MiB/s</td>
</tr>
<tr>
<td>Oracle</td>
<td>Between 200 and 65,536 GiB</td>
<td>1,000–256,000 IOPS</td>
<td>4,000 MiB/s</td>
</tr>
<tr>
<td>SQL Server</td>
<td>Between 20 and 16,384 GiB</td>
<td>1,000–64,000 IOPS</td>
<td>1,000 MiB/s</td>
</tr>
</tbody>
</table>

**Note**

For SQL Server, the maximum 64,000 IOPS is guaranteed only on [Nitro-based instances](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/instance-types.html) that are on the m5*, m6i, r5*, r6i, and z1d instance types. Other instance types guarantee performance up to 32,000 IOPS.

For Oracle, you can provision the maximum 256,000 IOPS only on the r5b instance type.

The IOPS and storage size ranges have the following constraints:

- The ratio of IOPS to allocated storage (in GiB) must be from 1–50 on RDS for SQL Server, and 0.5–50 on other RDS DB engines.
- If you’re using storage autoscaling, the same ratios between IOPS and maximum storage threshold (in GiB) also apply.

For more information on storage autoscaling, see [Managing capacity automatically with Amazon RDS storage autoscaling (p. 480)](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_AutoScaling.html).

**Combining Provisioned IOPS storage with Multi-AZ deployments or read replicas**

For production OLTP use cases, we recommend that you use Multi-AZ deployments for enhanced fault tolerance with Provisioned IOPS storage for fast and predictable performance.

You can also use Provisioned IOPS SSD storage with read replicas for MySQL, MariaDB or PostgreSQL. The type of storage for a read replica is independent of that on the primary DB instance. For example,
you might use General Purpose SSD for read replicas with a primary DB instance that uses Provisioned IOPS SSD storage to reduce costs. However, your read replica’s performance in this case might differ from that of a configuration where both the primary DB instance and the read replicas use Provisioned IOPS SSD storage.

**Provisioned IOPS storage costs**

With Provisioned IOPS storage, you are charged for the provisioned resources whether or not you use them in a given month.

For more information about pricing, see [Amazon RDS pricing](#).

**Getting the best performance from Amazon RDS Provisioned IOPS SSD storage**

If your workload is I/O constrained, using Provisioned IOPS SSD storage can increase the number of I/O requests that the system can process concurrently. Increased concurrency allows for decreased latency because I/O requests spend less time in a queue. Decreased latency allows for faster database commits, which improves response time and allows for higher database throughput.

Provisioned IOPS SSD storage provides a way to reserve I/O capacity by specifying IOPS. However, as with any other system capacity attribute, its maximum throughput under load is constrained by the resource that is consumed first. That resource might be network bandwidth, CPU, memory, or database internal resources.

For more information about getting the most out of your Provisioned IOPS volumes, see [Amazon EBS volume performance](#).

**Comparing solid-state drive (SSD) storage types**

The following table shows use cases and performance characteristics for the SSD storage volumes used by Amazon RDS.

<table>

</table>

**Magnetic storage**

Amazon RDS also supports magnetic storage for backward compatibility. We recommend that you use General Purpose SSD or Provisioned IOPS SSD for any new storage needs. The following are some limitations for magnetic storage:

- Doesn't allow you to scale storage when using the SQL Server database engine.
- Doesn't support storage autoscaling.
- Doesn't support elastic volumes.
- Limited to a maximum size of 3 TiB.
- Limited to a maximum of 1,000 IOPS.

**Monitoring storage performance**

Amazon RDS provides several metrics that you can use to determine how your DB instance is performing. You can view the metrics on the summary page for your instance in Amazon RDS Management Console. You can also use Amazon CloudWatch to monitor these metrics. For more information, see Viewing metrics in the Amazon RDS console (p. 696). Enhanced Monitoring provides more detailed I/O metrics; for more information, see Monitoring OS metrics with Enhanced Monitoring (p. 797).

The following metrics are useful for monitoring storage for your DB instance:

- **IOPS** – The number of I/O operations completed each second. This metric is reported as the average IOPS for a given time interval. Amazon RDS reports read and write IOPS separately on 1-minute intervals. Total IOPS is the sum of the read and write IOPS. Typical values for IOPS range from zero to tens of thousands per second.
- **Latency** – The elapsed time between the submission of an I/O request and its completion. This metric is reported as the average latency for a given time interval. Amazon RDS reports read and write latency separately at 1-minute intervals. Typical values for latency are in milliseconds (ms).
• **Throughput** – The number of bytes each second that are transferred to or from disk. This metric is reported as the average throughput for a given time interval. Amazon RDS reports read and write throughput separately on 1-minute intervals using units of megabytes per second (MB/s). Typical values for throughput range from zero to the I/O channel’s maximum bandwidth.

• **Queue Depth** – The number of I/O requests in the queue waiting to be serviced. These are I/O requests that have been submitted by the application but have not been sent to the device because the device is busy servicing other I/O requests. Time spent waiting in the queue is a component of latency and service time (not available as a metric). This metric is reported as the average queue depth for a given time interval. Amazon RDS reports queue depth in 1-minute intervals. Typical values for queue depth range from zero to several hundred.

Measured IOPS values are independent of the size of the individual I/O operation. This means that when you measure I/O performance, make sure to look at the throughput of the instance, not simply the number of I/O operations.

**Factors that affect storage performance**

System activities, database workload, and DB instance class can affect storage performance.

**System activities**

The following system-related activities consume I/O capacity and might reduce DB instance performance while in progress:

• Multi-AZ standby creation
• Read replica creation
• Changing storage types

**Database workload**

In some cases, your database or application design results in concurrency issues, locking, or other forms of database contention. In these cases, you might not be able to use all the provisioned bandwidth directly. In addition, you might encounter the following workload-related situations:

• The throughput limit of the underlying instance type is reached.
• Queue depth is consistently less than 1 because your application isn't driving enough I/O operations.
• You experience query contention in the database even though some I/O capacity is unused.

In some cases, there isn't a system resource that is at or near a limit, and adding threads doesn’t increase the database transaction rate. In such cases, the bottleneck is most likely contention in the database. The most common forms are row lock and index page lock contention, but there are many other possibilities. If this is your situation, seek the advice of a database performance tuning expert.

**DB instance class**

To get the most performance out of your Amazon RDS DB instance, choose a current generation instance type with enough bandwidth to support your storage type. For example, you can choose Amazon EBS–optimized instances and instances with 10-gigabit network connectivity.

**Important**

Depending on the instance class you're using, you might see lower IOPS performance than the maximum that you can provision with RDS. For specific information on IOPS performance for DB instance classes, see [Amazon EBS–optimized instances](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/) in the *Amazon EC2 User Guide*. 
We recommend that you determine the maximum IOPS for the instance class before setting a Provisioned IOPS value for your DB instance.

We encourage you to use the latest generation of instances to get the best performance. Previous generation DB instances can also have lower maximum storage.

Some older 32-bit file systems might have lower storage capacities. To determine the storage capacity of your DB instance, you can use the describe-valid-db-instance-modifications AWS CLI command.

The following list shows the maximum storage that most DB instance classes can scale to for each database engine:

- MariaDB – 64 TiB
- Microsoft SQL Server – 16 TiB
- MySQL – 64 TiB
- Oracle – 64 TiB
- PostgreSQL – 64 TiB

The following table shows some exceptions for maximum storage (in TiB). All RDS for Microsoft SQL Server DB instances have a maximum storage of 16 TiB, so there are no entries for SQL Server.

For more details about all instance classes supported, see [Previous generation DB instances](#).
Regions, Availability Zones, and Local Zones

Amazon cloud computing resources are hosted in multiple locations worldwide. These locations are composed of AWS Regions, Availability Zones, and Local Zones. Each AWS Region is a separate geographic area. Each AWS Region has multiple, isolated locations known as Availability Zones.

**Note**
For information about finding the Availability Zones for an AWS Region, see [Describe your Availability Zones](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/using-availability-zones.html) in the Amazon EC2 documentation.

By using Local Zones, you can place resources, such as compute and storage, in multiple locations closer to your users. Amazon RDS enables you to place resources, such as DB instances, and data in multiple locations. Resources aren't replicated across AWS Regions unless you do so specifically.

Amazon operates state-of-the-art, highly-available data centers. Although rare, failures can occur that affect the availability of DB instances that are in the same location. If you host all your DB instances in one location that is affected by such a failure, none of your DB instances will be available.

It is important to remember that each AWS Region is completely independent. Any Amazon RDS activity you initiate (for example, creating database instances or listing available database instances) runs only in your current default AWS Region. The default AWS Region can be changed in the console, or by setting the `AWS_DEFAULT_REGION` environment variable. Or it can be overridden by using the `--region` parameter with the AWS Command Line Interface (AWS CLI). For more information, see [Configuring the AWS Command Line Interface](https://docs.aws.amazon.com/cli/latest/userguide/cli-configure-overview.html), specifically the sections about environment variables and command line options.

Amazon RDS supports special AWS Regions called AWS GovCloud (US). These are designed to allow US government agencies and customers to move more sensitive workloads into the cloud. The AWS GovCloud (US) Regions address the US government's specific regulatory and compliance requirements. For more information, see [What is AWS GovCloud (US)](https://aws.amazon.com/govcloud/)

To create or work with an Amazon RDS DB instance in a specific AWS Region, use the corresponding regional service endpoint.
AWS Regions

Each AWS Region is designed to be isolated from the other AWS Regions. This design achieves the greatest possible fault tolerance and stability.

When you view your resources, you see only the resources that are tied to the AWS Region that you specified. This is because AWS Regions are isolated from each other, and we don’t automatically replicate resources across AWS Regions.

Region availability

The following table shows the AWS Regions where Amazon RDS is currently available and the endpoint for each Region.

</tbody>
</table>

If you do not explicitly specify an endpoint, the US West (Oregon) endpoint is the default.

When you work with a DB instance using the AWS CLI or API operations, make sure that you specify its regional endpoint.

**Availability Zones**

When you create a DB instance, you can choose an Availability Zone or have Amazon RDS choose one for you randomly. An Availability Zone is represented by an AWS Region code followed by a letter identifier (for example, us-east-1a).
Use the `describe-availability-zones` Amazon EC2 command as follows to describe the Availability Zones within the specified Region that are enabled for your account.

```
aws ec2 describe-availability-zones --region region-name
```

For example, to describe the Availability Zones within the US East (N. Virginia) Region (us-east-1) that are enabled for your account, run the following command:

```
aws ec2 describe-availability-zones --region us-east-1
```

You can't choose the Availability Zones for the primary and secondary DB instances in a Multi-AZ DB deployment. Amazon RDS chooses them for you randomly. For more information about Multi-AZ deployments, see Configuring and managing a Multi-AZ deployment (p. 492).

**Note**
Random selection of Availability Zones by RDS doesn't guarantee an even distribution of DB instances among Availability Zones within a single account or DB subnet group. You can request a specific AZ when you create or modify a Single-AZ instance, and you can use more-specific DB subnet groups for Multi-AZ instances. For more information, see Creating an Amazon RDS DB instance (p. 300) and Modifying an Amazon RDS DB instance (p. 401).

### Local Zones

A Local Zone is an extension of an AWS Region that is geographically close to your users. You can extend any VPC from the parent AWS Region into Local Zones. To do so, create a new subnet and assign it to the AWS Local Zone. When you create a subnet in a Local Zone, your VPC is extended to that Local Zone. The subnet in the Local Zone operates the same as other subnets in your VPC.

When you create a DB instance, you can choose a subnet in a Local Zone. Local Zones have their own connections to the internet and support AWS Direct Connect. Thus, resources created in a Local Zone can serve local users with very low-latency communications. For more information, see AWS Local Zones.

A Local Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example `us-west-2-lax-1a`.

**Note**
A Local Zone can't be included in a Multi-AZ deployment.

### To use a Local Zone

1. Enable the Local Zone in the Amazon EC2 console.
   For more information, see Enabling Local Zones in the Amazon EC2 User Guide for Linux Instances.
2. Create a subnet in the Local Zone.
   For more information, see Creating a subnet in your VPC in the Amazon VPC User Guide.
3. Create a DB subnet group in the Local Zone.
   When you create a DB subnet group, choose the Availability Zone group for the Local Zone.
   For more information, see Creating a DB instance in a VPC (p. 2713).
4. Create a DB instance that uses the DB subnet group in the Local Zone.
   For more information, see Creating an Amazon RDS DB instance (p. 300).

**Important**
Currently, the only AWS Local Zone where Amazon RDS is available is Los Angeles in the US West (Oregon) Region.
Supported features in Amazon RDS by AWS Region and DB engine

Support for Amazon RDS features and options varies across AWS Regions and specific versions of each DB engine. To identify RDS DB engine version support and availability in a given AWS Region, you can use the following sections.

Amazon RDS features are different from engine-native features and options. For more information on engine-native features and options, see Engine-native features. (p. 162)

Topics
- Table conventions (p. 116)
- Feature quick reference (p. 116)
- Blue/Green Deployments (p. 118)
- Cross-Region automated backups (p. 118)
- Cross-Region read replicas (p. 119)
- Database activity streams (p. 121)
- Dual-stack mode (p. 125)
- Export snapshots to S3 (p. 133)
- IAM database authentication (p. 138)
- Kerberos authentication (p. 141)
- Multi-AZ DB clusters (p. 147)
- Performance Insights (p. 150)
- RDS Custom (p. 151)
- Amazon RDS Proxy (p. 155)
- Secrets Manager integration (p. 161)
- Engine-native features (p. 162)

Table conventions

The tables in the feature sections use these patterns to specify version numbers and level of availability:

- **Version x.y** – The specific version alone is available.
- **Version x.y and higher** – The specified version and all higher minor versions of its major version are supported. For example, "version 10.11 and higher" means that versions 10.11, 10.11.1, and 10.12 are available.
- **—** – The feature isn't currently available for the selected RDS DB engine or in the specified AWS Region.

Feature quick reference

The following quick reference table lists each feature and available RDS DB engine. Region and specific version availability appears in the later feature sections.

</table>
Blue/Green Deployments

A blue/green deployment copies a production database environment in a separate, synchronized staging environment. By using Amazon RDS Blue/Green Deployments, you can make changes to the database in the staging environment without affecting the production environment. For example, you can upgrade the major or minor DB engine version, change database parameters, or make schema changes in the staging environment. When you are ready, you can promote the staging environment to be the new production database environment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates (p. 566).

The Blue/Green Deployments feature is supported for the following engines:

- RDS for MariaDB version 10.2 and higher
- RDS for MySQL version 5.7 and higher
- RDS for MySQL version 8.0.15 and higher

The Blue/Green Deployments feature isn't supported with the following engines:

- RDS for SQL Server
- RDS for Oracle
- RDS for PostgreSQL

The Blue/Green Deployments feature is supported in all AWS Regions except Israel (Tel Aviv).

Cross-Region automated backups

By using backup replication in Amazon RDS, you can configure your RDS DB instance to replicate snapshots and transaction logs to a destination Region. When backup replication is configured for a DB instance, RDS starts a cross-Region copy of all snapshots and transaction logs when they're ready. For more information, see Replicating automated backups to another AWS Region (p. 602).

Backup replication is available in all AWS Regions except the following:

- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Hyderabad)
- Asia Pacific (Jakarta)
- Europe (Milan)
- Europe (Spain)
- Europe (Zurich)
- Middle East (Bahrain)
- Middle East (UAE)

For more detailed information on limitations for source and destination backup Regions, see Replicating automated backups to another AWS Region (p. 602).

Topics

- Backup replication with RDS for MariaDB (p. 119)
- Backup replication with RDS for MySQL (p. 119)
- Backup replication with RDS for Oracle (p. 119)
- Backup replication with RDS for PostgreSQL (p. 119)
Backup replication with RDS for MariaDB

Amazon RDS supports backup replication for all currently available versions of RDS for MariaDB.

Backup replication with RDS for MySQL

Amazon RDS supports backup replication for all currently available versions of RDS for MySQL.

Backup replication with RDS for Oracle

Amazon RDS supports backup replication for all currently available versions of RDS for Oracle.

Backup replication with RDS for PostgreSQL

Amazon RDS supports backup replication for all currently available versions of RDS for PostgreSQL.

Backup replication with RDS for SQL Server

Amazon RDS supports backup replication for all currently available versions of RDS for SQL Server.

Cross-Region read replicas

By using cross-Region read replicas in Amazon RDS, you can create a MariaDB, MySQL, Oracle, PostgreSQL, or SQL Server read replica in a different Region from the source DB instance. For more information about cross-Region read replicas, including source and destination Region considerations, see Creating a read replica in a different AWS Region (p. 452).

Topics

- Cross-Region read replicas with RDS for MariaDB (p. 119)
- Cross-Region read replicas with RDS for MySQL (p. 119)
- Cross-Region read replicas with RDS for Oracle (p. 120)
- Cross-Region read replicas with RDS for PostgreSQL (p. 120)
- Cross-Region read replicas with RDS for SQL Server (p. 120)

Cross-Region read replicas with RDS for MariaDB

Cross-Region read replicas with RDS for MariaDB are available in all Regions for the following versions:

- RDS for MariaDB 10.11 (All available versions)
- RDS for MariaDB 10.6 (All available versions)
- RDS for MariaDB 10.5 (All available versions)
- RDS for MariaDB 10.4 (All available versions)
- RDS for MariaDB 10.3 (All available versions)

Cross-Region read replicas with RDS for MySQL

Cross-Region read replicas with RDS for MySQL are available in all Regions for the following versions:

- RDS for MySQL 8.0 (All available versions)
Cross-Region read replicas with RDS for Oracle

Cross-Region read replicas for RDS for Oracle are available in all Regions with the following version limitations:

- For RDS for Oracle 21c, cross-Region read replicas aren't available.
- For RDS for Oracle 19c, cross-Region read replicas are available for instances of Oracle Database 19c that aren't container database (CBD) instances.
- For RDS for Oracle 12c, cross-Region read replicas are available for Oracle Enterprise Edition (EE) of Oracle Database 12c Release 1 (12.1) using 12.1.0.2.v10 and higher 12c releases.

For more information on additional requirements for cross-Region read replicas with RDS for Oracle, see Requirements and considerations for RDS for Oracle replicas (p. 1990).

Cross-Region read replicas with RDS for PostgreSQL

Cross-Region read replicas with RDS for PostgreSQL are available in all Regions for the following versions:

- RDS for PostgreSQL 15 (All available versions)
- RDS for PostgreSQL 14 (All available versions)
- RDS for PostgreSQL 13 (All available versions)
- RDS for PostgreSQL 12 (All available versions)
- RDS for PostgreSQL 11 (All available versions)
- RDS for PostgreSQL 10 (All available versions)

Cross-Region read replicas with RDS for SQL Server

Cross-Region read replicas with RDS for SQL Server are available in all Regions except the following:

- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Hyderabad)
- Asia Pacific (Jakarta)
- Asia Pacific (Melbourne)
- Europe (Milan)
- Europe (Spain)
- Europe (Zurich)
- Middle East (Bahrain)
- Middle East (UAE)

Cross-Region read replicas with RDS for SQL Server are available for the following versions using Microsoft SQL Server Enterprise Edition:

- RDS for SQL Server 2019 (Version 15.00.4073.23 and higher)
- RDS for SQL Server 2017 (Version 14.00.3281.6 and higher)
- RDS for SQL Server 2016 (Version 13.00.6300.2 and higher)
Database activity streams

By using Database Activity Streams in Amazon RDS, you can monitor and set alarms for auditing activity in your Oracle database and SQL Server database. For more information, see Overview of Database Activity Streams (p. 944).

Database activity streams aren't available with the following engines:

- RDS for MariaDB
- RDS for MySQL
- RDS for PostgreSQL

Topics

- Database activity streams with RDS for Oracle (p. 121)
- Database activity streams with RDS for SQL Server (p. 124)

Database activity streams with RDS for Oracle

The following Regions and engine versions are available for database activity streams with RDS for Oracle.

For more information on additional requirements for database activity streams with RDS for Oracle, see Overview of Database Activity Streams (p. 944).

### Dual-stack mode

By using dual-stack mode in RDS, resources can communicate with a DB instance over Internet Protocol version 4 (IPv4), Internet Protocol version 6 (IPv6), or both. For more information, see [Dual-stack mode](p. 2708).

Export snapshots to S3

You can export RDS DB snapshot data to an Amazon S3 bucket. You can export all types of DB snapshots—including manual snapshots, automated system snapshots, and snapshots created by AWS Backup. After the data is exported, you can analyze the exported data directly through tools like Amazon Athena or Amazon Redshift Spectrum. For more information, see Exporting DB snapshot data to Amazon S3 (p. 642).

Topics

- Export snapshots to S3 with RDS for MariaDB (p. 133)
- Export snapshots to S3 with RDS for MySQL (p. 135)
- Export snapshots to S3 with RDS for PostgreSQL (p. 136)

IAM database authentication

By using IAM database authentication in Amazon RDS, you can authenticate without a password when you connect to a DB instance. Instead, you use an authentication token. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2659).

IAM database authentication isn't available with the following engines:

- RDS for Oracle
- RDS for SQL Server

Topics

- IAM database authentication with RDS for MariaDB (p. 138)
- IAM database authentication with RDS for MySQL (p. 140)
- IAM database authentication with RDS for PostgreSQL (p. 140)

IAM database authentication with RDS for MariaDB

IAM database authentication with RDS for MySQL

IAM database authentication with RDS for MySQL is available in all Regions for the following versions:

- RDS for MySQL 8.0 – All available versions
- RDS for MySQL 5.7 – All available versions

IAM database authentication with RDS for PostgreSQL

IAM database authentication with RDS for PostgreSQL is available in all Regions for the following versions:

- RDS for PostgreSQL 15 – All available versions
- RDS for PostgreSQL 14 – All available versions
- RDS for PostgreSQL 13 – All available versions
- RDS for PostgreSQL 12 – All available versions
- RDS for PostgreSQL 11 – All available versions
- RDS for PostgreSQL 10 – All available versions
Kerberos authentication

By using Kerberos authentication in Amazon RDS, you can support external authentication of database users using Kerberos and Microsoft Active Directory. Using Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. For more information, see Kerberos authentication (p. 2584).

Kerberos authentication isn't available with the following engines:

- RDS for MariaDB

Topics

- Kerberos authentication with RDS for MySQL (p. 141)
- Kerberos authentication with RDS for Oracle (p. 142)
- Kerberos authentication with RDS for PostgreSQL (p. 143)
- Kerberos authentication with RDS for SQL Server (p. 145)

Multi-AZ DB clusters

A Multi-AZ DB cluster deployment in Amazon RDS provides a high availability deployment mode of Amazon RDS with two readable standby DB instances. A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones in the same Region. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower write latency when compared to Multi-AZ DB instance deployments. For more information, see Multi-AZ DB cluster deployments (p. 499).

Multi-AZ DB clusters aren't available with the following engines:

- RDS for MariaDB
- RDS for Oracle
- RDS for SQL Server

Topics

- Multi-AZ DB clusters with RDS for MySQL (p. 147)
- Multi-AZ DB clusters with RDS for PostgreSQL (p. 148)

Multi-AZ DB clusters with RDS for MySQL

The following Regions and engine versions are available for Multi-AZ DB clusters with RDS for MySQL.

<table>
<thead>
<tr>
<th>Region</th>
<th>RDS for MySQL 8.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>Version 8.0.28 and higher</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>Version 8.0.28 and higher</td>
</tr>
<tr>
<td>US West (N. California)</td>
<td>--</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>Version 8.0.28 and higher</td>
</tr>
<tr>
<td>Africa (Cape Town)</td>
<td>Version 8.0.28 and higher</td>
</tr>
<tr>
<td>Asia Pacific (Hong Kong)</td>
<td>Version 8.0.28 and higher</td>
</tr>
<tr>
<td>Asia Pacific (Hyderabad)</td>
<td>--</td>
</tr>
<tr>
<td>Asia Pacific (Jakarta)</td>
<td>Version 8.0.28 and higher</td>
</tr>
<tr>
<td>Asia Pacific (Melbourne)</td>

</tbody>
</table>
You can also list the available versions in a Region for the db.r5d.large DB instance class by running the following AWS CLI command.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options
  --engine mysql
  --db-instance-class db.r5d.large
  --query '*[]|[?SupportsClusters == `true`].[EngineVersion]' 
  --output text
```

For Windows:

```
aws rds describe-orderable-db-instance-options
  --engine mysql
  --db-instance-class db.r5d.large
  --query "*[]|[?SupportsClusters == `true`].[EngineVersion]" 
  --output text
```

You can change the DB instance class to show the available engine versions for it.

### Multi-AZ DB clusters with RDS for PostgreSQL

The following Regions and engine versions are available for Multi-AZ DB clusters with RDS for PostgreSQL.
<table>
<thead>
<tr>
<th>Region</th>
<th>RDS for PostgreSQL 15</th>

<td>Version 13.4 and version 13.7 and higher</td>
</tr>
</tbody>
</table>
You can also list the available versions in a Region for the `db.r5d.large` DB instance class by running the following AWS CLI command.

For Linux, macOS, or Unix:

```bash
aws rds describe-orderable-db-instance-options \
  --engine postgres \
  --db-instance-class db.r5d.large \
  --query '*[]|?[?SupportsClusters == `true`].[EngineVersion]' \
  --output text
```

For Windows:

```bash
aws rds describe-orderable-db-instance-options ^
  --engine postgres ^
  --db-instance-class db.r5d.large ^
  --query "*[]|?[?SupportsClusters == `true`].[EngineVersion]" ^
  --output text
```

You can change the DB instance class to show the available engine versions for it.

### Performance Insights

Performance Insights in Amazon RDS expands on existing Amazon RDS monitoring features to illustrate and help you analyze your database performance. With the Performance Insights dashboard, you can visualize the database load on your Amazon RDS DB instance. You can also filter the load by waits, SQL statements, hosts, or users. For more information, see [Monitoring DB load with Performance Insights on Amazon RDS](p. 720).

Performance Insights is available for all RDS DB engines and all versions.
Performance Insights is available in all AWS Regions.

For the region, DB engine, and instance class support information for Performance Insights features, see Amazon RDS DB engine, Region, and instance class support for Performance Insights features (p. 725).

**RDS Custom**

Amazon RDS Custom automates database administration tasks and operations. By using RDS Custom, as a database administrator you can access and customize your database environment and operating system. With RDS Custom, you can customize to meet the requirements of legacy, custom, and packaged applications. For more information, see Working with Amazon RDS Custom (p. 978).

RDS Custom is supported for the following DB engines only:

- RDS for Oracle
- RDS for SQL Server

**Topics**

- RDS Custom for Oracle (p. 151)
- RDS Custom for SQL Server (p. 153)

**RDS Custom for Oracle**

The following Regions and engine versions are available for RDS Custom for Oracle.

<table>

RDS Custom for SQL Server

You can deploy RDS Custom for SQL Server by using either an RDS provided engine version (RPEV) or a custom engine version (CEV):

- If you use an RPEV, it includes the default Amazon Machine Image (AMI) and SQL Server installation. If you customize or modify the operating system (OS), your changes might not persist during patching, snapshot restore, or automatic recovery.
- If you use a CEV, you choose your own AMI with either pre-installed Microsoft SQL Server or SQL Server that you install using your own media. When using an AWS provided CEV, you choose the latest Amazon EC2 image (AMI) available by AWS, which has the cumulative update (CU) supported by RDS Custom for SQL Server. With a CEV, you can customize both the OS and SQL Server configuration to meet your enterprise needs.

The following AWS Regions and DB engine versions are available for RDS Custom for SQL Server. The engine version support depends on whether you’re using RDS Custom for SQL Server with an RPEV, AWS provided CEV, or customer-provided CEV.

Amazon RDS Proxy

Amazon RDS Proxy is a fully managed, highly available database proxy that makes applications more scalable by pooling and sharing established database connections. For more information, see Using Amazon RDS Proxy (p. 1215).

RDS Proxy isn’t available with RDS for Oracle.

Topics

• RDS Proxy with RDS for MariaDB (p. 155)
• RDS Proxy with RDS for MySQL (p. 157)
• RDS Proxy with RDS for PostgreSQL (p. 158)
• RDS Proxy with RDS for SQL Server (p. 160)

RDS Proxy with RDS for MariaDB

Secrets Manager integration

With AWS Secrets Manager, you can replace hard-coded credentials in your code, including database passwords, with an API call to Secrets Manager to retrieve the secret programmatically. For more information about Secrets Manager, see AWS Secrets Manager User Guide.

You can specify that Amazon RDS manages the master user password in Secrets Manager for an Amazon RDS DB instance or Multi-AZ DB cluster. RDS generates the password, stores it in Secrets Manager, and rotates it regularly. For more information, see Password management with Amazon RDS and AWS Secrets Manager (p. 2585).

Secrets Manager integration is supported for all RDS DB engines and all versions.

Secrets Manager integration is supported in all AWS Regions except the following:

- Israel (Tel Aviv)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)
Engine-native features

Amazon RDS database engines also support many of the most common engine-native features and functionality. These features are different than the Amazon RDS-native features listed on this page. Some engine-native features might have limited support or restricted privileges.

For more information on engine-native features, see:

- MariaDB feature support on Amazon RDS (p. 1272)
- MySQL feature support on Amazon RDS (p. 1640)
- RDS for Oracle features (p. 1802)
- Working with PostgreSQL features supported by Amazon RDS for PostgreSQL (p. 2175)
- Microsoft SQL Server features on Amazon RDS (p. 1380)
DB instance billing for Amazon RDS

Amazon RDS instances are billed based on the following components:

- **DB instance hours (per hour)** – Based on the DB instance class of the DB instance (for example, `db.t2.small` or `db.m4.large`). Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is billed in 1-second increments, with a minimum of 10 minutes. For more information, see [DB instance classes (p. 11)](#).
- **Storage (per GiB per month)** – Storage capacity that you have provisioned to your DB instance. If you scale your provisioned storage capacity within the month, your bill is prorated. For more information, see [Amazon RDS DB instance storage (p. 101)](#).
- **Input/output (I/O) requests (per 1 million requests)** – Total number of storage I/O requests that you have made in a billing cycle, for Amazon RDS magnetic storage only.
- **Provisioned IOPS (per IOPS per month)** – Provisioned IOPS rate, regardless of IOPS consumed, for Amazon RDS Provisioned IOPS (SSD) and General Purpose (SSD) gp3 storage. Provisioned storage for EBS volumes are billed in 1-second increments, with a minimum of 10 minutes.
- **Backup storage (per GiB per month)** – *Backup storage* is the storage that is associated with automated database backups and any active database snapshots that you have taken. Increasing your backup retention period or taking additional database snapshots increases the backup storage consumed by your database. Per second billing doesn’t apply to backup storage (metered in GB-month).
  
  For more information, see [Backing up and restoring (p. 590)](#).
- **Data transfer (per GB)** – Data transfer in and out of your DB instance from or to the internet and other AWS Regions.

Amazon RDS provides the following purchasing options to enable you to optimize your costs based on your needs:

- **On-Demand instances** – Pay by the hour for the DB instance hours that you use. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is now billed in 1-second increments, with a minimum of 10 minutes.
- **Reserved instances** – Reserve a DB instance for a one-year or three-year term and get a significant discount compared to the on-demand DB instance pricing. With Reserved Instance usage, you can launch, delete, start, or stop multiple instances within an hour and get the Reserved Instance benefit for all of the instances.

For Amazon RDS pricing information, see the [Amazon RDS pricing page](#).

**Topics**

- [On-Demand DB instances for Amazon RDS (p. 164)](#)
- [Reserved DB instances for Amazon RDS (p. 165)](#)
On-Demand DB instances for Amazon RDS

Amazon RDS on-demand DB instances are billed based on the class of the DB instance (for example, db.t3.small or db.m5.large). For Amazon RDS pricing information, see the Amazon RDS product page.

Billing starts for a DB instance as soon as the DB instance is available. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. Amazon RDS usage is billed in one-second increments, with a minimum of 10 minutes. In the case of billable configuration change, such as scaling compute or storage capacity, you're charged a 10-minute minimum. Billing continues until the DB instance terminates, which occurs when you delete the DB instance or if the DB instance fails.

If you no longer want to be charged for your DB instance, you must stop or delete it to avoid being billed for additional DB instance hours. For more information about the DB instance states for which you are billed, see Viewing Amazon RDS DB instance status (p. 684).

Stopped DB instances

While your DB instance is stopped, you're charged for provisioned storage, including Provisioned IOPS. You are also charged for backup storage, including storage for manual snapshots and automated backups within your specified retention window. You aren't charged for DB instance hours.

Multi-AZ DB instances

If you specify that your DB instance should be a Multi-AZ deployment, you're billed according to the Multi-AZ pricing posted on the Amazon RDS pricing page.
Reserved DB instances for Amazon RDS

Using reserved DB instances, you can reserve a DB instance for a one- or three-year term. Reserved DB instances provide you with a significant discount compared to on-demand DB instance pricing. Reserved DB instances are not physical instances, but rather a billing discount applied to the use of certain on-demand DB instances in your account. Discounts for reserved DB instances are tied to instance type and AWS Region.

The general process for working with reserved DB instances is: First get information about available reserved DB instance offerings, then purchase a reserved DB instance offering, and finally get information about your existing reserved DB instances.

Overview of reserved DB instances

When you purchase a reserved DB instance in Amazon RDS, you purchase a commitment to getting a discounted rate, on a specific DB instance type, for the duration of the reserved DB instance. To use an Amazon RDS reserved DB instance, you create a new DB instance just like you do for an on-demand instance.

The new DB instance that you create must have the same specifications as the reserved DB instance for the following:

- AWS Region
- DB engine
- DB instance type
- Edition (for RDS for Oracle and RDS for SQL Server)
- License type (license-included or bring-your-own-license)
- Deployment model (Single-AZ or Multi-AZ)

If the specifications of the new DB instance match an existing reserved DB instance for your account, you are billed at the discounted rate offered for the reserved DB instance. Otherwise, the DB instance is billed at an on-demand rate.

You can modify a DB instance that you’re using as a reserved DB instance. If the modification is within the specifications of the reserved DB instance, part or all of the discount still applies to the modified DB instance. If the modification is outside the specifications, such as changing the instance class, the discount no longer applies. For more information, see Size-flexible reserved DB instances (p. 166).

Topics

- Offering types (p. 165)
- Size-flexible reserved DB instances (p. 166)
- Reserved DB instance billing example (p. 168)
- Reserved DB instances for a Multi-AZ DB cluster (p. 168)
- Deleting a reserved DB instance (p. 169)

For more information about reserved DB instances, including pricing, see Amazon RDS reserved instances.

Offering types

Reserved DB instances are available in three varieties—No Upfront, Partial Upfront, and All Upfront—that let you optimize your Amazon RDS costs based on your expected usage.
No Upfront

This option provides access to a reserved DB instance without requiring an upfront payment. Your No Upfront reserved DB instance bills a discounted hourly rate for every hour within the term, regardless of usage, and no upfront payment is required. This option is only available as a one-year reservation.

Partial Upfront

This option requires a part of the reserved DB instance to be paid upfront. The remaining hours in the term are billed at a discounted hourly rate, regardless of usage. This option is the replacement for the previous Heavy Utilization option.

All Upfront

Full payment is made at the start of the term, with no other costs incurred for the remainder of the term regardless of the number of hours used.

If you are using consolidated billing, all the accounts in the organization are treated as one account. This means that all accounts in the organization can receive the hourly cost benefit of reserved DB instances that are purchased by any other account. For more information about consolidated billing, see Amazon RDS reserved DB instances in the AWS Billing and Cost Management User Guide.

Size-flexible reserved DB instances

When you purchase a reserved DB instance, one thing that you specify is the instance class, for example db.r5.large. For more information about DB instance classes, see DB instance classes (p. 11).

If you have a DB instance, and you need to scale it to larger capacity, your reserved DB instance is automatically applied to your scaled DB instance. That is, your reserved DB instances are automatically applied across all DB instance class sizes. Size-flexible reserved DB instances are available for DB instances with the same AWS Region and database engine. Size-flexible reserved DB instances can only scale in their instance class type. For example, a reserved DB instance for a db.r5.large can apply to a db.r5.xlarge, but not to a db.r6g.large, because db.r5 and db.r6g are different instance class types.

Reserved DB instance benefits also apply for both Multi-AZ and Single-AZ configurations. Flexibility means that you can move freely between configurations within the same DB instance class type. For example, you can move from a Single-AZ deployment running on one large DB instance (four normalized units per hour) to a Multi-AZ deployment running on two small DB instances (2*2 = 4 normalized units per hour).

Size-flexible reserved DB instances are available for the following Amazon RDS database engines:

- MariaDB
- MySQL
- Oracle, Bring Your Own License
- PostgreSQL

For details about using size-flexible reserved instances with Aurora, see Reserved DB instances for Aurora.

You can compare usage for different reserved DB instance sizes by using normalized units per hour. For example, one unit of usage on two db.r3.large DB instances is equivalent to eight normalized units per hour of usage on one db.r3.small. The following table shows the number of normalized units per hour for each DB instance size.
Reserved DB instances

<table>
<thead>
<tr>
<th>Instance size</th>
<th>Single-AZ normalized units per hour (deployment with one DB instance)</th>
<th>Multi-AZ DB instance normalized units per hour (deployment with one DB instance and one standby)</th>
<th>Multi-AZ DB cluster normalized units per hour (deployment with one DB instance and two standbys)</th>
</tr>
</thead>
<tbody>

<td>384</td>
<td>576</td>
</tr>
<tr>
<td>32xlarge</td>
<td>256</td>
<td>512</td>
<td>768</td>
</tr>
</tbody>
</table>

For example, suppose that you purchase a `db.t2.medium` reserved DB instance, and you have two running `db.t2.small` DB instances in your account in the same AWS Region. In this case, the billing benefit is applied in full to both instances.

Alternatively, if you have one `db.t2.large` instance running in your account in the same AWS Region, the billing benefit is applied to 50 percent of the usage of the DB instance.
Reserved DB instance billing example

The price for a reserved DB instance doesn’t provide a discount for the costs associated with storage, backups, and I/O. It provides a discount only on the hourly, on-demand instance usage. The following example illustrates the total cost per month for a reserved DB instance:

- An RDS for MySQL reserved Single-AZ db.r5.large DB instance class in US East (N. Virginia) with the No Upfront option at a cost of $0.12 for the instance, or $90 per month
- 400 GiB of General Purpose SSD (gp2) storage at a cost of 0.115 per GiB per month, or $45.60 per month
- 600 GiB of backup storage at $0.095, or $19 per month (400 GiB free)

Add all of these charges ($90 + $45.60 + $19) with the reserved DB instance, and the total cost per month is $154.60.

If you choose to use an on-demand DB instance instead of a reserved DB instance, an RDS for MySQL Single-AZ db.r5.large DB instance class in US East (N. Virginia) costs $0.1386 per hour, or $101.18 per month. So, for an on-demand DB instance, add all of these options ($101.18 + $45.60 + $19), and the total cost per month is $165.78. You save a little over $11 per month by using the reserved DB instance.

Note
The prices in this example are sample prices and might not match actual prices. For Amazon RDS pricing information, see Amazon RDS pricing.

Reserved DB instances for a Multi-AZ DB cluster

To purchase the equivalent reserved DB instances for a Multi-AZ DB cluster, you can do one of the following:

- Reserve three Single-AZ DB instances that are the same size as the instances in the cluster.
- Reserve one Multi-AZ DB instance and one Single-AZ DB instance that are the same size as the DB instances in the cluster.

For example, suppose that you have one cluster consisting of three db.m6gd.large DB instances. In this case, you can either purchase three db.m6gd.large Single-AZ reserved DB instances, or one db.m6gd.large Multi-AZ reserved DB instance and one db.m6gd.large Single-AZ reserved DB instance. Either of these options reserves the maximum reserved instance discount for the Multi-AZ DB cluster.
Alternately, you can use size-flexible DB instances and purchase a larger DB instance to cover smaller DB instances in one or more clusters. For example, if you have two clusters with six total db.m6gd.large DB instances, you can purchase three db.m6gd.xl Single-AZ reserved DB instances. Doing so reserves all six DB instances in the two clusters. For more information, see Size-flexible reserved DB instances (p. 166).

You might reserve DB instances that are the same size as the DB instances in the cluster, but reserve fewer DB instances than the total number of DB instances in the cluster. However, if you do so, the cluster is only partially reserved. For example, suppose that you have one cluster with three db.m6gd.large DB instances, and you purchase one db.m6gd.large Multi-AZ reserved DB instance. In this case, the cluster is only partially reserved, because only two of the three instances in the cluster are covered by reserved DB instances. The remaining DB instance is charged at the on-demand db.m6gd.large hourly rate.

For more information about Multi-AZ DB clusters, see Multi-AZ DB cluster deployments (p. 499).

Deleting a reserved DB instance

The terms for a reserved DB instance involve a one-year or three-year commitment. You can’t cancel a reserved DB instance. However, you can delete a DB instance that is covered by a reserved DB instance discount. The process for deleting a DB instance that is covered by a reserved DB instance discount is the same as for any other DB instance.

You're billed for the upfront costs regardless of whether you use the resources.

If you delete a DB instance that is covered by a reserved DB instance discount, you can launch another DB instance with compatible specifications. In this case, you continue to get the discounted rate during the reservation term (one or three years).

Working with reserved DB instances

You can use the AWS Management Console, the AWS CLI, and the RDS API to work with reserved DB instances.

Console

You can use the AWS Management Console to work with reserved DB instances as shown in the following procedures.

To get pricing and information about available reserved DB instance offerings

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Reserved instances.
3. Choose Purchase Reserved DB Instance.
4. For Product description, choose the DB engine and licensing type.
5. For DB instance class, choose the DB instance class.
6. For Deployment Option, choose whether you want a Single-AZ or Multi-AZ DB instance deployment.

   Note
   To purchase the equivalent reserved DB instances for a Multi-AZ DB cluster deployment, either purchase three Single-AZ reserved DB instances, or one Multi-AZ and one Single-AZ reserved DB instance. For more information, see Reserved DB instances for a Multi-AZ DB cluster (p. 168).
7. For Term, choose the length of time to reserve the DB instance.
8. For Offering type, choose the offering type.

   After you select the offering type, you can see the pricing information.
Reserved DB instances

Important
Choose Cancel to avoid purchasing the reserved DB instance and incurring any charges.

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering as shown in the following procedure.

To purchase a reserved DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Reserved instances.
3. Choose Purchase reserved DB instance.
4. For Product description, choose the DB engine and licensing type.
5. For DB instance class, choose the DB instance class.
6. For Multi-AZ deployment, choose whether you want a Single-AZ or Multi-AZ DB instance deployment.

Note
To purchase the equivalent reserved DB instances for a Multi-AZ DB cluster deployment, either purchase three Single-AZ reserved DB instances, or one Multi-AZ and one Single-AZ reserved DB instance. For more information, see Reserved DB instances for a Multi-AZ DB cluster (p. 168).

7. For Term, choose the length of time you want the DB instance reserved.
8. For Offering type, choose the offering type.

After you choose the offering type, you can see the pricing information.

9. (Optional) You can assign your own identifier to the reserved DB instances that you purchase to help you track them. For Reserved Id, type an identifier for your reserved DB instance.
10. Choose Submit.

Your reserved DB instance is purchased, then displayed in the Reserved instances list.

After you have purchased reserved DB instances, you can get information about your reserved DB instances as shown in the following procedure.

To get information about reserved DB instances for your AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Navigation pane, choose Reserved instances.

The reserved DB instances for your account appear. To see detailed information about a particular reserved DB instance, choose that instance in the list. You can then see detailed information about that instance in the detail pane at the bottom of the console.

AWS CLI

You can use the AWS CLI to work with reserved DB instances as shown in the following examples.

Example of getting available reserved DB instance offerings

To get information about available reserved DB instance offerings, call the AWS CLI command describe-reserved-db-instances-offerings.
reserved db instances

aws rds describe-reserved-db-instances-offerings

This call returns output similar to the following:

<table>
<thead>
<tr>
<th>OFFERING</th>
<th>OfferingId</th>
<th>Class</th>
<th>Multi-AZ</th>
<th>Duration</th>
<th>Fixed Price</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>649fd0c8-cf6d-47a0-bfa6-060f8e75e95f</td>
<td>db.r3.large</td>
<td>y</td>
<td>1y</td>
<td>1820.00 USD</td>
</tr>
<tr>
<td></td>
<td>12345657-e890-4052-8d33-72e0e706</td>
<td>db.r3.small</td>
<td>n</td>
<td>1y</td>
<td>227.50 USD</td>
</tr>
<tr>
<td></td>
<td>12345678-9012-4321-5678-90123456789</td>
<td>db.r3.xlarge</td>
<td>n</td>
<td>2y</td>
<td>4242.00 USD</td>
</tr>
</tbody>
</table>

Recurring Charges: Amount  Currency  Frequency

<table>
<thead>
<tr>
<th>Recurring Charges</th>
<th>Amount</th>
<th>Currency</th>
<th>Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0.123</td>
<td>USD</td>
<td>Hourly</td>
</tr>
<tr>
<td></td>
<td>1.25</td>
<td>USD</td>
<td>Hourly</td>
</tr>
</tbody>
</table>

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering.

To purchase a reserved DB instance, use the AWS CLI command `purchase-reserved-db-instances-offering` with the following parameters:

- `--reserved-db-instances-offering-id` – The ID of the offering that you want to purchase. See the preceding example to get the offering ID.
- `--reserved-db-instance-id` – You can assign your own identifier to the reserved DB instances that you purchase to help track them.

Example of purchasing a reserved DB instance

The following example purchases the reserved DB instance offering with ID `649fd0c8-cf6d-47a0-bfa6-060f8e75e95f`, and assigns the identifier of `MyReservation`.

For Linux, macOS, or Unix:

```bash
aws rds purchase-reserved-db-instances-offering \
    --reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f \
    --reserved-db-instance-id MyReservation
```

For Windows:

```bash
aws rds purchase-reserved-db-instances-offering ^
    --reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f ^
    --reserved-db-instance-id MyReservation
```

The command returns output similar to the following:

<table>
<thead>
<tr>
<th>RESERVATION</th>
<th>ReservationId</th>
<th>Class</th>
<th>Multi-AZ</th>
<th>Start Time</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>MyReservation</td>
<td>db.r3.small</td>
<td>y</td>
<td>2011-12-19T00:30:23.247Z</td>
<td>1y</td>
</tr>
</tbody>
</table>
After you have purchased reserved DB instances, you can get information about your reserved DB instances.

To get information about reserved DB instances for your AWS account, call the AWS CLI command `describe-reserved-db-instances`, as shown in the following example.

**Example of getting your reserved DB instances**

```bash
aws rds describe-reserved-db-instances
```

The command returns output similar to the following:

<table>
<thead>
<tr>
<th>RESERVATION</th>
<th>ReservationId</th>
<th>Class</th>
<th>Multi-AZ</th>
<th>Start Time</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>MyReservation</td>
<td>db.r3.small</td>
<td>y</td>
<td>2011-12-05T23:37:44.720Z</td>
<td>1y</td>
</tr>
<tr>
<td></td>
<td></td>
<td>455.00 USD</td>
<td>0.092 USD</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**RDS API**

You can use the RDS API to work with reserved DB instances:

- To get information about available reserved DB instance offerings, call the Amazon RDS API operation `DescribeReservedDBInstancesOfferings`.
- After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering. Call the `PurchaseReservedDBInstancesOffering` RDS API operation with the following parameters:
  - `--reserved-db-instances-offering-id` – The ID of the offering that you want to purchase.
  - `--reserved-db-instance-id` – You can assign your own identifier to the reserved DB instances that you purchase to help track them.
- After you have purchased reserved DB instances, you can get information about your reserved DB instances. Call the `DescribeReservedDBInstances` RDS API operation.

**Viewing the billing for your reserved DB instances**

You can view the billing for your reserved DB instances in the Billing Dashboard in the AWS Management Console.

**To view reserved DB instance billing**

1. Sign in to the AWS Management Console.
2. From the **account menu** at the upper right, choose **Billing Dashboard**.
3. Choose **Bill Details** at the upper right of the dashboard.
4. Under **AWS Service Charges**, expand **Relational Database Service**.
5. Expand the AWS Region where your reserved DB instances are, for example **US West (Oregon)**.

Your reserved DB instances and their hourly charges for the current month are shown under Amazon Relational Database Service for **Database Engine Reserved Instances**.

The reserved DB instance in this example was purchased All Upfront, so there are no hourly charges.

6. Choose the **Cost Explorer** (bar graph) icon next to the **Reserved Instances** heading.

   The Cost Explorer displays the Monthly EC2 running hours costs and usage graph.
7. Clear the **Usage Type Group** filter to the right of the graph.
8. Choose the time period and time unit for which you want to examine usage costs.

The following example shows usage costs for on-demand and reserved DB instances for the year to date by month.

The reserved DB instance costs from January through June 2021 are monthly charges for a Partial Upfront instance, while the cost in August 2021 is a one-time charge for an All Upfront instance.

The reserved instance discount for the Partial Upfront instance expired in June 2021, but the DB instance wasn't deleted. After the expiration date, it was simply charged at the on-demand rate.
Setting up for Amazon RDS

Before you use Amazon Relational Database Service for the first time, complete the following tasks.

Topics
- Sign up for an AWS account (p. 174)
- Create an administrative user (p. 174)
- Grant programmatic access (p. 175)
- Determine requirements (p. 176)
- Provide access to your DB instance in your VPC by creating a security group (p. 177)

If you already have an AWS account, know your Amazon RDS requirements, and prefer to use the defaults for IAM and VPC security groups, skip ahead to Getting started with Amazon RDS (p. 180).

Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

To sign up for an AWS account
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an AWS account root user is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to an administrative user, and use only the root user to perform tasks that require root user access.

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to https://aws.amazon.com/ and choosing My Account.

Create an administrative user

After you sign up for an AWS account, create an administrative user so that you don't use the root user for everyday tasks.

Secure your AWS account root user
1. Sign in to the AWS Management Console as the account owner by choosing Root user and entering your AWS account email address. On the next page, enter your password.

For help signing in by using root user, see Signing in as the root user in the AWS Sign-In User Guide.
2. Turn on multi-factor authentication (MFA) for your root user.

   For instructions, see [Enable a virtual MFA device for your AWS account root user (console)](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users.html) in the IAM User Guide.

Create an administrative user

- For your daily administrative tasks, grant administrative access to an administrative user in AWS IAM Identity Center (successor to AWS Single Sign-On).

Sign in as the administrative user

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

   For help signing in using an IAM Identity Center user, see [Signing in to the AWS access portal](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users.html) in the AWS Sign-In User Guide.

Grant programmatic access

Users need programmatic access if they want to interact with AWS outside of the AWS Management Console. The way to grant programmatic access depends on the type of user that's accessing AWS.

To grant users programmatic access, choose one of the following options.

<table>
<thead>
<tr>
<th>Which user needs programmatic access?</th>
<th>To</th>
<th>By</th>
</tr>
</thead>
<tbody>
<tr>
<td>Workforce identity (Users managed in IAM Identity Center)</td>
<td>Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.</td>
<td>Following the instructions for the interface that you want to use.</td>
</tr>
<tr>
<td>- For the AWS CLI, see <a href="https://docs.aws.amazon.com/cli/index.html">Configuring the AWS CLI to use AWS IAM Identity Center (successor to AWS Single Sign-On)</a> in the AWS Command Line Interface User Guide.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- For AWS SDKs, tools, and AWS APIs, see <a href="https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users.html">IAM Identity Center authentication</a> in the AWS SDKs and Tools Reference Guide.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>IAM</td>
<td>Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.</td>
<td>Following the instructions in <a href="https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users.html">Using temporary credentials with AWS resources</a> in the IAM User Guide.</td>
</tr>
<tr>
<td>IAM</td>
<td>(Not recommended) Use long-term credentials to sign programmatic requests to</td>
<td>Following the instructions for the interface that you want to use.</td>
</tr>
</tbody>
</table>
Determine requirements

The basic building block of Amazon RDS is the DB instance. In a DB instance, you create your databases. A DB instance provides a network address called an endpoint. Your applications use this endpoint to connect to your DB instance. When you create a DB instance, you specify details like storage, memory, database engine and version, network configuration, security, and maintenance periods. You control network access to a DB instance through a security group.

Before you create a DB instance and a security group, you must know your DB instance and network needs. Here are some important things to consider:

- **Resource requirements** – What are the memory and processor requirements for your application or service? You use these settings to help you determine what DB instance class to use. For specifications about DB instance classes, see DB instance classes (p. 11).

- **VPC, subnet, and security group** – Your DB instance will most likely be in a virtual private cloud (VPC). To connect to your DB instance, you need to set up security group rules. These rules are set up differently depending on what kind of VPC you use and how you use it. For example, you can use: a default VPC or a user-defined VPC.

The following list describes the rules for each VPC option:

- **Default VPC** – If your AWS account has a default VPC in the current AWS Region, that VPC is configured to support DB instances. If you specify the default VPC when you create the DB instance, do the following:
  - Make sure to create a VPC security group that authorizes connections from the application or service to the Amazon RDS DB instance. Use the Security Group option on the VPC console or the AWS CLI to create VPC security groups. For information, see Step 3: Create a VPC security group (p. 2717).
  - Specify the default DB subnet group. If this is the first DB instance you have created in this AWS Region, Amazon RDS creates the default DB subnet group when it creates the DB instance.

- **User-defined VPC** – If you want to specify a user-defined VPC when you create a DB instance, be aware of the following:
  - Make sure to create a VPC security group that authorizes connections from the application or service to the Amazon RDS DB instance. Use the Security Group option on the VPC console or the AWS CLI to create VPC security groups. For information, see Step 3: Create a VPC security group (p. 2717).
  - The VPC must meet certain requirements in order to host DB instances, such as having at least two subnets, each in a separate Availability Zone. For information, see Amazon VPC VPCs and Amazon RDS (p. 2705).
• Make sure to specify a DB subnet group that defines which subnets in that VPC can be used by the DB instance. For information, see the DB subnet group section in Working with a DB instance in a VPC (p. 2706).

• High availability – Do you need failover support? On Amazon RDS, a Multi-AZ deployment creates a primary DB instance and a secondary standby DB instance in another Availability Zone for failover support. We recommend Multi-AZ deployments for production workloads to maintain high availability. For development and test purposes, you can use a deployment that isn’t Multi-AZ. For more information, see Configuring and managing a Multi-AZ deployment (p. 492).

• IAM policies – Does your AWS account have policies that grant the permissions needed to perform Amazon RDS operations? If you are connecting to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS operations. For more information, see Identity and access management for Amazon RDS (p. 2623).

• Open ports – What TCP/IP port does your database listen on? The firewalls at some companies might block connections to the default port for your database engine. If your company firewall blocks the default port, choose another port for the new DB instance. When you create a DB instance that listens on a port you specify, you can change the port by modifying the DB instance.

• AWS Region – What AWS Region do you want your database in? Having your database in close proximity to your application or web service can reduce network latency. For more information, see Regions, Availability Zones, and Local Zones (p. 110).

• DB disk subsystem – What are your storage requirements? Amazon RDS provides three storage types:
  • General Purpose (SSD)
  • Provisioned IOPS (PIOPS)
  • Magnetic (also known as standard storage)

For more information on Amazon RDS storage, see Amazon RDS DB instance storage (p. 101).

When you have the information you need to create the security group and the DB instance, continue to the next step.

Provide access to your DB instance in your VPC by creating a security group

VPC security groups provide access to DB instances in a VPC. They act as a firewall for the associated DB instance, controlling both inbound and outbound traffic at the DB instance level. DB instances are created by default with a firewall and a default security group that protect the DB instance.

Before you can connect to your DB instance, you must add rules to a security group that enable you to connect. Use your network and configuration information to create rules to allow access to your DB instance.

For example, suppose that you have an application that accesses a database on your DB instance in a VPC. In this case, you must add a custom TCP rule that specifies the port range and IP addresses that your application uses to access the database. If you have an application on an Amazon EC2 instance, you can use the security group that you set up for the Amazon EC2 instance.

You can configure connectivity between an Amazon EC2 instance a DB instance when you create the DB instance. For more information, see Configure automatic network connectivity with an EC2 instance (p. 300).

Tip
You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. For more information, see Configure automatic network connectivity with an EC2 instance (p. 300).
For information about common scenarios for accessing a DB instance, see [Scenarios for accessing a DB instance in a VPC](p. 2718).

**To create a VPC security group**

   
   **Note**
   
   Make sure you are in the VPC console, not the RDS console.

2. In the upper-right corner of the AWS Management Console, choose the AWS Region where you want to create your VPC security group and DB instance. In the list of Amazon VPC resources for that AWS Region, you should see at least one VPC and several subnets. If you don't, you don't have a default VPC in that AWS Region.

3. In the navigation pane, choose **Security Groups**.

4. Choose **Create security group**.
   
   The **Create security group** page appears.

5. In **Basic details**, enter the **Security group name** and **Description**. For **VPC**, choose the VPC that you want to create your DB instance in.

6. In **Inbound rules**, choose **Add rule**.
   
   a. For **Type**, choose **Custom TCP**.
   
   b. For **Port range**, enter the port value to use for your DB instance.
   
   c. For **Source**, choose a security group name or type the IP address range (CIDR value) from where you access the DB instance. If you choose **My IP**, this allows access to the DB instance from the IP address detected in your browser.

7. If you need to add more IP addresses or different port ranges, choose **Add rule** and enter the information for the rule.

8. (Optional) In **Outbound rules**, add rules for outbound traffic. By default, all outbound traffic is allowed.

9. Choose **Create security group**.

You can use the VPC security group that you just created as the security group for your DB instance when you create it.

**Note**

If you use a default VPC, a default subnet group spanning all of the VPC's subnets is created for you. When you create a DB instance, you can select the default VPC and use **default** for **DB Subnet Group**.

After you have completed the setup requirements, you can create a DB instance using your requirements and security group. To do so, follow the instructions in [Creating an Amazon RDS DB instance](p. 300). For information about getting started by creating a DB instance that uses a specific DB engine, see the relevant documentation in the following table.

<table>
<thead>
<tr>

</tbody>
</table>

**Note**
If you can't connect to a DB instance after you create it, see the troubleshooting information in Can't connect to Amazon RDS DB instance (p. 2744).
Getting started with Amazon RDS

In the following examples, you can find how to create and connect to a DB instance using Amazon Relational Database Service (Amazon RDS). You can create a DB instance that uses MariaDB, MySQL, Microsoft SQL Server, Oracle, or PostgreSQL.

**Important**
Before you can create or connect to a DB instance, make sure to complete the tasks in Setting up for Amazon RDS (p. 174).

Creating a DB instance and connecting to a database on a DB instance is slightly different for each of the DB engines. Choose one of the following DB engines that you want to use for detailed information on creating and connecting to the DB instance. After you have created and connected to your DB instance, there are instructions to help you delete the DB instance.

**Topics**
- Creating and connecting to a MariaDB DB instance (p. 181)
- Creating and connecting to a Microsoft SQL Server DB instance (p. 194)
- Creating and connecting to a MySQL DB instance (p. 209)
- Creating and connecting to an Oracle DB instance (p. 222)
- Creating and connecting to a PostgreSQL DB instance (p. 235)
- Tutorial: Create a web server and an Amazon RDS DB instance (p. 249)
- Tutorial: Using a Lambda function to access an Amazon RDS database (p. 273)
Creating and connecting to a MariaDB DB instance

This tutorial creates an EC2 instance and an RDS for MariaDB DB instance. The tutorial shows you how to access the DB instance from the EC2 instance using a standard MySQL client. As a best practice, this tutorial creates a private DB instance in a virtual private cloud (VPC). In most cases, other resources in the same VPC, such as EC2 instances, can access the DB instance, but resources outside of the VPC can't access it.

After you complete the tutorial, there is a public and private subnet in each Availability Zone in your VPC. In one Availability Zone, the EC2 instance is in the public subnet, and the DB instance is in the private subnet.

Important

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

The following diagram shows the configuration when the tutorial is complete.

This tutorial uses **Easy create** to create a DB instance running MariaDB with the AWS Management Console. With **Easy create**, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options. The DB instance created by **Easy create** is private.

When you use **Standard create** instead of **Easy create**, you can specify more configuration options when you create a DB instance, including ones for availability, security, backups, and maintenance. To create a public DB instance, you must use **Standard create**. For information about creating DB instances with **Standard create**, see **Creating an Amazon RDS DB instance (p. 300)**.

Topics

- Prerequisites (p. 182)
- Step 1: Create an EC2 instance (p. 182)
- Step 2: Create a MariaDB DB instance (p. 185)
- Step 3: Connect to a MariaDB DB instance (p. 190)
- Step 4: Delete the EC2 instance and DB instance (p. 193)
- (Optional) Connect your DB instance to a Lambda function (p. 193)
Prerequisites

Before you begin, complete the steps in the following sections:

- Sign up for an AWS account (p. 174)
- Create an administrative user (p. 174)

Step 1: Create an EC2 instance

Create an Amazon EC2 instance that you will use to connect to your database.

To create an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the EC2 instance.
3. Choose EC2 Dashboard, and then choose Launch instance, as shown in the following image.
The Launch an instance page opens.

4. Choose the following settings on the Launch an instance page.

a. Under Name and tags, for Name, enter ec2-database-connect.

b. Under Application and OS Images (Amazon Machine Image), choose Amazon Linux, and then choose the Amazon Linux 2023 AMI. Keep the default selections for the other choices.

c. Under Instance type, choose t2.micro.

d. Under Key pair (login), choose a Key pair name to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose Create new key pair and then use the Create key pair window to create it.

For more information about creating a new key pair, see Create a key pair in the Amazon EC2 User Guide for Linux Instances.

e. For Allow SSH traffic in Network settings, choose the source of SSH connections to the EC2 instance.

You can choose My IP if the displayed IP address is correct for SSH connections. Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at https://checkip.amazonaws.com. An example of an IP address is 192.0.2.1/32.
In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

**Warning**
If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.

The following image shows an example of the **Network settings** section.

---

<table>
<thead>
<tr>
<th><strong>Network settings</strong></th>

</tr>
</thead>
</table>

Network: vpc-1a2b3c4d

Subnet: No preference (Default subnet in any availability zone)

Auto-assign public IP: Enable

Firewall (security groups): A security group is a set of firewall rules that control the traffic for your instance. Add rules to allow specific traffic to reach your instance.

- Create security group
- Select existing security group

We'll create a new security group called `launch-wizard-1` with the following rules:

- Allow SSH traffic from My IP
- Allow HTTPS traffic from the internet
  - To set up an endpoint, for example when creating a web server
- Allow HTTP traffic from the internet
  - To set up an endpoint, for example when creating a web server

---

f. Leave the default values for the remaining sections.

g. Review a summary of your EC2 instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

5. On the **Launch Status** page, note the identifier for your new EC2 instance, for example: `i-1234567890abcdef0`. 
6. Choose the EC2 instance identifier to open the list of EC2 instances, and then select your EC2 instance.

7. In the Details tab, note the following values, which you need when you connect using SSH:
   a. In Instance summary, note the value for Public IPv4 DNS.
   b. In Instance details, note the value for Key pair name.

8. Wait until the Instance state for your EC2 instance has a status of Running before continuing.

Step 2: Create a MariaDB DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your MariaDB databases.
In this example, you use Easy create to create a DB instance running the MariaDB database engine with a db.t3.micro DB instance class.

**To create a MariaDB DB instance with Easy create**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.

5. In **Configuration**, choose **MariaDB**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier**, enter **database-test1**.
8. For **Master username**, enter a name for the master user, or keep the default name.

The **Create database** page should look similar to the following image.
9. To use an automatically generated master password for the DB instance, select **Auto generate a password**.

   To enter your master password, make sure **Auto generate a password** is cleared, and then enter the same password in **Master password** and **Confirm password**.

10. To set up a connection with the EC2 instance you created previously, open **Set up EC2 connection - optional**.

   Select **Connect to an EC2 compute resource**. Choose the EC2 instance you created previously.
11. Open View default settings for Easy create.
You can examine the default settings used with Easy create. The Editable after database is created column shows which options you can change after you create the database.

- If a setting has No in that column, and you want a different setting, you can use Standard create to create the DB instance.
- If a setting has Yes in that column, and you want a different setting, you can either use Standard create to create the DB instance, or modify the DB instance after you create it to change the setting.

12. Choose Create database.

To view the master username and password for the DB instance, choose View credential details.

You can use the username and password that appears to connect to the DB instance as the master user.
Important
You can't view the master user password again. If you don't record it, you might have to change it.
If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401).

13. In the Databases list, choose the name of the new MariaDB DB instance to show its details.

The DB instance has a status of Creating until it is ready to use.

<table>
<thead>
<tr>
<th>Summary</th>
<th></th>
<th>Status</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB identifier</td>
<td>CPU</td>
<td>Current activity</td>
<td>Engine</td>
</tr>
<tr>
<td>database-test1</td>
<td>-</td>
<td></td>
<td>MariaDB</td>
</tr>
<tr>
<td>Role</td>
<td>Status</td>
<td>Class</td>
<td></td>
</tr>
<tr>
<td>Instance</td>
<td>Creating</td>
<td>db.t3.micro</td>
<td></td>
</tr>
</tbody>
</table>

When the status changes to Available, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

Step 3: Connect to a MariaDB DB instance

You can use any standard SQL client application to connect to the DB instance. In this example, you connect to a MariaDB DB instance using the mysql command-line client.

To connect to a MariaDB DB instance

1. Find the endpoint (DNS name) and port number for your DB instance.
   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the upper-right corner of the Amazon RDS console, choose the AWS Region for the DB instance.
   c. In the navigation pane, choose Databases.
   d. Choose the MariaDB DB instance name to display its details.
   e. On the Connectivity & security tab, copy the endpoint. Also note the port number. You need both the endpoint and the port number to connect to the DB instance.
2. Connect to the EC2 instance that you created earlier by following the steps in Connect to your Linux instance in the Amazon EC2 User Guide for Linux Instances.

We recommend that you connect to your EC2 instance using SSH. If the SSH client utility is installed on Windows, Linux, or Mac, you can connect to the instance using the following command format:

```
ssh -i location_of_pem_file ec2-user@ec2-instance-public-dns-name
```

For example, assume that ec2-database-connect-key-pair.pem is stored in /dir1 on Linux, and the public IPv4 DNS for your EC2 instance is ec2-12-345-678-90.compute-1.amazonaws.com. Your SSH command would look as follows:
3. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do this, use the following command.

   **Note**
   The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

   ```bash
   sudo dnf update -y
   ```

4. Install the `mysql` command-line client from MariaDB.

   To install the MariaDB command-line client on Amazon Linux 2023, run the following command:

   ```bash
   sudo dnf install mariadb105
   ```

5. Connect to the MariaDB DB instance. For example, enter the following command. This action lets you connect to the MariaDB DB instance using the MySQL client.

   Substitute the DB instance endpoint (DNS name) for `endpoint`, and substitute the master username that you used for `admin`. Provide the master password that you used when prompted for a password.

   ```bash
   mysql -h endpoint -P 3306 -u admin -p
   ```

   After you enter the password for the user, you should see output similar to the following.

   Welcome to the MariaDB monitor. Commands end with ; or \g.
   Your MariaDB connection id is 156
   Server version: 10.6.10-MariaDB-log managed by https://aws.amazon.com/rds/
   Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.
   Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.
   MariaDB [(none)]>

   For more information about connecting to a MariaDB DB instance, see Connecting to a DB instance running the MariaDB database engine (p. 1285). If you can't connect to your DB instance, see Can't connect to Amazon RDS DB instance (p. 2744).

   For security, it is a best practice to use encrypted connections. Only use an unencrypted MariaDB connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting from the MySQL command-line client with SSL/TLS (encrypted) (p. 1292).

6. Run SQL commands.

   For example, the following SQL command shows the current date and time:

   ```sql
   SELECT CURRENT_TIMESTAMP;
   ```
Step 4: Delete the EC2 instance and DB instance

After you connect to and explore the sample EC2 instance and DB instance that you created, delete them so you're no longer charged for them.

To delete the EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.  
2. In the navigation pane, choose Instances.  
3. Select the EC2 instance, and choose Instance state, Terminate instance.  
4. Choose Terminate when prompted for confirmation.

For more information about deleting an EC2 instance, see Terminate your instance in the Amazon EC2 User Guide for Linux Instances.

To delete the DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.  
2. In the navigation pane, choose Databases.  
3. Choose the DB instance you want to delete.  
4. For Actions, choose Delete.  
6. Complete the acknowledgement and choose Delete.

(Optional) Connect your DB instance to a Lambda function

You can also connect your RDS for MariaDB DB instance to a Lambda serverless compute resource. Lambda functions allow you to run code without provisioning or managing infrastructure. A Lambda function also allows you to automatically respond to code execution requests at any scale, from a dozen events a day to hundreds of per second. For more information, see Automatically connecting a Lambda function and a DB instance (p. 392).
Creating and connecting to a Microsoft SQL Server DB instance

This tutorial creates an EC2 instance and an RDS for Microsoft SQL Server DB instance. The tutorial shows you how to access the DB instance from the EC2 instance using the Microsoft SQL Server Management Studio client. As a best practice, this tutorial creates a private DB instance in a virtual private cloud (VPC). In most cases, other resources in the same VPC, such as EC2 instances, can access the DB instance, but resources outside of the VPC can’t access it.

After you complete the tutorial, there is a public and private subnet in each Availability Zone in your VPC. In one Availability Zone, the EC2 instance is in the public subnet, and the DB instance is in the private subnet.

**Important**

There’s no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

The following diagram shows the configuration when the tutorial is complete.

This tutorial uses **Easy create** to create a DB instance running Microsoft SQL Server with the AWS Management Console. With **Easy create**, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options. The DB instance created by **Easy create** is private.

When you use **Standard create** instead of **Easy create**, you can specify more configuration options when you create a DB instance, including ones for availability, security, backups, and maintenance. To create a public DB instance, you must use **Standard create**. For information about creating DB instances with **Standard create**, see [Creating an Amazon RDS DB instance](p. 300).

**Topics**

- Prerequisites (p. 195)
- Step 1: Create an EC2 instance (p. 195)
- Step 2: Create a SQL Server DB instance (p. 199)
- Step 3: Connect to your SQL Server DB instance (p. 204)
• Step 4: Explore your sample SQL Server DB instance (p. 206)
• Step 5: Delete the EC2 instance and DB instance (p. 208)
• (Optional) Connect your DB instance to a Lambda function (p. 208)

Prerequisites

Before you begin, complete the steps in the following sections:

• Sign up for an AWS account (p. 174)
• Create an administrative user (p. 174)

Step 1: Create an EC2 instance

Create an Amazon EC2 instance that you will use to connect to your database.

To create an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region you used for the database previously.
3. Choose EC2 Dashboard, and then choose Launch instance, as shown in the following image.
The **Launch an instance** page opens.

4. Choose the following settings on the **Launch an instance** page.

   a. Under **Name and tags**, for **Name**, enter `ec2-database-connect`.

   b. Under **Application and OS Images (Amazon Machine Image)**, choose **Windows**, and then choose the **Microsoft Windows Server 2022 Base**. Keep the default selections for the other choices.
c. Under **Instance type**, choose **t2.micro**.

d. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

For more information about creating a new key pair, see [Create a key pair](#) in the Amazon EC2 User Guide for Windows Instances.

e. For **Firewall (security groups)** in **Network settings**, choose **Allow RDP traffic from** to connect to the EC2 instance.

You can choose **My IP** if the displayed IP address is correct for RDP connections. Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using RDP. To determine your public IP address, in a different browser window or tab, you can use the service at [https://checkip.amazonaws.com](https://checkip.amazonaws.com). An example of an IP address is 192.0.2.1/32.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

**Warning**

If you use `0.0.0.0/0` for RDP access, you make it possible for all IP addresses to access your public EC2 instances using RDP. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using RDP.
The following image shows an example of the **Network settings** section.

![Network settings](image)

- **Network**
  - vpc-1a2b3c4d

- **Subnet**
  - No preference (Default subnet in any availability zone)

- **Auto-assign public IP**
  - Enable

- **Firewall (security groups)**
  - A security group is a set of firewall rules that control the traffic for your instance. Add rules to allow specific traffic to reach your instance.

  - [ ] Create security group
  - [ ] Select existing security group

We'll create a new security group called 'launch-wizard-2' with the following rules:

- **Allow RDP traffic from**
  - Helps you connect to your instance
  - My IP

- **Allow HTTPS traffic from the internet**
  - To set up an endpoint, for example when creating a web server

- **Allow HTTP traffic from the internet**
  - To set up an endpoint, for example when creating a web server

f. Keep the default values for the remaining sections.
g. Review a summary of your EC2 instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

5. On the **Launch Status** page, note the identifier for your new EC2 instance, for example: *i-1234567890abcdef0*. 
6. Choose the EC2 instance identifier to open the list of EC2 instances.
7. Wait until the **Instance state** for your EC2 instance has a status of **Running** before continuing.

**Step 2: Create a SQL Server DB instance**

The basic building block of Amazon RDS is the DB instance. This environment is where you run your SQL Server databases.

In this example, you use **Easy create** to create a DB instance running the SQL Server database engine with a db.t2.micro DB instance class.

**To create a Microsoft SQL Server DB instance with Easy create**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.
5. In **Configuration**, choose **Microsoft SQL Server**.
7. For **DB instance size**, choose **Free tier**.
8. For **DB instance identifier**, enter **database-test1**.

The **Create database** page should look similar to the following image.
9. For **Master username**, enter a name for the master user, or keep the default name.

10. To set up a connection with the EC2 instance you created previously, open **Set up EC2 connection - optional**.

    Select **Connect to an EC2 compute resource**. Choose the EC2 instance you created previously.
11. To use an automatically generated master password for the DB instance, select the **Auto generate a password** box. To enter your master password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

12. Open **View default settings for Easy create**.
You can examine the default settings used with Easy create. The Editable after database is created column shows which options you can change after you create the database.

- If a setting has No in that column, and you want a different setting, you can use Standard create to create the DB instance.
- If a setting has Yes in that column, and you want a different setting, you can either use Standard create to create the DB instance, or modify the DB instance after you create it to change the setting.

13. Choose Create database.

To view the master username and password for the DB instance, choose View credential details.

You can use the username and password that appears to connect to the DB instance as the master user.
Important
You can't view the master user password again. If you don't record it, you might have to change it.
If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401).

14. In the Databases list, choose the name of the new SQL Server DB instance to show its details.

The DB instance has a status of Creating until it is ready to use.

<table>
<thead>
<tr>
<th>Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB identifier</td>
</tr>
<tr>
<td>database-test1</td>
</tr>
<tr>
<td>Role Instance</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

When the status changes to Available, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

Step 3: Connect to your SQL Server DB instance

In the following procedure, you connect to your DB instance by using Microsoft SQL Server Management Studio (SSMS).

To connect to an RDS for SQL Server DB instance using SSMS

1. Find the endpoint (DNS name) and port number for your DB instance.
   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the upper-right corner of the Amazon RDS console, choose the AWS Region for the DB instance.
   c. In the navigation pane, choose Databases.
   d. Choose the SQL Server DB instance name to display its details.
   e. On the Connectivity tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
2. Connect to the EC2 instance that you created earlier by following the steps in Connect to your Microsoft Windows instance in the Amazon EC2 User Guide for Windows Instances.
3. Install the SQL Server Management Studio (SSMS) client from Microsoft.
To download a standalone version of SSMS to your EC2 instance, see Download SQL Server Management Studio (SSMS) in the Microsoft documentation.

a. Use the Start menu to open Internet Explorer.
b. Use Internet Explorer to download and install a standalone version of SSMS. If you are prompted that the site isn't trusted, add the site to the list of trusted sites.

The Connect to Server dialog box appears.

5. Provide the following information for your sample DB instance:
   a. For Server type, choose Database Engine.
   b. For Server name, enter the DNS name, followed by a comma and the port number (the default port is 1433). For example, your server name should look as follows:

   database-test1.0123456789012.us-west-2.rds.amazonaws.com,1433

   c. For Authentication, choose SQL Server Authentication.
   d. For Login, enter the username that you chose to use for your sample DB instance. This is also known as the master username.
   e. For Password, enter the password that you chose earlier for your sample DB instance. This is also known as the master user password.

6. Choose Connect.

   After a few moments, SSMS connects to your DB instance. For security, it is a best practice to use encrypted connections. Only use an unencrypted SQL Server connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Using SSL with a Microsoft SQL Server DB instance (p. 1472)

For more information about connecting to a Microsoft SQL Server DB instance, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 1396).

For information about connection issues, see Can't connect to Amazon RDS DB instance (p. 2744).

### Step 4: Explore your sample SQL Server DB instance

You can explore your sample DB instance by using Microsoft SQL Server Management Studio (SSMS).

**To explore a DB instance using SSMS**

1. Your SQL Server DB instance comes with SQL Server's standard built-in system databases (master, model, msdb, and tempdb). To explore the system databases, do the following:
   a. In SSMS, on the View menu, choose Object Explorer.
   b. Expand your DB instance, expand Databases, and then expand System Databases as shown.
Your SQL Server DB instance also comes with a database named rdsadmin. Amazon RDS uses this database to store the objects that it uses to manage your database. The rdsadmin database also includes stored procedures that you can run to perform advanced tasks.

2. Start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your sample DB instance, do the following:

   a. In SSMS, on the File menu, point to New and then choose Query with Current Connection.
   b. Enter the following SQL query:

```
select @@VERSION
```

   c. Run the query. SSMS returns the SQL Server version of your Amazon RDS DB instance.
Step 5: Delete the EC2 instance and DB instance

After you connect to and explore the sample EC2 instance and DB instance that you created, delete them so you’re no longer charged for them.

To delete the EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the EC2 instance, and choose Instance state, Terminate instance.
4. Choose Terminate when prompted for confirmation.

For more information about deleting an EC2 instance, see Terminate your instance in the User Guide for Windows Instances.

To delete the DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to delete.
4. For Actions, choose Delete.
6. Complete the acknowledgement and choose Delete.

(Optional) Connect your DB instance to a Lambda function

You can also connect your RDS for SQL Server DB instance to a Lambda serverless compute resource. Lambda functions allow you to run code without provisioning or managing infrastructure. A Lambda function also allows you to automatically respond to code execution requests at any scale, from a dozen events a day to hundreds of per second. For more information, see Automatically connecting a Lambda function and a DB instance (p. 392).
Creating and connecting to a MySQL DB instance

This tutorial creates an EC2 instance and an RDS for MySQL DB instance. The tutorial shows you how to access the DB instance from the EC2 instance using a standard MySQL client. As a best practice, this tutorial creates a private DB instance in a virtual private cloud (VPC). In most cases, other resources in the same VPC, such as EC2 instances, can access the DB instance, but resources outside of the VPC can’t access it.

After you complete the tutorial, there is a public and private subnet in each Availability Zone in your VPC. In one Availability Zone, the EC2 instance is in the public subnet, and the DB instance is in the private subnet.

**Important**
There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

The following diagram shows the configuration when the tutorial is complete.

This tutorial uses **Easy create** to create a DB instance running MySQL with the AWS Management Console. With **Easy create**, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options. The DB instance created by **Easy create** is private.

When you use **Standard create** instead of **Easy create**, you can specify more configuration options when you create a DB instance, including ones for availability, security, backups, and maintenance. To create a public DB instance, you must use **Standard create**. For information about creating DB instances with **Standard create**, see *Creating an Amazon RDS DB instance* (p. 300).

**Topics**

- [Prerequisites](p. 210)
- [Step 1: Create an EC2 instance](p. 210)
- [Step 2: Create a MySQL DB instance](p. 213)
- [Step 3: Connect to a MySQL DB instance](p. 218)
- [Step 4: Delete the EC2 instance and DB instance](p. 221)
- *(Optional) Connect your DB instance to a Lambda function* (p. 221)
Prerequisites

Before you begin, complete the steps in the following sections:

- [Sign up for an AWS account](p. 174) (p. 174)
- [Create an administrative user](p. 174) (p. 174)

Step 1: Create an EC2 instance

Create an Amazon EC2 instance that you will use to connect to your database.

To create an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the EC2 instance.
3. Choose EC2 Dashboard, and then choose Launch instance, as shown in the following image.
The Launch an instance page opens.

4. Choose the following settings on the Launch an instance page.
   
a. Under Name and tags, for Name, enter ec2-database-connect.

b. Under Application and OS Images (Amazon Machine Image), choose Amazon Linux, and then choose the Amazon Linux 2023 AMI. Keep the default selections for the other choices.

c. Under Instance type, choose t2.micro.

d. Under Key pair (login), choose a Key pair name to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose Create new key pair and then use the Create key pair window to create it.

   For more information about creating a new key pair, see Create a key pair in the Amazon EC2 User Guide for Linux Instances.

e. For Allow SSH traffic in Network settings, choose the source of SSH connections to the EC2 instance.

   You can choose My IP if the displayed IP address is correct for SSH connections. Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at https://checkip.amazonaws.com. An example of an IP address is 192.0.2.1/32.
Step 1: Create an EC2 instance

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

**Warning**
If you use 0.0.0.0/0 for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it’s unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.

The following image shows an example of the **Network settings** section.

![Network settings](image)

f. Leave the default values for the remaining sections.

g. Review a summary of your EC2 instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

5. On the **Launch Status** page, note the identifier for your new EC2 instance, for example: i-1234567890abcdef0.
6. Choose the EC2 instance identifier to open the list of EC2 instances, and then select your EC2 instance.

7. In the Details tab, note the following values, which you need when you connect using SSH:
   - In Instance summary, note the value for **Public IPv4 DNS**.
   - In Instance details, note the value for **Key pair name**.

8. Wait until the Instance state for your EC2 instance has a status of **Running** before continuing.

**Step 2: Create a MySQL DB instance**

The basic building block of Amazon RDS is the DB instance. This environment is where you run your MySQL databases.
In this example, you use Easy create to create a DB instance running the MySQL database engine with a db.t3.micro DB instance class.

**To create a MySQL DB instance with Easy create**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region you used for the EC2 instance previously.
3. In the navigation pane, choose Databases.
4. Choose Create database and make sure that Easy create is chosen.
5. In Configuration, choose MySQL.
6. For DB instance size, choose Free tier.
7. For DB instance identifier, enter database-test1.
8. For Master username, enter a name for the master user, or keep the default name.

The Create database page should look similar to the following image.
9. To use an automatically generated master password for the DB instance, select **Auto generate a password**.

To enter your master password, make sure **Auto generate a password** is cleared, and then enter the same password in **Master password** and **Confirm password**.

10. To set up a connection with the EC2 instance you created previously, open **Set up EC2 connection - optional**.

    Select **Connect to an EC2 compute resource**. Choose the EC2 instance you created previously.
Set up EC2 connection - optional

You can also set up a connection to an EC2 instance after creating the database. Go to the database list page or the database details page, choose Actions, and then choose Set up to EC2 connection.

Compute resource
Choose whether to set up a connection to a compute resource for this database. Setting up a connection will automatically change connectivity settings so that the compute resource can connect to this database.

- Don’t connect to an EC2 compute resource
  Don’t set up a connection to a compute resource for this database. You can manually set up a connection to a compute resource later.

- Connect to an EC2 compute resource
  Set up a connection to an EC2 compute resource for this database.

EC2 instance info
Choose the EC2 instance to add as the compute resource for this database. A VPC security group is added to this EC2 instance. A VPC security group is also added to the database with an inbound rule that allows the EC2 instance to access the database.

11. (Optional) Open View default settings for Easy create.
Step 2: Create a MySQL DB instance

View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use Standard create.

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Value</th>
<th>Editable after database is created</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encryption</td>
<td>Enabled</td>
<td>No</td>
</tr>
<tr>
<td>VPC</td>
<td>Default VPC (vpc-1a2b3c4d)</td>
<td>No</td>
</tr>
<tr>
<td>Option group</td>
<td>default:mysql-8.0</td>
<td>Yes</td>
</tr>
<tr>
<td>Subnet group</td>
<td>default</td>
<td>Yes</td>
</tr>
<tr>
<td>Automatic backups</td>
<td>Enabled</td>
<td>Yes</td>
</tr>
<tr>
<td>VPC security group</td>
<td>sg-0cc53dec1b4d17b5c6f</td>
<td>Yes</td>
</tr>
<tr>
<td>Publicly accessible</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Database port</td>
<td>3306</td>
<td>Yes</td>
</tr>
<tr>
<td>DB Instance Identifier</td>
<td>database-test1</td>
<td>Yes</td>
</tr>
<tr>
<td>DB engine version</td>
<td>8.0.28</td>
<td>Yes</td>
</tr>
<tr>
<td>DB parameter group</td>
<td>default.mysql8.0</td>
<td>Yes</td>
</tr>
<tr>
<td>Performance insights</td>
<td>Enabled</td>
<td>Yes</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Enabled</td>
<td>Yes</td>
</tr>
<tr>
<td>Maintenance</td>
<td>Auto minor version upgrade enabled</td>
<td>Yes</td>
</tr>
<tr>
<td>Delete protection</td>
<td>Not enabled</td>
<td>Yes</td>
</tr>
</tbody>
</table>

You can examine the default settings used with Easy create. The Editable after database is created column shows which options you can change after you create the database.

- If a setting has No in that column, and you want a different setting, you can use Standard create to create the DB instance.
- If a setting has Yes in that column, and you want a different setting, you can either use Standard create to create the DB instance, or modify the DB instance after you create it to change the setting.

12. Choose Create database.

To view the master username and password for the DB instance, choose View credential details.

You can use the username and password that appears to connect to the DB instance as the master user.
Important
You can't view the master user password again. If you don't record it, you might have to change it.
If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401).

13. In the Databases list, choose the name of the new MySQL DB instance to show its details.

The DB instance has a status of Creating until it is ready to use.

<table>
<thead>
<tr>
<th>Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB Identifier</td>
</tr>
<tr>
<td>database-test1</td>
</tr>
<tr>
<td>Role</td>
</tr>
<tr>
<td>Instance</td>
</tr>
</tbody>
</table>

When the status changes to Available, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

Step 3: Connect to a MySQL DB instance

You can use any standard SQL client application to connect to the DB instance. In this example, you connect to a MySQL DB instance using the mysql command-line client.

To connect to a MySQL DB instance

1. Find the endpoint (DNS name) and port number for your DB instance.
   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the upper-right corner of the Amazon RDS console, choose the AWS Region for the DB instance.
   c. In the navigation pane, choose Databases.
   d. Choose the MySQL DB instance name to display its details.
   e. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
2. Connect to the EC2 instance that you created earlier by following the steps in Connect to your Linux instance in the Amazon EC2 User Guide for Linux Instances.

We recommend that you connect to your EC2 instance using SSH. If the SSH client utility is installed on Windows, Linux, or Mac, you can connect to the instance using the following command format:

```
ssh -i location_of_pem_file ec2-user@ec2-instance-public-dns-name
```

For example, assume that ec2-database-connect-key-pair.pem is stored in /dir1 on Linux, and the public IPv4 DNS for your EC2 instance is ec2-12-345-678-90.compute-1.amazonaws.com. Your SSH command would look as follows:
3. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do this, use the following command.

   Note
   The -y option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

   ```
   sudo dnf update -y
   ```

4. To install the mysql command-line client from MariaDB on Amazon Linux 2023, run the following command:

   ```
   sudo dnf install mariadb105
   ```

5. Connect to the MySQL DB instance. For example, enter the following command. This action lets you connect to the MySQL DB instance using the MySQL client.

   Substitute the DB instance endpoint (DNS name) for `endpoint`, and substitute the master username that you used for `admin`. Provide the master password that you used when prompted for a password.

   ```
   mysql -h endpoint -P 3306 -u admin -p
   ```

   After you enter the password for the user, you should see output similar to the following.

   ```
   Welcome to the MariaDB monitor. Commands end with ; or \g.
   Your MySQL connection id is 3082
   Server version: 8.0.28 Source distribution
   Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.
   Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.
   MySQL [(none)]>
   ```

   For more information about connecting to a MySQL DB instance, see [Connecting to a DB instance running the MySQL database engine](p. 1646). If you can't connect to your DB instance, see [Can't connect to Amazon RDS DB instance](p. 2744).

   For security, it is a best practice to use encrypted connections. Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see [Connecting from the MySQL command-line client with SSL/TLS (encrypted)](p. 1656).

6. Run SQL commands.

   For example, the following SQL command shows the current date and time:

   ```
   SELECT CURRENT_TIMESTAMP;
   ```
Step 4: Delete the EC2 instance and DB instance

After you connect to and explore the sample EC2 instance and DB instance that you created, delete them so you’re no longer charged for them.

**To delete the EC2 instance**

1. Sign in to the AWS Management Console and open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the EC2 instance, and choose **Instance state, Terminate instance**.
4. Choose **Terminate** when prompted for confirmation.

**To delete the DB instance with no final DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. Clear **Create final snapshot?** and **Retain automated backups**.
6. Complete the acknowledgement and choose **Delete**.

(Optional) Connect your DB instance to a Lambda function

You can also connect your RDS MySQL DB instance to a Lambda serverless compute resource. Lambda functions allow you to run code without provisioning or managing infrastructure. A Lambda function also allows you to automatically respond to code execution requests at any scale, from a dozen events a day to hundreds of per second. For more information, see [Automatically connecting a Lambda function and a DB instance](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/ConnectingLambdas.html) (p. 392).
Creating and connecting to an Oracle DB instance

This tutorial creates an EC2 instance and an RDS for Oracle DB instance. The tutorial shows you how to access the DB instance from the EC2 instance using a standard Oracle client. As a best practice, this tutorial creates a private DB instance in a virtual private cloud (VPC). In most cases, other resources in the same VPC, such as EC2 instances, can access the DB instance, but resources outside of the VPC can’t access it.

After you complete the tutorial, there is a public and private subnet in each Availability Zone in your VPC. In one Availability Zone, the EC2 instance is in the public subnet, and the DB instance is in the private subnet.

Important
There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

The following diagram shows the configuration when the tutorial is complete.

This tutorial uses Easy create to create a DB instance running Oracle with the AWS Management Console. With Easy create, you specify only the DB engine type, DB instance size, and DB instance identifier. Easy create uses the default settings for the other configuration options. The DB instance created by Easy create is private.

When you use Standard create instead of Easy create, you can specify more configuration options when you create a DB instance, including ones for availability, security, backups, and maintenance. To create a public DB instance, you must use Standard create. For information about creating DB instances with Standard create, see Creating an Amazon RDS DB instance (p. 300).

Topics
- Prerequisites (p. 223)
- Step 1: Create an EC2 instance (p. 223)
- Step 2: Create an Oracle DB instance (p. 226)
- Step 3: Connect your SQL client to an Oracle DB instance (p. 231)
- Step 4: Delete the EC2 instance and DB instance (p. 234)
- (Optional) Connect your DB instance to a Lambda function (p. 234)
Prerequisites

Before you begin, complete the steps in the following sections:

- Sign up for an AWS account (p. 174)
- Create an administrative user (p. 174)

Step 1: Create an EC2 instance

Create an Amazon EC2 instance that you will use to connect to your database.

To create an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the EC2 instance.
3. Choose EC2 Dashboard, and then choose Launch instance, as shown in the following image.
The **Launch an instance** page opens.

4. Choose the following settings on the **Launch an instance** page.

   a. Under **Name and tags**, for **Name**, enter `ec2-database-connect`.

   b. Under **Application and OS Images (Amazon Machine Image)**, choose **Amazon Linux**, and then choose the **Amazon Linux 2023 AMI**. Keep the default selections for the other choices.

   c. Under **Instance type**, choose **t2.micro**.

   d. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

   For more information about creating a new key pair, see **Create a key pair** in the **Amazon EC2 User Guide for Linux Instances**.

   e. For **Allow SSH traffic** in **Network settings**, choose the source of SSH connections to the EC2 instance.

   You can choose **My IP** if the displayed IP address is correct for SSH connections. Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at [https://checkip.amazonaws.com](https://checkip.amazonaws.com). An example of an IP address is 192.0.2.1/32.
Step 1: Create an EC2 instance

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

**Warning**

If you use 0.0.0.0/0 for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.

The following image shows an example of the **Network settings** section.

![Network settings section](image)

f. Leave the default values for the remaining sections.

g. Review a summary of your EC2 instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

5. On the **Launch Status** page, note the identifier for your new EC2 instance, for example: `i-1234567890abcdef0`. 

225
6. Choose the EC2 instance identifier to open the list of EC2 instances, and then select your EC2 instance.

7. In the Details tab, note the following values, which you need when you connect using SSH:
   a. In Instance summary, note the value for Public IPv4 DNS.
   b. In Instance details, note the value for Key pair name.

8. Wait until the Instance state for your EC2 instance has a status of Running before continuing.

**Step 2: Create an Oracle DB instance**

The basic building block of Amazon RDS is the DB instance. This environment is where you run your Oracle databases.
In this example, you use **Easy create** to create a DB instance running the Oracle database engine with a db.m5.large DB instance class.

**To create an Oracle DB instance with Easy create**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.

5. In **Configuration**, choose **Oracle**.
6. For **DB instance size**, choose **Dev/Test**.
7. For **DB instance identifier**, enter **database-test1**.
8. For **Master username**, enter a name for the master user, or keep the default name.

The **Create database** page should look similar to the following image.
Step 2: Create an Oracle DB instance

Configuration

- **Engine type**
  - Aurora (MySQL Compatible)
  - Aurora (PostgreSQL Compatible)
  - MySQL
  - MariaDB
  - PostgreSQL
  - Oracle
  - Microsoft SQL Server

- **Edition**
  - Oracle Enterprise Edition
    - Affordable and full-featured database management system supporting up to 16 vCPUs.
  - Oracle Standard Edition Two

- **DB instance size**
  - Production
    - db.r5.large
    - 2 vCPUs
    - 16 GB RAM
    - 500 GB
  - Dev/Test
    - db.m5.large
    - 2 vCPUs
    - 8 GB RAM
    - 100 GB

- **DB instance identifier**
  - Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in the current AWS Region.
  - database-test1
  - The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "myDbInstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

- **Master username**
  - Type a login ID for the master user of your DB instance.
  - admin
  - 1 to 16 alphanumeric characters. First character must be a letter.
9. To use an automatically generated master password for the DB instance, select **Auto generate a password**.

   To enter your master password, make sure **Auto generate a password** is cleared, and then enter the same password in **Master password** and **Confirm password**.

10. To set up a connection with the EC2 instance you created previously, open **Set up EC2 connection - optional**.

   Select **Connect to an EC2 compute resource**. Choose the EC2 instance you created previously.

   ![Set up EC2 connection - optional](image)

11. Open **View default settings for Easy create**.
You can examine the default settings used with Easy create. The Editable after database is created column shows which options you can change after you create the database.

- If a setting has No in that column, and you want a different setting, you can use Standard create to create the DB instance.
- If a setting has Yes in that column, and you want a different setting, you can either use Standard create to create the DB instance, or modify the DB instance after you create it to change the setting.

12. Choose Create database.

To view the master username and password for the DB instance, choose View credential details.

You can use the username and password that appears to connect to the DB instance as the master user.
Important
You can't view the master user password again. If you don't record it, you might have to change it.
If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401).

13. In the Databases list, choose the name of the new Oracle DB instance to show its details.

The DB instance has a status of Creating until it is ready to use.

<table>
<thead>
<tr>
<th>Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DB identifier</strong></td>
</tr>
<tr>
<td>database-test1</td>
</tr>
<tr>
<td><strong>Role</strong></td>
</tr>
<tr>
<td>Instance</td>
</tr>
</tbody>
</table>

When the status changes to Available, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available. While the DB instance is being created, you can move on to the next step and create an EC2 instance.

**Step 3: Connect your SQL client to an Oracle DB instance**

You can use any standard SQL client application to connect to your DB instance. In this example, you connect to an Oracle DB instance using the Oracle command-line client.

**To connect to an Oracle DB instance**

1. Find the endpoint (DNS name) and port number for your DB instance.
   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the upper-right corner of the Amazon RDS console, choose the AWS Region for the DB instance.
   c. In the navigation pane, choose Databases.
   d. Choose the Oracle DB instance name to display its details.
   e. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
2. Connect to the EC2 instance that you created earlier by following the steps in Connect to your Linux instance in the Amazon EC2 User Guide for Linux Instances.

We recommend that you connect to your EC2 instance using SSH. If the SSH client utility is installed on Windows, Linux, or Mac, you can connect to the instance using the following command format:

```bash
ssh -i location_of_pem_file ec2-user@ec2-instance-public-dns-name
```

For example, assume that ec2-database-connect-key-pair.pem is stored in /dir1 on Linux, and the public IPv4 DNS for your EC2 instance is ec2-12-345-678-90.compute-1.amazonaws.com. Your SSH command would look as follows:

```bash
ssh -i /dir1/ec2-database-connect-key-pair.pem ec2-user@ec2-12-345-678-90.compute-1.amazonaws.com
```

3. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do so, use the following command.

**Note**
The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

```bash
sudo dnf update -y
```

5. For the latest database version that appears on the web page, copy the .rpm links (not the .zip links) for the Instant Client Basic Package and SQL*Plus Package. For example, the following links are for Oracle Database version 21.9:
Step 3: Connect your SQL client to an Oracle DB instance

6. In your SSH session, run the `wget` command to download the `.rpm` files from the links that you obtained in the previous step. The following example downloads the `.rpm` files for Oracle Database version 21.9:

```bash
wget https://download.oracle.com/otn_software/linux/instantclient/219000/oracle-instantclient-basic-21.9.0.0.0-1.el8.x86_64.rpm
wget https://download.oracle.com/otn_software/linux/instantclient/219000/oracle-instantclient-sqlplus-21.9.0.0.0-1.el8.x86_64.rpm
```

7. Install the packages by running the `dnf` command as follows:

```bash
sudo dnf install oracle-instantclient-*.rpm
```

8. Start SQL*Plus and connect to the Oracle DB instance. For example, enter the following command.

```
sqlplus admin@oracle-db-instance-endpoint:1521/DATABASE
```

After you enter the password for the user, you should see output similar to the following.

```
SQL*Plus: Release 21.0.0.0.0 - Production on Wed Mar 1 16:41:28 2023
Version 21.9.0.0.0
Copyright (c) 1982, 2022, Oracle. All rights reserved.
Enter password:
Last Successful login time: Wed Mar 01 2023 16:30:52 +00:00
Connected to:
Oracle Database 19c Standard Edition 2 Release 19.0.0.0.0 - Production
Version 19.18.0.0.0
SQL>
```

For more information about connecting to an RDS for Oracle DB instance, see Connecting to your RDS for Oracle DB instance (p. 1822). If you can't connect to your DB instance, see Can't connect to Amazon RDS DB instance (p. 2744).

For security, it is a best practice to use encrypted connections. Only use an unencrypted Oracle connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Securing Oracle DB instance connections (p. 1832).

9. Run SQL commands.

For example, the following SQL command shows the current date:

```
SELECT SYSDATE FROM DUAL;
```
Step 4: Delete the EC2 instance and DB instance

After you connect to and explore the sample EC2 instance and DB instance that you created, delete them so you're no longer charged for them.

To delete the EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the EC2 instance, and choose Instance state, Terminate instance.
4. Choose Terminate when prompted for confirmation.

For more information about deleting an EC2 instance, see Terminate your instance in the Amazon EC2 User Guide for Linux Instances.

To delete the DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to delete.
4. For Actions, choose Delete.
6. Complete the acknowledgement and choose Delete.

(Optional) Connect your DB instance to a Lambda function

You can also connect your RDS for Oracle DB instance to a Lambda serverless compute resource. Lambda functions allow you to run code without provisioning or managing infrastructure. A Lambda function also allows you to automatically respond to code execution requests at any scale, from a dozen events a day to hundreds of per second. For more information, see Automatically connecting a Lambda function and a DB instance (p. 392).
Creating and connecting to a PostgreSQL DB instance

This tutorial creates an EC2 instance and an RDS for PostgreSQL DB instance. The tutorial shows you how to access the DB instance from the EC2 instance using a standard PostgreSQL client. As a best practice, this tutorial creates a private DB instance in a virtual private cloud (VPC). In most cases, other resources in the same VPC, such as EC2 instances, can access the DB instance, but resources outside of the VPC can't access it.

After you complete the tutorial, there is a public and private subnet in each Availability Zone in your VPC. In one Availability Zone, the EC2 instance is in the public subnet, and the DB instance is in the private subnet.

Important
There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

The following diagram shows the configuration when the tutorial is complete.

This tutorial uses Easy create to create a DB instance running PostgreSQL with the AWS Management Console. With Easy create, you specify only the DB engine type, DB instance size, and DB instance identifier. Easy create uses the default settings for the other configuration options. The DB instance created by Easy create is private.

When you use Standard create instead of Easy create, you can specify more configuration options when you create a DB instance, including ones for availability, security, backups, and maintenance. To create a public DB instance, you must use Standard create. For information about creating DB instances with Standard create, see Creating an Amazon RDS DB instance (p. 300).

Topics
- Prerequisites (p. 236)
- Step 1: Create an EC2 instance (p. 236)
- Step 2: Create a PostgreSQL DB instance (p. 240)
- Step 3: Connect to a PostgreSQL DB instance (p. 245)
Prerequisites

Before you begin, complete the steps in the following sections:

- [Sign up for an AWS account](#) (p. 174)
- [Create an administrative user](#) (p. 174)

Step 1: Create an EC2 instance

Create an Amazon EC2 instance that you will use to connect to your database.

To create an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the EC2 instance.
3. Choose **EC2 Dashboard**, and then choose **Launch instance**, as shown in the following image.
The Launch an instance page opens.

4. Choose the following settings on the Launch an instance page.
   a. Under Name and tags, for Name, enter `ec2-database-connect`.
   b. Under Application and OS Images (Amazon Machine Image), choose Amazon Linux, and then choose the Amazon Linux 2023 AMI. Keep the default selections for the other choices.
c. Under **Instance type**, choose **t2.micro**.

d. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

For more information about creating a new key pair, see [Create a key pair](#) in the [Amazon EC2 User Guide for Linux Instances](#).

e. For **Allow SSH traffic in Network settings**, choose the source of SSH connections to the EC2 instance.

You can choose **My IP** if the displayed IP address is correct for SSH connections. Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at [https://checkip.amazonaws.com](https://checkip.amazonaws.com). An example of an IP address is 192.0.2.1/32.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

**Warning**

If you use 0.0.0.0/0 for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.
f. Leave the default values for the remaining sections.
g. Review a summary of your EC2 instance configuration in the Summary panel, and when you're ready, choose Launch instance.

5. On the Launch Status page, note the identifier for your new EC2 instance, for example: `i-1234567890abcdef0`. 
6. Choose the EC2 instance identifier to open the list of EC2 instances, and then select your EC2 instance.

7. In the Details tab, note the following values, which you need when you connect using SSH:
   a. In Instance summary, note the value for Public IPv4 DNS.
   b. In Instance details, note the value for Key pair name.

8. Wait until the Instance state for your EC2 instance has a status of Running before continuing.

Step 2: Create a PostgreSQL DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your PostgreSQL databases.
In this example, you use Easy create to create a DB instance running the PostgreSQL database engine with a db.t3.micro DB instance class.

**To create a PostgreSQL DB instance with Easy create**

1. Sign in to the AWS Management Console and open the Amazon RDS console at `https://console.aws.amazon.com/rds/`.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose Databases.
4. Choose Create database and make sure that Easy create is chosen.
5. In Configuration, choose PostgreSQL.
6. For DB instance size, choose Free tier.
7. For DB instance identifier, enter database-test1.
8. For Master username, enter a name for the master user, or keep the default name (postgres).

The Create database page should look similar to the following image.
9. To use an automatically generated master password for the DB instance, select **Auto generate a password**.

   To enter your master password, make sure **Auto generate a password** is cleared, and then enter the same password in **Master password** and **Confirm password**.

10. To set up a connection with the EC2 instance you created previously, open **Set up EC2 connection - optional**.

    Select **Connect to an EC2 compute resource**. Choose the EC2 instance you created previously.
11. Open View default settings for Easy create.
View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use Standard create.

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Value</th>
<th>Editable after database is created</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encryption</td>
<td>Enabled</td>
<td>No</td>
</tr>
<tr>
<td>VPC</td>
<td>Default VPC (vpc-1a2b3c4d)</td>
<td>No</td>
</tr>
<tr>
<td>Option group</td>
<td>default:postgres-14</td>
<td>No</td>
</tr>
<tr>
<td>Subnet group</td>
<td>default</td>
<td>Yes</td>
</tr>
<tr>
<td>Automatic backups</td>
<td>Enabled</td>
<td>Yes</td>
</tr>
<tr>
<td>VPC security group</td>
<td>sg-1234567</td>
<td>Yes</td>
</tr>
<tr>
<td>Publicly accessible</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Database port</td>
<td>5432</td>
<td>Yes</td>

<tr>
<td>Maintenance</td>
<td>Auto minor version upgrade enabled</td>
<td>Yes</td>
</tr>
<tr>
<td>Delete protection</td>
<td>Not enabled</td>
<td>Yes</td>
</tr>
</tbody>
</table>

You can examine the default settings used with Easy create. The Editable after database is created column shows which options you can change after you create the database.

- If a setting has No in that column, and you want a different setting, you can use Standard create to create the DB instance.
- If a setting has Yes in that column, and you want a different setting, you can either use Standard create to create the DB instance, or modify the DB instance after you create it to change the setting.

12. Choose Create database.

To view the master username and password for the DB instance, choose View credential details.

You can use the username and password that appears to connect to the DB instance as the master user.
Step 3: Connect to a PostgreSQL DB instance

You can connect to the DB instance using pgadmin or psql. This example explains how to connect to a PostgreSQL DB instance using the psql command-line client.

To connect to a PostgreSQL DB instance using psql

1. Find the endpoint (DNS name) and port number for your DB instance.
   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the upper-right corner of the Amazon RDS console, choose the AWS Region for the DB instance.
   c. In the navigation pane, choose Databases.
   d. Choose the PostgreSQL DB instance name to display its details.
   e. On the Connectivity & security tab, copy the endpoint. Also note the port number. You need both the endpoint and the port number to connect to the DB instance.
Step 3: Connect to a PostgreSQL DB instance

2. Connect to the EC2 instance that you created earlier by following the steps in Connect to your Linux instance in the Amazon EC2 User Guide for Linux Instances.

We recommend that you connect to your EC2 instance using SSH. If the SSH client utility is installed on Windows, Linux, or Mac, you can connect to the instance using the following command format:

```bash
ssh -i location_of_pem_file ec2-user@ec2-instance-public-dns-name
```
For example, assume that `ec2-database-connect-key-pair.pem` is stored in `/dir1` on Linux, and the public IPv4 DNS for your EC2 instance is `ec2-12-345-678-90.compute-1.amazonaws.com`. Your SSH command would look as follows:

```
ssh -i /dir1/ec2-database-connect-key-pair.pem ec2-user@ec2-12-345-678-90.compute-1.amazonaws.com
```

3. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do this, use the following command.

**Note**
The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

```
sudo dnf update -y
```

4. To install the `psql` command-line client from PostgreSQL on Amazon Linux 2023, run the following command:

```
sudo dnf install postgresql15
```

5. Connect to the PostgreSQL DB instance. For example, enter the following command at a command prompt on a client computer. This action lets you connect to the PostgreSQL DB instance using the `psql` client.

```
psql --host=endpoint --port=5432 --dbname=postgres --username=postgres
```

After you enter the password for the user, you should see output similar to the following:

```
psql (14.3, server 14.6)
Type "help" for help.
postgres=>
```

For more information on connecting to a PostgreSQL DB instance, see [Connecting to a DB instance running the PostgreSQL database engine](p. 2184). If you can't connect to your DB instance, see [Troubleshooting connections to your RDS for PostgreSQL instance](p. 2189).

For security, it is a best practice to use encrypted connections. Only use an unencrypted PostgreSQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see [Connecting to a PostgreSQL DB instance over SSL](p. 2191).

6. Run SQL commands.

For example, the following SQL command shows the current date and time:

```
SELECT CURRENT_TIMESTAMP;
```
Step 4: Delete the EC2 instance and DB instance

After you connect to and explore the sample EC2 instance and DB instance that you created, delete them so you’re no longer charged for them.

To delete the EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the EC2 instance, and choose Instance state, Terminate instance.
4. Choose Terminate when prompted for confirmation.

For more information about deleting an EC2 instance, see Terminate your instance in the Amazon EC2 User Guide for Linux Instances.

To delete a DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to delete.
4. For Actions, choose Delete.
6. Complete the acknowledgement and choose Delete.

(Optional) Connect your DB instance to a Lambda function

You can also connect your RDS for PostgreSQL DB instance to a Lambda serverless compute resource. Lambda functions allow you to run code without provisioning or managing infrastructure. A Lambda function also allows you to automatically respond to code execution requests at any scale, from a dozen events a day to hundreds of per second. For more information, see Automatically connecting a Lambda function and a DB instance (p. 392).
Tutorial: Create a web server and an Amazon RDS DB instance

This tutorial shows you how to install an Apache web server with PHP and create a MySQL or PostgreSQL database. The web server runs on an Amazon EC2 instance using Amazon Linux 2023, and you can choose between a MySQL or PostgreSQL DB instance. Both the Amazon EC2 instance and the DB instance run in a virtual private cloud (VPC) based on the Amazon VPC service.

Important
There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

Note
This tutorial works with Amazon Linux 2023 and might not work for other versions of Linux.

In the tutorial that follows, you create an EC2 instance that uses the default VPC, subnets, and security group for your AWS account. This tutorial shows you how to create the DB instance and automatically set up connectivity with the EC2 instance that you created. The tutorial then shows you how to install the web server on the EC2 instance. You connect your web server to your DB instance in the VPC using the DB instance endpoint.

1. Launch an EC2 instance (p. 250)
2. Create an Amazon RDS DB instance (p. 255)
3. Install a web server on your EC2 instance (p. 264)

The following diagram shows the configuration when the tutorial is complete.
Launch an EC2 instance

Create an Amazon EC2 instance in the public subnet of your VPC.

**To launch an EC2 instance**

1. Sign in to the AWS Management Console and open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the upper-right corner of the AWS Management Console, choose the AWS Region where you want to create the EC2 instance.
3. Choose EC2 Dashboard, and then choose Launch instance, as shown following.
4. Choose the following settings in the **Launch an instance** page.
   
   a. Under **Name and tags**, for **Name**, enter `tutorial-ec2-instance-web-server`.
   
   b. Under **Application and OS Images (Amazon Machine Image)**, choose **Amazon Linux**, and then choose the **Amazon Linux 2023 AMI**. Keep the defaults for the other choices.
c. Under **Instance type**, choose **t2.micro**.

d. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

For more information about creating a new key pair, see [Create a key pair](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/) in the *Amazon EC2 User Guide for Linux Instances*.

e. Under **Network settings**, set these values and keep the other values as their defaults:

- **Allow SSH traffic from**, choose the source of SSH connections to the EC2 instance.

You can choose **My IP** if the displayed IP address is correct for SSH connections.

Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at [https://checkip.amazonaws.com](https://checkip.amazonaws.com). An example of an IP address is `203.0.113.25/32`.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

**Warning**

If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time...
in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

- Turn on **Allow HTTPS traffic from the internet**.
- Turn on **Allow HTTP traffic from the internet**.

f. Leave the default values for the remaining sections.

g. Review a summary of your instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

5. On the **Launch Status** page, note the identifier for your new EC2 instance, for example: `i-1234567890abcdef0`. 
6. Choose the EC2 instance identifier to open the list of EC2 instances, and then select your EC2 instance.

7. In the Details tab, note the following values, which you need when you connect using SSH:
   a. In Instance summary, note the value for Public IPv4 DNS.

   ![Image of Instance summary]

   - Instance ID: i-1234567890abcdef0
   - Public IPv4 address: xxx.xxx.xxx.xxx
   - Public IPv4 DNS: ec2-12-345-67-890.compute-1.amazonaws.com

   ![Image of Instance details]

   - AMI Launch index: 0
   - Key pair name: ec2-database-connect-key-pair

   b. In Instance details, note the value for Key pair name.

8. Wait until Instance state for your instance is Running before continuing.

Create an Amazon RDS DB instance

Create an RDS for MySQL or RDS for PostgreSQL DB instance that maintains the data used by a web application.

RDS for MySQL

**To create a MySQL DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the upper-right corner of the AWS Management Console, check the AWS Region. It should be the same as the one where you created your EC2 instance.
3. In the navigation pane, choose Databases.
4. Choose Create database.
5. On the Create database page, choose Standard create.
6. For Engine options, choose MySQL.
7. For Templates, choose Free tier.

Your DB instance configuration should look similar to the following image.
8. In the Availability and durability section, keep the defaults.

9. In the Settings section, set these values:
   - DB instance identifier – Type `tutorial-db-instance`.
   - Master username – Type `tutorial_user`.
   - Auto generate a password – Leave the option turned off.
   - Master password – Type a password.
   - Confirm password – Retype the password.
10. In the **Instance configuration** section, set these values:

   - **Burstable classes (includes t classes)**
   - **db.t3.micro**

11. In the **Storage** section, keep the defaults.

12. In the **Connectivity** section, set these values and keep the other values as their defaults:
- For **Compute resource**, choose **Connect to an EC2 compute resource**.
- For **EC2 instance**, choose the EC2 instance you created previously, such as `tutorial-ec2-instance-web-server`.

13. In the **Database authentication** section, make sure **Password authentication** is selected.
14. Open the **Additional configuration** section, and enter `sample` for **Initial database name**. Keep the default settings for the other options.
15. To create your MySQL DB instance, choose **Create database**.

Your new DB instance appears in the **Databases** list with the status **Creating**.
16. Wait for the **Status** of your new DB instance to show as **Available**. Then choose the DB instance name to show its details.
17. In the **Connectivity & security** section, view the **Endpoint** and **Port** of the DB instance.
Note the endpoint and port for your DB instance. You use this information to connect your web server to your DB instance.

18. Complete Install a web server on your EC2 instance (p. 264).

RDS for PostgreSQL

To create a PostgreSQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, check the AWS Region. It should be the same as the one where you created your EC2 instance.
3. In the navigation pane, choose Databases.
4. Choose Create database.
5. On the Create database page, choose Standard create.
6. For Engine options, choose PostgreSQL.
7. For Templates, choose Free tier.
Your DB instance configuration should look similar to the following image.
8. In the **Availability and durability** section, keep the defaults.

9. In the **Settings** section, set these values:
   - **DB instance identifier** – Type *tutorial-db-instance*.
   - **Master username** – Type *tutorial_user*.
   - **Auto generate a password** – Leave the option turned off.
   - **Master password** – Type a password.
   - **Confirm password** – Retype the password.

![Settings](image)

10. In the **Instance configuration** section, set these values:
   - **Burstable classes (includes t classes)**
   - **db.t3.micro**
11. In the **Storage** section, keep the defaults.

12. In the **Connectivity** section, set these values and keep the other values as their defaults:
   - For **Compute resource**, choose **Connect to an EC2 compute resource**.
   - For **EC2 instance**, choose the EC2 instance you created previously, such as `tutorial-ec2-instance-web-server`.

13. In the **Database authentication** section, make sure **Password authentication** is selected.

14. Open the **Additional configuration** section, and enter `sample` for **Initial database name**. Keep the default settings for the other options.
15. To create your PostgreSQL DB instance, choose **Create database**. Your new DB instance appears in the **Databases** list with the status **Creating**.

16. Wait for the **Status** of your new DB instance to show as **Available**. Then choose the DB instance name to show its details.

17. In the **Connectivity & security** section, view the **Endpoint** and **Port** of the DB instance.

![DB instance details](image)

Note the endpoint and port for your DB instance. You use this information to connect your web server to your DB instance.

18. Complete **Install a web server on your EC2 instance (p. 264)**.

### Install a web server on your EC2 instance

Install a web server on the EC2 instance you created in **Launch an EC2 instance (p. 250)**. The web server connects to the Amazon RDS DB instance that you created in **Create an Amazon RDS DB instance (p. 255)**.
Install an Apache web server with PHP and MariaDB

Connect to your EC2 instance and install the web server.

**To connect to your EC2 instance and install the Apache web server with PHP**

1. Connect to the EC2 instance that you created earlier by following the steps in [Connect to your Linux instance](#) in the Amazon EC2 User Guide for Linux Instances.

   We recommend that you connect to your EC2 instance using SSH. If the SSH client utility is installed on Windows, Linux, or Mac, you can connect to the instance using the following command format:

   ```
   ssh -i location_of_pem_file ec2-user@ec2-instance-public-dns-name
   ```

   For example, assume that `ec2-database-connect-key-pair.pem` is stored in `/dir1` on Linux, and the public IPv4 DNS for your EC2 instance is `ec2-12-345-678-90.compute-1.amazonaws.com`. Your SSH command would look as follows:

   ```
   ssh -i /dir1/ec2-database-connect-key-pair.pem ec2-user@ec2-12-345-678-90.compute-1.amazonaws.com
   ```

2. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do this, use the following command.

   **Note**
   The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

   ```
   sudo dnf update -y
   ```

3. After the updates complete, install the Apache web server, PHP, and MariaDB or PostgreSQL software using the following commands. This command installs multiple software packages and related dependencies at the same time.

   **MySQL**

   ```
   sudo dnf install -y httpd php php-mysqli mariadb105
   ```

   **PostgreSQL**

   ```
   sudo dnf install -y httpd php php-pgsql postgresql15
   ```

   If you receive an error, your instance probably wasn't launched with an Amazon Linux 2023 AMI. You might be using the Amazon Linux 2 AMI instead. You can view your version of Amazon Linux using the following command.

   ```
   cat /etc/system-release
   ```

   For more information, see [Updating instance software](#).

4. Start the web server with the command shown following.

   ```
   sudo systemctl start httpd
   ```
You can test that your web server is properly installed and started. To do this, enter the public Domain Name System (DNS) name of your EC2 instance in the address bar of a web browser, for example: http://ec2-42-8-168-21.us-west-1.compute.amazonaws.com. If your web server is running, then you see the Apache test page.

If you don’t see the Apache test page, check your inbound rules for the VPC security group that you created in Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2723). Make sure that your inbound rules include one allowing HTTP (port 80) access for the IP address to connect to the web server.

Note
The Apache test page appears only when there is no content in the document root directory, /var/www/html. After you add content to the document root directory, your content appears at the public DNS address of your EC2 instance. Before this point, it appears on the Apache test page.

5. Configure the web server to start with each system boot using the systemctl command.

```
sudo systemctl enable httpd
```

To allow ec2-user to manage files in the default root directory for your Apache web server, modify the ownership and permissions of the /var/www directory. There are many ways to accomplish this task. In this tutorial, you add ec2-user to the apache group, to give the apache group ownership of the /var/www directory and assign write permissions to the group.

**To set file permissions for the Apache web server**

1. Add the ec2-user user to the apache group.

```
sudo usermod -a -G apache ec2-user
```

2. Log out to refresh your permissions and include the new apache group.

```
exit
```

3. Log back in again and verify that the apache group exists with the groups command.

```
groups
```

Your output looks similar to the following:

```
ec2-user adm wheel apache systemd-journal
```

4. Change the group ownership of the /var/www directory and its contents to the apache group.

```
sudo chown -R ec2-user:apache /var/www
```

5. Change the directory permissions of /var/www and its subdirectories to add group write permissions and set the group ID on subdirectories created in the future.

```
sudo chmod 2775 /var/www
find /var/www -type d -exec sudo chmod 2775 {} \;
```

6. Recursively change the permissions for files in the /var/www directory and its subdirectories to add group write permissions.
Install a web server

```sh
find /var/www -type f -exec sudo chmod 0664 {} \;
```

Now, `ec2-user` (and any future members of the `apache` group) can add, delete, and edit files in the Apache document root. This makes it possible for you to add content, such as a static website or a PHP application.

**Note**
A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, much information is visible to eavesdroppers anywhere along the network pathway. This information includes the URLs that you visit, the content of web pages that you receive, and the contents (including passwords) of any HTML forms.

The best practice for securing your web server is to install support for HTTPS (HTTP Secure). This protocol protects your data with SSL/TLS encryption. For more information, see Tutorial: Configure SSL/TLS with the Amazon Linux AMI in the Amazon EC2 User Guide.

**Connect your Apache web server to your DB instance**

Next, you add content to your Apache web server that connects to your Amazon RDS DB instance.

**To add content to the Apache web server that connects to your DB instance**

1. While still connected to your EC2 instance, change the directory to `/var/www` and create a new subdirectory named `inc`.

   ```sh
cd /var/www
mkdir inc
cd inc
```

2. Create a new file in the `inc` directory named `dbinfo.inc`, and then edit the file by calling nano (or the editor of your choice).

   ```
   >dbinfo.inc
   nano dbinfo.inc
   ```

3. Add the following contents to the `dbinfo.inc` file. Here, `db_instance_endpoint` is your DB instance endpoint, without the port, for your DB instance.

   **Note**
   We recommend placing the user name and password information in a folder that isn't part of the document root for your web server. Doing this reduces the possibility of your security information being exposed.
   Make sure to change `master password` to a suitable password in your application.

   ```php
   <?php
   define('DB_SERVER', 'db_instance_endpoint');
   define('DB_USERNAME', 'tutorial_user');
   define('DB_PASSWORD', 'master password');
   define('DB_DATABASE', 'sample');
   ?>
   ```

4. Save and close the `dbinfo.inc` file. If you are using nano, save and close the file by using Ctrl+S and Ctrl+X.

5. Change the directory to `/var/www/html`.
cd /var/www/html

6. Create a new file in the html directory named SamplePage.php, and then edit the file by calling nano (or the editor of your choice).

   >SamplePage.php
   nano SamplePage.php

7. Add the following contents to the SamplePage.php file:

MySQL

```php
<?php include "../inc/dbinfo.inc"; ?>
<html>
<body>
<h1>Sample page</h1>
<?php
/* Connect to MySQL and select the database. */
$connection = mysqli_connect(DB_SERVER, DB_USERNAME, DB_PASSWORD);
if (mysqli_connect_errno()) echo "Failed to connect to MySQL: " .
mysqli_connect_error();
$database = mysqli_select_db($connection, DB_DATABASE);
/* Ensure that the EMPLOYEES table exists. */
VerifyEmployeesTable($connection, DB_DATABASE);
/* If input fields are populated, add a row to the EMPLOYEES table. */
$employee_name = htmlspecialchars($_POST['NAME']);
$employee_address = htmlspecialchars($_POST['ADDRESS']);
if (strlen($employee_name) && strlen($employee_address)) {
   AddEmployee($connection, $employee_name, $employee_address);
}
?>
<!-- Input form -->
<form action="<?PHP echo $_SERVER['SCRIPT_NAME'] ?>" method="POST">
<table border="0">
   <tr>
      <td>NAME</td>
      <td>ADDRESS</td>
   </tr>
   <tr>
      <td>
         <input type="text" name="NAME" maxlength="45" size="30" />
      </td>
      <td>
         <input type="text" name="ADDRESS" maxlength="90" size="60" />
      </td>
      <td>
         <input type="submit" value="Add Data" />
      </td>
   </tr>
</table>
</form>
<!-- Display table data. -->
<table border="1" cellpadding="2" cellspacing="2">
   <tr>
```

268
<?php
$result = mysqli_query($connection, "SELECT * FROM EMPLOYEES");
while($query_data = mysqli_fetch_row($result)) {
    echo "<tr>",
    echo "<td>".$query_data[0]."</td>",
    echo "<td>".$query_data[1]."</td>",
    echo "<td>".$query_data[2]."</td>";
    echo "</tr>";
}?>
</table>
<!-- Clean up. -->
<?php
mysqli_free_result($result);
mysqli_close($connection);
?>
</body>
</html>

<?php
/* Add an employee to the table. */
function AddEmployee($connection, $name, $address) {
    $n = mysqli_real_escape_string($connection, $name);
    $a = mysqli_real_escape_string($connection, $address);
    $query = "INSERT INTO EMPLOYEES (NAME, ADDRESS) VALUES ('$n', '$a');";
    if(!mysqli_query($connection, $query)) echo("<p>Error adding employee data.</p>" );
}

/* Check whether the table exists and, if not, create it. */
function VerifyEmployeesTable($connection, $dbName) {
    if(!TableExists("EMPLOYEES", $connection, $dbName)) {
        $query = "CREATE TABLE EMPLOYEES (ID int(11) UNSIGNED AUTO_INCREMENT PRIMARY KEY, NAME VARCHAR(45), ADDRESS VARCHAR(90) )";
        if(!mysqli_query($connection, $query)) echo("<p>Error creating table.</p>");
    }
}

/* Check for the existence of a table. */
function TableExists($tableName, $connection, $dbName) {
    $t = mysqli_real_escape_string($connection, $tableName);
    $d = mysqli_real_escape_string($connection, $dbName);
    $checktable = mysqli_query($connection, "SELECT * FROM "$t" WHERE "database" = ""$d""");
    if($checktable) {
        echo("<p>Table exists.</p>" );
    }
}
POSTGRESQL

<?php include '../inc/dbinfo.inc'; ?>

<html>
<body>
<h1>Sample page</h1>

<?php

/* Connect to PostgreSQL and select the database. */
$conn = pg_connect($constring);

if (!$conn)
    echo "Failed to connect to PostgreSQL";
    exit;
}

/* Ensure that the EMPLOYEES table exists. */
VerifyEmployeesTable($conn, DB_DATABASE);

/* If input fields are populated, add a row to the EMPLOYEES table. */
$employee_name = htmlentities($_POST['NAME']);
$employee_address = htmlentities($_POST['ADDRESS']);

if (strlen($employee_name) || strlen($employee_address)) {
    AddEmployee($conn, $employee_name, $employee_address);
}

?>

<!-- Input form -->

<form action="<?php echo $_SERVER['SCRIPT_NAME'] ?>" method="POST">
<table border="0">
    <tr>
        <td>NAME</td>
        <td>ADDRESS</td>
    </tr>
    <tr>
        <td>NAME</td>
        <td>ADDRESS</td>
    </tr>
    <tr>
        <td>
            <input type="text" name="NAME" maxlength="45" size="30" />
        </td>
        <td>
            <input type="text" name="ADDRESS" maxlength="90" size="60" />
        </td>
        <td>
            <input type="submit" value="Add Data" />
        </td>
    </tr>
</table>
</form>

<!-- Display table data. -->
<table border="1" cellspacing="2">
    <!-- Table content -->
</table>

270
<?php
$result = pg_query($connection, "SELECT * FROM EMPLOYEES");

while($query_data = pg_fetch_row($result)) {
    echo "<tr>",
    echo "<td>" ,$query_data[0], "</td>",
    echo "<td>" ,$query_data[1], "</td>",
    echo "<td>" ,$query_data[2], "</td>",
    echo "</tr>";
}

<?php
pg_free_result($result);
pg_close($connection);
?>
</body>
</html>

<?php
/* Add an employee to the table. */
function AddEmployee($connection, $name, $address) {
    $n = pg_escape_string($name);
    $a = pg_escape_string($address);
    echo "Forming Query";
    $query = "INSERT INTO EMPLOYEES (NAME, ADDRESS) VALUES ('$n', '$a');";
    if(!pg_query($connection, $query)) echo("<p>Error adding employee data.</p>");}

/* Check whether the table exists and, if not, create it. */
function VerifyEmployeesTable($connection, $dbName) {
    if(!TableExists("EMPLOYEES", $connection, $dbName)) {
        $query = "CREATE TABLE EMPLOYEES (ID serial PRIMARY KEY,
                                           NAME VARCHAR(45),
                                           ADDRESS VARCHAR(90))";
        if(!pg_query($connection, $query)) echo("<p>Error creating table.</p>");}

/* Check for the existence of a table. */
function TableExists($tableName, $connection, $dbName) {
    $t = strtolower(pg_escape_string($tableName)); //table name is case sensitive
    $d = pg_escape_string($dbName); //schema is 'public' instead of 'sample' db name
    $query = "SELECT TABLE_NAME FROM information_schema.TABLES WHERE TABLE_NAME = '" . $t . '";
    $checktable = pg_query($connection, $query);
    if (pg_num_rows($checktable) > 0) return true;
return false;
}
?>

8. Save and close the SamplePage.php file.

You can use SamplePage.php to add data to your DB instance. The data that you add is then displayed on the page. To verify that the data was inserted into the table, install MySQL client on the Amazon EC2 instance. Then connect to the DB instance and query the table.

For information about installing the MySQL client and connecting to a DB instance, see Connecting to a DB instance running the MySQL database engine (p. 1646).

To make sure that your DB instance is as secure as possible, verify that sources outside of the VPC can't connect to your DB instance.

After you have finished testing your web server and your database, you should delete your DB instance and your Amazon EC2 instance.

• To delete a DB instance, follow the instructions in Deleting a DB instance (p. 489). You don't need to create a final snapshot.
• To terminate an Amazon EC2 instance, follow the instruction in Terminate your instance in the Amazon EC2 User Guide.
Tutorial: Using a Lambda function to access an Amazon RDS database

In this tutorial, you use a Lambda function to write data to an Amazon Relational Database Service (Amazon RDS) database through RDS Proxy. Your Lambda function reads records from an Amazon Simple Queue Service (Amazon SQS) queue and writes a new item to a table in your database whenever a message is added. In this example, you use the AWS Management Console to manually add messages to your queue. The following diagram shows the AWS resources you use to complete the tutorial.

With Amazon RDS, you can run a managed relational database in the cloud using common database products like Microsoft SQL Server, MariaDB, MySQL, Oracle Database, and PostgreSQL. By using Lambda to access your database, you can read and write data in response to events, such as a new customer registering with your website. Your function, database instance, and proxy scale automatically to meet periods of high demand.

To complete this tutorial, you carry out the following tasks:

1. Launch an RDS for MySQL database instance and a proxy in your AWS account's default VPC.
2. Create and test a Lambda function that creates a new table in your database and writes data to it.
3. Create an Amazon SQS queue and configure it to invoke your Lambda function whenever a new message is added.
4. Test the complete setup by adding messages to your queue using the AWS Management Console and monitoring the results using CloudWatch Logs.

By completing these steps, you learn:

- How to use Amazon RDS to create a database instance and a proxy, and connect a Lambda function to the proxy.
- How to use Lambda to perform create and read operations on an Amazon RDS database.
- How to use Amazon SQS to invoke a Lambda function.

You can complete this tutorial using the AWS Management Console or the AWS Command Line Interface (AWS CLI).
Prerequisites

Before you begin, complete the steps in the following sections:

- Sign up for an AWS account (p. 174)
- Create an administrative user (p. 174)

Create an Amazon RDS DB instance

An Amazon RDS DB instance is an isolated database environment running in the AWS Cloud. An instance can contain one or more user-created databases. Unless you specify otherwise, Amazon RDS creates new database instances in the default VPC included in your AWS account. For more information about Amazon VPC, see the Amazon Virtual Private Cloud User Guide.

In this tutorial, you create a new instance in your AWS account's default VPC and create a database named ExampleDB in that instance. You can create your DB instance and database using either the AWS Management Console or the AWS CLI.

To create a database instance

1. Open the Amazon RDS console and choose Create database.
2. Leave the Standard create option selected, then in Engine options, choose MySQL.
3. In Templates, choose Free tier.
4. In Settings, for DB instance identifier, enter MySQLForLambda.
5. Set your username and password by doing the following:
   a. In Credentials settings, leave Master username set to admin.
   b. For Master password, enter and confirm a password to access your database.
6. Specify the database name by doing the following:
   • Leave all the remaining default options selected and scroll down to the Additional configuration section.
   • Expand this section and enter ExampleDB as the Initial database name.
7. Leave all the remaining default options selected and choose Create database.
Create Lambda function and proxy

You can use the RDS console to create a Lambda function and a proxy in the same VPC as the database.

**Note**
You can only create these associated resources when your database has completed creation and is in **Available** status.

**To create an associated function and proxy**

1. From the **Databases** page, check if your database is in the **Available** status. If so, proceed to the next step. Else, wait till your database is available.
2. Select your database and choose **Set up Lambda connection** from **Actions**.
3. In the **Set up Lambda connection** page, choose **Create new function**.

   - Set the **New Lambda function name** to **LambdaFunctionWithRDS**.
4. In the **RDS Proxy** section, select the **Connect using RDS Proxy** option. Further choose **Create new proxy**.
   - For **Database credentials**, choose **Database username and password**.
   - For **Username**, specify **admin**.
   - For **Password**, enter the password you created for your database instance.
5. Select **Set up** to complete the proxy and Lambda function creation.

The wizard completes the set up and provides a link to the Lambda console to review your new function. Note the proxy endpoint before switching to the Lambda console.

Create a function execution role

Before you create your Lambda function, you create an execution role to give your function the necessary permissions. For this tutorial, Lambda needs permission to manage the network connection to the VPC containing your database instance and to poll messages from an Amazon SQS queue.

To give your Lambda function the permissions it needs, this tutorial uses IAM managed policies. These are policies that grant permissions for many common use cases and are available in your AWS account. For more information about using managed policies, see **Policy best practices** (p. 2633).
To create the Lambda execution role

1. Open the Roles page of the IAM console and choose Create role.
2. For the Trusted entity type, choose AWS service, and for the Use case, choose Lambda.
3. Choose Next.
4. Add the IAM managed policies by doing the following:
   a. Using the policy search box, search for AWSLambdaSQSQueueExecutionRole.
   b. In the results list, select the check box next to the role, then choose Clear filters.
   c. Using the policy search box, search for AWSLambdaVPCAccessExecutionRole.
   d. In the results list, select the check box next to the role, then choose Next.
5. For the Role name, enter lambda-vpc-sqs-role, then choose Create role.

Later in the tutorial, you need the Amazon Resource Name (ARN) of the execution role you just created.

To find the execution role ARN

1. Open the Roles page of the IAM console and choose your role (lambda-vpc-sqs-role).
2. Copy the ARN displayed in the Summary section.

Create a Lambda deployment package

The following example Python code uses the PyMySQL package to open a connection to your database. The first time you invoke your function, it also creates a new table called Customer. The table uses the following schema, where CustID is the primary key:

| Customer(CustID, Name) |

The function also uses PyMySQL to add records to this table. The function adds records using customer IDs and names specified in messages you will add to your Amazon SQS queue.

The code creates the connection to your database outside of the handler function. Creating the connection in the initialization code allows the connection to be re-used by subsequent invocations of your function and improves performance. In a production application, you can also use provisioned concurrency to initialize a requested number of database connections. These connections are available as soon as your function is invoked.

```python
import sys
import logging
import pymysql
import json
import os
```
Create a Lambda deployment package

```python
# rds settings
user_name = os.environ['USER_NAME']
password = os.environ['PASSWORD']
rds_proxy_host = os.environ['RDS_PROXY_HOST']
db_name = os.environ['DB_NAME']

logger = logging.getLogger()
logger.setLevel(logging.INFO)

# create the database connection outside of the handler to allow connections to be
# re-used by subsequent function invocations.
try:
    conn = pymysql.connect(host=rds_proxy_host, user=user_name, passwd=password,
                        db=db_name, connect_timeout=5)
except pymysql.MySQLError as e:
    logger.error("ERROR: Unexpected error: Could not connect to MySQL instance.")
    logger.error(e)
    sys.exit()

logger.info("SUCCESS: Connection to RDS for MySQL instance succeeded")

def lambda_handler(event, context):
    """
    This function creates a new RDS database table and writes records to it
    """
    message = event['Records'][0]['body']
data = json.loads(message)
CustID = data['CustID']
Name = data['Name']

    item_count = 0
    sql_string = f"insert into Customer (CustID, Name) values({CustID}, '{Name}')"

    with conn.cursor() as cur:
        cur.execute("create table if not exists Customer ( CustID  int NOT NULL, Name
                        varchar(255) NOT NULL, PRIMARY KEY (CustID))")
        cur.execute(sql_string)
        conn.commit()
        logger.info("The following items have been added to the database:")
        for row in cur:
            item_count += 1
            logger.info(row)
        conn.commit()

    return "Added %d items to RDS for MySQL table" %(item_count)
```

**Note**

In this example, your database access credentials are stored as environment variables. In
production applications, we recommend that you use [AWS Secrets Manager](https://aws.amazon.com/secretsmanager) as a more secure
option. Note that if your Lambda function is in a VPC, to connect to Secrets Manager you need
to create a VPC endpoint. See [How to connect to Secrets Manager service within a Virtual
Private Cloud](https://docs.aws.amazon.com/vpc/latest/userguide/VPC_SecretsManager.html) to learn more.

To include the PyMySQL dependency with your function code, create a .zip deployment package. The
following commands work for Linux, macOS, or Unix:

**To create a .zip deployment package**

1. Save the example code as a file named `lambda_function.py`.
2. In the same directory in which you created your `lambda_function.py` file, create a new directory
   named package and install the PyMySQL library.

---

277
Update the Lambda function

Using the .zip package you just created, you now update your Lambda function using the Lambda console. To enable your function to access your database, you also need to configure environment variables with your access credentials.

To update the Lambda function

1. Open the Functions page of the Lambda console and choose your function LambdaFunctionWithRDS.
2. Change the Runtime of the function to Python 3.10.
3. Change the Handler to lambda_function.lambda_handler.
4. In the Code tab, choose Upload from and then .zip file.
5. Select the lambda_function.zip file you created in the previous stage and choose Save.

Now configure the function with the execution role you created earlier. This grants the function the permissions it needs to access your database instance and poll an Amazon SQS queue.

To configure the function's execution role

1. In the Functions page of the Lambda console, select the Configuration tab, then choose Permissions.
2. In Execution role, choose Edit.
3. In Existing role, choose your execution role (lambda-vpc-sqs-role).
4. Choose Save.

To configure your function's environment variables

1. In the Functions page of the Lambda console, select the Configuration tab, then choose Environment variables.
2. Choose Edit.
3. To add your database access credentials, do the following:
   a. Choose Add environment variable, then for Key enter USER_NAME and for Value enter admin.
Test your Lambda function in the console

You can now use the Lambda console to test your function. You create a test event which mimics the data your function will receive when you invoke it using Amazon SQS in the final stage of the tutorial. Your test event contains a JSON object specifying a customer ID and customer name to add to the Customer table your function creates.

**To test the Lambda function**

1. Open the [Functions](#) page of the Lambda console and choose your function.
2. Choose the Test section.
3. Choose Create new event and enter `myTestEvent` for the event name.
4. Copy the following code into Event JSON and choose Save.

```json
{
   "Records": [
      {
         "messageId": "059f36b4-87a3-44ab-83d2-661975830a7d",
         "receiptHandle": "AQEBwJnKyrHigUMZj6rYigCgxlaS3SLy0a...",
         "body": "{\n             "CustID": 1021,\n             "Name": "Martha Rivera\n           }",
         "attributes": {
           "ApproximateReceiveCount": "1",
           "SentTimestamp": "1545082649183",
           "SenderId": "AIDAIENQZJOLO23YVJ4VO",
           "ApproximateFirstReceiveTimestamp": "1545082649185"
         },
         "messageAttributes": {},
         "md5OfBody": "e4e68f6f7bd0e697a0ae8f1bb342846b3",
         "eventSource": "aws:sqs",
         "awsRegion": "us-west-2"
      }
   ]
}
```

5. Choose Test.
In the **Execution results** tab, you should see results similar to the following displayed in the **Function Logs**:

```
[INFO] 2023-02-14T19:31:35.149Z bdd06682-00c7-4d6f-9abb-89f4bb4a27f The following items have been added to the database:
[INFO] 2023-02-14T19:31:35.149Z bdd06682-00c7-4d6f-9abb-89f4bb4a27f (1021, 'Martha Rivera')
```

### Create an Amazon SQS queue

You have successfully tested the integration of your Lambda function and Amazon RDS database instance. Now you create the Amazon SQS queue you will use to invoke your Lambda function in the final stage of the tutorial.

**To create the Amazon SQS queue (console)**

1. Open the **Queues** page of the Amazon SQS console and select **Create queue**.
2. Leave the **Type** as **Standard** and enter **LambdaRDSQueue** for the name of your queue.
3. Leave all the default options selected and choose **Create queue**.

### Create an event source mapping to invoke your Lambda function

An **event source mapping** is a Lambda resource which reads items from a stream or queue and invokes a Lambda function. When you configure an event source mapping, you can specify a batch size so that records from your stream or queue are batched together into a single payload. In this example, you set the batch size to 1 so that your Lambda function is invoked every time you send a message to your queue. You can configure the event source mapping using either the AWS CLI or the Lambda console.

**To create an event source mapping (console)**

1. Open the **Functions** page of the Lambda console and select your function (LambdaFunctionWithRDS).
2. In the Function overview section, choose Add trigger.
3. For the source, select Amazon SQS, then select the name of your queue (LambdaRDSQueue).
4. For Batch size, enter 1.
5. Leave all the other options set to the default values and choose Add.

You are now ready to test your complete setup by adding a message to your Amazon SQS queue.

Test and monitor your setup

To test your complete setup, add messages to your Amazon SQS queue using the console. You then use CloudWatch Logs to confirm that your Lambda function is writing records to your database as expected.

To test and monitor your setup

1. Open the Queues page of the Amazon SQS console and select your queue (LambdaRDSQueue).
2. Choose Send and receive messages and paste the following JSON into the Message body in the Send message section.

   ```json
   {
   "CustID": 1054,
   "Name": "Richard Roe"
   }
   ```
3. Choose Send message.

   Sending your message to the queue will cause Lambda to invoke your function through your event source mapping. To confirm that Lambda has invoked your function as expected, use CloudWatch Logs to verify that the function has written the customer name and ID to your database table.
4. Open the Log groups page of the CloudWatch console and select the log group for your function (/aws/lambda/LambdaFunctionWithRDS).
5. In the Log streams section, choose the most recent log stream.

   Your table should contain two customer records, one from each invocation of your function. In the log stream, you should see messages similar to the following:

   ```
   [INFO] 2023-02-14T19:06:43.873Z 45368126-3eee-47f7-88ca-3086ae6d3a77 The following items have been added to the database:
   [INFO] 2023-02-14T19:06:43.873Z 45368126-3eee-47f7-88ca-3086ae6d3a77 (1054, 'Richard Roe')
   ```
Clean up your resources

You can now delete the resources that you created for this tutorial, unless you want to retain them. By deleting AWS resources that you’re no longer using, you prevent unnecessary charges to your AWS account.

To delete the Lambda function
1. Open the Functions page of the Lambda console.
2. Select the function that you created.
3. Choose Actions, Delete.
4. Choose Delete.

To delete the execution role
1. Open the Roles page of the IAM console.
2. Select the execution role that you created.
3. Choose Delete role.
4. Choose Yes, delete.

To delete the MySQL DB instance
1. Open the Databases page of the Amazon RDS console.
2. Select the database you created.
3. Choose Actions, Delete.
4. Clear the Create final snapshot check box.
5. Enter delete me in the text box.
6. Choose Delete.

To delete the Amazon SQS queue
1. Sign in to the AWS Management Console and open the Amazon SQS console at https://console.aws.amazon.com/sqs/
2. Select the queue you created.
3. Choose Delete.
4. Enter delete in the text box.
5. Choose Delete.
Amazon RDS tutorials and sample code

The AWS documentation includes several tutorials that guide you through common Amazon RDS use cases. Many of these tutorials show you how to use Amazon RDS with other AWS services. In addition, you can access sample code in GitHub.

Note
You can find more tutorials at the AWS Database Blog. For information about training, see AWS Training and Certification.

Topics
• Tutorials in this guide (p. 283)
• Tutorials in other AWS guides (p. 284)
• AWS workshop and lab content portal for Amazon RDS PostgreSQL (p. 284)
• AWS workshop and lab content portal for Amazon RDS MySQL (p. 284)
• Tutorials and sample code in GitHub (p. 285)
• Using this service with an AWS SDK (p. 285)

Tutorials in this guide

The following tutorials in this guide show you how to perform common tasks with Amazon RDS:

• Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2723)
  Learn how to include a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. In this case, the VPC shares data with a web server that is running on an Amazon EC2 instance in the same VPC.

• Tutorial: Create a VPC for use with a DB instance (dual-stack mode) (p. 2728)
  Learn how to include a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. In this case, the VPC shares data with an Amazon EC2 instance in the same VPC. In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode.

• Tutorial: Create a web server and an Amazon RDS DB instance (p. 249)
  Learn how to install an Apache web server with PHP and create a MySQL database. The web server runs on an Amazon EC2 instance using Amazon Linux, and the MySQL database is a MySQL DB instance. Both the Amazon EC2 instance and the DB instance run in an Amazon VPC.

• Tutorial: Restore an Amazon RDS DB instance from a DB snapshot (p. 665)
  Learn how to restore a DB instance from a DB snapshot.

• Tutorial: Using a Lambda function to access an Amazon RDS database (p. 273)
  Learn how to create a Lambda function from the RDS console to access a database through a proxy, create a table, add a few records, and retrieve the records from the table. You also learn how to invoke the Lambda function and verify the query results.

• Tutorial: Use tags to specify which DB instances to stop (p. 466)
  Learn how to use tags to specify which DB instances to stop.

• Tutorial: Log DB instance state changes using Amazon EventBridge (p. 871)
Learn how to log a DB instance state change using Amazon EventBridge and AWS Lambda.

- **Tutorial: Creating an Amazon CloudWatch alarm for Multi-AZ DB cluster replica lag** (p. 713)

Learn how to create a CloudWatch alarm that sends an Amazon SNS message when replica lag for a Multi-AZ DB cluster has exceeded a threshold. An alarm watches the `ReplicaLag` metric over a time period that you specify. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

### Tutorials in other AWS guides

The following tutorials in other AWS guides show you how to perform common tasks with Amazon RDS:

- **Tutorial: Rotating a Secret for an AWS Database** in the *AWS Secrets Manager User Guide*

  Learn how to create a secret for an AWS database and configure the secret to rotate on a schedule. You trigger one rotation manually, and then confirm that the new version of the secret continues to provide access.

- **Tutorials and samples** in the *AWS Elastic Beanstalk Developer Guide*

  Learn how to deploy applications that use Amazon RDS databases with AWS Elastic Beanstalk.

- **Using Data from an Amazon RDS Database to Create an Amazon ML Datasource** in the *Amazon Machine Learning Developer Guide*

  Learn how to create an Amazon Machine Learning (Amazon ML) datasource object from data stored in a MySQL DB instance.

- **Manually Enabling Access to an Amazon RDS Instance in a VPC** in the *Amazon QuickSight User Guide*

  Learn how to enable Amazon QuickSight access to an Amazon RDS DB instance in a VPC.

### AWS workshop and lab content portal for Amazon RDS PostgreSQL

The following collection of workshops and other hands-on content helps you to gain an understanding of the Amazon RDS PostgreSQL features and capabilities:

- **Creating a DB instance**

  Learn how to create the DB instance.

- **Performance Monitoring with RDS Tools**

  Learn how to use AWS and SQL tools (Cloudwatch, Enhanced Monitoring, Slow Query Logs, Performance Insights, PostgreSQL Catalog Views) to understand performance issues and identify ways to improve performance of your database.

### AWS workshop and lab content portal for Amazon RDS MySQL

The following collection of workshops and other hands-on content helps you to gain an understanding of the Amazon RDS MySQL features and capabilities:
Creating a DB instance

Learn how to create the DB instance.

Using Performance Insights

Learn how to monitor and tune your DB instance using Performance insights.

Tutorials and sample code in GitHub

The following tutorials and sample code in GitHub show you how to perform common tasks with Amazon RDS:

Creating the Amazon Relational Database Service item tracker

Learn how to create an application that tracks and reports on work items. This application uses Amazon RDS, Amazon Simple Email Service, Elastic Beanstalk, and SDK for Java 2.x.

Using this service with an AWS SDK

AWS software development kits (SDKs) are available for many popular programming languages. Each SDK provides an API, code examples, and documentation that make it easier for developers to build applications in their preferred language.

- Best practices for working with SQL Server (p. 296)
- Working with DB parameter groups (p. 297)
- Best practices for automating DB instance creation (p. 297)
- Amazon RDS new features and best practices presentation video (p. 298)

Note
For common recommendations for Amazon RDS, see Viewing Amazon RDS recommendations (p. 688).

Amazon RDS basic operational guidelines

The following are basic operational guidelines that everyone should follow when working with Amazon RDS. Note that the Amazon RDS Service Level Agreement requires that you follow these guidelines:

- Use metrics to monitor your memory, CPU, replica lag, and storage usage. You can set up Amazon CloudWatch to notify you when usage patterns change or when you approach the capacity of your deployment. This way, you can maintain system performance and availability.
- Scale up your DB instance when you are approaching storage capacity limits. You should have some buffer in storage and memory to accommodate unforeseen increases in demand from your applications.
- Enable automatic backups and set the backup window to occur during the daily low in write IOPS. That's when a backup is least disruptive to your database usage.
- If your database workload requires more I/O than you have provisioned, recovery after a failover or database failure will be slow. To increase the I/O capacity of a DB instance, do any or all of the following:
  - Migrate to a different DB instance class with high I/O capacity.
  - Convert from magnetic storage to either General Purpose or Provisioned IOPS storage, depending on how much of an increase you need. For information on available storage types, see Amazon RDS storage types (p. 101).
If you convert to Provisioned IOPS storage, make sure you also use a DB instance class that is optimized for Provisioned IOPS. For information on Provisioned IOPS, see Provisioned IOPS SSD storage (p. 104).

- If you are already using Provisioned IOPS storage, provision additional throughput capacity.
- If your client application is caching the Domain Name Service (DNS) data of your DB instances, set a time-to-live (TTL) value of less than 30 seconds. The underlying IP address of a DB instance can change after a failover. Caching the DNS data for an extended time can thus lead to connection failures. Your application might try to connect to an IP address that's no longer in service.
- Test failover for your DB instance to understand how long the process takes for your particular use case. Also test failover to ensure that the application that accesses your DB instance can automatically connect to the new DB instance after failover occurs.

**DB instance RAM recommendations**

An Amazon RDS performance best practice is to allocate enough RAM so that your working set resides almost completely in memory. The working set is the data and indexes that are frequently in use on your instance. The more you use the DB instance, the more the working set will grow.

To tell if your working set is almost all in memory, check the ReadIOPS metric (using Amazon CloudWatch) while the DB instance is under load. The value of ReadIOPS should be small and stable. In some cases, scaling up the DB instance class to a class with more RAM results in a dramatic drop in ReadIOPS. In these cases, your working set was not almost completely in memory. Continue to scale up until ReadIOPS no longer drops dramatically after a scaling operation, or ReadIOPS is reduced to a very small amount. For information on monitoring a DB instance's metrics, see Viewing metrics in the Amazon RDS console (p. 696).

**Using Enhanced Monitoring to identify operating system issues**

When Enhanced Monitoring is enabled, Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view the metrics for your DB instance using the console. You can also consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information about Enhanced Monitoring, see Monitoring OS metrics with Enhanced Monitoring (p. 797).

**Using metrics to identify performance issues**

To identify performance issues caused by insufficient resources and other common bottlenecks, you can monitor the metrics available for your Amazon RDS DB instance.

**Viewing performance metrics**

You should monitor performance metrics on a regular basis to see the average, maximum, and minimum values for a variety of time ranges. If you do so, you can identify when performance is degraded. You can also set Amazon CloudWatch alarms for particular metric thresholds so you are alerted if they are reached.
To troubleshoot performance issues, it's important to understand the baseline performance of the system. When you set up a DB instance and run it with a typical workload, capture the average, maximum, and minimum values of all performance metrics. Do so at a number of different intervals (for example, one hour, 24 hours, one week, two weeks). This can give you an idea of what is normal. It helps to get comparisons for both peak and off-peak hours of operation. You can then use this information to identify when performance is dropping below standard levels.

If you use Multi-AZ DB clusters, monitor the time difference between the latest transaction on the writer DB instance and the latest applied transaction on a reader DB instance. This difference is called replica lag. For more information, see Replica lag and Multi-AZ DB clusters (p. 504).

You can view the combined Performance Insights and CloudWatch metrics in the Performance Insights dashboard and monitor your DB instance. To use this monitoring view, Performance Insights must be turned on for your DB instance. For information about this monitoring view, see Viewing combined metrics in the Amazon RDS console (p. 699).

You can create a performance analysis report for a specific time period and view the insights identified and the recommendations to resolve the issues. For more information see, Creating a performance analysis report (p. 750).

**To view performance metrics**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose a DB instance.
3. Choose Monitoring.

   The dashboard provides the performance metrics. The metrics default to show the information for the last three hours.

4. Use the numbered buttons in the upper-right to page through the additional metrics, or adjust the settings to see more metrics.
5. Choose a performance metric to adjust the time range in order to see data for other than the current day. You can change the Statistic, Time Range, and Period values to adjust the information displayed. For example, you might want to see the peak values for a metric for each day of the last two weeks. If so, set Statistic to Maximum, Time Range to Last 2 Weeks, and Period to Day.

You can also view performance metrics using the CLI or API. For more information, see Viewing metrics in the Amazon RDS console (p. 696).

**To set a CloudWatch alarm**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose a DB instance.
3. Choose Logs & events.
4. In the CloudWatch alarms section, choose Create alarm.
5. For **Send notifications**, choose **Yes**, and for **Send notifications to**, choose **New email or SMS topic**.

6. For **Topic name**, enter a name for the notification, and for **With these recipients**, enter a comma-separated list of email addresses and phone numbers.

7. For **Metric**, choose the alarm statistic and metric to set.

8. For **Threshold**, specify whether the metric must be greater than, less than, or equal to the threshold, and specify the threshold value.

9. For **Evaluation period**, choose the evaluation period for the alarm. For **consecutive period(s) of**, choose the period during which the threshold must have been reached in order to trigger the alarm.

10. For **Name of alarm**, enter a name for the alarm.

11. Choose **Create Alarm**.
The alarm appears in the CloudWatch alarms section.

Evaluating performance metrics

A DB instance has a number of different categories of metrics, and how to determine acceptable values depends on the metric.

CPU

• CPU Utilization – Percentage of computer processing capacity used.

Memory

• Freeable Memory – How much RAM is available on the DB instance, in megabytes. The red line in the Monitoring tab metrics is marked at 75% for CPU, Memory and Storage Metrics. If instance memory consumption frequently crosses that line, then this indicates that you should check your workload or upgrade your instance.

• Swap Usage – How much swap space is used by the DB instance, in megabytes.

Disk space

• Free Storage Space – How much disk space is not currently being used by the DB instance, in megabytes.

Input/output operations

• Read IOPS, Write IOPS – The average number of disk read or write operations per second.

• Read Latency, Write Latency – The average time for a read or write operation in milliseconds.

• Read Throughput, Write Throughput – The average number of megabytes read from or written to disk per second.

• Queue Depth – The number of I/O operations that are waiting to be written to or read from disk.

Network traffic

• Network Receive Throughput, Network Transmit Throughput – The rate of network traffic to and from the DB instance in bytes per second.

Database connections

• DB Connections – The number of client sessions that are connected to the DB instance.

For more detailed individual descriptions of the performance metrics available, see Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 706).

Generally speaking, acceptable values for performance metrics depend on what your baseline looks like and what your application is doing. Investigate consistent or trending variances from your baseline. Advice about specific types of metrics follows:

• High CPU or RAM consumption – High values for CPU or RAM consumption might be appropriate. For example, they might be so if they are in keeping with your goals for your application (like throughput or concurrency) and are expected.
• **Disk space consumption** – Investigate disk space consumption if space used is consistently at or above 85 percent of the total disk space. See if it is possible to delete data from the instance or archive data to a different system to free up space.

• **Network traffic** – For network traffic, talk with your system administrator to understand what expected throughput is for your domain network and internet connection. Investigate network traffic if throughput is consistently lower than expected.

• **Database connections** – Consider constraining database connections if you see high numbers of user connections in conjunction with decreases in instance performance and response time. The best number of user connections for your DB instance will vary based on your instance class and the complexity of the operations being performed. To determine the number of database connections, associate your DB instance with a parameter group. In this group, set the **User Connections** parameter to other than 0 (unlimited). You can either use an existing parameter group or create a new one. For more information, see [Working with parameter groups](p. 347).

• **IOPS metrics** – The expected values for IOPS metrics depend on disk specification and server configuration, so use your baseline to know what is typical. Investigate if values are consistently different than your baseline. For best IOPS performance, make sure your typical working set will fit into memory to minimize read and write operations.

For issues with performance metrics, a first step to improve performance is to tune the most used and most expensive queries. Tune them to see if doing so lowers the pressure on system resources. For more information, see [Tuning queries](p. 291).

If your queries are tuned and an issue persists, consider upgrading your Amazon RDS DB instance classes (p. 11). You might upgrade it to one with more of the resource (CPU, RAM, disk space, network bandwidth, I/O capacity) that is related to the issue.

### Tuning queries

One of the best ways to improve DB instance performance is to tune your most commonly used and most resource-intensive queries. Here, you tune them to make them less expensive to run. For information on improving queries, use the following resources:

• MySQL – See [Optimizing SELECT statements](#) in the MySQL documentation. For additional query tuning resources, see [MySQL performance tuning and optimization resources](#).

• Oracle – See [Database SQL Tuning Guide](#) in the Oracle Database documentation.

• SQL Server – See [Analyzing a query](#) in the Microsoft documentation. You can also use the execution-, index-, and I/O-related data management views (DMVs) described in [System Dynamic Management Views](#) in the Microsoft documentation to troubleshoot SQL Server query issues.

A common aspect of query tuning is creating effective indexes. For potential index improvements for your DB instance, see [Database Engine Tuning Advisor](#) in the Microsoft documentation. For information on using Tuning Advisor on RDS for SQL Server, see [Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor](p. 1621).

• PostgreSQL – See [Using EXPLAIN](#) in the PostgreSQL documentation to learn how to analyze a query plan. You can use this information to modify a query or underlying tables in order to improve query performance.

For information about how to specify joins in your query for the best performance, see [Controlling the planner with explicit JOIN clauses](#).

• MariaDB – See [Query optimizations](#) in the MariaDB documentation.
Best practices for working with MySQL

Both table sizes and number of tables in a MySQL database can affect performance.

Table size

Typically, operating system constraints on file sizes determine the effective maximum table size for MySQL databases. So, the limits usually aren't determined by internal MySQL constraints.

On a MySQL DB instance, avoid tables in your database growing too large. Although the general storage limit is 64 TiB, provisioned storage limits restrict the maximum size of a MySQL table file to 16 TiB. Partition your large tables so that file sizes are well under the 16 TiB limit. This approach can also improve performance and recovery time. For more information, see MySQL file size limits in Amazon RDS (p. 1770).

Very large tables (greater than 100 GB in size) can negatively affect performance for both reads and writes (including DML statements and especially DDL statements). Indexes on large tables can significantly improve select performance, but they can also degrade the performance of DML statements. DDL statements, such as ALTER TABLE, can be significantly slower for the large tables because those operations might completely rebuild a table in some cases. These DDL statements might lock the tables for the duration of the operation.

The amount of memory required by MySQL for reads and writes depends on the tables involved in the operations. It is a best practice to have at least enough RAM to the hold the indexes of actively used tables. To find the ten largest tables and indexes in a database, use the following query:

```
select table_schema, TABLE_NAME, dat, idx from
(SELECT table_schema, TABLE_NAME,
     ( data_length ) / 1024 / 1024 as dat,
     ( index_length ) / 1024 / 1024 as idx
FROM information_schema.TABLES
order by 3 desc ) a
order by 3 desc
limit 10;
```

Number of tables

Your underlying file system might have a limit on the number of files that represent tables. However, MySQL has no limit on the number of tables. Despite this, the total number of tables in the MySQL InnoDB storage engine can contribute to the performance degradation, regardless of the size of those tables. To limit the operating system impact, you can split the tables across multiple databases in the same MySQL DB instance. Doing so might limit the number of files in a directory but won't solve the overall problem.

When there is performance degradation because of a large number of tables (more than 10 thousand), it is caused by MySQL working with storage files, including opening and closing them. To address this issue, you can increase the size of the table_open_cache and table_definition_cache parameters. However, increasing the values of those parameters might significantly increase the amount of memory MySQL uses, and might even use all of the available memory. For more information, see How MySQL Opens and Closes Tables in the MySQL documentation.

In addition, too many tables can significantly affect MySQL startup time. Both a clean shutdown and restart and a crash recovery can be affected, especially in versions prior to MySQL 8.0.

We recommend having fewer than 10,000 tables total across all of the databases in a DB instance. For a use case with a large number of tables in a MySQL database, see One Million Tables in MySQL 8.0.
Storage engine

The point-in-time restore and snapshot restore features of Amazon RDS for MySQL require a crash-recoverable storage engine. These features are supported for the InnoDB storage engine only. Although MySQL supports multiple storage engines with varying capabilities, not all of them are optimized for crash recovery and data durability. For example, the MyISAM storage engine doesn't support reliable crash recovery and might prevent a point-in-time restore or snapshot restore from working as intended. This might result in lost or corrupt data when MySQL is restarted after a crash.

InnoDB is the recommended and supported storage engine for MySQL DB instances on Amazon RDS. InnoDB instances can also be migrated to Aurora, while MyISAM instances can't be migrated. However, MyISAM performs better than InnoDB if you require intense, full-text search capability. If you still choose to use MyISAM with Amazon RDS, following the steps outlined in Automated backups with unsupported MySQL storage engines (p. 599) can be helpful in certain scenarios for snapshot restore functionality.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the process outlined in the MySQL documentation. MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

In addition, Federated Storage Engine is currently not supported by Amazon RDS for MySQL.

Best practices for working with MariaDB

Both table sizes and number of tables in a MariaDB database can affect performance.

Table size

Typically, operating system constraints on file sizes determine the effective maximum table size for MariaDB databases. So, the limits usually aren't determined by internal MariaDB constraints.

On a MariaDB DB instance, avoid tables in your database growing too large. Although the general storage limit is 64 TiB, provisioned storage limits restrict the maximum size of a MariaDB table file to 16 TiB. Partition your large tables so that file sizes are well under the 16 TiB limit. This approach can also improve performance and recovery time.

Very large tables (greater than 100 GB in size) can negatively affect performance for both reads and writes (including DML statements and especially DDL statements). Indexes on larges tables can significantly improve select performance, but they can also degrade the performance of DML statements. DDL statements, such as ALTER TABLE, can be significantly slower for the large tables because those operations might completely rebuild a table in some cases. These DDL statements might lock the tables for the duration of the operation.

The amount of memory required by MariaDB for reads and writes depends on the tables involved in the operations. It is a best practice to have at least enough RAM to hold the indexes of actively used tables. To find the ten largest tables and indexes in a database, use the following query:

```
select table_schema, TABLE_NAME, dat, idx from
(SELECT table_schema, TABLE_NAME,
     ( data_length ) / 1024 / 1024 as dat,
     ( index_length ) / 1024 / 1024 as idx
FROM information_schema.TABLES
order by 3 desc ) a
order by 3 desc
limit 10;
```
Number of tables

Your underlying file system might have a limit on the number of files that represent tables. However, MariaDB has no limit on the number of tables. Despite this, the total number of tables in the MariaDB InnoDB storage engine can contribute to the performance degradation, regardless of the size of those tables. To limit the operating system impact, you can split the tables across multiple databases in the same MariaDB DB instance. Doing so might limit the number of files in a directory but doesn't solve the overall problem.

When there is performance degradation because of a large number of tables (more than 10,000), it's caused by MariaDB working with storage files. This work includes MariaDB opening and closing storage files. To address this issue, you can increase the size of the `table_open_cache` and `table_definition_cache` parameters. However, increasing the values of those parameters might significantly increase the amount of memory MariaDB uses. It might even use all of the available memory. For more information, see Optimizing table_open_cache in the MariaDB documentation.

In addition, too many tables can significantly affect MariaDB startup time. Both a clean shutdown and restart and a crash recovery can be affected. We recommend having fewer than ten thousand tables total across all of the databases in a DB instance.

Storage engine

The point-in-time restore and snapshot restore features of Amazon RDS for MariaDB require a crash-recoverable storage engine. Although MariaDB supports multiple storage engines with varying capabilities, not all of them are optimized for crash recovery and data durability. For example, although Aria is a crash-safe replacement for MyISAM, it might still prevent a point-in-time restore or snapshot restore from working as intended. This might result in lost or corrupt data when MariaDB is restarted after a crash. InnoDB is the recommended and supported storage engine for MariaDB DB instances on Amazon RDS. If you still choose to use Aria with Amazon RDS, following the steps outlined in Automated backups with unsupported MariaDB storage engines (p. 600) can be helpful in certain scenarios for snapshot restore functionality.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the process outlined in the MariaDB documentation. MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

Best practices for working with Oracle

For information about best practices for working with Amazon RDS for Oracle, see Best practices for running Oracle database on Amazon Web Services.

A 2020 AWS virtual workshop included a presentation on running production Oracle databases on Amazon RDS. A video of the presentation is available here.

Best practices for working with PostgreSQL

Of two important areas where you can improve performance with RDS for PostgreSQL, one is when loading data into a DB instance. Another is when using the PostgreSQL autovacuum feature. The following sections cover some of the practices we recommend for these areas.

For information on how Amazon RDS implements other common PostgreSQL DBA tasks, see Common DBA tasks for Amazon RDS for PostgreSQL (p. 2287).
Loading data into a PostgreSQL DB instance

When loading data into an Amazon RDS for PostgreSQL DB instance, modify your DB instance settings and your DB parameter group values. Set these to allow for the most efficient importing of data into your DB instance.

Modify your DB instance settings to the following:

- Disable DB instance backups (set backup_retention to 0)
- Disable Multi-AZ

Modify your DB parameter group to include the following settings. Also, test the parameter settings to find the most efficient settings for your DB instance.

- Increase the value of the `maintenance_work_mem` parameter. For more information about PostgreSQL resource consumption parameters, see the PostgreSQL documentation.
- Increase the value of the `max_wal_size` and `checkpoint_timeout` parameters to reduce the number of writes to the write-ahead log (WAL) log.
- Disable the `synchronous_commit` parameter.
- Disable the PostgreSQL autovacuum parameter.
- Make sure that none of the tables you're importing are unlogged. Data stored in unlogged tables can be lost during a failover. For more information, see `CREATE TABLE UNLOGGED`.

Use the `pg_dump -Fc` (compressed) or `pg_restore -j` (parallel) commands with these settings.

After the load operation completes, return your DB instance and DB parameters to their normal settings.

Working with the PostgreSQL autovacuum feature

The autovacuum feature for PostgreSQL databases is a feature that we strongly recommend you use to maintain the health of your PostgreSQL DB instance. Autovacuum automates the execution of the VACUUM and ANALYZE command. Using autovacuum is required by PostgreSQL, not imposed by Amazon RDS, and its use is critical to good performance. The feature is enabled by default for all new Amazon RDS for PostgreSQL DB instances, and the related configuration parameters are appropriately set by default.

Your database administrator needs to know and understand this maintenance operation. For the PostgreSQL documentation on autovacuum, see The Autovacuum Daemon.

Autovacuum is not a "resource free" operation, but it works in the background and yields to user operations as much as possible. When enabled, autovacuum checks for tables that have had a large number of updated or deleted tuples. It also protects against loss of very old data due to transaction ID wraparound. For more information, see Preventing transaction ID wraparound failures.

Autovacuum should not be thought of as a high-overhead operation that can be reduced to gain better performance. On the contrary, tables that have a high velocity of updates and deletes will quickly deteriorate over time if autovacuum is not run.

Important

Not running autovacuum can result in an eventual required outage to perform a much more intrusive vacuum operation. In some cases, an RDS for PostgreSQL DB instance might become unavailable because of an over-conservative use of autovacuum. In these cases, the PostgreSQL database shuts down to protect itself. At that point, Amazon RDS must perform a single-user-mode full vacuum directly on the DB instance. This full vacuum can result in a multi-hour outage.
Thus, we strongly recommend that you do not turn off autovacuum, which is turned on by default.

The autovacuum parameters determine when and how hard autovacuum works. The `autovacuum_vacuum_threshold` and `autovacuum_vacuum_scale_factor` parameters determine when autovacuum is run. The `autovacuum_max_workers`, `autovacuum_nap_time`, `autovacuum_cost_limit`, and `autovacuum_cost_delay` parameters determine how hard autovacuum works. For more information about autovacuum, when it runs, and what parameters are required, see Routine Vacuuming in the PostgreSQL documentation.

The following query shows the number of "dead" tuples in a table named table1:

```sql
SELECT relname, n_dead_tup, last_vacuum, last_autovacuum FROM pg_catalog.pg_stat_all_tables WHERE n_dead_tup > 0 and relname = 'table1';
```

The results of the query will resemble the following:

<table>
<thead>
<tr>
<th>relname</th>
<th>n_dead_tup</th>
<th>last_vacuum</th>
<th>last_autovacuum</th>
</tr>
</thead>
<tbody>
<tr>
<td>tasks</td>
<td>81430522</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
(1 row)

Amazon RDS for PostgreSQL best practices video

The 2020 AWS re:Invent conference included a presentation on new features and best practices for working with PostgreSQL on Amazon RDS. A video of the presentation is available [here](#).

Best practices for working with SQL Server

Best practices for a Multi-AZ deployment with a SQL Server DB instance include the following:

- Use Amazon RDS DB events to monitor failovers. For example, you can be notified by text message or email when a DB instance fails over. For more information about Amazon RDS events, see [Working with Amazon RDS event notification](p. 855).

- If your application caches DNS values, set time to live (TTL) to less than 30 seconds. Setting TTL as so is a good practice in case there is a failover. In a failover, the IP address might change and the cached value might no longer be in service.

- We recommend that you do not enable the following modes because they turn off transaction logging, which is required for Multi-AZ:
  - Simple recover mode
  - Offline mode
  - Read-only mode

- Test to determine how long it takes for your DB instance to failover. Failover time can vary due to the type of database, the instance class, and the storage type you use. You should also test your application's ability to continue working if a failover occurs.

- To shorten failover time, do the following:
  - Ensure that you have sufficient Provisioned IOPS allocated for your workload. Inadequate I/O can lengthen failover times. Database recovery requires I/O.
  - Use smaller transactions. Database recovery relies on transactions, so if you can break up large transactions into multiple smaller transactions, your failover time should be shorter.
• Take into consideration that during a failover, there will be elevated latencies. As part of the failover process, Amazon RDS automatically replicates your data to a new standby instance. This replication means that new data is being committed to two different DB instances. So there might be some latency until the standby DB instance has caught up to the new primary DB instance.
• Deploy your applications in all Availability Zones. If an Availability Zone does go down, your applications in the other Availability Zones will still be available.

When working with a Multi-AZ deployment of SQL Server, remember that Amazon RDS creates replicas for all SQL Server databases on your instance. If you don't want specific databases to have secondary replicas, set up a separate DB instance that doesn't use Multi-AZ for those databases.

Amazon RDS for SQL Server best practices video

Working with DB parameter groups

We recommend that you try out DB parameter group changes on a test DB instance before applying parameter group changes to your production DB instances. Improperly setting DB engine parameters in a DB parameter group can have unintended adverse effects, including degraded performance and system instability. Always exercise caution when modifying DB engine parameters and back up your DB instance before modifying a DB parameter group.

For information about backing up your DB instance, see Backing up and restoring (p. 590).

Best practices for automating DB instance creation

It's an Amazon RDS best practice to create a DB instance with the preferred minor version of the database engine. You can use the AWS CLI, Amazon RDS API, or AWS CloudFormation to automate DB instance creation. When you use these methods, you can specify only the major version and Amazon RDS automatically creates the instance with the preferred minor version. For example, if PostgreSQL 12.5 is the preferred minor version, and if you specify version 12 with create-db-instance, the DB instance will be version 12.5.

To determine the preferred minor version, you can run the describe-db-engine-versions command with the --default-only option as shown in the following example.

```
aws rds describe-db-engine-versions --default-only --engine postgres
{
  "DBEngineVersions": [
    {
      "Engine": "postgres",
      "EngineVersion": "12.5",
      "DBParameterGroupFamily": "postgres12",
      "DBEngineDescription": "PostgreSQL",
      "DBEngineVersionDescription": "PostgreSQL 12.5-R1",
      ...some output truncated...
    }
  ]
}
```

For information on creating DB instances programmatically, see the following resources:

For information on creating DB instances programmatically, see the following resources:
Amazon RDS new features and best practices presentation video

The 2019 AWS re:Invent conference included a presentation on new Amazon RDS features and best practices for monitoring, analyzing, and tuning database performance using RDS. A video of the presentation is available here.

- Using the AWS CLI – `create-db-instance`
- Using the Amazon RDS API – `CreateDBInstance`
- Using AWS CloudFormation – `AWS::RDS::DBInstance`
Configuring an Amazon RDS DB instance

This section shows how to set up your Amazon RDS DB instance. Before creating a DB instance, decide on the DB instance class that will run the DB instance. Also, decide where the DB instance will run by choosing an AWS Region. Next, create the DB instance.

You can configure a DB instance with an option group and a DB parameter group.

- An option group specifies features, called options, that are available for a particular Amazon RDS DB instance.
- A DB parameter group acts as a container for engine configuration values that are applied to one or more DB instances.

The options and parameters that are available depend on the DB engine and DB engine version. You can specify an option group and a DB parameter group when you create a DB instance. You can also modify a DB instance to specify them.

Topics
- [Creating an Amazon RDS DB instance (p. 300)]
- [Creating Amazon RDS resources with AWS CloudFormation (p. 324)]
- [Connecting to an Amazon RDS DB instance (p. 325)]
- [Working with option groups (p. 331)]
- [Working with parameter groups (p. 347)]
- [Creating an Amazon ElastiCache cluster using Amazon RDS DB instance settings (p. 374)]
Creating an Amazon RDS DB instance

The basic building block of Amazon RDS is the DB instance, where you create your databases. You choose the engine-specific characteristics of the DB instance when you create it. You also choose the storage capacity, CPU, memory, and so on, of the AWS instance on which the database server runs.

Topics
- DB instance prerequisites (p. 300)
- Creating a DB instance (p. 303)
- Settings for DB instances (p. 308)

DB instance prerequisites

**Important**
Before you can create an Amazon RDS DB instance, you must complete the tasks in Setting up for Amazon RDS (p. 174).

The following are prerequisites to complete before creating a DB instance.

Topics
- Configure the network for the DB instance (p. 300)
- Additional prerequisites (p. 303)

Configure the network for the DB instance

You can create an Amazon RDS DB instance only in a virtual private cloud (VPC) based on the Amazon VPC service. Also, it must be in an AWS Region that has at least two Availability Zones. The DB subnet group that you choose for the DB instance must cover at least two Availability Zones. This configuration ensures that you can configure a Multi-AZ deployment when you create the DB instance or easily move to one in the future.

To set up connectivity between your new DB instance and an Amazon EC2 instance in the same VPC, do so when you create the DB instance. To connect to your DB instance from resources other than EC2 instances in the same VPC, configure the network connections manually.

Topics
- Configure automatic network connectivity with an EC2 instance (p. 300)
- Configure the network manually (p. 303)

Configure automatic network connectivity with an EC2 instance

When you create an RDS DB instance, you can use the AWS Management Console to set up connectivity between an EC2 instance and the new DB instance. When you do so, RDS configures your VPC and network settings automatically. The DB instance is created in the same VPC as the EC2 instance so that the EC2 instance can access the DB instance.

The following are requirements for connecting an EC2 instance with the DB instance:

- The EC2 instance must exist in the AWS Region before you create the DB instance.
- If no EC2 instances exist in the AWS Region, the console provides a link to create one.
- The user who is creating the DB instance must have permissions to perform the following operations:
  - ec2:AssociateRouteTable
Amazon Relational Database Service User Guide
Prerequisites

- ec2:AuthorizeSecurityGroupEgress
- ec2:AuthorizeSecurityGroupIngress
- ec2:CreateRouteTable
- ec2:CreateSubnet
- ec2:CreateSecurityGroup
- ec2:DescribeInstances
- ec2:DescribeNetworkInterfaces
- ec2:DescribeRouteTables
- ec2:DescribeSecurityGroups
- ec2:DescribeSubnets
- ec2:ModifyNetworkInterfaceAttribute
- ec2:RevokeSecurityGroupEgress

Using this option creates a private DB instance. The DB instance uses a DB subnet group with only private subnets to restrict access to resources within the VPC.

To connect an EC2 instance to the DB instance, choose **Connect to an EC2 compute resource** in the **Connectivity** section on the **Create database** page.

<table>

</tr>
<tr>
<td>DB subnet group</td>
<td>RDS requires a DB subnet group with a private subnet in the same Availability Zone as the EC2 instance. If a DB subnet group that meets this requirement exists, then RDS uses the existing DB subnet group. By default, this option is set to <strong>Automatic setup</strong>.</td>
</tr>
</tbody>
</table>
### Prerequisites

<table>
<thead>
<tr>
<th>Console option</th>
<th>Automatic setting</th>
</tr>
</thead>
</table>
| **Console option**              | When you choose **Automatic setup** and there is no DB subnet group that meets this requirement, the following action happens. RDS uses three available private subnets in three Availability Zones where one of the Availability Zones is the same as the EC2 instance. If a private subnet isn't available in an Availability Zone, RDS creates a private subnet in the Availability Zone. Then RDS creates the DB subnet group.  

When a private subnet is available, RDS uses the route table associated with the subnet and adds any subnets it creates to this route table. When no private subnet is available, RDS creates a route table without internet gateway access and adds the subnets it creates to the route table.  

RDS also allows you to use existing DB subnet groups. Select **Choose existing** if you want to use an existing DB subnet group of your choice. |
| **Public access**               | RDS chooses **No** so that the DB instance isn't publicly accessible.  

For security, it is a best practice to keep the database private and make sure it isn't accessible from the internet. |
| **VPC security group (firewall)** | RDS creates a new security group that is associated with the DB instance. The security group is named `rds-ec2-n`, where `n` is a number. This security group includes an inbound rule with the EC2 VPC security group (firewall) as the source. This security group that is associated with the DB instance allows the EC2 instance to access the DB instance.  

RDS also creates a new security group that is associated with the EC2 instance. The security group is named `ec2-rds-n`, where `n` is a number. This security group includes an outbound rule with the VPC security group of the DB instance as the source. This security group allows the EC2 instance to send traffic to the DB instance.  

You can add another new security group by choosing **Create new** and typing the name of the new security group.  

You can add existing security groups by choosing **Choose existing** and selecting security groups to add. |
| **Availability Zone**           | When you choose **Single DB instance** in **Availability & durability** (Single-AZ deployment), RDS chooses the Availability Zone of the EC2 instance.  

When you choose **Multi-AZ DB instance** in **Availability & durability** (Multi-AZ DB instance deployment), RDS chooses the Availability Zone of the EC2 instance for one DB instance in the deployment. RDS randomly chooses a different Availability Zone for the other DB instance. Either the primary DB instance or the standby replica is created in the same Availability Zone as the EC2 instance. When you choose **Multi-AZ DB instance**, there is the possibility of cross Availability Zone costs if the DB instance and EC2 instance are in different Availability Zones. |

For more information about these settings, see [Settings for DB instances](p. 308).  

If you change these settings after the DB instance is created, the changes might affect the connection between the EC2 instance and the DB instance.
Configure the network manually

To connect to your DB instance from resources other than EC2 instances in the same VPC, configure the network connections manually. If you use the AWS Management Console to create your DB instance, you can have Amazon RDS automatically create a VPC for you. Or you can use an existing VPC or create a new VPC for your DB instance. With any approach, your VPC requires at least one subnet in each of at least two Availability Zones for use with an RDS DB instance.

By default, Amazon RDS creates the DB instance an Availability Zone automatically for you. To choose a specific Availability Zone, you need to change the **Availability & durability** setting to **Single DB instance**. Doing so exposes an **Availability Zone** setting that lets you choose from among the Availability Zones in your VPC. However, if you choose a Multi-AZ deployment, RDS chooses the Availability Zone of the primary or writer DB instance automatically, and the **Availability Zone** setting doesn't appear.

In some cases, you might not have a default VPC or haven't created a VPC. In these cases, you can have Amazon RDS automatically create a VPC for you when you create a DB instance using the console. Otherwise, do the following:

- Create a VPC with at least one subnet in each of at least two of the Availability Zones in the AWS Region where you want to deploy your DB instance. For more information, see **Working with a DB instance in a VPC** (p. 2706) and **Tutorial: Create a VPC for use with a DB instance (IPv4 only)** (p. 2723).
- Specify a VPC security group that authorizes connections to your DB instance. For more information, see **Provide access to your DB instance in your VPC by creating a security group** (p. 177) and **Controlling access with security groups** (p. 2697).
- Specify an RDS DB subnet group that defines at least two subnets in the VPC that can be used by the DB instance. For more information, see **Working with DB subnet groups** (p. 2706).

If you want to connect to a resource that isn't in the same VPC as the DB instance, see the appropriate scenarios in **Scenarios for accessing a DB instance in a VPC** (p. 2718).

### Additional prerequisites

Before you create your DB instance, consider the following additional prerequisites:

- If you are connecting to AWS using AWS Identity and Access Management (IAM) credentials, your AWS account must have certain IAM policies. These grant the permissions required to perform Amazon RDS operations. For more information, see **Identity and access management for Amazon RDS** (p. 2623).
  
  To use IAM to access the RDS console, sign in to the AWS Management Console with your IAM user credentials. Then go to the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

- To tailor the configuration parameters for your DB instance, specify a DB parameter group with the required parameter settings. For information about creating or modifying a DB parameter group, see **Working with parameter groups** (p. 347).

- Determine the TCP/IP port number to specify for your DB instance. The firewalls at some companies block connections to the default ports for RDS DB instances. If your company firewall blocks the default port, choose another port for your DB instance.

### Creating a DB instance

You can create an Amazon RDS DB instance using the AWS Management Console, the AWS CLI, or the RDS API.

#### Console

You can create a DB instance by using the AWS Management Console with **Easy create** enabled or not enabled. With **Easy create** enabled, you specify only the DB engine type, DB instance size, and DB
instance identifier. **Easy create** uses the default setting for other configuration options. With **Easy create** not enabled, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

**Note**
In the following procedure, **Standard create** is enabled, and **Easy create** isn't enabled. This procedure uses Microsoft SQL Server as an example. For examples that use **Easy create** to walk you through creating and connecting to sample DB instances for each engine, see [Getting started with Amazon RDS](#) (p. 180).

**To create a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**, then choose **Standard create**.
5. For **Engine type**, choose MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL.

**Microsoft SQL Server** is shown here.
6. For **Database management type**, if you're using Oracle or SQL Server choose **Amazon RDS** or **Amazon RDS Custom**.

   **Amazon RDS** is shown here. For more information on RDS Custom, see *Working with Amazon RDS Custom* (p. 978).

7. For **Edition**, if you're using Oracle or SQL Server choose the DB engine edition that you want to use.

   MySQL has only one option for the edition, and MariaDB and PostgreSQL have none.

8. For **Version**, choose the engine version.

9. In **Templates**, choose the template that matches your use case. If you choose **Production**, the following are preselected in a later step:

   - **Multi-AZ** failover option
• **Provisioned IOPS SSD (io1)** storage option
• **Enable deletion protection** option

We recommend these features for any production environment.

**Note**
Template choices vary by edition.

10. To enter your master password, do the following:
   a. In the **Settings** section, open **Credential Settings**.
   b. If you want to specify a password, clear the **Auto generate a password** check box if it is selected.
   c. (Optional) Change the **Master username** value.
   d. Enter the same password in **Master password** and **Confirm password**.

11. (Optional) Set up a connection to a compute resource for this DB instance.

   You can configure connectivity between an Amazon EC2 instance and the new DB instance during DB instance creation. For more information, see [Configure automatic network connectivity with an EC2 instance](p. 300).

12. In the **Connectivity** section under **VPC security group (firewall)**, if you select **Create new**, a VPC security group is created with an inbound rule that allows your local computer's IP address to access the database.

13. For the remaining sections, specify your DB instance settings. For information about each setting, see [Settings for DB instances](p. 308).

14. Choose **Create database**.

   If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

   To view the master user name and password for the DB instance, choose **View credential details**.

   To connect to the DB instance as the master user, use the user name and password that appear.

   **Important**
   You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB instance is available, modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](p. 401).

15. For **Databases**, choose the name of the new DB instance.

   On the RDS console, the details for the new DB instance appear. The DB instance has a status of **Creating** until the DB instance is created and ready for use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and storage allocated, it can take several minutes for the new instance to be available.
AWS CLI

To create a DB instance by using the AWS CLI, call the `create-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--db-instance-class`
- `--vpc-security-group-ids`
- `--db-subnet-group`
- `--engine`
- `--master-username`
- `--master-user-password`
- `--allocated-storage`
- `--backup-retention-period`

For information about each setting, see Settings for DB instances (p. 308).

This example uses Microsoft SQL Server.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --engine sqlserver-se \
  --db-instance-identifier mymsftsqlserver \
  --allocated-storage 250 \
  --db-instance-class db.t3.large \
  --vpc-security-group-ids mysecuritygroup \
  --db-subnet-group mydbsubnetgroup \
  --master-username masterawsuser \
  --manage-master-user-password \
  --backup-retention-period 3
```

For Windows:

```
aws rds create-db-instance ^
  --engine sqlserver-se ^
  --db-instance-identifier mydbinstance ^
  --allocated-storage 250 ^
```
This command produces output similar to the following.

```
DBINSTANCE  mydbinstance  db.t3.large  sqlserver-se  250  sa  creating  3  ****  n
10.50.2789
SECGROUP  default  active
PARAMGRP  default.sqlserver-se-14  in-sync
```

**RDS API**

To create a DB instance by using the Amazon RDS API, call the `CreateDBInstance` operation.

For information about each setting, see [Settings for DB instances](p. 308).

### Settings for DB instances

In the following table, you can find details about settings that you choose when you create a DB instance. The table also shows the DB engines for which each setting is supported.

You can create a DB instance using the console, the `create-db-instance` CLI command, or the `CreateDBInstance` RDS API operation.

<table>
<thead>
<tr>
<th>Console setting</th>
<th>Setting description</th>
<th>CLI option and RDS API parameter</th>
<th>Supported DB engines</th>
</tr>
</thead>
</table>
| Allocated storage | The amount of storage to allocate for your DB instance (in gibibytes). In some cases, allocating a higher amount of storage for your DB instance than the size of your database can improve I/O performance. For more information, see [Amazon RDS DB instance storage](p. 101). | CLI option:  
`--allocated-storage`  
API parameter:  
AllocatedStorage | All |
| Architecture settings | The architecture of the database: CDB (single-tenant) or non-CDB. Oracle Database 21c uses CDB architecture only. Oracle Database 19c can use either CDB or non-CDB architecture. Releases lower than Oracle Database 19c use non-CDB only.  
If you choose [Use multitenant architecture](p. 212), RDS for Oracle creates a container database (CDB). This CDB contains one pluggable database (PDB). If you don’t choose this option, RDS for Oracle creates | CLI option:  
`--engine oracle-ee-cdb` (multitenant)  
`--engine oracle-se2-cdb` (multitenant)  
`--engine oracle-ee` (traditional)  
`--engine oracle-se2` (traditional)  
API parameter:  
Engine | Oracle |
<table>

</tr>
</thead>
<tbody>
<tr>
<td>a non-CDB. A non-CDB uses the traditional Oracle architecture. For more information, see [Overview of RDS for Oracle CDBs](p. 1856).</td>
<td></td>
<td></td>
<td>All</td>
</tr>
</tbody>
</table>
| Auto minor version upgrade   | Enable auto minor version upgrade to enable your DB instance to receive preferred minor DB engine version upgrades automatically when they become available. Amazon RDS performs automatic minor version upgrades in the maintenance window. For more information, see [Automatically upgrading the minor engine version](p. 431). | **CLI option:**  
--auto-minor-version-upgrade  
--no-auto-minor-version-upgrade  
**API parameter:**  
AutoMinorVersionUpgrade | All                  |
| Availability zone            | The Availability Zone for your DB instance. Use the default value of No Preference unless you want to specify an Availability Zone. For more information, see [Regions, Availability Zones, and Local Zones](p. 110). | **CLI option:**  
--availability-zone  
**API parameter:**  
AvailabilityZone | All                  |
| AWS KMS key                  | Only available if Encryption is set to Enable encryption. Choose the AWS KMS key to use for encrypting this DB instance. For more information, see [Encrypting Amazon RDS resources](p. 2603). | **CLI option:**  
--kms-key-id  
**API parameter:**  
KmsKeyId | All                  |
| Backup replication           | Choose Enable replication in another AWS Region to create backups in an additional Region for disaster recovery. Then choose the Destination Region for the additional backups. Not available when creating a DB instance. For information on enabling cross-Region backups using the AWS CLI or RDS API, see [Enabling cross-Region automated backups](p. 604). | **CLI option:**  
--backup-retention-period  
**API parameter:**  
BackupRetentionPeriod | Oracle PostgreSQL SQL Server |
| Backup retention period      | The number of days that you want automatic backups of your DB instance to be retained. For any nontrivial DB instance, set this value to 1 or greater. For more information, see [Working with backups](p. 591). | **CLI option:**  
--backup-retention-period  
**API parameter:**  
BackupRetentionPeriod | All                  |

</table>
| Database port      | The port that you want to access the DB instance through. The default port is shown. **Note** The firewalls at some companies block connections to the default MariaDB, MySQL, and PostgreSQL ports. If your company firewall blocks the default port, enter another port for your DB instance.                                                                                                                                | CLI option: --port  
RDS API parameter: Port                                                                                     | All                  |
| DB engine version  | The version of database engine that you want to use.                                                                                                                                                                                                                                                                                                                                                                   | CLI option: --engine-version  
RDS API parameter: EngineVersion                                                                                       | All                  |
| DB instance class  | The configuration for your DB instance. For example, a `db.t3.small` DB instance class has 2 GiB memory, 2 vCPUs, 1 virtual core, a variable ECU, and a moderate I/O capacity. If possible, choose a DB instance class large enough that a typical query working set can be held in memory. When working sets are held in memory, the system can avoid writing to disk, which improves performance. For more information, see [DB instance classes](#). In RDS for Oracle, you can select Include additional memory configurations. These configurations are optimized for a high ratio of memory to vCPU. For example, `db.r5.6xlarge.tpc2.mem4x` is a `db.r5.8x` DB instance that has 2 threads per core (tpc2) and 4x the memory of a standard `db.r5.6xlarge` DB instance. For more information, see [RDS for Oracle instance classes](#). | CLI option: --db-instance-class  
RDS API parameter: DBInstanceClass                                                                                      | All                  |
<table>
<thead>
<tr>
<th>Console setting</th>
<th>Setting description</th>

</thead>
</table>
| **DB instance identifier** | The name for your DB instance. Name your DB instances in the same way that you name your on-premises servers. Your DB instance identifier can contain up to 63 alphanumeric characters, and must be unique for your account in the AWS Region you chose.                                                                                           | **CLI option:**<br>  --db-instance-identifier  
  RDS API parameter:  
  DBInstanceIdentifier | All |
| **DB parameter group**   | A parameter group for your DB instance. You can choose the default parameter group, or you can create a custom parameter group.  
  For more information, see Working with parameter groups (p. 347).                                                                                                                                                                                                                     | **CLI option:**  
  --db-parameter-group-name  
  RDS API parameter:  
  DBParameterGroupName | All |
| **DB subnet group**      | The DB subnet group you want to use for the DB cluster. Select **Choose existing** to use an existing DB subnet group. Then choose the required subnet group from the **Existing DB subnet groups** dropdown list.  
  Choose **Automatic setup** to let RDS select a compatible DB subnet group. If none exist, RDS creates a new subnet group for your cluster.  
  For more information, see Working with DB subnet groups (p. 2706).                                                                                                                                                     | **CLI option:**  
  --db-subnet-group-name  
  RDS API parameter:  
  DBSubnetGroupName | All |
| **Deletion protection**  | Enable deletion protection to prevent your DB instance from being deleted. If you create a production DB instance with the AWS Management Console, deletion protection is enabled by default.  
  For more information, see Deleting a DB instance (p. 489).                                                                                                                                                                         | **CLI option:**  
  --deletion-protection  
  --no-deletion-protection  
  RDS API parameter:  
  DeletionProtection | All |
| **Encryption**           | Enable Encryption to enable encryption at rest for this DB instance.  
  For more information, see Encrypting Amazon RDS resources (p. 2603).                                                                                                                                                                                                                   | **CLI option:**  
  --storage-encrypted  
  --no-storage-encrypted  
  RDS API parameter:  
  StorageEncrypted | All |

| Enhanced Monitoring   | **Enable enhanced monitoring** to enable gathering metrics in real time for the operating system that your DB instance runs on.                                                                                                                                                                                                                                              | **CLI options:**  
  --monitoring-interval  
  --monitoring-role-arn  
  **RDS API parameters:**  
  MonitoringInterval  
  MonitoringRoleArn                                                                                                                                                                                                                               | All                  |
| Engine type           | Choose the database engine to be used for this DB instance.                                                                                                                                                                                                                                                                                                              | **CLI option:**  
  --engine  
  **RDS API parameter:**  
  Engine                                                                                                                                                                                                                                                                                                        | All                  |
| Initial database name | The name for the database on your DB instance. If you don't provide a name, Amazon RDS doesn't create a database on the DB instance (except for Oracle and PostgreSQL). The name can't be a word reserved by the database engine, and has other constraints depending on the DB engine.  
  **MariaDB and MySQL:**  
  • It must contain 1–64 alphanumeric characters.  
  **Oracle:**  
  • It must contain 1–8 alphanumeric characters.  
  • It can't be NULL. The default value is ORCL.  
  • It must begin with a letter.  
  **PostgreSQL:**  
  • It must contain 1–63 alphanumeric characters.  
  • It must begin with a letter or an underscore. Subsequent characters can be letters, underscores, or digits (0-9).  
  • The initial database name is postgres.                                                                                                                                                                                                                                                                | CLIs option:  
  --db-name  
  **RDS API parameter:**  
  DBName                                                                                                                                                                                                                                                                                                         | All except SQL Server |

| **Master password**                   | The password for your master user account. The password has the following number of printable ASCII characters (excluding '/', ',', a space, and @) depending on the DB engine:  
  - Oracle: 8–30  
  - MariaDB and MySQL: 8–41  
  - SQL Server and PostgreSQL: 8–128                                                                                                               | **CLI option:**  
  --master-user-password  
  
  **RDS API parameter:**  
  MasterUserPassword                                                                                                                                  | All                                                               |
| **Master username**                   | The name that you use as the master user name to log on to your DB instance with all database privileges.  
  - It can contain 1–16 alphanumeric characters and underscores.  
  - Its first character must be a letter.  
  - It can't be a word reserved by the database engine.  
  You can't change the master user name after the DB instance is created.  
  For more information on privileges granted to the master user, see [Master user account privileges](p. 2699). | **CLI option:**  
  --master-username  
  
  **RDS API parameter:**  
  MasterUsername                                                                                                                                       | All                                                               |
| **Microsoft SQL Server Windows Authentication** | Enable Microsoft SQL Server Windows authentication, then **Browse Directory** to choose the directory where you want to allow authorized domain users to authenticate with this SQL Server instance using Windows Authentication. | **CLI options:**

| **Multi-AZ deployment** | Create a standby instance to create a passive secondary replica of your DB instance in another Availability Zone for failover support. We recommend Multi-AZ for production workloads to maintain high availability. For development and testing, you can choose **Do not create a standby instance**. | **CLI option:**  
--multi-az  
--no-multi-az  
**RDS API parameter:**  
MultiAZ | All |
| **National character set (NCHAR)** | The national character set for your DB instance, commonly called the NCHAR character set. You can set the national character set to either AL16UTF16 (default) or UTF-8. You can't change the national character set after you create the DB instance. The national character set is different from the DB character set. Unlike the DB character set, the national character set specifies the encoding only for NCHAR data types (NCHAR, NVARCHAR2, and NCLOB) columns without affecting database metadata. | **CLI option:**  
--nchar-character-set-name  
**API parameter:**  
NcharCharacterSetName | Oracle |

For more information, see Configuring and managing a Multi-AZ deployment (p. 492). RDS for Oracle character sets (p. 1817).

</thead>
</table>
| Public access   | Yes to give the DB instance a public IP address, meaning that it's accessible outside the VPC. To be publicly accessible, the DB instance also has to be in a public subnet in the VPC. No to make the DB instance accessible only from inside the VPC. For more information, see [Hiding a DB instance in a VPC from the internet](p. 2712). To connect to a DB instance from outside of its VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group. In addition, other requirements must be met. For more information, see [Can't connect to Amazon RDS DB instance](p. 2744). If your DB instance isn't publicly accessible, use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see [Internetwork traffic privacy](p. 2622). | CLI option:  
--publicly-accessible  
--no-publicly-accessible  
RDS API parameter:  
PubliclyAccessible | All |
|                  |                      |                                   | MariaDB  
MySQL  
PostgreSQL |
| RDS Proxy        | Choose [Create an RDS Proxy](#) to create a proxy for your DB instance. Amazon RDS automatically creates an IAM role and a Secrets Manager secret for the proxy. For more information, see [Using Amazon RDS Proxy](p. 1215). | Not available when creating a DB instance. | MariaDB  
MySQL  
PostgreSQL |

Creating Amazon RDS resources with AWS CloudFormation

Amazon RDS is integrated with AWS CloudFormation, a service that helps you to model and set up your AWS resources so that you can spend less time creating and managing your resources and infrastructure. You create a template that describes all the AWS resources that you want (such as DB instances and DB parameter groups), and AWS CloudFormation provisions and configures those resources for you.

When you use AWS CloudFormation, you can reuse your template to set up your RDS resources consistently and repeatedly. Describe your resources once, and then provision the same resources over and over in multiple AWS accounts and Regions.

RDS and AWS CloudFormation templates

To provision and configure resources for RDS and related services, you must understand AWS CloudFormation templates. Templates are formatted text files in JSON or YAML. These templates describe the resources that you want to provision in your AWS CloudFormation stacks. If you’re unfamiliar with JSON or YAML, you can use AWS CloudFormation Designer to help you get started with AWS CloudFormation templates. For more information, see What is AWS CloudFormation Designer? in the AWS CloudFormation User Guide.

RDS supports creating resources in AWS CloudFormation. For more information, including examples of JSON and YAML templates for these resources, see the RDS resource type reference in the AWS CloudFormation User Guide.

Learn more about AWS CloudFormation

To learn more about AWS CloudFormation, see the following resources:

- AWS CloudFormation
- AWS CloudFormation User Guide
- AWS CloudFormation API Reference
- AWS CloudFormation Command Line Interface User Guide
Connecting to a DB instance

Before you can connect to a DB instance, you must create the DB instance. For information, see Creating an Amazon RDS DB instance (p. 300). After Amazon RDS provisions your DB instance, use any standard client application or utility for your DB engine to connect to the DB instance. In the connection string, specify the DNS address from the DB instance endpoint as the host parameter. Also, specify the port number from the DB instance endpoint as the port parameter.

Topics

• Finding the connection information for an Amazon RDS DB instance (p. 325)
• Database authentication options (p. 328)
• Encrypted connections (p. 329)
• Scenarios for accessing a DB instance in a VPC (p. 329)
• Connecting to a DB instance that is running a specific DB engine (p. 329)
• Managing connections with RDS Proxy (p. 330)

Finding the connection information for an Amazon RDS DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, for a MySQL DB instance, suppose that the endpoint value is mydb.123456789012.us-east-1.rds.amazonaws.com. In this case, the port value is 3306, and the database user is admin. Given this information, you specify the following values in a connection string:

• For host or host name or DNS name, specify mydb.123456789012.us-east-1.rds.amazonaws.com.
• For port, specify 3306.
• For user, specify admin.

The endpoint is unique for each DB instance, and the values of the port and user can vary. The following list shows the most common port for each DB engine:

• MariaDB – 3306
• Microsoft SQL Server – 1433
• MySQL – 3306
• Oracle – 1521
• PostgreSQL – 5432

To connect to a DB instance, use any client for a DB engine. For example, you might use the mysql utility to connect to a MariaDB or MySQL DB instance. You might use Microsoft SQL Server Management Studio to connect to a SQL Server DB instance. You might use Oracle SQL Developer to connect to an Oracle DB instance. Similarly, you might use the psql command line utility to connect to a PostgreSQL DB instance.

To find the connection information for a DB instance, use the AWS Management Console. You can also use the AWS Command Line Interface (AWS CLI) describe-db-instances command or the RDS API DescribeDBInstances operation.
Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases to display a list of your DB instances.
3. Choose the name of the DB instance to display its details.
4. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
5. If you need to find the master user name, choose the Configuration tab and view the Master username value.

**AWS CLI**

To find the connection information for a DB instance by using the AWS CLI, call the `describe-db-instances` command. In the call, query for the DB instance ID, endpoint, port, and master user name.
Database authentication options

Amazon RDS supports the following ways to authenticate database users:

- **Password authentication** – Your DB instance performs all administration of user accounts. You create users and specify passwords with SQL statements. The SQL statements you can use depend on your DB engine.

- **AWS Identity and Access Management (IAM) database authentication** – You don’t need to use a password when you connect to a DB instance. Instead, you use an authentication token.

- **Kerberos authentication** – You use external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

IAM database authentication and Kerberos authentication are available only for specific DB engines and versions.
Encrypted connections

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB instance. Each DB engine has its own process for implementing SSL/TLS. For more information, see "Using SSL/TLS to encrypt a connection to a DB instance" (p. 2608).

Scenarios for accessing a DB instance in a VPC

Using Amazon Virtual Private Cloud (Amazon VPC), you can launch AWS resources, such as Amazon RDS DB instances, into a virtual private cloud (VPC). When you use Amazon VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists.

A VPC security group controls access to DB instances inside a VPC. Each VPC security group rule enables a specific source to access a DB instance in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group.

Before attempting to connect to your DB instance, configure your VPC for your use case. The following are common scenarios for accessing a DB instance in a VPC:

• **A DB instance in a VPC accessed by an Amazon EC2 instance in the same VPC** – A common use of a DB instance in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC. The EC2 instance might run a web server with an application that interacts with the DB instance.

• **A DB instance in a VPC accessed by an EC2 instance in a different VPC** – In some cases, your DB instance is in a different VPC from the EC2 instance that you're using to access it. If so, you can use VPC peering to access the DB instance.

• **A DB instance in a VPC accessed by a client application through the internet** – To access a DB instance in a VPC from a client application through the internet, you configure a VPC with a single public subnet. You also configure an internet gateway to enable communication over the internet.

  To connect to a DB instance from outside of its VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see "Can't connect to Amazon RDS DB instance" (p. 2744).

• **A DB instance in a VPC accessed by a private network** – If your DB instance isn't publicly accessible, you can use one of the following options to access it from a private network:
  • An AWS Site-to-Site VPN connection
  • An AWS Direct Connect connection
  • An AWS Client VPN connection

  For more information, see "Scenarios for accessing a DB instance in a VPC" (p. 2718).

Connecting to a DB instance that is running a specific DB engine

For information about connecting to a DB instance that is running a specific DB engine, follow the instructions for your DB engine:

• **Connecting to a DB instance running the MariaDB database engine** (p. 1285)
• Connecting to a DB instance running the Microsoft SQL Server database engine (p. 1396)
• Connecting to a DB instance running the MySQL database engine (p. 1646)
• Connecting to your RDS for Oracle DB instance (p. 1822)
• Connecting to a DB instance running the PostgreSQL database engine (p. 2184)

Managing connections with RDS Proxy

You can also use Amazon RDS Proxy to manage connections to RDS for MariaDB, RDS for Microsoft SQL Server, RDS for MySQL, and RDS for PostgreSQL DB instances. RDS Proxy allows applications to pool and share database connections to improve scalability. For more information, see Using Amazon RDS Proxy (p. 1215).
Working with option groups

Some DB engines offer additional features that make it easier to manage data and databases, and to provide additional security for your database. Amazon RDS uses option groups to enable and configure these features. An option group can specify features, called options, that are available for a particular Amazon RDS DB instance. Options can have settings that specify how the option works. When you associate a DB instance with an option group, the specified options and option settings are enabled for that DB instance.

Amazon RDS supports options for the following database engines:

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Relevant documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB</td>
<td>Options for MariaDB database engine (p. 1350)</td>
</tr>
<tr>
<td>Microsoft SQL Server</td>
<td>Options for the Microsoft SQL Server database engine (p. 1530)</td>
</tr>
<tr>
<td>MySQL</td>
<td>Options for MySQL DB instances (p. 1748)</td>
</tr>
<tr>
<td>Oracle</td>
<td>Adding options to Oracle DB instances (p. 2006)</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>PostgreSQL does not use options and option groups. PostgreSQL uses extensions and modules to provide additional features. For more information, see Supported PostgreSQL extension versions (p. 2173).</td>
</tr>
</tbody>
</table>

Option groups overview

Amazon RDS provides an empty default option group for each new DB instance. You can't modify or delete this default option group, but any new option group that you create derives its settings from the default option group. To apply an option to a DB instance, you must do the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add one or more options to the option group.
3. Associate the option group with the DB instance.

To associate an option group with a DB instance, modify the DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 401).

Both DB instances and DB snapshots can be associated with an option group. In some cases, you might restore from a DB snapshot or perform a point-in-time restore for a DB instance. In these cases, the option group associated with the DB snapshot or DB instance is, by default, associated with the restored DB instance. You can associate a different option group with a restored DB instance. However, the new option group must contain any persistent or permanent options that were included in the original option group. Persistent and permanent options are described following.

Options require additional memory to run on a DB instance. Thus, you might need to launch a larger instance to use them, depending on your current use of your DB instance. For example, Oracle Enterprise Manager Database Control uses about 300 MB of RAM. If you enable this option for a small DB instance, you might encounter performance problems or out-of-memory errors.

Persistent and permanent options

Two types of options, persistent and permanent, require special consideration when you add them to an option group.
Persistent options can't be removed from an option group while DB instances are associated with the option group. An example of a persistent option is the TDE option for Microsoft SQL Server transparent data encryption (TDE). You must disassociate all DB instances from the option group before a persistent option can be removed from the option group. In some cases, you might restore or perform a point-in-time restore from a DB snapshot. In these cases, if the option group associated with that DB snapshot contains a persistent option, you can only associate the restored DB instance with that option group.

Permanent options, such as the TDE option for Oracle Advanced Security TDE, can never be removed from an option group. You can change the option group of a DB instance that is using the permanent option. However, the option group associated with the DB instance must include the same permanent option. In some cases, you might restore or perform a point-in-time restore from a DB snapshot. In these cases, if the option group associated with that DB snapshot contains a permanent option, you can only associate the restored DB instance with an option group with that permanent option.

For Oracle DB instances, you can copy shared DB snapshots that have the options Timezone or OLS (or both). To do so, specify a target option group that includes these options when you copy the DB snapshot. The OLS option is permanent and persistent only for Oracle DB instances running Oracle version 12.2 or higher. For more information about these options, see Oracle time zone (p. 2103) and Oracle Label Security (p. 2065).

**VPC considerations**

The option group associated with the DB instance is linked to the DB instance's VPC. This means that you can't use the option group assigned to a DB instance if you try to restore the instance to a different VPC. If you restore a DB instance to a different VPC, you can do one of the following:

- Assign the default option group to the DB instance.
- Assign an option group that is linked to that VPC.
- Create a new option group and assign it to the DB instance.

With persistent or permanent options, such as Oracle TDE, you must create a new option group. This option group must include the persistent or permanent option when restoring a DB instance into a different VPC.

Option settings control the behavior of an option. For example, the Oracle Advanced Security option `NATIVE_NETWORK_ENCRYPTION` has a setting that you can use to specify the encryption algorithm for network traffic to and from the DB instance. Some options settings are optimized for use with Amazon RDS and cannot be changed.

**Mutually exclusive options**

Some options are mutually exclusive. You can use one or the other, but not both at the same time. The following options are mutually exclusive:

- Oracle Enterprise Manager Database Express (p. 2051) and Oracle Management Agent for Enterprise Manager Cloud Control (p. 2055).
- Oracle native network encryption (p. 2073) and Oracle Secure Sockets Layer (p. 2084).

**Creating an option group**

You can create a new option group that derives its settings from the default option group. You then add one or more options to the new option group. Or, if you already have an existing option group, you can copy that option group with all of its options to a new option group. For more information, see Copying an option group (p. 334).
After you create a new option group, it has no options. To learn how to add options to the option group, see Adding an option to an option group (p. 335). After you have added the options you want, you can then associate the option group with a DB instance. This way, the options become available on the DB instance. For information about associating an option group with a DB instance, see the documentation for your engine in Working with option groups (p. 331).

Console

One way of creating an option group is by using the AWS Management Console.

To create a new option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose Create group.
4. In the Create option group window, do the following:
   a. For Name, type a name for the option group that is unique within your AWS account. The name can contain only letters, digits, and hyphens.
   b. For Description, type a brief description of the option group. The description is used for display purposes.
   c. For Engine, choose the DB engine that you want.
   d. For Major engine version, choose the major version of the DB engine that you want.
5. To continue, choose Create. To cancel the operation instead, choose Cancel.

AWS CLI

To create an option group, use the AWS CLI create-option-group command with the following required parameters.

- --option-group-name
- --engine-name
- --major-engine-version
- --option-group-description

Example

The following example creates an option group named testoptiongroup, which is associated with the Oracle Enterprise Edition DB engine. The description is enclosed in quotation marks.

For Linux, macOS, or Unix:

```
aws rds create-option-group \
  --option-group-name testoptiongroup \
  --engine-name oracle-ee \
  --major-engine-version 12.1 \
  --option-group-description "Test option group"
```

For Windows:
Amazon Relational Database Service User Guide

Copying an option group

aws rds create-option-group ^
  --option-group-name testoptiongroup ^
  --engine-name oracle-ee ^
  --major-engine-version 12.1 ^
  --option-group-description "Test option group"

RDS API

To create an option group, call the Amazon RDS API CreateOptionGroup operation. Include the following parameters:

- OptionGroupName
- EngineName
- MajorEngineVersion
- OptionGroupDescription

Copying an option group

You can use the AWS CLI or the Amazon RDS API copy an option group. Copying an option group can be convenient. An example is when you have an existing option group and want to include most of its custom parameters and values in a new option group. You can also make a copy of an option group that you use in production and then modify the copy to test other option settings.

Note
Currently, you can't copy an option group to a different AWS Region.

AWS CLI

To copy an option group, use the AWS CLI copy-option-group command. Include the following required options:

- --source-option-group-identifier
- --target-option-group-identifier
- --target-option-group-description

Example

The following example creates an option group named new-option-group, which is a local copy of the option group my-option-group.

For Linux, macOS, or Unix:

aws rds copy-option-group \  
  --source-option-group-identifier my-option-group \  
  --target-option-group-identifier new-option-group \  
  --target-option-group-description "My new option group"

For Windows:

aws rds copy-option-group ^  
  --source-option-group-identifier my-option-group ^  
  --target-option-group-identifier new-option-group ^  
  --target-option-group-description "My new option group"
RDS API

To copy an option group, call the Amazon RDS API CopyOptionGroup operation. Include the following required parameters.

- SourceOptionGroupIdentifier
- TargetOptionGroupIdentifier
- TargetOptionGroupDescription

Adding an option to an option group

You can add an option to an existing option group. After you have added the options you want, you can then associate the option group with a DB instance so that the options become available on the DB instance. For information about associating an option group with a DB instance, see the documentation for your specific DB engine listed at Working with option groups (p. 331).

Option group changes must be applied immediately in two cases:

- When you add an option that adds or updates a port value, such as the OEM option.
- When you add or remove an option group with an option that includes a port value.

In these cases, choose the Apply Immediately option in the console. Or you can include the --apply-immediately option when using the AWS CLI or set the ApplyImmediately parameter to true when using the Amazon RDS API. Options that don’t include port values can be applied immediately, or can be applied during the next maintenance window for the DB instance.

Note
If you specify a security group as a value for an option in an option group, manage the security group by modifying the option group. You can’t change or remove this security group by modifying a DB instance. Also, the security group doesn’t appear in the DB instance details in the AWS Management Console or in the output for the AWS CLI command describe-db-instances.

Console

You can use the AWS Management Console to add an option to an option group.

To add an option to an option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the option group that you want to modify, and then choose Add option.
4. In the Add option window, do the following:
   
a. Choose the option that you want to add. You might need to provide additional values, depending on the option that you select. For example, when you choose the OEM option, you must also type a port value and specify a security group.

b. To enable the option on all associated DB instances as soon as you add it, for Apply Immediately, choose Yes. If you choose No (the default), the option is enabled for each associated DB instance during its next maintenance window.
5. When the settings are as you want them, choose **Add option**.

**AWS CLI**

To add an option to an option group, run the AWS CLI **add-option-to-option-group** command with the option that you want to add. To enable the new option immediately on all associated DB instances, include the **--apply-immediately** parameter. By default, the option is enabled for each associated DB instance during its next maintenance window. Include the following required parameter:

- **--option-group-name**

**Example**

The following example adds the Oracle Enterprise Manager Database Control (OEM) option to an option group named testoptiongroup and immediately enables it. Even if you use the default security group, you must specify that security group.

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
```
Adding an option to an option group

```
--option-group-name testoptiongroup \
--options OptionName=OEM,Port=5500,DBSecurityGroupMemberships=default \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name testoptiongroup ^
--options OptionName=OEM,Port=5500,DBSecurityGroupMemberships=default ^
--apply-immediately
```

Command output is similar to the following:

```
Test Option Group  testoptiongroup default
OPTIONS Oracle 12c EM Express   OEM     False   False   5500
DBSECURITYGROUPMEMBERSHIPS   default authorized
```

**Example**

The following example adds the Oracle OEM option to an option group. It also specifies a custom port and a pair of Amazon EC2 VPC security groups to use for that port.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
--option-group-name testoptiongroup \
--options OptionName=OEM,Port=5500,VpcSecurityGroupMemberships="sg-test1,sg-test2" \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name testoptiongroup ^
--options OptionName=OEM,Port=5500,VpcSecurityGroupMemberships="sg-test1,sg-test2" ^
--apply-immediately
```

Command output is similar to the following:

```
Test Option Group  testoptiongroup vpc-test
OPTIONS Oracle 12c EM Express   OEM     False   False   5500
VPCSECURITYGROUPMEMBERSHIPS   active  sg-test1
VPCSECURITYGROUPMEMBERSHIPS   active  sg-test2
```

**Example**

The following example adds the Oracle option NATIVE_NETWORK_ENCRYPTION to an option group and specifies the option settings. If no option settings are specified, default values are used.
For Linux, macOS, or Unix:

```bash/aws rds add-option-to-option-group \
--option-group-name testoptiongroup \
--options '[["OptionSettings":[["Name":"SQLNET.ENCRYPTION_SERVER","Value":"REQUIRED"], \
"Name":"SQLNET.ENCRYPTION_TYPES_SERVER","Value":"AES256,AES192,DES"}},"OptionName":"NATIVE_NETWORK_ENCRYPTION" \
--apply-immediately
```

For Windows:

```bash
/aws rds add-option-to-option-group \\n--option-group-name testoptiongroup \\n--options "OptionSettings"=[{"Name"="SQLNET.ENCRYPTION_SERVER","Value"="REQUIRED"}, \
{"Name"="SQLNET.ENCRYPTION_TYPES_SERVER","Value"="AES256,AES192,DES"}],"OptionName"="NATIVE_NETWORK_ENCRYPTION" \\n--apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP  False  oracle-ee  12.1  arn:aws:rds:us-east-1:1234567890:og:testoptiongroup Test Option Group testoptiongroup OPTIONS Oracle Advanced Security - Native Network Encryption NATIVE_NETWORK_ENCRYPTION False  False OPTIONSETTINGS RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40 STATIC  STRING RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40 Specifies list of encryption algorithms in order of intended use True  True SQLNET.ENCRYPTION_TYPES_SERVER AES256,AES192,DES OPTIONSETTINGS ACCEPTED,REJECTED,REQUESTED,REQUIRED STATIC STRING REQUESTED Specifies the desired encryption behavior False  True SQLNET.ENCRYPTION_SERVER REQUIRED OPTIONSETTINGS SHA1,MD5 STATIC STRING SHA1,MD5 Specifies list of checksumming algorithms in order of intended use True  True SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER SHA1,MD5
```

**RDS API**

To add an option to an option group using the Amazon RDS API, call the `ModifyOptionGroup` operation with the option that you want to add. To enable the new option immediately on all associated DB instances, include the `ApplyImmediately` parameter and set it to `true`. By default, the option is enabled for each associated DB instance during its next maintenance window. Include the following required parameter:

- OptionGroupName

**Listing the options and option settings for an option group**

You can list all the options and option settings for an option group.
Modifying an option setting

**Console**

You can use the AWS Management Console to list all of the options and option settings for an option group.

**To list the options and option settings for an option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Option groups**.
3. Choose the name of the option group to display its details. The options and option settings in the option group are listed.

**AWS CLI**

To list the options and option settings for an option group, use the AWS CLI `describe-option-groups` command. Specify the name of the option group whose options and settings you want to view. If you don't specify an option group name, all option groups are described.

**Example**

The following example lists the options and option settings for all option groups.

```bash
aws rds describe-option-groups
```

**Example**

The following example lists the options and option settings for an option group named `testoptiongroup`.

```bash
aws rds describe-option-groups --option-group-name testoptiongroup
```

**RDS API**

To list the options and option settings for an option group, use the Amazon RDS API `DescribeOptionGroups` operation. Specify the name of the option group whose options and settings you want to view. If you don't specify an option group name, all option groups are described.

**Modifying an option setting**

After you have added an option that has modifiable option settings, you can modify the settings at any time. If you change options or option settings in an option group, those changes are applied to all DB instances that are associated with that option group. For more information on what settings are available for the various options, see the documentation for your engine in **Working with option groups** (p. 331).

Option group changes must be applied immediately in two cases:

- When you add an option that adds or updates a port value, such as the OEM option.
- When you add or remove an option group with an option that includes a port value.

In these cases, choose the **Apply Immediately** option in the console. Or you can include the `--apply-immediately` option when using the AWS CLI or set the `ApplyImmediately` parameter to `true` when...
using the RDS API. Options that don't include port values can be applied immediately, or can be applied during the next maintenance window for the DB instance.

**Note**

If you specify a security group as a value for an option in an option group, you manage the security group by modifying the option group. You can't change or remove this security group by modifying a DB instance. Also, the security group doesn't appear in the DB instance details in the AWS Management Console or in the output for the AWS CLI command describe-db-instances.

**Console**

You can use the AWS Management Console to modify an option setting.

**To modify an option setting by using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Select the option group whose option that you want to modify, and then choose **Modify option**.
4. In the **Modify option** window, from **Installed Options**, choose the option whose setting you want to modify. Make the changes that you want.
5. To enable the option as soon as you add it, for **Apply Immediately**, choose **Yes**. If you choose **No** (the default), the option is enabled for each associated DB instance during its next maintenance window.
6. When the settings are as you want them, choose **Modify Option**.

**AWS CLI**

To modify an option setting, use the AWS CLI `add-option-to-option-group` command with the option group and option that you want to modify. By default, the option is enabled for each associated DB instance during its next maintenance window. To apply the change immediately to all associated DB instances, include the `--apply-immediately` parameter. To modify an option setting, use the `--settings` argument.

**Example**

The following example modifies the port that the Oracle Enterprise Manager Database Control (OEM) uses in an option group named testoptiongroup and immediately applies the change.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
  --option-group-name testoptiongroup \
  --options OptionName=OEM,Port=5432,DBSecurityGroupMemberships=default \
  --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
  --option-group-name testoptiongroup ^
  --options OptionName=OEM,Port=5432,DBSecurityGroupMemberships=default ^
  --apply-immediately
```
Command output is similar to the following:

```
Test  Option  Group  testoptiongroup
OPTIONS  Oracle 12c  EM  Express  OEM  False  False  5432
DBSECURITYGROUPMEMBERSHIPS  default  authorized
```

Example

The following example modifies the Oracle option `NATIVE_NETWORK_ENCRYPTION` and changes the option settings.

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
  --option-group-name testoptiongroup \
  --options '[["OptionSettings":[["Name":"SQLNET.ENCRYPTION_SERVER","Value":"REQUIRED"], \
  ["Name":"SQLNET.ENCRYPTION_TYPES_SERVER","Value":"AES256,AES192,DES,RC4_256"]],"OptionName":"NATIVE_NETWORK_ENCRYPTION"]]' \
  --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^
  --option-group-name testoptiongroup ^
  --options "OptionSettings"= ["Name"="SQLNET.ENCRYPTION_SERVER","Value"="REQUIRED"], \
  ["Name"="SQLNET.ENCRYPTION_TYPES_SERVER","Value"="AES256\,AES192\,DES\,RC4_256"]],"OptionName"="NATIVE_NETWORK_ENCRYPTION" ^
  --apply-immediately
```

Command output is similar to the following:

```
Test  Option  Group  testoptiongroup
OPTIONS  Oracle Advanced Security - Native Network Encryption  NATIVE_NETWORK_ENCRYPTION  False  False
OPTIONSETTINGS
  RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40 STATIC STRING
  RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40 Specifies list of encryption algorithms in order of intended use
  True  True  SQLNET.ENCRYPTION_TYPES_SERVER  AES256,AES192,DES,RC4_256
OPTIONSETTINGS ACCEPTED,REJECTED,REQUESTED,REQUIRED STATIC STRING REQUESTED Specifies the desired encryption behavior  False  True  SQLNET.ENCRYPTION_SERVER REQUESTED
OPTIONSETTINGS  SHA1,MD5  STATIC STRING  SHA1,MD5  Specifies list of checksumming algorithms in order of intended use  True  True
SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER  SHA1,MD5
OPTIONSETTINGS ACCEPTED,REJECTED,REQUESTED,REQUIRED STATIC STRING REQUESTED Specifies the desired data integrity behavior  False  True SQLNET.CRYPTO_CHECKSUM_SERVER REQUESTED
```
RDS API

To modify an option setting, use the Amazon RDS API ModifyOptionGroup command with the option group and option that you want to modify. By default, the option is enabled for each associated DB instance during its next maintenance window. To apply the change immediately to all associated DB instances, include the ApplyImmediately parameter and set it to true.

Removing an option from an option group

Some options can be removed from an option group, and some cannot. A persistent option cannot be removed from an option group until all DB instances associated with that option group are disassociated. A permanent option can never be removed from an option group. For more information about what options are removable, see the documentation for your specific engine listed at Working with option groups (p. 331).

If you remove all options from an option group, Amazon RDS doesn’t delete the option group. DB instances that are associated with the empty option group continue to be associated with it; they just won’t have any active options. Alternatively, to remove all options from a DB instance, you can associate the DB instance with the default (empty) option group.

Console

You can use the AWS Management Console to remove an option from an option group.

To remove an option from an option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Select the option group whose option you want to remove, and then choose Delete option.
4. In the Delete option window, do the following:
   - Select the check box for the option that you want to delete.
   - For the deletion to take effect as soon as you make it, for Apply immediately, choose Yes. If you choose No (the default), the option is deleted for each associated DB instance during its next maintenance window.
5. When the settings are as you want them, choose Yes, Delete.

**AWS CLI**

To remove an option from an option group, use the AWS CLI `remove-option-from-option-group` command with the option that you want to delete. By default, the option is removed from each associated DB instance during its next maintenance window. To apply the change immediately, include the `--apply-immediately` parameter.

**Example**

The following example removes the Oracle Enterprise Manager Database Control (OEM) option from an option group named `testoptiongroup` and immediately applies the change.

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
   --option-group-name testoptiongroup \
   --options OEM \
   --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^
   --option-group-name testoptiongroup ^
   --options OEM ^
   --apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP    testoptiongroup oracle-ee   12.1    Test option group
```

**RDS API**

To remove an option from an option group, use the Amazon RDS API `ModifyOptionGroup` action. By default, the option is removed from each associated DB instance during its next maintenance window. To apply the change immediately, include the `ApplyImmediately` parameter and set it to `true`.

Include the following parameters:

- `OptionGroupName`
- `OptionsToRemove.OptionName`

**Deleting an option group**

You can delete an option group that is not associated with any Amazon RDS resource. An option group can be associated with a DB instance, a manual DB snapshot, or an automated DB snapshot.

You can't delete a default option group. If you try to delete an option group that is associated with an RDS resource, an error like the following is returned.
An error occurred (InvalidOptionGroupStateFault) when calling the DeleteOptionGroup operation: The option group 'optionGroupName' cannot be deleted because it is in use.

To find the Amazon RDS resources associated with an option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the name of the option group to show its details.
4. Check the Associated Instances and Snapshots section for the associated Amazon RDS resources.

If a DB instance is associated with the option group, modify the DB instance to use a different option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).

If a manual DB snapshot is associated with the option group, modify the DB snapshot to use a different option group. You can do so using the AWS CLI modify-db-snapshot command.

Note
You can't modify the option group of an automated DB snapshot.

Console

One way of deleting an option group is by using the AWS Management Console.

To delete an option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the option group.
4. Choose Delete group.
5. On the confirmation page, choose Delete to finish deleting the option group, or choose Cancel to cancel the deletion.

AWS CLI

To delete an option group, use the AWS CLI delete-option-group command with the following required parameter.

- --option-group-name

Example

The following example deletes an option group named testoptiongroup.

For Linux, macOS, or Unix:

```
aws rds delete-option-group \
  --option-group-name testoptiongroup
```
For Windows:

```bash
aws rds delete-option-group
   --option-group-name testoptiongroup
```

**RDS API**

To delete an option group, call the Amazon RDS API [DeleteOptionGroup](https://docs.aws.amazon.com/AmazonRDS/latest/api/ApiGuide-rds-delete-option-group.html) operation. Include the following parameter:

- OptionGroupName
Working with parameter groups

Database parameters specify how the database is configured. For example, database parameters can specify the amount of resources, such as memory, to allocate to a database.

You manage your database configuration by associating your DB instances and Multi-AZ DB clusters with parameter groups. Amazon RDS defines parameter groups with default settings. You can also define your own parameter groups with customized settings.

Note
Some DB engines offer additional features that you can add to your database as options in an option group. For information about option groups, see Working with option groups (p. 331).

Topics

- Overview of parameter groups (p. 347)
- Working with DB parameter groups (p. 349)
- Working with DB cluster parameter groups for Multi-AZ DB clusters (p. 360)
- Comparing parameter groups (p. 368)
- Specifying DB parameters (p. 369)

Overview of parameter groups

A DB parameter group acts as a container for engine configuration values that are applied to one or more DB instances. DB cluster parameter groups apply to Multi-AZ DB clusters only. In a Multi-AZ DB cluster, the settings in the DB cluster parameter group apply to all of the DB instances in the cluster. The default DB parameter group for the DB engine and DB engine version is used for each DB instance in the DB cluster.

Topics

- Default and custom parameter groups (p. 347)
- Static and dynamic DB instance parameters (p. 348)
- Static and dynamic DB cluster parameters (p. 348)
- Character set parameters (p. 349)
- Supported parameters and parameter values (p. 349)

Default and custom parameter groups

If you create a DB instance without specifying a DB parameter group, the DB instance uses a default DB parameter group. Likewise, if you create a Multi-AZ DB cluster without specifying a DB cluster parameter group, the DB cluster uses a default DB cluster parameter group. Each default parameter group contains database engine defaults and Amazon RDS system defaults based on the engine, compute class, and allocated storage of the instance.

You can’t modify the parameter settings of a default parameter group. Instead, you can do the following:

1. Create a new parameter group.
2. Change the settings of your desired parameters. Not all DB engine parameters in a parameter group are eligible to be modified.
3. Modify your DB instance or DB cluster to use the custom parameter group. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401). For information about modifying a Multi-AZ DB clusters, see Modifying a Multi-AZ DB cluster (p. 539).
Note
If you have modified your DB instance to use a custom parameter group, and you start the DB instance, RDS automatically reboots the DB instance as part of the startup process.

If you update parameters within a DB parameter group, the changes apply to all DB instances that are associated with that parameter group. Likewise, if you update parameters within a Multi-AZ DB cluster parameter group, the changes apply to all Aurora DB clusters that are associated with that DB cluster parameter group.

If you don't want to create a parameter group from scratch, you can copy an existing parameter group with the AWS CLI `copy-db-parameter-group` command or `copy-db-cluster-parameter-group` command. You might find that copying a parameter group is useful in some cases. For example, you might want to include most of an existing DB parameter group's custom parameters and values in a new DB parameter group.

**Static and dynamic DB instance parameters**

DB instance parameters are either static or dynamic. They differ as follows:

- When you change a static parameter and save the DB parameter group, the parameter change takes effect after you manually reboot the associated DB instances. For static parameters, the console always uses `pending-reboot` for the `ApplyMethod`.
- When you change a dynamic parameter, by default the parameter change takes effect immediately, without requiring a reboot. When you use the AWS Management Console to change DB instance parameter values, it always uses `immediate` for the `ApplyMethod` for dynamic parameters. To defer the parameter change until after you reboot an associated DB instance, use the AWS CLI or RDS API. Set the `ApplyMethod` to `pending-reboot` for the parameter change.

  Note
  Using `pending-reboot` with dynamic parameters in the AWS CLI or RDS API on RDS for SQL Server DB instances generates an error. Use `apply-immediately` on RDS for SQL Server.

For more information about using the AWS CLI to change a parameter value, see `modify-db-parameter-group`. For more information about using the RDS API to change a parameter value, see `ModifyDBParameterGroup`.

When you associate a new DB parameter group with a DB instance, RDS applies the modified static and dynamic parameters only after the DB instance is rebooted. However, if you modify dynamic parameters in the DB parameter group after you associate it with the DB instance, these changes are applied immediately without a reboot. For more information about changing the DB parameter group, see `Modifying an Amazon RDS DB instance (p. 401)`.

If a DB instance isn't using the latest changes to its associated DB parameter group, the console shows a status of `pending-reboot` for the DB parameter group. This status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

**Static and dynamic DB cluster parameters**

DB cluster parameters are either static or dynamic. They differ as follows:

- When you change a static parameter and save the DB cluster parameter group, the parameter change takes effect after you manually reboot the associated DB clusters. For static parameters, the console always uses `pending-reboot` for the `ApplyMethod`.
- When you change a dynamic parameter, by default the parameter change takes effect immediately, without requiring a reboot. When you use the AWS Management Console to change DB cluster
parameter values, it always uses immediate for the ApplyMethod for dynamic parameters. To defer the parameter change until after an associated DB cluster is rebooted, use the AWS CLI or RDS API. Set the ApplyMethod to pending-reboot for the parameter change.

For more information about using the AWS CLI to change a parameter value, see modify-db-cluster-parameter-group. For more information about using the RDS API to change a parameter value, see ModifyDBClusterParameterGroup.

**Character set parameters**

Before you create a DB instance or Multi-AZ DB cluster, set any parameters that relate to the character set or collation of your database in your parameter group. Also do so before you create a database in it. In this way, you ensure that the default database and new databases use the character set and collation values that you specify. If you change character set or collation parameters, the parameter changes aren't applied to existing databases.

For some DB engines, you can change character set or collation values for an existing database using the ALTER DATABASE command, for example:

```
ALTER DATABASE database_name CHARACTER SET character_set_name COLLATE collation;
```

For more information about changing the character set or collation values for a database, check the documentation for your DB engine.

**Supported parameters and parameter values**

To determine the supported parameters for your DB engine, view the parameters in the DB parameter group and DB cluster parameter group used by the DB instance or DB cluster. For more information, see Viewing parameter values for a DB parameter group (p. 359) and Viewing parameter values for a DB cluster parameter group (p. 367).

In many cases, you can specify integer and Boolean parameter values using expressions, formulas, and functions. Functions can include a mathematical log expression. However, not all parameters support expressions, formulas, and functions for parameter values. For more information, see Specifying DB parameters (p. 369).

Improperly setting parameters in a parameter group can have unintended adverse effects, including degraded performance and system instability. Always be cautious when modifying database parameters, and back up your data before modifying a parameter group. Try parameter group setting changes on a test DB instance or DB cluster before applying those parameter group changes to a production DB instance or DB cluster.

**Working with DB parameter groups**

DB instances use DB parameter groups. The following sections describe configuring and managing DB instance parameter groups.

**Topics**

- Creating a DB parameter group (p. 350)
- Associating a DB parameter group with a DB instance (p. 351)
- Modifying parameters in a DB parameter group (p. 352)
- Resetting parameters in a DB parameter group to their default values (p. 354)
- Copying a DB parameter group (p. 356)
Creating a DB parameter group

You can create a new DB parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

The following limitations apply to the DB parameter group name:

- The name must be 1 to 255 letters, numbers, or hyphens.
- Default parameter group names can include a period, such as default.mysql8.0. However, custom parameter group names can't include a period.
- The first character must be a letter.
- The name can't end with a hyphen or contain two consecutive hyphens.

**Console**

**To create a DB parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
4. In the Parameter group family list, select a DB parameter group family.
5. In the Type list, select DB Parameter Group.
6. In the Group name box, enter the name of the new DB parameter group.
7. In the Description box, enter a description for the new DB parameter group.
8. Choose Create.

**AWS CLI**

To create a DB parameter group, use the AWS CLI create-db-parameter-group command. The following example creates a DB parameter group named mydbparametergroup for MySQL version 8.0 with a description of "My new parameter group."

```
aws rds create-db-parameter-group --db-parameter-group-name mydbparametergroup --db-parameter-group-family mysql --description "My new parameter group."
```

Include the following required parameters:

- --db-parameter-group-name
- --db-parameter-group-family
- --description

To list all of the available parameter group families, use the following command:

```
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```

**Note**
The output contains duplicates.
Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-parameter-group
  --db-parameter-group-name mydbparametergroup
  --db-parameter-group-family MySQL8.0
  --description "My new parameter group"
```

For Windows:

```bash
aws rds create-db-parameter-group
  --db-parameter-group-name mydbparametergroup
  --db-parameter-group-family MySQL8.0
  --description "My new parameter group"
```

This command produces output similar to the following:

```
DBPARAMETERGROUP  mydbparametergroup  mysql8.0  My new parameter group
```

RDS API

To create a DB parameter group, use the RDS API `CreateDBParameterGroup` operation. Include the following required parameters:

- `DBParameterGroupName`
- `DBParameterGroupFamily`
- `Description`

Associating a DB parameter group with a DB instance

You can create your own DB parameter groups with customized settings. You can associate a DB parameter group with a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. You can do so when you create or modify a DB instance.

For information about creating a DB parameter group, see Creating a DB parameter group (p. 350). For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 300). For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401).

Note

When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the DB parameter group after you associate it with the DB instance, these changes are applied immediately without a reboot.

Console

To associate a DB parameter group with a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.
3. Choose Modify. The Modify DB Instance page appears.
4. Change the DB parameter group setting.
5. Choose **Continue** and check the summary of modifications.
6. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause an outage in some cases. For more information, see *Using the Apply Immediately setting (p. 402)*.
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance** to save your changes.

   Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

**AWS CLI**

To associate a DB parameter group with a DB instance, use the AWS CLI `modify-db-instance` command with the following options:

- `--db-instance-identifier`
- `--db-parameter-group-name`

The following example associates the `mydbpg` DB parameter group with the `database-1` DB instance. The changes are applied immediately by using `--apply-immediately`. Use `--no-apply-immediately` to apply the changes during the next maintenance window. For more information, see *Using the Apply Immediately setting (p. 402)*.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
   --db-instance-identifier database-1
   --db-parameter-group-name mydbpg
   --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier database-1 ^
   --db-parameter-group-name mydbpg ^
   --apply-immediately
```

**RDS API**

To associate a DB parameter group with a DB instance, use the RDS API `ModifyDBInstance` operation with the following parameters:

- `DBInstanceName`
- `DBParameterGroupName`

**Modifying parameters in a DB parameter group**

You can modify parameter values in a customer-created DB parameter group; you can't change the parameter values in a default DB parameter group. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status of the DB parameter group associated with a DB instance on the **Configuration** tab. For example,
suppose that the DB instance isn't using the latest changes to its associated DB parameter group. If so, the RDS console shows the DB parameter group with a status of **pending-reboot**. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

**Console**

**To modify a DB parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group that you want to modify.
4. For **Parameter group actions**, choose **Edit**.
5. Change the values of the parameters that you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

   You can't change values in a default parameter group.
6. Choose **Save changes**.

**AWS CLI**

To modify a DB parameter group, use the AWS CLI `modify-db-parameter-group` command with the following required options:
• `--db-parameter-group-name`  
• `--parameters`

The following example modifies the `max_connections` and `max_allowed_packet` values in the DB parameter group named `mydbparametergroup`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
  --db-parameter-group-name mydbparametergroup \
  --parameters "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" \
  "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
  --db-parameter-group-name mydbparametergroup ^
  --parameters "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" ^
  "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBPARAMETERGROUP  mydbparametergroup
```

**RDS API**

To modify a DB parameter group, use the RDS API `ModifyDBParameterGroup` operation with the following required parameters:

• `DBParameterGroupName`
• `Parameters`

**Resetting parameters in a DB parameter group to their default values**

You can reset parameter values in a customer-created DB parameter group to their default values. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

When you use the console, you can reset specific parameters to their default values. However, you can't easily reset all of the parameters in the DB parameter group at once. When you use the AWS CLI or RDS API, you can reset specific parameters to their default values. You can also reset all of the parameters in the DB parameter group at once.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status of the DB parameter group associated with a DB instance on the `Configuration` tab. For example, suppose that the DB instance isn't using the latest changes to its associated DB parameter group. If so, the RDS console shows the DB parameter group with a status of `pending-reboot`. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.
Note
In a default DB parameter group, parameters are always set to their default values.

Console

To reset parameters in a DB parameter group to their default values
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the parameter group.
4. For Parameter group actions, choose Edit.
5. Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

You can't reset values in a default parameter group.
6. Choose Reset and then confirm by choosing Reset parameters.

AWS CLI

To reset some or all of the parameters in a DB parameter group, use the AWS CLI reset-db-parameter-group command with the following required option: --db-parameter-group-name.
To reset all of the parameters in the DB parameter group, specify the `--reset-all-parameters` option. To reset specific parameters, specify the `--parameters` option.

The following example resets all of the parameters in the DB parameter group named *mydbparametergroup* to their default values.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds reset-db-parameter-group
    --db-parameter-group-name mydbparametergroup
    --reset-all-parameters
```

For Windows:

```bash
aws rds reset-db-parameter-group
    --db-parameter-group-name mydbparametergroup
    --reset-all-parameters
```

The following example resets the `max_connections` and `max_allowed_packet` options to their default values in the DB parameter group named *mydbparametergroup*.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds reset-db-parameter-group
    --db-parameter-group-name mydbparametergroup
    --parameters "ParameterName=max_connections,ApplyMethod=immediate"
    "ParameterName=max_allowed_packet,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds reset-db-parameter-group
    --db-parameter-group-name mydbparametergroup
    --parameters "ParameterName=max_connections,ApplyMethod=immediate"
    "ParameterName=max_allowed_packet,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBParameterGroupName  mydbparametergroup
```

**RDS API**

To reset parameters in a DB parameter group to their default values, use the RDS API `ResetDBParameterGroup` command with the following required parameter: `DBParameterGroupName`.

To reset all of the parameters in the DB parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.

**Copying a DB parameter group**

You can copy custom DB parameter groups that you create. Copying a parameter group can be a convenient solution. An example is when you have created a DB parameter group and want to include most of its custom parameters and values in a new DB parameter group. You can copy a DB parameter group...
Working with DB parameter groups

You can copy a DB parameter group by using the AWS Management Console. You can also use the AWS CLI `copy-db-parameter-group` command or the RDS API `CopyDBParameterGroup` operation.

After you copy a DB parameter group, wait at least 5 minutes before creating your first DB instance that uses that DB parameter group as the default parameter group. Doing this allows Amazon RDS to fully complete the copy action before the parameter group is used. This is especially important for parameters that are critical when creating the default database for a DB instance. An example is the character set for the default database defined by the `character_set_database` parameter. Use the `Parameter Groups` option of the Amazon RDS console or the `describe-db-parameters` command to verify that your DB parameter group is created.

**Note**

You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.

You can't copy a DB parameter group to a different AWS account or AWS Region.

**Console**

**To copy a DB parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the custom parameter group that you want to copy.
4. For Parameter group actions, choose Copy.
5. In New DB parameter group identifier, enter a name for the new parameter group.
6. In Description, enter a description for the new parameter group.
7. Choose Copy.

**AWS CLI**

To copy a DB parameter group, use the AWS CLI `copy-db-parameter-group` command with the following required options:

- `--source-db-parameter-group-identifier`
- `--target-db-parameter-group-identifier`
- `--target-db-parameter-group-description`

The following example creates a new DB parameter group named `mygroup2` that is a copy of the DB parameter group `mygroup1`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds copy-db-parameter-group \
  --source-db-parameter-group-identifier mygroup1 \
  --target-db-parameter-group-identifier mygroup2 \
  --target-db-parameter-group-description "DB parameter group 2"
```

For Windows:

```bash
aws rds copy-db-parameter-group ^
  --source-db-parameter-group-identifier mygroup1 ^
  --target-db-parameter-group-identifier mygroup2 ^
  --target-db-parameter-group-description "DB parameter group 2"
```
RDS API

To copy a DB parameter group, use the RDS API CopyDBParameterGroup operation with the following required parameters:

• SourceDBParameterGroupIdentifier
• TargetDBParameterGroupIdentifier
• TargetDBParameterGroupDescription

Listing DB parameter groups

You can list the DB parameter groups you've created for your AWS account.

Note
Default parameter groups are automatically created from a default parameter template when you create a DB instance for a particular DB engine and version. These default parameter groups contain preferred parameter settings and can't be modified. When you create a custom parameter group, you can modify parameter settings.

Console

To list all DB parameter groups for an AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
   The DB parameter groups appear in a list.

AWS CLI

To list all DB parameter groups for an AWS account, use the AWS CLI describe-db-parameter-groups command.

Example

The following example lists all available DB parameter groups for an AWS account.

```
aws rds describe-db-parameter-groups
```

The command returns a response like the following:

```
DBPARAMETERGROUP  default.mysql8.0     mysql8.0  Default parameter group for MySQL8.0
DBPARAMETERGROUP  mydbparametergroup   mysql8.0  My new parameter group
```

The following example describes the mydbparamgroup1 parameter group.

For Linux, macOS, or Unix:

```
aws rds describe-db-parameter-groups \  
  --db-parameter-group-name mydbparamgroup1
```

For Windows:

```
aws rds describe-db-parameter-groups ^  
  --db-parameter-group-name mydbparamgroup1
```
The command returns a response like the following:

<table>
<thead>
<tr>
<th>DBPARAMETERGROUP</th>
<th>Parameter Name</th>
<th>Parameter Value</th>
<th>Source</th>
<th>Data Type</th>
<th>Apply</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydbparametergroup1</td>
<td>mysql8.0</td>
<td>My new parameter group</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**RDS API**

To list all DB parameter groups for an AWS account, use the RDS API `DescribeDBParameterGroups` operation.

**Viewing parameter values for a DB parameter group**

You can get a list of all parameters in a DB parameter group and their values.

**Console**

**To view the parameter values for a DB parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
   - The DB parameter groups appear in a list.
3. Choose the name of the parameter group to see its list of parameters.

**AWS CLI**

To view the parameter values for a DB parameter group, use the AWS CLI `describe-db-parameters` command with the following required parameter.

- `--db-parameter-group-name`

**Example**

The following example lists the parameters and parameter values for a DB parameter group named `mydbparametergroup`.

```bash
aws rds describe-db-parameters --db-parameter-group-name mydbparametergroup
```

The command returns a response like the following:

<table>
<thead>
<tr>
<th>DBPARAMETER</th>
<th>Parameter Name</th>
<th>Parameter Value</th>
<th>Source</th>
<th>Data Type</th>
<th>Apply</th>
</tr>
</thead>
<tbody>
<tr>
<td>false</td>
<td>allow-suspicious-udfs</td>
<td>engine-default</td>
<td>boolean</td>
<td>static</td>
<td></td>
</tr>
<tr>
<td>true</td>
<td>auto_increment_increment</td>
<td>engine-default</td>
<td>integer</td>
<td>dynamic</td>
<td></td>
</tr>
<tr>
<td>true</td>
<td>auto_increment_offset</td>
<td>engine-default</td>
<td>integer</td>
<td>dynamic</td>
<td></td>
</tr>
<tr>
<td>true</td>
<td>binlog_cache_size</td>

Working with DB cluster parameter groups for Multi-AZ DB clusters

Multi-AZ DB clusters use DB cluster parameter groups. The following sections describe configuring and managing DB cluster parameter groups.

Topics

- Creating a DB cluster parameter group (p. 360)
- Modifying parameters in a DB cluster parameter group (p. 362)
- Resetting parameters in a DB cluster parameter group (p. 363)
- Copying a DB cluster parameter group (p. 364)
- Listing DB cluster parameter groups (p. 366)
- Viewing parameter values for a DB cluster parameter group (p. 367)

Creating a DB cluster parameter group

You can create a new DB cluster parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

After you create a DB cluster parameter group, wait at least 5 minutes before creating a DB cluster that uses that DB cluster parameter group. Doing this allows Amazon RDS to fully create the parameter group before it is used by the new DB cluster. You can use the Parameter groups page in the Amazon RDS console or the describe-db-cluster-parameters command to verify that your DB cluster parameter group is created.

The following limitations apply to the DB cluster parameter group name:

- The name must be 1 to 255 letters, numbers, or hyphens.
- Default parameter group names can include a period, such as default.aurora-mysql5.7. However, custom parameter group names can't include a period.
- The first character must be a letter.
- The name can't end with a hyphen or contain two consecutive hyphens.

Console

To create a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
   - The Create parameter group window appears.
4. In the Parameter group family list, select a DB parameter group family
5. In the Type list, select DB Cluster Parameter Group.
6. In the Group name box, enter the name of the new DB cluster parameter group.
7. In the Description box, enter a description for the new DB cluster parameter group.
8. Choose **Create**.

**AWS CLI**

To create a DB cluster parameter group, use the AWS CLI `create-db-cluster-parameter-group` command.

The following example creates a DB cluster parameter group named `mydbclusterparametergroup` for RDS for MySQL version 8.0 with a description of "My new cluster parameter group."

Include the following required parameters:

- `--db-cluster-parameter-group-name`
- `--db-parameter-group-family`
- `--description`

To list all of the available parameter group families, use the following command:

```bash
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```

**Note**
The output contains duplicates.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster-parameter-group \
   --db-cluster-parameter-group-name mydbclusterparametergroup \
   --db-parameter-group-family mysql8.0 \
   --description "My new cluster parameter group"
```

For Windows:

```bash
aws rds create-db-cluster-parameter-group ^
   --db-cluster-parameter-group-name mydbclusterparametergroup ^
   --db-parameter-group-family mysql8.0 ^
   --description "My new cluster parameter group"
```

This command produces output similar to the following:

```json
{
   "DBClusterParameterGroup": {
      "DBClusterParameterGroupName": "mydbclusterparametergroup",
      "DBParameterGroupFamily": "mysql8.0",
      "Description": "My new cluster parameter group",
      "DBClusterParameterGroupArn": "arn:aws:rds:us-east-1:123456789012:cluster-pg:mydbclusterparametergroup2"
   }
}
```

**RDS API**

To create a DB cluster parameter group, use the RDS API `CreateDBClusterParameterGroup` action.

Include the following required parameters:
### Modifying parameters in a DB cluster parameter group

You can modify parameter values in a customer-created DB cluster parameter group. You can't change the parameter values in a default DB cluster parameter group. Changes to parameters in a customer-created DB cluster parameter group are applied to all DB clusters that are associated with the DB cluster parameter group.

**Console**

**To modify a DB cluster parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group that you want to modify.
4. For **Parameter group actions**, choose **Edit**.
5. Change the values of the parameters you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.
   
   You can't change values in a default parameter group.
6. Choose **Save changes**.
7. Reboot the primary DB instance in the cluster to apply the changes to all of the DB instances in the cluster.

**AWS CLI**

To modify a DB cluster parameter group, use the AWS CLI `modify-db-cluster-parameter-group` command with the following required parameters:

- `--db-cluster-parameter-group-name`
- `--parameters`

The following example modifies the `server_audit_logging` and `server_audit_logs_upload` values in the DB cluster parameter group named `mydbclustparametergroup`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-parameter-group \
    --db-cluster-parameter-group-name mydbclustparametergroup \
    --parameters
"ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" \
"ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-cluster-parameter-group ^
```
Working with DB cluster parameter groups

--db-cluster-parameter-group-name mydbclusterparametergroup
--parameters
"ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" ^
"ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"

The command produces output like the following:

| DBCLUSTERPARAMETERGROUP mydbclusterparametergroup |

RDS API

To modify a DB cluster parameter group, use the RDS API ModifyDBClusterParameterGroup command with the following required parameters:

- DBClusterParameterGroupName
- Parameters

Resetting parameters in a DB cluster parameter group

You can reset parameters to their default values in a customer-created DB cluster parameter group. Changes to parameters in a customer-created DB cluster parameter group are applied to all DB clusters that are associated with the DB cluster parameter group.

Note
In a default DB cluster parameter group, parameters are always set to their default values.

Console

To reset parameters in a DB cluster parameter group to their default values

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the parameter group.
4. For Parameter group actions, choose Edit.
5. Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.
   You can't reset values in a default parameter group.
6. Choose Reset and then confirm by choosing Reset parameters.
7. Reboot the primary DB instance in the DB cluster to apply the changes to all of the DB instances in the DB cluster.

AWS CLI

To reset parameters in a DB cluster parameter group to their default values, use the AWS CLI reset-db-cluster-parameter-group command with the following required option: --db-cluster-parameter-group-name.

To reset all of the parameters in the DB cluster parameter group, specify the --reset-all-parameters option. To reset specific parameters, specify the --parameters option.

The following example resets all of the parameters in the DB parameter group named mydbparametergroup to their default values.

363
Example

For Linux, macOS, or Unix:

```
aws rds reset-db-cluster-parameter-group  
   --db-cluster-parameter-group-name mydbparametergroup  
   --reset-all-parameters
```

For Windows:

```
aws rds reset-db-cluster-parameter-group ^
   --db-cluster-parameter-group-name mydbparametergroup ^
   --reset-all-parameters
```

The following example resets the `server_audit_logging` and `server_audit_logs_upload` to their default values in the DB cluster parameter group named `mydbclusterparametergroup`.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-cluster-parameter-group  
   --db-cluster-parameter-group-name mydbclusterparametergroup  
   --parameters "ParameterName=server_audit_logging,ApplyMethod=immediate"  
   "ParameterName=server_audit_logs_upload,ApplyMethod=immediate"
```

For Windows:

```
aws rds reset-db-cluster-parameter-group ^
   --db-cluster-parameter-group-name mydbclusterparametergroup ^
   --parameters  
   "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate"  
   "ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

The command produces output like the following:

| DBClusterParameterGroupName | mydbclusterparametergroup |

RDS API

To reset parameters in a DB cluster parameter group to their default values, use the RDS API `ResetDBClusterParameterGroup` command with the following required parameter: `DBClusterParameterGroupName`.

To reset all of the parameters in the DB cluster parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.

Copying a DB cluster parameter group

You can copy custom DB cluster parameter groups that you create. Copying a parameter group is a convenient solution when you have already created a DB cluster parameter group and you want to include most of the custom parameters and values from that group in a new DB cluster parameter group.

You can copy a DB cluster parameter group by using the AWS CLI `copy-db-cluster-parameter-group` command or the RDS API `CopyDBClusterParameterGroup` operation.

After you copy a DB cluster parameter group, wait at least 5 minutes before creating a DB cluster that uses that DB cluster parameter group. Doing this allows Amazon RDS to fully copy the parameter group.
before it is used by the new DB cluster. You can use the Parameter groups page in the Amazon RDS console or the describe-db-cluster-parameters command to verify that your DB cluster parameter group is created.

Note
You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.
You can't copy a DB cluster parameter group to a different AWS account or AWS Region.

Console

To copy a DB cluster parameter group
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the custom parameter group that you want to copy.
4. For Parameter group actions, choose Copy.
5. In New DB parameter group identifier, enter a name for the new parameter group.
6. In Description, enter a description for the new parameter group.
7. Choose Copy.

AWS CLI

To copy a DB cluster parameter group, use the AWS CLI copy-db-cluster-parameter-group command with the following required parameters:

• --source-db-cluster-parameter-group-identifier
• --target-db-cluster-parameter-group-identifier
• --target-db-cluster-parameter-group-description

The following example creates a new DB cluster parameter group named mygroup2 that is a copy of the DB cluster parameter group mygroup1.

Example

For Linux, macOS, or Unix:

aws rds copy-db-cluster-parameter-group \
--source-db-cluster-parameter-group-identifier mygroup1 \
--target-db-cluster-parameter-group-identifier mygroup2 \
--target-db-cluster-parameter-group-description "DB parameter group 2"

For Windows:

aws rds copy-db-cluster-parameter-group ^
--source-db-cluster-parameter-group-identifier mygroup1 ^
--target-db-cluster-parameter-group-identifier mygroup2 ^
--target-db-cluster-parameter-group-description "DB parameter group 2"

RDS API

To copy a DB cluster parameter group, use the RDS API CopyDBClusterParameterGroup operation with the following required parameters:
Listing DB cluster parameter groups

You can list the DB cluster parameter groups you’ve created for your AWS account.

**Note**
Default parameter groups are automatically created from a default parameter template when you create a DB cluster for a particular DB engine and version. These default parameter groups contain preferred parameter settings and can’t be modified. When you create a custom parameter group, you can modify parameter settings.

**Console**

**To list all DB cluster parameter groups for an AWS account**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.

   The DB cluster parameter groups appear in the list with DB cluster parameter group for Type.

**AWS CLI**

To list all DB cluster parameter groups for an AWS account, use the AWS CLI `describe-db-cluster-parameter-groups` command.

**Example**

The following example lists all available DB cluster parameter groups for an AWS account.

```bash
aws rds describe-db-cluster-parameter-groups
```

The following example describes the `mydbclusterparametergroup` parameter group.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-cluster-parameter-groups \
   --db-cluster-parameter-group-name mydbclusterparametergroup
```

For Windows:

```bash
aws rds describe-db-cluster-parameter-groups ^ \
   --db-cluster-parameter-group-name mydbclusterparametergroup
```

The command returns a response like the following:

```json
{
   "DBClusterParameterGroups": [
      {
         "DBClusterParameterGroupName": "mydbclusterparametergroup2",
         "DBParameterGroupFamily": "mysql8.0",
      }
   ]
}
```
RDS API

To list all DB cluster parameter groups for an AWS account, use the RDS API DescribeDBClusterParameterGroups action.

Viewing parameter values for a DB cluster parameter group

You can get a list of all parameters in a DB cluster parameter group and their values.

Console

To view the parameter values for a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
   The DB cluster parameter groups appear in the list with DB cluster parameter group for Type.
3. Choose the name of the DB cluster parameter group to see its list of parameters.

AWS CLI

To view the parameter values for a DB cluster parameter group, use the AWS CLI describe-db-cluster-parameters command with the following required parameter.

• --db-cluster-parameter-group-name

Example

The following example lists the parameters and parameter values for a DB cluster parameter group named mydbclusterparametergroup, in JSON format.

The command returns a response like the following:

```
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name mydbclusterparametergroup

[
  "Parameters": [
   {
     "ParameterName": "activate_all_roles_on_login",
     "ParameterValue": "0",
     "Description": "Automatically set all granted roles as active after the user has authenticated successfully.",
     "Source": "engine-default",
     "ApplyType": "dynamic",
     "DataType": "boolean",
     "AllowedValues": "$0,1",
     "IsModifiable": true,
     "ApplyMethod": "pending-reboot",
   }
  ]
]
```
Comparing parameter groups

You can use the AWS Management Console to view the differences between two parameter groups.

To compare two parameter groups

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the two parameter groups that you want to compare.
4. For **Parameter group actions**, choose **Compare**.

**Note**
The specified parameter groups must both be DB parameter groups, or they both must be DB cluster parameter groups. This is true even when the DB engine and version are the same. For example, you can't compare an Aurora MySQL 8.0 DB parameter group and an Aurora MySQL 8.0 DB cluster parameter group.

You can compare Aurora MySQL and RDS for MySQL DB parameter groups, even for different versions, but you can't compare Aurora PostgreSQL and RDS for PostgreSQL DB parameter groups.

### Specifying DB parameters

DB parameter types include the following:

- Integer
- Boolean
- String
- Long
- Double
- Timestamp
- Object of other defined data types
- Array of values of type integer, Boolean, string, long, double, timestamp, or object

You can also specify integer and Boolean parameters using expressions, formulas, and functions.

For the Oracle engine, you can use the `DBInstanceClassHugePagesDefault` formula variable to specify a Boolean DB parameter. See [DB parameter formula variables](p. 370).

For the PostgreSQL engine, you can use an expression to specify a Boolean DB parameter. See [Boolean DB parameter expressions](p. 371).

### Contents

- [DB parameter formulas](p. 369)
  - [DB parameter formula variables](p. 370)
  - [DB parameter formula operators](p. 370)
- [DB parameter functions](p. 371)
- [Boolean DB parameter expressions](p. 371)
- [DB parameter log expressions](p. 372)
- [DB parameter value examples](p. 373)

### DB parameter formulas

A DB parameter formula is an expression that resolves to an integer value or a Boolean value. You enclose the expression in braces: `{}`. You can use a formula for either a DB parameter value or as an argument to a DB parameter function.

**Syntax**

```
{FormulaVariable}
{FormulaVariable*Integer}
{FormulaVariable*Integer/Integer}
```
DB parameter formula variables

Each formula variable returns an integer or a Boolean value. The names of the variables are case-sensitive.

**AllocatedStorage**

Returns an integer representing the size, in bytes, of the data volume.

**DBInstanceClassHugePagesDefault**

Returns a Boolean value. Currently, it's only supported for Oracle engines.

For more information, see Turning on HugePages for an RDS for Oracle instance (p. 1958).

**DBInstanceClassMemory**

Returns an integer for the number of bytes of memory available to the database process. This number is internally calculated by starting with the total amount of memory for the DB instance class. From this, the calculation subtracts memory reserved for the operating system and the RDS processes that manage the instance. Therefore, the number is always somewhat lower than the memory figures shown in the instance class tables in DB instance classes (p. 11). The exact value depends on a combination of factors. These include instance class, DB engine, and whether it applies to an RDS instance or an instance that's part of an Aurora cluster.

**DBInstanceVCPU**

Returns an integer representing the number of virtual central processing units (vCPUs) used by Amazon RDS to manage the instance. Currently, it's only supported for the PostgreSQL engine.

**EndPointPort**

Returns an integer representing the port used when connecting to the DB instance.

DB parameter formula operators

DB parameter formulas support two operators: division and multiplication.

**Division operator: /**

Divides the dividend by the divisor, returning an integer quotient. Decimals in the quotient are truncated, not rounded.

**Syntax**

```plaintext
dividend / divisor
```

The dividend and divisor arguments must be integer expressions.

**Multiplication operator: ***

Multiplies the expressions, returning the product of the expressions. Decimals in the expressions are truncated, not rounded.

**Syntax**

```plaintext
expression * expression
```

Both expressions must be integers.
DB parameter functions

You specify the arguments of DB parameter functions as either integers or formulas. Each function must have at least one argument. Specify multiple arguments as a comma-separated list. The list can't have any empty members, such as `argument1, argument3`. Function names are case-insensitive.

**IF**

Returns an argument.

Currently, it's only supported for Oracle engines, and the only supported first argument is `{DBInstanceClassHugePagesDefault}`. For more information, see [Turning on HugePages for an RDS for Oracle instance](p. 1958).

Syntax

```plaintext
IF(argument1, argument2, argument3)
```

Returns the second argument if the first argument evaluates to true. Returns the third argument otherwise.

**GREATEST**

Returns the largest value from a list of integers or parameter formulas.

Syntax

```plaintext
GREATEST(argument1, argument2,...argumentn)
```

Returns an integer.

**LEAST**

Returns the smallest value from a list of integers or parameter formulas.

Syntax

```plaintext
LEAST(argument1, argument2,...argumentn)
```

Returns an integer.

**SUM**

Adds the values of the specified integers or parameter formulas.

Syntax

```plaintext
SUM(argument1, argument2,...argumentn)
```

Returns an integer.

**Boolean DB parameter expressions**

A Boolean DB parameter expression resolves to a Boolean value of 1 or 0. The expression is enclosed in quotation marks.

**Note**

Boolean DB parameter expressions are only supported for the PostgreSQL engine.
Specifying DB parameters

Syntax

"expression operator expression"

Both expressions must resolve to integers. An expression can be the following:

- integer constant
- DB parameter formula
- DB parameter function
- DB parameter variable

Boolean DB parameter expressions support the following inequality operators:

The greater than operator: >

Syntax

"expression > expression"

The less than operator: <

Syntax

"expression < expression"

The greater than or equal to operators: >=, =>

Syntax

"expression >= expression"
"expression => expression"

The less than or equal to operators: <=, =<

Syntax

"expression <= expression"
"expression =< expression"

Example using a Boolean DB parameter expression

The following Boolean DB parameter expression example compares the result of a parameter formula with an integer. It does so to modify the Boolean DB parameter wal_compression for a PostgreSQL DB instance. The parameter expression compares the number of vCPUs with the value 2. If the number of vCPUs is greater than 2, then the wal_compression DB parameter is set to true.

```
aws rds modify-db-parameter-group --db-parameter-group-name group-name \
--parameters "ParameterName=wal_compression,ParameterValue="{DBInstanceVCPU} > 2" "
```

DB parameter log expressions

You can set an integer DB parameter value to a log expression. You enclose the expression in braces: {}. For example:
The log function represents log base 2. This example also uses the DBInstanceClassMemory formula variable. See DB parameter formula variables (p. 370).

Note
Currently, you can't specify the MySQL innodb_log_file_size parameter with any value other than an integer.

DB parameter value examples

These examples show using formulas, functions, and expressions for the values of DB parameters.

Note
DB Parameter functions are currently supported only in the console and aren't supported in the AWS CLI.

Warning
Improperly setting parameters in a DB parameter group can have unintended adverse effects. These might include degraded performance and system instability. Use caution when modifying database parameters and back up your data before modifying your DB parameter group. Try out parameter group changes on a test DB instance, created using point-in-time-restores, before applying those parameter group changes to your production DB instances.

Example using the DB parameter function GREATEST

You can specify the GREATEST function in an Oracle processes parameter. Use it to set the number of user processes to the larger of either 80 or DBInstanceClassMemory divided by 9,868,951.

\[ \text{GREATEST} \left( \frac{\text{DBInstanceClassMemory}}{9868951}, 80 \right) \]

Example using the DB parameter function LEAST

You can specify the LEAST function in a MySQL max_binlog_cache_size parameter value. Use it to set the maximum cache size a transaction can use in a MySQL instance to the lesser of 1 MB or DBInstanceClass/256.

\[ \text{LEAST} \left( \frac{\text{DBInstanceClassMemory}}{256}, 10485760 \right) \]
Creating an Amazon ElastiCache cluster using Amazon RDS DB instance settings

ElastiCache is a fully managed, in-memory caching service that provides microsecond read and write latencies that support flexible, real-time use cases. ElastiCache can help you accelerate application and database performance. You can use ElastiCache as a primary data store for use cases that don't require data durability, such as gaming leaderboards, streaming, and data analytics. ElastiCache helps remove the complexity associated with deploying and managing a distributed computing environment. For more information, see Common ElastiCache Use Cases and How ElastiCache Can Help for Memcached and Common ElastiCache Use Cases and How ElastiCache Can Help for Redis. You can use the Amazon RDS console for creating ElastiCache clusters.

Amazon ElastiCache works with both the Redis and Memcached engines. If you're unsure which engine you want to use, see Comparing Memcached and Redis. For more information about Amazon ElastiCache, see the Amazon ElastiCache User Guide.

Topics

• Overview of ElastiCache cluster creation with RDS DB instance settings (p. 374)
• Creating an ElastiCache cluster with settings from a new RDS DB instance (p. 375)
• Creating an ElastiCache cluster with settings from an existing RDS DB instance (p. 377)

Overview of ElastiCache cluster creation with RDS DB instance settings

You can create an ElastiCache cluster from Amazon RDS using the same configuration settings as a newly created or existing RDS DB instance.

Some use-cases to associate an ElastiCache cluster with your DB instance:

• You can save costs and improve your performance by using ElastiCache with RDS versus running on RDS alone.

  For example, you can save up to 55% in cost and gain up to 80x faster read performance by using ElastiCache with RDS for MySQL versus RDS for MySQL alone.

• You can use the ElastiCache cluster as a primary data store for applications that don't require data durability. Your applications that use Redis or Memcached can use ElastiCache with almost no modification.

When you create an ElastiCache cluster from RDS, the ElastiCache cluster inherits the following settings from the associated RDS DB instance:

• ElastiCache connectivity settings
• ElastiCache security settings

You can also set the cluster configuration settings according to your requirements.

Setting up ElastiCache in your applications

Your applications must be set up to utilize ElastiCache clusters. You can also optimize and improve cluster performance by setting up your applications to use caching strategies depending on your requirements.
Creating an ElastiCache cluster with settings from a new RDS DB instance

After creating a new RDS DB instance in the RDS console, you can create add-ons for your RDS DB instance from the Suggested add-ons window.

In the Suggested add-ons window, you can create an ElastiCache cluster from RDS with the same settings as your newly created RDS DB instance.

Create an ElastiCache cluster with settings from a new DB instance

1. To create a DB instance, follow the instructions in Creating an Amazon RDS DB instance (p. 300).
2. After creating a new RDS DB instance, the console displays the Suggested add-ons window. Select Create an ElastiCache cluster from RDS using your DB settings.

   In the ElastiCache configuration section, the Source DB identifier displays which DB instance the ElastiCache cluster inherits settings from.
3. Choose whether you want to create a Redis or Memcached cluster. For more information, see Comparing Memcached and Redis.

If you choose Redis cluster, then choose whether you want to keep the cluster mode Enabled or Disabled. For more information, see Replication: Redis (Cluster Mode Disabled) vs. Redis (Cluster Mode Enabled).
4. Enter values for **Name**, **Description**, and **Engine version**.

   For **Engine version**, the recommended default value is the latest engine version. You can also choose an **Engine version** for the ElastiCache cluster that best meets your requirements.

5. Choose the node type in the **Node type** option. For more information, see [Managing nodes](#).

   If you choose to create a Redis cluster with the **Cluster mode** set to **Enabled**, then enter the number of shards (partitions/node groups) in the **Number of shards** option.

   Enter the number of replicas of each shard in **Number of replicas**.

   **Note**
   The selected node type, the number of shards, and the number of replicas all affect your cluster performance and resource costs. Be sure these settings match your database needs. For pricing information, see [Amazon ElastiCache pricing](#).

6. Confirm the ElastiCache connectivity settings.

   RDS automatically fills the **Port** and the **Network type**. ElastiCache creates an equivalent **Subnet group** from the source database. To customize these settings, select **Customize your connectivity settings**.

```
Elasticache connectivity settings
You can configure your connectivity settings by using inherited and default values or define your own.

- ElastiCache default connectivity settings
  Use the following default values.

- Customize your connectivity settings
  Edit the default values according to your requirements.
```

   **Note**
   We will create a subnet group using the same subnets associated to the source RDS database database-1. You can use the newly created subnet group or change the subnet group in the ElastiCache connectivity settings. You can’t change this setting after the cluster is created. [Learn more](#).

7. Confirm the ElastiCache security settings.

   ElastiCache provides the default values for **Encryption at rest**, **Encryption key**, **Encryption in transit**, **Access control**, and **Security groups**. To customize these settings, select **Customize your security settings**.
8. Verify the default and inherited settings of your ElastiCache cluster. Some settings can't be changed after creation.

**Note**
RDS might adjust the backup window of your ElastiCache cluster to meet the minimum window requirement of 60 minutes. The backup window of your source database remains the same.

9. When you're ready, choose **Create ElastiCache cluster**.

The console displays a confirmation banner for the ElastiCache cluster creation. Follow the link in the banner to the ElastiCache console to view the cluster details. The ElastiCache console displays the newly created ElastiCache cluster.

### Creating an ElastiCache cluster with settings from an existing RDS DB instance

You can create an ElastiCache cluster for your existing RDS DB instances from the **Actions** dropdown menu in the console.

#### Create an ElastiCache cluster with settings from an existing DB instance

1. In the **Databases** page, select the required DB instance.
2. In the **Actions** dropdown menu, choose **Create ElastiCache cluster** to create an ElastiCache cluster in RDS that has the same settings as your existing RDS DB instance.

   In the **ElastiCache configuration section**, the **Source DB identifier** shows which DB instance the ElastiCache cluster inherits settings from.

3. Choose whether you want to create a Redis or Memcached cluster. For more information, see [Comparing Memcached and Redis](#).

   If you choose **Redis cluster**, then choose whether you want to keep the cluster mode **Enabled** or **Disabled**. For more information, see [Replication: Redis (Cluster Mode Disabled) vs. Redis (Cluster Mode Enabled)](#).
4. Enter values for **Name**, **Description**, and **Engine version**.

   For **Engine version**, the recommended default value is the latest engine version. You can also choose an **Engine version** for the ElastiCache cluster that best meets your requirements.

5. Choose the node type in the **Node type** option. For more information, see [Managing nodes](#).

   If you choose to create a Redis cluster with the **Cluster mode** set to **Enabled**, then enter the number of shards (partitions/node groups) in the **Number of shards** option.

   Enter the number of replicas of each shard in **Number of replicas**.

   **Note**

   The selected node type, the number of shards, and the number of replicas all affect your cluster performance and resource costs. Be sure these settings match your database needs. For pricing information, see [Amazon ElastiCache pricing](#).

6. Confirm the ElastiCache connectivity settings.

   RDS automatically fills the **Port** and the **Network type**. ElastiCache creates an equivalent Subnet group from the source database. To customize these settings, select **Customize your connectivity settings**.
7. **Confirm the ElastiCache security settings.**

ElastiCache provides the default values for **Encryption at rest**, **Encryption key**, **Encryption in transit**, **Access control**, and **Security groups**. To customize these settings, select **Customize your security settings**.

8. **Verify the default and inherited settings of your ElastiCache cluster.** Some settings can’t be changed after creation.

   **Note**
   
   RDS might adjust the backup window of your ElastiCache cluster to meet the minimum window requirement of 60 minutes. The backup window of your source database remains the same.

9. **When you’re ready, choose Create ElastiCache cluster.**

   The console displays a confirmation banner for the ElastiCache cluster creation. Follow the link in the banner to the ElastiCache console to view the cluster details. The ElastiCache console displays the newly created ElastiCache cluster.
Managing an Amazon RDS DB instance

Following, you can find instructions for managing and maintaining your Amazon RDS DB instance.

Topics

- Stopping an Amazon RDS DB instance temporarily (p. 381)
- Starting an Amazon RDS DB instance that was previously stopped (p. 384)
- Automatically connecting an AWS compute resource and a DB instance (p. 385)
- Modifying an Amazon RDS DB instance (p. 401)
- Maintaining a DB instance (p. 418)
- Upgrading a DB instance engine version (p. 429)
- Renaming a DB instance (p. 434)
- Rebooting a DB instance (p. 436)
- Working with DB instance read replicas (p. 438)
- Tagging Amazon RDS resources (p. 461)
- Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 471)
- Working with storage for Amazon RDS DB instances (p. 478)
- Deleting a DB instance (p. 489)
Stopping an Amazon RDS DB instance temporarily

Suppose that you use a DB instance intermittently, for temporary testing, or for a daily development activity. If so, you can stop your Amazon RDS DB instance temporarily to save money. While your DB instance is stopped, you are charged for provisioned storage (including Provisioned IOPS). You're also charged for backup storage, including manual snapshots and automated backups within your specified retention window. However, you're not charged for DB instance hours. For more information, see Billing FAQs.

Note
In some cases, a large amount of time is required to stop a DB instance. If you want to stop your DB instance and restart it immediately, you can reboot the DB instance. For information about rebooting a DB instance, see Rebooting a DB instance (p. 436).

Supported DB engines, instance classes, and Regions

You can stop and start Amazon RDS DB instances that are running the following DB engines:

- MariaDB
- Microsoft SQL Server, including RDS Custom for SQL Server.
- MySQL
- Oracle
- PostgreSQL

Stopping and starting a DB instance is supported for all DB instance classes, and in all AWS Regions.

Stopping a DB instance in a Multi-AZ deployment

You can stop and start a DB instance whether it is configured for a single Availability Zone or Multi-AZ. For Multi-AZ, you database engine must support Multi-AZ deployments. For more information, see Multi-AZ DB clusters (p. 147).

For a Multi-AZ deployment, a long time might be required to stop a DB instance. If you have at least one backup after a previous failover, then you can speed up the stop DB instance operation. To do so, before stopping the DB instance, perform a reboot with failover operation.

How stopping a DB instance works

The stopping operation occurs in the following stages:

1. The DB instance initiates the normal shutdown process.
   
   The status of the DB instance changes to stopping.
2. The instance stops running, up to a maximum of 7 consecutive days.

   The status of the DB instance changes to stopped. Consider the following characteristics of the stopped state:

   - Any storage volumes remain attached to the DB instance, and their data is kept. RDS deletes any data stored in the RAM of the DB instance.
   - RDS removes pending actions, except for pending actions for the option group or DB parameter group of the DB instance.
If you don't manually start your DB instance after it is stopped for seven consecutive days, RDS automatically starts your DB instance for you. This way, it doesn't fall behind any required maintenance updates. To learn how to stop and start your instance on a schedule, see How can I use Step Functions to stop an Amazon RDS instance for longer than 7 days?

Occasionally, an RDS for PostgreSQL DB instance doesn't shut down cleanly. If this happens, you see that the instance goes through a recovery process when you restart it later. This is expected behavior of the database engine, intended to protect database integrity. Some memory-based statistics and counters don't retain history and are re-initialized after restart, to capture the operational workload moving forward.

Benefits of stopping your DB instance

Stopping and starting a DB instance is faster than creating a DB snapshot, and then restoring the snapshot.

When you stop a DB instance, it retains the following:

- Instance ID
- Domain Name Server (DNS) endpoint
- Parameter group
- Security group
- Option group
- Amazon S3 transaction logs (necessary for a point-in-time restore)

When you restart a DB instance, it has the same configuration as when you stopped it.

Limitations of stopping your DB instance

The following are some limitations to stopping and starting a DB instance:

- You can't stop a DB instance that has a read replica, or that is a read replica.
- You can't modify a stopped DB instance.
- You can't delete an option group that is associated with a stopped DB instance.
- You can't delete a DB parameter group that is associated with a stopped DB instance.
- In a Multi-AZ deployment, the primary and secondary Availability Zones might be switched after you start the DB instance.

Additional limitations apply to RDS Custom for SQL Server. For more information, see Starting and stopping an RDS Custom for SQL Server DB instance (p. 1162).

Option and parameter group considerations

You can't remove persistent options (including permanent options) from an option group if there are DB instances associated with that option group. This functionality is also true of any DB instance with a state of stopping, stopped, or starting.

You can change the option group or DB parameter group that is associated with a stopped DB instance. However, the change doesn't occur until the next time you start the DB instance. If you chose to apply changes immediately, the change occurs when you start the DB instance. Otherwise the change occurs during the next maintenance window after you start the DB instance.
Public IP address

When you stop a DB instance, it retains its DNS endpoint. If you stop a DB instance that has a public IP address, Amazon RDS releases its public IP address. When the DB instance is restarted, it has a different public IP address.

**Note**
You should always connect to a DB instance using the DNS endpoint, not the IP address.

Stopping a DB instance temporarily

You can stop a DB using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

To stop a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to stop.
3. For **Actions**, choose **Stop temporarily**.
4. In the **Stop DB instance temporarily** window, select the acknowledgement that the DB instance will restart automatically after 7 days.
5. (Optional) Select **Save the DB instance in a snapshot** and enter the snapshot name for **Snapshot name**. Choose this option if you want to create a snapshot of the DB instance before stopping it.
6. Choose **Stop temporarily** to stop the DB instance, or choose **Cancel** to cancel the operation.

**AWS CLI**

To stop a DB instance by using the AWS CLI, call the **stop-db-instance** command with the following option:

- --db-instance-identifier – the name of the DB instance.

**Example**

```
aws rds stop-db-instance --db-instance-identifier mydbinstance
```

**RDS API**

To stop a DB instance by using the Amazon RDS API, call the **StopDBInstance** operation with the following parameter:

- DBInstanceIdentifier – the name of the DB instance.
Starting an Amazon RDS DB instance that was previously stopped

You can stop your Amazon RDS DB instance temporarily to save money. After you stop your DB instance, you can restart it to begin using it again. For more details about stopping and starting DB instances, see Stopping an Amazon RDS DB instance temporarily (p. 381).

When you start a DB instance that you previously stopped, the DB instance retains certain information. This information is the ID, Domain Name Server (DNS) endpoint, parameter group, security group, and option group. When you start a stopped instance, you are charged a full instance hour.

**Console**

**To start a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to start.
3. For Actions, choose Start.

**AWS CLI**

To start a DB instance by using the AWS CLI, call the start-db-instance command with the following option:

- --db-instance-identifier – The name of the DB instance.

**Example**

```bash
aws rds start-db-instance --db-instance-identifier mydbinstance
```

**RDS API**

To start a DB instance by using the Amazon RDS API, call the StartDBInstance operation with the following parameter:

- DBInstanceIdentifier – The name of the DB instance.
Automatically connecting an AWS compute resource and a DB instance

You can automatically connect a DB instance and AWS compute resources such as Amazon Elastic Compute Cloud (Amazon EC2) instances and AWS Lambda functions.

Topics
- Automatically connecting an EC2 instance and a DB instance (p. 385)
- Automatically connecting a Lambda function and a DB instance (p. 392)

Automatically connecting an EC2 instance and a DB instance

You can use the Amazon RDS console to simplify setting up a connection between an Amazon Elastic Compute Cloud (Amazon EC2) instance and a DB instance. Often, your DB instance is in a private subnet and your EC2 instance is in a public subnet within a VPC. You can use a SQL client on your EC2 instance to connect to your DB instance. The EC2 instance can also run web servers or applications that access your private DB instance. For instructions on setting up a connection between an EC2 instance and a Multi-AZ DB cluster, see the section called “Connecting an EC2 instance and a Multi-AZ DB cluster” (p. 525).

If you want to connect to an EC2 instance that isn't in the same VPC as the DB instance, see the scenarios in Scenarios for accessing a DB instance in a VPC (p. 2718).

Topics
- Overview of automatic connectivity with an EC2 instance (p. 386)
Connecting an EC2 instance

- Automatically connecting an EC2 instance and an RDS database (p. 388)
- Viewing connected compute resources (p. 390)
- Connecting to a DB instance that is running a specific DB engine (p. 391)

Overview of automatic connectivity with an EC2 instance

When you set up a connection between an EC2 instance and an RDS database, Amazon RDS automatically configures the VPC security group for your EC2 instance and for your RDS database.

The following are requirements for connecting an EC2 instance with an RDS database:

- The EC2 instance must exist in the same VPC as the RDS database.
- The user who sets up connectivity must have permissions to perform the following Amazon EC2 operations:
  - `ec2:AuthorizeSecurityGroupEgress`
  - `ec2:AuthorizeSecurityGroupIngress`
  - `ec2:CreateSecurityGroup`
  - `ec2:DescribeInstances`
  - `ec2:DescribeNetworkInterfaces`
  - `ec2:DescribeSecurityGroups`
  - `ec2:ModifyNetworkInterfaceAttribute`
  - `ec2:RevokeSecurityGroupEgress`

If the DB instance and EC2 instance are in different Availability Zones, your account may incur cross-Availability Zone costs.

When you set up a connection to an EC2 instance, Amazon RDS acts according to the current configuration of the security groups associated with the RDS database and EC2 instance, as described in the following table.

<table>
<thead>
<tr>
<th>Current RDS security group configuration</th>
<th>Current EC2 security group configuration</th>
<th>RDS action</th>
</tr>
</thead>
<tbody>
<tr>
<td>There are one or more security groups associated with the RDS database with a name that matches the pattern <code>rds-ec2-n</code> (where <code>n</code> is a number). A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the EC2 instance as the source.</td>
<td>There are one or more security groups associated with the EC2 instance with a name that matches the pattern <code>rds-ec2-n</code> (where <code>n</code> is a number). A security group that matches the pattern hasn't been modified. This security group has only one outbound rule with the VPC security group of the RDS database as the source.</td>
<td>RDS takes no action.</td>
</tr>
</tbody>
</table>
| Either of the following conditions apply:  
  - There is no security group associated with the RDS database with a name that matches the pattern `rds-ec2-n`. | Either of the following conditions apply:  
  - There is no security group associated with the EC2 instance with a name that matches the pattern `ec2-rds-n`. | RDS action: create new security groups |

If no EC2 instances exist in the same VPC, then the console provides a link to create one.

If the DB instance and EC2 instance are in different Availability Zones, your account may incur cross-Availability Zone costs.

When you set up a connection to an EC2 instance, Amazon RDS acts according to the current configuration of the security groups associated with the RDS database and EC2 instance, as described in the following table.

<table>
<thead>
<tr>
<th>Current RDS security group configuration</th>
<th>Current EC2 security group configuration</th>

Amazon RDS also can't use a security group that has been modified.</td>
<td>RDS action: create new security groups</td>
</tr>
<tr>
<td>A valid EC2 security group for the connection exists, but it is not associated with the EC2 instance. This security group has a name that matches the pattern rds-ec2-n. It hasn't been modified. It has only one outbound rule with the VPC security group of the RDS database as the source.</td>
<td>There are one or more security groups associated with the EC2 instance with a name that matches the pattern ec2-rds-n. However, Amazon RDS can't use any of these security groups for the connection with the RDS database. Amazon RDS can't use a security group that doesn't have one inbound rule with the VPC security group of the RDS database as the source. Amazon RDS also can't use a security group that has been modified.</td>
<td>RDS action: create new security groups</td>
</tr>
</tbody>
</table>
Either of the following conditions apply:

- There is no security group associated with the RDS database with a name that matches the pattern `rds-ec2-n`.
- There are one or more security groups associated with the RDS database with a name that matches the pattern `rds-ec2-n`. However, Amazon RDS can’t use any of these security groups for the connection with the EC2 instance. Amazon RDS can’t use a security group that doesn’t have one inbound rule with the VPC security group of the EC2 instance as the source. Amazon RDS also can’t use security group that has been modified.

There are one or more security groups associated with the EC2 instance with a name that matches the pattern `rds-ec2-n`. A security group that matches the pattern hasn’t been modified. This security group has only one outbound rule with the VPC security group of the RDS database as the source.

RDS action: create new security groups

Amazon RDS takes the following actions:

- Creates a new security group that matches the pattern `rds-ec2-n`. This security group has an inbound rule with the VPC security group of the EC2 instance as the source. This security group is associated with the RDS database and allows the EC2 instance to access the RDS database.
- Creates a new security group that matches the pattern `ec2-rds-n`. This security group has an outbound rule with the VPC security group of the RDS database as the source. This security group is associated with the EC2 instance and allows the EC2 instance to send traffic to the RDS database.

RDS action: associate EC2 security group

Amazon RDS associates the valid, existing EC2 security group with the EC2 instance. This security group allows the EC2 instance to send traffic to the RDS database.

Automatically connecting an EC2 instance and an RDS database

Before setting up a connection between an EC2 instance and an RDS database, make sure you meet the requirements described in Overview of automatic connectivity with an EC2 instance (p. 386).

If you make changes to security groups after you configure connectivity, the changes might affect the connection between the EC2 instance and the RDS database.

**Note**

You can only set up a connection between an EC2 instance and an RDS database automatically by using the AWS Management Console. You can't set up a connection automatically with the AWS CLI or RDS API.
To connect an EC2 instance and an RDS database automatically

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the RDS database.
3. From Actions, choose Set up EC2 connection.

The Set up EC2 connection page appears.
4. On the Set up EC2 connection page, choose the EC2 instance.

If no EC2 instances exist in the same VPC, choose Create EC2 instance to create one. In this case, make sure the new EC2 instance is in the same VPC as the RDS database.
5. Choose Continue.

The Review and confirm page appears.
6. On the **Review and confirm** page, review the changes that RDS will make to set up connectivity with the EC2 instance.

   If the changes are correct, choose **Confirm and set up**.

   If the changes aren't correct, choose **Previous** or **Cancel**.

**Viewing connected compute resources**

You can use the AWS Management Console to view the compute resources that are connected to an RDS database. The resources shown include compute resource connections that were set up automatically. You can set up connectivity with compute resources automatically in the following ways:

- You can select the compute resource when you create the database.
For more information, see Creating an Amazon RDS DB instance (p. 300) and Creating a Multi-AZ DB cluster (p. 508).

- You can set up connectivity between an existing database and a compute resource.

For more information, see Automatically connecting an EC2 instance and an RDS database (p. 388).

The listed compute resources don’t include ones that were connected to the database manually. For example, you can allow a compute resource to access a database manually by adding a rule to the VPC security group associated with the database.

For a compute resource to be listed, the following conditions must apply:

- The name of the security group associated with the compute resource matches the pattern ec2-rds-n (where n is a number).
- The security group associated with the compute resource has an outbound rule with the port range set to the port that the RDS database uses.
- The security group associated with the compute resource has an outbound rule with the source set to a security group associated with the RDS database.
- The name of the security group associated with the RDS database matches the pattern rds-ec2-n (where n is a number).
- The security group associated with the RDS database has an inbound rule with the port range set to the port that the RDS database uses.
- The security group associated with the RDS database has an inbound rule with the source set to a security group associated with the compute resource.

To view compute resources connected to an RDS database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the name of the RDS database.
3. On the Connectivity & security tab, view the compute resources in the Connected compute resources.

Connecting to a DB instance that is running a specific DB engine

For information about connecting to a DB instance that is running a specific DB engine, follow the instructions for your DB engine:

- Connecting to a DB instance running the MariaDB database engine (p. 1285)
- Connecting to a DB instance running the Microsoft SQL Server database engine (p. 1396)
- Connecting to a DB instance running the MySQL database engine (p. 1646)
- Connecting to your RDS for Oracle DB instance (p. 1822)
- Connecting to a DB instance running the PostgreSQL database engine (p. 2184)
Automatically connecting a Lambda function and a DB instance

You can use the Amazon RDS console to simplify setting up a connection between a Lambda function and a DB instance. Often, your DB instance is in a private subnet within a VPC. The Lambda function can be used by applications to access your private DB instance.

For instructions on setting up a connection between a Lambda function and a Multi-AZ DB cluster, see the section called “Connecting a Lambda function and a Multi-AZ DB cluster” (p. 530).

The following image shows a direct connection between your DB instance and your Lambda function.

You can set up the connection between your Lambda function and your DB instance through RDS Proxy to improve your database performance and resiliency. Often, Lambda functions make frequent, short database connections that benefit from connection pooling that RDS Proxy offers. You can take advantage of any AWS Identity and Access Management (IAM) authentication that you already have for Lambda functions, instead of managing database credentials in your Lambda application code. For more information, see Using Amazon RDS Proxy (p. 1215).

When you use the console to connect with an existing proxy, Amazon RDS updates the proxy security group to allow connections from your DB instance and Lambda function.

You can also create a new proxy from the same console page. When you create a proxy in the console, to access the DB instance, you must input your database credentials or select an AWS Secrets Manager secret.
Overview of automatic connectivity with a Lambda function

The following are requirements for connecting a Lambda function with an RDS DB instance:

- The Lambda function must exist in the same VPC as the DB instance.
- The user who sets up connectivity must have permissions to perform the following Amazon RDS, Amazon EC2, Lambda, Secrets Manager, and IAM operations:
  - Amazon RDS
    - rds:CreateDBProxies
    - rds:DescribeDBInstances
    - rds:DescribeDBProxies
    - rds:ModifyDBInstance
    - rds:ModifyDBProxy
    - rds:RegisterProxyTargets
  - Amazon EC2
    - ec2:AuthorizeSecurityGroupEgress
    - ec2:AuthorizeSecurityGroupIngress
    - ec2:CreateSecurityGroup
    - ec2:DeleteSecurityGroup
    - ec2:DescribeSecurityGroups
• ec2:RevokeSecurityGroupEgress
• ec2:RevokeSecurityGroupIngress
• Lambda
  • lambda:CreateFunctions
  • lambda:ListFunctions
  • lambda:UpdateFunctionConfiguration
• Secrets Manager
  • secretsmanager:CreateSecret
  • secretsmanager:DescribeSecret
• IAM
  • iam:AttachPolicy
  • iam:CreateRole
  • iam:CreatePolicy
• AWS KMS
  • kms:describeKey

**Note**
If the DB instance and Lambda function are in different Availability Zones, your account might incur cross-Availability Zone costs.

When you set up a connection between a Lambda function and an RDS database, Amazon RDS configures the VPC security group for your function and for your DB instance. If you use RDS Proxy, then Amazon RDS also configures the VPC security group for the proxy. Amazon RDS acts according to the current configuration of the security groups associated with the DB instance, Lambda function, and proxy, as described in the following table.

<table>
<thead>
<tr>
<th>Current RDS security group configuration</th>
<th>Current Lambda security group configuration</th>
<th>Current proxy security group configuration</th>
<th>RDS action</th>
</tr>
</thead>
<tbody>
<tr>
<td>There are one or more security groups associated with the DB instance with a name that matches the pattern rds-lambda-( n ) or if a proxy is already connected to your DB instance, RDS checks if the TargetHealth of an associated proxy is AVAILABLE. A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the Lambda function or proxy as the source.</td>
<td>There are one or more security groups associated with the Lambda function with a name that matches the pattern lambda-rds-( n ) or lambda-rdsproxy-( n ) (where ( n ) is a number). A security group that matches the pattern hasn't been modified. This security group has only one outbound rule with either the VPC security group of the DB instance or the proxy as the destination.</td>
<td>There are one or more security groups associated with the proxy with a name that matches the pattern rdsproxy-lambda-( n ) (where ( n ) is a number). A security group that matches the pattern hasn't been modified. This security group has inbound and outbound rules with the VPC security groups of the Lambda function and the DB instance.</td>
<td>Amazon RDS takes no action. A connection was already configured automatically between the Lambda function, the proxy (optional), and DB instance. Because a connection already exists between the function, proxy, and the database, the security groups aren't modified.</td>
</tr>
<tr>
<td>Either of the following conditions apply:</td>
<td>Either of the following conditions apply:</td>

### Connecting a Lambda function

#### Current RDS security group configuration

Either of the following conditions apply:

- There is no security group associated with the DB instance with a name that matches the pattern `rdslambda-n` or if the TargetHealth of an associated proxy is AVAILABLE.
- There are one or more security groups associated with the DB instance with a name that matches the pattern `rdslambda-n` or if the TargetHealth of an associated proxy is AVAILABLE. However, Amazon RDS can't use any of these security groups for the connection with the Lambda function or proxy.

Amazon RDS can't use a security group that doesn't have one inbound rule with the VPC security group of the Lambda function or proxy as the source. Amazon RDS also can't use a security group that has been modified.

### Current Lambda security group configuration

Either of the following conditions apply:

- There is no security group associated with the Lambda function with a name that matches the pattern `lambdards-n` or `lambdardsproxy-n`.
- There are one or more security groups associated with the Lambda function with a name that matches the pattern `lambdards-n` or `lambdardsproxy-n`. However, Amazon RDS can't use any of these security groups for the connection with the DB instance.

Amazon RDS can't use a security group that doesn't have one outbound rule with the VPC security group of the DB instance or proxy as the source. Amazon RDS also can't use a security group that has been modified.

### Current proxy security group configuration

Either of the following conditions apply:

- There is no security group associated with the proxy with a name that matches the pattern `rdsproxy-lambda-n`.
- There are one or more security groups associated with the proxy with a name that matches `rdsproxy-lambda-n`. However, Amazon RDS can't use any of these security groups for the connection with the DB instance or Lambda function.

Amazon RDS can't use a security group that doesn't have inbound and outbound rules with the VPC security group of the DB instance and the Lambda function. Amazon RDS also can't use a security group that has been modified.

### RDS action: create new security groups

Amazon RDS takes the following actions:

- Creates a new security group that matches the pattern `rdslambda-n` or `rdsproxy-lambda-n` (if you choose to use RDS Proxy). This security group has an inbound rule with the VPC security group of the Lambda function or proxy as the source. This security group is associated with the DB instance and allows the function or proxy to access the DB instance.

- Creates a new security group that matches the pattern `lambdards-n` or `lambdardsproxy-n`. This security group has an outbound rule with the VPC security group of the DB instance or proxy as the destination. This security group is associated with the Lambda function and allows the function to send traffic to the DB instance or send traffic through a proxy.

- Creates a new security group that matches the pattern `rdsproxy-lambda-n`. This security group has inbound and outbound rules with the VPC security group of the DB instance and the Lambda function.
RDS action: associate Lambda security group
Amazon RDS associates the valid, existing Lambda security group with the Lambda function. This security group allows the function to send traffic to the DB instance or send traffic through a proxy.

Automatically connecting a Lambda function and an RDS database
You can use the Amazon RDS console to automatically connect a Lambda function to your DB instance. This simplifies the process of setting up a connection between these resources.

You can also use RDS Proxy to include a proxy in your connection. Lambda functions make frequent short database connections that benefit from the connection pooling that RDS Proxy offers. You can also use any IAM authentication that you've already set up for your Lambda function, instead of managing database credentials in your Lambda application code.

You can connect an existing DB instance to new and existing Lambda functions using the Set up Lambda connection page. The setup process automatically sets up the required security groups for you.

Before setting up a connection between a Lambda function and a DB instance, make sure that:

- Your Lambda function and DB instance are in the same VPC.
- You have the right permissions for your user account. For more information about the requirements, see Overview of automatic connectivity with a Lambda function (p. 393).

If you change security groups after you configure connectivity, the changes might affect the connection between the Lambda function and the DB instance.

Note
You can automatically set up a connection between a DB instance and a Lambda function only in the AWS Management Console. To connect a Lambda function, the DB instance must be in the Available state.

To automatically connect a Lambda function and a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to connect to a Lambda function.
3. For Actions, choose Set up Lambda connection.
4. On the Set up Lambda connection page, under Select Lambda function, do either of the following:
   - If you have an existing Lambda function in the same VPC as your DB instance, choose Choose existing function, and then choose the function.
   - If you don't have a Lambda function in the same VPC, choose Create new function, and then enter a Function name. The default runtime is set to Nodejs.18. You can modify the settings for your new Lambda function in the Lambda console after you complete the connection setup.
5. (Optional) Under RDS Proxy, select Connect using RDS Proxy, and then do any of the following:
   - If you have an existing proxy that you want to use, choose Choose existing proxy, and then choose the proxy.
• If you don’t have a proxy, and you want Amazon RDS to automatically create one for you, choose Create new proxy. Then, for Database credentials, do either of the following:
  a. Choose Database username and password, and then enter the Username and Password for your DB instance.
  b. Choose Secrets Manager secret. Then, for Select secret, choose an AWS Secrets Manager secret. If you don’t have a Secrets Manager secret, choose Create new Secrets Manager secret to create a new secret. After you create the secret, for Select secret, choose the new secret.

After you create the new proxy, choose Choose existing proxy, and then choose the proxy. Note that it might take some time for your proxy to be available for connection.

6. (Optional) Expand Connection summary and verify the highlighted updates for your resources.

7. Choose Set up.

**Viewing connected compute resources**

You can use the AWS Management Console to view the Lambda functions that are connected to your DB instance. The resources shown include compute resource connections that Amazon RDS set up automatically.

The listed compute resources don’t include those that are manually connected to the DB instance. For example, you can allow a compute resource to access your DB instance manually by adding a rule to your VPC security group associated with the database.

For the console to list a Lambda function, the following conditions must apply:

• The name of the security group associated with the compute resource matches the pattern lambda-rds-n or lambda-rdsproxy-n (where n is a number).
• The security group associated with the compute resource has an outbound rule with the port range set to the port of the DB instance or an associated proxy. The destination for the outbound rule must be set to a security group associated with the DB instance or an associated proxy.
• If the configuration includes a proxy, the name of the security group attached to the proxy associated with your database matches the pattern rdsproxy-lambda-n (where n is a number).
• The security group associated with the function has an outbound rule with the port set to the port that the DB instance or associated proxy uses. The destination must be set to a security group associated with the DB instance or associated proxy.

**To view compute resources automatically connected to an DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance.
3. On the Connectivity & security tab, view the compute resources under Connected compute resources.
Modifying an Amazon RDS DB instance

You can change the settings of a DB instance to accomplish tasks such as adding additional storage or changing the DB instance class. In this topic, you can find out how to modify an Amazon RDS DB instance and learn about the settings for DB instances.

We recommend that you test any changes on a test instance before modifying a production instance. Doing this helps you to fully understand the impact of each change. Testing is especially important when upgrading database versions.

Most modifications to a DB instance you can either apply immediately or defer until the next maintenance window. Some modifications, such as parameter group changes, require that you manually reboot your DB instance for the change to take effect.

**Important**

Some modifications result in downtime because Amazon RDS must reboot your DB instance for the change to take effect. Review the impact to your database and applications before modifying your DB instance settings.

**Console**

To modify a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.
4. Change any of the settings that you want. For information about each setting, see Settings for DB instances (p. 402).
5. When all the changes are as you want them, choose Continue and check the summary of modifications.
6. (Optional) Choose Apply immediately to apply the changes immediately. Choosing this option can cause downtime in some cases. For more information, see Using the Apply Immediately setting (p. 402).
7. On the confirmation page, review your changes. If they are correct, choose Modify DB instance to save your changes.
   Or choose Back to edit your changes or Cancel to cancel your changes.

**AWS CLI**

To modify a DB instance by using the AWS CLI, call the `modify-db-instance` command. Specify the DB instance identifier and the values for the options that you want to modify. For information about each option, see Settings for DB instances (p. 402).

**Example**

The following code modifies mydbinstance by setting the backup retention period to 1 week (7 days). The code enables deletion protection by using `--deletion-protection`. To disable deletion protection, use `--no-deletion-protection`. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see Using the Apply Immediately setting (p. 402).
Apply Immediately setting

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
   --db-instance-identifier mydbinstance
   --backup-retention-period 7
   --deletion-protection
   --no-apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance
   --db-instance-identifier mydbinstance
   --backup-retention-period 7
   --deletion-protection
   --no-apply-immediately
```

RDS API

To modify a DB instance by using the Amazon RDS API, call the `ModifyDBInstance` operation. Specify the DB instance identifier, and the parameters for the settings that you want to modify. For information about each parameter, see Settings for DB instances (p. 402).

Using the Apply Immediately setting

When you modify a DB instance, you can apply the changes immediately. To apply changes immediately, you choose the Apply Immediately option in the AWS Management Console. Or you use the --apply-immediately parameter when calling the AWS CLI or set the ApplyImmediately parameter to true when using the Amazon RDS API.

If you don't choose to apply changes immediately, the changes are put into the pending modifications queue. During the next maintenance window, any pending changes in the queue are applied. If you choose to apply changes immediately, your new changes and any changes in the pending modifications queue are applied.

**Important**

If any of the pending modifications require the DB instance to be temporarily unavailable (downtime), choosing the apply immediately option can cause unexpected downtime. When you choose to apply a change immediately, any pending modifications are also applied immediately, instead of during the next maintenance window. If you don't want a pending change to be applied in the next maintenance window, you can modify the DB instance to revert the change. You can do this by using the AWS CLI and specifying the --apply-immediately option.

Changes to some database settings are applied immediately, even if you choose to defer your changes. To see how the different database settings interact with the apply immediately setting, see Settings for DB instances (p. 402).

Settings for DB instances

In the following table, you can find details about which settings you can and can't modify. You can also find when changes can be applied and whether the changes cause downtime for your DB instance. By using Amazon RDS features such as Multi-AZ, you can minimize downtime if you later modify the DB instance. For more information, see Configuring and managing a Multi-AZ deployment (p. 492).

You can modify a DB instance using the console, the `modify-db-instance` CLI command, or the `ModifyDBInstance` RDS API operation.
## Available settings

<table>
<thead>

<tr>
<td>The storage, in gibibytes, that you want to allocate for your DB instance. You can only increase the allocated storage. You can't reduce the allocated storage. You can't modify the storage of some older DB instances, or DB instances restored from older DB snapshots. The <strong>Allocated storage</strong> setting is disabled in the console if your DB instance isn't eligible. You can check whether you can allocate more storage by using the CLI command <code>describe-valid-db-instance-modifications</code>. This command returns the valid storage options for your DB instance. You can't modify allocated storage if the DB instance status is <strong>storage-optimization</strong>. You also can't modify allocated storage for a DB instance if it's been modified in the last six hours. The maximum storage allowed depends on your DB engine and the storage type. For more information, see [Amazon RDS DB instance storage](p. 101).</td>
<td><strong>--allocated-storage</strong></td>
<td><strong>AllocatedStorage</strong></td>
<td>If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.</td>
<td>Downtime doesn't occur during this change. Performance might be degraded during the change.</td>
</tr>
</tbody>
</table>

## Architecture settings

The architecture of the database: CDB (single-tenant) or non-CDB. Oracle Database 21c uses CDB architecture only. Oracle Database 19c can use either CDB or non-CDB architecture. Releases lower than Oracle Database 19c use non-CDB only. If you choose **Multitenant architecture**, RDS for Oracle converts your non-CDB into a CDB. This setting is supported only if your database is a non-CDB running Oracle Database 19c with the April 2021 or higher RU. After conversion, your CDB contains one pluggable database (PDB). For more information, see [Overview of RDS for Oracle CDBs](p. 1856). |

| **CLI option:** | **API parameter:** | | | |
| **--engine oracle-ee-cdb (multitenant)** | **Engine** | | | Oracle |
| **--engine oracle-se2-cdb (multitenant)** | | | | |

Downtime occurs during this change.

| **Manage master credentials in AWS Secrets Manager**  
Select Manage master credentials in AWS Secrets Manager to manage the master user password in a secret in Secrets Manager.  
Optionally, choose a KMS key to use to protect the secret. Choose from the KMS keys in your account, or enter the key from a different account.  
If RDS is already managing the master user password for the DB instance, you can rotate the master user password by choosing Rotate secret immediately.  
For more information, see Password management with Amazon RDS and AWS Secrets Manager (p. 2585). | **CLI option:**  
--manage-master-user-password | If you are turning on or turning off automatic master user password management, the change occurs immediately. This change ignores the apply immediately setting.  
If you are rotating the master user password, you must specify that the change is applied immediately. | Downtime doesn’t occur during this change. | All DB engines |
| **Multi-AZ deployment**  
Yes to deploy your DB instance in multiple Availability Zones. Otherwise, No.  
For more information, see Configuring and managing a Multi-AZ deployment (p. 492). | **CLI option:**  
--multi-az|--no-multi-az | If you choose to apply the change immediately, it occurs immediately.  
If you don’t choose to apply the change immediately, it occurs during the next maintenance window. | Downtime doesn’t occur during this change. However, there is a possible performance impact. For more information, see Modifying a DB instance to be a Multi-AZ DB instance deployment (p. 494). | All DB engines |

The password for your master user. The password must contain 8–41 alphanumeric characters.

| **Option group**                | **CLI option:**                  | **RDS API parameter:** |                |                     |
|                                 | `--option-group-name`            | `OptionGroupName`      |                |                     |
|                                 |                                  |                        |                |                     |
|                                 |                                  |                        |                |                     |

The option group that you want associated with the DB instance.

For more information, see [Working with option groups](p. 331).
### Performance Insights

**Enable Performance Insights** to monitor your DB instance load so that you can analyze and troubleshoot your database performance.

Performance Insights isn't available for some DB engine versions and DB instance classes. The **Performance Insights** section doesn't appear in the console if it isn't available for your DB instance.

For more information, see [Monitoring DB load with Performance Insights on Amazon RDS](p. 720) and [Amazon RDS DB engine, Region, and instance class support for Performance Insights](p. 724).

#### CLI option:

```
--enable-performance-insights|--no-enable-performance-insights
```

#### RDS API parameter:

`EnablePerformanceInsights`

The change occurs immediately. This setting ignores the apply immediately setting.

Downtime doesn't occur during this change.

All DB engines

---

### Performance Insights AWS KMS key

The AWS KMS key identifier for the AWS KMS key for encryption of Performance Insights data. The key identifier is the Amazon Resource Name (ARN), AWS KMS key identifier, or the key alias for the KMS key.

For more information, see [Turning Performance Insights on and off](p. 727).

#### CLI option:

```
--performance-insights-kms-key-id
```

#### RDS API parameter:

`PerformanceInsightsKMSKeyId`

The change occurs immediately. This setting ignores the apply immediately setting.

Downtime doesn't occur during this change.

All DB engines

---

### Performance Insights Retention period

The amount of time, in days, to retain Performance Insights data. The retention setting in the free tier is **Default (7 days)**. To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see [Pricing and data retention for Performance Insights](p. 726).

For more information, see [Turning Performance Insights on and off](p. 727).

#### CLI option:

```
--performance-insights-retention-period
```

#### RDS API parameter:

`PerformanceInsightsRetentionPeriod`

The change occurs immediately. This setting ignores the apply immediately setting.

Downtime doesn't occur during this change.

*For more information, see [Configuring the processor for a DB instance class in RDS for Oracle](#) (p. 71).*

*For more information, see [Provisioned IOPS SSD storage](#) and [Amazon RDS DB instance storage](#).*
## Public access

**Publicly accessible** to give the DB instance a public IP address, meaning that it's accessible outside the VPC. To be publicly accessible, the DB instance also has to be in a public subnet in the VPC.

**Not publicly accessible** to make the DB instance accessible only from inside the VPC.

For more information, see [Hiding a DB instance in a VPC from the internet](p. 2712).

To connect to a DB instance from outside its VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group. In addition, other requirements must be met. For more information, see [Can't connect to Amazon RDS DB instance](p. 2744).

If your DB instance isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see [Internetwork traffic privacy](p. 2622).

### CLI option:
```
--publicly-accessible|--no-publicly-accessible
```

### RDS API parameter:
```
PubliclyAccessible
```

The change occurs immediately. This setting ignores the apply immediately setting.

Downtime doesn't occur during this change.

### Supported DB engines
All DB engines

## Security group

The VPC security group that you want associated with the DB instance.

For more information, see [Controlling access with security groups](p. 2697).

### CLI option:
```
--vpc-security-group-ids
```

### RDS API parameter:
```
VpcSecurityGroupIds
```

The change is applied asynchronously, as soon as possible. This setting ignores the apply immediately setting.

Downtime doesn't occur during this change.

### Supported DB engines
All DB engines
### Storage autoscaling

**Enable storage autoscaling** to enable Amazon RDS to automatically increase storage when needed to avoid having your DB instance run out of storage space.

Use **Maximum storage threshold** to set the upper limit for Amazon RDS to automatically increase storage for your DB instance. The default is 1,000 GiB.

For more information, see [Managing capacity automatically with Amazon RDS storage autoscaling](p. 480).

<table>
<thead>

</thead>
<tbody>
<tr>
<td></td>
<td>RDS API parameter: <code>StorageThroughput</code></td>
<td>If you don’t choose to apply the change immediately, it occurs during the next maintenance window.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Storage type

The storage type that you want to use.

If you choose **General Purpose SSD (gp3)**, you can provision additional **Provisioned IOPS** and Storage throughput under Advanced settings.

If you choose **Provisioned IOPS SSD (io1)**, enter the Provisioned IOPS value.

After Amazon RDS begins to modify your DB instance to change the storage size or type, you can’t submit another request to change the storage size, performance, or type for six hours.

For more information, see [Amazon RDS storage types](p. 101).

<table>

</tbody>
</table>
Maintaining a DB instance

Periodically, Amazon RDS performs maintenance on Amazon RDS resources. Maintenance most often involves updates to the following resources in your DB instance:

- Underlying hardware
- Underlying operating system (OS)
- Database engine version

Updates to the operating system most often occur for security issues. You should do them as soon as possible.

Some maintenance items require that Amazon RDS take your DB instance offline for a short time. Maintenance items that require a resource to be offline include required operating system or database patching. Required patching is automatically scheduled only for patches that are related to security and instance reliability. Such patching occurs infrequently, typically once every few months. It seldom requires more than a fraction of your maintenance window.

Deferred DB instance modifications that you have chosen not to apply immediately are also applied during the maintenance window. For example, you might choose to change the DB instance class or parameter group during the maintenance window. Such modifications that you specify using the pending reboot setting don't show up in the Pending maintenance list. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401).

Topics
- Viewing pending maintenance (p. 418)
- Applying updates for a DB instance (p. 421)
- Maintenance for Multi-AZ deployments (p. 422)
- The Amazon RDS maintenance window (p. 423)
- Adjusting the preferred DB instance maintenance window (p. 424)
- Working with operating system updates (p. 426)

Viewing pending maintenance

View whether a maintenance update is available for your DB instance by using the RDS console, the AWS CLI, or the RDS API. If an update is available, it is indicated in the Maintenance column for the DB instance on the Amazon RDS console, as shown following.
If no maintenance update is available for a DB instance, the column value is `none` for it.

If a maintenance update is available for a DB instance, the following column values are possible:

- **required** – The maintenance action will be applied to the resource and can't be deferred indefinitely.
- **available** – The maintenance action is available, but it will not be applied to the resource automatically. You can apply it manually.
- **next window** – The maintenance action will be applied to the resource during the next maintenance window.
- **In progress** – The maintenance action is in the process of being applied to the resource.

If an update is available, you can take one of the actions:

- If the maintenance value is `next window`, defer the maintenance items by choosing **Defer upgrade** from Actions. You can't defer a maintenance action if it has already started.
- Apply the maintenance items immediately.
- Schedule the maintenance items to start during your next maintenance window.
- Take no action.

To take an action, choose the DB instance to show its details, then choose **Maintenance & backups**. The pending maintenance items appear.
The maintenance window determines when pending operations start, but doesn't limit the total run time of these operations. Maintenance operations aren't guaranteed to finish before the maintenance window ends, and can continue beyond the specified end time. For more information, see The Amazon RDS maintenance window (p. 423).

You can also view whether a maintenance update is available for your DB instance by running the `describe-pending-maintenance-actions` AWS CLI command.
Applying updates for a DB instance

With Amazon RDS, you can choose when to apply maintenance operations. You can decide when Amazon RDS applies updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API.

Console

To manage an update for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that has a required update.
4. For Actions, choose one of the following:
   - Upgrade now
   - Upgrade at next window

   **Note**
   If you choose Upgrade at next window and later want to delay the update, you can choose Deferr upgrade. You can't defer a maintenance action if it has already started. To cancel a maintenance action, modify the DB instance and disable Auto minor version upgrade.

AWS CLI

To apply a pending update to a DB instance, use the apply-pending-maintenance-action AWS CLI command.

**Example**

For Linux, macOS, or Unix:

```
aws rds apply-pending-maintenance-action
   --apply-action system-update
   --opt-in-type immediate
```

For Windows:

```
aws rds apply-pending-maintenance-action
   --apply-action system-update
   --opt-in-type immediate
```

**Note**
To defer a maintenance action, specify undo-opt-in for --opt-in-type. You can't specify undo-opt-in for --opt-in-type if the maintenance action has already started.
To cancel a maintenance action, run the modify-db-instance AWS CLI command and specify --no-auto-minor-version-upgrade.

To return a list of resources that have at least one pending update, use the describe-pending-maintenance-actions AWS CLI command.

**Example**

For Linux, macOS, or Unix:
aws rds describe-pending-maintenance-actions \

For Windows:

aws rds describe-pending-maintenance-actions ^

You can also return a list of resources for a DB instance by specifying the --filters parameter of the describe-pending-maintenance-actions AWS CLI command. The format for the --filters command is Name=filter-name,Value=resource-id,....

The following are the accepted values for the Name parameter of a filter:

- **db-instance-id** – Accepts a list of DB instance identifiers or Amazon Resource Names (ARNs). The returned list only includes pending maintenance actions for the DB instances identified by these identifiers or ARNs.
- **db-cluster-id** – Accepts a list of DB cluster identifiers or ARNs for Amazon Aurora. The returned list only includes pending maintenance actions for the DB clusters identified by these identifiers or ARNs.

For example, the following example returns the pending maintenance actions for the sample-instance1 and sample-instance2 DB instances.

**Example**

For Linux, macOS, or Unix:

aws rds describe-pending-maintenance-actions \
  --filters Name=db-instance-id,Values=sample-instance1,sample-instance2

For Windows:

aws rds describe-pending-maintenance-actions ^
  --filters Name=db-instance-id,Values=sample-instance1,sample-instance2

**RDS API**

To apply an update to a DB instance, call the Amazon RDS API ApplyPendingMaintenanceAction operation.

To return a list of resources that have at least one pending update, call the Amazon RDS API DescribePendingMaintenanceActions operation.

**Maintenance for Multi-AZ deployments**

Running a DB instance as a Multi-AZ deployment can further reduce the impact of a maintenance event. This result is because Amazon RDS applies operating system updates by following these steps:

1. Perform maintenance on the standby.
2. Promote the standby to primary.
3. Perform maintenance on the old primary, which becomes the new standby.

If you upgrade the database engine for your DB instance in a Multi-AZ deployment, Amazon RDS modifies both primary and secondary DB instances at the same time. In this case, both the primary and
secondary DB instances in the Multi-AZ deployment are unavailable during the upgrade. This operation causes downtime until the upgrade is complete. The duration of the downtime varies based on the size of your DB instance.

If your DB instance runs RDS for MySQL or RDS for MariaDB, you can minimize the downtime required for an upgrade by using a blue/green deployment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates (p. 566). If you upgrade an RDS for SQL Server DB instance in a Multi-AZ deployment, then Amazon RDS performs rolling upgrades, so you have an outage only for the duration of a failover. For more information, see Multi-AZ and in-memory optimization considerations (p. 1433).

For more information about Multi-AZ deployments, see Configuring and managing a Multi-AZ deployment (p. 492).

The Amazon RDS maintenance window

Every DB instance has a weekly maintenance window during which any system changes are applied. Think of the maintenance window as an opportunity to control when modifications and software patching occur. If a maintenance event is scheduled for a given week, it’s initiated during the 30-minute maintenance window you identify. Most maintenance events also complete during the 30-minute maintenance window, although larger maintenance events may take more than 30 minutes to complete.

The 30-minute maintenance window is selected at random from an 8-hour block of time per region. If you don’t specify a maintenance window when you create the DB instance, RDS assigns a 30-minute maintenance window on a randomly selected day of the week.

RDS consumes some of the resources on your DB instance while maintenance is being applied. You might observe a minimal effect on performance. For a DB instance, on rare occasions, a Multi-AZ failover might be required for a maintenance update to complete.

Following, you can find the time blocks for each region from which default maintenance windows are assigned.

<table>
<thead>
<tr>
<th>Region Name</th>

</tr>
</tbody>
</table>
Adjusting the maintenance window for a DB instance

The maintenance window should fall at the time of lowest usage and thus might need modification from time to time. Your DB instance is unavailable during this time only if the system changes, such as a change in DB instance class, are being applied and require an outage. Your DB instance is unavailable only for the minimum amount of time required to make the necessary changes.

In the following example, you adjust the preferred maintenance window for a DB instance.

For this example, we assume that a DB instance named *mydbinstance* exists and has a preferred maintenance window of “Sun:05:00-Sun:06:00” UTC.
Console

To adjust the preferred maintenance window

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then select the DB instance that you want to modify.
4. In the Maintenance section, update the maintenance window.

   Note
   The maintenance window and the backup window for the DB instance cannot overlap. If you enter a value for the maintenance window that overlaps the backup window, an error message appears.
5. Choose Continue.

   On the confirmation page, review your changes.
6. To apply the changes to the maintenance window immediately, select Apply immediately.
7. Choose Modify DB instance to save your changes.

   Alternatively, choose Back to edit your changes, or choose Cancel to cancel your changes.

AWS CLI

To adjust the preferred maintenance window, use the AWS CLI modify-db-instance command with the following parameters:

• --db-instance-identifier
• --preferred-maintenance-window

Example

The following code example sets the maintenance window to Tuesdays from 4:00-4:30AM UTC.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
   --db-instance-identifier mydbinstance
   --preferred-maintenance-window Tue:04:00-Tue:04:30
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier mydbinstance ^
   --preferred-maintenance-window Tue:04:00-Tue:04:30
```

RDS API

To adjust the preferred maintenance window, use the Amazon RDS API ModifyDBInstance operation with the following parameters:

• DBInstanceIdentifier
• PreferredMaintenanceWindow
Working with operating system updates

RDS for MariaDB, RDS for MySQL, RDS for PostgreSQL, and RDS for Oracle DB instances occasionally require operating system updates. Amazon RDS upgrades the operating system to a newer version to improve database performance and customers' overall security posture. Typically, the updates take about 10 minutes. Operating system updates don't change the DB engine version or DB instance class of a DB instance.

Operating system updates can be either optional or mandatory:

- **An optional update** can be applied at any time. While these updates are optional, we recommend that you apply them periodically to keep your RDS fleet up to date. RDS does not apply these updates automatically.

  To be notified when a new, optional operating system patch becomes available, you can subscribe to RDS-EVENT-0230 (p. 889) in the security patching event category. For information about subscribing to RDS events, see Subscribing to Amazon RDS event notification (p. 860).

  **Note**
  RDS-EVENT-0230 doesn't apply to operating system distribution upgrades.

- **A mandatory update** is required and has an apply date. Plan to schedule your update before this apply date. After the specified apply date, Amazon RDS automatically upgrades the operating system for your DB instance to the latest version during one of your assigned maintenance windows.

  **Note**
  Staying current on all optional and mandatory updates might be required to meet various compliance obligations. We recommend that you apply all updates made available by RDS routinely during your maintenance windows.

You can use the AWS Management Console or the AWS CLI to get information about the type of operating system upgrade.

**Console**

**To get update information using the AWS Management Console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then select the DB instance.
3. Choose Maintenance & backups.
4. In the Pending maintenance section, find the operating system update, and check the Status value.

   In the AWS Management Console, an optional update has its maintenance Status set to available and doesn't have an Apply date, as shown in the following image.
A mandatory update has its maintenance Status set to **required** and has an **Apply date**, as shown in the following image.

AWS CLI

To get update information from the AWS CLI, use the **describe-pending-maintenance-actions** command.

```
aws rds describe-pending-maintenance-actions
```

A mandatory operating system update includes an **AutoAppliedAfterDate** value and a **CurrentApplyDate** value. An optional operating system update doesn't include these values.

The following output shows a mandatory operating system update.

```
{
    "PendingMaintenanceActionDetails": [
        {
            "Action": "system-update",
            "AutoAppliedAfterDate": "2022-08-31T00:00:00+00:00",
            "CurrentApplyDate": "2022-08-31T00:00:00+00:00",
            "Description": "New Operating System update is available"
        }
    ]
}
```

The following output shows an optional operating system update.
Availability of operating system updates

Operating system updates are specific to DB engine version and DB instance class. Therefore, DB instances receive or require updates at different times. When an operating system update is available for your DB instance based on its engine version and instance class, the update appears in the console. It can also be viewed by running AWS CLI `describe-pending-maintenance-actions` command or by calling the RDS DescribePendingMaintenanceActions API operation. If an update is available for your instance, you can update your operating system by following the instructions in Applying updates for a DB instance (p. 421).

Mandatory operating system updates schedule

We plan to use the following schedule for mandatory operating system updates. The **Apply date** refers to when Amazon RDS starts to apply mandatory updates. For each date in the table, the start time is 00:00 Universal Coordinated Time (UTC).

<table>
<thead>
<tr>
<th>DB engine</th>
<th>Apply date</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDS for MySQL</td>
<td>January 30, 2023</td>
</tr>
<tr>
<td>RDS for MariaDB</td>
<td>January 30, 2023</td>
</tr>
<tr>
<td>RDS for PostgreSQL</td>
<td>March 31, 2023</td>
</tr>
</tbody>
</table>

**Note**

The dates in the table apply to customers who didn't experience mandatory operating system updates in 2022. To confirm whether the mandatory operating system updates in 2023 impact you, check the Pending maintenance section in the console for operating system updates. For more information, see the Console section under Working with operating system updates (p. 426).

After the apply date, Amazon RDS automatically upgrades the operating system for your DB instances to the latest version in a subsequent maintenance window. To avoid an automatic upgrade, we recommend that you schedule your update before the apply date.
Upgrading a DB instance engine version

Amazon RDS provides newer versions of each supported database engine so you can keep your DB instance up-to-date. Newer versions can include bug fixes, security enhancements, and other improvements for the database engine. When Amazon RDS supports a new version of a database engine, you can choose how and when to upgrade your database DB instances.

There are two kinds of upgrades: major version upgrades and minor version upgrades. In general, a major engine version upgrade can introduce changes that are not compatible with existing applications. In contrast, a minor version upgrade includes only changes that are backward-compatible with existing applications.

For Multi-AZ DB clusters, major version upgrades are only supported for RDS for PostgreSQL. Minor version upgrades are supported for all engines that support Multi-AZ DB clusters. For more information, see the section called “Upgrading the engine version of a Multi-AZ DB cluster” (p. 503).

The version numbering sequence is specific to each database engine. For example, RDS for MySQL 5.7 and 8.0 are major engine versions and upgrading from any 5.7 version to any 8.0 version is a major version upgrade. RDS for MySQL version 5.7.22 and 5.7.23 are minor versions and upgrading from 5.7.22 to 5.7.23 is a minor version upgrade.

**Important**
You can't modify a DB instance when it is being upgraded. During an upgrade, the DB instance status is upgrading.

For more information about major and minor version upgrades for a specific DB engine, see the following documentation for your DB engine:

- Upgrading the MariaDB DB engine (p. 1305)
- Upgrading the Microsoft SQL Server DB engine (p. 1430)
- Upgrading the MySQL DB engine (p. 1680)
- Upgrading the RDS for Oracle DB engine (p. 2119)
- Upgrading the PostgreSQL DB engine for Amazon RDS (p. 2214)

For major version upgrades, you must manually modify the DB engine version through the AWS Management Console, AWS CLI, or RDS API. For minor version upgrades, you can manually modify the engine version, or you can choose to enable the Auto minor version upgrade option.

**Note**
Database engine upgrades require downtime. You can minimize the downtime required for DB instance upgrade by using a blue/green deployment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates (p. 566).

Topics

- Manually upgrading the engine version (p. 429)
- Automatically upgrading the minor engine version (p. 431)

Manually upgrading the engine version

To manually upgrade the engine version of a DB instance, you can use the AWS Management Console, the AWS CLI, or the RDS API.
Console

To upgrade the engine version of a DB instance by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to upgrade.
4. For DB engine version, choose the new version.
5. Choose Continue and check the summary of modifications.
6. To apply the changes immediately, choose Apply immediately. Choosing this option can cause an outage in some cases. For more information, see Using the Apply Immediately setting (p. 402).
7. On the confirmation page, review your changes. If they are correct, choose Modify DB instance to save your changes.

Alternatively, choose Back to edit your changes, or choose Cancel to cancel your changes.

AWS CLI

To upgrade the engine version of a DB instance, use the CLI modify-db-instance command. Specify the following parameters:

- --db-instance-identifier – the name of the DB instance.
- --engine-version – the version number of the database engine to upgrade to.

For information about valid engine versions, use the AWS CLI describe-db-engine-versions command.

- --allow-major-version-upgrade – to upgrade the major version.
- --no-apply-immediately – to apply changes during the next maintenance window. To apply changes immediately, use --apply-immediately.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --engine-version new_version \
    --allow-major-version-upgrade \
    --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --engine-version new_version ^
    --allow-major-version-upgrade ^
    --no-apply-immediately
```

RDS API

To upgrade the engine version of a DB instance, use the ModifyDBInstance action. Specify the following parameters:
Automatically upgrading the minor engine version

A minor engine version is an update to a DB engine version within a major engine version. For example, a major engine version might be 9.6 with the minor engine versions 9.6.11 and 9.6.12 within it.

If you want Amazon RDS to upgrade the DB engine version of a database automatically, you can enable auto minor version upgrades for the database.

Topics

- How automatic minor version upgrades work (p. 431)
- Turning on automatic minor version upgrades (p. 431)
- Determining the availability of maintenance updates (p. 432)
- Finding automatic minor version upgrade targets (p. 432)

How automatic minor version upgrades work

Amazon RDS designates a minor engine version as the preferred minor engine version when the following conditions are met:

- The database is running a minor version of the DB engine that is lower than the preferred minor engine version.

You can find your current engine version for your DB instance by looking on the Configuration tab of the database details page or running the CLI command describe-db-instances.

- The database has auto minor version upgrade enabled.

RDS schedules the upgrades to run automatically in the maintenance window. During the upgrade, RDS performs the following basic steps:

1. Runs a precheck to make sure the database is healthy and ready to be upgraded
2. Upgrades the DB engine
3. Runs post-upgrade checks
4. Marks the database upgrade as complete

Automatic upgrades incur downtime. The length of the downtime depends on various factors, including the DB engine type and the size of the database.

Turning on automatic minor version upgrades

You can control whether auto minor version upgrade is enabled for a DB instance when you perform the following tasks:
• Creating a DB instance (p. 300)
• Modifying a DB instance (p. 401)
• Creating a read replica (p. 445)
• Restoring a DB instance from a snapshot (p. 615)
• Restoring a DB instance to a specific time (p. 660)
• Importing a DB instance from Amazon S3 (p. 1696) (for a MySQL backup on Amazon S3)

When you perform these tasks, you can control whether auto minor version upgrade is enabled for the DB instance in the following ways:

• Using the console, set the Auto minor version upgrade option.
• Using the AWS CLI, set the --auto-minor-version-upgrade|--no-auto-minor-version-upgrade option.
• Using the RDS API, set the AutoMinorVersionUpgrade parameter.

Determining the availability of maintenance updates

To determine whether a maintenance update, such as a DB engine version upgrade, is available for your DB instance, you can use the console, AWS CLI, or RDS API. You can also upgrade the DB engine version manually and adjust the maintenance window. For more information, see Maintaining a DB instance (p. 418).

Finding automatic minor version upgrade targets

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified minor DB engine version in a specific AWS Region. You can find the possible --engine values for this command in the description for the Engine parameter in CreateDBInstance.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine engine \n  --engine-version minor-version \n  --region region \n  --query "DBEngineVersions[*].ValidUpgradeTarget[*].\n  {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \n  --output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine engine ^
  --engine-version minor-version ^
  --region region ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].\n  {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
  --output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MySQL minor version 8.0.11 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
```
Automatically upgrading the minor engine version

```bash
--engine mysql \
--engine-version 8.0.11 \
--region us-east-2 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].\n{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}"
--output table
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
--engine mysql ^
--engine-version 8.0.11 ^
--region us-east-2 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].\n{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output table
```

Your output is similar to the following.

```
----------------------------------
|    DescribeDBEngineVersions    |
+--------------+-----------------+
|  AutoUpgrade |  EngineVersion  |
+--------------+-----------------+
|  False       |  8.0.15         |
|  False       |  8.0.16         |
|  False       |  8.0.17         |
|  False       |  8.0.19         |
|  False       |  8.0.20         |
|  False       |  8.0.21         |
|  True        |  8.0.23         |
|  False       |  8.0.25         |
+--------------+-----------------+
```

In this example, the `AutoUpgrade` value is `True` for MySQL version 8.0.23. So, the automatic minor upgrade target is MySQL version 8.0.23, which is highlighted in the output.

**Important**

If you plan to migrate an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster soon, we strongly recommend that you turn off auto minor version upgrades for the DB instance early during planning. Migration to Aurora PostgreSQL might be delayed if the RDS for PostgreSQL version isn't yet supported by Aurora PostgreSQL. For information about Aurora PostgreSQL versions, see [Engine versions for Amazon Aurora PostgreSQL](#).
Renaming a DB instance

You can rename a DB instance by using the AWS Management Console, the AWS CLI `modify-db-instance` command, or the Amazon RDS API `ModifyDBInstance` action. Renaming a DB instance can have far-reaching effects. The following is a list of considerations before you rename a DB instance.

- When you rename a DB instance, the endpoint for the DB instance changes, because the URL includes the name you assigned to the DB instance. You should always redirect traffic from the old URL to the new one.
- When you rename a DB instance, the old DNS name that was used by the DB instance is immediately deleted, although it could remain cached for a few minutes. The new DNS name for the renamed DB instance becomes effective in about 10 minutes. The renamed DB instance is not available until the new name becomes effective.
- You cannot use an existing DB instance name when renaming an instance.
- All read replicas associated with a DB instance remain associated with that instance after it is renamed. For example, suppose you have a DB instance that serves your production database and the instance has several associated read replicas. If you rename the DB instance and then replace it in the production environment with a DB snapshot, the DB instance that you renamed will still have the read replicas associated with it.
- Metrics and events associated with the name of a DB instance are maintained if you reuse a DB instance name. For example, if you promote a read replica and rename it to be the name of the previous primary DB instance, the events and metrics associated with the primary DB instance are associated with the renamed instance.
- DB instance tags remain with the DB instance, regardless of renaming.
- DB snapshots are retained for a renamed DB instance.

**Note**
A DB instance is an isolated database environment running in the cloud. A DB instance can host multiple databases, or a single Oracle database with multiple schemas. For information about changing a database name, see the documentation for your DB engine.

Renaming to replace an existing DB instance

The most common reasons for renaming a DB instance are that you are promoting a read replica or you are restoring data from a DB snapshot or point-in-time recovery (PITR). By renaming the database, you can replace the DB instance without having to change any application code that references the DB instance. In these cases, you would do the following:

1. Stop all traffic going to the primary DB instance. This can involve redirecting traffic from accessing the databases on the DB instance or some other way you want to use to prevent traffic from accessing your databases on the DB instance.
2. Rename the primary DB instance to a name that indicates it is no longer the primary DB instance as described later in this topic.
3. Create a new primary DB instance by restoring from a DB snapshot or by promoting a read replica, and then give the new instance the name of the previous primary DB instance.
4. Associate any read replicas with the new primary DB instance.

If you delete the old primary DB instance, you are responsible for deleting any unwanted DB snapshots of the old primary DB instance.

For information about promoting a read replica, see [Promoting a read replica to be a standalone DB instance](p. 447).
Important
The DB instance is rebooted when it is renamed.

**Console**

**To rename a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to rename.
4. Choose **Modify**.
5. In **Settings**, enter a new name for **DB instance identifier**.
6. Choose **Continue**.
7. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see *Modifying an Amazon RDS DB instance* (p. 401).
8. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

**AWS CLI**

To rename a DB instance, use the AWS CLI command `modify-db-instance`. Provide the current `--db-instance-identifier` value and `--new-db-instance-identifier` parameter with the new name of the DB instance.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier DBInstanceIdentifier \
  --new-db-instance-identifier NewDBInstanceIdentifier
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier DBInstanceIdentifier ^
  --new-db-instance-identifier NewDBInstanceIdentifier
```

**RDS API**

To rename a DB instance, call Amazon RDS API operation `ModifyDBInstance` with the following parameters:

- `DBInstanceIdentifier` — existing name for the instance
- `NewDBInstanceIdentifier` — new name for the instance
Rebooting a DB instance

You might need to reboot your DB instance, usually for maintenance reasons. For example, if you make certain modifications, or if you change the DB parameter group associated with the DB instance, you must reboot the instance for the changes to take effect.

**Note**
If a DB instance isn't using the latest changes to its associated DB parameter group, the AWS Management Console shows the DB parameter group with a status of **pending-reboot**. The **pending-reboot** parameter groups status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance. For more information about parameter groups, see [Working with parameter groups](p. 347).

If the Amazon RDS DB instance is configured for Multi-AZ, you can perform the reboot with a failover. An Amazon RDS event is created when the reboot is completed. If your DB instance is a Multi-AZ deployment, you can force a failover from one Availability Zone (AZ) to another when you reboot. When you force a failover of your DB instance, Amazon RDS automatically switches to a standby replica in another Availability Zone, and updates the DNS record for the DB instance to point to the standby DB instance. As a result, you need to clean up and re-establish any existing connections to your DB instance. Rebooting with failover is beneficial when you want to simulate a failure of a DB instance for testing, or restore operations to the original AZ after a failover occurs. For more information, see [Configuring and managing a Multi-AZ deployment](p. 492).

**Warning**
When you force a failover of your DB instance, the database is abruptly interrupted. The DB instance and its client sessions might not have time to shut down gracefully. To avoid the possibility of data loss, we recommend stopping transactions on your DB instance before rebooting with a failover.

On RDS for Microsoft SQL Server, reboot with failover reboots only the primary DB instance. After the failover, the primary DB instance becomes the new secondary DB instance. Parameters might not be updated for Multi-AZ instances. For reboot without failover, both the primary and secondary DB instances reboot, and parameters are updated after the reboot. If the DB instance is unresponsive, we recommend reboot without failover.

**Note**
When you force a failover from one Availability Zone to another when you reboot, the Availability Zone change might not be reflected in the AWS Management Console, and in calls to the AWS CLI and RDS API, for several minutes.

Rebooting a DB instance restarts the database engine service. Rebooting a DB instance results in a momentary outage, during which the DB instance status is set to **rebooting**. An outage occurs for both a Single-AZ deployment and a Multi-AZ DB instance deployment, even when you reboot with a failover.

You can't reboot your DB instance if it isn't in the available state. Your database can be unavailable for several reasons, such as an in-progress backup, a previously requested modification, or a maintenance-window action.

The time required to reboot your DB instance depends on the crash recovery process, database activity at the time of reboot, and the behavior of your specific DB engine. To improve the reboot time, we recommend that you reduce database activity as much as possible during the reboot process. Reducing database activity reduces rollback activity for in-transit transactions.

For a DB instance with read replicas, you can reboot the source DB instance and its read replicas independently. After a reboot completes, replication resumes automatically.
Console

To reboot a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to reboot.
3. For Actions, choose Reboot.
   The Reboot DB Instance page appears.
4. (Optional) Choose Reboot with failover? to force a failover from one AZ to another.
5. Choose Reboot to reboot your DB instance.
   Alternatively, choose Cancel.

AWS CLI

To reboot a DB instance by using the AWS CLI, call the reboot-db-instance command.

Example Simple reboot

For Linux, macOS, or Unix:

```
aws rds reboot-db-instance --db-instance-identifier mydbinstance
```

For Windows:

```
aws rds reboot-db-instance --db-instance-identifier mydbinstance
```

Example Reboot with failover

To force a failover from one AZ to the other, use the --force-failover parameter.

For Linux, macOS, or Unix:

```
aws rds reboot-db-instance --db-instance-identifier mydbinstance --force-failover
```

For Windows:

```
aws rds reboot-db-instance --db-instance-identifier mydbinstance --force-failover
```

RDS API

To reboot a DB instance by using the Amazon RDS API, call the RebootDBInstance operation.
Working with DB instance read replicas

A read replica is a read-only copy of a DB instance. You can reduce the load on your primary DB instance by routing queries from your applications to the read replica. In this way, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads.

To create a read replica from a source DB instance, Amazon RDS uses the built-in replication features of the DB engine. For information about using read replicas with a specific engine, see the following sections:

- Working with MariaDB read replicas (p. 1334)
- Working with read replicas for Microsoft SQL Server in Amazon RDS (p. 1462)
- Working with MySQL read replicas (p. 1724)
- Working with read replicas for Amazon RDS for Oracle (p. 1989)
- Working with read replicas for Amazon RDS for PostgreSQL (p. 2229)

After you create a read replica from a source DB instance, the source becomes the primary DB instance. When you make updates to the primary DB instance, Amazon RDS copies them asynchronously to the read replica. The following diagram shows a source DB instance replicating to a read replica in a different Availability Zone (AZ). Client have read/write access to the primary DB instance and read-only access to the replica.
Overview of Amazon RDS read replicas

The following sections discuss DB instance read replicas. For information about Multi-AZ DB cluster read replicas, see the section called "Working with Multi-AZ DB cluster read replicas" (p. 554).

Topics
- Use cases for read replicas (p. 440)
- How read replicas work (p. 440)
- Read replicas in a Multi-AZ deployment (p. 440)
Use cases for read replicas

Deploying one or more read replicas for a given source DB instance might make sense in a variety of scenarios, including the following:

- Scaling beyond the compute or I/O capacity of a single DB instance for read-heavy database workloads. You can direct this excess read traffic to one or more read replicas.
- Serving read traffic while the source DB instance is unavailable. In some cases, your source DB instance might not be able to take I/O requests, for example due to I/O suspension for backups or scheduled maintenance. In these cases, you can direct read traffic to your read replicas. For this use case, keep in mind that the data on the read replica might be "stale" because the source DB instance is unavailable.
- Business reporting or data warehousing scenarios where you might want business reporting queries to run against a read replica, rather than your production DB instance.
- Implementing disaster recovery. You can promote a read replica to a standalone instance as a disaster recovery solution if the primary DB instance fails.

How read replicas work

When you create a read replica, you first specify an existing DB instance as the source. Then Amazon RDS takes a snapshot of the source instance and creates a read-only instance from the snapshot. Amazon RDS then uses the asynchronous replication method for the DB engine to update the read replica whenever there is a change to the primary DB instance.

The read replica operates as a DB instance that allows only read-only connections. An exception is the RDS for Oracle DB engine, which supports replica databases in mounted mode. A mounted replica doesn't accept user connections and so can't serve a read-only workload. The primary use for mounted replicas is cross-Region disaster recovery. For more information, see Working with read replicas for Amazon RDS for Oracle (p. 1989).

Applications connect to a read replica just as they do to any DB instance. Amazon RDS replicates all databases from the source DB instance.

Read replicas in a Multi-AZ deployment

You can configure a read replica for a DB instance that also has a standby replica configured for high availability in a Multi-AZ deployment. Replication with the standby replica is synchronous. Unlike a read replica, a standby replica can't serve read traffic.

In the following scenario, clients have read/write access to a primary DB instance in one AZ. The primary instance copies updates asynchronously to a read replica in a second AZ and also copies them synchronously to a standby replica in a third AZ. Clients have read access only to the read replica.
Cross-Region read replicas

In some cases, a read replica resides in a different AWS Region from its primary DB instance. In these cases, Amazon RDS sets up a secure communications channel between the primary DB instance and the read replica. Amazon RDS establishes any AWS security configurations needed to enable the secure channel, such as adding security group entries. For more information about cross-Region read replicas, see Configuring and managing a Multi-AZ deployment (p. 492).

The information in this chapter applies to creating Amazon RDS read replicas either in the same AWS Region as the source DB instance, or in a separate AWS Region. The following information doesn't apply to setting up replication with an instance that is running on an Amazon EC2 instance or that is on-premises.

Differences among read replicas for DB engines

Because Amazon RDS DB engines implement replication differently, there are several significant differences you should know about, as shown in the following table.
<table>
<thead>
<tr>
<th>Feature or behavior</th>
<th>MySQL and MariaDB</th>
<th>Oracle</th>
<th>PostgreSQL</th>
<th>SQL Server</th>
</tr>
</thead>
<tbody>
<tr>
<td>How are transaction logs purged?</td>
<td>RDS for MySQL and RDS for MariaDB keep any binary logs that haven't been applied.</td>
<td>If a primary DB instance has no cross-Region read replicas, Amazon RDS for Oracle keeps a minimum of two hours of transaction logs on the source DB instance. Logs are purged from the source DB instance after two hours or after the archive log retention hours setting has passed, whichever is longer. Logs are purged from the read replica after the archive log retention hours setting has passed only if they have been successfully applied to the database. In some cases, a primary DB instance might have one or more cross-Region read replicas. If so, Amazon RDS for Oracle keeps the transaction logs on the source DB instance until they have been transmitted and applied to all cross-Region read replicas. For information about setting archive log retention hours, see Retaining archived redo logs (p. 1909).</td>
<td>PostgreSQL has the parameter wal_keep_segments that dictates how many write ahead log (WAL) files are kept to provide data to the read replicas. The parameter value specifies the number of logs to keep.</td>
<td>The Virtual Log File (VLF) of the transaction log file on the primary replica can be truncated after it is no longer required for the secondary replicas. The VLF can only be marked as inactive when the log records have been hardened in the replicas. Regardless of how fast the disk subsystems are in the primary replica, the transaction log will keep the VLFs until the slowest replica has hardened it.</td>
</tr>
<tr>
<td>Can a replica be made writable?</td>

<td>General Purpose, Magnetic</td>
</tr>
</tbody>
</table>

**Note**
When you increase the allocated storage of a read replica, it must be by at least 10 percent. If you try to increase the value by less than 10 percent, you get an error.

Restrictions for creating a replica from a replica

Amazon RDS doesn't support circular replication. You can't configure a DB instance to serve as a replication source for an existing DB instance. You can only create a new read replica from an existing DB instance. For example, if `MySourceDBInstance` replicates to `ReadReplica1`, you can't configure `ReadReplica1` to replicate back to `MySourceDBInstance`.

For RDS for MariaDB and RDS for MySQL, and for certain versions of RDS for PostgreSQL, you can create a read replica from an existing read replica. For example, you can create new read replica `ReadReplica2` from existing replica `ReadReplica1`. For RDS for Oracle and RDS for SQL Server, you can't create a read replica from an existing read replica.
Considerations when deleting replicas

If you no longer need read replicas, you can explicitly delete them using the same mechanisms for deleting a DB instance. If you delete a source DB instance without deleting its read replicas in the same AWS Region, each read replica is promoted to a standalone DB instance. For information about deleting a DB instance, see Deleting a DB instance (p. 489). For information about read replica promotion, see Promoting a read replica to be a standalone DB instance (p. 447).

If you have cross-Region read replicas, see Cross-Region replication considerations (p. 456) for information related to deleting the source DB instance for a cross-Region read replica.

Creating a read replica

You can create a read replica from an existing DB instance using the AWS Management Console, AWS CLI, or RDS API. You create a read replica by specifying SourceDBInstanceIdentifier, which is the DB instance identifier of the source DB instance that you want to replicate from.

When you create a read replica, Amazon RDS takes a DB snapshot of your source DB instance and begins replication. As a result, you experience a brief I/O suspension on your source DB instance while the DB snapshot occurs.

Note
The I/O suspension typically lasts about one minute. You can avoid the I/O suspension if the source DB instance is a Multi-AZ deployment, because in that case the snapshot is taken from the secondary DB instance.

An active, long-running transaction can slow the process of creating the read replica. We recommend that you wait for long-running transactions to complete before creating a read replica. If you create multiple read replicas in parallel from the same source DB instance, Amazon RDS takes only one snapshot at the start of the first create action.

When creating a read replica, there are a few things to consider. First, you must enable automatic backups on the source DB instance by setting the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica. To enable automatic backups on an RDS for MySQL read replica, first create the read replica, then modify the read replica to enable automatic backups.

Note
Within an AWS Region, we strongly recommend that you create all read replicas in the same virtual private cloud (VPC) based on Amazon VPC as the source DB instance. If you create a read replica in a different VPC from the source DB instance, classless inter-domain routing (CIDR) ranges can overlap between the replica and the RDS system. CIDR overlap makes the replica unstable, which can negatively impact applications connecting to it. If you receive an error when creating the read replica, choose a different destination DB subnet group. For more information, see Working with a DB instance in a VPC (p. 2705).

There is no direct way to create a read replica in another AWS account using the console or AWS CLI.

Console

To create a read replica from a source DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to use as the source for a read replica.
4. For Actions, choose Create read replica.
5. For DB instance identifier, enter a name for the read replica.
6. Choose your instance configuration. We recommend that you use the same or larger DB instance class and storage type as the source DB instance for the read replica.

7. For AWS Region, specify the destination Region for the read replica.

8. For Storage, specify the allocated storage size and whether you want to use storage autoscaling.

9. For Availability, choose whether to create a standby of your replica in another Availability Zone for failover support for the replica.

   **Note**
   Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

10. Specify other DB instance settings. For information about each available setting, see [Settings for DB instances](p. 308).

11. To create an encrypted read replica, expand **Additional configuration** and specify the following settings:
   a. Choose **Enable encryption**.
   b. For **AWS KMS key**, choose the AWS KMS key identifier of the KMS key.

   **Note**
   The source DB instance must be encrypted. To learn more about encrypting the source DB instance, see [Encrypting Amazon RDS resources](p. 2603).

12. Choose **Create read replica**.

After the read replica is created, you can see it on the **Databases** page in the RDS console. It shows **Replica** in the **Role** column.

**AWS CLI**

To create a read replica from a source DB instance, use the AWS CLI command `create-db-instance-read-replica`. This example also sets the allocated storage size and enables storage autoscaling.

You can specify other settings. For information about each setting, see [Settings for DB instances](p. 308).

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance-read-replica \
    --db-instance-identifier myreadreplica \
    --source-db-instance-identifier mydbinstance \
    --allocated-storage 100 \
    --max-allocated-storage 1000
```

For Windows:

```bash
aws rds create-db-instance-read-replica ^
    --db-instance-identifier myreadreplica ^
    --source-db-instance-identifier mydbinstance ^
    --allocated-storage 100 ^
    --max-allocated-storage 1000
```

**RDS API**

To create a read replica from a source MySQL, MariaDB, Oracle, PostgreSQL, or SQL Server DB instance, call the Amazon RDS API `CreateDBInstanceReadReplica` operation with the following required parameters:
There are several reasons you might want to promote a read replica to a standalone DB instance:
• **Performing DDL operations (MySQL and MariaDB only)** – DDL operations, such as creating or rebuilding indexes, can take time and impose a significant performance penalty on your DB instance. You can perform these operations on a MySQL or MariaDB read replica once the read replica is in sync with its primary DB instance. Then you can promote the read replica and direct your applications to use the promoted instance.

• **Sharding** – Sharding embodies the “share-nothing” architecture and essentially involves breaking a large database into several smaller databases. One common way to split a database is splitting tables that are not joined in the same query onto different hosts. Another method is duplicating a table across multiple hosts and then using a hashing algorithm to determine which host receives a given update. You can create read replicas corresponding to each of your shards (smaller databases) and promote them when you decide to convert them into standalone shards. You can then carve out the key space (if you are splitting rows) or distribution of tables for each of the shards depending on your requirements.

• **Implementing failure recovery** – You can use read replica promotion as a data recovery scheme if the primary DB instance fails. This approach complements synchronous replication, automatic failure detection, and failover.

If you are aware of the ramifications and limitations of asynchronous replication and you still want to use read replica promotion for data recovery, you can. To do this, first create a read replica and then monitor the primary DB instance for failures. In the event of a failure, do the following:

1. Promote the read replica.
2. Direct database traffic to the promoted DB instance.
3. Create a replacement read replica with the promoted DB instance as its source.

When you promote a read replica, the new DB instance that is created retains the option group and the parameter group of the former read replica. The promotion process can take several minutes or longer to complete, depending on the size of the read replica. After you promote the read replica to a new DB instance, it's just like any other DB instance. For example, you can create read replicas from the new DB instance and perform point-in-time restore operations. Because the promoted DB instance is no longer a read replica, you can't use it as a replication target. If a source DB instance has several read replicas, promoting one of the read replicas to a DB instance has no effect on the other replicas.

Backup duration is a function of the number of changes to the database since the previous backup. If you plan to promote a read replica to a standalone instance, we recommend that you enable backups and complete at least one backup prior to promotion. In addition, you can't promote a read replica to a standalone instance when it has the backing-up status. If you have enabled backups on your read replica, configure the automated backup window so that daily backups don't interfere with read replica promotion.

The following steps show the general process for promoting a read replica to a DB instance:

1. Stop any transactions from being written to the primary DB instance, and then wait for all updates to be made to the read replica. Database updates occur on the read replica after they have occurred on the primary DB instance, and this replication lag can vary significantly. Use the **Replica Lag** metric to determine when all updates have been made to the read replica.

2. For MySQL and MariaDB only: If you need to make changes to the MySQL or MariaDB read replica, you must set the `read_only` parameter to 0 in the DB parameter group for the read replica. You can then perform all needed DDL operations, such as creating indexes, on the read replica. Actions taken on the read replica don't affect the performance of the primary DB instance.

3. Promote the read replica by using the **Promote** option on the Amazon RDS console, the AWS CLI command `promote-read-replica`, or the `PromoteReadReplica` Amazon RDS API operation.

   **Note**
   The promotion process takes a few minutes to complete. When you promote a read replica, replication is stopped and the read replica is rebooted. When the reboot is complete, the read replica is available as a new DB instance.
4. (Optional) Modify the new DB instance to be a Multi-AZ deployment. For more information, see Modifying an Amazon RDS DB instance (p. 401) and Configuring and managing a Multi-AZ deployment (p. 492).

Console

To promote a read replica to a standalone DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose Databases.
   - The Databases pane appears. Each read replica shows Replica in the Role column.
3. Choose the read replica that you want to promote.
4. For Actions, choose Promote.
5. On the Promote Read Replica page, enter the backup retention period and the backup window for the newly promoted DB instance.
6. When the settings are as you want them, choose Continue.
7. On the acknowledgment page, choose Promote Read Replica.

AWS CLI

To promote a read replica to a standalone DB instance, use the AWS CLI promote-read-replica command.

Example

For Linux, macOS, or Unix:

```bash
aws rds promote-read-replica \
   --db-instance-identifier myreadreplica
```

For Windows:

```bash
aws rds promote-read-replica ^
   --db-instance-identifier myreadreplica
```

RDS API

To promote a read replica to a standalone DB instance, call the Amazon RDS API PromoteReadReplica operation with the required parameter DBInstanceIdentifier.

Monitoring read replication

You can monitor the status of a read replica in several ways. The Amazon RDS console shows the status of a read replica in the Replication section of the Connectivity & security tab in the read replica details. To view the details for a read replica, choose the name of the read replica in the list of DB instances in the Amazon RDS console.
You can also see the status of a read replica using the AWS CLI `describe-db-instances` command or the Amazon RDS API `DescribeDBInstances` operation.

The status of a read replica can be one of the following:

- **replicating** – The read replica is replicating successfully.
- **replication degraded (SQL Server only)** – Replicas are receiving data from the primary instance, but one or more databases might not be getting updates. This can occur, for example, when a replica is in the process of setting up newly created databases. The status doesn't transition from replication degraded to error, unless an error occurs during the degraded state.
- **error** – An error has occurred with the replication. Check the Replication Error field in the Amazon RDS console or the event log to determine the exact error. For more information about troubleshooting a replication error, see Troubleshooting a MySQL read replica problem (p. 1734).
- **terminated (MariaDB, MySQL, or PostgreSQL only)** – Replication is terminated. This occurs if replication is stopped for more than 30 consecutive days, either manually or due to a replication error. In this case, Amazon RDS terminates replication between the primary DB instance and all read replicas. Amazon RDS does this to prevent increased storage requirements on the source DB instance and long failover times.

Broken replication can affect storage because the logs can grow in size and number due to the high volume of errors messages being written to the log. Broken replication can also affect failure recovery due to the time Amazon RDS requires to maintain and process the large number of logs during recovery.

- **terminated (Oracle only)** – Replication is terminated. This occurs if replication is stopped for more than 8 hours because there isn't enough storage remaining on the read replica. In this case, Amazon RDS terminates replication between the primary DB instance and the affected read replica. This status is a terminal state, and the read replica must be re-created.
- **stopped (MariaDB or MySQL only)** – Replication has stopped because of a customer-initiated request.
- **replication stop point set (MySQL only)** – A customer-initiated stop point was set using the `mysql.rds_start_replication_until` stored procedure and the replication is in progress.
- **replication stop point reached (MySQL only)** – A customer-initiated stop point was set using the `mysql.rds_start_replication_until` stored procedure and replication is stopped because the stop point was reached.
You can see where a DB instance is being replicated and if so, check its replication status. On the Databases page in the RDS console, it shows Primary in the Role column. Choose its DB instance name. On its detail page, on the Connectivity & security tab, its replication status is under Replication.

## Monitoring replication lag

You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric.

For MariaDB and MySQL, the ReplicaLag metric reports the value of the Seconds_Behind_Master field of the SHOW REPLICA STATUS command. Common causes for replication lag for MySQL and MariaDB are the following:

- A network outage.
- Writing to tables with indexes on a read replica. If the read_only parameter is not set to 0 on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MySQL and the XtraDB storage engine on MariaDB.

### Note

Previous versions of MariaDB and MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MariaDB version before 10.5 or a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

When the ReplicaLag metric reaches 0, the replica has caught up to the primary DB instance. If the ReplicaLag metric returns -1, then replication is currently not active. ReplicaLag = -1 is equivalent to Seconds_Behind_Master = NULL.

For Oracle, the ReplicaLag metric is the sum of the Apply Lag value and the difference between the current time and the apply lag's DATUM_TIME value. The DATUM_TIME value is the last time the read replica received data from its source DB instance. For more information, see V$DATAGUARD_STATS in the Oracle documentation.

For SQL Server, the ReplicaLag metric is the maximum lag of databases that have fallen behind, in seconds. For example, if you have two databases that lag 5 seconds and 10 seconds, respectively, then ReplicaLag is 10 seconds. The ReplicaLag metric returns the value of the following query.

```
SELECT MAX(secondary_lag_seconds) max_lag FROM sys.dm_hadr_database_replica_states;
```

For more information, see secondary_lag_seconds in the Microsoft documentation.

ReplicaLag returns -1 if RDS can't determine the lag, such as during replica setup, or when the read replica is in the error state.

### Note

New databases aren't included in the lag calculation until they are accessible on the read replica.

For PostgreSQL, the ReplicaLag metric returns the value of the following query.

```
SELECT extract(epoch from now() - pg_last_xact_replay_timestamp()) AS reader_lag
```

PostgreSQL versions 9.5.2 and later use physical replication slots to manage write ahead log (WAL) retention on the source instance. For each cross-Region read replica instance, Amazon RDS creates a physical replication slot and associates it with the instance. Two Amazon CloudWatch metrics, Oldest
Replication Slot Lag and Transaction Logs Disk Usage, show how far behind the most lagging replica is in terms of WAL data received and how much storage is being used for WAL data. The Transaction Logs Disk Usage value can substantially increase when a cross-Region read replica is lagging significantly.

For more information about monitoring a DB instance with CloudWatch, see Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 706).

Creating a read replica in a different AWS Region

With Amazon RDS, you can create a read replica in a different AWS Region from the source DB instance.

You create a read replica in a different AWS Region to do the following:

- Improve your disaster recovery capabilities.
- Scale read operations into an AWS Region closer to your users.
- Make it easier to migrate from a data center in one AWS Region to a data center in another AWS Region.

Creating a read replica in a different AWS Region from the source instance is similar to creating a replica in the same AWS Region. You can use the AWS Management Console, run the `create-db-instance-read-replica` command, or call the `CreateDBInstanceReadReplica` API operation.

**Note**

To create an encrypted read replica in a different AWS Region from the source DB instance, the source DB instance must be encrypted.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with cross-Region replication, see Cross-Region read replicas (p. 119).
Creating a cross-Region read replica

The following procedures show how to create a read replica from a source MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL DB instance in a different AWS Region.

Console

You can create a read replica across AWS Regions using the AWS Management Console.

To create a read replica across AWS Regions with the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL DB instance that you want to use as the source for a read replica.
4. For Actions, choose Create read replica.
5. For DB instance identifier, enter a name for the read replica.
6. Choose the Destination Region.
7. Choose the instance specifications that you want to use. We recommend that you use the same or larger DB instance class and storage type for the read replica.
8. To create an encrypted read replica in another AWS Region:
   a. Choose Enable encryption.
   b. For AWS KMS key, choose the AWS KMS key identifier of the KMS key in the destination AWS Region.

   Note
   To create an encrypted read replica, the source DB instance must be encrypted. To learn more about encrypting the source DB instance, see Encrypting Amazon RDS resources (p. 2603).
9. Choose other options, such as storage autoscaling.
10. Choose Create read replica.

AWS CLI

To create a read replica from a source MySQL, Microsoft SQL Server, MariaDB, Oracle, or PostgreSQL DB instance in a different AWS Region, you can use the create-db-instance-read-replica command. In this case, you use create-db-instance-read-replica from the AWS Region where you want the read replica (destination Region) and specify the Amazon Resource Name (ARN) for the source DB instance. An ARN uniquely identifies a resource created in Amazon Web Services.

For example, if your source DB instance is in the US East (N. Virginia) Region, the ARN looks similar to this example:

```
arn:aws:rds:us-east-1:123456789012:db:mydbinstance
```

For information about ARNs, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 471).

To create a read replica in a different AWS Region from the source DB instance, you can use the AWS CLI create-db-instance-read-replica command from the destination AWS Region. The following parameters are required for creating a read replica in another AWS Region:
Cross-Region read replicas

- `--region` – The destination AWS Region where the read replica is created.
- `--source-db-instance-identifier` – The DB instance identifier for the source DB instance. This identifier must be in the ARN format for the source AWS Region.
- `--db-instance-identifier` – The identifier for the read replica in the destination AWS Region.

**Example of a cross-Region read replica**

The following code creates a read replica in the US West (Oregon) Region from a source DB instance in the US East (N. Virginia) Region.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance-read-replica \
  --db-instance-identifier myreadreplica \
  --region us-west-2 \
```

For Windows:

```bash
aws rds create-db-instance-read-replica ^
  --db-instance-identifier myreadreplica ^
  --region us-west-2 ^
```

The following parameter is also required for creating an encrypted read replica in another AWS Region:
- `--kms-key-id` – The AWS KMS key identifier of the KMS key to use to encrypt the read replica in the destination AWS Region.

**Example of an encrypted cross-Region read replica**

The following code creates an encrypted read replica in the US West (Oregon) Region from a source DB instance in the US East (N. Virginia) Region.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance-read-replica \
  --db-instance-identifier myreadreplica \
  --region us-west-2 \
  --source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance \
  --kms-key-id my-us-west-2-key
```

For Windows:

```bash
aws rds create-db-instance-read-replica ^
  --db-instance-identifier myreadreplica ^
  --region us-west-2 ^
  --kms-key-id my-us-west-2-key
```

The `--source-region` option is required when you're creating an encrypted read replica between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions. For `--source-region`, specify the AWS Region of the source DB instance.
Amazon Relational Database Service User Guide
Cross-Region read replicas

If --source-region isn't speciﬁed, specify a --pre-signed-url value. A presigned URL is a URL that
contains a Signature Version 4 signed request for the create-db-instance-read-replica command
that's called in the source AWS Region. To learn more about the pre-signed-url option, see createdb-instance-read-replica in the AWS CLI Command Reference.

RDS API
To create a read replica from a source MySQL, Microsoft SQL Server, MariaDB, Oracle, or
PostgreSQL DB instance in a diﬀerent AWS Region, you can call the Amazon RDS API operation
CreateDBInstanceReadReplica. In this case, you call CreateDBInstanceReadReplica from the AWS Region
where you want the read replica (destination Region) and specify the Amazon Resource Name (ARN) for
the source DB instance. An ARN uniquely identiﬁes a resource created in Amazon Web Services.
To create an encrypted read replica in a diﬀerent AWS Region from the source DB instance, you can use
the Amazon RDS API CreateDBInstanceReadReplica operation from the destination AWS Region. To
create an encrypted read replica in another AWS Region, you must specify a value for PreSignedURL.
PreSignedURL should contain a request for the CreateDBInstanceReadReplica operation to call
in the source AWS Region where the read replica is created in. To learn more about PreSignedUrl, see
CreateDBInstanceReadReplica.
For example, if your source DB instance is in the US East (N. Virginia) Region, the ARN looks similar to the
following.
arn:aws:rds:us-east-1:123456789012:db:mydbinstance

For information about ARNs, see Working with Amazon Resource Names (ARNs) in Amazon
RDS (p. 471).

How Amazon RDS does cross-Region replication

Amazon RDS uses the following process to create a cross-Region read replica. Depending on the AWS Regions involved and the amount of data in the databases, this process can take hours to complete. You can use this information to determine how far the process has proceeded when you create a cross-Region read replica:

1. Amazon RDS begins configuring the source DB instance as a replication source and sets the status to *modifying*.
2. Amazon RDS begins setting up the specified read replica in the destination AWS Region and sets the status to *creating*.
3. Amazon RDS creates an automated DB snapshot of the source DB instance in the source AWS Region. The format of the DB snapshot name is `rds:<InstanceID>-<timestamp>`, where `<InstanceID>` is the identifier of the source instance, and `<timestamp>` is the date and time the copy started. For example, `rds:mysourceinstance-2013-11-14-09-24` was created from the instance `mysourceinstance` at `2013-11-14-09-24`. During the creation of an automated DB snapshot, the source DB instance status remains *modifying*, the read replica status remains *creating*, and the DB snapshot status is *creating*. The progress column of the DB snapshot page in the console reports how far the DB snapshot creation has progressed. When the DB snapshot is complete, the status of both the DB snapshot and source DB instance are set to *available*.
4. Amazon RDS begins a cross-Region snapshot copy for the initial data transfer. The snapshot copy is listed as an automated snapshot in the destination AWS Region with a status of *creating*. It has the same name as the source DB snapshot. The progress column of the DB snapshot display indicates how far the copy has progressed. When the copy is complete, the status of the DB snapshot copy is set to *available*.
5. Amazon RDS then uses the copied DB snapshot for the initial data load on the read replica. During this phase, the read replica is in the list of DB instances in the destination, with a status of *creating*. When the load is complete, the read replica status is set to *available*, and the DB snapshot copy is deleted.
6. When the read replica reaches the available status, Amazon RDS starts by replicating the changes made to the source instance since the start of the create read replica operation. During this phase, the replication lag time for the read replica is greater than 0.

For information about replication lag time, see Monitoring read replication (p. 449).

Cross-Region replication considerations

All of the considerations for performing replication within an AWS Region apply to cross-Region replication. The following extra considerations apply when replicating between AWS Regions:

- A source DB instance can have cross-Region read replicas in multiple AWS Regions.
- You can replicate between the GovCloud (US-East) and GovCloud (US-West) Regions, but not into or out of GovCloud (US).
- For Microsoft SQL Server, Oracle, and PostgreSQL DB instances, you can only create a cross-Region Amazon RDS read replica from a source Amazon RDS DB instance that is not a read replica of another Amazon RDS DB instance. This limitation doesn't apply to MariaDB and MySQL DB instances.
- You can expect to see a higher level of lag time for any read replica that is in a different AWS Region than the source instance. This lag time comes from the longer network channels between regional data centers.
- For cross-Region read replicas, any of the create read replica commands that specify the `--db-subnet-group-name` parameter must specify a DB subnet group from the same VPC.
- Because of the limit on the number of access control list (ACL) entries for the source VPC, we can't guarantee more than five cross-Region read replica instances.
• In most cases, the read replica uses the default DB parameter group and DB option group for the specified DB engine.

For the MySQL and Oracle DB engines, you can specify a custom parameter group for the read replica in the `--db-parameter-group-name` option of the AWS CLI command `create-db-instance-read-replica`. You can’t specify a custom parameter group when you use the AWS Management Console.

• The read replica uses the default security group.

• For MariaDB, Microsoft SQL Server, MySQL, and Oracle DB instances, when the source DB instance for a cross-Region read replica is deleted, the read replica is promoted.

• For PostgreSQL DB instances, when the source DB instance for a cross-Region read replica is deleted, the replication status of the read replica is set to `terminated`. The read replica isn’t promoted.

You have to promote the read replica manually or delete it.

Requesting a cross-Region read replica

To communicate with the source Region to request the creation of a cross-Region read replica, the requester (IAM role or IAM user) must have access to the source DB instance and the source Region.

Certain conditions in the requester’s IAM policy can cause the request to fail. The following examples assume that the source DB instance is in US East (Ohio) and the read replica is created in US East (N. Virginia). These examples show conditions in the requester’s IAM policy that cause the request to fail:

• The requester’s policy has a condition for `aws:RequestedRegion`.

```json
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "**",
"Condition": {
  "StringEquals": {
    "aws:RequestedRegion": "us-east-1"
  }
}

The request fails because the policy doesn’t allow access to the source Region. For a successful request, specify both the source and destination Regions.

```json
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "**",
"Condition": {
  "StringEquals": {
    "aws:RequestedRegion": [
      "us-east-1",
      "us-east-2"
    ]
  }
}

• The requester’s policy doesn’t allow access to the source DB instance.

```json
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
```
For a successful request, specify both the source instance and the replica.

```
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": [
]
```

- The requester's policy denies `aws:ViaAWSService`.

```
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
  "Bool": {"aws:ViaAWSService": "false"}
}
```

Communication with the source Region is made by RDS on the requester's behalf. For a successful request, don't deny calls made by AWS services.

- The requester's policy has a condition for `aws:SourceVpc` or `aws:SourceVpce`.

These requests might fail because when RDS makes the call to the remote Region, it isn't from the specified VPC or VPC endpoint.

If you need to use one of the previous conditions that would cause a request to fail, you can include a second statement with `aws:CalledVia` in your policy to make the request succeed. For example, you can use `aws:CalledVia` with `aws:SourceVpce` as shown here:

```
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
  "Condition": {
    "ForAnyValue:StringEquals": {"aws:SourceVpce": "vpce-1a2b3c4d"}
  }
},

"Effect": "Allow",
"Action": [
  "rds:CreateDBInstanceReadReplica"
],
"Resource": "*",
"Condition": {
  "ForAnyValue:StringEquals": {"aws:CalledVia": ["rds.amazonaws.com"]}
}
```
For more information, see Policies and permissions in IAM in the IAM User Guide.

Authorizing the read replica

After a cross-Region DB read replica creation request returns success, RDS starts the replica creation in the background. An authorization for RDS to access the source DB instance is created. This authorization links the source DB instance to the read replica, and allows RDS to copy only to the specified read replica.

The authorization is verified by RDS using the rds:CrossRegionCommunication permission in the service-linked IAM role. If the replica is authorized, RDS communicates with the source Region and completes the replica creation.

RDS doesn't have access to DB instances that weren't authorized previously by a CreateDBInstanceReadReplica request. The authorization is revoked when read replica creation completes.

RDS uses the service-linked role to verify the authorization in the source Region. If you delete the service-linked role during the replication creation process, the creation fails.

For more information, see Using service-linked roles in the IAM User Guide.

Using AWS Security Token Service credentials

Session tokens from the global AWS Security Token Service (AWS STS) endpoint are valid only in AWS Regions that are enabled by default (commercial Regions). If you use credentials from the assumeRole API operation in AWS STS, use the regional endpoint if the source Region is an opt-in Region. Otherwise, the request fails. This happens because your credentials must be valid in both Regions, which is true for opt-in Regions only when the regional AWS STS endpoint is used.

To use the global endpoint, make sure that it's enabled for both Regions in the operations. Set the global endpoint to Valid in all AWS Regions in the AWS STS account settings.

The same rule applies to credentials in the presigned URL parameter.

For more information, see Managing AWS STS in an AWS Region in the IAM User Guide.

Cross-Region replication costs

The data transferred for cross-Region replication incurs Amazon RDS data transfer charges. These cross-Region replication actions generate charges for the data transferred out of the source AWS Region:

- When you create a read replica, Amazon RDS takes a snapshot of the source instance and transfers the snapshot to the read replica AWS Region.
- For each data modification made in the source databases, Amazon RDS transfers data from the source AWS Region to the read replica AWS Region.

For more information about data transfer pricing, see Amazon RDS pricing.

For MySQL and MariaDB instances, you can reduce your data transfer costs by reducing the number of cross-Region read replicas that you create. For example, suppose that you have a source DB instance in one AWS Region and want to have three read replicas in another AWS Region. In this case, you create only one of the read replicas from the source DB instance. You create the other two replicas from the first read replica instead of the source DB instance.

For example, if you have source-instance-1 in one AWS Region, you can do the following:

- Create read-replica-1 in the new AWS Region, specifying source-instance-1 as the source.
- Create read-replica-2 from read-replica-1.
• Create read-replica-3 from read-replica-1.

In this example, you are only charged for the data transferred from source-instance-1 to read-replica-1. You aren’t charged for the data transferred from read-replica-1 to the other two replicas because they are all in the same AWS Region. If you create all three replicas directly from source-instance-1, you are charged for the data transfers to all three replicas.
Tagging Amazon RDS resources

You can use Amazon RDS tags to add metadata to your Amazon RDS resources. You can use the tags to add your own notations about database instances, snapshots, Aurora clusters, and so on. Doing so can help you to document your Amazon RDS resources. You can also use the tags with automated maintenance procedures.

In particular, you can use these tags with IAM policies. You can use them to manage access to RDS resources and to control what actions can be applied to the RDS resources. You can also use these tags to track costs by grouping expenses for similarly tagged resources.

You can tag the following Amazon RDS resources:

- DB instances
- DB clusters
- Read replicas
- DB snapshots
- DB cluster snapshots
- Reserved DB instances
- Event subscriptions
- DB option groups
- DB parameter groups
- DB cluster parameter groups
- DB subnet groups
- RDS Proxies
- RDS Proxy endpoints
- Blue/green deployments
- Zero-ETL integrations (preview)

**Note**
Currently, you can't tag RDS Proxies and RDS Proxy endpoints by using the AWS Management Console.

**Overview of Amazon RDS resource tags**

An Amazon RDS tag is a name-value pair that you define and associate with an Amazon RDS resource. The name is referred to as the key. Supplying a value for the key is optional. You can use tags to assign
You can use tags with IAM policies to manage access to Amazon RDS resources. You can also use tags to control what actions can be applied to the Amazon RDS resources.

For information on managing access to tagged resources with IAM policies, see Identity and access management for Amazon RDS (p. 2623).

### Using tags to produce detailed billing reports

You can also use tags to track costs by grouping expenses for similarly tagged resources.

Use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. Then, to see the cost of combined resources, organize your
billing information according to resources with the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see Using Cost Allocation Tags in the AWS Billing User Guide.

**Note**
You can add a tag to a snapshot, however, your bill will not reflect this grouping.

### Adding, listing, and removing tags

The following procedures show how to perform typical tagging operations on resources related to DB instances.

#### Console

The process to tag an Amazon RDS resource is similar for all resources. The following procedure shows how to tag an Amazon RDS DB instance.

**To add a tag to a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases.
   
   **Note**
   To filter the list of DB instances in the Databases pane, enter a text string for Filter databases. Only DB instances that contain the string appear.
3. Choose the name of the DB instance that you want to tag to show its details.
4. In the details section, scroll down to the Tags section.
5. Choose Add. The Add tags window appears.

![Add tags window](https://i.imgur.com/3Q5Q5Q5.png)

6. Enter a value for Tag key and Value.
7. To add another tag, you can choose Add another Tag and enter a value for its Tag key and Value.
   
   Repeat this step as many times as necessary.
8. Choose Add.
To delete a tag from a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.

   Note
   To filter the list of DB instances in the Databases pane, enter a text string in the Filter databases box. Only DB instances that contain the string appear.

3. Choose the name of the DB instance to show its details.
4. In the details section, scroll down to the Tags section.
5. Choose the tag you want to delete.

6. Choose Delete, and then choose Delete in the Delete tags window.

AWS CLI

You can add, list, or remove tags for a DB instance using the AWS CLI.

- To add one or more tags to an Amazon RDS resource, use the AWS CLI command `add-tags-to-resource`.
- To list the tags on an Amazon RDS resource, use the AWS CLI command `list-tags-for-resource`.
- To remove one or more tags from an Amazon RDS resource, use the AWS CLI command `remove-tags-from-resource`.

To learn more about how to construct the required ARN, see Constructing an ARN for Amazon RDS (p. 471).

RDS API

You can add, list, or remove tags for a DB instance using the Amazon RDS API.

- To add a tag to an Amazon RDS resource, use the `AddTagsToResource` operation.
- To list tags that are assigned to an Amazon RDS resource, use the `ListTagsForResource`.
- To remove tags from an Amazon RDS resource, use the `RemoveTagsFromResource` operation.

To learn more about how to construct the required ARN, see Constructing an ARN for Amazon RDS (p. 471).

When working with XML using the Amazon RDS API, tags use the following schema:

```xml
<Tagging>
  <TagSet>
    <!-- Tag entries here -->
  </TagSet>
</Tagging>
```
Amazon Relational Database Service User Guide
Using the AWS Tag Editor

The following table provides a list of the allowed XML tags and their characteristics. Values for Key and Value are case-dependent. For example, project=Trinity and PROJECT=Trinity are two distinct tags.

<table>
<thead>
<tr>
<th>Tagging element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TagSet</td>
<td>A tag set is a container for all tags assigned to an Amazon RDS resource. There can be only one tag set per resource. You work with a TagSet only through the Amazon RDS API.</td>
</tr>
<tr>
<td>Tag</td>
<td>A tag is a user-defined key-value pair. There can be from 1 to 50 tags in a tag set.</td>
</tr>
<tr>
<td>Key</td>
<td>A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with aws: or rds:. The string can only contain only the set of Unicode letters, digits, white space, ‘\’, ‘\’=’, ‘\’+, ‘\’-’ (Java regex: “^[\p{L}\p{Z}\p{N}_.:/=+-]+$”). Keys must be unique to a tag set. For example, you cannot have a key-pair in a tag set with the key the same but with different values, such as project/Trinity and project/Xanadu.</td>
</tr>
<tr>
<td>Value</td>
<td>A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with aws: or rds:. The string can only contain only the set of Unicode letters, digits, white space, ‘\’, ‘\’=’, ‘\’+, ‘\’-’ (Java regex: “^[\p{L}\p{Z}\p{N}_.:/=+-]+$”). Values do not have to be unique in a tag set and can be null. For example, you can have a key-value pair in a tag set of project/Trinity and cost-center/Trinity.</td>
</tr>
</tbody>
</table>

Using the AWS Tag Editor

You can browse and edit the tags on your RDS resources in the AWS Management Console by using the AWS Tag editor. For more information, see Tag Editor in the AWS Resource Groups User Guide.

Copying tags to DB instance snapshots

When you create or restore a DB instance, you can specify that the tags from the DB instance are copied to snapshots of the DB instance. Copying tags ensures that the metadata for the DB snapshots matches that of the source DB instance. It also ensures that any access policies for the DB snapshots also match those of the source DB instance.

You can specify that tags are copied to DB snapshots for the following actions:
- Creating a DB instance.
• Restoring a DB instance.
• Creating a read replica.
• Copying a DB snapshot.

In most cases, tags aren't copied by default. However, when you restore a DB instance from a DB
snapshot, RDS checks whether you specify new tags. If yes, the new tags are added to the restored DB
instance. If there are no new tags, RDS adds the tags from the source DB instance at the time of snapshot
creation to the restored DB instance.

To prevent tags from source DB instances from being added to restored DB instances, we recommend
that you specify new tags when restoring a DB instance.

**Note**
In some cases, you might include a value for the `--tag-key` parameter of the `create-db-
snapshot` AWS CLI command. Or you might supply at least one tag to the `CreateDBSnapshot`
API operation. In these cases, RDS doesn't copy tags from the source DB instance to the new DB
snapshot. This functionality applies even if the source DB instance has the `--copy-tags-to-
snapshot` (CopyTagsToSnapshot) option turned on.

If you take this approach, you can create a copy of a DB instance from a DB snapshot. This
approach avoids adding tags that don't apply to the new DB instance. You create your DB
snapshot using the AWS CLI `create-db-snapshot` command (or the `CreateDBSnapshot`
RDS API operation). After you create your DB snapshot, you can add tags as described later in
this topic.

**Tutorial: Use tags to specify which DB instances to stop**

Suppose that you're creating a number of DB instances in a development or test environment. You
need to keep all of these DB instances for several days. Some of the DB instances run tests overnight.
Other DB instances can be stopped overnight and started again the next day. The following example
shows how to assign a tag to those DB instances that are suitable to stop overnight. Then the example
shows how a script can detect which DB instances have that tag and then stop those DB instances. In this
example, the value portion of the key-value pair doesn't matter. The presence of the `stoppable` tag
signifies that the DB instance has this user-defined property.

**To specify which DB instances to stop**

1. Determine the ARN of a DB instance that you want to designate as stoppable.

   The commands and APIs for tagging work with ARNs. That way, they can work seamlessly across
   AWS Regions, AWS accounts, and different types of resources that might have identical short
   names. You can specify the ARN instead of the DB instance ID in CLI commands that operate on
   DB instances. Substitute the name of your own DB instances for `dev-test-db-instance`. In
   subsequent commands that use ARN parameters, substitute the ARN of your own DB instance. The
   ARN includes your own AWS account ID and the name of the AWS Region where your DB instance is
   located.

   ```
   $ aws rds describe-db-instances --db-instance-identifier dev-test-db-instance
   --query '[]
   [].{DBInstance:DBInstanceArn}' --output text
   arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance
   ```

2. Add the tag `stoppable` to this DB instance.

   You choose the name for this tag. This approach means that you can avoid devising a naming
   convention that encodes all relevant information in names. In such a convention, you might encode
   information in the DB instance name or names of other resources. Because this example treats
the tag as an attribute that is either present or absent, it omits the Value part of the --tags parameter.

```bash
$ aws rds add-tags-to-resource --resource-name arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance --tags Key=stoppable
```

3. Confirm that the tag is present in the DB instance.

These commands retrieve the tag information for the DB instance in JSON format and in plain tab-separated text.

```bash
$ aws rds list-tags-for-resource --resource-name arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance
{
"TagList": [

  {
    "Key": "stoppable",
    "Value": ""
  }
]
}
```

```bash
aws rds list-tags-for-resource --resource-name arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance --output text
TAGLIST stoppable
```

4. To stop all the DB instances that are designated as stoppable, prepare a list of all your DB instances. Loop through the list and check if each DB instance is tagged with the relevant attribute.

This Linux example uses shell scripting. This scripting saves the list of DB instance ARNs to a temporary file and then performs CLI commands for each DB instance.

```bash
$ aws rds describe-db-instances --query "*[].[DBInstanceArn]" --output text > /tmp/db_instance_arns.lst
$ for arn in $(cat /tmp/db_instance_arns.lst)
do
  match="$(aws rds list-tags-for-resource --resource-name $arn --output text | grep stoppable)"
  if [[ ! -z "$match" ]]
    then
      echo "DB instance $arn is tagged as stoppable. Stopping it now."
      # Note that you need to get the DB instance identifier from the ARN.
      dbid=$(echo $arn | sed -e 's/.*://')
      aws rds stop-db-instance --db-instance-identifier $dbid
  fi
done
```

You can run a script like this at the end of each day to make sure that nonessential DB instances are stopped. You might also schedule a job using a utility such as `cron` to perform such a check each night. For example, you might do this in case some DB instances were left running by mistake. Here, you might fine-tune the command that prepares the list of DB instances to check.
The following command produces a list of your DB instances, but only the ones in available state. The script can ignore DB instances that are already stopped, because they will have different status values such as stopped or stopping.

```
$ aws rds describe-db-instances
   --query '.*{DBInstanceArn:DBInstanceArn, DBInstanceStatus:DBInstanceStatus}[? DBInstanceStatus == `available`].{DBInstanceArn:DBInstanceArn}'
   --output text

arn:aws:rds:us-east-1:123456789102:db:db-instance-2447
arn:aws:rds:us-east-1:123456789102:db:db-instance-3395
arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance
arn:aws:rds:us-east-1:123456789102:db:pg2-db-instance
```

Tip
You can use assigning tags and finding DB instances with those tags to reduce costs in other ways. For example, take this scenario with DB instances used for development and testing. In this case, you might designate some DB instances to be deleted at the end of each day. Or you might designate them to have their DB instances changed to small DB instance classes during times of expected low usage.

Using tags to enable backups in AWS Backup

AWS Backup is a fully managed backup service that makes it easy to centralize and automate the backup of data across AWS services in the cloud and on premises. You can manage backups of your Amazon RDS DB instances in AWS Backup.

To enable backups in AWS Backup, you use resource tagging to associate your DB instance with a backup plan.

This example assumes that you have already created a backup plan in AWS Backup. You use exactly the same tag for your DB instance that is in your backup plan, as shown in the following figure.

For more information about AWS Backup, see the AWS Backup Developer Guide.

You can assign a tag to a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. The following examples are for the console and CLI.

Console

To assign a tag to a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the link for the DB instance to which you want to assign a tag.
4. On the database details page, choose the Tags tab.
5. Under Tags, choose Add tags.
6. Under Add tags:
a. For **Tag key**, enter **BackupPlan**.
b. For **Value**, enter **Test**.
c. Choose **Add**.

The result is shown under **Tags**.

**CLI**

**To assign a tag to a DB instance**

- Use the following CLI command:

  For Linux, macOS, or Unix:

  ```bash
  aws rds add-tags-to-resource
  --tags Key=BackupPlan,Value=Test
  ```

  For Windows:

  ```bash
  aws rds add-tags-to-resource
  --tags Key=BackupPlan,Value=Test
  ```

  The `add-tags-to-resource` CLI command returns no output.

**To confirm that the DB instance is tagged**

- Use the following CLI command:

  For Linux, macOS, or Unix:

  ```bash
  aws rds list-tags-for-resource
  ```

  For Windows:
The `list-tags-for-resource` CLI command returns the following output:

```json
{
  "TagList": [
    {
      "Key": "BackupPlan",
      "Value": "Test"
    }
  ]
}
```
Working with Amazon Resource Names (ARNs) in Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). For certain Amazon RDS operations, you must uniquely identify an Amazon RDS resource by specifying its ARN. For example, when you create an RDS DB instance read replica, you must supply the ARN for the source DB instance.

Constructing an ARN for Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). You can construct an ARN for an Amazon RDS resource using the following syntax.

`arn:aws:rds:<region>:<account number>:<resourcetype>:<name>`

<table>
<thead>

<td>arn:aws:rds:&lt;region&gt;::&lt;account&gt;:cluster:&lt;name&gt;</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
</tr>
<tr>
<td>Event subscription</td>
<td>arn:aws:rds:&lt;region&gt;::&lt;account&gt;:es:&lt;name&gt;</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
</tr>
<tr>
<td>DB option group</td>
<td>arn:aws:rds:&lt;region&gt;::&lt;account&gt;:og:&lt;name&gt;</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
</tr>
<tr>
<td>DB parameter group</td>
<td>arn:aws:rds:&lt;region&gt;::&lt;account&gt;:pg:&lt;name&gt;</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
</tr>
<tr>
<td>DB cluster parameter group</td>
<td>arn:aws:rds:&lt;region&gt;::&lt;account&gt;:cluster-pg:&lt;name&gt;</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
</tr>
<tr>
<td>Reserved DB instance</td>
<td>arn:aws:rds:&lt;region&gt;::&lt;account&gt;:ri:&lt;name&gt;</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
</tr>
<tr>
<td>DB security group</td>
<td>arn:aws:rds:&lt;region&gt;::&lt;account&gt;:secgrp:&lt;name&gt;</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
</tr>
<tr>
<td>Automated DB snapshot</td>
<td>arn:aws:rds:&lt;region&gt;::&lt;account&gt;:snapshot:rds:&lt;name&gt;</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
</tr>
</tbody>
</table>
### Resource type | ARN format
--- | ---
DB subnet group | `arn:aws:rds:<region>:<account>:subgrp:<name>`
For example: | `arn:aws:rds:us-east-2:123456789012:subgrp:my-subnet-10`

### Getting an existing ARN

You can get the ARN of an RDS resource by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or RDS API.

#### Console

To get an ARN from the AWS Management Console, navigate to the resource you want an ARN for, and view the details for that resource.

For example, you can get the ARN for a DB instance from the **Configuration** tab of the DB instance details.

#### AWS CLI

To get an ARN from the AWS CLI for a particular RDS resource, you use the `describe` command for that resource. The following table shows each AWS CLI command, and the ARN property used with the command to get an ARN.

<table>
<thead>
<tr>
<th>AWS CLI command</th>
<th>ARN property</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>describe-event-subscriptions</code></td>
<td>EventSubscriptionArn</td>
</tr>
<tr>
<td><code>describe-certificates</code></td>
<td>CertificateArn</td>
</tr>
</tbody>
</table>
For example, the following AWS CLI command gets the ARN for a DB instance.

**Example**

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
  --db-instance-identifier DBInstanceIdentifier \
  --region us-west-2 \
  --query "[*].{DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceArn:DBInstanceArn}"
```

For Windows:

```
aws rds describe-db-instances ^ \
  --db-instance-identifier DBInstanceIdentifier ^ \
  --region us-west-2 ^ \
  --query "[*].{DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceArn:DBInstanceArn}"
```

The output of that command is like the following:

```
[
  {
    "DBInstanceIdentifier": "instance_id"
  }
]
```

**RDS API**

To get an ARN for a particular RDS resource, you can call the following RDS API operations and use the ARN properties shown following.
## Getting an existing ARN

<table>
<thead>
<tr>
<th>RDS API operation</th>
<th>ARN property</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DescribeEventSubscriptions</code></td>
<td>EventSubscriptionArn</td>
</tr>
<tr>
<td><code>DescribeCertificates</code></td>
<td>CertificateArn</td>
</tr>
<tr>
<td><code>DescribeDBParameterGroups</code></td>
<td>DBParameterGroupArn</td>
</tr>
<tr>
<td><code>DescribeDBClusterParameterGroups</code></td>
<td>DBClusterParameterGroupArn</td>
</tr>
<tr>
<td><code>DescribeDBInstances</code></td>
<td>DBInstanceArn</td>
</tr>
<tr>
<td><code>DescribeDBSecurityGroups</code></td>
<td>DBSecurityGroupArn</td>
</tr>
<tr>
<td><code>DescribeDBSnapshots</code></td>
<td>DBSnapshotArn</td>
</tr>
<tr>
<td><code>DescribeEvents</code></td>
<td>SourceArn</td>
</tr>
<tr>
<td><code>DescribeReservedDBInstances</code></td>
<td>ReservedDBInstanceArn</td>
</tr>
<tr>
<td><code>DescribeDBSubnetGroups</code></td>
<td>DBSubnetGroupArn</td>
</tr>
<tr>
<td><code>DescribeOptionGroups</code></td>
<td>OptionGroupArn</td>
</tr>
<tr>
<td><code>DescribeDBClusters</code></td>
<td>DBClusterArn</td>
</tr>
<tr>
<td><code>DescribeDBClusterSnapshots</code></td>
<td>DBClusterSnapshotArn</td>
</tr>
</tbody>
</table>
Working with storage for Amazon RDS DB instances

To specify how you want your data stored in Amazon RDS, choose a storage type and provide a storage size when you create or modify a DB instance. Later, you can increase the amount or change the type of storage by modifying the DB instance. For more information about which storage type to use for your workload, see Amazon RDS storage types (p. 101).

Topics
- Increasing DB instance storage capacity (p. 478)
- Managing capacity automatically with Amazon RDS storage autoscaling (p. 480)
- Modifying settings for Provisioned IOPS SSD storage (p. 484)
- I/O-intensive storage modifications (p. 486)
- Modifying settings for General Purpose SSD (gp3) storage (p. 486)

Increasing DB instance storage capacity

If you need space for additional data, you can scale up the storage of an existing DB instance. To do so, you can use the Amazon RDS Management Console, the Amazon RDS API, or the AWS Command Line Interface (AWS CLI). For information about storage limits, see Amazon RDS DB instance storage (p. 101).

Note
Scaling storage for Amazon RDS for Microsoft SQL Server DB instances is supported only for General Purpose SSD or Provisioned IOPS SSD storage types.

To monitor the amount of free storage for your DB instance so you can respond when necessary, we recommend that you create an Amazon CloudWatch alarm. For more information on setting CloudWatch alarms, see Using CloudWatch alarms.

Scaling storage usually doesn't cause any outage or performance degradation of the DB instance. After you modify the storage size for a DB instance, the status of the DB instance is storage-optimization.

Note
Storage optimization can take several hours. You can't make further storage modifications for either six (6) hours or until storage optimization has completed on the instance, whichever is longer. You can view the storage optimization progress in the AWS Management Console or by using the describe-db-instances AWS CLI command.

However, a special case is if you have a SQL Server DB instance and haven't modified the storage configuration since November 2017. In this case, you might experience a short outage of a few minutes when you modify your DB instance to increase the allocated storage. After the outage, the DB instance is online but in the storage-optimization state. Performance might be degraded during storage optimization.

Note
You can't reduce the amount of storage for a DB instance after storage has been allocated. When you increase the allocated storage, it must be by at least 10 percent. If you try to increase the value by less than 10 percent, you get an error.

Console

To increase storage for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. Enter a new value for **Allocated storage**. It must be greater than the current value.

![Allocated storage](image)

6. Choose **Continue** to move to the next screen.
7. Choose **Apply immediately** in the **Scheduling of modifications** section to apply the storage changes to the DB instance immediately.

   Or choose **Apply during the next scheduled maintenance window** to apply the changes during the next maintenance window.
8. When the settings are as you want them, choose **Modify DB instance**.

**AWS CLI**

To increase the storage for a DB instance, use the AWS CLI command `modify-db-instance`. Set the following parameters:

- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `--apply-immediately` – Use `--apply-immediately` to apply the storage changes immediately.

   Or use `--no-apply-immediately` (the default) to apply the changes during the next maintenance window. An immediate outage occurs when the changes are applied.

For more information about storage, see [Amazon RDS DB instance storage (p. 101)](#).

**RDS API**

To increase storage for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameters:

- `AllocatedStorage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `ApplyImmediately` – Set this option to True to apply the storage changes immediately. Set this option to False (the default) to apply the changes during the next maintenance window. An immediate outage occurs when the changes are applied.

For more information about storage, see [Amazon RDS DB instance storage (p. 101)](#).
Managing capacity automatically with Amazon RDS storage autoscaling

If your workload is unpredictable, you can enable storage autoscaling for an Amazon RDS DB instance. To do so, you can use the Amazon RDS console, the Amazon RDS API, or the AWS CLI.

For example, you might use this feature for a new mobile gaming application that users are adopting rapidly. In this case, a rapidly increasing workload might exceed the available database storage. To avoid having to manually scale up database storage, you can use Amazon RDS storage autoscaling.

With storage autoscaling enabled, when Amazon RDS detects that you are running out of free database space it automatically scales up your storage. Amazon RDS starts a storage modification for an autoscaling-enabled DB instance when these factors apply:

- Free available space is less than or equal to 10 percent of the allocated storage.
- The low-storage condition lasts at least five minutes.
- At least six hours have passed since the last storage modification, or storage optimization has completed on the instance, whichever is longer.

The additional storage is in increments of whichever of the following is greater:

- 10 GiB
- 10 percent of currently allocated storage
- Predicted storage growth exceeding the current allocated storage size in the next 7 hours based on the FreeStorageSpace metrics from the past hour. For more information on metrics, see Monitoring with Amazon CloudWatch.

The maximum storage threshold is the limit that you set for autoscaling the DB instance. It has the following constraints:

- You must set the maximum storage threshold to at least 10% more than the current allocated storage. We recommend setting it to at least 26% more to avoid receiving an event notification (p. 886) that the storage size is approaching the maximum storage threshold.

For example, if you have DB instance with 1000 GiB of allocated storage, then set the maximum storage threshold to at least 1100 GiB. If you don't, you get an error such as invalid max storage size for engine_name. However, we recommend that you set the maximum storage threshold to at least 1260 GiB to avoid the event notification.

- For a DB instance that uses Provisioned IOPS storage, the ratio of IOPS to maximum storage threshold (in GiB) must be from 1–50 on RDS for SQL Server, and 0.5–50 on other RDS DB engines.

- You can't set the maximum storage threshold for autoscaling-enabled instances to a value greater than the maximum allocated storage for the database engine and DB instance class.

For example, SQL Server Standard Edition on db.m5.xlarge has a default allocated storage for the instance of 20 GiB (the minimum) and a maximum allocated storage of 16,384 GiB. The default maximum storage threshold for autoscaling is 1,000 GiB. If you use this default, the instance doesn't autoscale above 1,000 GiB. This is true even though the maximum allocated storage for the instance is 16,384 GiB.

**Note**

We recommend that you carefully choose the maximum storage threshold based on usage patterns and customer needs. If there are any aberrations in the usage patterns, the maximum storage threshold can prevent scaling storage to an unexpectedly high value when autoscaling.
predicts a very high threshold. After a DB instance has been autoscaled, its allocated storage can't be reduced.

Topics
• Limitations (p. 481)
• Enabling storage autoscaling for a new DB instance (p. 481)
• Changing the storage autoscaling settings for a DB instance (p. 482)
• Turning off storage autoscaling for a DB instance (p. 483)

Limitations
The following limitations apply to storage autoscaling:

• Autoscaling doesn't occur if the maximum storage threshold would be equaled or exceeded by the storage increment.
• When autoscaling, RDS predicts the storage size for subsequent autoscaling operations. If a subsequent operation is predicted to exceed the maximum storage threshold, then RDS autoscales to the maximum storage threshold.
• Autoscaling can't completely prevent storage-full situations for large data loads. This is because further storage modifications can't be made for either six (6) hours or until storage optimization has completed on the instance, whichever is longer.

If you perform a large data load, and autoscaling doesn't provide enough space, the database might remain in the storage-full state for several hours. This can harm the database.
• If you start a storage scaling operation at the same time that Amazon RDS starts an autoscaling operation, your storage modification takes precedence. The autoscaling operation is canceled.
• Autoscaling can't be used with magnetic storage.
• Autoscaling can't be used with the following previous-generation instance classes that have less than 6 TiB of orderable storage: db.m3.large, db.m3.xlarge, and db.m3.2xlarge.
• Autoscaling operations aren't logged by AWS CloudTrail. For more information on CloudTrail, see Monitoring Amazon RDS API calls in AWS CloudTrail (p. 940).

Although automatic scaling helps you to increase storage on your Amazon RDS DB instance dynamically, you should still configure the initial size for your DB instance to an appropriate size for your typical workload.

Enabling storage autoscaling for a new DB instance

When you create a new Amazon RDS DB instance, you can choose whether to enable storage autoscaling. You can also set an upper limit on the storage that Amazon RDS can allocate for the DB instance.

Note
When you clone an Amazon RDS DB instance that has storage autoscaling enabled, that setting isn't automatically inherited by the cloned instance. The new DB instance has the same amount of allocated storage as the original instance. You can turn storage autoscaling on again for the new instance if the cloned instance continues to increase its storage requirements.

Console

To enable storage autoscaling for a new DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where you want to create the DB instance.
3. In the navigation pane, choose Databases.
4. Choose Create database. On the Select engine page, choose your database engine and specify your DB instance information as described in Getting started with Amazon RDS (p. 180).
5. In the Storage autoscaling section, set the Maximum storage threshold value for the DB instance.
6. Specify the rest of your DB instance information as described in Getting started with Amazon RDS (p. 180).

**AWS CLI**

To enable storage autoscaling for a new DB instance, use the AWS CLI command `create-db-instance`. Set the following parameter:

- `--max-allocated-storage` – Turns on storage autoscaling and sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the AWS CLI `describe-valid-db-instance-modifications` command. To check based on the instance class before creating an instance, use the `describe-orderable-db-instance-options` command. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance or instance class supports storage autoscaling.

For more information about storage, see Amazon RDS DB instance storage (p. 101).

**RDS API**

To enable storage autoscaling for a new DB instance, use the Amazon RDS API operation `CreateDBInstance`. Set the following parameter:

- `MaxAllocatedStorage` – Turns on Amazon RDS storage autoscaling and sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the Amazon RDS API `DescribeValidDbInstanceModifications` operation for an existing instance, or the `DescribeOrderableDBInstanceOptions` operation before creating an instance. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see Amazon RDS DB instance storage (p. 101).

**Changing the storage autoscaling settings for a DB instance**

You can turn storage autoscaling on for an existing Amazon RDS DB instance. You can also change the upper limit on the storage that Amazon RDS can allocate for the DB instance.

**Console**

**To change the storage autoscaling settings for a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
Managing capacity automatically with storage autoscaling

2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify, and choose **Modify**. The **Modify DB instance** page appears.
4. Change the storage limit in the **Autoscaling** section. For more information, see *Modifying an Amazon RDS DB instance* (p. 401).
5. When all the changes are as you want them, choose **Continue** and check your modifications.
6. On the confirmation page, review your changes. If they're correct, choose **Modify DB Instance** to save your changes. If they aren't correct, choose **Back** to edit your changes or **Cancel** to cancel your changes.

Changing the storage autoscaling limit occurs immediately. This setting ignores the **Apply immediately** setting.

**AWS CLI**

To change the storage autoscaling settings for a DB instance, use the AWS CLI command `modify-db-instance`. Set the following parameter:

- `--max-allocated-storage` – Sets the upper limit on storage size, in gibibytes. If the value is greater than the `--allocated-storage` parameter, storage autoscaling is turned on. If the value is the same as the `--allocated-storage` parameter, storage autoscaling is turned off.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the AWS CLI `describe-valid-db-instance-modifications` command. To check based on the instance class before creating an instance, use the `describe-orderable-db-instance-options` command. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see *Amazon RDS DB instance storage* (p. 101).

**RDS API**

To change the storage autoscaling settings for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameter:

- `MaxAllocatedStorage` – Sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the Amazon RDS API `DescribeValidDbInstanceModifications` operation for an existing instance, or the `DescribeOrderableDBInstanceOptions` operation before creating an instance. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see *Amazon RDS DB instance storage* (p. 101).

**Turning off storage autoscaling for a DB instance**

If you no longer need Amazon RDS to automatically increase the storage for an Amazon RDS DB instance, you can turn off storage autoscaling. After you do, you can still manually increase the amount of storage for your DB instance.
Console

To turn off storage autoscaling for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to modify and choose Modify. The Modify DB instance page appears.
4. Clear the Enable storage autoscaling check box in the Storage autoscaling section. For more information, see Modifying an Amazon RDS DB instance (p. 401).
5. When all the changes are as you want them, choose Continue and check the modifications.
6. On the confirmation page, review your changes. If they're correct, choose Modify DB Instance to save your changes. If they aren't correct, choose Back to edit your changes or Cancel to cancel your changes.

Changing the storage autoscaling limit occurs immediately. This setting ignores the Apply immediately setting.

AWS CLI

To turn off storage autoscaling for a DB instance, use the AWS CLI command `modify-db-instance` and the following parameter:

• `--max-allocated-storage` – Specify a value equal to the `--allocated-storage` setting to prevent further Amazon RDS storage autoscaling for the specified DB instance.

For more information about storage, see Amazon RDS DB instance storage (p. 101).

RDS API

To turn off storage autoscaling for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameter:

• `MaxAllocatedStorage` – Specify a value equal to the `AllocatedStorage` setting to prevent further Amazon RDS storage autoscaling for the specified DB instance.

For more information about storage, see Amazon RDS DB instance storage (p. 101).

Modifying settings for Provisioned IOPS SSD storage

You can modify the settings for a DB instance that uses Provisioned IOPS SSD storage by using the Amazon RDS console, AWS CLI, or Amazon RDS API. Specify the storage type, allocated storage, and the amount of Provisioned IOPS that you require. The range depends on your database engine and instance type.

Although you can reduce the amount of IOPS provisioned for your instance, you can't reduce the storage size.

In most cases, scaling storage doesn't require any outage and doesn't degrade performance of the server. After you modify the storage IOPS for a DB instance, the status of the DB instance is storage-optimization.
Note
Storage optimization can take several hours. You can’t make further storage modifications for
either six (6) hours or until storage optimization has completed on the instance, whichever is
longer.

For information on the ranges of allocated storage and Provisioned IOPS available for each database
engine, see Provisioned IOPS SSD storage (p. 104).

Console

To change the Provisioned IOPS settings for a DB instance
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://
console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
   To filter the list of DB instances, for Filter databases enter a text string for Amazon RDS to use to
filter the results. Only DB instances whose names contain the string appear.
3. Choose the DB instance with Provisioned IOPS that you want to modify.
4. Choose Modify.
5. On the Modify DB instance page, choose Provisioned IOPS SSD (io1) for Storage type.
6. For Provisioned IOPS, enter a value.
   If the value that you specify for either Allocated storage or Provisioned IOPS is outside the limits
supported by the other parameter, a warning message is displayed. This message gives the range of
values required for the other parameter.
7. Choose Continue.
8. Choose Apply immediately in the Scheduling of modifications section to apply the changes to the
DB instance immediately. Or choose Apply during the next scheduled maintenance window to
apply the changes during the next maintenance window.
9. Review the parameters to be changed, and choose Modify DB instance to complete the
modification.
   The new value for allocated storage or for Provisioned IOPS appears in the Status column.

AWS CLI

To change the Provisioned IOPS setting for a DB instance, use the AWS CLI command modify-db-
instance. Set the following parameters:

- --storage-type – Set to io1 for Provisioned IOPS.
- --allocated-storage – Amount of storage to be allocated for the DB instance, in gibibytes.
- --iops – The new amount of Provisioned IOPS for the DB instance, expressed in I/O operations per
second.
- --apply-immediately – Use --apply-immediately to apply changes immediately. Use --no-
apply-immediately (the default) to apply changes during the next maintenance window.

RDS API

To change the Provisioned IOPS settings for a DB instance, use the Amazon RDS API operation
ModifyDBInstance. Set the following parameters:

- StorageType – Set to io1 for Provisioned IOPS.
AllocatedStorage – Amount of storage to be allocated for the DB instance, in gibibytes.

Iops – The new IOPS rate for the DB instance, expressed in I/O operations per second.

ApplyImmediately – Set this option to True to apply changes immediately. Set this option to False (the default) to apply changes during the next maintenance window.

**I/O-intensive storage modifications**

Amazon RDS DB instances use Amazon Elastic Block Store (EBS) volumes for database and log storage. Depending on the amount of storage requested, RDS (except for RDS for SQL Server) automatically stripes across multiple Amazon EBS volumes to enhance performance. RDS DB instances with SSD storage types are backed by either one or four striped Amazon EBS volumes in a RAID 0 configuration. By design, storage modification operations for an RDS DB instance have minimal impact on ongoing database operations.

In most cases, storage scaling modifications are completely offloaded to the Amazon EBS layer and are transparent to the database. This process is typically completed within a few minutes. However, some older RDS storage volumes require a different process for modifying the size, Provisioned IOPS, or storage type. This involves making a full copy of the data using a potentially I/O-intensive operation.

Storage modification uses an I/O-intensive operation if any of the following factors apply:

- The source storage type is magnetic. Magnetic storage doesn't support elastic volume modification.
- The RDS DB instance isn't on a one- or four-volume Amazon EBS layout. You can view the number of Amazon EBS volumes in use on your RDS DB instances by using Enhanced Monitoring metrics. For more information, see [Viewing OS metrics in the RDS console](p. 802).
- The target size of the modification request increases the allocated storage above 400 GiB for RDS for MariaDB, MySQL, and PostgreSQL instances, and 200 GiB for RDS for Oracle. Storage autoscaling operations have the same effect when they increase the allocated storage size of your DB instance above these thresholds.

If your storage modification involves an I/O-intensive operation, it consumes I/O resources and increases the load on your DB instance. Storage modifications with I/O-intensive operations involving General Purpose SSD (gp2) storage can deplete your I/O credit balance, resulting in longer conversion times.

We recommend as a best practice to schedule these storage modification requests outside of peak hours to help reduce the time required to complete the storage modification operation. Alternatively, you can create a read replica of the DB instance and perform the storage modification on the read replica. Then promote the read replica to be the primary DB instance. For more information, see [Working with DB instance read replicas](p. 438).

For more information, see [Why is an Amazon RDS DB instance stuck in the modifying state when I try to increase the allocated storage?](

**Modifying settings for General Purpose SSD (gp3) storage**

You can modify the settings for a DB instance that uses General Purpose SSD (gp3) storage by using the Amazon RDS console, AWS CLI, or Amazon RDS API. Specify the storage type, allocated storage, amount of Provisioned IOPS, and storage throughput that you require. Although you can reduce the amount of IOPS provisioned for your instance, you can't reduce the storage size.

In most cases, scaling storage doesn't require any outage. After you modify the storage IOPS for a DB instance, the status of the DB instance is **storage-optimization**. You can expect elevated latencies,
but still within the single-digit millisecond range, during storage optimization. The DB instance is fully operational after a storage modification.

**Note**
You can't make further storage modifications until six (6) hours after storage optimization has completed on the instance.

For information on the ranges of allocated storage, Provisioned IOPS, and storage throughput available for each database engine, see [gp3 storage](p. 103).

**Console**

**To change the storage performance settings for a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
   
   To filter the list of DB instances, for **Filter databases** enter a text string for Amazon RDS to use to filter the results. Only DB instances whose names contain the string appear.
3. Choose the DB instance with gp3 storage that you want to modify.
4. Choose **Modify**.
5. On the **Modify DB Instance page**, choose **General Purpose SSD (gp3)** for **Storage type**, then do the following:
   
   a. For **Provisioned IOPS**, choose a value.
      
      If the value that you specify for either **Allocated storage** or **Provisioned IOPS** is outside the limits supported by the other parameter, a warning message appears. This message gives the range of values required for the other parameter.
   
   b. For **Storage throughput**, choose a value.
      
      If the value that you specify for either **Provisioned IOPS** or **Storage throughput** is outside the limits supported by the other parameter, a warning message appears. This message gives the range of values required for the other parameter.
6. Choose **Continue**.
7. Choose **Apply immediately** in the **Scheduling of modifications** section to apply the changes to the DB instance immediately. Or choose **Apply during the next scheduled maintenance window** to apply the changes during the next maintenance window.
8. Review the parameters to be changed, and choose **Modify DB instance** to complete the modification.

   The new value for Provisioned IOPS appears in the **Status** column.

**AWS CLI**

To change the storage performance settings for a DB instance, use the AWS CLI command **modify-db-instance**. Set the following parameters:

- **--storage-type** – Set to gp3 for General Purpose SSD (gp3).
- **--allocated-storage** – Amount of storage to be allocated for the DB instance, in gibibytes.
- **--iops** – The new amount of Provisioned IOPS for the DB instance, expressed in I/O operations per second.
- **--storage-throughput** – The new storage throughput for the DB instance, expressed in MiBps.
• `--apply-immediately` — Use `--apply-immediately` to apply changes immediately. Use `--no-apply-immediately` (the default) to apply changes during the next maintenance window.

RDS API

To change the storage performance settings for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameters:

• `StorageType` — Set to `gp3` for General Purpose SSD (gp3).
• `AllocatedStorage` — Amount of storage to be allocated for the DB instance, in gibibytes.
• `Iops` — The new IOPS rate for the DB instance, expressed in I/O operations per second.
• `StorageThroughput` — The new storage throughput for the DB instance, expressed in MiBps.
• `ApplyImmediately` — Set this option to `True` to apply changes immediately. Set this option to `False` (the default) to apply changes during the next maintenance window.
Deleting a DB instance

You can delete a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. If you want to delete a DB instance in an Aurora DB cluster, see Deleting Aurora DB clusters and DB instances.

Topics
- Prerequisites for deleting a DB instance (p. 489)
- Considerations when deleting a DB instance (p. 489)
- Deleting a DB instance (p. 490)

Prerequisites for deleting a DB instance

Before you try to delete your DB instance, make sure that deletion protection is turned off. By default, deletion protection is turned on for a DB instance that was created with the console.

If your DB instance has deletion protection turned on, you can turn it off by modifying your instance settings. Choose Modify in the database details page or call the modify-db-instance command. This operation doesn't cause an outage. For more information, see Settings for DB instances (p. 402).

Considerations when deleting a DB instance

Deleting a DB instance has an effect on instance recoverability, backup availability, and read replica status. Consider the following issues:

- You can choose whether to create a final DB snapshot. You have the following options:
  - If you take a final snapshot, you can use it to restore your deleted DB instance. RDS retains both the final snapshot and any manual snapshots that you took previously. You can't create a final DB snapshot of your DB instance if it isn't in the Available state. For more information, see Viewing Amazon RDS DB instance status (p. 684).
  - If you don't take a final snapshot, deletion is faster. However, you can't use a final snapshot to restore your DB instance. If you later decide to restore your deleted DB instance, either retain automated backups or use an earlier manual snapshot to restore your DB instance to the point in time of the snapshot.
- You can choose whether to retain automated backups. You have the following options:
  - If you retain automated backups, RDS keeps them for the retention period that is in effect for the DB instance at the time when you delete it. You can use automated backups to restore your DB instance to a time during but not after your retention period. The retention period is in effect regardless of whether you create a final DB snapshot. To delete a retained automated backup, see Deleting retained automated backups (p. 596).
  - Retained automated backups and manual snapshots incur billing charges until they're deleted. For more information, see Retention costs (p. 596).
  - If you don't retain automated backups, RDS deletes the automated backups that reside in the same AWS Region as your DB instance. You can't recover these backups. If your automated backups have been replicated to another AWS Region, RDS keeps them even if you don't choose to retain automated backups. For more information, see Replicating automated backups to another AWS Region (p. 602).

  Note
  Typically, if you create a final DB snapshot, you don't need to retain automated backups.

- When you delete your DB instance, RDS doesn't delete manual DB snapshots. For more information, see Creating a DB snapshot (p. 613).
- If you want to delete all RDS resources, note that the following resources incur billing charges:
• DB instances
• DB snapshots
• DB clusters

If you purchased reserved instances, then they are billed according to contract that you agreed to when you purchased the instance. For more information, see Reserved DB instances for Amazon RDS (p. 165). You can get billing information for all your AWS resources by using the AWS Cost Explorer. For more information, see Analyzing your costs with AWS Cost Explorer.

• If you delete a DB instance that has read replicas in the same AWS Region, each read replica is automatically promoted to a standalone DB instance. For more information, see Promoting a read replica to be a standalone DB instance (p. 447). If your DB instance has read replicas in different AWS Regions, see Cross-Region replication considerations (p. 456) for information related to deleting the source DB instance for a cross-Region read replica.

• When the status for a DB instance is deleting, its CA certificate value doesn't appear in the RDS console or in output for AWS CLI commands or RDS API operations. For more information about CA certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).

• The time required to delete a DB instance varies depending on the backup retention period (that is, how many backups to delete), how much data is deleted, and whether a final snapshot is taken.

Deleting a DB instance

You can delete a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. You must do the following:

• Provide the name of the DB instance
• Enable or disable the option to take a final DB snapshot of the instance
• Enable or disable the option to retain automated backups

Note
You can't delete a DB instance when deletion protection is turned on. For more information, see Prerequisites for deleting a DB instance (p. 489).

Console

To delete a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to delete.
3. For Actions, choose Delete.
4. To create a final DB snapshot for the DB instance, choose Create final snapshot?.
5. If you chose to create a final snapshot, enter the Final snapshot name.
6. To retain automated backups, choose Retain automated backups.
7. Enter delete me in the box.
8. Choose Delete.

AWS CLI

To find the instance IDs of the DB instances in your account, call the describe-db-instances command:
To delete a DB instance by using the AWS CLI, call the `delete-db-instance` command with the following options:

- `--db-instance-identifier`
- `--final-db-snapshot-identifier` or `--skip-final-snapshot`

**Example With a final snapshot and no retained automated backups**

For Linux, macOS, or Unix:

```bash/aws rds delete-db-instance  
   --db-instance-identifier mydbinstance  
   --final-db-snapshot-identifier mydbinstancefinalsnapshot  
   --delete-automated-backups
```

For Windows:

```bash
/aws rds delete-db-instance ^
   --db-instance-identifier mydbinstance ^
   --final-db-snapshot-identifier mydbinstancefinalsnapshot ^
   --delete-automated-backups
```

**Example With retained automated backups and no final snapshot**

For Linux, macOS, or Unix:

```bash/aws rds delete-db-instance  
   --db-instance-identifier mydbinstance  
   --skip-final-snapshot  
   --no-delete-automated-backups
```

For Windows:

```bash
/aws rds delete-db-instance ^
   --db-instance-identifier mydbinstance ^
   --skip-final-snapshot ^
   --no-delete-automated-backups
```

**RDS API**

To delete a DB instance by using the Amazon RDS API, call the `DeleteDBInstance` operation with the following parameters:

- `DBInstanceIdentifier`
- `FinalDBSnapshotIdentifier` or `SkipFinalSnapshot`
Configuring and managing a Multi-AZ deployment

Multi-AZ deployments can have one standby or two standby DB instances. When the deployment has one standby DB instance, it’s called a Multi-AZ DB instance deployment. A Multi-AZ DB instance deployment has one standby DB instance that provides failover support, but doesn’t serve read traffic. When the deployment has two standby DB instances, it’s called a Multi-AZ DB cluster deployment. A Multi-AZ DB cluster deployment has standby DB instances that provide failover support and can also serve read traffic.

You can use the AWS Management Console to determine whether a Multi-AZ deployment is a Multi-AZ DB instance deployment or a Multi-AZ DB cluster deployment. In the navigation pane, choose Databases, and then choose a DB identifier.

- A Multi-AZ DB instance deployment has the following characteristics:
  - There is only one row for the DB instance.
  - The value of Role is Instance or Primary.
  - The value of Multi-AZ is Yes.
- A Multi-AZ DB cluster deployment has the following characteristics:
  - There is a cluster-level row with three DB instance rows under it.
  - For the cluster-level row, the value of Role is Multi-AZ DB cluster.
  - For each instance-level row, the value of Role is Writer instance or Reader instance.
  - For each instance-level row, the value of Multi-AZ is 3 Zones.

Topics
- Multi-AZ DB instance deployments (p. 493)
- Multi-AZ DB cluster deployments (p. 499)

In addition, the following topics apply to both DB instances and Multi-AZ DB clusters:

- the section called “Tagging RDS resources” (p. 461)
- the section called “Working with ARNs” (p. 471)
- the section called “Working with storage” (p. 478)
- the section called “Maintaining a DB instance” (p. 418)
- the section called “Upgrading the engine version” (p. 429)
Multi-AZ DB instance deployments

Amazon RDS provides high availability and failover support for DB instances using Multi-AZ deployments with a single standby DB instance. This type of deployment is called a Multi-AZ DB instance deployment. Amazon RDS uses several different technologies to provide this failover support. Multi-AZ deployments for MariaDB, MySQL, Oracle, PostgreSQL, and RDS Custom for SQL Server DB instances use the Amazon failover technology. Microsoft SQL Server DB instances use SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). For information on SQL Server version support for Multi-AZ, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 1466). For information on working with RDS Custom for SQL Server for Multi-AZ, see Managing a Multi-AZ deployment for RDS Custom for SQL Server (p. 1163).

In a Multi-AZ DB instance deployment, Amazon RDS automatically provisions and maintains a synchronous standby replica in a different Availability Zone. The primary DB instance is synchronously replicated across Availability Zones to a standby replica to provide data redundancy and minimize latency spikes during system backups. Running a DB instance with high availability can enhance availability during planned system maintenance. It can also help protect your databases against DB instance failure and Availability Zone disruption. For more information on Availability Zones, see Regions, Availability Zones, and Local Zones (p. 110).

Note
The high availability option isn't a scaling solution for read-only scenarios. You can't use a standby replica to serve read traffic. To serve read-only traffic, use a Multi-AZ DB cluster or a read replica instead. For more information about Multi-AZ DB clusters, see Multi-AZ DB cluster deployments (p. 499). For more information about read replicas, see Working with DB instance read replicas (p. 438).

Using the RDS console, you can create a Multi-AZ DB instance deployment by simply specifying Multi-AZ when creating a DB instance. You can use the console to convert existing DB instances to Multi-AZ.
DB instance deployments by modifying the DB instance and specifying the Multi-AZ option. You can also specify a Multi-AZ DB instance deployment with the AWS CLI or Amazon RDS API. Use the create-db-instance or modify-db-instance CLI command, or the CreateDBInstance or ModifyDBInstance API operation.

The RDS console shows the Availability Zone of the standby replica (called the secondary AZ). You can also use the describe-db-instances CLI command or the DescribeDBInstances API operation to find the secondary AZ.

DB instances using Multi-AZ DB instance deployments can have increased write and commit latency compared to a Single-AZ deployment. This can happen because of the synchronous data replication that occurs. You might have a change in latency if your deployment fails over to the standby replica, although AWS is engineered with low-latency network connectivity between Availability Zones. For production workloads, we recommend that you use Provisioned IOPS (input/output operations per second) for fast, consistent performance. For more information about DB instance classes, see DB instance classes (p. 11).

Modifying a DB instance to be a Multi-AZ DB instance deployment

If you have a DB instance in a Single-AZ deployment and modify it to a Multi-AZ DB instance deployment (for engines other than Amazon Aurora), Amazon RDS performs several actions:

1. Takes a snapshot of the primary DB instance’s Amazon Elastic Block Store (EBS) volumes.
2. Creates new volumes for the standby replica from the snapshot. These volumes initialize in the background, and maximum volume performance is achieved after the data is fully initialized.
3. Turns on synchronous block-level replication between the volumes of the primary and standby replicas.

**Important**

Using a snapshot to create the standby instance avoids downtime when you convert from Single-AZ to Multi-AZ, but you can experience a performance impact during and after converting to Multi-AZ. This impact can be significant for workloads that are sensitive to write latency.

While this capability lets large volumes be restored from snapshots quickly, it can cause a significant increase in the latency of I/O operations because of the synchronous replication. This latency can impact your database performance. We highly recommend as a best practice not to perform Multi-AZ conversion on a production DB instance.

To avoid the performance impact on the DB instance currently serving the sensitive workload, create a read replica and enable backups on the read replica. Convert the read replica to Multi-AZ, and run queries that load the data into the read replica’s volumes (on both AZs). Then promote the read replica to be the primary DB instance. For more information, see Working with DB instance read replicas (p. 438).

There are two ways to modify a DB instance to be a Multi-AZ DB instance deployment:

**Topics**

- Convert to a Multi-AZ DB instance deployment with the RDS console (p. 494)
- Modifying a DB instance to be a Multi-AZ DB instance deployment (p. 495)

**Convert to a Multi-AZ DB instance deployment with the RDS console**

You can use the RDS console to convert a DB instance to a Multi-AZ DB instance deployment.
You can only use the console to complete the conversion. To use the AWS CLI or RDS API, follow the instructions in *Modifying a DB instance to be a Multi-AZ DB instance deployment (p. 495).*

**To convert to a Multi-AZ DB instance deployment with the RDS console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. From **Actions**, choose **Convert to Multi-AZ deployment**.
4. On the confirmation page, choose **Apply immediately** to apply the changes immediately. Choosing this option doesn't cause downtime, but there is a possible performance impact. Alternatively, you can choose to apply the update during the next maintenance window. For more information, see *Using the Apply Immediately setting (p. 402).*
5. Choose **Convert to Multi-AZ**.

**Modifying a DB instance to be a Multi-AZ DB instance deployment**

You can modify a DB instance to be a MultiAZ DB instance deployment in the following ways:

- Using the RDS console, modify the DB instance, and set **Multi-AZ deployment** to **Yes**.
- Using the AWS CLI, call the `modify-db-instance` command, and set the `--multi-az` option.
- Using the RDS API, call the `ModifyDBInstance` operation, and set the `MultiAZ` parameter to `true`.

For information about modifying a DB instance, see *Modifying an Amazon RDS DB instance (p. 401).* After the modification is complete, Amazon RDS triggers an event (RDS-EVENT-0025) that indicates the process is complete. You can monitor Amazon RDS events. For more information about events, see *Working with Amazon RDS event notification (p. 855).*

**Failover process for Amazon RDS**

If a planned or unplanned outage of your DB instance results from an infrastructure defect, Amazon RDS automatically switches to a standby replica in another Availability Zone if you have turned on Multi-AZ. The time that it takes for the failover to complete depends on the database activity and other conditions at the time the primary DB instance became unavailable. Failover times are typically 60–120 seconds. However, large transactions or a lengthy recovery process can increase failover time. When the failover is complete, it can take additional time for the RDS console to reflect the new Availability Zone.

*Note*

You can force a failover manually when you reboot a DB instance. For more information, see *Rebooting a DB instance (p. 436).*

Amazon RDS handles failovers automatically so you can resume database operations as quickly as possible without administrative intervention. The primary DB instance switches over automatically to the standby replica if any of the conditions described in the following table occurs. You can view these failover reasons in the event log.

<table>
<thead>
<tr>
<th>Failover reason</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The operating system underlying the RDS database instance is being patched in an offline operation.</td>
<td>A failover was triggered during the maintenance window for an OS patch or a security update.</td>
</tr>
</tbody>
</table>
### Failover reason

<table>
<thead>
<tr>
<th>Failover reason</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The primary host of the RDS Multi-AZ instance is unhealthy.</td>
<td>The Multi-AZ DB instance deployment detected an impaired primary DB instance and failed over.</td>
</tr>
<tr>
<td>The primary host of the RDS Multi-AZ instance is unreachable due to loss of network connectivity.</td>
<td>RDS monitoring detected a network reachability failure to the primary DB instance and triggered a failover.</td>
</tr>
<tr>
<td>The RDS instance was modified by customer.</td>
<td>An RDS DB instance modification triggered a failover.</td>
</tr>
<tr>
<td>The RDS Multi-AZ primary instance is busy and unresponsive.</td>
<td>The primary DB instance is unresponsive. We recommend that you do the following:</td>
</tr>
<tr>
<td></td>
<td>• Examine the event and CloudWatch logs for excessive CPU, memory, or swap space usage. For more information, see Working with Amazon RDS event notification (p. 855) and Creating a rule that triggers on an Amazon RDS event (p. 870).</td>
</tr>
<tr>
<td></td>
<td>• Evaluate your workload to determine whether you're using the appropriate DB instance class. For more information, see DB instance classes (p. 11).</td>
</tr>
<tr>
<td></td>
<td>• Use Enhanced Monitoring for real-time operating system metrics. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 797).</td>
</tr>
<tr>
<td></td>
<td>• Use Performance Insights to help analyze any issues that affect your DB instance's performance. For more information, see Monitoring DB load with Performance Insights on Amazon RDS (p. 720).</td>
</tr>
<tr>
<td></td>
<td>For more information on these recommendations, see Overview of monitoring metrics in Amazon RDS (p. 679) and Best practices for Amazon RDS (p. 286).</td>
</tr>
<tr>
<td>The storage volume underlying the primary host of the RDS Multi-AZ instance experienced a failure.</td>
<td>The Multi-AZ DB instance deployment detected a storage issue on the primary DB instance and failed over.</td>
</tr>
<tr>
<td>The user requested a failover of the DB instance.</td>
<td>You rebooted the DB instance and chose Reboot with failover.</td>
</tr>
<tr>
<td></td>
<td>For more information, see Rebooting a DB instance (p. 436).</td>
</tr>
</tbody>
</table>

To determine if your Multi-AZ DB instance has failed over, you can do the following:
• Set up DB event subscriptions to notify you by email or SMS that a failover has been initiated. For more information about events, see Working with Amazon RDS event notification (p. 855).
• View your DB events by using the RDS console or API operations.
• View the current state of your Multi-AZ DB instance deployment by using the RDS console or API operations.

For information on how you can respond to failovers, reduce recovery time, and other best practices for Amazon RDS, see Best practices for Amazon RDS (p. 286).

Setting the JVM TTL for DNS name lookups

The failover mechanism automatically changes the Domain Name System (DNS) record of the DB instance to point to the standby DB instance. As a result, you need to re-establish any existing connections to your DB instance. In a Java virtual machine (JVM) environment, due to how the Java DNS caching mechanism works, you might need to reconfigure JVM settings.

The JVM caches DNS name lookups. When the JVM resolves a host name to an IP address, it caches the IP address for a specified period of time, known as the time-to-live (TTL).

Because AWS resources use DNS name entries that occasionally change, we recommend that you configure your JVM with a TTL value of no more than 60 seconds. Doing this makes sure that when a resource's IP address changes, your application can receive and use the resource's new IP address by requerying the DNS.

On some Java configurations, the JVM default TTL is set so that it never refreshes DNS entries until the JVM is restarted. Thus, if the IP address for an AWS resource changes while your application is still running, it can't use that resource until you manually restart the JVM and the cached IP information is refreshed. In this case, it's crucial to set the JVM's TTL so that it periodically refreshes its cached IP information.

You can get the JVM default TTL by retrieving the networkaddress.cache.ttl property value:

```java
String ttl = java.security.Security.getProperty("networkaddress.cache.ttl");
```

**Note**
The default TTL can vary according to the version of your JVM and whether a security manager is installed. Many JVMs provide a default TTL less than 60 seconds. If you're using such a JVM and not using a security manager, you can ignore the rest of this topic. For more information on security managers in Oracle, see The security manager in the Oracle documentation.

To modify the JVM's TTL, set the networkaddress.cache.ttl property value. Use one of the following methods, depending on your needs:

• To set the property value globally for all applications that use the JVM, set networkaddress.cache.ttl in the $JAVA_HOME/jre/lib/security/java.security file.

```java
networkaddress.cache.ttl=60
```

• To set the property locally for your application only, set networkaddress.cache.ttl in your application's initialization code before any network connections are established.

```java
java.security.Security.setProperty("networkaddress.cache.ttl" , "60");
```
Multi-AZ DB cluster deployments

A Multi-AZ DB cluster deployment is a semisynchronous, high availability deployment mode of Amazon RDS with two readable standby DB instances. A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones in the same AWS Region. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower write latency when compared to Multi-AZ DB instance deployments.

You can import data from an on-premises database to a Multi-AZ DB cluster by following the instructions in Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime (p. 1706).

You can purchase reserved DB instances for a Multi-AZ DB cluster. For more information, see Reserved DB instances for a Multi-AZ DB cluster (p. 168).

- Deleting a Multi-AZ DB cluster (p. 563)

Important
Multi-AZ DB clusters aren't the same as Aurora DB clusters. For information about Aurora DB clusters, see the Amazon Aurora User Guide.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with Multi-AZ DB clusters, see Multi-AZ DB clusters (p. 147).

Instance class availability

Multi-AZ DB cluster deployments are supported for a subset of DB instance classes. For a list of supported instance classes, see the DB instance class row in the section called "Available settings" (p. 514).
Overview of Multi-AZ DB clusters

With a Multi-AZ DB cluster, Amazon RDS replicates data from the writer DB instance to both of the reader DB instances using the DB engine's native replication capabilities. When a change is made on the writer DB instance, it's sent to each reader DB instance.

Multi-AZ DB cluster deployments use semisynchronous replication, which requires acknowledgment from at least one reader DB instance in order for a change to be committed. It doesn't require acknowledgment that events have been fully executed and committed on all replicas.

Reader DB instances act as automatic failover targets and also serve read traffic to increase application read throughput. If an outage occurs on your writer DB instance, RDS manages failover to one of the reader DB instances. RDS does this based on which reader DB instance has the most recent change record.

The following diagram shows a Multi-AZ DB cluster.

Multi-AZ DB clusters typically have lower write latency when compared to Multi-AZ DB instance deployments. They also allow read-only workloads to run on reader DB instances. The RDS console
shows the Availability Zone of the writer DB instance and the Availability Zones of the reader DB instances. You can also use the `describe-db-clusters` CLI command or the `DescribeDBClusters` API operation to find this information.

**Important**
To prevent replication errors in RDS for MySQL Multi-AZ DB clusters, we strongly recommend that all tables have a primary key.

## Limitations for Multi-AZ DB clusters

The following limitations apply to Multi-AZ DB clusters:

- Multi-AZ DB clusters only support Provisioned IOPS storage.
- You can't change a Single-AZ DB instance deployment or Multi-AZ DB instance deployment into a Multi-AZ DB cluster. As an alternative, you can restore a snapshot of a Single-AZ DB instance deployment or Multi-AZ DB instance deployment to a Multi-AZ DB cluster.
- You can't change a Multi-AZ DB cluster deployment into a Single-AZ DB instance or Multi-AZ DB instance. As an alternative, you can restore a snapshot of a Multi-AZ DB cluster deployment to a Single-AZ DB instance deployment or Multi-AZ DB instance deployment.
- Multi-AZ DB clusters don't support modifications at the DB instance level because all modifications are done at the DB cluster level.
- RDS for MySQL Multi-AZ DB clusters support replicating from an external MySQL source only if the source has GTID enabled. For more information, see the section called "mysql.rds_set_external_master_with_auto_position" (p. 1788). Position-based binlog replication is not supported.
- Multi-AZ DB clusters don't support the following features:
  - Amazon RDS Proxy
  - Support for IPv6 connections (dual-stack mode)
  - Cross-Region automated backups
  - Exporting Multi-AZ DB cluster snapshot data to an Amazon S3 bucket
  - IAM DB authentication
  - Kerberos authentication
  - Modifying the port

As an alternative, you can restore a Multi-AZ DB cluster to a point in time and specify a different port.
- Option groups
- Point-in-time-recovery (PITR) for deleted clusters
- Restoring a Multi-AZ DB cluster snapshot from an Amazon S3 bucket
- Storage autoscaling by setting the maximum allocated storage

As an alternative, you can scale storage manually.
- Stopping and starting the DB cluster
- Copying a snapshot of a Multi-AZ DB cluster
- Encrypting an unencrypted Multi-AZ DB cluster
- RDS for MySQL Multi-AZ DB clusters don't support replication to an external target database.
- RDS for MySQL Multi-AZ DB clusters support only the following system stored procedures:
  - `mysql.rds_rotate_general_log`
  - `mysql.rds_rotate_slow_log`
  - `mysql.rds_show_configuration`
  - `mysql.rds_set_external_master_with_auto_position`
Managing a Multi-AZ DB cluster with the AWS Management Console

You can manage a Multi-AZ DB cluster with the console.

To manage a Multi-AZ DB cluster with the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the Multi-AZ DB cluster that you want to manage.

The following image shows a Multi-AZ DB cluster in the console.

The available actions in the Actions menu depend on whether the Multi-AZ DB cluster is selected or a DB instance in the cluster is selected.

Choose the Multi-AZ DB cluster to view the cluster details and perform actions at the cluster level.
Choose a DB instance in a Multi-AZ DB cluster to view the DB instance details and perform actions at the DB instance level.

Working with parameter groups for Multi-AZ DB clusters

In a Multi-AZ DB cluster, a **DB cluster parameter group** acts as a container for engine configuration values that are applied to every DB instance in the Multi-AZ DB cluster.

In a Multi-AZ DB cluster, a **DB parameter group** is set to the default DB parameter group for the DB engine and DB engine version. The settings in the DB cluster parameter group are used for all of the DB instances in the cluster.

For information about parameter groups, see [Working with parameter groups](#) (p. 347).

Upgrading the engine version of a Multi-AZ DB cluster

Amazon RDS provides newer versions of each supported database engine so you can keep your Multi-AZ DB cluster up-to-date. When Amazon RDS supports a new version of a database engine, you can choose how and when to upgrade your Multi-AZ DB cluster. When you initiate an upgrade, the writer DB instance is upgraded first, then the reader DB instances are upgraded simultaneously.

There are two kinds of upgrades: major version upgrades and minor version upgrades. In general, a **major engine version upgrade** can introduce changes that aren't compatible with existing applications. In contrast, a **minor version upgrade** includes only changes that are backward-compatible with existing applications.

**Note**
Currently, major version upgrades are only supported for RDS for PostgreSQL Multi-AZ DB clusters. Minor version upgrades are supported for all DB engines that support Multi-AZ DB clusters.

Amazon RDS doesn't automatically upgrade Multi-AZ DB cluster read replicas. For **minor version upgrades**, you must first manually upgrade all read replicas and then upgrade the cluster, otherwise the upgrade is blocked. When you perform a **major version upgrade** of a cluster, the replication state of all read replicas changes to **terminated**. You must delete and recreate the read replicas after the upgrade completes. For more information, see the section called "Monitoring read replication" (p. 449).

The process for upgrading the engine version of a Multi-AZ DB cluster is the same as the process for upgrading a DB instance engine version. For instructions, see the section called "Upgrading the engine
version" (p. 429). The only difference is that when using the AWS CLI, you use the `modify-db-cluster` command and specify the `--db-cluster-identifier` parameter (as well as the `--allow-major-version-upgrade` parameter).

For more information about major and minor version upgrades for RDS for PostgreSQL, see the following documentation for your DB engine:

- the section called “Upgrading the PostgreSQL DB engine” (p. 2214)
- the section called “Upgrading the MySQL DB engine” (p. 1680)

### Replica lag and Multi-AZ DB clusters

*Replica lag* is the difference in time between the latest transaction on the writer DB instance and the latest applied transaction on a reader DB instance. The Amazon CloudWatch metric `ReplicaLag` represents this time difference. For more information about CloudWatch metrics, see Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 706).

Although Multi-AZ DB clusters allow for high write performance, replica lag can still occur due to the nature of engine-based replication. Because any failover must first resolve the replica lag before it promotes a new writer DB instance, monitoring and managing this replica lag is a consideration.

For RDS for MySQL Multi-AZ DB clusters, failover time depends on replica lag of both remaining reader DB instances. Both the reader DB instances must apply unapplied transactions before one of them is promoted to the new writer DB instance.

For RDS for PostgreSQL Multi-AZ DB clusters, failover time depends on the lowest replica lag of the two remaining reader DB instances. The reader DB instance with the lowest replica lag must apply unapplied transactions before it is promoted to the new writer DB instance.

For a tutorial that shows you how to create a CloudWatch alarm when replica lag exceeds a set amount of time, see Tutorial: Creating an Amazon CloudWatch alarm for Multi-AZ DB cluster replica lag (p. 713).

### Common causes of replica lag

In general, replica lag occurs when the write workload is too high for the reader DB instances to apply the transactions efficiently. Various workloads can incur temporary or continuous replica lag. Some examples of common causes are the following:

- High write concurrency or heavy batch updating on the writer DB instance, causing the apply process on the reader DB instances to fall behind.
- Heavy read workload that is using resources on one or more reader DB instances. Running slow or large queries can affect the apply process and can cause replica lag.
- Transactions that modify large amounts of data or DDL statements can sometimes cause a temporary increase in replica lag because the database must preserve commit order.

### Mitigating replica lag

For Multi-AZ DB clusters for RDS for MySQL and RDS for PostgreSQL, you can mitigate replica lag by reducing the load on your writer DB instance. You can also use flow control to reduce replica lag. **Flow control** works by throttling writes on the writer DB instance, which ensures that replica lag doesn’t continue to grow unbounded. Write throttling is accomplished by adding a delay into the end of a transaction, which decreases the write throughput on the writer DB instance. Although flow control doesn’t guarantee lag elimination, it can help reduce overall lag in many workloads. The following sections provide information about using flow control with RDS for MySQL and RDS for PostgreSQL.
Mitigating replica lag with flow control for RDS for MySQL

When you are using RDS for MySQL Multi-AZ DB clusters, flow control is turned on by default using the dynamic parameter `rpl_semi_sync_master_target_apply_lag`. This parameter specifies the upper limit that you want for replica lag. As replica lag approaches this configured limit, flow control throttles the write transactions on the writer DB Instance to try to contain the replica lag below the specified value. In some cases, replica lag can exceed the specified limit. By default, this parameter is set to 120 seconds. To turn off flow control, set this parameter to its maximum value of 86400 seconds (one day).

To view the current delay injected by flow control, show the parameter `Rpl_semi_sync_master_flow_control_current_delay` by running the following query.

```sql
SHOW GLOBAL STATUS like '%flow_control%';
```

Your output looks similar to the following.

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rpl_semi_sync_master_flow_control_current_delay</td>
<td>2010</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

**Note**
The delay is shown in microseconds.

When you have Performance Insights turned on for an RDS for MySQL Multi-AZ DB cluster, you can monitor the wait event corresponding to a SQL statement indicating that the queries were delayed by a flow control. When a delay was introduced by a flow control, you can view the wait event `/wait/synch/cond/semisync/semi_sync_flow_control_delay_cond` corresponding to the SQL statement on the Performance Insights dashboard. To view these metrics, make sure that the Performance Schema is turned on. For information about Performance Insights, see [Monitoring DB load with Performance Insights on Amazon RDS](p. 720).

Mitigating replica lag with flow control for RDS for PostgreSQL

When you are using RDS for PostgreSQL Multi-AZ DB clusters, flow control is deployed as an extension. It turns on a background worker for all DB instances in the DB cluster. By default, the background workers on the reader DB instances communicate the current replica lag with the background worker on the writer DB instance. If the lag exceeds two minutes on any reader DB instance, the background worker on the writer DB instance adds a delay at the end of a transaction. To control the lag threshold, use the parameter `flow_control.target_standby_apply_lag`.

When a flow control throttles a PostgreSQL process, the Extension wait event in `pg_stat_activity` and Performance Insights indicates that. The function `get_flow_control_stats` displays details about how much delay is currently being added.

Flow control can benefit most online transaction processing (OLTP) workloads that have short but highly concurrent transactions. If the lag is caused by long-running transactions, such as batch operations, flow control doesn't provide as strong a benefit.

You can turn off flow control by removing the extension from the `preload_shared_libraries` and rebooting your DB instance.

Failover process for Multi-AZ DB clusters

If there is a planned or unplanned outage of your writer DB instance in a Multi-AZ DB cluster, Amazon RDS automatically fails over to a reader DB instance in different Availability Zone. The time it takes for
the failover to complete depends on the database activity and other conditions when the writer DB instance became unavailable. Failover times are typically under 35 seconds. Failover completes when both reader DB instances have applied outstanding transactions from the failed writer. When the failover is complete, it can take additional time for the RDS console to reflect the new Availability Zone.

**Topics**
- Automatic failovers (p. 506)
- Manually failing over a Multi-AZ DB cluster (p. 506)
- Determining whether a Multi-AZ DB cluster has failed over (p. 506)
- Setting the JVM TTL for DNS name lookups (p. 507)

**Automatic failovers**

Amazon RDS handles failovers automatically so you can resume database operations as quickly as possible without administrative intervention. To fail over, the writer DB instance switches automatically to a reader DB instance.

**Manually failing over a Multi-AZ DB cluster**

You can fail over a Multi-AZ DB cluster manually using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

To fail over a Multi-AZ DB cluster manually
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Multi-AZ DB cluster that you want to fail over.
4. For Actions, choose Failover.
   - The Failover DB Cluster page appears.
5. Choose Failover to confirm the manual failover.

**AWS CLI**

To fail over a Multi-AZ DB cluster manually, use the AWS CLI command `rds:failover-db-cluster`.

**Example**

```
aws rds failover-db-cluster --db-cluster-identifier mymultiazdbcluster
```

**RDS API**

To fail over a Multi-AZ DB cluster manually, call the Amazon RDS API `FailoverDBCluster` and specify the `DBClusterIdentifier`.

**Determining whether a Multi-AZ DB cluster has failed over**

To determine if your Multi-AZ DB cluster has failed over, you can do the following:

- Set up DB event subscriptions to notify you by email or SMS that a failover has been initiated. For more information about events, see Working with Amazon RDS event notification (p. 855).
• View your DB events by using the Amazon RDS console or API operations.
• View the current state of your Multi-AZ DB cluster by using the Amazon RDS console, the AWS CLI, and the RDS API.

For information on how you can respond to failovers, reduce recovery time, and other best practices for Amazon RDS, see Best practices for Amazon RDS (p. 286).

Setting the JVM TTL for DNS name lookups

The failover mechanism automatically changes the Domain Name System (DNS) record of the DB instance to point to the reader DB instance. As a result, you need to re-establish any existing connections to your DB instance. In a Java virtual machine (JVM) environment, due to how the Java DNS caching mechanism works, you might need to reconfigure JVM settings.

The JVM caches DNS name lookups. When the JVM resolves a host name to an IP address, it caches the IP address for a specified period of time, known as the time-to-live (TTL).

Because AWS resources use DNS name entries that occasionally change, we recommend that you configure your JVM with a TTL value of no more than 60 seconds. Doing this makes sure that when a resource's IP address changes, your application can receive and use the resource's new IP address by requerying the DNS.

On some Java configurations, the JVM default TTL is set so that it never refreshes DNS entries until the JVM is restarted. Thus, if the IP address for an AWS resource changes while your application is still running, it can't use that resource until you manually restart the JVM and the cached IP information is refreshed. In this case, it's crucial to set the JVM's TTL so that it periodically refreshes its cached IP information.

Note
The default TTL can vary according to the version of your JVM and whether a security manager is installed. Many JVMs provide a default TTL less than 60 seconds. If you're using such a JVM and not using a security manager, you can ignore the rest of this topic. For more information on security managers in Oracle, see The security manager in the Oracle documentation.

To modify the JVM's TTL, set the networkaddress.cache.ttl property value. Use one of the following methods, depending on your needs:

• To set the property value globally for all applications that use the JVM, set networkaddress.cache.ttl in the $JAVA_HOME/jre/lib/security/java.security file.

```java
networkaddress.cache.ttl=60
```

• To set the property locally for your application only, set networkaddress.cache.ttl in your application's initialization code before any network connections are established.

```java
java.security.Security.setProperty("networkaddress.cache.ttl" , "60");
```
Creating a Multi-AZ DB cluster

A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower latency when compared to Multi-AZ deployments. For more information about Multi-AZ DB clusters, see Multi-AZ DB cluster deployments (p. 499).

Note
Multi-AZ DB clusters are supported only for the MySQL and PostgreSQL DB engines.

DB cluster prerequisites

Important
Before you can create a Multi-AZ DB cluster, you must complete the tasks in Setting up for Amazon RDS (p. 174).

The following are prerequisites to complete before creating a Multi-AZ DB cluster.

Topics
- Configure the network for the DB cluster (p. 508)
- Additional prerequisites (p. 511)

Configure the network for the DB cluster

You can create a Multi-AZ DB cluster only in a virtual private cloud (VPC) based on the Amazon VPC service. It must be in an AWS Region that has at least three Availability Zones. The DB subnet group that you choose for the DB cluster must cover at least three Availability Zones. This configuration ensures that each DB instance in the DB cluster is in a different Availability Zone.

To set up connectivity between your new DB cluster and an Amazon EC2 instance in the same VPC, do so when you create the DB cluster. To connect to your DB cluster from resources other than EC2 instances in the same VPC, configure the network connections manually.

Topics
- Configure automatic network connectivity with an EC2 instance (p. 508)
- Configure the network manually (p. 510)

Configure automatic network connectivity with an EC2 instance

When you create a Multi-AZ DB cluster, you can use the AWS Management Console to set up connectivity between an EC2 instance and the new DB cluster. When you do so, RDS configures your VPC and network settings automatically. The DB cluster is created in the same VPC as the EC2 instance so that the EC2 instance can access the DB cluster.

The following are requirements for connecting an EC2 instance with the DB cluster:

- The EC2 instance must exist in the AWS Region before you create the DB cluster.

  If no EC2 instances exist in the AWS Region, the console provides a link to create one.
- The user who is creating the DB cluster must have permissions to perform the following operations:
  - ec2:AssociateRouteTable
  - ec2:AuthorizeSecurityGroupEgress
  - ec2:AuthorizeSecurityGroupIngress
  - ec2:CreateRouteTable

508
• ec2:CreateSubnet
• ec2:CreateSecurityGroup
• ec2:DescribeInstances
• ec2:DescribeNetworkInterfaces
• ec2:DescribeRouteTables
• ec2:DescribeSecurityGroups
• ec2:DescribeSubnets
• ec2:ModifyNetworkInterfaceAttribute
• ec2:RevokeSecurityGroupEgress

Using this option creates a private DB cluster. The DB cluster uses a DB subnet group with only private subnets to restrict access to resources within the VPC.

To connect an EC2 instance to the DB cluster, choose Connect to an EC2 compute resource in the Connectivity section on the Create database page.

---

**Connectivity Info**

**Compute resource**
Choose whether to set up a connection to a compute resource for this database. Setting up a connection will automatically change connectivity settings so that the compute resource can connect to this database.

- **Don’t connect to an EC2 compute resource**
  Don’t set up a connection to a compute resource for this database. You can manually set up a connection to a compute resource later.

- **Connect to an EC2 compute resource**
  Set up a connection to an EC2 compute resource for this database.

**EC2 Instance Info**
Choose the EC2 instance to add as the compute resource for this database. A VPC security group is added to this EC2 instance. A VPC security group is also added to the database with an inbound rule that allows the EC2 instance to access the database.

Choose EC2 instances

---

When you choose Connect to an EC2 compute resource, RDS sets the following options automatically. You can’t change these settings unless you choose not to set up connectivity with an EC2 instance by choosing Don’t connect to an EC2 compute resource.

<table>
<thead>
<tr>
<th>Console option</th>
<th>Automatic setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual Private Cloud (VPC)</td>
<td>RDS sets the VPC to the one associated with the EC2 instance.</td>
</tr>
<tr>
<td>DB subnet group</td>
<td>RDS requires a DB subnet group with a private subnet in the same Availability Zone as the EC2 instance. If a DB subnet group that meets this requirement exists, then RDS uses the existing DB subnet group. By default, this option is set to Automatic setup. When you choose Automatic setup and there is no DB subnet group that meets this requirement, the following action happens. RDS uses three available private subnets in three Availability Zones where one of the Availability Zones is the same as the EC2 instance. If a private subnet isn't available in an Availability Zone, RDS creates a private subnet in the Availability Zone. Then RDS creates the DB subnet group.</td>
</tr>
</tbody>
</table>
### Console option

<table>
<thead>
<tr>
<th></th>
<th>Automatic setting</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>When a private subnet is available, RDS uses the route table associated with the subnet and adds any subnets it creates to this route table. When no private subnet is available, RDS creates a route table without internet gateway access and adds the subnets it creates to the route table. RDS also allows you to use existing DB subnet groups. Select <strong>Choose existing</strong> if you want to use an existing DB subnet group of your choice.</td>
</tr>
</tbody>
</table>

### Public access

|                        | RDS chooses **No** so that the DB cluster isn't publicly accessible. For security, it is a best practice to keep the database private and make sure it isn't accessible from the internet. |

### VPC security group (firewall)

|                        | RDS creates a new security group that is associated with the DB cluster. The security group is named `rds-ec2-n`, where `n` is a number. This security group includes an inbound rule with the EC2 VPC security group (firewall) as the source. This security group that is associated with the DB cluster allows the EC2 instance to access the DB cluster. RDS also creates a new security group that is associated with the EC2 instance. The security group is named `ec2-rds-n`, where `n` is a number. This security group includes an outbound rule with the VPC security group of the DB cluster as the source. This security group allows the EC2 instance to send traffic to the DB cluster. You can add another new security group by choosing **Create new** and typing the name of the new security group. You can add existing security groups by choosing **Choose existing** and selecting security groups to add. |

### Availability Zone

|                        | RDS chooses the Availability Zone of the EC2 instance for one DB instance in the Multi-AZ DB cluster deployment. RDS randomly chooses a different Availability Zone for both of the other DB instances. The writer DB instance is created in the same Availability Zone as the EC2 instance. There is the possibility of cross Availability Zone costs if a failover occurs and the writer DB instance is in a different Availability Zone. For more information about these settings, see **Settings for creating Multi-AZ DB clusters** (p. 514). If you change these settings after the DB cluster is created, the changes might affect the connection between the EC2 instance and the DB cluster. **Configure the network manually** To connect to your DB cluster from resources other than EC2 instances in the same VPC, configure the network connections manually. If you use the AWS Management Console to create your Multi-AZ DB cluster, you can have Amazon RDS automatically create a VPC for you. Or you can use an existing VPC or create a new VPC for your Multi-AZ DB cluster. Your VPC must have at least one subnet in each of at least three Availability Zones for you to use it with a Multi-AZ DB cluster. For information on VPCs, see **Amazon VPC, VPCs and Amazon RDS** (p. 2705). If you don't have a default VPC or you haven't created a VPC, and you don't plan to use the console, do the following: |
• Create a VPC with at least one subnet in each of at least three of the Availability Zones in the AWS Region where you want to deploy your DB cluster. For more information, see *Working with a DB instance in a VPC* (p. 2706).

• Specify a VPC security group that authorizes connections to your DB cluster. For more information, see *Provide access to your DB instance in your VPC by creating a security group* (p. 177) and *Controlling access with security groups* (p. 2697).

• Specify an RDS DB subnet group that defines at least three subnets in the VPC that can be used by the Multi-AZ DB cluster. For more information, see *Working with DB subnet groups* (p. 2706).

For information about limitations that apply to Multi-AZ DB clusters, see *Limitations for Multi-AZ DB clusters* (p. 501).

If you want to connect to a resource that isn't in the same VPC as the Multi-AZ DB cluster, see the appropriate scenarios in *Scenarios for accessing a DB instance in a VPC* (p. 2718).

**Additional prerequisites**

Before you create your Multi-AZ DB cluster, consider the following additional prerequisites:

• To connect to AWS using AWS Identity and Access Management (IAM) credentials, your AWS account must have certain IAM policies. These grant the permissions required to perform Amazon RDS operations. For more information, see *Identity and access management for Amazon RDS* (p. 2623).

If you use IAM to access the RDS console, first sign in to the AWS Management Console with your IAM user credentials. Then go to the RDS console at https://console.aws.amazon.com/rds/.

• To tailor the configuration parameters for your DB cluster, specify a DB cluster parameter group with the required parameter settings. For information about creating or modifying a DB cluster parameter group, see *Working with parameter groups for Multi-AZ DB clusters* (p. 503).

• Determine the TCP/IP port number to specify for your DB cluster. The firewalls at some companies block connections to the default ports. If your company firewall blocks the default port, choose another port for your DB cluster. All DB instances in a DB cluster use the same port.

**Creating a DB cluster**

You can create a Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

You can create a Multi-AZ DB cluster by choosing *Multi-AZ DB cluster* in the *Availability and durability* section.

**To create a Multi-AZ DB cluster using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the DB cluster.
3. For information about the AWS Regions that support Multi-AZ DB clusters, see *Limitations for Multi-AZ DB clusters* (p. 501).
4. In the navigation pane, choose *Databases*.
5. Choose *Create database*.

To create a Multi-AZ DB cluster, make sure that *Standard Create* is selected and *Easy Create* isn't.
5. In **Engine type**, choose MySQL or PostgreSQL.
6. For **Version**, choose the DB engine version.
   
   For information about the DB engine versions that support Multi-AZ DB clusters, see **Limitations for Multi-AZ DB clusters (p. 501)**.
7. In **Templates**, choose the appropriate template for your deployment.
8. In **Availability and durability**, choose **Multi-AZ DB cluster**.

   ![Availability and durability](image)

9. In **DB cluster identifier**, enter the identifier for your DB cluster.
10. In **Master username**, enter your master user name, or keep the default setting.
11. Enter your master password:
   
   a. In the **Settings** section, open **Credential Settings**.
   
   b. If you want to specify a password, clear the **Auto generate a password** box if it is selected.
   
   c. (Optional) Change the **Master username** value.
   
   d. Enter the same password in **Master password** and **Confirm password**.
12. For **DB instance class**, choose a DB instance class. For supported instance classes, see the **DB instance class** row in the section called "Available settings" (p. 514).
13. (Optional) Set up a connection to a compute resource for this DB cluster.
   
   You can configure connectivity between an Amazon EC2 instance and the new DB cluster during DB cluster creation. For more information, see **Configure automatic network connectivity with an EC2 instance (p. 508)**.
14. In the **Connectivity** section under **VPC security group (firewall)**, if you select **Create new**, a VPC security group is created with an inbound rule that allows your local computer's IP address to access the database.
15. For the remaining sections, specify your DB cluster settings. For information about each setting, see **Settings for creating Multi-AZ DB clusters (p. 514)**.
16. Choose **Create database**.

   If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

   To view the master user name and password for the DB cluster, choose **View credential details**.

   To connect to the DB cluster as the master user, use the user name and password that appear.

   **Important**
   
   You can't view the master user password again.
17. For **Databases**, choose the name of the new DB cluster.
On the RDS console, the details for the new DB cluster appear. The DB cluster has a status of **Creating** until the DB cluster is created and ready for use. When the state changes to **Available**, you can connect to the DB cluster. Depending on the DB cluster class and storage allocated, it can take several minutes for the new DB cluster to be available.

**AWS CLI**

Before you create a Multi-AZ DB cluster using the AWS CLI, make sure to fulfill the required prerequisites. These include creating a VPC and an RDS DB subnet group. For more information, see [DB cluster prerequisites](p. 508).

To create a Multi-AZ DB cluster by using the AWS CLI, call the `create-db-cluster` command. Specify the `--db-cluster-identifier`. For the `--engine` option, specify either `mysql` or `postgres`.

For information about each option, see [Settings for creating Multi-AZ DB clusters](p. 514).

For information about the AWS Regions, DB engines, and DB engine versions that support Multi-AZ DB clusters, see [Limitations for Multi-AZ DB clusters](p. 501).

The `create-db-cluster` command creates the writer DB instance for your DB cluster, and two reader DB instances. Each DB instance is in a different Availability Zone.

For example, the following command creates a MySQL 8.0 Multi-AZ DB cluster named `mysql-multi-az-db-cluster`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster \
  --db-cluster-identifier mysql-multi-az-db-cluster \
  --engine mysql \
  --engine-version 8.0.28 \
  --master-username admin \
  --manage-master-user-password \
  --port 3306 \
  --backup-retention-period 1 \
  --db-subnet-group-name default \
  --allocated-storage 4000 \
  --storage-type io1 \
  --iops 10000 \
  --db-cluster-instance-class db.m5d.xlarge
```

For Windows:

```bash
aws rds create-db-cluster ^
  --db-cluster-identifier mysql-multi-az-db-cluster ^
  --engine mysql ^
  --engine-version 8.0.28 ^
  --manage-master-user-password ^
  --master-username admin ^
  --port 3306 ^
  --backup-retention-period 1 ^
  --db-subnet-group-name default ^
  --allocated-storage 4000 ^
  --storage-type io1 ^
  --iops 10000 ^
  --db-cluster-instance-class db.m5d.xlarge
```

The following command creates a PostgreSQL 13.4 Multi-AZ DB cluster named `postgresql-multi-az-db-cluster`. 

---

513
Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster
    --db-cluster-identifier postgresql-multi-az-db-cluster
    --engine postgres
    --engine-version 13.4
    --manage-master-user-password
    --master-username postgres
    --port 5432
    --backup-retention-period 1
    --db-subnet-group-name default
    --allocated-storage 4000
    --storage-type io1
    --iops 10000
    --db-cluster-instance-class db.m5d.xlarge
```

For Windows:

```bash
aws rds create-db-cluster
    --db-cluster-identifier postgresql-multi-az-db-cluster
    --engine postgres
    --engine-version 13.4
    --manage-master-user-password
    --master-username postgres
    --port 5432
    --backup-retention-period 1
    --db-subnet-group-name default
    --allocated-storage 4000
    --storage-type io1
    --iops 10000
    --db-cluster-instance-class db.m5d.xlarge
```

RDS API

Before you can create a Multi-AZ DB cluster using the RDS API, make sure to fulfill the required prerequisites, such as creating a VPC and an RDS DB subnet group. For more information, see DB cluster prerequisites (p. 508).

To create a Multi-AZ DB cluster by using the RDS API, call the CreateDBCluster operation. Specify the DBClusterIdentifier. For the Engine parameter, specify either mysql or postgresql.

For information about each option, see Settings for creating Multi-AZ DB clusters (p. 514).

The CreateDBCluster operation creates the writer DB instance for your DB cluster, and two reader DB instances. Each DB instance is in a different Availability Zone.

Settings for creating Multi-AZ DB clusters

For details about settings that you choose when you create a Multi-AZ DB cluster, see the following table. For more information about the AWS CLI options, see create-db-cluster. For more information about the RDS API parameters, see CreateDBCluster.

<table>
<thead>

</tbody>
</table>
| Auto minor version upgrade | Enable auto minor version upgrade to have your DB cluster receive preferred minor DB engine version upgrades automatically when they become available. Amazon RDS performs automatic minor version upgrades in the maintenance window.                                                                                                                                                                                                                             | CLI option:  
`--auto-minor-version-upgrade`  
`--no-auto-minor-version-upgrade`  
API parameter:  
`AutoMinorVersionUpgrade`                                                                                                                     |
| Backup retention period | The number of days that you want automatic backups of your DB cluster to be retained. For a Multi-AZ DB cluster, this value must be set to 1 or greater.                                                                                                                                                                                                                     | CLI option:  
`--backup-retention-period`  
API parameter:  
`BackupRetentionPeriod`                                                                                                                                                                       |
| Copy tags to snapshots | This option copies any DB cluster tags to a DB snapshot when you create a snapshot.                                                                                                                                                                                                                                                                                                                                                                     | CLI option:  
`-copy-tags-to-snapshot`  
`-no-copy-tags-to-snapshot`  
RDS API parameter:  
`CopyTagsToSnapshot`                                                                                       |
<table>

</thead>
</table>
| DB cluster identifier   | The name for your DB cluster. Name your DB clusters in the same way that you name your on-premises servers. Your DB cluster identifier can contain up to 63 alphanumeric characters, and must be unique for your account in the AWS Region you chose.                                                                                     | **CLI option:** --db-cluster-identifier  
**RDS API parameter:** DBClusterIdentifier                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| DB instance class       | The compute and memory capacity of each DB instance in the Multi-AZ DB cluster, for example `db.m5d.xlarge`. If possible, choose a DB instance class large enough that a typical query working set can be held in memory. When working sets are held in memory the system can avoid writing to disk, which improves performance. Currently, Multi-AZ DB clusters only support `db.m5d`, `db.m6gd`, `db.r5d`, `db.m5d`, and `db.x2iedn` DB instance classes. For more information about DB instance classes, see [DB instance classes](p. 11). | **CLI option:** --db-cluster-instance-class  
**RDS API parameter:** DBClusterInstanceClass                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| DB cluster parameter group | The DB cluster parameter group that you want associated with the DB cluster. For more information, see [Working with parameter groups for Multi-AZ DB clusters](p. 503).                                                                                                                                                                                                                                                                                                                                                           | **CLI option:** --db-cluster-parameter-group-name  
**RDS API parameter:** DBClusterParameterGroupName                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| DB engine version       | The version of database engine that you want to use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | **CLI option:** --engine-version  
**RDS API parameter:** EngineVersion                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
<p>| DB parameter group      | The DB instance parameter group that you want associated with the DB instances in the DB cluster. For more information, see [Working with parameter groups for Multi-AZ DB clusters](p. 503). Not applicable. Amazon RDS associates each DB instance with the appropriate default parameter group.                                                                                             | Not applicable. Amazon RDS associates each DB instance with the appropriate default parameter group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |</p>

| **DB subnet group** | The DB subnet group you want to use for the DB cluster. Select **Choose existing** to use an existing DB subnet group. Then choose the required subnet group from the **Existing DB subnet groups** dropdown list. Choose **Automatic setup** to let RDS select a compatible DB subnet group. If none exist, RDS creates a new subnet group for your cluster. For more information, see **Working with DB subnet groups (p. 2706)**. | **CLI option:**
--db-subnet-group-name

**RDS API parameter:**
DBSubnetGroupName |
| **Deletion protection** | Enable deletion protection to prevent your DB cluster from being deleted. If you create a production DB cluster with the console, deletion protection is turned on by default. For more information, see **Deleting a DB instance (p. 489)**. | **CLI option:**
--deletion-protection
--no-deletion-protection

**RDS API parameter:**
DeletionProtection |
| **Encryption** | Enable Encryption to turn on encryption at rest for this DB cluster. Encryption is turned on by default for Multi-AZ DB clusters. For more information, see **Encrypting Amazon RDS resources (p. 2603)**. | **CLI options:**
--kms-key-id
--storage-encrypted
--no-storage-encrypted

**RDS API parameters:**

KmsKeyId
StorageEncrypted |
| **Enhanced Monitoring** | Enable enhanced monitoring to turn on metrics gathering in real time for the operating system that your DB cluster runs on. For more information, see **Monitoring OS metrics with Enhanced Monitoring (p. 797)**. | **CLI options:**
--monitoring-interval
--monitoring-role-arn

**RDS API parameters:**

MonitoringInterval
MonitoringRoleArn |

| Initial database name           | The name for the database on your DB cluster. If you don't provide a name, Amazon RDS doesn't create a database on the DB cluster for MySQL. However, it does create a database on the DB cluster for PostgreSQL. The name can't be a word reserved by the database engine. It has other constraints depending on the DB engine. MySQL:  
   • It must contain 1–64 alphanumeric characters.  
   PostgreSQL:  
   • It must contain 1–63 alphanumeric characters.  
   • It must begin with a letter or an underscore. Subsequent characters can be letters, underscores, or digits (0-9).  
   • The initial database name is postgres. | CLI option:  
   --database-name  
   RDS API parameter:  
   DatabaseName |
| Log exports                     | The types of database log files to publish to Amazon CloudWatch Logs.                                                                                                                                                  | CLI option:  
   -enable-cloudwatch-logs-exports  
   RDS API parameter:  
   EnableCloudwatchLogsExports |
| Maintenance window              | The 30-minute window in which pending modifications to your DB cluster are applied. If the time period doesn't matter, choose No preference. For more information, see The Amazon RDS maintenance window (p. 423). | CLI option:  
   --preferred-maintenance-window  
   RDS API parameter:  
   PreferredMaintenanceWindow |
| Manage master credentials in AWS Secrets Manager | Select Manage master credentials in AWS Secrets Manager to manage the master user password in a secret in Secrets Manager. Optionally, choose a KMS key to use to protect the secret. Choose from the KMS keys in your account, or enter the key from a different account. For more information, see Password management with Amazon RDS and AWS Secrets Manager (p. 2585). | CLI option:  
   --manage-master-user-password | 
   --no-manage-master-user-password  
   --master-user-secret-kms-key-id  
   RDS API parameter:  
   ManageMasterUserPassword  
   MasterUserSecretKmsKeyId |
<table>

| **Master password** | The password for your master user account. | **CLI option:**  
| |  
| | **RDS API parameter:**  
| | MasterUserPassword |
| **Master username** | The name that you use as the master user name to log on to your DB cluster with all database privileges.  
| | • It can contain 1–16 alphanumeric characters and underscores.  
| | • Its first character must be a letter.  
| | • It can't be a word reserved by the database engine.  
| |  
| | You can’t change the master user name after the Multi-AZ DB cluster is created.  
| | For more information on privileges granted to the master user, see [Master user account privileges](p. 2699). | **CLI option:**  
| | **RDS API parameter:**  
| | MasterUsername |
| **Performance Insights** | Enable Performance Insights to monitor your DB cluster load so that you can analyze and troubleshoot your database performance.  
| | Choose a retention period to determine how much Performance Insights data history to keep. The retention setting in the free tier is Default (7 days). To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see [Pricing and data retention for Performance Insights](p. 726).  
| | Choose a master key to use to protect the key used to encrypt this database volume. Choose from the master keys in your account, or enter the key from a different account.  
| | For more information, see [Monitoring DB load with Performance Insights on Amazon RDS](p. 720). | **CLI options:**  
| | **RDS API parameters:**  
| | EnablePerformanceInsights  
| | PerformanceInsightsRetentionPeriod  
<p>| | PerformanceInsightsKMSKeyId |</p>
<table>
<thead>
<tr>

Connecting to a Multi-AZ DB cluster

A Multi-AZ DB cluster has three DB instances instead of a single DB instance. Each connection is handled by a specific DB instance. When you connect to a Multi-AZ DB cluster, the hostname and port that you specify point to a fully qualified domain name called an *endpoint*. The Multi-AZ DB cluster uses the endpoint mechanism to abstract these connections so that you don't need to specify exactly which DB instance in the DB cluster to connect to. Thus, you don't have to hardcode all the hostnames or write your own logic for rerouting connections when some DB instances aren't available.

The writer endpoint connects to the writer DB instance of the DB cluster, which supports both read and write operations. The reader endpoint connects to either of the two reader DB instances, which support only read operations.

Using endpoints, you can map each connection to the appropriate DB instance or group of DB instances based on your use case. For example, to perform DDL and DML statements, you can connect to whichever DB instance is the writer DB instance. To perform queries, you can connect to the reader endpoint, with the Multi-AZ DB cluster automatically managing connections among the reader DB instances. For diagnosis or tuning, you can connect to a specific DB instance endpoint to examine details about a specific DB instance.

For information about connecting to a DB instance, see [Connecting to an Amazon RDS DB instance](p. 325).

Topics

- Types of Multi-AZ DB cluster endpoints (p. 522)
- Viewing the endpoints for a Multi-AZ DB cluster (p. 523)
- Using the cluster endpoint (p. 523)
- Using the reader endpoint (p. 524)
- Using the instance endpoints (p. 524)
- How Multi-AZ DB endpoints work with high availability (p. 524)

Types of Multi-AZ DB cluster endpoints

An endpoint is represented by a unique identifier that contains a host address. The following types of endpoints are available from a Multi-AZ DB cluster:

Cluster endpoint

*A cluster endpoint* (or *writer endpoint*) for a Multi-AZ DB cluster connects to the current writer DB instance for that DB cluster. This endpoint is the only one that can perform write operations such as DDL and DML statements. This endpoint can also perform read operations.

Each Multi-AZ DB cluster has one cluster endpoint and one writer DB instance.

You use the cluster endpoint for all write operations on the DB cluster, including inserts, updates, deletes, and DDL changes. You can also use the cluster endpoint for read operations, such as queries.

If the current writer DB instance of a DB cluster fails, the Multi-AZ DB cluster automatically fails over to a new writer DB instance. During a failover, the DB cluster continues to serve connection requests to the cluster endpoint from the new writer DB instance, with minimal interruption of service.

The following example illustrates a cluster endpoint for a Multi-AZ DB cluster.

`mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com`
Reader endpoint

A **reader endpoint** for a Multi-AZ DB cluster provides support for read-only connections to the DB cluster. Use the reader endpoint for read operations, such as SELECT queries. By processing those statements on the reader DB instances, this endpoint reduces the overhead on the writer DB instance. It also helps the cluster to scale the capacity to handle simultaneous SELECT queries. Each Multi-AZ DB cluster has one reader endpoint.

The reader endpoint sends each connection request to one of the reader DB instances. When you use the reader endpoint for a session, you can only perform read-only statements such as SELECT in that session.

The following example illustrates a reader endpoint for a Multi-AZ DB cluster. The read-only intent of a reader endpoint is denoted by the `-ro` within the cluster endpoint name.

```
mydbcluster.cluster-ro-123456789012.us-east-1.rds.amazonaws.com
```

Instance endpoint

An **instance endpoint** connects to a specific DB instance within a Multi-AZ DB cluster. Each DB instance in a DB cluster has its own unique instance endpoint. So there is one instance endpoint for the current writer DB instance of the DB cluster, and there is one instance endpoint for each of the reader DB instances in the DB cluster.

The instance endpoint provides direct control over connections to the DB cluster. This control can help you address scenarios where using the cluster endpoint or reader endpoint might not be appropriate. For example, your client application might require more fine-grained load balancing based on workload type. In this case, you can configure multiple clients to connect to different reader DB instances in a DB cluster to distribute read workloads.

The following example illustrates an instance endpoint for a DB instance in a Multi-AZ DB cluster.

```
mydbinstance.123456789012.us-east-1.rds.amazonaws.com
```

Viewing the endpoints for a Multi-AZ DB cluster

In the AWS Management Console, you see the cluster endpoint and the reader endpoint on the details page for each Multi-AZ DB cluster. You see the instance endpoint in the details page for each DB instance.

With the AWS CLI, you see the writer and reader endpoints in the output of the `describe-db-clusters` command. For example, the following command shows the endpoint attributes for all clusters in your current AWS Region.

```
aws rds describe-db-cluster-endpoints
```

With the Amazon RDS API, you retrieve the endpoints by calling the `DescribeDBClusterEndpoints` action. The output also shows Amazon Aurora DB cluster endpoints, if any exist.

Using the cluster endpoint

Each Multi-AZ DB cluster has a single built-in cluster endpoint, whose name and other attributes are managed by Amazon RDS. You can't create, delete, or modify this kind of endpoint.

You use the cluster endpoint when you administer your DB cluster, perform extract, transform, load (ETL) operations, or develop and test applications. The cluster endpoint connects to the writer DB instance of the cluster. The writer DB instance is the only DB instance where you can create tables and indexes, run INSERT statements, and perform other DDL and DML operations.
The physical IP address pointed to by the cluster endpoint changes when the failover mechanism promotes a new DB instance to be the writer DB instance for the cluster. If you use any form of connection pooling or other multiplexing, be prepared to flush or reduce the time-to-live for any cached DNS information. Doing so ensures that you don't try to establish a read/write connection to a DB instance that became unavailable or is now read-only after a failover.

**Using the reader endpoint**

You use the reader endpoint for read-only connections to your Multi-AZ DB cluster. This endpoint helps your DB cluster handle a query-intensive workload. The reader endpoint is the endpoint that you supply to applications that do reporting or other read-only operations on the cluster. The reader endpoint sends connections to available reader DB instances in a Multi-AZ DB cluster.

Each Multi-AZ cluster has a single built-in reader endpoint, whose name and other attributes are managed by Amazon RDS. You can't create, delete, or modify this kind of endpoint.

**Using the instance endpoints**

Each DB instance in a Multi-AZ DB cluster has its own built-in instance endpoint, whose name and other attributes are managed by Amazon RDS. You can't create, delete, or modify this kind of endpoint. With a Multi-AZ DB cluster, you typically use the writer and reader endpoints more often than the instance endpoints.

In day-to-day operations, the main way that you use instance endpoints is to diagnose capacity or performance issues that affect one specific DB instance in a Multi-AZ DB cluster. While connected to a specific DB instance, you can examine its status variables, metrics, and so on. Doing this can help you determine what's happening for that DB instance that's different from what's happening for other DB instances in the cluster.

**How Multi-AZ DB endpoints work with high availability**

For Multi-AZ DB clusters where high availability is important, use the writer endpoint for read/write or general-purpose connections and the reader endpoint for read-only connections. The writer and reader endpoints manage DB instance failover better than instance endpoints do. Unlike the instance endpoints, the writer and reader endpoints automatically change which DB instance they connect to if a DB instance in your cluster becomes unavailable.

If the writer DB instance of a DB cluster fails, Amazon RDS automatically fails over to a new writer DB instance. It does so by promoting a reader DB instance to a new writer DB instance. If a failover occurs, you can use the writer endpoint to reconnect to the newly promoted writer DB instance. Or you can use the reader endpoint to reconnect to one of the reader DB instances in the DB cluster. During a failover, the reader endpoint might direct connections to the new writer DB instance of a DB cluster for a short time after a reader DB instance is promoted to the new writer DB instance. If you design your own application logic to manage instance endpoint connections, you can manually or programmatically discover the resulting set of available DB instances in the DB cluster.
Automatically connecting an AWS compute resource and a Multi-AZ DB cluster

You can automatically connect a Multi-AZ DB cluster and AWS compute resources such as Amazon Elastic Compute Cloud (Amazon EC2) instances and AWS Lambda functions.

Topics
- Automatically connecting an EC2 instance and a Multi-AZ DB cluster (p. 525)
- Automatically connecting a Lambda function and a Multi-AZ DB cluster (p. 530)

Automatically connecting an EC2 instance and a Multi-AZ DB cluster

You can use the Amazon RDS console to simplify setting up a connection between an Amazon Elastic Compute Cloud (Amazon EC2) instance and a Multi-AZ DB cluster. Often, your Multi-AZ DB cluster is in a private subnet and your EC2 instance is in a public subnet within a VPC. You can use a SQL client on your EC2 instance to connect to your Multi-AZ DB cluster. The EC2 instance can also run web servers or applications that access your private Multi-AZ DB cluster.

If you want to connect to an EC2 instance that isn't in the same VPC as the Multi-AZ DB cluster, see the scenarios in the section called “Scenarios for accessing a DB instance in a VPC” (p. 2718).

Topics
- Overview of automatic connectivity with an EC2 instance (p. 525)
- Connecting an EC2 instance and a Multi-AZ DB cluster automatically (p. 528)
- Viewing connected compute resources (p. 529)

Overview of automatic connectivity with an EC2 instance

When you set up a connection between an EC2 instance and a Multi-AZ DB cluster automatically, Amazon RDS configures the VPC security group for your EC2 instance and for your DB cluster.

The following are requirements for connecting an EC2 instance with a Multi-AZ DB cluster:
- The EC2 instance must exist in the same VPC as the Multi-AZ DB cluster.

If no EC2 instances exist in the same VPC, the console provides a link to create one.
- The user who is setting up connectivity must have permissions to perform the following EC2 operations:
  - `ec2:AuthorizeSecurityGroupEgress`
  - `ec2:AuthorizeSecurityGroupIngress`
  - `ec2:CreateSecurityGroup`
  - `ec2:DescribeInstances`
  - `ec2:DescribeNetworkInterfaces`
  - `ec2:DescribeSecurityGroups`
  - `ec2:ModifyNetworkInterfaceAttribute`
  - `ec2:RevokeSecurityGroupEgress`

When you set up a connection to an EC2 instance, Amazon RDS acts according to the current configuration of the security groups associated with the Multi-AZ DB cluster and EC2 instance, as described in the following table.

<table>
<thead>
<tr>
<th>Current RDS security group configuration</th>
<th>Current EC2 security group configuration</th>
<th>RDS action</th>
</tr>
</thead>
<tbody>
<tr>
<td>There are one or more security groups associated with the Multi-AZ DB cluster with a name that matches the pattern <code>rds-ec2-n</code> (where <code>n</code> is a number). A security group that matches the pattern hasn’t been modified. This security group has only one inbound rule with the VPC security group of the EC2 instance as the source.</td>
<td>There are one or more security groups associated with the EC2 instance with a name that matches the pattern <code>rds-ec2-n</code> (where <code>n</code> is a number). A security group that matches the pattern hasn’t been modified. This security group has only one outbound rule with the VPC security group of the Multi-AZ DB cluster as the source.</td>
<td>Amazon RDS takes no action. A connection was already configured automatically between the EC2 instance and Multi-AZ DB cluster. Because a connection already exists between the EC2 instance and the RDS database, the security groups aren’t modified.</td>
</tr>
</tbody>
</table>

Either of the following conditions apply:

- There is no security group associated with the Multi-AZ DB cluster with a name that matches the pattern `rds-ec2-n`.
- There are one or more security groups associated with the Multi-AZ DB cluster with a name that matches the pattern `rds-ec2-n`. However, none of these security groups can be used for the connection with the EC2 instance. A security group can’t be used if it doesn’t have one inbound rule with the VPC security group of the EC2 instance as the source. A security group also can’t be used if it has been modified. Examples of modifications include adding a rule or changing the port of an existing rule.

Either of the following conditions apply:

- There is no security group associated with the EC2 instance with a name that matches the pattern `ec2-rds-n`.
- There are one or more security groups associated with the EC2 instance with a name that matches the pattern `ec2-rds-n`. However, none of these security groups can be used for the connection with the Multi-AZ DB cluster. A security group can’t be used if it doesn’t have one outbound rule with the VPC security group of the Multi-AZ DB cluster as the source. A security group also can’t be used if it has been modified.

RDS action: create new security groups
<table>
<thead>
<tr>

<td>RDS action: create new security groups</td>
</tr>
</tbody>
</table>

| There are one or more security groups associated with the Multi-AZ DB cluster with a name that matches the pattern rds-ec2-n. A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the EC2 instance as the source. | A valid EC2 security group for the connection exists, but it is not associated with the EC2 instance. This security group has a name that matches the pattern rds-ec2-n. It hasn't been modified. It has only one outbound rule with the VPC security group of the Multi-AZ DB cluster as the source. | RDS action: associate EC2 security group |

<table>
<thead>
<tr>
<th>Either of the following conditions apply:</th>
<th>There are one or more security groups associated with the EC2 instance with a name that matches the pattern rds-ec2-n. A security group that matches the pattern hasn't been modified. This security group has only one outbound rule with the VPC security group of the EC2 instance as the source.</th>
<th>RDS action: create new security groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>• There is no security group associated with the Multi-AZ DB cluster with a name that matches the pattern rds-ec2-n.</td>
<td>• There are one or more security groups associated with the Multi-AZ DB cluster with a name that matches the pattern rds-ec2-n. However, none of these security groups can be used for the connection with the EC2 instance. A security group can't be used if it doesn't have one inbound rule with the VPC security group of the EC2 instance as the source. A security group also can't be used if it has been modified.</td>
<td></td>
</tr>
</tbody>
</table>

**RDS action: create new security groups**

Amazon RDS takes the following actions:

- Creates a new security group that matches the pattern rds-ec2-n. This security group has an inbound rule with the VPC security group of the EC2 instance as the source. This security group is associated with the Multi-AZ DB cluster and allows the EC2 instance to access the Multi-AZ DB cluster.

- Creates a new security group that matches the pattern ec2-rds-n. This security group has an outbound rule with the VPC security group of the Multi-AZ DB cluster as the source. This security group...
group is associated with the EC2 instance and allows the EC2 instance to send traffic to the Multi-AZ DB cluster.

**RDS action: associate EC2 security group**

Amazon RDS associates the valid, existing EC2 security group with the EC2 instance. This security group allows the EC2 instance to send traffic to the Multi-AZ DB cluster.

**Connecting an EC2 instance and a Multi-AZ DB cluster automatically**

Before setting up a connection between an EC2 instance and an RDS database, make sure you meet the requirements described in [Overview of automatic connectivity with an EC2 instance](p. 386).

If you make changes to security groups after you configure connectivity, the changes might affect the connection between the EC2 instance and the RDS database.

**Note**

You can only set up a connection between an EC2 instance and an RDS database automatically by using the AWS Management Console. You can't set up a connection automatically with the AWS CLI or RDS API.

**To connect an EC2 instance and an RDS database automatically**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases, and then choose the RDS database.
3. From Actions, choose Set up EC2 connection.

   The Set up EC2 connection page appears.
4. On the Set up EC2 connection page, choose the EC2 instance.

   ![Set up EC2 connection](https://console.aws.amazon.com/rds/home#ec2-connection)

   If no EC2 instances exist in the same VPC, choose Create EC2 instance to create one. In this case, make sure the new EC2 instance is in the same VPC as the RDS database.
5. Choose Continue.

   The Review and confirm page appears.
6. On the Review and confirm page, review the changes that RDS will make to set up connectivity with the EC2 instance.

   If the changes are correct, choose Confirm and set up.

   If the changes aren't correct, choose Previous or Cancel.

**Viewing connected compute resources**

You can use the AWS Management Console to view the compute resources that are connected to an RDS database. The resources shown include compute resource connections that were set up automatically. You can set up connectivity with compute resources automatically in the following ways:

- You can select the compute resource when you create the database.

For more information, see Creating an Amazon RDS DB instance (p. 300) and Creating a Multi-AZ DB cluster (p. 508).
• You can set up connectivity between an existing database and a compute resource.

For more information, see Automatically connecting an EC2 instance and an RDS database (p. 388).

The listed compute resources don't include ones that were connected to the database manually. For example, you can allow a compute resource to access a database manually by adding a rule to the VPC security group associated with the database.

For a compute resource to be listed, the following conditions must apply:

• The name of the security group associated with the compute resource matches the pattern ec2-\(rds-n\) (where \(n\) is a number).
• The security group associated with the compute resource has an outbound rule with the port range set to the port that the RDS database uses.
• The security group associated with the compute resource has an outbound rule with the source set to a security group associated with the RDS database.
• The name of the security group associated with the RDS database matches the pattern \(rds-ec2-n\) (where \(n\) is a number).
• The security group associated with the RDS database has an inbound rule with the port range set to the port that the RDS database uses.
• The security group associated with the RDS database has an inbound rule with the source set to a security group associated with the compute resource.

To view compute resources connected to an RDS database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the name of the RDS database.
3. On the Connectivity & security tab, view the compute resources in the Connected compute resources.

Automatically connecting a Lambda function and a Multi-AZ DB cluster

You can use the RDS console to simplify setting up a connection between a Lambda function and a Multi-AZ DB cluster. You can use the RDS console to simplify setting up a connection between a Lambda function and a Multi-AZ DB cluster. Often, your Multi-AZ DB cluster is in a private subnet within a VPC. The Lambda function can be used by applications to access your private Multi-AZ DB cluster.

The following image shows a direct connection between your Multi-AZ DB cluster and your Lambda function.
You can set up the connection between your Lambda function and your database through RDS Proxy to improve your database performance and resiliency. Often, Lambda functions make frequent, short database connections that benefit from connection pooling that RDS Proxy offers. You can take advantage of any IAM authentication that you already have for Lambda functions, instead of managing database credentials in your Lambda application code. For more information, see Using Amazon RDS Proxy (p. 1215).

You can use the console to automatically create a proxy for your connection. You can also select existing proxies. The console updates the proxy security group to allow connections from your database and Lambda function. You can input your database credentials or select the Secrets Manager secret you require to access the database.

Topics
- Overview of automatic connectivity with a Lambda function (p. 532)
Overview of automatic connectivity with a Lambda function

When you set up a connection between a Lambda function and a Multi-AZ DB cluster automatically, Amazon RDS configures the VPC security group for your Lambda function and for your DB cluster. The following are requirements for connecting a Lambda function with a Multi-AZ DB cluster:

- The Lambda function must exist in the same VPC as the Multi-AZ DB cluster.

  If no Lambda function exists in the same VPC, the console provides a link to create one.

- The user who sets up connectivity must have permissions to perform the following Amazon RDS, Amazon EC2, Lambda, Secrets Manager, and IAM operations:

  - Amazon RDS
    - rds:CreateDBProxies
    - rds:DescribeDBInstances
    - rds:DescribeDBProxies
    - rds:ModifyDBInstance
    - rds:ModifyDBProxy
    - rds:RegisterProxyTargets
  
  - Amazon EC2
    - ec2:AuthorizeSecurityGroupEgress
    - ec2:AuthorizeSecurityGroupIngress
    - ec2:CreateSecurityGroup
    - ec2:DeleteSecurityGroup
    - ec2:DescribeSecurityGroups
    - ec2:RevokeSecurityGroupEgress
    - ec2:RevokeSecurityGroupIngress
  
  - Lambda
    - lambda:CreateFunctions
    - lambda:ListFunctions
    - lambda:UpdateFunctionConfiguration
  
  - Secrets Manager
    - secretsmanager:CreateSecret
    - secretsmanager:DescribeSecret
  
  - IAM
    - iam:AttachPolicy
    - iam:CreateRole
    - iam:CreatePolicy
  
  - AWS KMS
    - kms:describeKey

When you set up a connection between a Lambda function and a Multi-AZ DB cluster, Amazon RDS configures the VPC security group for your function and for your Multi-AZ DB cluster. If you use RDS Proxy, then Amazon RDS also configures the VPC security group for the proxy. Amazon RDS acts
Amazon RDS takes no action because security groups of all resources follow the correct naming pattern and have the right inbound and outbound rules.

<table>
<thead>
<tr>
<th>Current RDS security group configuration</th>
<th>Current Lambda security group configuration</th>
<th>Current proxy security group configuration</th>
<th>RDS action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon RDS takes no action because security groups of all resources follow the correct naming pattern and have the right inbound and outbound rules.</td>
<td>There are one or more security groups associated with the Multi-AZ DB cluster with a name that matches the pattern rds-lambda-n (where ( n ) is a number) or if the TargetHealth of an associated proxy is AVAILABLE. There is a security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the Lambda function or proxy as the source.</td>
<td>There are one or more security groups associated with the Lambda function with a name that matches the pattern lambda-( n ) or lambda-proxy-( n ) (where ( n ) is a number). | There are one or more security groups associated with the Multi-AZ DB cluster with a name that matches the pattern `rds-rdsproxy-n` (where `n` is a number). | Either of the following conditions apply:  
  - There is no security group associated with the Lambda function with a name that matches the pattern `lambda-ids-n` or `lambda-rdsproxy-n`.  
  - There are one or more security groups associated with the Lambda function with a name that matches the pattern `lambda-ids-n` or `lambda-rdsproxy-n`. However, Amazon RDS can't use any of these security groups for the connection with the Multi-AZ DB cluster. | Either of the following conditions apply:  
  - There is no security group associated with the proxy with a name that matches the pattern `rdsproxy-lambda-n`.  
  - There are one or more security groups associated with the proxy with a name that matches `rdsproxy-lambda-n`. However, Amazon RDS can't use any of these security groups for the connection with the Multi-AZ DB cluster or Lambda function. | RDS action: create new security groups |

Amazon RDS can't use a security group that doesn't have one outbound rule with the VPC security group of the Multi-AZ DB cluster or proxy as the destination. Amazon RDS also can't use a security group that has been modified.

Amazon RDS can't use a security group that doesn't have inbound and outbound rules with the VPC security group of the Multi-AZ DB cluster and the Lambda function. Amazon RDS also can't use a security group that has been modified.

RDS action: create new security groups

Amazon RDS takes the following actions:

- Creates a new security group that matches the pattern `rds-lambda-n`. This security group has an inbound rule with the VPC security group of the Lambda function or proxy as the source. This security group is associated with the Multi-AZ DB cluster and allows the function or proxy to access the Multi-AZ DB cluster.

- Creates a new security group that matches the pattern `lambda-ids-n`. This security group has an outbound rule with the VPC security group of the Multi-AZ DB cluster or proxy as the destination. This security group is associated with the Lambda function and allows the Lambda function to send traffic to the Multi-AZ DB cluster or send traffic through a proxy.

- Creates a new security group that matches the pattern `rdsproxy-lambda-n`. This security group has inbound and outbound rules with the VPC security group of the Multi-AZ DB cluster and the Lambda function.
RDS action: associate Lambda security group

Amazon RDS associates the valid, existing Lambda security group with the Lambda function. This security group allows the function to send traffic to the Multi-AZ DB cluster or send traffic through a proxy.

Automatically connecting a Lambda function and a Multi-AZ DB cluster

You can use the Amazon RDS console to automatically connect a Lambda function to your Multi-AZ DB cluster. This simplifies the process of setting up a connection between these resources.

You can also use RDS Proxy to include a proxy in your connection. Lambda functions make frequent short database connections that benefit from the connection pooling that RDS Proxy offers. You can also use any IAM authentication that you've already set up for your Lambda function, instead of managing database credentials in your Lambda application code.

You can connect an existing Multi-AZ DB cluster to new and existing Lambda functions using the Set up Lambda connection page. The setup process automatically sets up the required security groups for you.

Before setting up a connection between a Lambda function and a Multi-AZ DB cluster, make sure that:

- Your Lambda function and Multi-AZ DB cluster are in the same VPC.
- You have the right permissions for your user account. For more information about the requirements, see Overview of automatic connectivity with a Lambda function (p. 393).

If you change security groups after you configure connectivity, the changes might affect the connection between the Lambda function and the Multi-AZ DB cluster.

Note
You can automatically set up a connection between a Multi-AZ DB cluster and a Lambda function only in the AWS Management Console. To connect a Lambda function, all instances in the Multi-AZ DB cluster must be in the Available state.

To automatically connect a Lambda function and a Multi-AZ DB cluster

After you confirm the setup, Amazon RDS begins the process of connecting your Lambda function, RDS Proxy (if you used a proxy), and Multi-AZ DB cluster. The console shows the Connection details dialog box, which lists the security group changes that allow connections between your resources.

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the Multi-AZ DB cluster that you want to connect to a Lambda function.
3. For Actions, choose Set up Lambda connection.
4. On the Set up Lambda connection page, under Select Lambda function, do either of the following:
   - If you have an existing Lambda function in the same VPC as your Multi-AZ DB cluster, choose Choose existing function, and then choose the function.
   - If you don't have a Lambda function in the same VPC, choose Create new function, and then enter a Function name. The default runtime is set to Nodejs.18. You can modify the settings for your new Lambda function in the Lambda console after you complete the connection setup.
5. (Optional) Under RDS Proxy, select Connect using RDS Proxy, and then do any of the following:
   - If you have an existing proxy that you want to use, choose Choose existing proxy, and then choose the proxy.
If you don’t have a proxy, and you want Amazon RDS to automatically create one for you, choose **Create new proxy**. Then, for **Database credentials**, do either of the following:

a. Choose **Database username and password**, and then enter the **Username** and **Password** for your Multi-AZ DB cluster.

b. Choose **Secrets Manager secret**. Then, for **Select secret**, choose an AWS Secrets Manager secret. If you don’t have a Secrets Manager secret, choose **Create new Secrets Manager secret** to **create a new secret**. After you create the secret, for **Select secret**, choose the new secret.

After you create the new proxy, choose **Choose existing proxy**, and then choose the proxy. Note that it might take some time for your proxy to be available for connection.

6. (Optional) Expand **Connection summary** and verify the highlighted updates for your resources.

7. Choose **Set up**.

**Viewing connected compute resources**

You can use the AWS Management Console to view the compute resources that are connected to your Multi-AZ DB cluster. The resources shown include compute resource connections that Amazon RDS set up automatically.

The listed compute resources don’t include those that are manually connected to the Multi-AZ DB cluster. For example, you can allow a compute resource to access your Multi-AZ DB cluster manually by adding a rule to your VPC security group associated with the cluster.

For the console to list a Lambda function, the following conditions must apply:

- The name of the security group associated with the compute resource matches the pattern `lambda-rds-n` or `lambda-rdsproxy-n` (where `n` is a number).
- The security group associated with the compute resource has an outbound rule with the port range set to the port of the Multi-AZ DB cluster or an associated proxy. The destination for the outbound rule must be set to a security group associated with the Multi-AZ DB cluster or an associated proxy.
- The name of the security group attached to the proxy associated with your database matches the pattern `rds-rdsproxy-n` (where `n` is a number).
- The security group associated with the function has an outbound rule with the port set to the port that the Multi-AZ DB cluster or associated proxy uses. The destination must be set to a security group associated with the Multi-AZ DB cluster or associated proxy.

**To view compute resources automatically connected to a Multi-AZ DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the Multi-AZ DB cluster.
3. On the **Connectivity & security** tab, view the compute resources under **Connected compute resources**.
Modifying a Multi-AZ DB cluster

A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower latency when compared to Multi-AZ deployments. For more information about Multi-AZ DB clusters, see Multi-AZ DB cluster deployments (p. 499).

You can modify a Multi-AZ DB cluster to change its settings. You can also perform operations on a Multi-AZ DB cluster, such as taking a snapshot of it. However, you can't modify the DB instances in a Multi-AZ DB cluster, and the only supported operation is rebooting a DB instance.

**Note**
Multi-AZ DB clusters are supported only for the MySQL and PostgreSQL DB engines.

You can modify a Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

To modify a Multi-AZ DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the Multi-AZ DB cluster that you want to modify.
4. Change any of the settings that you want. For information about each setting, see Settings for modifying Multi-AZ DB clusters (p. 540).
5. When all the changes are as you want them, choose Continue and check the summary of modifications.
6. (Optional) Choose Apply immediately to apply the changes immediately. Choosing this option can cause downtime in some cases. For more information, see Applying changes immediately (p. 540).
7. On the confirmation page, review your changes. If they're correct, choose Modify DB cluster to save your changes.

Or choose Back to edit your changes or Cancel to cancel your changes.

**AWS CLI**

To modify a Multi-AZ DB cluster by using the AWS CLI, call the modify-db-cluster command. Specify the DB cluster identifier and the values for the options that you want to modify. For information about each option, see Settings for modifying Multi-AZ DB clusters (p. 540).

**Example**

The following code modifies my-multi-az-dbcluster by setting the backup retention period to 1 week (7 days). The code turns on deletion protection by using --deletion-protection. To turn off deletion protection, use --no-deletion-protection. The changes are applied during the next maintenance window by using --no-apply-immediately. Use --apply-immediately to apply the changes immediately. For more information, see Applying changes immediately (p. 540).

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier my-multi-az-dbcluster \
  --backup-retention-period 7 \
  --deletion-protection \
  --no-apply-immediately
```
For Windows:

```bash
aws rds modify-db-cluster ^
   --db-cluster-identifier my-multi-az-dbcluster ^
   --backup-retention-period 7 ^
   --deletion-protection ^
   --no-apply-immediately
```

**RDS API**

To modify a Multi-AZ DB cluster by using the Amazon RDS API, call the `ModifyDBCluster` operation. Specify the DB cluster identifier, and the parameters for the settings that you want to modify. For information about each parameter, see Settings for modifying Multi-AZ DB clusters (p. 540).

**Applying changes immediately**

When you modify a Multi-AZ DB cluster, you can apply the changes immediately. To apply changes immediately, you choose the **Apply Immediately** option in the AWS Management Console. Or you use the `--apply-immediately` option when calling the AWS CLI or set the `ApplyImmediately` parameter to `true` when using the Amazon RDS API.

If you don't choose to apply changes immediately, the changes are put into the pending modifications queue. During the next maintenance window, any pending changes in the queue are applied. If you choose to apply changes immediately, your new changes and any changes in the pending modifications queue are applied.

**Important**

- If any of the pending modifications require the DB cluster to be temporarily unavailable (**downtime**), choosing the apply immediately option can cause unexpected downtime.
- When you choose to apply a change immediately, any pending modifications are also applied immediately, instead of during the next maintenance window.
- If you don't want a pending change to be applied in the next maintenance window, you can modify the DB instance to revert the change. You can do this by using the AWS CLI and specifying the `--apply-immediately` option.

Changes to some database settings are applied immediately, even if you choose to defer your changes. To see how the different database settings interact with the apply immediately setting, see Settings for modifying Multi-AZ DB clusters (p. 540).

**Settings for modifying Multi-AZ DB clusters**

For details about settings that you can use to modify a Multi-AZ DB cluster, see the following table. For more information about the AWS CLI options, see `modify-db-cluster`. For more information about the RDS API parameters, see `ModifyDBCluster`.

<table>

| **DB cluster instance class** | The compute and memory capacity of each DB instance in the Multi-AZ DB cluster, for example db.r6gd.xlarge. If possible, choose a DB instance class large enough that a typical query working set can be held in memory. When working sets are held in memory, the system can avoid writing to disk, which improves performance. Currently, Multi-AZ DB clusters only support db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see [DB instance classes](p. 11). | **CLI option:** --db-cluster-instance-class  
**RDS API parameter:** DBClusterInstanceClass | If you choose to apply the change immediately, it occurs immediately.  
If you don't choose to apply the change immediately, it occurs during the next maintenance window.                                                                                                                                  | Downtime occurs during this change.                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                  |
| **DB cluster parameter group** | The DB cluster parameter group that you want associated with the DB cluster. For more information, see [Working with parameter groups for Multi-AZ DB clusters](p. 503).                                                                 | **CLI option:** --db-cluster-parameter-group-name  
**RDS API parameter:** DBClusterParameterGroupName | The parameter group change occurs immediately.                                                                                                                                       | An outage doesn't occur during this change. When you change the parameter group, changes to some parameters are applied to the DB instances in the Multi-AZ DB cluster immediately without a reboot. Changes to other parameters are applied only after the DB instances are rebooted. |                                                                                                                                                                                                                                                                                                                                 |
| **DB engine version**          | The version of database engine that you want to use.                                                                                                                                                                  | **CLI option:** --engine-version  
**RDS API parameter:** EngineVersion | If you choose to apply the change immediately, it occurs immediately.  
If you don't choose to apply the change immediately, it occurs during the next maintenance window.                                                                                                                                  | An outage occurs during this change.                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                  |

Renaming a Multi-AZ DB cluster

You can rename a Multi-AZ DB cluster by using the AWS Management Console, the AWS CLI `modify-db-cluster` command, or the Amazon RDS API `ModifyDBCluster` operation. Renaming a Multi-AZ DB cluster can have significant effects. The following is a list of considerations before you rename a Multi-AZ DB cluster.

- When you rename a Multi-AZ DB cluster, the cluster endpoints for the Multi-AZ DB cluster change. These endpoints change because they include the name you assigned to the Multi-AZ DB cluster. You can redirect traffic from an old endpoint to a new one. For more information about Multi-AZ DB cluster endpoints, see [Connecting to a Multi-AZ DB cluster](p. 522).
- When you rename a Multi-AZ DB cluster, the old DNS name that was used by the Multi-AZ DB cluster is deleted, although it could remain cached for a few minutes. The new DNS name for the renamed Multi-AZ DB cluster becomes effective in about two minutes. The renamed Multi-AZ DB cluster isn’t available until the new name becomes effective.
- You can’t use an existing Multi-AZ DB cluster name when renaming a cluster.
- Metrics and events associated with the name of a Multi-AZ DB cluster are maintained if you reuse a DB cluster name.
- Multi-AZ DB cluster tags remain with the Multi-AZ DB cluster, regardless of renaming.
- DB cluster snapshots are retained for a renamed Multi-AZ DB cluster.

**Note**

A Multi-AZ DB cluster is an isolated database environment running in the cloud. A Multi-AZ DB cluster can host multiple databases. For information about changing a database name, see the documentation for your DB engine.

Renaming to replace an existing Multi-AZ DB cluster

The most common scenarios for renaming a Multi-AZ DB cluster include restoring data from a DB cluster snapshot or performing point-in-time recovery (PITR). By renaming the Multi-AZ DB cluster, you can replace the Multi-AZ DB cluster without changing any application code that references the Multi-AZ DB cluster. In these cases, complete the following steps:

1. Stop all traffic going to the Multi-AZ DB cluster. You can redirect traffic from accessing the databases on the Multi-AZ DB cluster, or choose another way to prevent traffic from accessing your databases on the Multi-AZ DB cluster.
2. Rename the existing Multi-AZ DB cluster.
3. Create a new Multi-AZ DB cluster by restoring from a DB cluster snapshot or recovering to a point in time. Then, give the new Multi-AZ DB cluster the name of the previous Multi-AZ DB cluster.

If you delete the old Multi-AZ DB cluster, you are responsible for deleting any unwanted DB cluster snapshots of the old Multi-AZ DB cluster.

**Console**

**To rename a Multi-AZ DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the Multi-AZ DB cluster that you want to rename.
4. Choose **Modify**.
5. In Settings, enter a new name for **DB cluster identifier**.

6. Choose **Continue**.

7. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see Applying changes immediately (p. 540).

8. On the confirmation page, review your changes. If they are correct, choose **Modify cluster** to save your changes.

   Alternatively, choose **Back** to edit your changes, or choose **Cancel** to discard your changes.

**AWS CLI**

To rename a Multi-AZ DB cluster, use the AWS CLI command `modify-db-cluster`. Provide the current `--db-cluster-identifier` value and `--new-db-cluster-identifier` parameter with the new name of the Multi-AZ DB cluster.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier DBClusterIdentifier \
  --new-db-cluster-identifier NewDBClusterIdentifier
```

For Windows:

```bash
aws rds modify-db-cluster ^
  --db-cluster-identifier DBClusterIdentifier ^
  --new-db-cluster-identifier NewDBClusterIdentifier
```

**RDS API**

To rename a Multi-AZ DB cluster, call the Amazon RDS API operation `ModifyDBCluster` with the following parameters:

- **DBClusterIdentifier** – The existing name of the DB cluster.
- **NewDBClusterIdentifier** – The new name of the DB cluster.
Rebooting a Multi-AZ DB cluster and reader DB instances

You might need to reboot your Multi-AZ DB cluster, usually for maintenance reasons. For example, if you make certain modifications or change the DB cluster parameter group associated with a DB cluster, you reboot the DB cluster. Doing so causes the changes to take effect.

If a DB cluster isn't using the latest changes to its associated DB cluster parameter group, the AWS Management Console shows the DB cluster parameter group with a status of **pending-reboot**. The **pending-reboot** parameter groups status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB cluster, manually reboot the DB cluster. For more information about parameter groups, see [Working with parameter groups for Multi-AZ DB clusters](p. 503).

Rebooting a DB cluster restarts the database engine service. Rebooting a DB cluster results in a momentary outage, during which the DB cluster status is set to **rebooting**.

You can't reboot your DB cluster if it isn't in the **Available** state. Your database can be unavailable for several reasons, such as an in-progress backup, a previously requested modification, or a maintenance-window action.

The time required to reboot your DB cluster depends on the crash recovery process, the database activity at the time of reboot, and the behavior of your specific DB cluster. To improve the reboot time, we recommend that you reduce database activity as much as possible during the reboot process. Reducing database activity reduces rollback activity for in-transit transactions.

**Important**
Multi-AZ DB clusters don't support reboot with a failover. When you reboot the writer instance of a Multi-AZ DB cluster, it doesn't affect the reader DB instances in that DB cluster and no failover occurs. When you reboot a reader DB instance, no failover occurs. To fail over a Multi-AZ DB cluster, choose **Failover** in the console, call the AWS CLI command `failover-db-cluster`, or call the API operation `FailoverDBCluster`.

### Console

#### To reboot a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the Multi-AZ DB cluster that you want to reboot.
3. For **Actions**, choose **Reboot**.
   
   The **Reboot DB cluster** page appears.
4. Choose **Reboot** to reboot your DB cluster.
   
   Or choose **Cancel**.

### AWS CLI

To reboot a Multi-AZ DB cluster by using the AWS CLI, call the `reboot-db-cluster` command.

```bash
aws rds reboot-db-cluster --db-cluster-identifier mymultiazdbcluster
```
RDS API

To reboot a Multi-AZ DB cluster by using the Amazon RDS API, call the `RebootDBCluster` operation.
Working with Multi-AZ DB cluster read replicas

A DB cluster read replica is a special type of cluster that you create from a source DB instance. After you create a read replica, any updates made to the primary DB instance are asynchronously copied to the Multi-AZ DB cluster read replica. You can reduce the load on your primary DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads.

You can also create one or more DB instance read replicas from a Multi-AZ DB cluster. DB instance read replicas let you scale beyond the compute or I/O capacity of the source Multi-AZ DB cluster by directing excess read traffic to the read replicas. Currently, you can’t create a Multi-AZ DB cluster read replica from an existing Multi-AZ DB cluster.

Topics

• Migrating to a Multi-AZ DB cluster using a read replica (p. 554)
• Creating a DB instance read replica from a Multi-AZ DB cluster (p. 557)

Migrating to a Multi-AZ DB cluster using a read replica

To migrate a Single-AZ deployment or Multi-AZ DB instance deployment to a Multi-AZ DB cluster deployment with reduced downtime, you can create a Multi-AZ DB cluster read replica. For the source, you specify the DB instance in the Single-AZ deployment or the primary DB instance in the Multi-AZ DB instance deployment. The DB instance can process write transactions during the migration to a Multi-AZ DB cluster.

Consider the following before you create a Multi-AZ DB cluster read replica:

• The source DB instance must be on a version that supports Multi-AZ DB clusters. For more information, see Multi-AZ DB clusters (p. 147).
• The Multi-AZ DB cluster read replica must be on the same major version as its source, and the same or higher minor version.
• You must turn on automatic backups on the source DB instance by setting the backup retention period to a value other than 0.
• The allocated storage of the source DB instance must be 100 GiB or higher.
• For RDS for MySQL, both the gtid-mode and enforce_gtid_consistency parameters must be set to ON for the source DB instance. You must use a custom parameter group, not the default parameter group. For more information, see the section called “Working with DB parameter groups” (p. 349).
• An active, long-running transaction can slow the process of creating the read replica. We recommend that you wait for long-running transactions to complete before creating a read replica.
• If you delete the source DB instance for a Multi-AZ DB cluster read replica, the read replica is promoted to a standalone Multi-AZ DB cluster.

Creating and promoting the Multi-AZ DB cluster read replica

You can create and promote a Multi-AZ DB cluster read replica using the AWS Management Console, AWS CLI, or RDS API.

Note

We strongly recommend that you create all read replicas in the same virtual private cloud (VPC) based on Amazon VPC of the source DB instance.
If you create a read replica in a different VPC from the source DB instance, classless inter-domain routing (CIDR) ranges can overlap between the replica and the RDS system. CIDR overlap makes the replica unstable, which can negatively impact applications connecting to it. If you receive an
error when creating the read replica, choose a different destination DB subnet group. For more information, see Working with a DB instance in a VPC (p. 2705).

Console

To migrate a Single-AZ deployment or Multi-AZ DB instance deployment to a Multi-AZ DB cluster using a read replica, complete the following steps using the AWS Management Console.

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Create the Multi-AZ DB cluster read replica.
   a. In the navigation pane, choose Databases.
   b. Choose the DB instance that you want to use as the source for a read replica.
   c. For Actions, choose Create read replica.
   d. For Availability and durability, choose Multi-AZ DB cluster.
   e. For DB instance identifier, enter a name for the read replica.
   f. For the remaining sections, specify your DB cluster settings. For information about a setting, see Settings for creating Multi-AZ DB clusters (p. 514).
   g. Choose Create read replica.
3. When you are ready, promote the read replica to be a standalone Multi-AZ DB cluster:
   a. Stop any transactions from being written to the source DB instance, and then wait for all updates to be made to the read replica.
   
   Database updates occur on the read replica after they have occurred on the primary DB instance. This replication lag can vary significantly. Use the ReplicaLag metric to determine when all updates have been made to the read replica. For more information about replica lag, see Monitoring read replication (p. 449).
   b. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   c. In the Amazon RDS console, choose Databases.
   
   The Databases pane appears. Each read replica shows Replica in the Role column.
   d. Choose the Multi-AZ DB cluster read replica that you want to promote.
   e. For Actions, choose Promote.
   f. On the Promote read replica page, enter the backup retention period and the backup window for the newly promoted Multi-AZ DB cluster.
   g. When the settings are as you want them, choose Promote read replica.
   h. Wait for the status of the promoted Multi-AZ DB cluster to be Available.
   i. Direct your applications to use the promoted Multi-AZ DB cluster.

   Optionally, delete the Single-AZ deployment or Multi-AZ DB instance deployment if it is no longer needed. For instructions, see Deleting a DB instance (p. 489).

AWS CLI

To migrate a Single-AZ deployment or Multi-AZ DB instance deployment to a Multi-AZ DB cluster using a read replica, complete the following steps using the AWS CLI.

1. Create the Multi-AZ DB cluster read replica.
To create a read replica from the source DB instance, use the AWS CLI command `create-db-cluster`. For `--replication-source-identifier`, specify the Amazon Resource Name (ARN) of the source DB instance.

For Linux, macOS, or Unix:
```
aws rds create-db-cluster \
  --db-cluster-identifier mymultiazdbcluster \
```

For Windows:
```
aws rds create-db-cluster ^
  --db-cluster-identifier mymultiazdbcluster ^
```

2. Stop any transactions from being written to the source DB instance, and then wait for all updates to be made to the read replica.

   Database updates occur on the read replica after they have occurred on the primary DB instance. This replication lag can vary significantly. Use the Replica Lag metric to determine when all updates have been made to the read replica. For more information about replica lag, see Monitoring read replication (p. 449).

3. When you are ready, promote the read replica to be a standalone Multi-AZ DB cluster.

   To promote a Multi-AZ DB cluster read replica, use the AWS CLI command `promote-read-replica-db-cluster`. For `--db-cluster-identifier`, specify the identifier of the Multi-AZ DB cluster read replica.
```
aws rds promote-read-replica-db-cluster --db-cluster-identifier mymultiazdbcluster
```

4. Wait for the status of the promoted Multi-AZ DB cluster to be Available.

5. Direct your applications to use the promoted Multi-AZ DB cluster.

   Optionally, delete the Single-AZ deployment or Multi-AZ DB instance deployment if it is no longer needed. For instructions, see Deleting a DB instance (p. 489).

RDS API

To migrate a Single-AZ deployment or Multi-AZ DB instance deployment to a Multi-AZ DB cluster using a read replica, complete the following steps using the RDS API.

1. Create the Multi-AZ DB cluster read replica.

   To create a Multi-AZ DB cluster read replica, use the `CreateDBCluster` operation with the required parameter `DBClusterIdentifier`. For `ReplicationSourceIdentifier`, specify the Amazon Resource Name (ARN) of the source DB instance.

2. Stop any transactions from being written to the source DB instance, and then wait for all updates to be made to the read replica.

   Database updates occur on the read replica after they have occurred on the primary DB instance. This replication lag can vary significantly. Use the Replica Lag metric to determine when all updates have been made to the read replica. For more information about replica lag, see Monitoring read replication (p. 449).

3. When you are ready, promote read replica to be a standalone Multi-AZ DB cluster.
To promote a Multi-AZ DB cluster read replica, use the `PromoteReadReplicaDBCluster` operation with the required parameter `DBClusterIdentifier`. Specify the identifier of the Multi-AZ DB cluster read replica.

4. Wait for the status of the promoted Multi-AZ DB cluster to be `Available`.
5. Direct your applications to use the promoted Multi-AZ DB cluster.

Optionally, delete the Single-AZ deployment or Multi-AZ DB instance deployment if it is no longer needed. For instructions, see Deleting a DB instance (p. 489).

**Limitations for creating a Multi-AZ DB cluster read replica**

The following limitations apply to creating a Multi-AZ DB cluster read replica from a Single-AZ deployment or Multi-AZ DB instance deployment.

- You can't create a Multi-AZ DB cluster read replica in an AWS account that is different from the AWS account that owns the source DB instance.
- You can't create a Multi-AZ DB cluster read replica in a different AWS Region from the source DB instance.
- You can't recover a Multi-AZ DB cluster read replica to a point in time.
- Storage encryption must have the same settings on the source DB instance and Multi-AZ DB cluster.
- If the source DB instance is encrypted, the Multi-AZ DB cluster read replica must be encrypted using the same KMS key.
- To perform a minor version upgrade on the source DB instance, you must first perform the minor version upgrade on the Multi-AZ DB cluster read replica.
- You can't perform a major version upgrade on a Multi-AZ DB cluster.
- You can perform a major version upgrade on the source DB instance of a Multi-AZ DB cluster read replica, but replication to the read replica stops and can't be restarted.
- The Multi-AZ DB cluster read replica doesn't support cascading read replicas.
- For RDS for PostgreSQL, Multi-AZ DB cluster read replicas can't fail over.

**Creating a DB instance read replica from a Multi-AZ DB cluster**

You can create a DB instance read replica from a Multi-AZ DB cluster in order to scale beyond the compute or I/O capacity of the cluster for read-heavy database workloads. You can direct this excess read traffic to one or more DB instance read replicas. You can also use read replicas to migrate from a Multi-AZ DB cluster to a DB instance.

To create a read replica, specify a Multi-AZ DB cluster as the replication source. One of the reader instances of the Multi-AZ DB cluster is always the source of replication, not the writer instance. This condition ensures that the replica is always in sync with the source cluster, even in cases of failover.

**Topics**

- Comparing reader DB instances and DB instance read replicas (p. 558)
- Considerations (p. 558)
- Creating a DB instance read replica (p. 558)
- Promoting the DB instance read replica (p. 559)
- Limitations for creating a DB instance read replica from a Multi-AZ DB cluster (p. 560)
Comparing reader DB instances and DB instance read replicas

A DB instance read replica of a Multi-AZ DB cluster is different than the reader DB instances of the Multi-AZ DB cluster in the following ways:

- The reader DB instances act as automatic failover targets, while DB instance read replicas do not.
- Reader DB instances must acknowledge a change from the writer DB instance before the change can be committed. For DB instance read replicas, however, updates are asynchronously copied to the read replica without requiring acknowledgement.
- Reader DB instances always share the same instance class, storage type, and engine version as the writer DB instance of the Multi-AZ DB cluster. DB instance read replicas, however, don't necessarily have to share the same configurations as the source cluster.
- You can promote a DB instance read replica to a standalone DB instance. You can’t promote a reader DB instance of a Multi-AZ DB cluster to a standalone instance.
- The reader endpoint only routes requests to the reader DB instances of the Multi-AZ DB cluster. It never routes requests to a DB instance read replica.

For more information about reader and writer DB instances, see the section called “Overview of Multi-AZ DB clusters” (p. 500).

Considerations

Consider the following before you create a DB instance read replica from a Multi-AZ DB cluster:

- When you create the DB instance read replica, it must be on the same major version as its source cluster, and the same or higher minor version. After you create it, you can optionally upgrade the read replica to a higher minor version than the source cluster.
- When you create the DB instance read replica, the allocated storage must be the same as the allocated storage of the source Multi-AZ DB cluster. You can change the allocated storage after the read replica is created.
- For RDS for MySQL, the `gtid-mode` parameter must be set to ON for the source Multi-AZ DB cluster. For more information, see the section called “Working with DB cluster parameter groups” (p. 360).
- An active, long-running transaction can slow the process of creating the read replica. We recommend that you wait for long-running transactions to complete before creating a read replica.
- If you delete the source Multi-AZ DB cluster for a DB instance read replica, any read replicas that it's writing to are promoted to standalone DB instances.

Creating a DB instance read replica

You can create a DB instance read replica from a Multi-AZ DB cluster using the AWS Management Console, AWS CLI, or RDS API.

Note

We strongly recommend that you create all read replicas in the same virtual private cloud (VPC) based on Amazon VPC of the source Multi-AZ DB cluster.

If you create a read replica in a different VPC from the source Multi-AZ DB cluster, Classless Inter-Domain Routing (CIDR) ranges can overlap between the replica and the RDS system. CIDR overlap makes the replica unstable, which can negatively impact applications connecting to it. If you receive an error when creating the read replica, choose a different destination DB subnet group. For more information, see the section called “Working with a DB instance in a VPC” (p. 2705).

Console

To create a DB instance read replica from a Multi-AZ DB cluster, complete the following steps using the AWS Management Console.
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Multi-AZ DB cluster that you want to use as the source for a read replica.
4. For Actions, choose Create read replica.
5. For Replica source, make sure that the correct Multi-AZ DB cluster is selected.
6. For DB identifier, enter a name for the read replica.
7. For the remaining sections, specify your DB instance settings. For information about a setting, see the section called “Available settings” (p. 308).
   **Note**
   The allocated storage for the DB instance read replica must be the same as the allocated storage for the source Multi-AZ DB cluster.
8. Choose Create read replica.

**AWS CLI**

To create a DB instance read replica from a Multi-AZ DB cluster, use the AWS CLI command `create-db-instance-read-replica`. For `--source-db-cluster-identifier`, specify the identifier of the Multi-AZ DB cluster.

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
  --db-instance-identifier myreadreplica \
  --source-db-cluster-identifier mymultiazdbcluster
```

For Windows:

```
aws rds create-db-instance-read-replica ^
  --db-instance-identifier myreadreplica ^
  --source-db-cluster-identifier mymultiazdbcluster
```

**RDS API**

To create a DB instance read replica from a Multi-AZ DB cluster, use the `CreateDBInstanceReadReplica` operation.

**Promoting the DB instance read replica**

If you no longer need the DB instance read replica, you can promote it into a standalone DB instance. When you promote a read replica, the DB instance is rebooted before it becomes available. For instructions, see the section called “Promoting a read replica” (p. 447).

If you’re using the read replica to migrate a Multi-AZ DB cluster deployment to a Single-AZ or Multi-AZ DB instance deployment, make sure to stop any transactions that are being written to the source DB cluster. Then, wait for all updates to be made to the read replica. Database updates occur on the read replica after they occur on one of the reader DB instances of the Multi-AZ DB cluster. This replication lag can vary significantly. Use the `ReplicaLag` metric to determine when all updates have been made to the read replica. For more information about replica lag, see the section called “Monitoring read replication” (p. 449).

After you promote the read replica, wait for the status of the promoted DB instance to be Available before you direct your applications to use the promoted DB instance. Optionally, delete the Multi-AZ DB cluster deployment if you no longer need it. For instructions, see the section called “Deleting a Multi-AZ DB cluster” (p. 563).
Limitations for creating a DB instance read replica from a Multi-AZ DB cluster

The following limitations apply to creating a DB instance read replica from a Multi-AZ DB cluster deployment.

- You can't create a DB instance read replica in an AWS account that's different from the AWS account that owns the source Multi-AZ DB cluster.
- You can't create a DB instance read replica in a different AWS Region from the source Multi-AZ DB cluster.
- You can't recover a DB instance read replica to a point in time.
- Storage encryption must have the same settings on the source Multi-AZ DB cluster and DB instance read replica.
- If the source Multi-AZ DB cluster is encrypted, the DB instance read replica must be encrypted using the same KMS key.
- To perform a minor version upgrade on the source Multi-AZ DB cluster, you must first perform the minor version upgrade on the DB instance read replica.
- The DB instance read replica doesn't support cascading read replicas.
- For RDS for PostgreSQL, the source Multi-AZ DB cluster must be running PostgreSQL version 13.11, 14.8, or 15.2.R2 or higher in order to create a DB instance read replica.
- You can perform a major version upgrade on the source Multi-AZ DB cluster of a DB instance read replica, but replication to the read replica stops and can't be restarted.
Using PostgreSQL logical replication with Multi-AZ DB clusters

By using PostgreSQL logical replication with your Multi-AZ DB cluster, you can replicate and synchronize individual tables rather than the entire database instance. Logical replication uses a publish and subscribe model to replicate changes from a source to one or more recipients. It works by using change records from the PostgreSQL write-ahead log (WAL). For more information, see the section called "Logical replication" (p. 2177).

When you create a new logical replication slot on the writer DB instance of a Multi-AZ DB cluster, the slot is asynchronously copied to each reader DB instance in the cluster. The slots on the reader DB instances are continuously synchronized with those on the writer DB instance.

Logical replication is supported for Multi-AZ DB clusters running RDS for PostgreSQL version 14.8-R2 and higher, and 15.3-R2 and higher.

**Note**
In addition to the native PostgreSQL logical replication feature, Multi-AZ DB clusters running RDS for PostgreSQL also support the pglogical extension.

For more information about PostgreSQL logical replication, see Logical replication in the PostgreSQL documentation.

**Topics**
- Prerequisites (p. 561)
- Setting up logical replication (p. 561)

**Prerequisites**
To configure PostgreSQL logical replication for Multi-AZ DB clusters, you must meet the following prerequisites.

- Your user account must be a member of the rds_superuser group and have rds_superuser privileges. For more information, see the section called "Understanding PostgreSQL roles and permissions" (p. 2288).
- Your Multi-AZ DB cluster must be associated with a custom DB cluster parameter group so that you can configure the parameter values described in the following procedure. For more information, see the section called “Working with DB cluster parameter groups” (p. 360).

**Setting up logical replication**
To set up logical replication for a Multi-AZ DB cluster, you enable specific parameters within the associated DB cluster parameter group, then create logical replication slots.

**To set up logical replication for an RDS for PostgreSQL Multi-AZ DB cluster**

1. Open the custom DB cluster parameter group associated with your RDS for PostgreSQL Multi-AZ DB cluster.
2. In the Parameters search field, locate the rds.logical_replication static parameter and set its value to 1. This parameter change can increase WAL generation, so enable it only when you're using logical slots.
3. As part of this change, configure the following DB cluster parameters.
   - max_wal_senders
• max_replication_slots
• max_connections

Depending on your expected usage, you might also need to change the values of the following parameters. However, in many cases, the default values are sufficient.

• max_logical_replication_workers
• max_sync_workers_per_subscription

4. Reboot the Multi-AZ DB cluster for the parameter values to take effect. For instructions, see the section called “Rebooting a Multi-AZ DB cluster” (p. 552).

5. Create a logical replication slot on the writer DB instance of the Multi-AZ DB cluster as explained in the section called “Working with logical replication slots” (p. 2178). This process requires that you specify a decoding plugin. Currently, RDS for PostgreSQL supports the test_decoding, wal2json, and pgoutput plugins that ship with PostgreSQL.

The slot is asynchronously copied to each reader DB instance in the cluster.

6. Verify the state of the slot on all reader DB instances of the Multi-AZ DB cluster. To do so, inspect the pg_replication_slots view on all reader DB instances and make sure that the confirmed_flush_lsn state is making progress while the application is actively consuming logical changes.

The following commands demonstrate how to inspect the replication state on the reader DB instances.

```sql
% psql -h test-postgres-instance-2.abcdefabcdef.us-west-2.rds.amazonaws.com
postgre=> select slot_name, slot_type, confirmed_flush_lsn from pg_replication_slots;
    slot_name | slot_type | confirmed_flush_lsn |
------------+-----------+---------------------|
    logical_slot | logical   | 32/0001700          |
(1 row)

% psql -h test-postgres-instance-3.abcdefabcdef.us-west-2.rds.amazonaws.com
postgre=> select slot_name, slot_type, confirmed_flush_lsn from pg_replication_slots;
    slot_name | slot_type | confirmed_flush_lsn |
------------+-----------+---------------------|
    logical_slot | logical   | 32/0003628          |
(1 row)
```

After you complete your replication tasks, stop the replication process, drop replication slots, and turn off logical replication. To turn off logical replication, modify your DB cluster parameter group and set the value of rds.logical_replication back to 0. Reboot the cluster for the parameter change to take effect.
Deleting a Multi-AZ DB cluster

You can delete a DB Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

The time required to delete a Multi-AZ DB cluster can vary depending on certain factors. These are the backup retention period (that is, how many backups to delete), how much data is deleted, and whether a final snapshot is taken.

You can't delete a Multi-AZ DB cluster when deletion protection is turned on for it. For more information, see Prerequisites for deleting a DB instance (p. 489). You can turn off deletion protection by modifying the Multi-AZ DB cluster. For more information, see Modifying a Multi-AZ DB cluster (p. 539).

Console

To delete a Multi-AZ DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the Multi-AZ DB cluster that you want to delete.
3. For Actions, choose Delete.
4. Choose Create final snapshot? to create a final DB snapshot for the Multi-AZ DB cluster.
   - If you create a final snapshot, enter a name for Final snapshot name.
5. Choose Retain automated backups to retain automated backups.
6. Enter delete me in the box.
7. Choose Delete.

AWS CLI

To delete a Multi-AZ DB cluster by using the AWS CLI, call the delete-db-cluster command with the following options:

- --db-cluster-identifier
- --final-db-snapshot-identifier or --skip-final-snapshot

Example With a final snapshot

For Linux, macOS, or Unix:

```bash
aws rds delete-db-cluster \    
--db-cluster-identifier mymultiazdbcluster \    
--final-db-snapshot-identifier mymultiazdbclusterfinalsnapshot
```

For Windows:

```bash
aws rds delete-db-cluster ^    
--db-cluster-identifier mymultiazdbcluster ^    
--final-db-snapshot-identifier mymultiazdbclusterfinalsnapshot
```

Example With no final snapshot

For Linux, macOS, or Unix:

```bash
aws rds delete-db-cluster
```

For Windows:

```bash
aws rds delete-db-cluster ^
```
Deleting a Multi-AZ DB cluster

```
aws rds delete-db-cluster
   --db-cluster-identifier mymultiazdbcluster
   --skip-final-snapshot
```

For Windows:

```
aws rds delete-db-cluster ^
   --db-cluster-identifier mymultiazdbcluster ^
   --skip-final-snapshot
```

**RDS API**

To delete a Multi-AZ DB cluster by using the Amazon RDS API, call the [DeleteDBCluster](https://docs.aws.amazon.com/AmazonRDS/latest/APIReference/API_DeleteDBCluster.html) operation with the following parameters:

- `DBClusterIdentifier`
- `FinalDBSnapshotIdentifier` or `SkipFinalSnapshot`
Using Amazon RDS Extended Support

After a major engine version of your database reaches the RDS end of standard support date, Amazon RDS automatically upgrades your databases to the next supported major engine version. With Amazon RDS Extended Support, you can continue running your database on a major engine version past the RDS end of standard support date for an additional cost.

This paid feature gives you more time to upgrade to a supported major engine version. During Extended Support, Amazon RDS will supply patches for Critical and High CVEs as defined by the National Vulnerability Database (NVD) CVSS severity ratings. For more information, see Vulnerability Metrics. You can also create new databases with major engine versions that have reached the RDS end of standard support date. When you create these databases, Amazon RDS automatically enables Amazon RDS Extended Support.

For example, the RDS end of standard support date for RDS for MySQL version 5.7 is February 29, 2024. But you aren’t ready to manually upgrade to RDS for MySQL version 8.0 before that date or for Amazon RDS to automatically upgrade your DB instances to RDS for MySQL version 8.0 after that date. If you enable Extended Support for those DB instances before February 29, 2024, you can continue to run RDS for MySQL version 5.7, and starting March 1, 2024, Amazon RDS will automatically charge you for Extended Support.

This additional charge for Extended Support ends as soon as you upgrade to a supported major engine version or you delete the database that was running a major version past the RDS end of standard support date. For more information, see Amazon RDS for MySQL pricing and Amazon RDS for PostgreSQL pricing.

Note
Extended Support is only available on the last minor version released before the RDS end of standard support date. If you enable Extended Support, Amazon RDS automatically upgrades your DB instance to a minor version that supports Extended Support. Amazon RDS won’t upgrade your minor version until after the RDS end of standard support date for your major engine version. For more information, see Supported MySQL minor versions on Amazon RDS (p. 1643).

Extended Support is available for up to 3 years past the RDS end of standard support date for a major engine version. After 3 years, if you haven’t upgraded your major engine version to a supported version, then Amazon RDS will automatically upgrade your major engine version. We recommend that you upgrade to a supported major engine version as soon as possible.

Extended Support is available for RDS for MySQL 5.7 and 8.0, and for RDS for PostgreSQL 11 and higher. For more information, see Supported MySQL major versions on Amazon RDS (p. 1645) and Release calendar for Amazon RDS for PostgreSQL.

Note
You must enable Extended Support for a particular version before the RDS end of standard support date for that version. Extended Support will be available through the AWS Management Console or the Amazon RDS API in December 2023.
Using Amazon RDS Blue/Green Deployments for database updates

A blue/green deployment copies a production database environment to a separate, synchronized staging environment. By using Amazon RDS Blue/Green Deployments, you can make changes to the database in the staging environment without affecting the production environment. For example, you can upgrade the major or minor DB engine version, change database parameters, or make schema changes in the staging environment. When you are ready, you can promote the staging environment to be the new production database environment, with downtime typically under one minute.

**Note**
Currently, blue/green deployments are supported only for RDS for MariaDB and RDS for MySQL. For Amazon Aurora availability, see Using Amazon RDS Blue/Green Deployments for database updates in the Amazon Aurora User Guide.

**Topics**
- Overview of Amazon RDS Blue/Green Deployments (p. 567)
- Creating a blue/green deployment (p. 575)
- Viewing a blue/green deployment (p. 579)
- Switching a blue/green deployment (p. 582)
- Deleting a blue/green deployment (p. 587)
Overview of Amazon RDS Blue/Green Deployments

By using Amazon RDS Blue/Green Deployments, you can create a blue/green deployment for managed database changes. A blue/green deployment creates a staging environment that copies the production environment. In a blue/green deployment, the blue environment is the current production environment. The green environment is the staging environment. The staging environment stays in sync with the current production environment using logical replication.

You can make changes to the RDS DB instances in the green environment without affecting production workloads. For example, you can upgrade the major or minor DB engine version, change database parameters, or make schema changes in the staging environment. You can thoroughly test changes in the green environment to be the new production environment. The switchover typically takes under a minute with no data loss and no need for application changes.

Because the green environment is a copy of the topology of the production environment, the green environment includes the features used by the DB instance. These features include the read replicas, the storage configuration, DB snapshots, automated backups, Performance Insights, and Enhanced Monitoring. If the blue DB instance is a Multi-AZ DB instance deployment, then the green DB instance is also a Multi-AZ DB instance deployment.

Note
Currently, blue/green deployments are supported only for RDS for MariaDB and RDS for MySQL. For Amazon Aurora availability, see Using Amazon RDS Blue/Green Deployments for database updates in the Amazon Aurora User Guide.

Benefits of using Amazon RDS Blue/Green Deployments

By using Amazon RDS Blue/Green Deployments, you can stay current on security patches, improve database performance, and adopt newer database features with short, predictable downtime. Blue/green deployments reduce the risks and downtime for database updates, such as major or minor engine version upgrades.

Blue/green deployments provide the following benefits:

- Easily create a production-ready staging environment.
- Automatically replicate database changes from the production environment to the staging environment.
- Test database changes in a safe staging environment without affecting the production environment.
• Stay current with database patches and system updates.
• Implement and test newer database features.
• Switch over your staging environment to be the new production environment without changes to your application.
• Safely switch over through the use of built-in switchover guardrails.
• Eliminate data loss during switchover.
• Switch over quickly, typically under a minute depending on your workload.

**Workflow of a blue/green deployment**

Complete the following major steps when you use a blue/green deployment for database updates.

1. **Identify a production environment that requires updates.**

   For example, the production environment in this image has a Multi-AZ DB instance deployment (mydb1) and a read replica (mydb2).

![Production environment diagram](image)

2. **Create the blue/green deployment.** For instructions, see [Creating a blue/green deployment](p. 575).

   The following image shows an example of a blue/green deployment of the production environment from step 1. While creating the blue/green deployment, RDS copies the complete topology and configuration of the primary DB instance to create the green environment. The copied DB instance names are appended with `-green-random-characters`. The staging environment in the image contains a Multi-AZ DB instance deployment (mydb1-green-abc123) and a read replica (mydb2-green-abc123).
When you create the blue/green deployment, you can upgrade your DB engine version and specify a different DB parameter group for the DB instances in the green environment. RDS also configures logical replication from the primary DB instance in the blue environment to the primary DB instance in the green environment.

After you create the blue/green deployment, the DB instance in the green environment is read-only by default.

3. Make additional changes to the staging environment, if required.

For example, you might make schema changes to your database or change the DB instance class used by one or more DB instances in the green environment.
For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401).

4. Test your staging environment.

During testing, we recommend that you keep your databases in the green environment read only. We recommend that you enable write operations on the green environment with caution because they can result in replication conflicts. They can also result in unintended data in the production databases after switchover.

5. When ready, switch over to promote the staging environment to be the new production environment. For instructions, see Switching a blue/green deployment (p. 582).

The switchover results in downtime. The downtime is usually under one minute, but it can be longer depending on your workload.

The following image shows the DB instances after the switchover.
After the switchover, the DB instances that were in the green environment become the new production DB instances. The names and endpoints in the current production environment are assigned to the newly promoted production environment, requiring no changes to your application. As a result, your production traffic now flows to the new production environment. The DB instances in the previous blue environment are renamed by appending `-old` to the current name, where `n` is a number. For example, assume the name of the DB instance in the blue environment is `mydb1`. After switchover, the DB instance name might be `mydb1-old1`.

In the example in the image, the following changes occur during switchover:

- The green environment Multi-AZ DB instance deployment named `mydb1-green-abc123` becomes the production Multi-AZ DB instance deployment named `mydb1`.
- The green environment read replica named `mydb2-green-abc123` becomes the production read replica `mydb2`.

After the switchover, the DB instances that were in the green environment become the new production DB instances. The names and endpoints in the current production environment are assigned to the newly promoted production environment, requiring no changes to your application. As a result, your production traffic now flows to the new production environment. The DB instances in the previous blue environment are renamed by appending `-old` to the current name, where `n` is a number. For example, assume the name of the DB instance in the blue environment is `mydb1`. After switchover, the DB instance name might be `mydb1-old1`.

In the example in the image, the following changes occur during switchover:

- The green environment Multi-AZ DB instance deployment named `mydb1-green-abc123` becomes the production Multi-AZ DB instance deployment named `mydb1`.
- The green environment read replica named `mydb2-green-abc123` becomes the production read replica `mydb2`.

After the switchover, the DB instances that were in the green environment become the new production DB instances. The names and endpoints in the current production environment are assigned to the newly promoted production environment, requiring no changes to your application. As a result, your production traffic now flows to the new production environment. The DB instances in the previous blue environment are renamed by appending `-old` to the current name, where `n` is a number. For example, assume the name of the DB instance in the blue environment is `mydb1`. After switchover, the DB instance name might be `mydb1-old1`.

In the example in the image, the following changes occur during switchover:

- The green environment Multi-AZ DB instance deployment named `mydb1-green-abc123` becomes the production Multi-AZ DB instance deployment named `mydb1`.
- The green environment read replica named `mydb2-green-abc123` becomes the production read replica `mydb2`. 
• The blue environment Multi-AZ DB instance deployment named mydb1 becomes mydb1-old1.
• The blue environment read replica named mydb2 becomes mydb2-old1.

6. If you no longer need a blue/green deployment, you can delete it. For instructions, see Deleting a blue/green deployment (p. 587).

After switchover, the previous production environment isn't deleted so that you can use it for regression testing, if necessary.

**Authorizing access to blue/green deployment operations**

Users must have the required permissions to perform operations related to blue/green deployments. You can create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. You can then attach those policies to the IAM permission sets or roles that require those permissions. For more information, see Identity and access management for Amazon RDS (p. 2623).

The user who creates a blue/green deployment must have permissions to perform the following RDS operations:

- rds:AddTagsToResource
- rds:CreateDBInstanceReadReplica

The user who switches over a blue/green deployment must have permissions to perform the following RDS operations:

- rds:ModifyDBInstance
- rds:PromoteDBInstance

The user who deletes a blue/green deployment must have permissions to perform the following RDS operation:

- rds:DeleteDBInstance

**Considerations for blue/green deployments**

Amazon RDS tracks resources in blue/green deployments with the DbiResourceId of each resource. This resource ID is an AWS Region-unique, immutable identifier for the resource.

The resource ID is separate from the DB instance ID:
The name (instance ID) of a resource changes when you switch over a blue/green deployment, but each resource keeps the same resource ID. For example, a DB instance identifier might be mydb in the blue environment. After switchover, the same DB instance might be renamed to mydb-old1. However, the resource ID of the DB instance doesn’t change during switchover. So, when the green resources are promoted to be the new production resources, their resource IDs don’t match the blue resource IDs that were previously in production.

After switching over a blue/green deployment, consider updating the resource IDs to those of the newly promoted production resources for integrated features and services that you used with the production resources. Specifically, consider the following updates:

- If you perform filtering using the RDS API and resource IDs, adjust the resource IDs used in filtering after switchover.
- If you use CloudTrail for auditing resources, adjust the consumers of the CloudTrail to track the new resource IDs after switchover. For more information, see [Monitoring Amazon RDS API calls in AWS CloudTrail](p. 940).
- If you use the Performance Insights API, adjust the resource IDs in calls to the API after switchover. For more information, see [Monitoring DB load with Performance Insights on Amazon RDS](p. 720).

You can monitor a database with the same name after switchover, but it doesn’t contain the data from before the switchover.

- If you use resource IDs in IAM policies, make sure you add the resource IDs of the newly promoted resources when necessary. For more information, see [Identity and access management for Amazon RDS](p. 2623).
- If you authenticate to your DB instance using IAM database authentication (p. 2659), make sure that the IAM policy used for database access has both the blue and the green databases listed under the Resource element of the policy. This is required in order to connect to the green database after switchover. For more information, see the section called “Creating and using an IAM policy for IAM database access” (p. 2663).
- If you use AWS Backup to manage automated backups of resources in a blue/green deployment, adjust the resource IDs used by AWS Backup after switchover. For more information, see [Using AWS Backup to manage automated backups](p. 599).
If you want to restore a manual or automated DB snapshot for a DB instance that was part of a blue/green deployment, make sure you restore the correct DB snapshot by examining the time when the snapshot was taken. For more information, see Restoring from a DB snapshot (p. 615).

If you want to describe a previous blue environment DB instance automated backup or restore it to a point in time, use the resource ID for the operation.

Because the name of the DB instance changes during switchover, you can't use its previous name for DescribeDBInstanceAutomatedBackups or RestoreDBInstanceToPointInTime operations. For more information, see Restoring a DB instance to a specified time (p. 660).

When you add a read replica to a DB instance in the green environment of a blue/green deployment, the new read replica won't replace a read replica in the blue environment when you switch over. However, the new read replica is retained in the new production environment after switchover.

When you delete a DB instance in the green environment of a blue/green deployment, you can't create a new DB instance to replace it in the blue/green deployment. If you create a new DB instance with the same name and Amazon Resource Name (ARN) as the deleted DB instance, it has a different DbiResourceId, so it isn't part of the green environment.

The following behavior results if you delete a DB instance in the green environment:

- If the DB instance in the blue environment with the same name exists, it won't be switched over to the DB instance in the green environment. This DB instance won't be renamed by adding -oldn to the DB instance name.
- Any application that points to the DB instance in the blue environment continues to use the same DB instance after switchover.

The same behavior applies to DB instances and read replicas.

Best practices for blue/green deployments

The following are best practices for blue/green deployments:

- Avoid using non-transactional storage engines, such as MyISAM, that aren't optimized for replication.
- Optimize read replicas for binary log replication.

For example, if your DB engine version supports it, consider using GTID replication, parallel replication, and crash-safe replication in your production environment before deploying your blue/green deployment. These options promote consistency and durability of your data before you switch over your blue/green deployment. For more information about GTID replication for read replicas, see Using GTID-based replication for Amazon RDS for MySQL (p. 1735).

- Thoroughly test the DB instances in the green environment before switching over.
- Keep your databases in the green environment read only. We recommend that you enable write operations on the green environment with caution because they can result in replication conflicts. They can also result in unintended data in the production databases after switchover.
- When using a blue/green deployment to implement schema changes, make only replication-compatible changes.

For example, you can add new columns at the end of a table, create indexes, or drop indexes without disrupting replication from the blue deployment to the green deployment. However, schema changes, such as renaming columns or renaming tables, break binary log replication to the green deployment.

For more information about replication-compatible changes, see Replication with Differing Table Definitions on Source and Replica in the MySQL documentation.
After you create the blue/green deployment, handle lazy loading if necessary. Make sure data loading is complete before switching over. For more information, see Handling lazy loading when you create a blue/green deployment (p. 576).

When you switch over a blue/green deployment, follow the switchover best practices. For more information, see the section called “Switchover best practices” (p. 584).

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with Amazon RDS Blue/Green Deployments, see Blue/Green Deployments (p. 118).

Limitations for blue/green deployments

The following limitations apply to blue/green deployments:

- MySQL versions 8.0.11 through 8.0.13 have a community bug that prevents RDS from supporting them for blue/green deployments.
- The Event Scheduler (event_scheduler parameter) must be disabled on the green environment when you create a blue/green deployment. This prevents events from being generated in the green environment and causing inconsistencies.
- Blue/green deployments aren't supported for the following features:
  - Amazon RDS Proxy
  - Cascading read replicas
  - Cross-Region read replicas
  - AWS CloudFormation
  - Multi-AZ DB cluster deployments

  Blue/green deployments are supported for Multi-AZ DB instance deployments. For more information about Multi-AZ deployments, see Configuring and managing a Multi-AZ deployment (p. 492).

- The following are limitations for changes in a blue/green deployment:
  - You can't change an unencrypted DB instance into an encrypted DB instance.
  - You can't change an encrypted DB instance into an unencrypted DB instance.
  - You can't change a blue environment DB instance to a higher engine version than its corresponding green environment DB instance.
  - The resources in the blue environment and green environment must be in the same AWS account.
  - During switchover, the blue primary DB instance can't be the target of external replication.
  - If the source database is associated with a custom option group, you can't specify a major version upgrade when you create the blue/green deployment.

  In this case, you can create a blue/green deployment without specifying a major version upgrade. Then, you can upgrade the database in the green environment. For more information, see Upgrading a DB instance engine version (p. 429).

Creating a blue/green deployment

When you create a blue/green deployment, you specify the DB instance to copy in the deployment. The DB instance you choose is the production DB instance, and it becomes the primary DB instance in the blue environment. This DB instance is copied to the green environment, and RDS configures replication from the DB instance in the blue environment to the DB instance in the green environment.
RDS copies the blue environment’s topology to a staging area, along with its configured features. When the blue DB instance has read replicas, the read replicas are copied as read replicas of the green DB instance in the deployment. If the blue DB instance is a Multi-AZ DB instance deployment, then the green DB instance is created as a Multi-AZ DB instance deployment.

**Topics**
- Making changes in the green environment (p. 576)
- Handling lazy loading when you create a blue/green deployment (p. 576)
- Creating the blue/green deployment (p. 577)

### Making changes in the green environment

You can make the following changes to the DB instance in the green environment when you create the blue/green deployment:

- You can specify a higher engine version if you want to test a DB engine upgrade.
- You can specify a DB parameter group that is different from the one used by the DB instance in the blue environment. You can test how parameter changes affect the DB instances in the green environment or specify a parameter group for a new major DB engine version in the case of an upgrade.

If you specify a different DB parameter group, the specified DB parameter group is associated with all of the DB instances in the green environment. If you don't specify a different parameter group, each DB instance in the green environment is associated with the parameter group of its corresponding blue DB instance.

You can make other modifications to the DB instance in the green environment after it is deployed. For example, you might make schema changes to your database or change the DB instance class used by one or more DB instances in the green environment.

For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#) (p. 401).

### Handling lazy loading when you create a blue/green deployment

When you create a blue/green deployment, Amazon RDS creates the primary DB instance in the green environment by restoring from a DB snapshot. After it is created, the green DB instance continues to load data in the background, which is known as lazy loading. If the DB instance has read replicas, these are also created from DB snapshots and are subject to lazy loading.

If you access data that hasn't been loaded yet, the DB instance immediately downloads the requested data from Amazon S3, and then continues loading the rest of the data in the background. For more information, see [Amazon EBS snapshots](#).

To help mitigate the effects of lazy loading on tables to which you require quick access, you can perform operations that involve full-table scans, such as `SELECT *`. This operation allows Amazon RDS to download all of the backed-up table data from S3.

If an application attempts to access data that isn't loaded, the application can encounter higher latency than normal while the data is loaded. This higher latency due to lazy loading could lead to poor performance for latency-sensitive workloads.

**Important**
If you switch over a blue/green deployment before data loading is complete, your application could experience performance issues due to high latency.
Creating the blue/green deployment

You can create the blue/green deployment using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a blue/green deployment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to copy to a green environment.
3. For Actions, choose Create Blue/Green Deployment.

The Create Blue/Green Deployment page appears.

4. On the Create Blue/Green Deployment page, review the blue database identifiers. Make sure they match the DB instances that you expect in the blue environment. If they don't, choose Cancel.
5. For Blue/Green Deployment identifier, enter a name for your blue/green deployment.
Creating the blue/green deployment

6. (Optional) For **Blue/Green Deployment settings**, specify the settings for the green environment:
   - Choose a DB engine version if you want to test a DB engine version upgrade.
   - Choose a DB parameter group to associate with the DB instances in the green environment.

   You can make other modifications to the databases in the green environment after it is deployed.

7. Choose **Create Blue/Green Deployment**.

**AWS CLI**

To create a blue/green deployment by using the AWS CLI, use the `create-blue-green-deployment` command with the following options:

- `-blue-green-deployment-name` – Specify the name of the blue/green deployment.
- `-source` – Specify the ARN of the DB instance that you want to copy.
- `-target-engine-version` – Specify an engine version if you want to test a DB engine version upgrade in the green environment. This option upgrades the DB instances in the green environment to the specified DB engine version.

   If not specified, each DB instance in the green environment is created with the same engine version as the corresponding DB instance in the blue environment.
- `-target-db-parameter-group-name` – Specify a DB parameter group to associate with the DB instances in the green environment.

**Example Create a blue/green deployment**

For Linux, macOS, or Unix:

```bash
aws rds create-blue-green-deployment \
   --blue-green-deployment-name my-blue-green-deployment \
   --source arn:aws:rds:us-east-2:123456789012:db:mydb1 \
   --target-engine-version 8.0.31 \
   --target-db-parameter-group-name mydbparametergroup
```

For Windows:

```bash
aws rds create-blue-green-deployment ^
   --blue-green-deployment-name my-blue-green-deployment ^
   --source arn:aws:rds:us-east-2:123456789012:db:mydb1 ^
   --target-engine-version 8.0.31 ^
   --target-db-parameter-group-name mydbparametergroup
```

**RDS API**

To create a blue/green deployment by using the Amazon RDS API, use the `CreateBlueGreenDeployment` operation with the following parameters:

- `BlueGreenDeploymentName` – Specify the name of the blue/green deployment.
- `Source` – Specify the ARN of the DB instance that you want to copy to the green environment.
- `TargetEngineVersion` – Specify an engine version if you want to test a DB engine version upgrade in the green environment. This option upgrades the DB instances in the green environment to the specified DB engine version.
If not specified, each DB instance in the green environment is created with the same engine version as the corresponding DB instance in the blue environment.

- **TargetDBParameterGroupName** – Specify a DB parameter group to associate with the DB instances in the green environment.

### Viewing a blue/green deployment

You can view the details about a blue/green deployment using the AWS Management Console, the AWS CLI, or the RDS API.

You can also view and subscribe to events for information about a blue/green deployment. For more information, see [Blue/green deployment events](p. 892).

**Console**

**To view the details about a blue/green deployment**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then find the blue/green deployment in the list.

   ![Databases](image)

   The **Role** value for the blue/green deployment is **Blue/Green Deployment**.

3. Choose the name of blue/green deployment that you want to view to display its details.

   Each tab has a section for the blue deployment and a section for the green deployment. The section for the blue deployment shows the details about DB instances in the blue environment. The section for the green deployment shows the details about DB instances in the green environment. You can examine the details in both environments to see differences between them. For example, on the **Configuration** tab, the DB engine version might be different in the blue environment and in the green environment if you are upgrading the DB engine version in the green environment. Make sure the values for the DB instances in both environments are the expected values.

   The following image shows an example of the **Connectivity & security** tab.
The following image shows an example of the **Configuration** tab.
The following image shows an example of the **Status** tab.
AWS CLI

To view the details about a blue/green deployment by using the AWS CLI, use the `describe-blue-green-deployments` command.

Example View the details about a blue/green deployment by filtering on its name

When you use the `describe-blue-green-deployments` command, you can filter on the `--blue-green-deployment-name`. The following example shows the details for a blue/green deployment named `my-blue-green-deployment`.

```
aws rds describe-blue-green-deployments --filters Name=blue-green-deployment-name,Values=my-blue-green-deployment
```

Example View the details about a blue/green deployment by specifying its identifier

When you use the `describe-blue-green-deployments` command, you can specify the `--blue-green-deployment-identifier`. The following example shows the details for a blue/green deployment with the identifier `bgd-1234567890abcdef`.

```
aws rds describe-blue-green-deployments --blue-green-deployment-identifier bgd-1234567890abcdef
```

RDS API

To view the details about a blue/green deployment by using the Amazon RDS API, use the `DescribeBlueGreenDeployments` operation and specify the `BlueGreenDeploymentIdentifier`.

Switching a blue/green deployment

A `switchover` promotes the green environment to be the new production environment. When the green DB instance has read replicas, they are also promoted. Before you switch over, production traffic is routed to the DB instance and read replicas in the blue environment. After you switch over, production traffic is routed to the DB instance and read replicas in the green environment.

Topics
- Switchover timeout (p. 582)
- Switchover guardrails (p. 583)
- Switchover actions (p. 583)
- Switchover best practices (p. 584)
- Verifying CloudWatch metrics before switchover (p. 584)
- Switching over a blue/green deployment before switchover (p. 585)
- After switchover (p. 587)

Switchover timeout

You can specify a switchover timeout period between 30 seconds and 3,600 seconds (one hour). If the switchover takes longer than the specified duration, then any changes are rolled back and no changes are made to either environment. The default timeout period is 300 seconds (five minutes).
Switchover guardrails

When you start a switchover, Amazon RDS runs some basic checks to test the readiness of the blue and green environments for switchover. These checks are known as switchover guardrails. These switchover guardrails prevent a switchover if the environments aren't ready for it. Therefore, they avoid longer than expected downtime and prevent the loss of data between the blue and green environments that might result if the switchover started.

Amazon RDS runs the following guardrail checks on the green environment:

- Replication health – Check if green primary DB instance replication status is healthy. The green primary DB instance is a replica of the blue primary DB instance.
- Replication lag – Check if the replica lag of the green primary DB instance is within allowable limits for switchover. The allowable limits are based on the specified timeout period. Replica lag indicates how far the green primary DB instance is lagging behind its blue primary DB instance. Replica lag indicates how much time the green replica might require before it catches up with its blue source. For more information, see Diagnosing and resolving lag between read replicas (p. 2753).
- Active writes – Make sure there are no active writes on the green primary DB instance.

Amazon RDS runs the following guardrail checks on the blue environment:

- External replication – Make sure the blue primary DB instance isn't the target of external replication to prevent writes on the blue primary DB instance during switchover.
- Long-running active writes – Make sure there are no long-running active writes on the blue primary DB instance because they can increase replica lag.
- Long-running DDL statements – Make sure there are no long-running DDL statements on the blue primary DB instance because they can increase replica lag.

Switchover actions

When you switch over a blue/green deployment, RDS performs the following actions:

1. Runs guardrail checks to verify if the blue and green environments are ready for switchover.
2. Stops new write operations on the primary DB instance in both environments.
3. Drops connections to the DB instances in both environments and doesn't allow new connections.
4. Waits for replication to catch up in the green environment so that the green environment is in sync with the blue environment.
5. Renames the DB instances in the both environments.

RDS renames the DB instances in the green environment to match the corresponding DB instances in the blue environment. For example, assume the name of a DB instance in the blue environment is mydb. Also assume the name of the corresponding DB instance in the green environment is mydb-green-abc123. During switchover, the name of the DB instance in the green environment is changed to mydb.

RDS renames the DB instances in the blue environment by appending -oldn to the current name, where n is a number. For example, assume the name of a DB instance in the blue environment is mydb. After switchover, the DB instance name might be mydb-old1.

RDS also renames the endpoints in the green environment to match the corresponding endpoints in the blue environment so that application changes aren't required.
6. Allows connections to databases in both environments.
7. Allows write operations on the primary DB instance in the new production environment.

After switchover, the previous production primary DB instance only allows read operations until it is rebooted.

You can monitor the status of a switchover using Amazon EventBridge. For more information, see the section called “Blue/green deployment events” (p. 892).

If you have tags configured in the blue environment, these tags are moved to the new production environment during switchover. The previous production environment also retains these tags. For more information about tags, see Tagging Amazon RDS resources (p. 461).

If the switchover starts and then stops before finishing for any reason, then any changes are rolled back, and no changes are made to either environment.

Switchover best practices

Before you switchover, we strongly recommend that you adhere to best practices by completing the following tasks:

- Thoroughly test the resources in the green environment. Make sure they function properly and efficiently.
- Monitor relevant Amazon CloudWatch metrics. For more information, see the section called “Verifying CloudWatch metrics before switchover” (p. 584).
- Identify the best time for the switchover.

During the switchover, writes are cut off from databases in both environments. Identify a time when traffic is lowest on your production environment. Long-running transactions, such as active DDLs, can increase your switchover time, resulting in longer downtime for your production workloads.

If there's a large number of connections on your DB instances, consider manually reducing them to the minimum amount necessary for your application before you switch over the blue/green deployment. One way to achieve this is to create a script that monitors the status of the blue/green deployment and starts cleaning up connections when it detects that the status has changed to SWITCHOVER_IN_PROGRESS.

- Make sure the DB instances in both environments are in Available state.
- Make sure the primary DB instance in the green environment is healthy and replicating.
- Make sure that your network and client configurations don’t increase the DNS cache Time-To-Live (TTL) beyond five seconds, which is the default for RDS DNS zones. Otherwise, applications will continue to send write traffic to the blue environment after switchover.
- Make sure data loading is complete before switching over. For more information, see Handling lazy loading when you create a blue/green deployment (p. 576).

Note

During a switchover, you can't modify any DB instances included in the switchover.

Verifying CloudWatch metrics before switchover

Before you switch over a blue/green deployment, we recommend that you check the values of the following metrics within Amazon CloudWatch.

- ReplicaLag – Use this metric to identify the current replication lag on the green environment. To reduce downtime, make sure that this value is close to zero before you switch over.
• DatabaseConnections – Use this metric to estimate the level of activity on the blue/green deployment, and make sure that the value is at an acceptable level for your deployment before you switch over. If Performance Insights is turned on, DBLoad is a more accurate metric.

For more information about these metrics, see the section called "CloudWatch metrics for RDS" (p. 806).

Switching over a blue/green deployment

You can switch over a blue/green deployment using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To switch over a blue/green deployment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the blue/green deployment that you want to switch over.
3. For Actions, choose Switch over.

The Switch over page appears.
4. On the **Switch over** page, review the switchover summary. Make sure the resources in both environments match what you expect. If they don't, choose **Cancel**.

5. For **Timeout**, enter the time limit for switchover.

6. Choose **Switch over**.

**AWS CLI**

To switch over a blue/green deployment by using the AWS CLI, use the `switchover-blue-green-deployment` command with the following options:

- `--blue-green-deployment-identifier` – Specify the identifier of the blue/green deployment.
- `--switchover-timeout` – Specify the time limit for the switchover, in seconds. The default is 300.
Example Switch over a blue/green deployment

For Linux, macOS, or Unix:

```
aws rds switchover-blue-green-deployment \\
  --blue-green-deployment-identifier bgd-1234567890abcdef \\
  --switchover-timeout 600
```

For Windows:

```
aws rds switchover-blue-green-deployment ^
  --blue-green-deployment-identifier bgd-1234567890abcdef ^
  --switchover-timeout 600
```

RDS API

To switch over a blue/green deployment by using the Amazon RDS API, use the `SwitchoverBlueGreenDeployment` operation with the following parameters:

- BlueGreenDeploymentIdentifier – Specify the identifier of the blue/green deployment.
- SwitchoverTimeout – Specify the time limit for the switchover, in seconds. The default is 300.

After switchover

After a switchover, the DB instances in the previous blue environment are retained. Standard costs apply to these resources. Replication between the blue and green environments stops.

RDS renames the DB instances in the blue environment by appending `-oldn` to the current resource name, where `n` is a number. The DB instances are read-only until you set the `read_only` parameter to 0.

Deleting a blue/green deployment

You can delete a blue/green deployment before or after you switch it over.

When you delete a blue/green deployment before switching it over, Amazon RDS optionally deletes the DB instances in the green environment:

- If you choose to delete the DB instances in the green environment (`--delete-target`), they must have deletion protection turned off.
- If you don't delete the DB instances in the green environment (`--no-delete-target`), the instances are retained, but they're no longer part of a blue/green deployment. Replication continues between the environments.

The option to delete the green databases isn't available in the console after `switchover` (p. 582). When you delete blue/green deployments using the AWS CLI, you can't specify the `--delete-target` option if the deployment `status` is SWITCHOVER_COMPLETED.

**Important**
Deleting a blue/green deployment doesn't affect the blue environment.

You can delete a blue/green deployment using the AWS Management Console, the AWS CLI, or the RDS API.
**Console**

**To delete a blue/green deployment**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the blue/green deployment that you want to delete.
3. For **Actions**, choose **Delete**.

The **Delete Blue/Green Deployment?** window appears.

![Delete Blue/Green Deployment? window](image)

To delete the green databases, select **Delete the green databases in this Blue/Green Deployment**.

4. Enter **delete me** in the box.
5. Choose **Delete**.

**AWS CLI**

To delete a blue/green deployment by using the AWS CLI, use the **delete-blue-green-deployment** command with the following options:

- **--blue-green-deployment-identifier** – The identifier of the blue/green deployment to be deleted.
- **--delete-target** – Specifies that the DB instances in the green environment are deleted. You can't specify this option if the blue/green deployment has a status of SWITCHOVER_COMPLETED.
- **--no-delete-target** – Specifies that the DB instances in the green environment are retained.

**Example Delete a blue/green deployment and the DB instances in the green environment**

For Linux, macOS, or Unix:
aws rds delete-blue-green-deployment \
   --blue-green-deployment-identifier bgd-1234567890abcdef \
   --delete-target

For Windows:

aws rds delete-blue-green-deployment ^
   --blue-green-deployment-identifier bgd-1234567890abcdef ^
   --delete-target

Example Delete a blue/green deployment but retain the DB instances in the green environment

For Linux, macOS, or Unix:

aws rds delete-blue-green-deployment \
   --blue-green-deployment-identifier bgd-1234567890abcdef \
   --no-delete-target

For Windows:

aws rds delete-blue-green-deployment ^
   --blue-green-deployment-identifier bgd-1234567890abcdef ^
   --no-delete-target

RDS API

To delete a blue/green deployment by using the Amazon RDS API, use the DeleteBlueGreenDeployment operation with the following parameters:

- **BlueGreenDeploymentIdentifier** – The identifier of the blue/green deployment to be deleted.
- **DeleteTarget** – Specify TRUE to delete the DB instances in the green environment or FALSE to retain them. Cannot be TRUE if the blue/green deployment has a status of SWITCHOVER_COMPLETED.
Backing up and restoring

This section shows how to back up and restore an Amazon RDS DB instance or Multi-AZ DB cluster.

Topics

- Working with backups (p. 591)
- Backing up and restoring a DB instance (p. 600)
- Backing up and restoring a Multi-AZ DB cluster (p. 668)
Working with backups

Amazon RDS creates and saves automated backups of your DB instance or Multi-AZ DB cluster during the backup window of your DB instance. RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. RDS saves the automated backups of your DB instance according to the backup retention period that you specify. If necessary, you can recover your DB instance to any point in time during the backup retention period.

Automated backups follow these rules:

• Your DB instance must be in the **available** state for automated backups to occur. Automated backups don't occur while your DB instance is in a state other than **available**, for example, **storage_full**.
• Automated backups don't occur while a DB snapshot copy is running in the same AWS Region for the same database.

You can also back up your DB instance manually by creating a DB snapshot. For more information about manually creating a DB snapshot, see [Creating a DB snapshot](#). The first snapshot of a DB instance contains the data for the full database. Subsequent snapshots of the same database are incremental, which means that only the data that has changed after your most recent snapshot is saved.

You can copy both automatic and manual DB snapshots, and share manual DB snapshots. For more information about copying a DB snapshot, see [Copying a DB snapshot](#). For more information about sharing a DB snapshot, see [Sharing a DB snapshot](#).

Backup storage

Your Amazon RDS backup storage for each AWS Region is composed of the automated backups and manual DB snapshots for that Region. Total backup storage space equals the sum of the storage for all backups in that Region. Moving a DB snapshot to another Region increases the backup storage in the destination Region. Backups are stored in Amazon S3.

For more information about backup storage costs, see [Amazon RDS pricing](#).

If you choose to retain automated backups when you delete a DB instance, the automated backups are saved for the full retention period. If you don't choose **Retain automated backups** when you delete a DB instance, all automated backups are deleted with the DB instance. After they are deleted, the automated backups can't be recovered. If you choose to have Amazon RDS create a final DB snapshot before it deletes your DB instance, you can use that to recover your DB instance. Optionally, you can use a previously created manual snapshot. Manual snapshots are not deleted. You can have up to 100 manual snapshots per Region.

Backup window

Automated backups occur daily during the preferred backup window. If the backup requires more time than allotted to the backup window, the backup continues after the window ends until it finishes. The backup window can't overlap with the weekly maintenance window for the DB instance or Multi-AZ DB cluster.

During the automatic backup window, storage I/O might be suspended briefly while the backup process initializes (typically under a few seconds). You might experience elevated latencies for a few minutes during backups for Multi-AZ deployments. For MariaDB, MySQL, Oracle, and PostgreSQL, I/O activity isn't suspended on your primary during backup for Multi-AZ deployments because the backup is taken from the standby. For SQL Server, I/O activity is suspended briefly during backup for both Single-AZ and Multi-AZ deployments because the backup is taken from the primary.
Automated backups might occasionally be skipped if the DB instance or cluster has a heavy workload at the time it is supposed to start. If a backup is skipped, you can still do a point-in-time-recovery (PITR), and a backup is still attempted during the next backup window. For more information on PITR, see Restoring a DB instance to a specified time (p. 660).

If you don't specify a preferred backup window when you create the DB instance or Multi-AZ DB cluster, Amazon RDS assigns a default 30-minute backup window. This window is selected at random from an 8-hour block of time for each AWS Region. The following table lists the time blocks for each AWS Region from which the default backup windows are assigned.

<table>
<thead>
<tr>
<th>Region Name</th>

</table>
Backup retention period

You can set the backup retention period when you create a DB instance or Multi-AZ DB cluster. If you don't set the backup retention period, the default backup retention period is one day if you create the DB instance using the Amazon RDS API or the AWS CLI. The default backup retention period is seven days if you create the DB instance using the console.

After you create a DB instance or cluster, you can modify the backup retention period. You can set the backup retention period of a DB instance to between 0 and 35 days. Setting the backup retention period to 0 disables automated backups. You can set the backup retention period of a multi-AZ DB cluster to between 1 and 35 days. Manual snapshot limits (100 per Region) don’t apply to automated backups.

Automated backups aren’t created while a DB instance or cluster is stopped. Backups can be retained longer than the backup retention period if a DB instance has been stopped. RDS doesn’t include time spent in the stopped state when the backup retention window is calculated.

Important
An outage occurs if you change the backup retention period from 0 to a nonzero value or from a nonzero value to 0. This applies to both Single-AZ and Multi-AZ DB instances.

Enabling automated backups

If your DB instance doesn’t have automated backups enabled, you can enable them at any time. You enable automated backups by setting the backup retention period to a positive nonzero value. When automated backups are turned on, your DB instance is taken offline and a backup is immediately created.

Note
If you manage your backups in AWS Backup, you can't enable automated backups. For more information, see Using AWS Backup to manage automated backups (p. 599).

Console

To enable automated backups immediately

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance or Multi-AZ DB cluster that you want to modify.

3. Choose **Modify**.

4. For **Backup retention period**, choose a positive nonzero value, for example 3 days.

5. Choose **Continue**.

6. Choose **Apply immediately**.

7. Choose **Modify DB instance** or **Modify cluster** to save your changes and enable automated backups.

### AWS CLI

To enable automated backups, use the AWS CLI **modify-db-instance** or **modify-db-cluster** command.

Include the following parameters:

- `--db-instance-identifier` (or `--db-cluster-identifier` for a Multi-AZ DB cluster)
- `--backup-retention-period`
- `--apply-immediately` or `--no-apply-immediately`

In the following example, we enable automated backups by setting the backup retention period to three days. The changes are applied immediately.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \ 
   --db-instance-identifier mydbinstance \ 
   --backup-retention-period 3 \ 
   --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --backup-retention-period 3 ^
  --apply-immediately
```

### RDS API

To enable automated backups, use the RDS API **ModifyDBInstance** or **ModifyDBCluster** operation with the following required parameters:

- `DBInstanceIdentifier` or `DBClusterIdentifier`
- `BackupRetentionPeriod`

### Viewing automated backups

To view your automated backups, choose **Automated backups** in the navigation pane. To view individual snapshots associated with an automated backup, choose **Snapshots** in the navigation pane. Alternatively, you can describe individual snapshots associated with an automated backup. From there, you can restore a DB instance directly from one of those snapshots.
To describe the automated backups for your existing DB instances using the AWS CLI, use one of the following commands:

```
aws rds describe-db-instance-automated-backups --db-instance-identifier DBInstanceIdentifier
```

or

```
aws rds describe-db-instance-automated-backups --dbi-resource-id DbiResourceId
```

To describe the retained automated backups for your existing DB instances using the RDS API, call the `DescribeDBInstanceAutomatedBackups` action with one of the following parameters:

- `DBInstanceIdentifier`
- `DbiResourceId`

## Retaining automated backups

**Note**

You can only retain automated backups of DB instances, not Multi-AZ DB clusters.

When you delete a DB instance, you can choose to retain automated backups. Automated backups can be retained for a number of days equal to the backup retention period configured for the DB instance at the time when you delete it.

Retained automated backups contain system snapshots and transaction logs from a DB instance. They also include your DB instance properties like allocated storage and DB instance class, which are required to restore it to an active instance.

Retained automated backups and manual snapshots incur billing charges until they're deleted. For more information, see Retention costs (p. 596).

You can retain automated backups for RDS instances running the MySQL, MariaDB, PostgreSQL, Oracle, and Microsoft SQL Server engines.

You can restore or remove retained automated backups using the AWS Management Console, RDS API, and AWS CLI.

### Topics

- Retention period (p. 595)
- Viewing retained backups (p. 596)
- Restoration (p. 596)
- Retention costs (p. 596)
- Limitations (p. 596)

## Retention period

The system snapshots and transaction logs in a retained automated backup expire the same way that they expire for the source DB instance. Because there are no new snapshots or logs created for this instance, the retained automated backups eventually expire completely. Effectively, they live as long their last system snapshot would have done, based on the settings for retention period the source instance had when you deleted it. Retained automated backups are removed by the system after their last system snapshot expires.
You can remove a retained automated backup in the same way that you can delete a DB instance. You can remove retained automated backups using the console or the RDS API operation `DeleteDBInstanceAutomatedBackup`.

Final snapshots are independent of retained automated backups. We strongly suggest that you take a final snapshot even if you retain automated backups because the retained automated backups eventually expire. The final snapshot doesn't expire.

**Viewing retained backups**

To view your retained automated backups, choose **Automated backups** in the navigation pane, then choose **Retained**. To view individual snapshots associated with a retained automated backup, choose **Snapshots** in the navigation pane. Alternatively, you can describe individual snapshots associated with a retained automated backup. From there, you can restore a DB instance directly from one of those snapshots.

To describe your retained automated backups using the AWS CLI, use the following command:

```
aws rds describe-db-instance-automated-backups --dbi-resource-id DbiResourceId
```

To describe your retained automated backups using the RDS API, call the `DescribeDBInstanceAutomatedBackups` action with the `DbiResourceId` parameter.

**Restoration**

For information on restoring DB instances from automated backups, see [Restoring a DB instance to a specified time](p. 660).

**Retention costs**

The cost of a retained automated backup is the cost of total storage of the system snapshots that are associated with it. There is no additional charge for transaction logs or instance metadata. All other pricing rules for backups apply to restorable instances.

For example, suppose that your total allocated storage of running instances is 100 GB. Suppose also that you have 50 GB of manual snapshots plus 75 GB of system snapshots associated with a retained automated backup. In this case, you are charged only for the additional 25 GB of backup storage, like this: (50 GB + 75 GB) – 100 GB = 25 GB.

**Limitations**

The following limitations apply to retained automated backups:

- The maximum number of retained automated backups in one AWS Region is 40. It's not included in the DB instances quota. You can have 40 running DB instances and an additional 40 retained automated backups at the same time.
- Retained automated backups don't contain information about parameters or option groups.
- You can restore a deleted instance to a point in time that is within the retention period at the time of deletion.
- You can't modify a retained automated backup. That's because it consists of system backups, transaction logs, and the DB instance properties that existed at the time that you deleted the source instance.

**Deleting retained automated backups**

You can delete retained automated backups when they are no longer needed.
Disabling automated backups

**Console**

**To delete a retained automated backup**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Automated backups**.
3. On the **Retained** tab, choose the retained automated backup that you want to delete.
4. For **Actions**, choose **Delete**.
5. On the confirmation page, enter **delete me** and choose **Delete**.

**AWS CLI**

You can delete a retained automated backup by using the AWS CLI command `delete-db-instance-automated-backup` with the following option:

- `--dbi-resource-id` – The resource identifier for the source DB instance.

You can find the resource identifier for the source DB instance of a retained automated backup by running the AWS CLI command `describe-db-instance-automated-backups`.

**Example**

The following example deletes the retained automated backup with source DB instance resource identifier `db-123ABCEXAMPLE`.

For Linux, macOS, or Unix:

```bash
aws rds delete-db-instance-automated-backup \    --dbi-resource-id db-123ABCEXAMPLE
```

For Windows:

```bash
aws rds delete-db-instance-automated-backup ^    --dbi-resource-id db-123ABCEXAMPLE
```

**RDS API**

You can delete a retained automated backup by using the Amazon RDS API operation `DeleteDBInstanceAutomatedBackup` with the following parameter:

- `DbiResourceId` – The resource identifier for the source DB instance.

You can find the resource identifier for the source DB instance of a retained automated backup using the Amazon RDS API operation `DescribeDBInstanceAutomatedBackups`.

**Disabling automated backups**

You might want to temporarily disable automated backups in certain situations, for example while loading large amounts of data.

**Important**

We highly discourage disabling automated backups because it disables point-in-time recovery. Disabling automatic backups for a DB instance or Multi-AZ DB cluster deletes all existing
automated backups for the database. If you disable and then re-enable automated backups, you can restore starting only from the time you re-enabled automated backups.

**Console**

**To disable automated backups immediately**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the DB instance or Multi-AZ DB cluster that you want to modify.
3. Choose **Modify**.
4. For **Backup retention period**, choose **0 days**.
5. Choose **Continue**.
6. Choose **Apply immediately**.
7. Choose **Modify DB instance** or **Modify cluster** to save your changes and disable automated backups.

**AWS CLI**

To disable automated backups immediately, use the **modify-db-instance** or **modify-db-cluster** command and set the backup retention period to 0 with **--apply-immediately**.

**Example**

The following example immediately disables automatic backups on a Multi-AZ DB cluster.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster
--db-cluster-identifier mydbcluster
--backup-retention-period 0
--apply-immediately
```

For Windows:

```bash
aws rds modify-db-cluster
   --db-cluster-identifier mydbcluster
   --backup-retention-period 0
   --apply-immediately
```

To know when the modification is in effect, call **describe-db-instances** for the DB instance (or **describe-db-clusters** for a Multi-AZ DB cluster) until the value for backup retention period is 0 and mydbcluster status is available.

```bash
aws rds describe-db-clusters --db-cluster-identifier mydcluster
```

**RDS API**

To disable automated backups immediately, call the **ModifyDBInstance** or **ModifyDBCluster** operation with the following parameters:

- **DBInstanceIdentifier** = mydbinstance (or **DBClusterIdentifier** = mydbcluster)
- **BackupRetentionPeriod** = 0
Example

https://rds.amazonaws.com/
  ?Action=ModifyDBInstance
  &DBInstanceIdentifier=mydbinstance
  &BackupRetentionPeriod=0
  &SignatureVersion=2
  &SignatureMethod=HmacSHA256
  &Timestamp=2009-10-14T17%3A48%3A21.746Z
  &AWSAccessKeyId=<AWS Access Key ID>
  &Signature=<Signature>

Using AWS Backup to manage automated backups

AWS Backup is a fully managed backup service that makes it easy to centralize and automate the backup of data across AWS services in the cloud and on premises. You can manage backups of your Amazon RDS databases in AWS Backup.

To enable backups in AWS Backup, use resource tagging to associate your database with a backup plan. For more information, see Using tags to enable backups in AWS Backup (p. 468).

**Note**

Backups managed by AWS Backup are considered manual DB snapshots, but don't count toward the DB snapshot quota for RDS. Backups that were created with AWS Backup have names ending in awsbackup:backup-job-number.

For more information about AWS Backup, see the AWS Backup Developer Guide.

To view backups managed by AWS Backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the Backup service tab.

Your AWS Backup backups are listed under Backup service snapshots.

Automated backups with unsupported MySQL storage engines

For the MySQL DB engine, automated backups are only supported for the InnoDB storage engine. Using these features with other MySQL storage engines, including MyISAM, can lead to unreliable behavior when you're restoring from backups. Specifically, since storage engines like MyISAM don't support reliable crash recovery, your tables can be corrupted in the event of a crash. For this reason, we encourage you to use the InnoDB storage engine.

- To convert existing MyISAM tables to InnoDB tables, you can use the ALTER TABLE command, for example: ALTER TABLE `table_name` ENGINE=innodb, ALGORITHM=COPY;
- If you choose to use MyISAM, you can attempt to manually repair tables that become damaged after a crash by using the REPAIR command. For more information, see REPAIR TABLE statement in the MySQL documentation. However, as noted in the MySQL documentation, there is a good chance that you might not be able to recover all your data.
- If you want to take a snapshot of your MyISAM tables before restoring, follow these steps:
  1. Stop all activity to your MyISAM tables (that is, close all sessions).
You can close all sessions by calling the `mysql.rds_kill` command for each process that is returned from the `SHOW FULL PROCESSLIST` command.

2. Lock and flush each of your MyISAM tables. For example, the following commands lock and flush two tables named `myisam_table1` and `myisam_table2`:

```sql
mysql> FLUSH TABLES myisam_table, myisam_table2 WITH READ LOCK;
```

3. Create a snapshot of your DB instance or Multi-AZ DB cluster. When the snapshot has completed, release the locks and resume activity on the MyISAM tables. You can release the locks on your tables using the following command:

```sql
mysql> UNLOCK TABLES;
```

These steps force MyISAM to flush data stored in memory to disk, which ensures a clean start when you restore from a DB snapshot. For more information on creating a DB snapshot, see Creating a DB snapshot (p. 613).

## Automated backups with unsupported MariaDB storage engines

For the MariaDB DB engine, automated backups are only supported with the InnoDB storage engine. Using these features with other MariaDB storage engines, including Aria, can lead to unreliable behavior when you're restoring from backups. Even though Aria is a crash-resistant alternative to MyISAM, your tables can still be corrupted in the event of a crash. For this reason, we encourage you to use the InnoDB storage engine.

- To convert existing Aria tables to InnoDB tables, you can use the `ALTER TABLE` command. For example:
  ```sql
  ALTER TABLE table_name ENGINE=innodb, ALGORITHM=COPY;
  ```

- If you choose to use Aria, you can attempt to manually repair tables that become damaged after a crash by using the `REPAIR TABLE` command. For more information, see [http://mariadb.com/kb/en/mariadb/repair-table/](http://mariadb.com/kb/en/mariadb/repair-table/).

- If you want to take a snapshot of your Aria tables before restoring, follow these steps:
  1. Stop all activity to your Aria tables (that is, close all sessions).
  2. Lock and flush each of your Aria tables.
  3. Create a snapshot of your DB instance or Multi-AZ DB cluster. When the snapshot has completed, release the locks and resume activity on the Aria tables. These steps force Aria to flush data stored in memory to disk, thereby ensuring a clean start when you restore from a DB snapshot.

## Backing up and restoring a DB instance

This section shows how to back up and restore a DB instance.

**Topics**

- Replicating automated backups to another AWS Region (p. 602)
- Creating a DB snapshot (p. 613)
- Restoring from a DB snapshot (p. 615)
- Copying a DB snapshot (p. 619)
- Sharing a DB snapshot (p. 633)
- Exporting DB snapshot data to Amazon S3 (p. 642)
- Restoring a DB instance to a specified time (p. 660)
- Deleting a DB snapshot (p. 663)
- Tutorial: Restore an Amazon RDS DB instance from a DB snapshot (p. 665)
Replicating automated backups to another AWS Region

For added disaster recovery capability, you can configure your Amazon RDS database instance to replicate snapshots and transaction logs to a destination AWS Region of your choice. When backup replication is configured for a DB instance, RDS initiates a cross-Region copy of all snapshots and transaction logs as soon as they are ready on the DB instance.

DB snapshot copy charges apply to the data transfer. After the DB snapshot is copied, standard charges apply to storage in the destination Region. For more details, see RDS Pricing.

For an example of using backup replication, see the AWS online tech talk Managed Disaster Recovery with Amazon RDS for Oracle Cross-Region Automated Backups.

Topics

- Region and version availability (p. 602)
- Source and destination AWS Region support (p. 602)
- Enabling cross-Region automated backups (p. 604)
- Finding information about replicated backups (p. 606)
- Restoring to a specified time from a replicated backup (p. 609)
- Stopping automated backup replication (p. 610)
- Deleting replicated backups (p. 611)

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with cross-Region automated backups, see Cross-Region automated backups (p. 118).

Source and destination AWS Region support

Backup replication is supported between the following AWS Regions.

<table>
<thead>
<tr>
<th>Source Region</th>

</tbody>
</table>
You can also use the describe-source-regions AWS CLI command to find out which AWS Regions can replicate to each other. For more information, see Finding information about replicated backups (p. 606).

Enabling cross-Region automated backups

You can enable backup replication on new or existing DB instances using the Amazon RDS console. You can also use the start-db-instance-automated-backups-replication AWS CLI command or the StartDBInstanceAutomatedBackupsReplication RDS API operation. You can replicate up to 20 backups to each destination AWS Region for each AWS account.

Note
To be able to replicate automated backups, make sure to enable them. For more information, see Enabling automated backups (p. 593).

Console

You can enable backup replication for a new or existing DB instance:

- For a new DB instance, enable it when you launch the instance. For more information, see Settings for DB instances (p. 308).
- For an existing DB instance, use the following procedure.

To enable backup replication for an existing DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Automated backups.
3. On the Current Region tab, choose the DB instance for which you want to enable backup replication.
4. For Actions, choose Manage cross-Region replication.
5. Under Backup replication, choose Enable replication to another AWS Region.
6. Choose the Destination Region.
7. Choose the Replicated backup retention period.
8. If you've enabled encryption on the source DB instance, choose the AWS KMS key for encrypting the backups.
9. Choose **Save**.

In the source Region, replicated backups are listed on the **Current Region** tab of the **Automated backups** page. In the destination Region, replicated backups are listed on the **Replicated backups** tab of the **Automated backups** page.

**AWS CLI**

Enable backup replication by using the `start-db-instance-automated-backups-replication` AWS CLI command.

The following CLI example replicates automated backups from a DB instance in the US West (Oregon) Region to the US East (N. Virginia) Region. It also encrypts the replicated backups, using an AWS KMS key in the destination Region.

**To enable backup replication**

- Run one of the following commands.

  For Linux, macOS, or Unix:

  ```
  aws rds start-db-instance-automated-backups-replication \
  --region us-east-1 \
  --kms-key-id "arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE" \
  --backup-retention-period 7
  ```

  For Windows:

  ```
  aws rds start-db-instance-automated-backups-replication ^
  --region us-east-1 ^
  --kms-key-id "arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE" ^
  --backup-retention-period 7
  ```

The `--source-region` option is required when you encrypt backups between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions. For `--source-region`, specify the AWS Region of the source DB instance.

If `--source-region` isn't specified, make sure to specify a `--pre-signed-url` value. A *presigned URL* is a URL that contains a Signature Version 4 signed request for the `start-db-instance-automated-backups-replication` command that is called in the source AWS Region. To learn more about the `--pre-signed-url` option, see [start-db-instance-automated-backups-replication](https://docs.aws.amazon.com/cli/latest/reference/rds/start-db-instance-automated-backups-replication) in the **AWS CLI Command Reference**.

**RDS API**

Enable backup replication by using the `StartDBInstanceAutomatedBackupsReplication` RDS API operation with the following parameters:

- **Region**
- **SourceDBInstanceArn**
- **BackupRetentionPeriod**
- **KmsKeyId** (optional)
- **PreSignedUrl** (required if you use KmsKeyId)
Note
If you encrypt the backups, you must also include a presigned URL. For more information on presigned URLs, see Authenticating Requests: Using Query Parameters (AWS Signature Version 4) in the Amazon Simple Storage Service API Reference and Signature Version 4 signing process in the AWS General Reference.

Finding information about replicated backups
You can use the following CLI commands to find information about replicated backups:

- `describe-source-regions`
- `describe-db-instances`
- `describe-db-instance-automated-backups`

The following `describe-source-regions` example lists the source AWS Regions from which automated backups can be replicated to the US West (Oregon) destination Region.

To show information about source Regions

- Run the following command.

```
aws rds describe-source-regions --region us-west-2
```

The output shows that backups can be replicated from US East (N. Virginia), but not from US East (Ohio) or US West (N. California), into US West (Oregon).

```
{
   "SourceRegions": [
       ...
       {
           "RegionName": "us-east-1",
           "Endpoint": "https://rds.us-east-1.amazonaws.com",
           "Status": "available",
           "SupportsDBInstanceAutomatedBackupsReplication": true
       },
       {
           "RegionName": "us-east-2",
           "Endpoint": "https://rds.us-east-2.amazonaws.com",
           "Status": "available",
           "SupportsDBInstanceAutomatedBackupsReplication": false
       },
       {
           "RegionName": "us-west-1",
           "Endpoint": "https://rds.us-west-1.amazonaws.com",
           "Status": "available",
           "SupportsDBInstanceAutomatedBackupsReplication": false
       }
   ]
}
```

The following `describe-db-instances` example shows the automated backups for a DB instance.

To show the replicated backups for a DB instance

- Run one of the following commands.

For Linux, macOS, or Unix:
Cross-Region automated backups

```bash
aws rds describe-db-instances \
   --db-instance-identifier mydatabase
```

For Windows:

```bash
aws rds describe-db-instances ^ \
   --db-instance-identifier mydatabase
```

The output includes the replicated backups.

```
{
  "DBInstances": [
    {
      "StorageEncrypted": false,
      "Endpoint": {
        "HostedZoneId": "Z1PVIF0B656C1W",
        "Port": 1521,
        ...
        "BackupRetentionPeriod": 7,
        "DBInstanceAutomatedBackupsReplications": [{"DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE"}]
    }
  ]
}
```

The following `describe-db-instance-automated-backups` example shows the automated backups for a DB instance.

**To show automated backups for a DB instance**

- Run one of the following commands.
  - For Linux, macOS, or Unix:
    ```bash
    aws rds describe-db-instance-automated-backups \
    --db-instance-identifier mydatabase
    ```
  - For Windows:
    ```bash
    aws rds describe-db-instance-automated-backups ^ \
    --db-instance-identifier mydatabase
    ```

The output shows the source DB instance and automated backups in US West (Oregon), with backups replicated to US East (N. Virginia).

```
{
  "DBInstanceAutomatedBackups": [
    {
      "DbiResourceId": "db-L2IJCEXJP7XQ7HOJ4SIEXAMPLE",
      "BackupRetentionPeriod": 7,
      "DBInstanceAutomatedBackupsReplications": [{"DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE"}]
    }
  ]
}
```
The following describe-db-instance-automated-backups example uses the --db-instance-automated-backups-arn option to show the replicated backups in the destination Region.

To show replicated backups

- Run one of the following commands.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-instance-automated-backups \
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE"
```

For Windows:

```bash
aws rds describe-db-instance-automated-backups ^
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE"
```

The output shows the source DB instance in US West (Oregon), with replicated backups in US East (N. Virginia).

```
{
  "DBInstanceAutomatedBackups": [
    {
      "DbiResourceId": "db-L2IJCEXJP7XQ7HOJ4SIEXAMPLE",
      "DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE",
      "Region": "us-west-2",
      "DBInstanceIdentifier": "mydatabase",
      "RestoreWindow": {
        "EarliestTime": "2020-10-26T01:09:07Z",
        "LatestTime": "2020-10-31T19:09:53Z"
      },
      "AllocatedStorage": 50,
      "BackupRetentionPeriod": 7,
      "Status": "replicating",
      "Port": 1521,
      ...
    }
  ]
}
```
**Restoring to a specified time from a replicated backup**

You can restore a DB instance to a specific point in time from a replicated backup using the Amazon RDS console. You can also use the `restore-db-instance-to-point-in-time` AWS CLI command or the `RestoreDBInstanceToPointInTime` RDS API operation.

For general information on point-in-time recovery (PITR), see [Restoring a DB instance to a specified time](p. 660).

**Note**
On RDS for SQL Server, option groups aren’t copied across AWS Regions when automated backups are replicated. If you’ve associated a custom option group with your RDS for SQL Server DB instance, you can re-create that option group in the destination Region. Then restore the DB instance in the destination Region and associate the custom option group with it. For more information, see [Working with option groups](p. 331).

**Console**

**To restore a DB instance to a specified time from a replicated backup**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose the destination Region (where backups are replicated to) from the Region selector.
3. In the navigation pane, choose Automated backups.
4. On the Replicated backups tab, choose the DB instance that you want to restore.
5. For Actions, choose Restore to point in time.
6. Choose Latest restorable time to restore to the latest possible time, or choose Custom to choose a time.
   
   If you chose Custom, enter the date and time that you want to restore the instance to.
   
   **Note**
   Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.

7. For DB instance identifier, enter the name of the target restored DB instance.
8. (Optional) Choose other options as needed, such as enabling autoscaling.
9. Choose Restore to point in time.

**AWS CLI**

Use the `restore-db-instance-to-point-in-time` AWS CLI command to create a new DB instance.

**To restore a DB instance to a specified time from a replicated backup**

- Run one of the following commands.

  For Linux, macOS, or Unix:

  ```bash
  aws rds restore-db-instance-to-point-in-time
  --source-db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2I1CEXJ07XQ78H0J4S1EXAMPLE"
  --target-db-instance-identifier mytargetdbinstance
  --restore-time 2020-10-14T23:45:00Z
  ```

  For Windows:
aws rds restore-db-instance-to-point-in-time ^
   --source-db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2JCEXJP7XQ7H0J4S1EXAMPLE" ^
   --target-db-instance-identifier mytargetdbinstance ^
   --restore-time 2020-10-14T23:45:00.000Z

RDS API

To restore a DB instance to a specified time, call the RestoreDBInstanceToPointInTime Amazon RDS API operation with the following parameters:

- SourceDBInstanceAutomatedBackupsArn
- TargetDBInstanceIdentifier
- RestoreTime

Stopping automated backup replication

You can stop backup replication for DB instances using the Amazon RDS console. You can also use the stop-db-instance-automated-backups-replication AWS CLI command or the StopDBInstanceAutomatedBackupsReplication RDS API operation.

Replicated backups are retained, subject to the backup retention period set when they were created.

Console

Stop backup replication from the Automated backups page in the source Region.

To stop backup replication to an AWS Region

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the source Region from the Region selector.
3. In the navigation pane, choose Automated backups.
4. On the Current Region tab, choose the DB instance for which you want to stop backup replication.
5. For Actions, choose Manage cross-Region replication.
6. Under Backup replication, clear the Enable replication to another AWS Region check box.
7. Choose Save.

Replicated backups are listed on the Retained tab of the Automated backups page in the destination Region.

AWS CLI

Stop backup replication by using the stop-db-instance-automated-backups-replication AWS CLI command.

The following CLI example stops automated backups of a DB instance from replicating in the US West (Oregon) Region.

To stop backup replication

- Run one of the following commands.
Cross-Region automated backups

For Linux, macOS, or Unix:

```bash
aws rds stop-db-instance-automated-backups-replication
  --region us-east-1
```

For Windows:

```bash
aws rds stop-db-instance-automated-backups-replication
  --region us-east-1
```

RDS API

Stop backup replication by using the StopDBInstanceAutomatedBackupsReplication RDS API operation with the following parameters:

- Region
- SourceDBInstanceArn

Deleting replicated backups

You can delete replicated backups for DB instances using the Amazon RDS console. You can also use the delete-db-instance-automated-backups AWS CLI command or the DeleteDBInstanceAutomatedBackup RDS API operation.

Console

Delete replicated backups in the destination Region from the Automated backups page.

To delete replicated backups

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the destination Region from the Region selector.
3. In the navigation pane, choose Automated backups.
4. On the Replicated backups tab, choose the DB instance for which you want to delete the replicated backups.
5. For Actions, choose Delete.
6. On the confirmation page, enter delete me and choose Delete.

AWS CLI

Delete replicated backups by using the delete-db-instance-automated-backup AWS CLI command.

You can use the describe-db-instances CLI command to find the Amazon Resource Names (ARNs) of the replicated backups. For more information, see Finding information about replicated backups (p. 606).

To delete replicated backups

- Run one of the following commands.
For Linux, macOS, or Unix:

```
aws rds delete-db-instance-automated-backup \
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEX3P7XQ7H0J4SIEXAMPLE"
```

For Windows:

```
aws rds delete-db-instance-automated-backup ^
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEX3P7XQ7H0J4SIEXAMPLE"
```

**RDS API**

Delete replicated backups by using the `DeleteDBInstanceAutomatedBackup` RDS API operation with the `DBInstanceAutomatedBackupsArn` parameter.
Creating a DB snapshot

Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. Creating this DB snapshot on a Single-AZ DB instance results in a brief I/O suspension that can last from a few seconds to a few minutes, depending on the size and class of your DB instance. For MariaDB, MySQL, Oracle, and PostgreSQL, I/O activity is not suspended on your primary during backup for Multi-AZ deployments, because the backup is taken from the standby. For SQL Server, I/O activity is suspended briefly during backup for Multi-AZ deployments.

When you create a DB snapshot, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. The amount of time it takes to create a snapshot varies with the size of your databases. Since the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects the amount of time it takes to create the snapshot.

**Note**
Your DB instance must be in the available state to take a DB snapshot.
For PostgreSQL DB instances, data in unlogged tables might not be restored from snapshots.
For more information, see Best practices for working with PostgreSQL (p. 294).

Unlike automated backups, manual snapshots aren't subject to the backup retention period. Snapshots don't expire.

For very long-term backups of MariaDB, MySQL, and PostgreSQL data, we recommend exporting snapshot data to Amazon S3. If the major version of your DB engine is no longer supported, you can't restore to that version from a snapshot. For more information, see Exporting DB snapshot data to Amazon S3 (p. 642).

You can create a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To create a DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. In the list of DB instances, choose the DB instance for which you want to take a snapshot.
4. For Actions, choose Take snapshot.
   
   The Take DB snapshot window appears.
5. Enter the name of the snapshot in the Snapshot name box.

6. Choose Take snapshot.
The Snapshots page appears, with the new DB snapshot's status shown as Creating. After its status is Available, you can see its creation time.

**AWS CLI**

When you create a DB snapshot using the AWS CLI, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. You can do this by using the AWS CLI `create-db-snapshot` command with the following parameters:

- `--db-instance-identifier`
- `--db-snapshot-identifier`

In this example, you create a DB snapshot called `mydbsnapshot` for a DB instance called `mydbinstance`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-snapshot \
    --db-instance-identifier mydbinstance \
    --db-snapshot-identifier mydbsnapshot
```

For Windows:

```bash
aws rds create-db-snapshot ^
    --db-instance-identifier mydbinstance ^
    --db-snapshot-identifier mydbsnapshot
```

**RDS API**

When you create a DB snapshot using the Amazon RDS API, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. You can do this by using the Amazon RDS API `CreateDBSnapshot` command with the following parameters:

- `DBInstanceIdentifier`
- `DBSnapshotIdentifier`
Restoring from a DB snapshot

Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. You can create a new DB instance by restoring from a DB snapshot. You provide the name of the DB snapshot to restore from, and then provide a name for the new DB instance that is created from the restore. You can't restore from a DB snapshot to an existing DB instance; a new DB instance is created when you restore.

You can use the restored DB instance as soon as its status is available. The DB instance continues to load data in the background. This is known as lazy loading.

If you access data that hasn't been loaded yet, the DB instance immediately downloads the requested data from Amazon S3, and then continues loading the rest of the data in the background. For more information, see Amazon EBS snapshots.

To help mitigate the effects of lazy loading on tables to which you require quick access, you can perform operations that involve full-table scans, such as SELECT * . This allows Amazon RDS to download all of the backed-up table data from S3.

You can restore a DB instance and use a different storage type than the source DB snapshot. In this case, the restoration process is slower because of the additional work required to migrate the data to the new storage type. If you restore to or from magnetic storage, the migration process is the slowest. That's because magnetic storage doesn't have the IOPS capability of Provisioned IOPS or General Purpose (SSD) storage.

You can use AWS CloudFormation to restore a DB instance from a DB instance snapshot. For more information, see AWS::RDS::DBInstance in the AWS CloudFormation User Guide.

Note
You can't restore a DB instance from a DB snapshot that is both shared and encrypted. Instead, you can make a copy of the DB snapshot and restore the DB instance from the copy. For more information, see Copying a DB snapshot (p. 619).

Parameter group considerations

We recommend that you retain the DB parameter group for any DB snapshots you create, so that you can associate your restored DB instance with the correct parameter group.

The default DB parameter group is associated with the restored instance, unless you choose a different one. No custom parameter settings are available in the default parameter group.

You can specify the parameter group when you restore the DB instance.

For more information about DB parameter groups, see Working with parameter groups (p. 347).

Security group considerations

When you restore a DB instance, the default virtual private cloud (VPC), DB subnet group, and VPC security group are associated with the restored instance, unless you choose different ones.

- If you're using the Amazon RDS console, you can specify a custom VPC security group to associate with the instance or create a new VPC security group.
- If you're using the AWS CLI, you can specify a custom VPC security group to associate with the instance by including the --vpc-security-group-ids option in the restore-db-instance-from-db-snapshot command.
- If you're using the Amazon RDS API, you can include the VpcSecurityGroupIds.VpcSecurityGroupId.N parameter in the RestoreDBInstanceFromDBSnapshot action.
As soon as the restore is complete and your new DB instance is available, you can also change the VPC settings by modifying the DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 401).

Option group considerations

When you restore a DB instance, the default DB option group is associated with the restored DB instance in most cases.

The exception is when the source DB instance is associated with an option group that contains a persistent or permanent option. For example, if the source DB instance uses Oracle Transparent Data Encryption (TDE), the restored DB instance must use an option group that has the TDE option.

If you restore a DB instance into a different VPC, you must do one of the following to assign a DB option group:

- Assign the default option group for that VPC group to the instance.
- Assign another option group that is linked to that VPC.
- Create a new option group and assign it to the DB instance. With persistent or permanent options, such as Oracle TDE, you must create a new option group that includes the persistent or permanent option.

For more information about DB option groups, see Working with option groups (p. 331).

Resource tagging considerations

When you restore a DB instance from a DB snapshot, RDS checks whether you specify new tags. If yes, the new tags are added to the restored DB instance. If there are no new tags, RDS adds the tags from the source DB instance at the time of snapshot creation to the restored DB instance.

For more information, see Copying tags to DB instance snapshots (p. 465).

Microsoft SQL Server considerations

When you restore an RDS for Microsoft SQL Server DB snapshot to a new instance, you can always restore to the same edition as your snapshot. In some cases, you can also change the edition of the DB instance. The following limitations apply when you change editions:

- The DB snapshot must have enough storage allocated for the new edition.
- Only the following edition changes are supported:
  - From Standard Edition to Enterprise Edition
  - From Web Edition to Standard Edition or Enterprise Edition

If you want to change from one edition to a new edition that isn't supported by restoring a snapshot, you can try using the native backup and restore feature. SQL Server verifies whether your database is compatible with the new edition based on what SQL Server features you have enabled on the database. For more information, see Importing and exporting SQL Server databases using native backup and restore (p. 1435).

Oracle Database considerations

If you use Oracle GoldenGate, always retain the parameter group with the compatible parameter. When you restore a DB instance from a DB snapshot, specify a parameter group that has a matching or greater compatible value.
If you restore a snapshot of a CDB instance, you can change the PDB name. You can't change the CDB name, which is always RDSCDB. This CDB name is the same for all RDS instances that use a single-tenant architecture. For more information, see Backing up and restoring a CDB (p. 1860).

Before you restore a DB snapshot, you can upgrade it to a later release. For more information, see Upgrading an Oracle DB snapshot (p. 2128).

## Restoring from a snapshot

You can restore a DB instance from a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

### Note

You can't reduce the amount of storage when you restore a DB instance. When you increase the allocated storage, it must be by at least 10 percent. If you try to increase the value by less than 10 percent, you get an error. You can't increase the allocated storage when restoring RDS for SQL Server DB instances.

### Console

To restore a DB instance from a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Snapshots.
3. Choose the DB snapshot that you want to restore from.
4. For Actions, choose Restore snapshot.
5. On the Restore snapshot page, for DB instance identifier, enter the name for your restored DB instance.
6. Specify other settings, such as allocated storage size.

   For information about each setting, see Settings for DB instances (p. 308).
7. Choose Restore DB instance.

### AWS CLI

To restore a DB instance from a DB snapshot, use the AWS CLI command `restore-db-instance-from-db-snapshot`.

In this example, you restore from a previously created DB snapshot named mydbsnapshot. You restore to a new DB instance named mynewdbinstance. This example also sets the allocated storage size.

You can specify other settings. For information about each setting, see Settings for DB instances (p. 308).

### Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
  --db-instance-identifier mynewdbinstance \
  --db-snapshot-identifier mydbsnapshot \
  --allocated-storage 100
```

For Windows:
Restoring from a DB snapshot

```
aws rds restore-db-instance-from-db-snapshot ^
   --db-instance-identifier mynewdbinstance ^
   --db-snapshot-identifier mydbsnapshot ^
   --allocated-storage 100
```

This command returns output similar to the following:

```
DBINSTANCE  mynewdbinstance  db.t3.small  MySQL     50       sa              creating 3 n
           8.0.28  general-public-license
```

**RDS API**

To restore a DB instance from a DB snapshot, call the Amazon RDS API function `RestoreDBInstanceFromDBSnapshot` with the following parameters:

- `DBInstanceIdentifier`
- `DBSnapshotIdentifier`
Copying a DB snapshot

With Amazon RDS, you can copy automated backups or manual DB snapshots. After you copy a snapshot, the copy is a manual snapshot. You can make multiple copies of an automated backup or manual snapshot, but each copy must have a unique identifier.

You can copy a snapshot within the same AWS Region, you can copy a snapshot across AWS Regions, and you can copy shared snapshots.

Limitations

The following are some limitations when you copy snapshots:

- You can't copy a snapshot to or from the China (Beijing) Region or the China (Ningxia) Region.
- You can copy a snapshot between AWS GovCloud (US-East) and AWS GovCloud (US-West). However, you can't copy a snapshot between these GovCloud (US) Regions and Regions that aren't GovCloud (US) Regions.
- If you delete a source snapshot before the target snapshot becomes available, the snapshot copy might fail. Verify that the target snapshot has a status of AVAILABLE before you delete a source snapshot.
- You can have up to 20 snapshot copy requests in progress to a single destination Region per account.
- When you request multiple snapshot copies for the same source DB instance, they're queued internally. The copies requested later won't start until the previous snapshot copies are completed. For more information, see [Why is my EC2 AMI or EBS snapshot creation slow?](https://aws.amazon.com/premiumsupport/knowledge-center/why-is-my-ami-or-ebs-snapshot-creation-slow/) in the AWS Knowledge Center.
- Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete. In some cases, there might be a large number of cross-Region snapshot copy requests from a given source Region. In such cases, Amazon RDS might put new cross-Region copy requests from that source Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copy starts.
- If a copy is still pending when you start another copy, the second copy doesn't start until the first copy finishes.

Snapshot retention

Amazon RDS deletes automated backups in several situations:

- At the end of their retention period.
- When you disable automated backups for a DB instance.
- When you delete a DB instance.

If you want to keep an automated backup for a longer period, copy it to create a manual snapshot, which is retained until you delete it. Amazon RDS storage costs might apply to manual snapshots if they exceed your default storage space.

For more information about backup storage costs, see [Amazon RDS pricing](https://aws.amazon.com/rds/pricing).

Copying shared snapshots

You can copy snapshots shared to you by other AWS accounts. In some cases, you might copy an encrypted snapshot that has been shared from another AWS account. In these cases, you must have access to the AWS KMS key that was used to encrypt the snapshot.
You can copy a shared DB snapshot across AWS Regions if the snapshot is unencrypted. However, if the shared DB snapshot is encrypted, you can only copy it in the same Region.

**Note**
Copying shared incremental snapshots in the same AWS Region is supported when they're unencrypted, or encrypted using the same KMS key as the initial full snapshot. If you use a different KMS key to encrypt subsequent snapshots when copying them, those shared snapshots are full snapshots. For more information, see [Incremental snapshot copying](p. 620).

**Handling encryption**

You can copy a snapshot that has been encrypted using a KMS key. If you copy an encrypted snapshot, the copy of the snapshot must also be encrypted. If you copy an encrypted snapshot within the same AWS Region, you can encrypt the copy with the same KMS key as the original snapshot. Or you can specify a different KMS key.

If you copy an encrypted snapshot across Regions, you must specify a KMS key valid in the destination AWS Region. It can be a Region-specific KMS key, or a multi-Region key. For more information on multi-Region KMS keys, see [Using multi-Region keys in AWS KMS](#).

The source snapshot remains encrypted throughout the copy process. For more information, see [Limitations of Amazon RDS encrypted DB instances](p. 2606).

You can also encrypt a copy of an unencrypted snapshot. This way, you can quickly add encryption to a previously unencrypted DB instance. To do this, you create a snapshot of your DB instance when you are ready to encrypt it. You then create a copy of that snapshot and specify a KMS key to encrypt that snapshot copy. You can then restore an encrypted DB instance from the encrypted snapshot.

**Incremental snapshot copying**

An *incremental* snapshot contains only the data that has changed after the most recent snapshot of the same DB instance. Incremental snapshot copying is faster and results in lower storage costs than full snapshot copying.

**Note**
When you copy a source snapshot that is a snapshot copy itself, the new copy isn't incremental. This is because the source snapshot copy doesn't include the required metadata for incremental copies.

Whether a snapshot copy is incremental is determined by the most recently completed snapshot copy. If the most recent snapshot copy was deleted, the next copy is a full copy, not an incremental copy.

When you copy a snapshot across AWS accounts, the copy is an incremental copy only if all of the following conditions are met:

- A different snapshot of the same source DB instance was previously copied to the destination account.
- The most recent snapshot copy still exists in the destination account.
- All copies of the snapshot in the destination account are either unencrypted, or were encrypted using the same KMS key.
- If the source DB instance is a Multi-AZ instance, it hasn't failed over to another AZ since the last snapshot was taken from it.

The following examples illustrate the difference between full and incremental snapshots. They apply to both shared and unshared snapshots.

<table>
<thead>
<tr>
<th>Snapshot</th>
<th>Encryption key</th>
<th>Full or incremental</th>
</tr>
</thead>
<tbody>
<tr>
<td>S1</td>
<td>K1</td>
<td>Full</td>
</tr>
</tbody>
</table>

620
### Copying a DB snapshot

<table>
<thead>
<tr>
<th>Snapshot</th>
<th>Encryption key</th>
<th>Full or incremental</th>
</tr>
</thead>
<tbody>
<tr>
<td>S2</td>
<td>K1</td>
<td>Incremental of S1</td>
</tr>
<tr>
<td>S3</td>
<td>K1</td>
<td>Incremental of S2</td>
</tr>
<tr>
<td>S4</td>
<td>K1</td>
<td>Incremental of S3</td>
</tr>
<tr>
<td>Copy of S1 (S1C)</td>
<td>K2</td>
<td>Full</td>
</tr>
<tr>
<td>Copy of S2 (S2C)</td>
<td>K3</td>
<td>Full</td>
</tr>
<tr>
<td>Copy of S3 (S3C)</td>
<td>K3</td>
<td>Incremental of S2C</td>
</tr>
<tr>
<td>Copy of S4 (S4C)</td>
<td>K3</td>
<td>Incremental of S3C</td>
</tr>
<tr>
<td>Copy 2 of S4 (S4C2)</td>
<td>K4</td>
<td>Full</td>
</tr>
</tbody>
</table>

**Note**

In these examples, snapshots S2, S3, and S4 are incremental only if the previous snapshot still exists. The same applies to copies. Snapshot copies S3C and S4C are incremental only if the previous copy still exists.

For information on copying incremental snapshots across AWS Regions, see [Full and incremental copies](p. 624).

### Cross-Region snapshot copying

You can copy DB snapshots across AWS Regions. However, there are certain constraints and considerations for cross-Region snapshot copying.

**Requesting a cross-Region DB snapshot copy**

To communicate with the source Region to request a cross-Region DB snapshot copy, the requester (IAM role or IAM user) must have access to the source DB snapshot and the source Region.

Certain conditions in the requester's IAM policy can cause the request to fail. The following examples assume that you're copying the DB snapshot from US East (Ohio) to US East (N. Virginia). These examples show conditions in the requester's IAM policy that cause the request to fail:

- The requester's policy has a condition for `aws:RequestedRegion`.

```json
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "+",
"Condition": {
  "StringEquals": {
    "aws:RequestedRegion": "us-east-1"
  }
}
```

The request fails because the policy doesn't allow access to the source Region. For a successful request, specify both the source and destination Regions.

```json
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "+",
"Condition": {
  "StringEquals": {
    "aws:RequestedRegion": "us-east-1"
  }
  "StringEquals": {
    "aws:TargetRegion": "us-east-2"
  }
}
```
Copying a DB snapshot

- The requester's policy doesn't allow access to the source DB snapshot.

  ```json
  "Effect": "Allow",
  "Action": "rds:CopyDBSnapshot",
  ```

  For a successful request, specify both the source and target snapshots.

  ```json
  "Effect": "Allow",
  "Action": "rds:CopyDBSnapshot",
  "Resource": [
  ]
  ```

- The requester's policy denies `aws:ViaAWSService`.

  ```json
  "Effect": "Allow",
  "Action": "rds:CopyDBSnapshot",
  "Resource": "*",
  "Condition": {
    "Bool": {"aws:ViaAWSService": "false"}
  }
  ```

  Communication with the source Region is made by RDS on the requester's behalf. For a successful request, don't deny calls made by AWS services.

- The requester's policy has a condition for `aws:SourceVpc` or `aws:SourceVpce`.

  These requests might fail because when RDS makes the call to the remote Region, it isn't from the specified VPC or VPC endpoint.

  If you need to use one of the previous conditions that would cause a request to fail, you can include a second statement with `aws:CalledVia` in your policy to make the request succeed. For example, you can use `aws:CalledVia` with `aws:SourceVpce` as shown here:

  ```json
  "Effect": "Allow",
  "Action": "rds:CopyDBSnapshot",
  "Resource": "*",
  "Condition": {
    "Condition": {
      "ForAnyValue:StringEquals": {
        "aws:SourceVpce": "vpce-1a2b3c4d"
      }
    }
  }
  ```
Amazon Relational Database Service User Guide

Copying a DB snapshot

For more information, see Policies and permissions in IAM in the IAM User Guide.

Authorizing the snapshot copy

After a cross-Region DB snapshot copy request returns success, RDS starts the copy in the background. An authorization for RDS to access the source snapshot is created. This authorization links the source DB snapshot to the target DB snapshot, and allows RDS to copy only to the specified target snapshot.

The authorization is verified by RDS using the rds:CrossRegionCommunication permission in the service-linked IAM role. If the copy is authorized, RDS communicates with the source Region and completes the copy.

RDS doesn't have access to DB snapshots that weren't authorized previously by a CopyDBSnapshot request. The authorization is revoked when copying completes.

RDS uses the service-linked role to verify the authorization in the source Region. If you delete the service-linked role during the copy process, the copy fails.

For more information, see Using service-linked roles in the IAM User Guide.

Using AWS Security Token Service credentials

Session tokens from the global AWS Security Token Service (AWS STS) endpoint are valid only in AWS Regions that are enabled by default (commercial Regions). If you use credentials from the assumeRole API operation in AWS STS, use the regional endpoint if the source Region is an opt-in Region. Otherwise, the request fails. This happens because your credentials must be valid in both Regions, which is true for opt-in Regions only when the regional AWS STS endpoint is used.

To use the global endpoint, make sure that it's enabled for both Regions in the operations. Set the global endpoint to Valid in all AWS Regions in the AWS STS account settings.

The same rule applies to credentials in the presigned URL parameter.

For more information, see Managing AWS STS in an AWS Region in the IAM User Guide.

Latency and multiple copy requests

Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete.

In some cases, there might be a large number of cross-Region snapshot copy requests from a given source AWS Region. In such cases, Amazon RDS might put new cross-Region copy requests from that
source AWS Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copying starts.

**Full and incremental copies**

When you copy a snapshot to a different AWS Region from the source snapshot, the first copy is a full snapshot copy, even if you copy an incremental snapshot. A full snapshot copy contains all of the data and metadata required to restore the DB instance. After the first snapshot copy, you can copy incremental snapshots of the same DB instance to the same destination Region within the same AWS account. For more information on incremental snapshots, see Incremental snapshot copying (p. 620).

Incremental snapshot copying across AWS Regions is supported for both unencrypted and encrypted snapshots.

When you copy a snapshot across AWS Regions, the copy is an incremental copy if the following conditions are met:

- The snapshot was previously copied to the destination Region.
- The most recent snapshot copy still exists in the destination Region.
- All copies of the snapshot in the destination Region are either unencrypted, or were encrypted using the same KMS key.

**Option group considerations**

DB option groups are specific to the AWS Region that they are created in, and you can't use an option group from one AWS Region in another AWS Region.

For Oracle databases, you can use the AWS CLI or RDS API to copy the custom DB option group from a snapshot that has been shared with your AWS account. You can only copy option groups within the same AWS Region. The option group isn't copied if it has already been copied to the destination account and no changes have been made to it since being copied. If the source option group has been copied before, but has changed since being copied, RDS copies the new version to the destination account. Default option groups aren't copied.

When you copy a snapshot across Regions, you can specify a new option group for the snapshot. We recommend that you prepare the new option group before you copy the snapshot. In the destination AWS Region, create an option group with the same settings as the original DB instance. If one already exists in the new AWS Region, you can use that one.

In some cases, you might copy a snapshot and not specify a new option group for the snapshot. In these cases, when you restore the snapshot the DB instance gets the default option group. To give the new DB instance the same options as the original, do the following:

1. In the destination AWS Region, create an option group with the same settings as the original DB instance. If one already exists in the new AWS Region, you can use that one.
2. After you restore the snapshot in the destination AWS Region, modify the new DB instance and add the new or existing option group from the previous step.

**Parameter group considerations**

When you copy a snapshot across Regions, the copy doesn't include the parameter group used by the original DB instance. When you restore a snapshot to create a new DB instance, that DB instance gets the default parameter group for the AWS Region it is created in. To give the new DB instance the same parameters as the original, do the following:
1. In the destination AWS Region, create a DB parameter group with the same settings as the original DB instance. If one already exists in the new AWS Region, you can use that one.

2. After you restore the snapshot in the destination AWS Region, modify the new DB instance and add the new or existing parameter group from the previous step.

**Copying a DB snapshot**

Use the procedures in this topic to copy a DB snapshot. For an overview of copying a snapshot, see

Copying a DB snapshot (p. 619)

For each AWS account, you can copy up to 20 DB snapshots at a time from one AWS Region to another. If you copy a DB snapshot to another AWS Region, you create a manual DB snapshot that is retained in that AWS Region. Copying a DB snapshot out of the source AWS Region incurs Amazon RDS data transfer charges.

For more information about data transfer pricing, see Amazon RDS pricing.

After the DB snapshot copy has been created in the new AWS Region, the DB snapshot copy behaves the same as all other DB snapshots in that AWS Region.

You can copy a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

The following procedure copies an encrypted or unencrypted DB snapshot, in the same AWS Region or across Regions, by using the AWS Management Console.

**To copy a DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Select the DB snapshot that you want to copy.
4. For Actions, choose Copy snapshot.

The Copy snapshot page appears.
5. For **Target option group (optional)**, choose a new option group if you want.
Specify this option if you are copying a snapshot from one AWS Region to another, and your DB instance uses a nondefault option group.

If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this option when copying across Regions. For more information, see Option group considerations (p. 624).

6. (Optional) To copy the DB snapshot to a different AWS Region, for Destination Region, choose the new AWS Region.

   **Note**
   The destination AWS Region must have the same database engine version available as the source AWS Region.

7. For **New DB snapshot identifier**, type the name of the DB snapshot copy.

   You can make multiple copies of an automated backup or manual snapshot, but each copy must have a unique identifier.

8. (Optional) Select **Copy Tags** to copy tags and values from the snapshot to the copy of the snapshot.

9. (Optional) For **Encryption**, do the following:
   a. Choose **Enable Encryption** if the DB snapshot isn't encrypted but you want to encrypt the copy.

   **Note**
   If the DB snapshot is encrypted, you must encrypt the copy, so the check box is already selected.

   b. For **AWS KMS key**, specify the KMS key identifier to use to encrypt the DB snapshot copy.

10. Choose **Copy snapshot**.

### AWS CLI

You can copy a DB snapshot by using the AWS CLI command `copy-db-snapshot`. If you are copying the snapshot to a new AWS Region, run the command in the new AWS Region.

The following options are used to copy a DB snapshot. Not all options are required for all scenarios. Use the descriptions and the examples that follow to determine which options to use.

- `-source-db-snapshot-identifier` – The identifier for the source DB snapshot.
  - If the source snapshot is in the same AWS Region as the copy, specify a valid DB snapshot identifier. For example, `rds:mysql-instance1-snapshot-20130805`.
  - If the source snapshot is in the same AWS Region as the copy, and has been shared with your AWS account, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805`.
  - If the source snapshot is in a different AWS Region than the copy, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805`.
  - If you are copying from a shared manual DB snapshot, this parameter must be the Amazon Resource Name (ARN) of the shared DB snapshot.
  - If you are copying an encrypted snapshot this parameter must be in the ARN format for the source AWS Region, and must match the `SourceDBSnapshotIdentifier` in the `PreSignedUrl` parameter.

- `-target-db-snapshot-identifier` – The identifier for the new copy of the encrypted DB snapshot.

- `-copy-option-group` – Copy the option group from a snapshot that has been shared with your AWS account.
Copying a DB snapshot

- **--copy-tags** – Include the copy tags option to copy tags and values from the snapshot to the copy of the snapshot.
- **--option-group-name** – The option group to associate with the copy of the snapshot.

Specify this option if you are copying a snapshot from one AWS Region to another, and your DB instance uses a non-default option group.

If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this option when copying across Regions. For more information, see Option group considerations (p. 624).

- **--kms-key-id** – The KMS key identifier for an encrypted DB snapshot. The KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the KMS key.

If you copy an encrypted DB snapshot from your AWS account, you can specify a value for this parameter to encrypt the copy with a new KMS key. If you don't specify a value for this parameter, then the copy of the DB snapshot is encrypted with the same KMS key as the source DB snapshot.

If you copy an encrypted DB snapshot that is shared from another AWS account, then you must specify a value for this parameter.

If you specify this parameter when you copy an unencrypted snapshot, the copy is encrypted.

If you copy an encrypted snapshot to a different AWS Region, then you must specify a KMS key for the destination AWS Region. KMS keys are specific to the AWS Region that they are created in, and you cannot use encryption keys from one AWS Region in another AWS Region.

Example from unencrypted, to the same Region

The following code creates a copy of a snapshot, with the new name mydbsnapshotcopy, in the same AWS Region as the source snapshot. When the copy is made, the DB option group and tags on the original snapshot are copied to the snapshot copy.

For Linux, macOS, or Unix:

```bash
aws rds copy-db-snapshot
  --target-db-snapshot-identifier mydbsnapshotcopy
  --copy-option-group
  --copy-tags
```

For Windows:

```bash
aws rds copy-db-snapshot
  --target-db-snapshot-identifier mydbsnapshotcopy
  --copy-option-group
  --copy-tags
```

Example from unencrypted, across Regions

The following code creates a copy of a snapshot, with the new name mydbsnapshotcopy, in the AWS Region in which the command is run.

For Linux, macOS, or Unix:

```bash
aws rds copy-db-snapshot
```
Copying a DB snapshot

```
--target-db-snapshot-identifier mydbsnapshotcopy
```

For Windows:
```
aws rds copy-db-snapshot ^
  --target-db-snapshot-identifier mydbsnapshotcopy
```

Example from encrypted, across Regions

The following code example copies an encrypted DB snapshot from the US West (Oregon) Region in the US East (N. Virginia) Region. Run the command in the destination (us-east-1) Region.

For Linux, macOS, or Unix:
```
aws rds copy-db-snapshot \
  --target-db-snapshot-identifier mydbsnapshotcopy \
  --kms-key-id my-us-east-1-key \
  --option-group-name custom-option-group-name
```

For Windows:
```
aws rds copy-db-snapshot ^
  --target-db-snapshot-identifier mydbsnapshotcopy ^
  --kms-key-id my-us-east-1-key ^
  --option-group-name custom-option-group-name
```

The `--source-region` parameter is required when you're copying an encrypted snapshot between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions. For `--source-region`, specify the AWS Region of the source DB instance.

If `--source-region` isn't specified, specify a `--pre-signed-url` value. A presigned URL is a URL that contains a Signature Version 4 signed request for the `copy-db-snapshot` command that's called in the source AWS Region. To learn more about the `pre-signed-url` option, see `copy-db-snapshot` in the AWS CLI Command Reference.

RDS API

You can copy a DB snapshot by using the Amazon RDS API operation `CopyDBSnapshot`. If you are copying the snapshot to a new AWS Region, perform the action in the new AWS Region.

The following parameters are used to copy a DB snapshot. Not all parameters are required for all scenarios. Use the descriptions and the examples that follow to determine which parameters to use.

- **SourceDBSnapshotIdentifier** – The identifier for the source DB snapshot.
  - If the source snapshot is in the same AWS Region as the copy, specify a valid DB snapshot identifier. For example, `rds:mysql-instance1-snapshot-20130805`.
  - If the source snapshot is in the same AWS Region as the copy, and has been shared with your AWS account, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805`.
  - If the source snapshot is in a different AWS Region than the copy, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805`.  

• If you are copying from a shared manual DB snapshot, this parameter must be the Amazon Resource Name (ARN) of the shared DB snapshot.
• If you are copying an encrypted snapshot this parameter must be in the ARN format for the source AWS Region, and must match the SourceDBSnapshotIdentifier in the PreSignedUrl parameter.
• TargetDBSnapshotIdentifier – The identifier for the new copy of the encrypted DB snapshot.
• CopyOptionGroup – Set this parameter to true to copy the option group from a shared snapshot to the copy of the snapshot. The default is false.
• CopyTags – Set this parameter to true to copy tags and values from the snapshot to the copy of the snapshot. The default is false.
• OptionGroupName – The option group to associate with the copy of the snapshot.
  Specify this parameter if you are copying a snapshot from one AWS Region to another, and your DB instance uses a non-default option group.

If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this parameter when copying across Regions. For more information, see Option group considerations (p. 624).

• KmsKeyId – The KMS key identifier for an encrypted DB snapshot. The KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the KMS key.
  • If you copy an encrypted DB snapshot from your AWS account, you can specify a value for this parameter to encrypt the copy with a new KMS key. If you don't specify a value for this parameter, then the copy of the DB snapshot is encrypted with the same KMS key as the source DB snapshot.
  • If you copy an encrypted DB snapshot that is shared from another AWS account, then you must specify a value for this parameter.
  • If you specify this parameter when you copy an unencrypted snapshot, the copy is encrypted.
  • If you copy an encrypted snapshot to a different AWS Region, then you must specify a KMS key for the destination AWS Region. KMS keys are specific to the AWS Region that they are created in, and you cannot use encryption keys from one AWS Region in another AWS Region.
• PreSignedUrl – The URL that contains a Signature Version 4 signed request for the CopyDBSnapshot API operation in the source AWS Region that contains the source DB snapshot to copy.
  Specify this parameter when you copy an encrypted DB snapshot from another AWS Region by using the Amazon RDS API. You can specify the source Region option instead of this parameter when you copy an encrypted DB snapshot from another AWS Region by using the AWS CLI.

The presigned URL must be a valid request for the CopyDBSnapshot API operation that can be run in the source AWS Region containing the encrypted DB snapshot to be copied. The presigned URL request must contain the following parameter values:
• DestinationRegion – The AWS Region that the encrypted DB snapshot will be copied to. This AWS Region is the same one where the CopyDBSnapshot operation is called that contains this presigned URL.

For example, suppose that you copy an encrypted DB snapshot from the us-west-2 Region to the us-east-1 Region. You then call the CopyDBSnapshot operation in the us-east-1 Region and provide a presigned URL that contains a call to the CopyDBSnapshot operation in the us-west-2 Region. For this example, the DestinationRegion in the presigned URL must be set to the us-east-1 Region.
• KmsKeyId – The KMS key identifier for the key to use to encrypt the copy of the DB snapshot in the destination AWS Region. This is the same identifier for both the CopyDBSnapshot operation that is called in the destination AWS Region, and the operation contained in the presigned URL.
• SourceDBSnapshotIdentifier – The DB snapshot identifier for the encrypted snapshot to be copied. This identifier must be in the Amazon Resource Name (ARN) format for the source AWS Region. For example, if you are copying an encrypted DB snapshot from the us-west-2 Region,
then your SourceDBSnapshotIdentifier looks like the following example:

For more information on Signature Version 4 signed requests, see the following:

- Authenticating requests: Using query parameters (AWS signature version 4) in the Amazon Simple Storage Service API Reference
- Signature version 4 signing process in the AWS General Reference

Example from unencrypted, to the same Region

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the same AWS Region as the source snapshot. When the copy is made, all tags on the original snapshot are copied to the snapshot copy.

```
https://rds.us-west-1.amazonaws.com/
?Action=CopyDBSnapshot
&CopyTags=true
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&SourceDBSnapshotIdentifier=mysql-instance1-snapshot-20130805
&TargetDBSnapshotIdentifier=mydbsnapshotcopy
&Version=2013-09-09
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20140429/us-west-1/rds/aws4_request
&X-Amz-Date=20140429T175351Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=9164337efa99caf850e874a1cb7ef62f3cea29d0b448b9e0e7c53b288ddffed2
```

Example from unencrypted, across Regions

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the US West (N. California) Region.

```
https://rds.us-west-1.amazonaws.com/
?Action=CopyDBSnapshot
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&SourceDBSnapshotIdentifier=arn%3Aaws%3Ards%3Aus-east-1%3A123456789012%3Asnapshot%3Amysql-instance1-snapshot-20130805
&TargetDBSnapshotIdentifier=mydbsnapshotcopy
&Version=2013-09-09
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20140429/us-west-1/rds/aws4_request
&X-Amz-Date=20140429T175351Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=9164337efa99caf850e874a1cb7ef62f3cea29d0b448b9e0e7c53b288ddffed2
```

Example from encrypted, across Regions

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the US East (N. Virginia) Region.

```
https://rds.us-east-1.amazonaws.com/
?Action=CopyDBSnapshot
&KmsKeyId=my-us-east-1-key
&OptionGroupName=custom-option-group-name
&PreSignedUrl=https%253A%252F%252Frds.us-west-2.amazonaws.com%252F%25252FAction%252526CopyDBSnapshot
%2526DestinationRegion%2526us-east-1
```

631
Sharing a DB snapshot

Using Amazon RDS, you can share a manual DB snapshot in the following ways:

- Sharing a manual DB snapshot, whether encrypted or unencrypted, enables authorized AWS accounts to copy the snapshot.
- Sharing an unencrypted manual DB snapshot enables authorized AWS accounts to directly restore a DB instance from the snapshot instead of taking a copy of it and restoring from that. However, you can't restore a DB instance from a DB snapshot that is both shared and encrypted. Instead, you can make a copy of the DB snapshot and restore the DB instance from the copy.

**Note**

To share an automated DB snapshot, create a manual DB snapshot by copying the automated snapshot, and then share that copy. This process also applies to AWS Backup–generated resources.

For more information on copying a snapshot, see [Copying a DB snapshot](p. 619). For more information on restoring a DB instance from a DB snapshot, see [Restoring from a DB snapshot](p. 615).

You can share a manual snapshot with up to 20 other AWS accounts.

The following limitations apply when sharing manual snapshots with other AWS accounts:

- When you restore a DB instance from a shared snapshot using the AWS Command Line Interface (AWS CLI) or Amazon RDS API, you must specify the Amazon Resource Name (ARN) of the shared snapshot as the snapshot identifier.
- You can't share a DB snapshot that uses an option group with permanent or persistent options, except for Oracle DB instances that have the `timezone` or `OLS` option (or both).

A permanent option can't be removed from an option group. Option groups with persistent options can't be removed from a DB instance once the option group has been assigned to the DB instance.

The following table lists permanent and persistent options and their related DB engines.

<table>
<thead>
<tr>
<th>Option name</th>
<th>Persistent</th>
<th>Permanent</th>
<th>DB engine</th>
</tr>
</thead>
<tbody>
<tr>
<td>TDE</td>
<td>Yes</td>
<td>No</td>
<td>Microsoft SQL Server Enterprise Edition</td>
</tr>
<tr>
<td>TDE</td>
<td>Yes</td>
<td>Yes</td>
<td>Oracle Enterprise Edition</td>
</tr>
</tbody>
</table>

For Oracle DB instances, you can copy shared DB snapshots that have the `timezone` or `OLS` option (or both). To do so, specify a target option group that includes these options when you copy the DB snapshot. The OLS option is permanent and persistent only for Oracle DB instances running Oracle version 12.2 or higher. For more information about these options, see [Oracle time zone](p. 2103) and [Oracle Label Security](p. 2065).
Sharing public snapshots

You can also share an unencrypted manual snapshot as public, which makes the snapshot available to all AWS accounts. Make sure when sharing a snapshot as public that none of your private information is included in the public snapshot.

When a snapshot is shared publicly, it gives all AWS accounts permission both to copy the snapshot and to create DB instances from it.

You aren't billed for the backup storage of public snapshots owned by other accounts. You're billed only for snapshots that you own.

If you copy a public snapshot, you own the copy. You're billed for the backup storage of your snapshot copy. If you create a DB instance from a public snapshot, you're billed for that DB instance. For Amazon RDS pricing information, see the Amazon RDS product page.

You can delete only the public snapshots that you own. To delete a shared or public snapshot, make sure to log into the AWS account that owns the snapshot.

Viewing public snapshots owned by other AWS accounts

You can view public snapshots owned by other accounts in a particular AWS Region on the Public tab of the Snapshots page in the Amazon RDS console. Your snapshots (those owned by your account) don't appear on this tab.

To view public snapshots

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the Public tab.

The public snapshots appear. You can see which account owns a public snapshot in the Owner column.

Note
You might have to modify the page preferences, by selecting the gear icon at the upper right of the Public snapshots list, to see this column.

Viewing your own public snapshots

You can use the following AWS CLI command (Unix only) to view the public snapshots owned by your AWS account in a particular AWS Region.

```
aws rds describe-db-snapshots --snapshot-type public --include-public | grep account_number
```

The output returned is similar to the following example if you have public snapshots.

```
"DBSnapshotArn": "arn:aws:rds:us-east-1:123456789012:snapshot:mysnapshot1",
"DBSnapshotArn": "arn:aws:rds:us-east-1:123456789012:snapshot:mysnapshot2",
```

Note
You might see duplicate entries for DBSnapshotIdentifier or SourceDBSnapshotIdentifier.

Sharing encrypted snapshots

You can share DB snapshots that have been encrypted "at rest" using the AES-256 encryption algorithm, as described in Encrypting Amazon RDS resources (p. 2603). To do this, take the following steps:
1. Share the AWS KMS key that was used to encrypt the snapshot with any accounts that you want to be able to access the snapshot.

You can share KMS keys with another AWS account by adding the other account to the KMS key policy. For details on updating a key policy, see Key policies in the AWS KMS Developer Guide. For an example of creating a key policy, see Allowing access to an AWS KMS key (p. 635) later in this topic.

2. Use the AWS Management Console, AWS CLI, or Amazon RDS API to share the encrypted snapshot with the other accounts.

These restrictions apply to sharing encrypted snapshots:

- You can't share encrypted snapshots as public.
- You can't share Oracle or Microsoft SQL Server snapshots that are encrypted using Transparent Data Encryption (TDE).
- You can't share a snapshot that has been encrypted using the default KMS key of the AWS account that shared the snapshot.

Allowing access to an AWS KMS key

For another AWS account to copy an encrypted DB snapshot shared from your account, the account that you share your snapshot with must have access to the AWS KMS key that encrypted the snapshot.

To allow another AWS account access to a KMS key, update the key policy for the KMS key. You update it with the Amazon Resource Name (ARN) of the AWS account that you are sharing to as Principal in the KMS key policy. Then you allow the kms:CreateGrant action.

After you have given an AWS account access to your KMS key, to copy your encrypted snapshot that AWS account must create an AWS Identity and Access Management (IAM) role or user if it doesn't already have one. In addition, that AWS account must also attach an IAM policy to that IAM permission set or roles that allows the permission set or roles to copy an encrypted DB snapshot using your KMS key. The account must be an IAM user and can't be a root AWS account identity due to AWS KMS security restrictions.

In the following key policy example, user 111122223333 is the owner of the KMS key, and user 444455556666 is the account that the key is being shared with. This updated key policy gives the AWS account access to the KMS key by including the ARN for the root AWS account identity for user 444455556666 as a Principal for the policy, and by allowing the kms:CreateGrant action.

```
{
  "Id": "key-policy-1",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Allow use of the key",
      "Effect": "Allow",
      "Principal": {"AWS": ["arn:aws:iam::111122223333:user/KeyUser",
                          "arn:aws:iam::444455556666:root"],
                      "arn:aws:iam::444455556666:root"},
      "Action": ["kms:CreateGrant",
                  "kms:Encrypt",
                  "kms:Decrypt",
                  "kms:ReEncrypt*",
                  "kms:GenerateDataKey*",
                  "kms:DescribeKey"
                ],
    }
  ]
}```
Creating an IAM policy to enable copying of the encrypted snapshot

Once the external AWS account has access to your KMS key, the owner of that AWS account can create a policy that allows an IAM user created for that account to copy an encrypted snapshot encrypted with that KMS key.

The following example shows a policy that can be attached to an IAM user for AWS account 444455556666 that enables the IAM user to copy a shared snapshot from AWS account 111122223333 that has been encrypted with the KMS key c989c1dd-a3f2-4a5d-8d96-e793d082ab26 in the us-west-2 region.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowUseOfTheKey",
            "Effect": "Allow",
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey*",
                "kms:DescribeKey",
                "kms:CreateGrant",
                "kms:RetireGrant"
            ],
            "Resource": [
                "arn:aws:kms:us-west-2:111122223333:key/c989c1dd-a3f2-4a5d-8d96-e793d082ab26"
            ]
        },
        {
            "Sid": "AllowAttachmentOfPersistentResources",
            "Effect": "Allow",
            "Action": [
                "kms:CreateGrant",
                "kms:ListGrants",
                "kms:RevokeGrant"
            ],
            "Resource": [
                "arn:aws:kms:us-west-2:111122223333:key/c989c1dd-a3f2-4a5d-8d96-e793d082ab26"
            ],
            "Condition": {
                "Bool": {
                    "kms:GrantIsForAWSResource": true
                }
            }
        }
    ]
}
```
Sharing a snapshot

You can share a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

Using the Amazon RDS console, you can share a manual DB snapshot with up to 20 AWS accounts. You can also use the console to stop sharing a manual snapshot with one or more accounts.

To share a manual DB snapshot by using the Amazon RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Snapshots.
3. Select the manual snapshot that you want to share.
4. For Actions, choose Share snapshot.
5. Choose one of the following options for DB snapshot visibility.
   - If the source is unencrypted, choose Public to permit all AWS accounts to restore a DB instance from your manual DB snapshot, or choose Private to permit only AWS accounts that you specify to restore a DB instance from your manual DB snapshot.
     Warning
     If you set DB snapshot visibility to Public, all AWS accounts can restore a DB instance from your manual DB snapshot and have access to your data. Do not share any manual DB snapshots that contain private information as Public.
     - If the source is encrypted, DB snapshot visibility is set as Private because encrypted snapshots can't be shared as public.
6. For AWS Account ID, type the AWS account identifier for an account that you want to permit to restore a DB instance from your manual snapshot, and then choose Add. Repeat to include additional AWS account identifiers, up to 20 AWS accounts.

If you make an error when adding an AWS account identifier to the list of permitted accounts, you can delete it from the list by choosing Delete at the right of the incorrect AWS account identifier.
7. After you have added identifiers for all of the AWS accounts that you want to permit to restore the manual snapshot, choose Save to save your changes.

**To stop sharing a manual DB snapshot with an AWS account**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Select the manual snapshot that you want to stop sharing.
4. Choose Actions, and then choose Share snapshot.
5. To remove permission for an AWS account, choose Delete for the AWS account identifier for that account from the list of authorized accounts.
6. Choose **Save** to save your changes.

**AWS CLI**

To share a DB snapshot, use the `aws rds modify-db-snapshot-attribute` command. Use the `--values-to-add` parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

**Example of sharing a snapshot with a single account**

The following example enables AWS account identifier `123456789012` to restore the DB snapshot named `db7-snapshot`.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-snapshot-attribute \
--db-snapshot-identifier db7-snapshot \
--attribute-name restore \
--values-to-add 123456789012
```

For Windows:

```bash
aws rds modify-db-snapshot-attribute ^
--db-snapshot-identifier db7-snapshot ^
--attribute-name restore ^
--values-to-add 123456789012
```
Example of sharing a snapshot with multiple accounts

The following example enables two AWS account identifiers, 111122223333 and 444455556666, to restore the DB snapshot named manual-snapshot1.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-snapshot-attribute \
--db-snapshot-identifier manual-snapshot1 \
--attribute-name restore \
--values-to-add "111122223333","444455556666"
```

For Windows:

```bash
aws rds modify-db-snapshot-attribute ^
--db-snapshot-identifier manual-snapshot1 ^
--attribute-name restore ^
--values-to-add "\"111122223333\",\"444455556666\"
```

**Note**

When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

To remove an AWS account identifier from the list, use the --values-to-remove parameter.

Example of stopping snapshot sharing

The following example prevents AWS account ID 444455556666 from restoring the snapshot.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-snapshot-attribute \
--db-snapshot-identifier manual-snapshot1 \
--attribute-name restore \
--values-to-remove 444455556666
```

For Windows:

```bash
aws rds modify-db-snapshot-attribute ^
--db-snapshot-identifier manual-snapshot1 ^
--attribute-name restore ^
--values-to-remove 444455556666
```

To list the AWS accounts enabled to restore a snapshot, use the `describe-db-snapshot-attributes` AWS CLI command.

**RDS API**

You can also share a manual DB snapshot with other AWS accounts by using the Amazon RDS API. To do so, call the ModifyDBSnapshotAttribute operation. Specify restore for AttributeName, and use the ValuesToAdd parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

To make a manual snapshot public and restorable by all AWS accounts, use the value all. However, take care not to add the all value for any manual snapshots that contain private information that you don't want to be available to all AWS accounts. Also, don't specify all for encrypted snapshots, because making such snapshots public isn't supported.
To remove sharing permission for an AWS account, use the `ModifyDBSnapshotAttribute` operation with `AttributeName` set to `restore` and the `ValuesToRemove` parameter. To mark a manual snapshot as private, remove the value `all` from the values list for the `restore` attribute.

To list all of the AWS accounts permitted to restore a snapshot, use the `DescribeDBSnapshotAttributes` API operation.
Exporting DB snapshot data to Amazon S3

You can export DB snapshot data to an Amazon S3 bucket. The export process runs in the background and doesn't affect the performance of your active DB instance.

When you export a DB snapshot, Amazon RDS extracts data from the snapshot and stores it in an Amazon S3 bucket. The data is stored in an Apache Parquet format that is compressed and consistent.

You can export all types of DB snapshots—including manual snapshots, automated system snapshots, and snapshots created by the AWS Backup service. By default, all data in the snapshot is exported. However, you can choose to export specific sets of databases, schemas, or tables.

After the data is exported, you can analyze the exported data directly through tools like Amazon Athena or Amazon Redshift Spectrum. For more information on using Athena to read Parquet data, see Parquet SerDe in the Amazon Athena User Guide. For more information on using Redshift Spectrum to read Parquet data, see COPY from columnar data formats in the Amazon Redshift Database Developer Guide.

Topics

- Data conversion when exporting to an Amazon S3 bucket (p. 654)

Region and version availability

Feature availability and support varies across specific versions of each database engine and across AWS Regions. For more information on version and Region availability with exporting snapshots to S3, see Export snapshots to S3 (p. 133).

Limitations

Exporting DB snapshot data to Amazon S3 has the following limitations:

- You can't run multiple export tasks for the same DB snapshot simultaneously. This applies to both full and partial exports.
- Exporting snapshots from DB instances that use magnetic storage isn't supported.
- The following characters in the S3 file path are converted to underscores (_) during export:

```
\ " (space)
```
- If a database, schema, or table has characters in its name other than the following, partial export isn't supported. However, you can export the entire DB snapshot.
  - Latin letters (A–Z)
  - Digits (0–9)
  - Dollar symbol ($)
• Underscore (_)
• Spaces ( ) and certain characters aren’t supported in database table column names. Tables with the following characters in column names are skipped during export:

, ; { } ( ) \n \t = (space)

• Tables with slashes (/) in their names are skipped during export.
• RDS for PostgreSQL temporary and unlogged tables are skipped during export.
• If the data contains a large object, such as a BLOB or CLOB, that is close to or greater than 500 MB, then the export fails.
• If a table contains a large row that is close to or greater than 2 GB, then the table is skipped during export.
• We strongly recommend that you use a unique name for each export task. If you don't use a unique task name, you might receive the following error message:

ExportTaskAlreadyExistsFault: An error occurred (ExportTaskAlreadyExists) when calling the StartExportTask operation: The export task with the ID xxxxxx already exists.

• You can delete a snapshot while you're exporting its data to S3, but you're still charged for the storage costs for that snapshot until the export task has completed.
• You can't restore exported snapshot data from S3 to a new DB instance.

Overview of exporting snapshot data

You use the following process to export DB snapshot data to an Amazon S3 bucket. For more details, see the following sections.

1. Identify the snapshot to export.
   Use an existing automated or manual snapshot, or create a manual snapshot of a DB instance.
2. Set up access to the Amazon S3 bucket.

   A bucket is a container for Amazon S3 objects or files. To provide the information to access a bucket, take the following steps:

   a. Identify the S3 bucket where the snapshot is to be exported to. The S3 bucket must be in the same AWS Region as the snapshot. For more information, see Identifying the Amazon S3 bucket for export (p. 644).

   b. Create an AWS Identity and Access Management (IAM) role that grants the snapshot export task access to the S3 bucket. For more information, see Providing access to an Amazon S3 bucket using an IAM role (p. 644).

3. Create a symmetric encryption AWS KMS key for the server-side encryption. The KMS key is used by the snapshot export task to set up AWS KMS server-side encryption when writing the export data to S3. The KMS key policy must include both the kms:Encrypt and kms:Decrypt permissions. For more information on using KMS keys in Amazon RDS, see AWS KMS key management (p. 2606).

   If you have a deny statement in your KMS key policy, make sure to explicitly exclude the AWS service principal export.rds.amazonaws.com.

   You can use a KMS key within your AWS account, or you can use a cross-account KMS key. For more information, see Using a cross-account AWS KMS key for encrypting Amazon S3 exports (p. 646).

4. Export the snapshot to Amazon S3 using the console or the start-export-task CLI command. For more information, see Exporting a DB snapshot to an Amazon S3 bucket (p. 647).

5. To access your exported data in the Amazon S3 bucket, see Uploading, downloading, and managing objects in the Amazon Simple Storage Service User Guide.
Setting up access to an Amazon S3 bucket

To export DB snapshot data to an Amazon S3 file, you first give the snapshot permission to access the Amazon S3 bucket. You then create an IAM role to allow the Amazon RDS service to write to the Amazon S3 bucket.

Topics

- Identifying the Amazon S3 bucket for export (p. 644)
- Providing access to an Amazon S3 bucket using an IAM role (p. 644)
- Using a cross-account Amazon S3 bucket (p. 646)
- Using a cross-account AWS KMS key for encrypting Amazon S3 exports (p. 646)

Identifying the Amazon S3 bucket for export

Identify the Amazon S3 bucket to export the DB snapshot to. Use an existing S3 bucket or create a new S3 bucket.

**Note**
The S3 bucket to export to must be in the same AWS Region as the snapshot.

For more information about working with Amazon S3 buckets, see the following in the Amazon Simple Storage Service User Guide:

- How do I view the properties for an S3 bucket?
- How do I enable default encryption for an Amazon S3 bucket?
- How do I create an S3 bucket?

Providing access to an Amazon S3 bucket using an IAM role

Before you export DB snapshot data to Amazon S3, give the snapshot export tasks write-access permission to the Amazon S3 bucket.

To grant this permission, create an IAM policy that provides access to the bucket, then create an IAM role and attach the policy to the role. You later assign the IAM role to your snapshot export task.

**Important**
If you plan to use the AWS Management Console to export your snapshot, you can choose to create the IAM policy and the role automatically when you export the snapshot. For instructions, see Exporting a DB snapshot to an Amazon S3 bucket (p. 647).

To give DB snapshot tasks access to Amazon S3

1. Create an IAM policy. This policy provides the bucket and object permissions that allow your snapshot export task to access Amazon S3.

   In the policy, include the following required actions to allow the transfer of files from Amazon RDS to an S3 bucket:
   - s3:PutObject*
   - s3:GetObject*
   - s3:ListBucket
   - s3:DeleteObject*
   - s3:GetBucketLocation
In the policy, include the following resources to identify the S3 bucket and objects in the bucket. The following list of resources shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

- `arn:aws:s3:::your-s3-bucket`
- `arn:aws:s3:::your-s3-bucket/*`

The following AWS CLI command creates an IAM policy named `ExportPolicy` with these options. It grants access to a bucket named `your-s3-bucket`.

```bash
aws iam create-policy --policy-name ExportPolicy --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ExportPolicy",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject*",
        "s3:ListBucket",
        "s3:GetObject*",
        "s3:DeleteObject*",
        "s3:GetBucketLocation"
      ],
      "Resource": [
        "arn:aws:s3:::your-s3-bucket",
        "arn:aws:s3:::your-s3-bucket/*"
      ]
    }
  ]
}'
```

2. Create an IAM role, so that Amazon RDS can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see [Creating a role to delegate permissions to an IAM user](https://docs.aws.amazon.com/IAM/latest/UserGuide/creating-iam-roles-for-service-access.html) in the [IAM User Guide](https://docs.aws.amazon.com/IAM/latest/UserGuide/).

The following example shows using the AWS CLI command to create a role named `rds-s3-export-role`.

```bash
aws iam create-role --role-name rds-s3-export-role --assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "export.rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}'
```

3. Attach the IAM policy that you created to the IAM role that you created.
The following AWS CLI command attaches the policy created earlier to the role named rds-s3-export-role. Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

```bash
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-export-role
```

### Using a cross-account Amazon S3 bucket

You can use Amazon S3 buckets across AWS accounts. To use a cross-account bucket, add a bucket policy to allow access to the IAM role that you’re using for the S3 exports. For more information, see [Example 2: Bucket owner granting cross-account bucket permissions](#).

- Attach a bucket policy to your bucket, as shown in the following example.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:role/Admin"
      },
      "Action": [
        "s3:PutObject*",
        "s3:ListBucket",
        "s3:GetObject*",
        "s3:DeleteObject*",
        "s3:GetBucketLocation"
      ],
      "Resource": [
        "arn:aws:s3:::mycrossaccountbucket",
        "arn:aws:s3:::mycrossaccountbucket/*"
      ]
    }
  ]
}
```

### Using a cross-account AWS KMS key for encrypting Amazon S3 exports

You can use a cross-account AWS KMS key to encrypt Amazon S3 exports. First, you add a key policy to the local account, then you add IAM policies in the external account. For more information, see [Allowing users in other accounts to use a KMS key](#).

To use a cross-account KMS key

1. Add a key policy to the local account.

   The following example gives ExampleRole and ExampleUser in the external account 444455556666 permissions in the local account 123456789012.

```json
{
  "Sid": "Allow an external account to use this KMS key",
  "Effect": "Allow",
  "Principal": [
    "AWS": [
      "arn:aws:iam::444455556666:role/ExampleRole",
      "arn:aws:iam::444455556666:user/ExampleUser"
    ]
  ]
}
```
2. Add IAM policies to the external account.

The following example IAM policy allows the principal to use the KMS key in account 123456789012 for cryptographic operations. To give this permission to ExampleRole and ExampleUser in account 444455556666, attach the policy to them in that account.

```
{
    "Sid": "Allow use of KMS key in account 123456789012",
    "Effect": "Allow",
    "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:CreateGrant",
        "kms:DescribeKey",
        "kms:RetireGrant"
    ],
    "Resource": "arn:aws:kms:us-west-2:123456789012:key/1234abcd-12ab-34cd-56ef-1234567890ab"
}
```

Exporting a DB snapshot to an Amazon S3 bucket

You can have up to five concurrent DB snapshot export tasks in progress per AWS account.

**Note**

Exporting RDS snapshots can take a while depending on your database type and size. The export task first restores and scales the entire database before extracting the data to Amazon S3. The task’s progress during this phase displays as **Starting**. When the task switches to exporting data to S3, progress displays as **In progress**. The time it takes for the export to complete depends on the data stored in the database. For example, tables with well-distributed numeric primary key or index columns export the fastest. Tables that don't contain a column suitable for partitioning and tables with only one index on a string-based column take longer. This longer export time occurs because the export uses a slower single-threaded process.

You can export a DB snapshot to Amazon S3 using the AWS Management Console, the AWS CLI, or the RDS API.

If you use a Lambda function to export a snapshot, add the kms:DescribeKey action to the Lambda function policy. For more information, see [AWS Lambda permissions](https://docs.aws.amazon.com/lambda/latest/dg/managed-policies.html).

**Console**

The Export to Amazon S3 console option appears only for snapshots that can be exported to Amazon S3. A snapshot might not be available for export because of the following reasons:
• The DB engine isn't supported for S3 export.
• The DB instance version isn't supported for S3 export.
• S3 export isn't supported in the AWS Region where the snapshot was created.

To export a DB snapshot
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. From the tabs, choose the type of snapshot that you want to export.
4. In the list of snapshots, choose the snapshot that you want to export.
5. For Actions, choose Export to Amazon S3.

The Export to Amazon S3 window appears.
6. For Export identifier, enter a name to identify the export task. This value is also used for the name of the file created in the S3 bucket.
7. Choose the data to be exported:
   • Choose All to export all data in the snapshot.
   • Choose Partial to export specific parts of the snapshot. To identify which parts of the snapshot to export, enter one or more databases, schemas, or tables for Identifiers, separated by spaces.

Use the following format:

\[
\text{database}\.\text{schema}\.\text{table} \text{ database2}.\text{schema2}.\text{table2} \ldots \text{databaseN}.\text{schemaN}\text{.tableN}
\]

For example:

mydatabase mydatabase2.myschema1 mydatabase2.myschema2.mytable1 mydatabase2.myschema2.mytable2

8. For S3 bucket, choose the bucket to export to.

To assign the exported data to a folder path in the S3 bucket, enter the optional path for S3 prefix.
9. For IAM role, either choose a role that grants you write access to your chosen S3 bucket, or create a new role.

   • If you created a role by following the steps in Providing access to an Amazon S3 bucket using an IAM role (p. 644), choose that role.
   • If you didn't create a role that grants you write access to your chosen S3 bucket, then choose Create a new role to create the role automatically. Next, enter a name for the role in IAM role name.
10. For AWS KMS key, enter the ARN for the key to use for encrypting the exported data.
11. Choose Export to Amazon S3.

AWS CLI

To export a DB snapshot to Amazon S3 using the AWS CLI, use the start-export-task command with the following required options:

• --export-task-identifier
In the following examples, the snapshot export task is named `my-snapshot-export`, which exports a snapshot to an S3 bucket named `my-export-bucket`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds start-export-task
  --export-task-identifier my-snapshot-export
  --s3-bucket-name my-export-bucket
  --iam-role-arn iam-role
  --kms-key-id my-key
```

For Windows:

```bash
aws rds start-export-task
  --export-task-identifier my-snapshot-export
  --s3-bucket-name my-export-bucket
  --iam-role-arn iam-role
  --kms-key-id my-key
```

Sample output follows.

```json
{
  "Status": "STARTING",
  "IamRoleArn": "iam-role",
  "ExportTime": "2019-08-12T01:23:53.109Z",
  "S3Bucket": "my-export-bucket",
  "PercentProgress": 0,
  "KmsKeyId": "my-key",
  "ExportTaskIdentifier": "my-snapshot-export",
  "TotalExtractedDataInGB": 0,
  "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot: snapshot-name"
}
```

To provide a folder path in the S3 bucket for the snapshot export, include the `--s3-prefix` option in the `start-export-task` command.

**RDS API**

To export a DB snapshot to Amazon S3 using the Amazon RDS API, use the `StartExportTask` operation with the following required parameters:

- `ExportTaskIdentifier`
- `SourceArn`
- `S3BucketName`
- `IamRoleArn`
Monitoring snapshot exports

You can monitor DB snapshot exports using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To monitor DB snapshot exports**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Snapshots.
3. To view the list of snapshot exports, choose the **Exports in Amazon S3** tab.
4. To view information about a specific snapshot export, choose the export task.

**AWS CLI**

To monitor DB snapshot exports using the AWS CLI, use the `describe-export-tasks` command.

The following example shows how to display current information about all of your snapshot exports.

**Example**

```bash
aws rds describe-export-tasks
{
    "ExportTasks": [
        {
            "Status": "CANCELED",
            "TaskEndTime": "2019-11-01T17:36:46.961Z",
            "S3Prefix": "something",
            "S3Bucket": "examplebucket",
            "PercentProgress": 0,
            "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/K7MDENG/bPxRfiCYEXAMPLEKEY",
            "ExportTaskIdentifier": "anewtest",
            "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
            "TotalExtractedDataInGB": 0,
        },
        {
            "Status": "COMPLETE",
            "WarningMessage": "{"skippedTables":[]}","skippedObjectives":[]","general": [{"reason":"FAILED_TO_EXTRACT_TABLE_LIST_FOR_DATABASE"}]",
            "S3Prefix": "",
            "ExportTime": "2019-10-31T06:44:54.552Z",
            "S3Bucket": "examplebucket1",
            "PercentProgress": 100,
            "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/2Zp9Utk/h3yCo8nvbEXAMPLEKEY",
            "ExportTaskIdentifier": "thursday-events-test",
            "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
            "TotalExtractedDataInGB": 263,
            "TaskStartTime": "2019-10-31T20:58:06.998Z",
        }
    ]
}
```
To display information about a specific snapshot export, include the `--export-task-identifier` option with the `describe-export-tasks` command. To filter the output, include the `--Filters` option. For more options, see the `describe-export-tasks` command.

**RDS API**

To display information about DB snapshot exports using the Amazon RDS API, use the `DescribeExportTasks` operation.

To track completion of the export workflow or to initiate another workflow, you can subscribe to Amazon Simple Notification Service topics. For more information on Amazon SNS, see *Working with Amazon RDS event notification* (p. 855).

**Canceling a snapshot export task**

You can cancel a DB snapshot export task using the AWS Management Console, the AWS CLI, or the RDS API.

**Note**

Canceling a snapshot export task doesn't remove any data that was exported to Amazon S3. For information about how to delete the data using the console, see *How do I delete objects from an S3 bucket?* To delete the data using the CLI, use the `delete-object` command.

**Console**

**To cancel a snapshot export task**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Snapshots**.
3. Choose the **Exports in Amazon S3** tab.
4. Choose the snapshot export task that you want to cancel.
5. Choose **Cancel**.
6. Choose **Cancel export task** on the confirmation page.
AWS CLI

To cancel a snapshot export task using the AWS CLI, use the `cancel-export-task` command. The command requires the `--export-task-identifier` option.

**Example**

```bash
aws rds cancel-export-task --export-task-identifier my_export
```

```json
{
    "Status": "CANCELING",
    "S3Prefix": "",
    "ExportTime": "2019-08-12T01:23:53.109Z",
    "S3Bucket": "examplebucket",
    "PercentProgress": 0,
    "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/K7MDENG/bPXRfiCYLEXAMPLEKEY",
    "ExportTaskIdentifier": "my_export",
    "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
    "TotalExtractedDataInGB": 0,
    "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:export-example-1"
}
```

RDS API

To cancel a snapshot export task using the Amazon RDS API, use the `CancelExportTask` operation with the `ExportTaskIdentifier` parameter.

**Failure messages for Amazon S3 export tasks**

The following table describes the messages that are returned when Amazon S3 export tasks fail.

<table>
<thead>
<tr>
<th>Failure message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>An unknown internal error occurred.</td>
<td>The task has failed because of an unknown error, exception, or failure.</td>
</tr>
<tr>
<td>An unknown internal error occurred writing the export task's metadata to the S3 bucket [bucket name].</td>
<td>The task has failed because of an unknown error, exception, or failure.</td>
</tr>
<tr>
<td>The RDS export failed to write the export task's metadata because it can't assume the IAM role [role ARN].</td>
<td>The export task assumes your IAM role to validate whether it is allowed to write metadata to your S3 bucket. If the task can't assume your IAM role, it fails.</td>
</tr>
</tbody>
</table>
| The RDS export failed to write the export task's metadata to the S3 bucket [bucket name] using the IAM role [role ARN] with the KMS key [key ID]. Error code: [error code] | One or more permissions are missing, so the export task can't access the S3 bucket. This failure message is raised when receiving one of the following error codes:  
  - AWSSecurityTokenServiceException with the error code AccessDenied  
  - AmazonS3Exception with the error code NoSuchBucket, AccessDenied, KMS.KMSInvalidStateException, 403 Forbidden, or KMS.DisabledException  

These error codes indicate settings are misconfigured for the IAM role, S3 bucket, or KMS key.
### Exporting DB snapshot data to Amazon S3

<table>
<thead>
<tr>
<th>Failure message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The IAM role [role ARN] isn't authorized to call [S3 action] on the S3 bucket [bucket name]. Review your permissions and retry the export.</td>
<td>The IAM policy is misconfigured. Permission for the specific S3 action on the S3 bucket is missing, which causes the export task to fail.</td>
</tr>
<tr>
<td>KMS key check failed. Check the credentials on your KMS key and try again.</td>
<td>The KMS key credential check failed.</td>
</tr>
<tr>
<td>S3 credential check failed. Check the permissions on your S3 bucket and IAM policy.</td>
<td>The S3 credential check failed.</td>
</tr>
<tr>
<td>The S3 bucket [bucket name] isn't valid. Either it isn't located in the current AWS Region or it doesn't exist. Review your S3 bucket name and retry the export.</td>
<td>The S3 bucket is invalid.</td>
</tr>
<tr>
<td>The S3 bucket [bucket name] isn't located in the current AWS Region. Review your S3 bucket name and retry the export.</td>
<td>The S3 bucket is in the wrong AWS Region.</td>
</tr>
</tbody>
</table>

### Troubleshooting PostgreSQL permissions errors

When exporting PostgreSQL databases to Amazon S3, you might see a PERMISSIONS_D0_NOT_EXIST error stating that certain tables were skipped. This error usually occurs when the superuser, which you specified when creating the DB instance, doesn't have permissions to access those tables.

To fix this error, run the following command:

```
GRANT ALL PRIVILEGES ON ALL TABLES IN SCHEMA schema_name TO superuser_name
```

For more information on superuser privileges, see [Master user account privileges](p. 2699).

### File naming convention

Exported data for specific tables is stored in the format `base_prefix/files`, where the base prefix is the following:

```
export_identifier/database_name/schema_name.table_name/
```

For example:

```
export-1234567890123-459/rdststdb/rdststdb.DataInsert_7ADB5D19965123A2/
```

There are two conventions for how files are named. The current convention is the following:

```
partition_index/part-00000-random_uuid.format-based_extension
```

For example:

```
1/part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet
2/part-00000-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet
3/part-00000-f5a991ab-59aa-7fa6-3333-d41eccd540a7-c000.gz.parquet
```
The older convention is the following:

```
part-partition_index-random_uuid.format-based_extension
```

For example:

```
part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet
part-00001-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet
part-00002-f5a991ab-59aa-7fa6-3333-d41eccd540a7-c000.gz.parquet
```

The file naming convention is subject to change. Therefore, when reading target tables, we recommend that you read everything inside the base prefix for the table.

**Data conversion when exporting to an Amazon S3 bucket**

When you export a DB snapshot to an Amazon S3 bucket, Amazon RDS converts data to, exports data in, and stores data in the Parquet format. For more information about Parquet, see the [Apache Parquet](https://parquet.apache.org) website.

Parquet stores all data as one of the following primitive types:

- BOOLEAN
- INT32
- INT64
- INT96
- FLOAT
- DOUBLE
- BYTE_ARRAY – A variable-length byte array, also known as binary
- FIXED_LEN_BYTE_ARRAY – A fixed-length byte array used when the values have a constant size

The Parquet data types are few to reduce the complexity of reading and writing the format. Parquet provides logical types for extending primitive types. A *logical type* is implemented as an annotation with the data in a `LogicalType` metadata field. The logical type annotation explains how to interpret the primitive type.

When the STRING logical type annotates a BYTE_ARRAY type, it indicates that the byte array should be interpreted as a UTF-8 encoded character string. After an export task completes, Amazon RDS notifies you if any string conversion occurred. The underlying data exported is always the same as the data from the source. However, due to the encoding difference in UTF-8, some characters might appear different from the source when read in tools such as Athena.

For more information, see [Parquet logical type definitions](https://parquet.apache.org/docs/0.12.0/parquet-logical-type.html) in the Parquet documentation.

**MySQL and MariaDB data type mapping to Parquet**

The following table shows the mapping from MySQL and MariaDB data types to Parquet data types when data is converted and exported to Amazon S3.
<table>
<thead>
<tr>
<th>Source data type</th>
<th>Parquet primitive type</th>
<th>Logical type annotation</th>
<th>Conversion notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Numeric data types</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>BIGINT</td>
<td>INT64</td>
<td></td>
<td></td>
</tr>
<tr>
<td>BIGINT UNSIGNED</td>
<td>FIXED_LEN_BYTE_ARRAY(9)DECIMAL(20,0)</td>
<td>Parquet supports only signed types, so the mapping requires an additional byte (8 plus 1) to store the BIGINT UNSIGNED type.</td>
<td></td>
</tr>
<tr>
<td>BIT</td>
<td>BYTE_ARRAY</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DECIMAL</td>
<td>INT32</td>
<td>DECIMAL(p,s)</td>
<td>If the source value is less than $2^{31}$, it's stored as INT32.</td>
</tr>
<tr>
<td></td>
<td>INT64</td>
<td>DECIMAL(p,s)</td>
<td>If the source value is $2^{31}$ or greater, but less than $2^{63}$, it's stored as INT64.</td>
</tr>
<tr>
<td></td>
<td>FIXED_LEN_BYTE_ARRAY(N)DECIMAL(p,s)</td>
<td>If the source value is $2^{63}$ or greater, it's stored as FIXED_LEN_BYTE_ARRAY(N).</td>
<td></td>
</tr>
<tr>
<td>BYTE_ARRAY</td>
<td>STRING</td>
<td></td>
<td>Parquet doesn't support Decimal precision greater than 38. The Decimal value is converted to a string in a BYTE_ARRAY type and encoded as UTF8.</td>
</tr>

Restoring a DB instance to a specified time

You can restore a DB instance to a specific point in time, creating a new DB instance.

When you restore a DB instance to a point in time, you can choose the default virtual private cloud (VPC) security group. Or you can apply a custom VPC security group to your DB instance.

Restored DB instances are automatically associated with the default DB parameter and option groups. However, you can apply a custom parameter group and option group by specifying them during a restore.

If the source DB instance has resource tags, RDS adds the latest tags to the restored DB instance.

RDS uploads transaction logs for DB instances to Amazon S3 every five minutes. To see the latest restorable time for a DB instance, use the AWS CLI `describe-db-instances` command and look at the value returned in the `LatestRestorableTime` field for the DB instance. To see the latest restorable time for each DB instance in the Amazon RDS console, choose Automated backups.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for each DB instance, choose Automated backups in the Amazon RDS console.

Note
We recommend that you restore to the same or similar DB instance size—and IOPS if using Provisioned IOPS storage—as the source DB instance. You might get an error if, for example, you choose a DB instance size with an incompatible IOPS value.

Some of the database engines used by Amazon RDS have special considerations when restoring from a point in time:

- When you restore an Oracle DB instance to a point in time, you can specify a different Oracle DB engine, license model, and DBName (SID) to be used by the new DB instance.
- When you restore a Microsoft SQL Server DB instance to a point in time, each database within that instance is restored to a point in time within 1 second of each other database within the instance. Transactions that span multiple databases within the instance might be restored inconsistently.
- For a SQL Server DB instance, the OFFLINE, EMERGENCY, and SINGLE_USER modes aren't supported. Setting any database into one of these modes causes the latest restorable time to stop moving forward for the whole instance.
- Some actions, such as changing the recovery model of a SQL Server database, can break the sequence of logs that are used for point-in-time recovery. In some cases, Amazon RDS can detect this issue and the latest restorable time is prevented from moving forward. In other cases, such as when a SQL Server database uses the BULK_LOGGED recovery model, the break in log sequence isn't detected. It
might not be possible to restore a SQL Server DB instance to a point in time if there is a break in the log sequence. For these reasons, Amazon RDS doesn't support changing the recovery model of SQL Server databases.

You can also use AWS Backup to manage backups of Amazon RDS DB instances. If your DB instance is associated with a backup plan in AWS Backup, that backup plan is used for point-in-time recovery. Backups that were created with AWS Backup have names ending in `awsbackup:`. For information about AWS Backup, see the [AWS Backup Developer Guide](https://docs.aws.amazon.com/awsbackup/latest/devguide/whatisawsbackup.html).

**Note**

Information in this topic applies to Amazon RDS. For information on restoring an Amazon Aurora DB cluster, see [Restoring a DB cluster to a specified time](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Appendix.Aurora.Restore.html).

You can restore a DB instance to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

**Note**

You can't reduce the amount of storage when you restore a DB instance. When you increase the allocated storage, it must be by at least 10 percent. If you try to increase the value by less than 10 percent, you get an error. You can't increase the allocated storage when restoring RDS for SQL Server DB instances.

**Console**

**To restore a DB instance to a specified time**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Automated backups**.

   The automated backups are displayed on the **Current Region** tab.
3. Choose the DB instance that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

   The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

   If you chose **Custom**, enter the date and time to which you want to restore the instance.

   **Note**

   Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.
6. For **DB instance identifier**, enter the name of the target restored DB instance. The name must be unique.
7. Choose other options as needed, such as DB instance class, storage, and whether you want to use storage autoscaling.

   For information about each setting, see [Settings for DB instances](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/RDS-Concepts.AMazon-SSD-Efficiency-Storage-Autoscaling.html).
8. Choose **Restore to point in time**.

**AWS CLI**

To restore a DB instance to a specified time, use the AWS CLI command `restore-db-instance-to-point-in-time` to create a new DB instance. This example also sets the allocated storage size and enables storage autoscaling.
Resource tagging is supported for this operation. When you use the --tags option, the source DB instance tags are ignored and the provided ones are used. Otherwise, the latest tags from the source instance are used.

You can specify other settings. For information about each setting, see Settings for DB instances (p. 308).

**Example**

For Linux, macOS, or Unix:

```bash
aws rds restore-db-instance-to-point-in-time
    --source-db-instance-identifier mysourcedbinstance
    --target-db-instance-identifier mytargetdbinstance
    --restore-time 2017-10-14T23:45:00.000Z
    --allocated-storage 100
    --max-allocated-storage 1000
```

For Windows:

```bash
aws rds restore-db-instance-to-point-in-time
    --source-db-instance-identifier mysourcedbinstance
    --target-db-instance-identifier mytargetdbinstance
    --restore-time 2017-10-14T23:45:00.000Z
    --allocated-storage 100
    --max-allocated-storage 1000
```

**RDS API**

To restore a DB instance to a specified time, call the Amazon RDS API RestoreDBInstanceToPointInTime operation with the following parameters:

- **SourceDBInstanceIdentifier**
- **TargetDBInstanceIdentifier**
- **RestoreTime**
Deleting a DB snapshot

You can delete DB snapshots managed by Amazon RDS when you no longer need them.

**Note**
To delete backups managed by AWS Backup, use the AWS Backup console. For information about AWS Backup, see the [AWS Backup Developer Guide](#).

Deleting a DB snapshot

You can delete a manual, shared, or public DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

To delete a shared or public snapshot, you must sign in to the AWS account that owns the snapshot.

If you have automated DB snapshots that you want to delete without deleting the DB instance, change the backup retention period for the DB instance to 0. The automated snapshots are deleted when the change is applied. You can apply the change immediately if you don't want to wait until the next maintenance period. After the change is complete, you can then re-enable automatic backups by setting the backup retention period to a number greater than 0. For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

Retained automated backups and manual snapshots incur billing charges until they're deleted. For more information, see [Retention costs](#).

If you deleted a DB instance, you can delete its automated DB snapshots by removing the automated backups for the DB instance. For information about automated backups, see [Working with backups](#).

**Console**

**To delete a DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Snapshots**.
   
   The **Manual snapshots** list appears.
3. Choose the DB snapshot that you want to delete.
4. For **Actions**, choose **Delete snapshot**.
5. Choose **Delete** on the confirmation page.

**AWS CLI**

You can delete a DB snapshot by using the AWS CLI command `delete-db-snapshot`.

The following options are used to delete a DB snapshot.

- `--db-snapshot-identifier` – The identifier for the DB snapshot.

**Example**

The following code deletes the `mydbsnapshot` DB snapshot.

For Linux, macOS, or Unix:
aws rds delete-db-snapshot
  --db-snapshot-identifier mydbsnapshot

For Windows:

aws rds delete-db-snapshot ^
  --db-snapshot-identifier mydbsnapshot

RDS API

You can delete a DB snapshot by using the Amazon RDS API operation DeleteDBSnapshot. The following parameters are used to delete a DB snapshot.

- DBSnapshotIdentifier – The identifier for the DB snapshot.
Tutorial: Restore an Amazon RDS DB instance from a DB snapshot

Often, when working with Amazon RDS you might have a DB instance that you work with occasionally but don’t need full time. For example, suppose that you have a quarterly customer survey that uses an Amazon EC2 instance to host a customer survey website. You also have a DB instance that is used to store the survey results. One way to save money on such a scenario is to take a DB snapshot of the DB instance after the survey is completed. You then delete the DB instance and restore it when you need to conduct the survey again.

When you restore the DB instance, you provide the name of the DB snapshot to restore from. You then provide a name for the new DB instance that’s created from the restore operation.

For more detailed information on restoring DB instances from snapshots, see Restoring from a DB snapshot (p. 615).

Restoring a DB instance from a DB snapshot

Use the following procedure to restore from a snapshot in the AWS Management Console.

To restore a DB instance from a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the DB snapshot that you want to restore from.
4. For Actions, choose Restore snapshot.

The Restore snapshot page appears.
5. Under **DB instance settings**, use the default settings for **DB engine** and **License model** (for Oracle or Microsoft SQL Server).

6. Under **Settings**, for **DB instance identifier** enter the unique name that you want to use for the restored DB instance, for example **mynewdbinstance**.

   If you're restoring from a DB instance that you deleted after you made the DB snapshot, you can use the name of that DB instance.

7. Under **Availability & durability**, choose whether to create a standby instance in another Availability Zone.

   For this tutorial, don't create a standby instance.

8. Under **Connectivity**, use the default settings for the following:

   - **Virtual private cloud (VPC)**
   - **DB subnet group**
   - **Public access**
   - **VPC security group (firewall)**

9. Choose the **DB instance class**.

   For this tutorial, choose **Burstable classes (includes t classes)**, and then choose **db.t3.small**.

10. For **Encryption**, use the default settings.

    If the source DB instance for the snapshot was encrypted, the restored DB instance is also encrypted. You can't make it unencrypted.

11. Expand **Additional configuration** at the bottom of the page.
12. Do the following under **Database options**:
   
   a. **Choose the DB parameter group.**
      
      For this tutorial, use the default parameter group.
   
   b. **Choose the Option group.**
      
      For this tutorial, use the default option group.
      
      **Important**
      
      In some cases, you might restore from a DB snapshot of a DB instance that uses a persistent or permanent option. If so, make sure to choose an option group that uses the same option.
   
   c. **For Deletion protection, choose the Enable deletion protection check box.**

13. Choose **Restore DB instance**.

The **Databases** page displays the restored DB instance, with a status of **Creating**.
Backing up and restoring a Multi-AZ DB cluster

This section shows how to back up and restore Multi-AZ DB clusters.

Topics
- Creating a Multi-AZ DB cluster snapshot (p. 669)
- Restoring from a snapshot to a Multi-AZ DB cluster (p. 671)
- Restoring from a Multi-AZ DB cluster snapshot to a DB instance (p. 673)
- Restoring a Multi-AZ DB cluster to a specified time (p. 675)

In addition, the following topics apply to both DB instances and Multi-AZ DB clusters:
- the section called “Sharing a DB snapshot” (p. 633)
- the section called “Deleting a DB snapshot” (p. 663)
Creating a Multi-AZ DB cluster snapshot

When you create a Multi-AZ DB cluster snapshot, make sure to identify which Multi-AZ DB cluster you are going to back up, and then give your DB cluster snapshot a name so you can restore from it later. You can also share a Multi-AZ DB cluster snapshot. For instructions, see the section called “Sharing a DB snapshot” (p. 633).

You can create a Multi-AZ DB cluster snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a DB cluster snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. In the list, choose the Multi-AZ DB cluster for which you want to take a snapshot.
4. For Actions, choose Take snapshot.

   The Take DB snapshot window appears.
5. For Snapshot name, enter the name of the snapshot.
6. Choose Take snapshot.

The Snapshots page appears, with the new Multi-AZ DB cluster snapshot's status shown as Creating. After its status is Available, you can see its creation time.

AWS CLI

You can create a Multi-AZ DB cluster snapshot by using the AWS CLI create-db-cluster-snapshot command with the following options:

• --db-cluster-identifier
• --db-cluster-snapshot-identifier

In this example, you create a Multi-AZ DB cluster snapshot called mymultiazdbclustersnapshot for a DB cluster called mymultiazdbcluster.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster-snapshot \
   --db-cluster-identifier mymultiazdbcluster \
   --db-cluster-snapshot-identifier mymultiazdbclustersnapshot
```

For Windows:

```bash
aws rds create-db-cluster-snapshot ^
   --db-cluster-identifier mymultiazdbcluster ^
   --db-cluster-snapshot-identifier mymultiazdbclustersnapshot
```
RDS API

You can create a Multi-AZ DB cluster snapshot by using the Amazon RDS API `CreateDBClusterSnapshot` operation with the following parameters:

- `DBClusterIdentifier`
- `DBClusterSnapshotIdentifier`

Deleting a Multi-AZ DB cluster snapshot

You can delete Multi-AZ DB snapshots managed by Amazon RDS when you no longer need them. For instructions, see the section called “Deleting a DB snapshot” (p. 663).
Restoring from a snapshot to a Multi-AZ DB cluster

You can restore a snapshot to a Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API. You can restore each of these types of snapshots to a Multi-AZ DB cluster:

- A snapshot of a Single-AZ deployment
- A snapshot of a Multi-AZ DB instance deployment with a single DB instance
- A snapshot of a Multi-AZ DB cluster

For information about Multi-AZ deployments, see Configuring and managing a Multi-AZ deployment (p. 492).

Tip
You can migrate a Single-AZ deployment or a Multi-AZ DB instance deployment to a Multi-AZ DB cluster deployment by restoring a snapshot.

Console

To restore a snapshot to a Multi-AZ DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the snapshot that you want to restore from.
4. For Actions, choose Restore snapshot.
5. On the Restore snapshot page, in Availability and durability, choose Multi-AZ DB cluster.

6. For DB cluster identifier, enter the name for your restored Multi-AZ DB cluster.
7. For the remaining sections, specify your DB cluster settings. For information about each setting, see Settings for creating Multi-AZ DB clusters (p. 514).
8. Choose Restore DB instance.

AWS CLI

To restore a snapshot to a Multi-AZ DB cluster, use the AWS CLI command restore-db-cluster-from-snapshot.

In the following example, you restore from a previously created snapshot named mysnapshot. You restore to a new Multi-AZ DB cluster named mynewmultiazdbcluster. You also specify the DB
instance class used by the DB instances in the Multi-AZ DB cluster. Specify either mysql or postgres for the DB engine.

For the --snapshot-identifier option, you can use either the name or the Amazon Resource Name (ARN) to specify a DB cluster snapshot. However, you can use only the ARN to specify a DB snapshot.

For the --db-cluster-instance-class option, specify the DB instance class for the new Multi-AZ DB cluster. Multi-AZ DB clusters only support specific DB instance classes, such as the db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see DB instance classes (p. 11).

You can also specify other options.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds restore-db-cluster-from-snapshot \
  --db-cluster-identifier mynewmultiazdbcluster \
  --snapshot-identifier mysnapshot \
  --engine mysql|postgres \
  --db-cluster-instance-class db.r6gd.xlarge
```

For Windows:

```bash
aws rds restore-db-cluster-from-snapshot ^
  --db-cluster-identifier mynewmultiazdbcluster ^
  --snapshot-identifier mysnapshot ^
  --engine mysql|postgres ^
  --db-cluster-instance-class db.r6gd.xlarge
```

After you restore the DB cluster, you can add the Multi-AZ DB cluster to the security group associated with the DB cluster or DB instance that you used to create the snapshot, if applicable. Completing this action provides the same functions of the previous DB cluster or DB instance.

**RDS API**

To restore a snapshot to a Multi-AZ DB cluster, call the RDS API operation RestoreDBClusterFromSnapshot with the following parameters:

- DBClusterIdentifier
- SnapshotIdentifier
- Engine

You can also specify other optional parameters.

After you restore the DB cluster, you can add the Multi-AZ DB cluster to the security group associated with the DB cluster or DB instance that you used to create the snapshot, if applicable. Completing this action provides the same functions of the previous DB cluster or DB instance.
Restoring from a Multi-AZ DB cluster snapshot to a DB instance

A Multi-AZ DB cluster snapshot is a storage volume snapshot of your DB cluster, backing up the entire DB cluster and not just individual databases. You can restore a Multi-AZ DB cluster snapshot to a Single-AZ deployment or Multi-AZ DB instance deployment. For information about Multi-AZ deployments, see Configuring and managing a Multi-AZ deployment (p. 492).

Note
You can also restore a Multi-AZ DB cluster snapshot to a new Multi-AZ DB cluster. For instructions, see Restoring from a snapshot to a Multi-AZ DB cluster (p. 671).

Use the AWS Management Console, the AWS CLI, or the RDS API to restore a Multi-AZ DB cluster snapshot to a Single-AZ deployment or Multi-AZ DB instance deployment.

Console

To restore a Multi-AZ DB cluster snapshot to a Single-AZ deployment or Multi-AZ DB instance deployment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the Multi-AZ DB cluster snapshot that you want to restore from.
4. For Actions, choose Restore snapshot.
5. On the Restore snapshot page, in Availability and durability, choose one of the following:
   - Single DB instance – Restores the snapshot to one DB instance with no standby DB instance.
   - Multi-AZ DB instance – Restores the snapshot to a Multi-AZ DB instance deployment with one primary DB instance and one standby DB instance.
6. For DB instance identifier, enter the name for your restored DB instance.
7. For the remaining sections, specify your DB instance settings. For information about each setting, see Settings for DB instances (p. 308).
8. Choose Restore DB instance.

AWS CLI

To restore a Multi-AZ DB cluster snapshot to a DB instance deployment, use the AWS CLI command restore-db-instance-from-db-snapshot.

In the following example, you restore from a previously created Multi-AZ DB cluster snapshot named myclustersnapshot. You restore to a new Multi-AZ DB instance deployment with a primary DB instance named mynewdbinstance. For the --db-cluster-snapshot-identifier option, specify the name of the Multi-AZ DB cluster snapshot.

For the --db-instance-class option, specify the DB instance class for the new DB instance deployment. For more information about DB instance classes, see DB instance classes (p. 11).

You can also specify other options.

Example

For Linux, macOS, or Unix:
Restoring from a Multi-AZ DB cluster snapshot to a DB instance

```
aws rds restore-db-instance-from-db-snapshot
  --db-instance-identifier mynewdbinstance
  --db-cluster-snapshot-identifier myclustersnapshot
  --engine mysql
  --multi-az
  --db-instance-class db.r6g.xlarge
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot
  --db-instance-identifier mynewdbinstance
  --db-cluster-snapshot-identifier myclustersnapshot
  --engine mysql
  --multi-az
  --db-instance-class db.r6g.xlarge
```

After you restore the DB instance, you can add it to the security group associated with the Multi-AZ DB cluster that you used to create the snapshot, if applicable. Completing this action provides the same functions of the previous Multi-AZ DB cluster.

**RDS API**

To restore a Multi-AZ DB cluster snapshot to a DB instance deployment, call the RDS API operation `RestoreDBInstanceFromDBSnapshot` with the following parameters:

- `DBInstanceIdentifier`
- `DBClusterSnapshotIdentifier`
- `Engine`

You can also specify other optional parameters.

After you restore the DB instance, you can add it to the security group associated with the Multi-AZ DB cluster that you used to create the snapshot, if applicable. Completing this action provides the same functions of the previous Multi-AZ DB cluster.
Restoring a Multi-AZ DB cluster to a specified time

You can restore a Multi-AZ DB cluster to a specific point in time, creating a new Multi-AZ DB cluster.

RDS uploads transaction logs for Multi-AZ DB clusters to Amazon S3 continuously. You can restore to any point in time within your backup retention period. To see the earliest restorable time for a Multi-AZ DB cluster, use the AWS CLI `describe-db-clusters` command. Look at the value returned in the `EarliestRestorableTime` field for the DB cluster. To see the latest restorable time for a Multi-AZ DB cluster, look at the value returned in the `LatestRestorableTime` field for the DB cluster.

When you restore a Multi-AZ DB cluster to a point in time, you can choose the default VPC security group for your Multi-AZ DB cluster. Or you can apply a custom VPC security group to your Multi-AZ DB cluster.

Restored Multi-AZ DB clusters are automatically associated with the default DB cluster parameter group. However, you can apply a custom DB cluster parameter group by specifying it during a restore.

If the source DB instance has resource tags, RDS adds the latest tags to the restored DB instance.

Note
We recommend that you restore to the same or similar Multi-AZ DB cluster size as the source DB cluster. We also recommend that you restore with the same or similar IOPS value if you're using Provisioned IOPS storage. You might get an error if, for example, you choose a DB cluster size with an incompatible IOPS value.

You can restore a Multi-AZ DB cluster to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore a Multi-AZ DB cluster to a specified time

1. Sign in to the AWS Management Console and open the Amazon RDS console at `https://console.aws.amazon.com/rds/`.
2. In the navigation pane, choose Databases.
3. Choose the Multi-AZ DB cluster that you want to restore.
4. For Actions, choose Restore to point in time.
   The Restore to point in time window appears.
5. Choose Latest restorable time to restore to the latest possible time, or choose Custom to choose a time.
   If you chose Custom, enter the date and time to which you want to restore the Multi-AZ DB cluster.
   Note
   Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.
6. For DB cluster identifier, enter the name for your restored Multi-AZ DB cluster.
7. In Availability and durability, choose Multi-AZ DB cluster.
8. In **DB instance class**, choose a DB instance class.
   
   Currently, Multi-AZ DB clusters only support db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see [DB instance classes](p. 11).

9. For the remaining sections, specify your DB cluster settings. For information about each setting, see [Settings for creating Multi-AZ DB clusters](p. 514).

10. Choose **Restore to point in time**.

### AWS CLI

To restore a Multi-AZ DB cluster to a specified time, use the AWS CLI command `restore-db-cluster-to-point-in-time` to create a new Multi-AZ DB cluster.

Currently, Multi-AZ DB clusters only support db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see [DB instance classes](p. 11).

**Example**

For Linux, macOS, or Unix:

```bash
aws rds restore-db-cluster-to-point-in-time
  --source-db-cluster-identifier mysourcemultiazdbcluster
  --db-cluster-identifier mytargetmultiazdbcluster
  --restore-to-time 2021-08-14T23:45:00.000Z
  --db-cluster-instance-class db.r6gd.xlarge
```

For Windows:

```bash
aws rds restore-db-cluster-to-point-in-time
  --source-db-cluster-identifier mysourcemultiazdbcluster
  --db-cluster-identifier mytargetmultiazdbcluster
  --restore-to-time 2021-08-14T23:45:00.000Z
  --db-cluster-instance-class db.r6gd.xlarge
```

### RDS API

To restore a DB cluster to a specified time, call the Amazon RDS API `RestoreDBClusterToPointInTime` operation with the following parameters:

- `SourceDBClusterIdentifier`
- `DBClusterIdentifier`
• RestoreToTime
Monitoring metrics in an Amazon RDS instance

In the following sections, you can find an overview of Amazon RDS monitoring and an explanation about how to access metrics. To learn how to monitor events, logs, and database activity streams, see Monitoring events, logs, and streams in an Amazon RDS DB instance (p. 846).

Topics
- Overview of monitoring metrics in Amazon RDS (p. 679)
- Viewing instance status and recommendations (p. 683)
- Viewing metrics in the Amazon RDS console (p. 696)
- Viewing combined metrics in the Amazon RDS console (p. 699)
- Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 706)
- Monitoring DB load with Performance Insights on Amazon RDS (p. 720)
- Analyzing performance anomalies with Amazon DevOps Guru for Amazon RDS (p. 789)
- Monitoring OS metrics with Enhanced Monitoring (p. 797)
- Metrics reference for Amazon RDS (p. 806)
Overview of monitoring metrics in Amazon RDS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your AWS solutions. To more easily debug multi-point failures, we recommend that you collect monitoring data from all parts of your AWS solution.

Topics
- Monitoring plan (p. 679)
- Performance baseline (p. 679)
- Performance guidelines (p. 679)
- Monitoring tools (p. 680)

Monitoring plan

Before you start monitoring Amazon RDS, create a monitoring plan. This plan should answer the following questions:

- What are your monitoring goals?
- Which resources will you monitor?
- How often will you monitor these resources?
- Which monitoring tools will you use?
- Who will perform the monitoring tasks?
- Whom should be notified when something goes wrong?

Performance baseline

To achieve your monitoring goals, you need to establish a baseline. To do this, measure performance under different load conditions at various times in your Amazon RDS environment. You can monitor metrics such as the following:

- Network throughput
- Client connections
- I/O for read, write, or metadata operations
- Burst credit balances for your DB instances

We recommend that you store historical performance data for Amazon RDS. Using the stored data, you can compare current performance against past trends. You can also distinguish normal performance patterns from anomalies, and devise techniques to address issues.

Performance guidelines

In general, acceptable values for performance metrics depend on what your application is doing relative to your baseline. Investigate consistent or trending variances from your baseline. The following metrics are often the source of performance issues:

- **High CPU or RAM consumption** – High values for CPU or RAM consumption might be appropriate, if they're in keeping with your goals for your application (like throughput or concurrency) and are expected.
Monitoring tools

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your other AWS solutions. AWS provides various monitoring tools to watch Amazon RDS, report when something is wrong, and take automatic actions when appropriate.

Topics

- Automated monitoring tools (p. 680)
- Manual monitoring tools (p. 681)

Automated monitoring tools

We recommend that you automate monitoring tasks as much as possible.

Topics

- Amazon RDS instance status and recommendations (p. 680)
- Amazon CloudWatch metrics for Amazon RDS (p. 681)
- Amazon RDS Performance Insights and operating-system monitoring (p. 681)
- Integrated services (p. 681)

Amazon RDS instance status and recommendations

You can use the following automated tools to watch Amazon RDS and report when something is wrong:

- **Amazon RDS instance status** — View details about the current status of your instance by using the Amazon RDS console, the AWS CLI, or the RDS API.
- **Amazon RDS recommendations** — Respond to automated recommendations for database resources, such as DB instances, read replicas, and DB parameter groups. For more information, see Viewing Amazon RDS recommendations (p. 688).
Amazon RDS integrates with Amazon CloudWatch for additional monitoring capabilities.

- **Amazon CloudWatch** – This service monitors your AWS resources and the applications you run on AWS in real time. You can use the following Amazon CloudWatch features with Amazon RDS:
  - **Amazon CloudWatch metrics** – Amazon RDS automatically sends metrics to CloudWatch every minute for each active database. You don't get additional charges for Amazon RDS metrics in CloudWatch. For more information, see Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 706).
  - **Amazon CloudWatch alarms** – You can watch a single Amazon RDS metric over a specific time period. You can then perform one or more actions based on the value of the metric relative to a threshold that you set. For more information, see Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 706).

Amazon RDS Performance Insights and operating-system monitoring

You can use the following automated tools to monitor Amazon RDS performance:

- **Amazon RDS Performance Insights** – Assess the load on your database, and determine when and where to take action. For more information, see Monitoring DB load with Performance Insights on Amazon RDS (p. 720).
- **Amazon RDS Enhanced Monitoring** – Look at metrics in real time for the operating system. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 797).

Integrated services

The following AWS services are integrated with Amazon RDS:

- **Amazon EventBridge** is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. For more information, see Monitoring Amazon RDS events (p. 850).
- **Amazon CloudWatch Logs** lets you monitor, store, and access your log files from Amazon RDS instances, CloudTrail, and other sources. For more information, see Monitoring Amazon RDS log files (p. 895).
- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. For more information, see Monitoring Amazon RDS API calls in AWS CloudTrail (p. 940).
- **Database Activity Streams** is an Amazon RDS feature that provides a near-real-time stream of the activity in your Oracle DB instance. For more information, see Monitoring Amazon RDS with Database Activity Streams (p. 944).

Manual monitoring tools

You need to manually monitor those items that the CloudWatch alarms don't cover. The Amazon RDS, CloudWatch, AWS Trusted Advisor and other AWS console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on your DB instance.

- From the Amazon RDS console, you can monitor the following items for your resources:
  - The number of connections to a DB instance
  - The amount of read and write operations to a DB instance
  - The amount of storage that a DB instance is currently using
  - The amount of memory and CPU being used for a DB instance
• The amount of network traffic to and from a DB instance
• From the Trusted Advisor dashboard, you can review the following cost optimization, security, fault
tolerance, and performance improvement checks:
  • Amazon RDS Idle DB Instances
  • Amazon RDS Security Group Access Risk
  • Amazon RDS Backups
  • Amazon RDS Multi-AZ

For more information on these checks, see Trusted Advisor best practices (checks).
• CloudWatch home page shows:
  • Current alarms and status
  • Graphs of alarms and resources
  • Service health status

In addition, you can use CloudWatch to do the following:
• Create customized dashboards to monitor the services that you care about.
• Graph metric data to troubleshoot issues and discover trends.
• Search and browse all your AWS resource metrics.
• Create and edit alarms to be notified of problems.
Viewing instance status and recommendations

Using the Amazon RDS console, you can quickly access the status of your DB instance and respond to Amazon RDS recommendations.

Topics
- Viewing Amazon RDS DB instance status (p. 684)
- Viewing Amazon RDS recommendations (p. 688)
# Viewing Amazon RDS DB instance status

The status of a DB instance indicates the health of the DB instance. You can use the following procedures to view the DB instance status in the Amazon RDS console, the AWS CLI command, or the API operation.

**Note**

Amazon RDS also uses another status called *maintenance status*, which is shown in the Maintenance column of the Amazon RDS console. This value indicates the status of any maintenance patches that need to be applied to a DB instance. Maintenance status is independent of DB instance status. For more information about maintenance status, see [Applying updates for a DB instance](p. 421).

Find the possible status values for DB instances in the following table. This table also shows whether you will be billed for the DB instance and storage, billed only for storage, or not billed. For all DB instance statuses, you are always billed for backup usage.

<table>
<thead>
<tr>
<th>DB instance status</th>
<th>Billed</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Available</td>
<td>Billed</td>
<td>The DB instance is healthy and available.</td>
</tr>
<tr>
<td>Backing-up</td>
<td>Billed</td>
<td>The DB instance is currently being backed up.</td>
</tr>
<tr>
<td>Configuring-enhanced-monitoring</td>
<td>Billed</td>
<td>Enhanced Monitoring is being enabled or disabled for this DB instance.</td>
</tr>
<tr>
<td>Configuring-iam-database-auth</td>
<td>Billed</td>
<td>AWS Identity and Access Management (IAM) database authentication is being enabled or disabled for this DB instance.</td>
</tr>
<tr>
<td>Configuring-log-exports</td>
<td>Billed</td>
<td>Publishing log files to Amazon CloudWatch Logs is being enabled or disabled for this DB instance.</td>
</tr>
<tr>
<td>Converting-to-vpc</td>
<td>Billed</td>
<td>The DB instance is being converted from a DB instance that is not in an Amazon Virtual Private Cloud (Amazon VPC) to a DB instance that is in an Amazon VPC.</td>
</tr>
<tr>
<td>Creating</td>
<td>Not billed</td>
<td>The DB instance is being created. The DB instance is inaccessible while it is being created.</td>
</tr>
<tr>
<td>Delete-precheck</td>
<td>Not billed</td>
<td>Amazon RDS is validating that read replicas are healthy and are safe to delete.</td>
</tr>
<tr>
<td>Deleting</td>
<td>Not billed</td>
<td>The DB instance is being deleted.</td>
</tr>
<tr>
<td>Failed</td>
<td>Not billed</td>
<td>The DB instance has failed and Amazon RDS can't recover it. Perform a point-in-time restore to the latest restorable time of the DB instance to recover the data.</td>
</tr>
<tr>
<td>Inaccessible-encryption-credentials</td>
<td>Not billed</td>
<td>The AWS KMS key used to encrypt or decrypt the DB instance can't be accessed or recovered.</td>
</tr>
<tr>
<td>Inaccessible-encryption-credentials-recoverable</td>
<td>Billed for storage</td>
<td>The KMS key used to encrypt or decrypt the DB instance can't be accessed. However, if the KMS key is active, restarting the DB instance can recover it.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For more information, see [Encrypting a DB instance](p. 2604).</td>
</tr>
<tr>
<td>Incompatible-network</td>
<td>Not billed</td>
<td>Amazon RDS is attempting to perform a recovery action on a DB instance but can't do so because the VPC is in a state that prevents the action from being completed. This status can occur.</td>
</tr>
<tr>
<td>DB instance status</td>
<td>Billed</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DB instance status</td>
<td>Billed</td>
<td>Description</td>
</tr>
<tr>
<td>Incompatible-option-group</td>
<td>Billed</td>
<td>Amazon RDS attempted to apply an option group change but can't do so, and Amazon RDS can't roll back to the previous option group state. For more information, check the Recent Events list for the DB instance. This status can occur if, for example, the option group contains an option such as TDE and the DB instance doesn't contain encrypted information.</td>
</tr>
<tr>
<td>Incompatible-parameters</td>
<td>Billed</td>
<td>Amazon RDS can't start the DB instance because the parameters specified in the DB instance's DB parameter group aren't compatible with the DB instance. Revert the parameter changes or make them compatible with the DB instance to regain access to your DB instance. For more information about the incompatible parameters, check the Recent Events list for the DB instance.</td>
</tr>
<tr>
<td>Incompatible-restore</td>
<td>Not billed</td>
<td>Amazon RDS can't do a point-in-time restore. Common causes for this status include using temp tables, using MyISAM tables with MySQL, or using Aria tables with MariaDB.</td>
</tr>
<tr>
<td>Insufficient-capacity</td>
<td>Not billed</td>
<td>Amazon RDS can't create your instance because sufficient capacity isn't currently available. To create your DB instance in the same AZ with the same instance type, delete your DB instance, wait a few hours, and try to create again. Alternatively, create a new instance using a different instance class or AZ.</td>
</tr>
<tr>
<td>Maintenance</td>
<td>Billed</td>
<td>Amazon RDS is applying a maintenance update to the DB instance. This status is used for instance-level maintenance that RDS schedules well in advance.</td>
</tr>
<tr>
<td>Modifying</td>
<td>Billed</td>
<td>The DB instance is being modified because of a customer request to modify the DB instance.</td>
</tr>
<tr>
<td>Moving-to-vpc</td>
<td>Billed</td>
<td>The DB instance is being moved to a new Amazon Virtual Private Cloud (Amazon VPC).</td>
</tr>
<tr>
<td>Rebooting</td>
<td>Billed</td>
<td>The DB instance is being rebooted because of a customer request or an Amazon RDS process that requires the rebooting of the DB instance.</td>
</tr>
<tr>
<td>Resetting-master-credentials</td>
<td>Billed</td>
<td>The master credentials for the DB instance are being reset because of a customer request to reset them.</td>
</tr>
<tr>
<td>Renaming</td>
<td>Billed</td>
<td>The DB instance is being renamed because of a customer request to rename it.</td>
</tr>
<tr>
<td>Restore-error</td>
<td>Billed</td>
<td>The DB instance encountered an error attempting to restore to a point-in-time or from a snapshot.</td>
</tr>
<tr>
<td>Starting</td>
<td>Billed</td>
<td>The DB instance is starting.</td>
</tr>
<tr>
<td>Stopped</td>
<td>Billed</td>
<td>The DB instance is stopped.</td>
</tr>
</tbody>
</table>
### DB instance status

<table>
<thead>
<tr>
<th>Status</th>
<th>Billed</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stopping</td>
<td>Billed</td>
<td>The DB instance is being stopped.</td>
</tr>
<tr>
<td>Storage-full</td>
<td>Billed</td>
<td>The DB instance has reached its storage capacity allocation. This is a critical status, and we recommend that you fix this issue immediately. To do so, scale up your storage by modifying the DB instance. To avoid this situation, set Amazon CloudWatch alarms to warn you when storage space is getting low.</td>
</tr>
<tr>
<td>Storage-optimization</td>
<td>Billed</td>
<td>Amazon RDS is optimizing the storage of your DB instance. The DB instance is fully operational. The storage optimization process is usually short, but can sometimes take up to and even beyond 24 hours.</td>
</tr>
<tr>
<td>Upgrading</td>
<td>Billed</td>
<td>The database engine version is being upgraded.</td>
</tr>
</tbody>
</table>

### Console

**To view the status of a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.

The **Databases page** appears with the list of DB instances. For each DB instance, the status value is displayed.

![Databases page](image_url)

### CLI

To view DB instance and its status information by using the AWS CLI, use the `describe-db-instances` command. For example, the following AWS CLI command lists all the DB instances information:

```bash
aws rds describe-db-instances
```

To view a specific DB instance and its status, call the `describe-db-instances` command with the following option:

- `DBInstanceIdentifier` – The name of the DB instance.
To view just the status of all the DB instances, use the following query in AWS CLI.

```bash
aws rds describe-db-instances --query 'DBInstances[*].[DBInstanceIdentifier, DBInstanceStatus]' --output table
```

**API**

To view the status of the DB instance using the Amazon RDS API, call the [DescribeDBInstances](https://docs.aws.amazon.com/AmazonRDS/latest/APIReference/API_DescribeDBInstances.html) operation.
### Viewing Amazon RDS recommendations

Amazon RDS provides automated recommendations for database resources, such as DB instances, read replicas, and DB parameter groups. These recommendations provide best practice guidance by analyzing DB instance configuration, usage, and performance data.

You can find examples of these recommendations in the following table.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Recommendation</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB instance isn't a Multi-AZ DB instance</td>
<td>Your DB instance isn't using the Multi-AZ deployment.</td>
<td>We recommend that you use Multi-AZ deployment. The Multi-AZ deployments enhance the availability and durability of the DB instance. For information about Amazon RDS Multi-AZ pricing, see <a href="#">Pricing</a>.</td>
<td></td>
</tr>
<tr>
<td>Storage autoscaling isn't turned on</td>
<td>Your DB instance doesn't have Amazon RDS storage autoscaling turned on. Storage autoscaling automatically scales the storage capacity when there is an increase in the database size, with zero downtime.</td>
<td>We recommend that you turn on the storage autoscaling with a maximum allocated storage of ${{MaxAllocatedStorage}}$ GB for your DB instance ${{DBInstanceIdentifier}}$.</td>
<td>Managing capacity automatically with Amazon RDS storage autoscaling (p. 480)</td>
</tr>
<tr>
<td>Engine version outdated</td>
<td>Your DB instance is not running the latest minor engine version.</td>
<td>We recommend that you upgrade to the latest version because it contains the latest security fixes and other improvements.</td>
<td>Upgrading a DB instance engine version (p. 429)</td>
</tr>
<tr>
<td>Pending maintenance available</td>
<td>You have pending maintenance available on your DB instance.</td>
<td>We recommend that you perform the pending maintenance available on your DB instance. Updates to the operating system most often occur for security issues and should be done as soon as possible.</td>
<td>Maintaining a DB instance (p. 418)</td>
</tr>
<tr>
<td>Automated backups disabled</td>
<td>Your DB instance has automated backups disabled.</td>
<td>We recommend that you enable automated backups on your DB instance. Automated backups enable point-in-time recovery of your DB instance. You receive backup storage up to the storage size of your DB instance at no additional charge.</td>
<td>Working with backups (p. 591)</td>
</tr>
<tr>
<td>Magnetic volumes in use</td>
<td>Your DB instance is using magnetic storage.</td>
<td>Magnetic storage is not recommended for most DB instances. We recommend switching to General Purpose (SSD) storage or provisioned IOPS storage.</td>
<td>Amazon RDS DB instance storage (p. 101)</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td>Recommendation</td>
<td>Additional information</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Enhanced Monitoring disabled</td>
<td>Your DB instance doesn't have Enhanced Monitoring enabled.</td>
<td>We recommend enabling Enhanced Monitoring. Enhanced Monitoring provides real-time operating system metrics for monitoring and troubleshooting.</td>
<td>Monitoring OS metrics with Enhanced Monitoring (p. 797)</td>
</tr>
<tr>
<td>Performance Insights disabled</td>
<td>Your DB instance doesn't have Performance Insights enabled.</td>
<td>We recommend enabling Performance Insights. Performance Insights monitors your database load for better analysis and troubleshooting.</td>
<td>Overview of Performance Insights on Amazon RDS (p. 720)</td>
</tr>
<tr>
<td>Encryption disabled</td>
<td>Your DB instance doesn't have encryption enabled.</td>
<td>We recommend enabling encryption. You can encrypt your existing Amazon RDS DB instances by restoring from an encrypted snapshot.</td>
<td>Encrypting Amazon RDS resources (p. 2603)</td>
</tr>
<tr>
<td>Previous generation DB instance class in use</td>
<td>Your DB instance is running on a previous-generation DB instance class.</td>
<td>Previous-generation DB instance classes have been replaced by DB instance classes with better price, better performance, or both. We recommend running your DB instance on a later generation DB instance class.</td>
<td>DB instance classes (p. 11)</td>
</tr>
<tr>
<td>Huge pages not used for an Oracle DB instance</td>
<td>The use_large_pages parameter is not set to ONLY in the DB parameter group used by your DB instance.</td>
<td>For increased database scalability, we recommend setting use_large_pages to ONLY in the DB parameter group used by your DB instance.</td>
<td>Turning on HugePages for an RDS for Oracle instance (p. 1958)</td>
</tr>
<tr>
<td>Nondefault custom memory parameters</td>
<td>Your DB parameter group sets memory parameters that diverge too much from the default values.</td>
<td>Settings that diverge too much from the default values can cause poor performance and errors. We recommend setting custom memory parameters to their default values in the DB parameter group used by the DB instance.</td>
<td>Working with parameter groups (p. 347)</td>
</tr>
<tr>
<td>Found an unsafe durability parameter value for</td>
<td>Your DB instance has an unsafe value for the innodb_flush_log_at_trx_commit parameter. This parameter controls the persistence of commit operations to disk.</td>
<td>We recommend that you set the value of the innodb_flush_log_at_trx_commit parameter. The current value might improve performance but transactions can be lost if the database crashes.</td>
<td>Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance on the AWS Database Blog</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td>Recommendation</td>
<td>Additional information</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Optimizer statistics aren't persisted to the disk for a MySQL DB instance</td>
<td>Your DB instance isn't configured to persist the InnoDB statistics to the disk. When it isn't configured, the statistics may recalculate frequently, which leads to variations in query execution plan. You can modify the value of this global parameter at the table level.</td>
<td>Global statistics persistence is disabled. We recommend that you set the <code>innodb_stats_persistent</code> parameter to <code>ON</code>.</td>
<td>Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance on the AWS Database Blog</td>
</tr>
<tr>
<td>General logging is enabled for a MySQL DB instance</td>
<td>Your DB instance has the general logging turned on. Turning on general logging increases the amount of I/O operations and allocated storage space, which can lead to contention and performance degradation.</td>
<td>Evaluate your required general logging usage. General logging can increase the amount of I/O operations and allocated storage space, and lead to contention and performance degradation.</td>
<td>Managing table-based MySQL logs (p. 920)</td>
</tr>
<tr>
<td>Maximum InnoDB open files setting is misconfigured for a MySQL DB instance</td>
<td>Your DB instance has a low value for the maximum number of files InnoDB can open at one time.</td>
<td>We recommend that you set the <code>innodb_open_files</code> parameter to a minimum value of 65.</td>
<td>innodb_open_files</td>
</tr>
<tr>
<td>Number of allowed simultaneous connections for a given database user is misconfigured for a MySQL DB instance</td>
<td>Your DB instance has a low value for the maximum number of simultaneous connections for each database account.</td>
<td>We recommend that you increase the setting of the <code>max_user_connections</code> parameter to a number greater than 5. The current <code>max_user_connections</code> value is low which impacts the database health checks and regular operations.</td>
<td>Setting Account Resource Limits</td>
</tr>
<tr>
<td>Read replica is open in writable mode for a MySQL DB instance</td>
<td>Your DB instance has the Read replica in writable mode, which allows updates from clients.</td>
<td>We recommend that you don't change MySQL read replicas to writable mode for a long duration. This setting can cause replication errors and data consistency issues.</td>
<td>Best practices for configuring parameters for Amazon RDS for MySQL, part 2: Parameters related to replication on the AWS Database Blog</td>
</tr>
</tbody>
</table>
### Viewing Amazon RDS recommendations

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Recommendation</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Found an unsafe durability parameter value for a MySQL DB instance</td>
<td>The synchronization of the binary log to disk isn't enforced before the acknowledgement of the transactions commit in your DB instance.</td>
<td>We recommend that you set the sync_binlog parameter to 1. Currently, the synchronization of the binary log to disk isn't enforced before acknowledgement of the transactions commit. If there is a power failure or the operating system crashes, the committed transactions can be lost.</td>
<td>Best practices for configuring parameters for Amazon RDS for MySQL, part 2: Parameters related to replication on the AWS Database Blog</td>
</tr>
<tr>
<td>Found an unsafe setting of the innodb_default_row_format parameter for a MySQL DB instance</td>
<td>Your DB instance has a the following known issue: A table created in a MySQL version lower than 8.0.26 with row_format COMPACT or REDUNDANT will be inaccessible and unrecoverable when the index exceeds 767 bytes.</td>
<td>We recommend that you change the current value of the innodb_default_row_format parameter to DYNAMIC.</td>
<td>Changes in MySQL 8.0.26 (2021-07-20, General Availability)</td>
</tr>
<tr>
<td>Change buffering enabled for a MySQL DB instance</td>
<td>Your DB parameter group has change buffering enabled.</td>
<td>Change buffering allows a MySQL DB instance to defer some writes necessary to maintain secondary indexes. This configuration can improve performance slightly, but it can create a large delay in crash recovery. During crash recovery, the secondary index must be brought up to date. So, the benefits of change buffering are outweighed by the potentially very long crash recovery events. We recommend disabling change buffering.</td>
<td>Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance on the AWS Database Blog</td>
</tr>
<tr>
<td>Query cache enabled for a MySQL DB instance</td>
<td>Your DB parameter group has query cache parameter enabled.</td>
<td>The query cache can cause the DB instance to appear to stall when changes require the cache to be purged. Most workloads don't benefit from a query cache. The query cache was removed from MySQL version 8.0. We recommend that you disable the query cache parameter.</td>
<td>Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance on the AWS Database Blog</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td>Recommendation</td>
<td>Additional information</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Autovacuum is disabled for a PostgreSQL DB instance</td>
<td>Your DB instance has autovacuum turned off. Turning off autovacuum increases table and index bloat and impacts performance.</td>
<td>We recommend that you set the autovacuum parameter to on.</td>
<td><a href="#">Understanding autovacuum in Amazon RDS for PostgreSQL environments</a></td>
</tr>
<tr>
<td>Synchronous commit is turned off for a PostgreSQL DB instance</td>
<td>When the synchronous_commit parameter is set to OFF, it causes data loss when the database crashes, which can impact the durability of the database.</td>
<td>We recommend that you turn on the synchronous_commit parameter.</td>
<td><a href="#">Asynchronous Commit</a></td>
</tr>
<tr>
<td>track_counts parameter is disabled for a PostgreSQL DB instance</td>
<td>If the track_counts parameter is turned off, the database doesn't collect the database activity statistics. Autovacuum requires these statistics to work correctly.</td>
<td>We recommend that you set track_counts parameter to ON.</td>
<td><a href="#">track_counts</a></td>
</tr>
<tr>
<td>Index only scan plan type is disabled for a PostgreSQL DB instance</td>
<td>The query planner or optimizer can't use the index only scan plan when it is disabled.</td>
<td>We recommend that you set the parameter enable_indexonlyscan to ON.</td>
<td><a href="#">enable_indexonlyscan</a></td>
</tr>
<tr>
<td>Index only scan plan type is disabled for a PostgreSQL DB instance</td>
<td>The query planner or optimizer can't use the index scan plan types when it is disabled.</td>
<td>We recommend that you set the parameter enable_indexscan to ON.</td>
<td><a href="#">enable_indexscan</a></td>
</tr>
<tr>
<td>Logging to table</td>
<td>Your DB parameter group sets logging output to TABLE.</td>
<td>Setting logging output to TABLE uses more storage than setting this parameter to FILE. To avoid reaching the storage limit, we recommend setting the logging output parameter to FILE.</td>
<td>[MySQL database log files (p. 915)]</td>
</tr>
</tbody>
</table>
To view Amazon RDS recommendations

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Recommendations.

The Recommendations page appears.

3. On the Recommendations page, choose one of the following:
   - Active – Shows the current recommendations that you can apply, dismiss, or schedule.
• **Dismissed** – Shows the recommendations that have been dismissed. When you choose **Dismissed**, you can apply these dismissed recommendations.

• **Scheduled** – Shows the recommendations that are scheduled but not yet applied. These recommendations will be applied in the next scheduled maintenance window.

• **Applied** – Shows the recommendations that are currently applied.

From any list of recommendations, you can open a section to view the recommendations in that section.

![Recommendations](image)

To configure preferences for displaying recommendations in each section, choose the **Preferences** icon.

![Preferences](image)

From the **Preferences** window that appears, you can set display options. These options include the visible columns and the number of recommendations to display on the page.

4. (optional) Respond to your active recommendations as follows:
a. Choose **Active** and open one or more sections to view the recommendations in them.

b. Choose one or more recommendations and choose **Apply now** (to apply them immediately), **Schedule** (to apply them in next maintenance window), or **Dismiss**.

If the **Apply now** button appears for a recommendation but is unavailable (grayed out), the DB instance is not available. You can apply recommendations immediately only if the DB instance status is **available**. For example, you can't apply recommendations immediately to the DB instance if its status is **modifying**. In this case, wait for the DB instance to be available and then apply the recommendation.

If the **Apply now** button doesn't appear for a recommendation, you can't apply the recommendation using the **Recommendations** page. You can modify the DB instance to apply the recommendation manually.

For more information about modifying a DB instance, see *Modifying an Amazon RDS DB instance (p. 401).*

**Note**

When you choose **Apply now**, a brief DB instance outage might result.
Amazon RDS integrates with Amazon CloudWatch to display a variety of RDS DB instance metrics in the RDS console. For descriptions of these metrics, see Metrics reference for Amazon RDS (p. 806).

For your DB instance, the following categories of metrics are monitored:

- **CloudWatch** – Shows the Amazon CloudWatch metrics for RDS that you can access in the RDS console. You can also access these metrics in the CloudWatch console. Each metric includes a graph that shows the metric monitored over a specific time span. For a list of CloudWatch metrics, see Amazon CloudWatch metrics for Amazon RDS (p. 806).

- **Enhanced monitoring** – Shows a summary of operating-system metrics when your RDS DB instance has turned on Enhanced Monitoring. RDS delivers the metrics from Enhanced Monitoring to your Amazon CloudWatch Logs account. Each OS metric includes a graph showing the metric monitored over a specific time span. For an overview, see Monitoring OS metrics with Enhanced Monitoring (p. 797). For a list of Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring (p. 837).

- **OS Process list** – Shows details for each process running in your DB instance.

- **Performance Insights** – Opens the Amazon RDS Performance Insights dashboard for a DB instance. For an overview of Performance Insights, see Monitoring DB load with Performance Insights on Amazon RDS (p. 720). For a list of Performance Insights metrics, see Amazon CloudWatch metrics for Performance Insights (p. 813).

Amazon RDS now provides a consolidated view of Performance Insights and CloudWatch metrics in the Performance Insights dashboard. Performance Insights must be turned on for your DB instance to use this view. You can choose the new monitoring view in the Monitoring tab or Performance Insights in the navigation pane. To view the instructions for choosing this view, see Viewing combined metrics in the Amazon RDS console (p. 699).

If you want to continue with the legacy monitoring view, continue with this procedure.

**Note**

The legacy monitoring view will be discontinued on December 15, 2023.

**To view metrics for your DB instance in the legacy monitoring view:**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB instance that you want to monitor.

   The database page appears. The following example shows an Oracle database named orclb.
4. Scroll down and choose **Monitoring**.

The monitoring section appears. By default, CloudWatch metrics are shown. For descriptions of these metrics, see *Amazon CloudWatch metrics for Amazon RDS* (p. 806).

5. Choose **Monitoring** to see the metric categories.

6. Choose the category of metrics that you want to see.

The following example shows Enhanced Monitoring metrics. For descriptions of these metrics, see *OS metrics in Enhanced Monitoring* (p. 837).

**Note**

Currently, viewing OS metrics for a Multi-AZ standby replica is not supported for MariaDB DB instances.
Viewing metrics in the Amazon RDS console

**Tip**
To choose the time range of the metrics represented by the graphs, you can use the time range list.
To bring up a more detailed view, you can choose any graph. You can also apply metric-specific filters to the data.
Viewing combined metrics in the Amazon RDS console

Amazon RDS now provides a consolidated view of Performance Insights and CloudWatch metrics for your DB instance in the Performance Insights dashboard. You can use the preconfigured dashboard or create a custom dashboard. The preconfigured dashboard provides the most commonly used metrics to help diagnose performance issues for a database engine. Alternatively, you can create a custom dashboard with the metrics for a database engine that meet your analysis requirements. Then, use this dashboard for all the DB instances of that database engine type in your AWS account.

You can choose the new monitoring view in the Monitoring tab or Performance Insights in the navigation pane. When you navigate to the Performance Insights page, you see the options to choose between the new monitoring view and legacy view. The option you choose is saved as the default view.

Performance Insights must be turned on for your DB instance to view the combined metrics in the Performance Insights dashboard. For more information about turning on Performance Insights, see Turning Performance Insights on and off (p. 727).

Note
We recommend that you choose the new monitoring view. You can continue to use the legacy monitoring view until it is discontinued on December 15, 2023.

Choosing the new monitoring view in the Monitoring tab

To choose the new monitoring view in the Monitoring tab:

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose Databases.
3. Choose the DB instance that you want to monitor.

   The database page appears.

4. Scroll down and choose the Monitoring tab.

   A banner appears with the option to choose the new monitoring view. The following example shows the banner to choose the new monitoring view.

5. Choose Go to new monitoring view to open the Performance Insights dashboard with Performance Insights and CloudWatch metrics for your DB instance.
6. (Optional) If Performance Insights is turned off for your DB instance, a banner appears with the option to modify your DB cluster and turn on Performance Insights.

   The following example shows the banner to modify the DB cluster in the Monitoring tab.
Choosing the new monitoring view with **Performance Insights** in the navigation pane

To choose the new monitoring view with **Performance Insights** in the navigation pane:

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance to open a window that has the monitoring view options.

   The following example shows the window with the monitoring view options.

   Choose **Modify** to modify your DB cluster and turn on Performance Insights. For more information about turning on Performance Insights, see **Turning Performance Insights on and off** (p. 727)

   4. Choose the **Performance Insights and CloudWatch metrics view (New)** option, and then choose **Continue**.

      You can now view the Performance Insights dashboard that shows both Performance Insights and CloudWatch metrics for your DB instance. The following example shows the Performance Insights and CloudWatch metrics in the dashboard.
You can choose the legacy monitoring view to view only the Performance Insights metrics for your DB instance.

**Note**
This view will be discontinued on December 15, 2023.

**To choose the legacy monitoring view with Performance Insights in the navigation pane:**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.

You can now see the **Settings** window that shows the option to choose the legacy Performance Insights view.

The following example shows the window with the option for the legacy monitoring view.
5. Select the Performance Insights view option and choose Continue.

A warning message appears. Any dashboard configurations that you saved won't be available in this view.

6. Choose Confirm to continue to the legacy Performance Insights view.

You can now view the Performance Insights dashboard that shows only Performance Insights metrics for the DB instance.

Creating a custom dashboard with Performance Insights in the navigation pane

In the new monitoring view, you can create a custom dashboard with the metrics you need to meet your analysis requirements.

You can create a custom dashboard by selecting Performance Insights and CloudWatch metrics for your DB instance. You can use this custom dashboard for other DB instances of the same database engine type in your AWS account.

Note
The customized dashboard supports up to 50 metrics.

Use the widget settings menu to edit or delete the dashboard, and move or resize the widget window.

To create a custom dashboard with Performance Insights in the navigation pane:

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose Performance Insights.
3. Choose a DB instance.
4. Scroll down to the **Metrics tab** in the window.
5. Select the custom dashboard from the drop down list. The following example shows the custom dashboard creation.

![Custom Dashboard Example](image)

6. Choose **Add widget** to open the **Add widget** window. You can open and view the available operating system (OS) metrics, database metrics, and CloudWatch metrics in the window.

   The following example shows the **Add widget** window with the metrics.
7. Select the metrics that you want to view in the dashboard and choose **Add widget**. You can use the search field to find a specific metric.

The selected metrics appear on your dashboard.
Choosing the preconfigured dashboard with Performance Insights in the navigation pane

You can view the most commonly used metrics with the preconfigured dashboard. This dashboard helps diagnose performance issues with a database engine and reduce the average recovery time from hours to minutes.

**Note**
This dashboard can't be edited.

To choose the preconfigured dashboard with Performance Insights in the navigation pane:

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the left navigation pane, choose Performance Insights.
3. Choose a DB instance.
4. Scroll down to the Metrics tab in the window.
5. Select a preconfigured dashboard from the drop down list.

You can view the metrics for the DB instance in the dashboard. The following example shows a preconfigured metrics dashboard.
Monitoring Amazon RDS metrics with Amazon CloudWatch

Amazon CloudWatch is a metrics repository. The repository collects and processes raw data from Amazon RDS into readable, near real-time metrics. For a complete list of Amazon RDS metrics sent to CloudWatch, see Metrics reference for Amazon RDS.

Topics

- Overview of Amazon RDS and Amazon CloudWatch (p. 707)
- Viewing DB instance metrics in the CloudWatch console and AWS CLI (p. 708)
- Creating CloudWatch alarms to monitor Amazon RDS (p. 713)
- Tutorial: Creating an Amazon CloudWatch alarm for Multi-AZ DB cluster replica lag (p. 713)
Overview of Amazon RDS and Amazon CloudWatch

By default, Amazon RDS automatically sends metric data to CloudWatch in 1-minute periods. For example, the CPUUtilization metric records the percentage of CPU utilization for a DB instance over time. Data points with a period of 60 seconds (1 minute) are available for 15 days. This means that you can access historical information and see how your web application or service is performing.

As shown in the following diagram, you can set up alarms for your CloudWatch metrics. For example, you might create an alarm that signals when the CPU utilization for an instance is over 70%. You can configure Amazon Simple Notification Service to email you when the threshold is passed.

Amazon RDS publishes the following types of metrics to Amazon CloudWatch:

- Metrics for your RDS DB instances
  
  For a table of these metrics, see Amazon CloudWatch metrics for Amazon RDS (p. 806).

- Performance Insights metrics
  
  For a table of these metrics, see Amazon CloudWatch metrics for Performance Insights (p. 813) and Performance Insights counter metrics (p. 814).
• Enhanced Monitoring metrics (published to Amazon CloudWatch Logs)
  
  For a table of these metrics, see OS metrics in Enhanced Monitoring (p. 837).

• Usage metrics for the Amazon RDS service quotas in your AWS account
  
  For a table of these metrics, see Amazon CloudWatch usage metrics for Amazon RDS (p. 812). For more information about Amazon RDS quotas, see Quotas and constraints for Amazon RDS (p. 2737).

For more information about CloudWatch, see What is Amazon CloudWatch? in the Amazon CloudWatch User Guide. For more information about CloudWatch metrics retention, see Metrics retention.

**Viewing DB instance metrics in the CloudWatch console and AWS CLI**

Following, you can find details about how to view metrics for your DB instance using CloudWatch. For information on monitoring metrics for your DB instance's operating system in real time using CloudWatch Logs, see Monitoring OS metrics with Enhanced Monitoring (p. 797).

When you use Amazon RDS resources, Amazon RDS sends metrics and dimensions to Amazon CloudWatch every minute. You can use the following procedures to view the metrics for Amazon RDS in the CloudWatch console and CLI.

**Console**

**To view metrics using the Amazon CloudWatch console**

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

   The CloudWatch overview home page appears.
2. If necessary, change the AWS Region. From the navigation bar, choose the AWS Region where your AWS resources are. For more information, see Regions and endpoints.

3. In the navigation pane, choose Metrics and then All metrics.

4. Scroll down and choose the RDS metric namespace.

The page displays the Amazon RDS dimensions. For descriptions of these dimensions, see Amazon CloudWatch dimensions for Amazon RDS (p. 813).

5. Choose a metric dimension, for example By Database Class.
6. Do any of the following actions:
   - To sort the metrics, use the column heading.
   - To graph a metric, select the check box next to the metric.
   - To filter by resource, choose the resource ID, and then choose Add to search.
   - To filter by metric, choose the metric name, and then choose Add to search.

The following example filters on the `db.t3.medium` class and graphs the `CPUUtilization` metric.
AWS CLI

To obtain metric information by using the AWS CLI, use the CloudWatch command `list-metrics`. In the following example, you list all metrics in the AWS/RDS namespace.

```
aws cloudwatch list-metrics --namespace AWS/RDS
```

To obtain metric statistics, use the command `get-metric-statistics`. The following command gets CPUUtilization statistics for instance `my-instance` over the specific 24-hour period, with a 5-minute granularity.

**Example**

For Linux, macOS, or Unix:

```
aws cloudwatch get-metric-statistics --namespace AWS/RDS --metric-name CPUUtilization --start-time 2021-12-15T00:00:00Z --end-time 2021-12-16T00:00:00Z --period 360 --statistics Minimum --dimensions Name=DBInstanceIdentifier,Value=my-instance
```

For Windows:

```
aws cloudwatch get-metric-statistics --namespace AWS/RDS --metric-name CPUUtilization --start-time 2021-12-15T00:00:00Z --end-time 2021-12-16T00:00:00Z --period 360 --statistics Minimum --dimensions Name=DBInstanceIdentifier,Value=my-instance
```

Sample output appears as follows:

```
{
    "Datapoints": [
        {
            "Timestamp": "2021-12-15T18:00:00Z",
            "Minimum": 8.7,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2021-12-15T23:54:00Z",
            "Minimum": 8.12486458559024,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2021-12-15T17:24:00Z",
            "Minimum": 8.841666666666667,
            "Unit": "Percent"
        },
        ..., 
        {
            "Timestamp": "2021-12-15T22:48:00Z",
            "Minimum": 8.366248354248954,
            "Unit": "Percent"
        }
    ],
    "Label": "CPUUtilization"
}
```
Creating CloudWatch alarms to monitor Amazon RDS

You can create a CloudWatch alarm that sends an Amazon SNS message when the alarm changes state. An alarm watches a single metric over a time period that you specify. The alarm can also perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

Alarms invoke actions for sustained state changes only. CloudWatch alarms don't invoke actions simply because they are in a particular state. The state must have changed and have been maintained for a specified number of time periods.

You can use the `DB_PERF_INSIGHTS` metric math function in the CloudWatch console to query Amazon RDS for Performance Insights counter metrics. The `DB_PERF_INSIGHTS` function also includes the `DBLoad` metric at sub-minute intervals. You can set CloudWatch alarms on these metrics.

For more details on how to create an alarm, see [Create an alarm on Performance Insights counter metrics from an AWS database](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Overview.AmazonCloudWatch.Alarms.PerformanceInsights.html).

To set an alarm using the AWS CLI

- Call `put-metric-alarm`. For more information, see [AWS CLI Command Reference](https://docs.aws.amazon.com/cli/latest/reference/cloudwatch/put-metric-alarm.html).

To set an alarm using the CloudWatch API

- Call `PutMetricAlarm`. For more information, see [Amazon CloudWatch API Reference](https://docs.aws.amazon.com/AmazonCloudWatch/latest/APIReference/ApiReference开发者的.html).

For more information about setting up Amazon SNS topics and creating alarms, see [Using Amazon CloudWatch alarms](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/SNS_notifications.html).

Tutorial: Creating an Amazon CloudWatch alarm for Multi-AZ DB cluster replica lag

You can create an Amazon CloudWatch alarm that sends an Amazon SNS message when replica lag for a Multi-AZ DB cluster has exceeded a threshold. An alarm watches the `ReplicaLag` metric over a time period that you specify. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

To set a CloudWatch alarm for Multi-AZ DB cluster replica lag

2. In the navigation pane, choose Alarms, All alarms.
3. Choose Create alarm.
4. On the Specify metric and conditions page, choose Select metric.
5. In the search box, enter the name of your Multi-AZ DB cluster and press Enter.

The following image shows the Select metric page with a Multi-AZ DB cluster named `rds-cluster` entered.
6. Choose RDS, Per-Database Metrics.
7. In the search box, enter `ReplicaLag` and press Enter, then select each DB instance in the DB cluster.

The following image shows the Select metric page with the DB instances selected for the `ReplicaLag` metric.

This alarm considers the replica lag for all three of the DB instances in the Multi-AZ DB cluster. The alarm responds when any DB instance exceeds the threshold. It uses a math expression that returns
the maximum value of the three metrics. Start by sorting by metric name, and then choose all three ReplicaLag metrics.

8. From Add math, choose All functions, MAX.

![Add math and All functions](image)

9. Choose the Graphed metrics tab, and edit the details for Expression1 to \( \text{MAX}([m1, m2, m3]) \).

10. For all three ReplicaLag metrics, change the Period to 1 minute.

11. Clear selection from all metrics except for Expression1.

The Select metric page should look similar to the following image.
12. Choose **Select metric**.

13. On the **Specify metric and conditions** page, change the label to a meaningful name, such as **ClusterReplicaLag**, and enter a number of seconds in **Define the threshold value**. For this tutorial, enter **1200** seconds (20 minutes). You can adjust this value for your workload requirements.

   The **Specify metric and conditions** page should look similar to the following image.
14. Choose Next, and the Configure actions page appears.

15. Keep In alarm selected, choose Create new topic, and enter the topic name and a valid email address.
16. Choose Create topic, and then choose Next.

17. On the Add name and description page, enter the Alarm name and Alarm description, and then choose Next.
18. Preview the alarm that you're about to create on the Preview and create page, and then choose Create alarm.
Monitoring DB load with Performance Insights on Amazon RDS

Performance Insights expands on existing Amazon RDS monitoring features to illustrate and help you analyze your database performance. With the Performance Insights dashboard, you can visualize the database load on your Amazon RDS DB instance load and filter the load by waits, SQL statements, hosts, or users. For information about using Performance Insights with Amazon DocumentDB, see Amazon DocumentDB Developer Guide.

Topics
- Overview of Performance Insights on Amazon RDS (p. 720)
- Turning Performance Insights on and off (p. 727)
- Turning on the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL (p. 731)
- Configuring access policies for Performance Insights (p. 734)
- Analyzing metrics with the Performance Insights dashboard (p. 738)
- Retrieving metrics with the Performance Insights API (p. 769)
- Logging Performance Insights calls using AWS CloudTrail (p. 786)

Overview of Performance Insights on Amazon RDS

By default, Performance Insights is turned on in the console create wizard for all Amazon RDS engines. If you have more than one database on a DB instance, Performance Insights aggregates performance data.

You can find an overview of Performance Insights for Amazon RDS in the following video.

Using Performance Insights to Analyze Performance of Amazon Aurora PostgreSQL

Important
The following topics describe using Amazon RDS Performance Insights with non-Aurora DB engines. For information about using Amazon RDS Performance Insights with Amazon Aurora, see Using Amazon RDS Performance Insights in the Amazon Aurora User Guide.

Topics
- Database load (p. 720)
- Maximum CPU (p. 724)
- Amazon RDS DB engine, Region, and instance class support for Performance Insights (p. 724)
- Pricing and data retention for Performance Insights (p. 726)

Database load

Database load (DB load) measures the level of session activity in your database. The key metric in Performance Insights is DBLoad, which is collected every second.

Topics
- Active sessions (p. 721)
- Average active sessions (p. 721)
- Average active executions (p. 721)
- Dimensions (p. 722)
Active sessions

A database session represents an application's dialogue with a relational database. An active session is a connection that has submitted work to the DB engine and is waiting for a response.

A session is active when it's either running on CPU or waiting for a resource to become available so that it can proceed. For example, an active session might wait for a page (or block) to be read into memory, and then consume CPU while it reads data from the page.

Average active sessions

The average active sessions (AAS) is the unit for the DBLoad metric in Performance Insights. It measures how many sessions are concurrently active on the database.

Every second, Performance Insights samples the number of sessions concurrently running a query. For each active session, Performance Insights collects the following data:

- SQL statement
- Session state (running on CPU or waiting)
- Host
- User running the SQL

Performance Insights calculates the AAS by dividing the total number of sessions by the number of samples for a specific time period. For example, the following table shows 5 consecutive samples of a running query taken at 1-second intervals.

<table>
<thead>
<tr>
<th>Sample</th>
<th>Number of sessions running query</th>
<th>AAS</th>
<th>Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>2</td>
<td>2 total sessions / 1 sample</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>1</td>
<td>2 total sessions / 2 samples</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>2</td>
<td>6 total sessions / 3 samples</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>1.5</td>
<td>6 total sessions / 4 samples</td>
</tr>
<tr>
<td>5</td>
<td>4</td>
<td>2</td>
<td>10 total sessions / 5 samples</td>
</tr>
</tbody>
</table>

In the preceding example, the DB load for the time interval was 2 AAS. This measurement means that, on average, 2 sessions were active at any given time during the interval when the 5 samples were taken.

An analogy for DB load is worker activity in a warehouse. Suppose that the warehouse employs 100 workers. If 1 order comes in, 1 worker fulfills the order while 99 workers are idle. If 100 orders come in, all 100 workers fulfill orders simultaneously. If every 15 minutes a manager writes down how many workers are simultaneously active, adds these numbers at the end of the day, and then divides the total by the number of samples, the manager calculates the average number of workers active at any given time. If the average was 50 workers yesterday and 75 workers today, then the average activity level in the warehouse increased. Similarly, DB load increases as database session activity increases.

Average active executions

The average active executions (AAE) per second is related to AAS. To calculate the AAE, Performance Insights divides the total execution time of a query by the time interval. The following table shows the AAE calculation for the same query in the preceding table.
### Elapsed time (sec) | Total execution time (sec) | AAE | Calculation |
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>60</td>
<td>120</td>
<td>2</td>
<td>120 execution seconds/60 elapsed seconds</td>
</tr>
<tr>
<td>120</td>
<td>120</td>
<td>1</td>
<td>120 execution seconds/120 elapsed seconds</td>
</tr>
<tr>
<td>180</td>
<td>380</td>
<td>2.11</td>
<td>380 execution seconds/180 elapsed seconds</td>
</tr>
<tr>
<td>240</td>
<td>380</td>
<td>1.58</td>
<td>380 execution seconds/240 elapsed seconds</td>
</tr>
<tr>
<td>300</td>
<td>600</td>
<td>2</td>
<td>600 execution seconds/300 elapsed seconds</td>
</tr>
</tbody>
</table>

In most cases, the AAS and AAE for a query are approximately the same. However, because the inputs to the calculations are different data sources, the calculations often vary slightly.

**Dimensions**

The `db.load` metric is different from the other time-series metrics because you can break it into subcomponents called *dimensions*. You can think of dimensions as "slice by" categories for the different characteristics of the DBLoad metric.

When you are diagnosing performance issues, the following dimensions are often the most useful:

**Topics**
- [Wait events](#) (p. 722)
- [Top SQL](#) (p. 723)
- [Plans](#) (p. 723)

For a complete list of dimensions for the Amazon RDS engines, see [DB load sliced by dimensions](#) (p. 743).

**Wait events**

A *wait event* causes a SQL statement to wait for a specific event to happen before it can continue running. Wait events are an important dimension, or category, for DB load because they indicate where work is impeded.

Every active session is either running on the CPU or waiting. For example, sessions consume CPU when they search memory for a buffer, perform a calculation, or run procedural code. When sessions aren't consuming CPU, they might be waiting for a memory buffer to become free, a data file to be read, or a log to be written to. The more time that a session waits for resources, the less time it runs on the CPU.

When you tune a database, you often try to find out the resources that sessions are waiting for. For example, two or three wait events might account for 90 percent of DB load. This measure means that, on average, active sessions are spending most of their time waiting for a small number of resources. If you can find out the cause of these waits, you can attempt a solution.
Consider the analogy of a warehouse worker. An order comes in for a book. The worker might be delayed in fulfilling the order. For example, a different worker might be currently restocking the shelves, a trolley might not be available. Or the system used to enter the order status might be slow. The longer the worker waits, the longer it takes to fulfill the order. Waiting is a natural part of the warehouse workflow, but if wait time becomes excessive, productivity decreases. In the same way, repeated or lengthy session waits can degrade database performance. For more information, see Tuning with wait events for Aurora PostgreSQL and Tuning with wait events for Aurora MySQL in the Amazon Aurora User Guide.

Wait events vary by DB engine:

- For information about all MariaDB and MySQL wait events, see Wait Event Summary Tables in the MySQL documentation.
- For information about all PostgreSQL wait events, see The Statistics Collector > Wait Event tables in the PostgreSQL documentation.
- For information about all Oracle wait events, see Descriptions of Wait Events in the Oracle documentation.
- For information about all SQL Server wait events, see Types of Waits in the SQL Server documentation.

Note

For Oracle, background processes sometimes do work without an associated SQL statement. In these cases, Performance Insights reports the type of background process concatenated with a colon and the wait class associated with that background process. Types of background process include LGWR, ARC0, PMON, and so on.

For example, when the archiver is performing I/O, the Performance Insights report for it is similar to ARC1:System I/O. Occasionally, the background process type is also missing, and Performance Insights only reports the wait class, for example :System I/O.

Top SQL

Where wait events show bottlenecks, top SQL shows which queries are contributing the most to DB load. For example, many queries might be currently running on the database, but a single query might consume 99 percent of the DB load. In this case, the high load might indicate a problem with the query.

By default, the Performance Insights console displays top SQL queries that are contributing to the database load. The console also shows relevant statistics for each statement. To diagnose performance problems for a specific statement, you can examine its execution plan.

Plans

An execution plan, also called simply a plan, is a sequence of steps that access data. For example, a plan for joining tables t1 and t2 might loop through all rows in t1 and compare each row to a row in t2. In a relational database, an optimizer is built-in code that determines the most efficient plan for a SQL query.

For Oracle DB instances, Performance Insights collects execution plans automatically. To diagnose SQL performance problems, examine the captured plans for high-resource Oracle SQL queries. The plans show how Oracle Database has parsed and run queries.

To learn how to analyze DB load using plans, see Analyzing Oracle execution plans using the Performance Insights dashboard (p. 766).

Plan capture

Every five minutes, Performance Insights identifies the most resource-intensive Oracle queries and captures their plans. Thus, you don't need to manually collect and manage a huge number of plans. Instead, you can use the Top SQL tab to focus on the plans for the most problematic queries.
Note
Performance Insights doesn't capture plans for queries whose text exceeds the maximum collectable query text limit. For more information, see Accessing more SQL text in the Performance Insights dashboard (p. 761).

The retention period for execution plans is the same as for your Performance Insights data. The retention setting in the free tier is Default (7 days). To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see Pricing and data retention for Performance Insights (p. 726).

Digest queries

The Top SQL tab shows digest queries by default. A digest query doesn't itself have a plan, but all queries that use literal values have plans. For example, a digest query might include the text WHERE `email` = ?. The digest might contain two queries, one with the text WHERE email=user1@example.com and another with WHERE email=user2@example.com. Each of these literal queries might include multiple plans.

If you select a digest query, the console shows all plans for child statements of the selected digest. Thus, you don't need to look through all the child statements to find the plan. You might see plans that aren't in the displayed list of top 10 child statements. The console shows plans for all child queries for which plans have been collected, regardless of whether the queries are in the top 10.

Maximum CPU

In the dashboard, the Database load chart collects, aggregates, and displays session information. To see whether active sessions are exceeding the maximum CPU, look at their relationship to the Max vCPU line. The Max vCPU value is determined by the number of vCPU (virtual CPU) cores for your DB instance.

One process can run on a vCPU at a time. If the number of processes exceed the number of vCPUs, the processes start queuing. When the queuing increase, the performance is impacted. If the DB load is often above the Max vCPU line, and the primary wait state is CPU, the CPU is overloaded. In this case, you might want to throttle connections to the instance, tune any SQL queries with a high CPU load, or consider a larger instance class. High and consistent instances of any wait state indicate that there might be bottlenecks or resource contention issues to resolve. This can be true even if the DB load doesn't cross the Max vCPU line.

Amazon RDS DB engine, Region, and instance class support for Performance Insights

The following table provides Amazon RDS DB engines that support Performance Insights.

<table>
<thead>
<tr>
<th>Amazon RDS DB engine</th>
<th>Supported engine versions and Regions</th>
<th>Instance class restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon RDS for MariaDB</td>
<td>For more information on version and Region availability of Performance Insights with RDS for MariaDB, see Performance Insights (p. 150).</td>
<td>Performance Insights isn't supported for the following instance classes:</td>

### Pricing and data retention for Performance Insights

By default, Performance Insights offers a free tier that includes 7 days of performance data history and 1 million API requests per month. You can also purchase longer retention periods. For complete pricing information, see [Performance Insights Pricing](#).

In the RDS console, you can choose any of the following retention periods for your Performance Insights data:

- **Default (7 days)**
- **n months**, where $n$ is a number from 1–24
### Performance Insights

**Turn on Performance Insights**

**Retention period**

- 7 days (free tier)
- 1 month
- 2 months
- 3 months
- 4 months
- 5 months
- 6 months
- 7 months
- 8 months
- 9 months
- 10 months
- 11 months
- 12 months
- 13 months
- 14 months

To learn how to set a retention period using the AWS CLI, see [AWS CLI](p. 729).

### Turning Performance Insights on and off

You can turn on Performance Insights for your DB instance or Multi-AZ DB cluster when you create it. If needed, you can turn it off later. Turning Performance Insights on and off doesn't cause downtime, a reboot, or a failover.

**Note**

Performance Schema is an optional performance tool used by Amazon RDS for MariaDB or MySQL. If you turn Performance Schema on or off, you need to reboot. If you turn Performance Insights on or off, however, you don't need to reboot. For more information, see [Turning on the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL](p. 731).
The Performance Insights agent consumes limited CPU and memory on the DB host. When the DB load is high, the agent limits the performance impact by collecting data less frequently.

**Console**

In the console, you can turn Performance Insights on or off when you create or modify a DB instance or Multi-AZ DB cluster.

**Turning Performance Insights on or off when creating a DB instance or Multi-AZ DB cluster**

When you create a new DB instance or Multi-AZ DB cluster, turn on Performance Insights by choosing **Enable Performance Insights** in the **Performance Insights** section. Or choose **Disable Performance Insights**. For more information, see the following topics:

- To create a DB instance, follow the instructions for your DB engine in [Creating an Amazon RDS DB instance](p. 300).
- To create a Multi-AZ DB cluster, follow the instructions for your DB engine in [Creating a Multi-AZ DB cluster](p. 508).

The following screenshot shows the **Performance Insights** section.

If you choose **Enable Performance Insights**, you have the following options:

- **Retention** – The amount of time to retain Performance Insights data. The retention setting in the free tier is **Default (7 days)**. To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see [Pricing and data retention for Performance Insights](p. 726).
- **AWS KMS key** – Specify your AWS KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see [Configuring an AWS KMS policy for Performance Insights](p. 736).

**Turning Performance Insights on or off when modifying a DB instance or Multi-AZ DB cluster**

In the console, you can modify a DB instance or Multi-AZ DB cluster to turn Performance Insights on or off.

**To turn Performance Insights on or off for a DB instance or Multi-AZ DB cluster using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose **Databases**.
3. Choose a DB instance or Multi-AZ DB cluster, and choose **Modify**.
4. In the **Performance Insights** section, choose either **Enable Performance Insights** or **Disable Performance Insights**.
If you choose **Enable Performance Insights**, you have the following options:

- **Retention** – The amount of time to retain Performance Insights data. The retention setting in the free tier is **Default (7 days)**. To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see [Pricing and data retention for Performance Insights](p. 726).

- **AWS KMS key** – Specify your KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see [Encrypting Amazon RDS resources](p. 2603).  

5. Choose **Continue**.

6. For **Scheduling of Modifications**, choose Apply immediately. If you choose Apply during the next scheduled maintenance window, your instance ignores this setting and turns on Performance Insights immediately.

7. Choose **Modify instance**.

**AWS CLI**

You can also specify these values using the following AWS CLI commands:

- [create-db-instance-read-replica]
- [modify-db-instance]
- [restore-db-instance-from-s3]
- [create-db-cluster] (Multi-AZ DB cluster)
- [modify-db-cluster] (Multi-AZ DB cluster)

The following procedure describes how to turn Performance Insights on or off for an existing DB instance using the AWS CLI.

**To turn Performance Insights on or off for a DB instance using the AWS CLI**

- Call the [modify-db-instance] AWS CLI command and supply the following values:

  - --db-instance-identifier – The name of the DB instance.
  - --enable-performance-insights to turn on or --no-enable-performance-insights to turn off

The following example turns on Performance Insights for *sample-db-instance*.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \  --db-instance-identifier sample-db-instance \  --enable-performance-insights
```

For Windows:

```bash
aws rds modify-db-instance ^  --db-instance-identifier sample-db-instance ^
```
--enable-performance-insights

When you turn on Performance Insights in the CLI, you can optionally specify the number of days to retain Performance Insights data with the `--performance-insights-retention-period` option. You can specify 7, month * 31 (where month is a number from 1–23), or 731. For example, if you want to retain your performance data for 3 months, specify 93, which is 3 * 31. The default is 7 days. For more information about retention periods, see [Pricing and data retention for Performance Insights (p. 726)].

The following example turns on Performance Insights for `sample-db-instance` and specifies that Performance Insights data is retained for 93 days (3 months).

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
  --db-instance-identifier sample-db-instance
  --enable-performance-insights
  --performance-insights-retention-period 93
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier sample-db-instance ^
  --enable-performance-insights ^
  --performance-insights-retention-period 93
```

If you specify a retention period such as 94 days, which isn't a valid value, RDS issues an error.

```
An error occurred (InvalidParameterValue) when calling the CreateDBInstance operation: Invalid Performance Insights retention period. Valid values are: [7, 31, 62, 93, 124, 155, 186, 217, 248, 279, 310, 341, 372, 403, 434, 465, 496, 527, 558, 589, 620, 651, 682, 713, 731]`
```

**RDS API**

When you create a new DB instance using the `CreateDBInstance` operation Amazon RDS API operation, turn on Performance Insights by setting `EnablePerformanceInsights` to True. To turn off Performance Insights, set `EnablePerformanceInsights` to False.

You can also specify the `EnablePerformanceInsights` value using the following API operations:

- `ModifyDBInstance`
- `CreateDBInstanceReadReplica`
- `RestoreDBInstanceFromS3`
- `CreateDBCluster` (Multi-AZ DB cluster)
- `ModifyDBCluster` (Multi-AZ DB cluster)

When you turn on Performance Insights, you can optionally specify the amount of time, in days, to retain Performance Insights data with the `PerformanceInsightsRetentionPeriod` parameter. You can specify 7, month * 31 (where month is a number from 1–23), or 731. For example, if you want to retain your performance data for 3 months, specify 93, which is 3 * 31. The default is 7 days. For more information about retention periods, see [Pricing and data retention for Performance Insights (p. 726)].
Turning on the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL

The Performance Schema is an optional feature for monitoring Amazon RDS for MariaDB or MySQL runtime performance at a low level of detail. The Performance Schema is designed to have minimal impact on database performance. Performance Insights is a separate feature that you can use with or without the Performance Schema.

Topics

- Overview of the Performance Schema (p. 731)
- Performance Insights and the Performance Schema (p. 731)
- Automatic management of the Performance Schema by Performance Insights (p. 732)
- Effect of a reboot on the Performance Schema (p. 732)
- Determining whether Performance Insights is managing the Performance Schema (p. 733)
- Configuring the Performance Schema for automatic management (p. 733)

Overview of the Performance Schema

The Performance Schema monitors events in MariaDB and MySQL databases. An event is a database server action that consumes time and has been instrumented so that timing information can be collected. Examples of events include the following:

- Function calls
- Waits for the operating system
- Stages of SQL execution
- Groups of SQL statements

The PERFORMANCE_SCHEMA storage engine is a mechanism for implementing the Performance Schema feature. This engine collects event data using instrumentation in the database source code. The engine stores events in memory-only tables in the performance_schema database. You can query performance_schema just as you can query any other tables. For more information, see MySQL Performance Schema in the MySQL Reference Manual.

Performance Insights and the Performance Schema

Performance Insights and the Performance Schema are separate features, but they are connected. The behavior of Performance Insights for Amazon RDS for MariaDB or MySQL depends on whether the Performance Schema is turned on, and if so, whether Performance Insights manages the Performance Schema automatically. The following table describes the behavior.

<table>
<thead>
<tr>
<th>Performance Schema turned on</th>
<th>Performance Insights management mode</th>
<th>Performance Insights behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>Automatic</td>
<td>• Collects detailed, low-level monitoring information</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Collects active session metrics every second</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Displays DB load categorized by detailed wait events, which you can use to identify bottlenecks</td>
</tr>
<tr>
<td>Yes</td>
<td>Manual</td>
<td>• Collects wait events and per-SQL metrics</td>
</tr>
</tbody>
</table>

731
Performance Schema turned on | Performance Insights management mode | Performance Insights behavior
--- | --- | ---
| | | • Collects active session metrics every five seconds instead of every second  
• Reports user states such as inserting and sending, which don't help you identify bottlenecks
| No | N/A | • Doesn't collect wait events, per-SQL metrics, or other detailed, low-level monitoring information  
• Collects active session metrics every five seconds instead of every second  
• Reports user states such as inserting and sending, which don't help you identify bottlenecks

### Automatic management of the Performance Schema by Performance Insights

When you create an Amazon RDS for MariaDB or MySQL DB instance with Performance Insights turned on, the Performance Schema is also turned on. In this case, Performance Insights automatically manages your Performance Schema parameters. This is the recommended configuration.

**Note**  
Automatic management of the Performance Schema isn't supported for the t4g.medium instance class.

For automatic management of the Performance Schema, the following conditions must be true:

- The `performance_schema` parameter is set to 0.
- The `Source` is set to `system`, which is the default.

If you change the `performance_schema` parameter value manually, and then later want to change to automatic management, see Configuring the Performance Schema for automatic management (p. 733).

**Important**  
When Performance Insights turns on the Performance Schema, it doesn't change the parameter group values. However, the values are changed on the DB instances that are running. The only way to see the changed values is to run the `SHOW GLOBAL VARIABLES` command.

### Effect of a reboot on the Performance Schema

Performance Insights and the Performance Schema differ in their requirements for DB instance reboots:

**Performance Schema**

To turn this feature on or off, you must reboot the DB instance.

**Performance Insights**

To turn this feature on or off, you don't need to reboot the DB instance.

If the Performance Schema isn't currently turned on, and you turn on Performance Insights without rebooting the DB instance, the Performance Schema won't be turned on.
Determining whether Performance Insights is managing the Performance Schema

To find out whether Performance Insights is currently managing the Performance Schema for major engine versions 5.6, 5.7, and 8.0, review the following table.

<table>
<thead>
<tr>
<th>Setting of <code>performance_schema</code> parameter</th>
<th>Setting of the <code>Source</code> column</th>
<th>Performance Insights is managing the Performance Schema?</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><code>system</code></td>
<td>Yes</td>
</tr>
<tr>
<td>0 or 1</td>
<td><code>user</code></td>
<td>No</td>
</tr>
</tbody>
</table>

To determine whether Performance Insights is managing the Performance Schema automatically

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Parameter groups.
3. Select the name of the parameter group for your DB instance.
4. Enter `performance_schema` in the search bar.
5. Check whether `Source` is the system default and `Values` is 0. If so, Performance Insights is managing the Performance Schema automatically. If not, Performance Insights isn't managing the Performance Schema automatically.

Configuring the Performance Schema for automatic management

Assume that Performance Insights is turned on for your DB instance or Multi-AZ DB cluster but isn't currently managing the Performance Schema. If you want to allow Performance Insights to manage the Performance Schema automatically, complete the following steps.

To configure the Performance Schema for automatic management

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Parameter groups.
3. Select the name of the parameter group for your DB instance or Multi-AZ DB cluster.
4. Enter `performance_schema` in the search bar.
5. Select the `performance_schema` parameter.
6. Choose Edit parameters.
7. Select the `performance_schema` parameter.
8. In **Values**, choose **0**.
9. Choose **Reset** and then **Reset parameters**.
10. Reboot the DB instance or Multi-AZ DB cluster.

**Important**
Whenever you turn the Performance Schema on or off, make sure to reboot the DB instance or Multi-AZ DB cluster.

For more information about modifying instance parameters, see [Modifying parameters in a DB parameter group](p. 352). For more information about the dashboard, see [Analyzing metrics with the Performance Insights dashboard](p. 738). For more information about the MySQL performance schema, see [MySQL 8.0 Reference Manual](p. 738).

### Configuring access policies for Performance Insights

To access Performance Insights, a principal must have the appropriate permissions from AWS Identity and Access Management (IAM). You can grant access in the following ways:

- Attach the `AmazonRDSPerformanceInsightsReadOnly` managed policy to a permission set or role to access all read-only operations of the Performance Insights API.
- Attach the `AmazonRDSPerformanceInsightsFullAccess` managed policy to a permission set or role to access all operations of the Performance Insights API.
- Create a custom IAM policy and attach it to a permission set or role.

If you specified a customer managed key when you turned on Performance Insights, make sure that users in your account have the `kms:Decrypt` and `kms:GenerateDataKey` permissions on the KMS key.

#### Attaching the `AmazonRDSPerformanceInsightsReadOnly` policy to an IAM principal

`AmazonRDSPerformanceInsightsReadOnly` is an AWS-managed policy that grants access to all read-only operations of the Amazon RDS Performance Insights API.

If you attach `AmazonRDSPerformanceInsightsReadOnly` to a permission set or role, the recipient can use Performance Insights with other console features.

For more information, see [AWS managed policy: AmazonRDSPerformanceInsightsReadOnly](p. 2647).

#### Attaching the `AmazonRDSPerformanceInsightsFullAccess` policy to an IAM principal

`AmazonRDSPerformanceInsightsFullAccess` is an AWS-managed policy that grants access to all operations of the Amazon RDS Performance Insights API.

If you attach `AmazonRDSPerformanceInsightsFullAccess` to a permission set or role, the recipient can use Performance Insights with other console features.

For more information, see [AWS managed policy: AmazonRDSPerformanceInsightsFullAccess](p. 2647).

#### Creating a custom IAM policy for Performance Insights

For users who don't have the `AmazonRDSPerformanceInsightsReadOnly` or `AmazonRDSPerformanceInsightsFullAccess` policy, you can grant access to Performance Insights.
by creating or modifying a user-managed IAM policy. When you attach the policy to an IAM permission set or role, the recipient can use Performance Insights.

**To create a custom policy**

2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Create Policy** page, choose the JSON tab.
5. Copy and paste the text provided in the **JSON policy document** section in the AWS Managed Policy Reference Guide for AmazonRDSPerformanceInsightsReadOnly or AmazonRDSPerformanceInsightsFullAccess policy.
6. Choose **Review policy**.
7. Provide a name for the policy and optionally a description, and then choose **Create policy**.

You can now attach the policy to a permission set or role. The following procedure assumes that you already have a user available for this purpose.

**To attach the policy to a user**

2. In the navigation pane, choose **Users**.
3. Choose an existing user from the list.

   **Important**
   To use Performance Insights, make sure that you have access to Amazon RDS in addition to the custom policy. For example, the AmazonRDSPerformanceInsightsReadOnly predefined policy provides read-only access to Amazon RDS. For more information, see Managing access using policies (p. 2626).

4. On the **Summary** page, choose **Add permissions**.
5. Choose **Attach existing policies directly**. For **Search**, type the first few characters of your policy name, as shown following.

6. Choose your policy, and then choose **Next: Review**.
7. Choose **Add permissions**.
Configuring an AWS KMS policy for Performance Insights

Performance Insights uses an AWS KMS key to encrypt sensitive data. When you enable Performance Insights through the API or the console, you can do either of the following:

- Choose the default AWS managed key.

  Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region.

- Choose a customer managed key.

  If you specify a customer managed key, users in your account that call the Performance Insights API need the kms:Decrypt and kms:GenerateDataKey permissions on the KMS key. You can configure these permissions through IAM policies. However, we recommend that you manage these permissions through your KMS key policy. For more information, see Using key policies in AWS KMS.

Example

The following example shows how to add statements to your KMS key policy. These statements allow access to Performance Insights. Depending on how you use the KMS key, you might want to change some restrictions. Before adding statements to your policy, remove all comments.

```json
{
  "Version": "2012-10-17",
  "Id": "your-policy",
  "Statement": [
    //This represents a statement that currently exists in your policy. 
    
    //Starting here, add new statement to your policy for Performance Insights.
    //We recommend that you add one new statement for every RDS instance
    
    "Sid": "Allow viewing RDS Performance Insights",
    "Effect": "Allow",
    "Principal": {
      "AWS": [
        //One or more principals allowed to access Performance Insights
        "arn:aws:iam::444455556666:role/Role1"
      ]
    },
    "Action": [
      "kms:Decrypt",
      "kms:GenerateDataKey"
    ],
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        //Restrict access to only RDS APIs (including Performance Insights).
        //Replace region with your AWS Region.
        //For example, specify us-west-2.
        "kms:ViaService": "rds.region.amazonaws.com"
      },
      "ForAnyValue:StringEquals": {
        //Restrict access to only data encrypted by Performance Insights.
        "kms:EncryptionContext:aws:pi:service": "rds",
        "kms:EncryptionContext:service": "pi",
        //Restrict access to a specific RDS instance.
        //The value is a DbiResourceId.
        "kms:EncryptionContext:aws:rds:db-id": "db-AAAAABBBBBCCCCDDDDDEEEEE"
      }
    }
  }
}
```
How Performance Insights uses AWS KMS customer managed key

Performance Insights uses customer managed keys to encrypt sensitive data. When you turn on Performance Insights, you can provide an AWS KMS key through the API. Performance Insights creates KMS permissions on this key. It uses the key and performs the necessary operations to process sensitive data. Sensitive data includes fields such as user, database, application, and SQL query text. Performance Insights ensures that the data remains encrypted both at rest and in-flight.

How Performance Insights IAM works with AWS KMS

IAM gives permissions to specific APIs. Performance Insights has the following public APIs, which you can restrict using IAM policies:

- DescribeDimensionKeys
- GetDimensionKeyDetails
- GetResourceMetadata
- GetResourceMetrics
- ListAvailableResourceDimensions
- ListAvailableResourceMetrics

You can use the following API requests to get sensitive data.

- DescribeDimensionKeys
- GetDimensionKeyDetails
- GetResourceMetrics

When you use the API to get sensitive data, Performance Insights leverages the caller’s credentials. This check ensures that access to sensitive data is limited to those with access to the KMS key.

When calling these APIs, you need permissions to call the API through the IAM policy and permissions to invoke the kms:decrypt action through the AWS KMS key policy.

The GetResourceMetrics API can return both sensitive and non-sensitive data. The request parameters determine whether the response should include sensitive data. The API returns sensitive data when the request includes a sensitive dimension in either the filter or group-by parameters.

For more information about the dimensions that you can use with the GetResourceMetrics API, see DimensionGroup.

Example Examples

The following example requests the sensitive data for the db.user group:

```
POST / HTTP/1.1
Host: <Hostname>
Accept-Encoding: identity
X-Amz-Target: PerformanceInsightsv20180227.GetResourceMetrics
Content-Type: application/x-amz-json-1.1
User-Agent: <UserAgentString>
X-Amz-Date: <Date>
Authorization: AWS4-HMAC-SHA256 Credential=<Credential>, SignedHeaders=<Headers>, Signature=<Signature>
```
Analyzing metrics with the Performance Insights dashboard

The Performance Insights dashboard contains database performance information to help you analyze and troubleshoot performance issues. On the main dashboard page, you can view information about the database load. You can “slice” DB load by dimensions such as wait events or SQL.

Performance Insights dashboard

- Overview of the Performance Insights dashboard (p. 739)
- Accessing the Performance Insights dashboard (p. 746)
- Analyzing DB load by wait events (p. 749)
• Analyzing database performance for a period of time (p. 750)
• Analyzing queries in the Performance Insights dashboard (p. 756)
• Analyzing Oracle execution plans using the Performance Insights dashboard (p. 766)

Overview of the Performance Insights dashboard

The dashboard is the easiest way to interact with Performance Insights. The following example shows the dashboard for a MySQL DB instance.

Topics
• Time range filter (p. 739)
• Counter metrics chart (p. 741)
• Database load chart (p. 743)
• Top dimensions table (p. 745)

Time range filter

By default, the Performance Insights dashboard shows DB load for the last hour. You can adjust this range to be as short as 5 minutes or as long as 2 years. You can also select a custom relative range.
You can select an absolute range with a beginning and ending date and time. The following example shows the time range beginning at midnight on 4/11/22 and ending at 11:59 PM on 4/14/22.
Counter metrics chart

With counter metrics, you can customize the Performance Insights dashboard to include up to 10 additional graphs. These graphs show a selection of dozens of operating system and database performance metrics. You can correlate this information with DB load to help identify and analyze performance problems.

The Counter metrics chart displays data for performance counters. The default metrics depend on the DB engine:

- MySQL and MariaDB – `db.SQL.Innodb_rows_read.avg`
- Oracle – `db.User.user calls.avg`
- PostgreSQL – `db.Transactions.xact_commit.avg`
To change the performance counters, choose **Manage Metrics**. You can select multiple **OS metrics** or **Database metrics**, as shown in the following screenshot. To see details for any metric, hover over the metric name.

For descriptions of the counter metrics that you can add for each DB engine, see **Performance Insights counter metrics** (p. 814).
**Database load chart**

The **Database load** chart shows how the database activity compares to DB instance capacity as represented by the **Max vCPU** line. By default, the stacked line chart represents DB load as average active sessions per unit of time. The DB load is sliced (grouped) by wait states.

![Database Load Chart](image)

**DB load sliced by dimensions**

You can choose to display load as active sessions grouped by any supported dimensions. The following table shows which dimensions are supported for the different engines.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Oracle</th>
<th>SQL Server</th>
<th>PostgreSQL</th>
<th>MySQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>SQL</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>User</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Waits</td>
<td>Yes</td>

<td>No</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Session type</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

The following image shows the dimensions for a PostgreSQL DB instance.
Analyzing metrics with the Performance Insights dashboard

**DB load details for a dimension item**

To see details about a DB load item within a dimension, hover over the item name. The following image shows details for a SQL statement.

To see details for any item for the selected time period in the legend, hover over that item.
Top dimensions table

The Top dimensions table slices DB load by different dimensions. A dimension is a category or "slice by" for different characteristics of DB load. If the dimension is SQL, Top SQL shows the SQL statements that contribute the most to DB load.

Choose any of the following dimension tabs.

<table>
<thead>
<tr>
<th>Tab</th>
<th>Description</th>
<th>Supported engines</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top SQL</td>
<td>The SQL statements that are currently running</td>
<td>All</td>
</tr>
<tr>
<td>Top waits</td>
<td>The event for which the database backend is waiting</td>
<td>All</td>
</tr>
</tbody>
</table>
To access the Performance Insights dashboard, use the following procedure.

To view the Performance Insights dashboard in the AWS Management Console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose Performance Insights.
3. Choose a DB instance.
4. Choose the default monitoring view in the displayed window.
   - Select the Performance Insights and CloudWatch metrics view (New) option and choose Continue to view Performance Insights and CloudWatch metrics.
   - Select the Performance Insights view option and choose Continue for the legacy monitoring view. Then, continue with this procedure.

   **Note**
   This view will be discontinued on December 15, 2023.

The Performance Insights dashboard appears for the DB instance.

For DB instances with Performance Insights turned on, you can also access the dashboard by choosing the Sessions item in the list of DB instances. Under Current activity, the Sessions item shows the database load in average active sessions over the last five minutes. The bar graphically shows the load. When the bar is empty, the DB instance is idle. As the load increases, the bar fills with blue. When the load passes the number of virtual CPUs (vCPUs) on the DB instance class, the bar turns red, indicating a potential bottleneck.
5. **(Optional)** Choose the date or time range in the upper right and specify a different relative or absolute time interval. You can now specify a time period, and generate a database performance analysis report. The report provides the identified insights and recommendations. For more information, see Creating a performance analysis report (p. 750).

   2023-04-27T10:01:02-07:00 — 2023-04-27T10:19:09-07:00

   **Relative range**  **Absolute range**

   Choose a range
   - Last 5 minutes
   - Last 1 hour
   - Last 5 hours
   - Last 24 hours
   - Last 1 week
   - Custom range
     Based on your current retention period, the maximum range is 1 week.
     You can increase the retention period by modifying your database.

   Clear and dismiss  **Cancel**  **Apply**

   In the following screenshot, the DB load interval is 5 hours.
6. (Optional) To zoom in on a portion of the DB load chart, choose the start time and drag to the end of the time period you want.

The selected area is highlighted in the DB load chart.

When you release the mouse, the DB load chart zooms in on the selected AWS Region, and the Top dimensions table is recalculated.
(Optional) To refresh your data automatically, select Auto refresh.

The Performance Insights dashboard automatically refreshes with new data. The refresh rate depends on the amount of data displayed:

- 5 minutes refreshes every 10 seconds.
- 1 hour refreshes every 5 minutes.
- 5 hours refreshes every 5 minutes.
- 24 hours refreshes every 30 minutes.
- 1 week refreshes every day.
- 1 month refreshes every day.

Analyzing DB load by wait events

If the Database load chart shows a bottleneck, you can find out where the load is coming from. To do so, look at the top load items table below the Database load chart. Choose a particular item, like a SQL query or a user, to drill down into that item and see details about it.

DB load grouped by waits and top SQL queries is the default Performance Insights dashboard view. This combination typically provides the most insight into performance issues. DB load grouped by waits
shows if there are any resource or concurrency bottlenecks in the database. In this case, the SQL tab of the top load items table shows which queries are driving that load.

Your typical workflow for diagnosing performance issues is as follows:

1. Review the Database load chart and see if there are any incidents of database load exceeding the Max CPU line.
2. If there is, look at the Database load chart and identify which wait state or states are primarily responsible.
3. Identify the digest queries causing the load by seeing which of the queries the SQL tab on the top load items table are contributing most to those wait states. You can identify these by the DB Load by Wait column.
4. Choose one of these digest queries in the SQL tab to expand it and see the child queries that it is composed of.

For example, in the dashboard following, log file sync waits account for most of the DB load. The LGWR all worker groups wait is also high. The Top SQL chart shows what is causing the log file sync waits: frequent COMMIT statements. In this case, committing less frequently will reduce DB load.

Analyzing database performance for a period of time

You can create a performance analysis report for a period of time and find out any performance issues such as resource bottlenecks or changes in a query in your DB instance. The Performance Insights dashboard allows you to select a time period and create a performance analysis report. You can also add one or more tags to the report.

To use this feature, you must be using the paid tier retention period. For more information, see Pricing and data retention for Performance Insights (p. 726)
The report is available in the Performance analysis reports - new tab to select and view. The report contains the insights, related metrics, and recommendations to resolve the performance issue. The report is available to view for the duration of Performance Insights retention period.

The report is deleted if the start time of the report analysis period is outside of the retention period. You can also delete the report before the retention period ends.

To detect the performance issues and generate the analysis report for your DB instance, you must turn on Performance Insights. For more information about turning on Performance Insights, see Turning Performance Insights on and off (p. 727).

For the region, DB engine, and instance class support information for this feature, see Amazon RDS DB engine, Region, and instance class support for Performance Insights features (p. 725)

Creating a performance analysis report

You can create a performance analysis report for a specific period in the Performance Insights dashboard. You can select a time period and add one or more tags to the analysis report.

The analysis period can range from 5 minutes to 6 days. There must be at least 24 hours of performance data before the analysis start time.

To create a performance analysis report for a time period

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose Performance Insights.
3. Choose a DB instance.
   The Performance Insights dashboard appears for the DB instance.
4. Choose Analyze performance in Database load section on the dashboard.
   The fields to set the time period and add one or more tags to the performance analysis report are displayed.

5. Choose the time period. If you set a time period in the Relative range or Absolute range in the upper right, you can only enter or select the analysis report date and time within this time period. If you select the analysis period outside of this time period, an error message displays.

To set the time period, you can do any of the following:

- Press and drag any of the sliders on the DB load chart.
  The Performance analysis period box displays the selected time period and DB load chart highlights the selected time period.
- Choose the Start date, Start time, End date, and End time in the Performance analysis period box.
6. (Optional) Enter **Key** and **Value-optional** to add a tag for the report.

7. Choose **Analyze performance**.

A banner displays a message whether the report generation is successful or failed. The message also provides the link to view the report.

The following example shows the banner with the report creation successful message.
The report is available to view in **Performance analysis reports - new** tab.

You can create a performance analysis report using the AWS CLI. For an example on how to create a report using AWS CLI, see [Creating a performance analysis report for a time period (p. 783)](#).

### Viewing a performance analysis report

The **Performance analysis reports - new** tab lists all the reports that are created for the DB instance. The following are displayed for each report:

- **ID**: Unique identifier of the report.
- **Name**: Tag key added to the report.
- **Report creation time**: Time you created the report.
- **Analysis start time**: Start time of the analysis in the report.
- **Analysis end time**: End time of the analysis in the report.

### To view a performance analysis report

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance for which you want to view the analysis report.
   
   The Performance Insights dashboard appears for the DB instance.
4. Scroll down and choose **Performance analysis reports - new** tab.

   All the analysis reports for the different time periods are displayed.
5. Choose **ID** of the report you want to view.

   The DB load chart displays the entire analysis period by default if more than one insight is identified. If the report has identified one insight then the DB load chart displays the insight by default.

   The dashboard also lists the tags for the report in the **Tags** section.

   The following example shows the entire analysis period for the report.

6. Choose the insight in the **Database load insights** list you want to view if more than one insight is identified in the report.
Analyzing metrics with the Performance Insights dashboard

The dashboard displays the insight message, DB load chart highlighting the time period of the insight, analysis and recommendations, and the list of report tags.

The following example shows the DB load insight in the report.

Adding tags to a performance analysis report

You can add a tag when you create or view a report. You can add up to 50 tags for a report.

You need permissions to add the tags. For more information about the access policies for Performance Insights, see Configuring access policies for Performance Insights (p. 734)

To add one or more tags while creating a report, see step 6 in the procedure Creating a performance analysis report (p. 751).

To add one or more tags when viewing a report

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose Performance Insights.
3. Choose a DB instance.
   The Performance Insights dashboard appears for the DB instance.
4. Scroll down and choose Performance analysis reports - new tab.
5. Choose the report for which you want to add the tags.
   The dashboard displays the report.
6. Scroll down to Tags and choose Manage tags.
7. Choose Add new tag.
8. Enter the Key and Value - optional, and choose Add new tag.
   The following example provides the option to add a new tag for the selected report.
A new tag is created for the report.

The list of tags for the report is displayed in the **Tags** section on the dashboard. If you want to remove a tag from the report, choose **Remove** next to the tag.

**Deleting a performance analysis report**

You can delete a report from the list of reports displayed in the **Performance analysis reports** tab or while viewing a report.

**To delete a report**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.

    The Performance Insights dashboard appears for the DB instance.
4. Scroll down and choose **Performance analysis reports - new** tab.
5. Select the report you want to delete and choose **Delete** in the upper right.

A confirmation window is displayed. The report is deleted after you choose confirm.

6. (Optional) Choose ID of the report you want to delete.

    In the report page, choose **Delete** in the upper right.
Analyzing queries in the Performance Insights dashboard

In the Amazon RDS Performance Insights dashboard, you can find information about running and recent queries in the Top SQL tab in the Top dimensions table. You can use this information to tune your queries.

Note
RDS for SQL Server doesn't show SQL-level statistics.

Topics
- Overview of the Top SQL tab (p. 756)
- Accessing more SQL text in the Performance Insights dashboard (p. 761)
- Viewing SQL statistics in the Performance Insights dashboard (p. 763)

Overview of the Top SQL tab

By default, the Top SQL tab shows the 25 queries that are contributing the most to DB load. To help tune your queries, you can analyze information such as the query text and SQL statistics. You can also choose the statistics that you want to appear in the Top SQL tab.

Topics
- SQL text (p. 756)
- SQL statistics (p. 757)
- Load by waits (AAS) (p. 758)
- SQL information (p. 759)
- Preferences (p. 759)

SQL text

By default, each row in the Top SQL table shows 500 bytes of text for each statement.

To learn how to see more than the default 500 bytes of SQL text, see Accessing more SQL text in the Performance Insights dashboard (p. 761).
A **SQL digest** is a composite of multiple actual queries that are structurally similar but might have different literal values. The digest replaces hardcoded values with a question mark. For example, a digest might be `SELECT * FROM emp WHERE lname= ?`. This digest might include the following child queries:

- `SELECT * FROM emp WHERE lname = 'Sanchez'
- `SELECT * FROM emp WHERE lname = 'Olagappan'
- `SELECT * FROM emp WHERE lname = 'Wu'

To see the literal SQL statements in a digest, select the query, and then choose the plus symbol (+). In the following example, the selected query is a digest.

---

**Note**

A SQL digest groups similar SQL statements, but doesn't redact sensitive information.

Performance Insights can show Oracle SQL text as **Unknown**. The text has this status in the following situations:

- An Oracle database user other than SYS is active but not currently executing SQL. For example, when a parallel query completes, the query coordinator waits for helper processes to send their session statistics. For the duration of the wait, the query text shows Unknown.
- For an RDS for Oracle instance on Standard Edition 2, Oracle Resource Manager limits the number of parallel threads. The background process doing this work causes the query text to show as Unknown.

**SQL statistics**

**SQL statistics** are performance-related metrics about SQL queries. For example, Performance Insights might show executions per second or rows processed per second. Performance Insights collects statistics for only the most common queries. Typically, these match the top queries by load shown in the Performance Insights dashboard.

Every line in the **Top SQL** table shows relevant statistics for the SQL statement or digest, as shown in the following example.
Performance Insights can report 0.00 and - (unknown) for SQL statistics. This situation occurs under the following conditions:

- Only one sample exists. For example, Performance Insights calculates rates of change for RDS PostgreSQL queries based on multiple samples from the pg_stats_statements view. When a workload runs for a short time, Performance Insights might collect only one sample, which means that it can't calculate a rate of change. The unknown value is represented with a dash (-).

- Two samples have the same values. Performance Insights can't calculate a rate of change because no change has occurred, so it reports the rate as 0.00.

- An RDS PostgreSQL statement lacks a valid identifier. PostgreSQL creates a identifier for a statement only after parsing and analysis. Thus, a statement can exist in the PostgreSQL internal in-memory structures with no identifier. Because Performance Insights samples internal in-memory structures once per second, low-latency queries might appear for only a single sample. If the query identifier isn't available for this sample, Performance Insights can't associate this statement with its statistics. The unknown value is represented with a dash (-).

For a description of the SQL statistics for the Amazon RDS engines, see SQL statistics for Performance Insights (p. 830).

**Load by waits (AAS)**

In **Top SQL**, the **Load by waits (AAS)** column illustrates the percentage of the database load associated with each top load item. This column reflects the load for that item by whatever grouping is currently selected in the **DB Load Chart**. For more information about Average active sessions (AAS), see Average active sessions (p. 721).

For example, you might group the DB load chart by wait states. You examine SQL queries in the top load items table. In this case, the **DB Load by Waits** bar is sized, segmented, and color-coded to show how much of a given wait state that query is contributing to. It also shows which wait states are affecting the selected query.
SQL information

In the Top SQL table, you can open a statement to view its information. The information appears in the bottom pane.

The following types of identifiers (IDs) that are associated with SQL statements:

- **Support SQL ID** – A hash value of the SQL ID. This value is only for referencing a SQL ID when you are working with AWS Support. AWS Support doesn’t have access to your actual SQL IDs and SQL text.

- **Support Digest ID** – A hash value of the digest ID. This value is only for referencing a digest ID when you are working with AWS Support. AWS Support doesn’t have access to your actual digest IDs and SQL text.

Preferences

You can control the statistics displayed in the Top SQL tab by choosing the Preferences icon.
When you choose the Preferences icon, the Preferences window opens. The following screenshot is an example of the Preferences window.

To enable the statistics that you want to appear in the Top SQL tab, use your mouse to scroll to the bottom of the window, and then choose Continue.
For more information about per-second or per-call statistics for the Amazon RDS engines, see the engine specific SQL statistics section in SQL statistics for Performance Insights (p. 830).

Accessing more SQL text in the Performance Insights dashboard

By default, each row in the Top SQL table shows 500 bytes of SQL text for each SQL statement.

When a SQL statement exceeds 500 bytes, you can view more text in the SQL text section below the Top SQL table. In this case, the maximum length for the text displayed in SQL text is 4 KB. This limit is introduced by the console and is subject to the limits set by the database engine. To save the text shown in SQL text, choose Download.

Topics

- Text size limits for Amazon RDS engines (p. 761)
- Setting the SQL text limit for Amazon RDS for PostgreSQL DB instances (p. 761)
- Viewing and downloading SQL text in the Performance Insights dashboard (p. 762)

Text size limits for Amazon RDS engines

When you download SQL text, the database engine determines its maximum length. You can download SQL text up to the following per-engine limits.

<table>
<thead>
<tr>
<th>DB engine</th>
<th>Maximum length of downloaded text</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon RDS for MySQL and MariaDB</td>
<td>1,024 bytes</td>
</tr>
<tr>
<td>Amazon RDS for Microsoft SQL Server</td>
<td>4,096 characters</td>
</tr>
<tr>
<td>Amazon RDS for Oracle</td>
<td>1,000 bytes</td>
</tr>
</tbody>
</table>

The SQL text section of the Performance Insights console displays up to the maximum that the engine returns. For example, if MySQL returns at most 1 KB to Performance Insights, it can only collect and show 1 KB, even if the original query is larger. Thus, when you view the query in SQL text or download it, Performance Insights returns the same number of bytes.

If you use the AWS CLI or API, Performance Insights doesn't have the 4 KB limit enforced by the console. DescribeDimensionKeys and GetResourceMetrics return at most 500 bytes. GetDimensionKeyDetails returns the full query, but the size is subject to the engine limit.

Setting the SQL text limit for Amazon RDS for PostgreSQL DB instances

Amazon RDS for PostgreSQL handles text differently. You can set the text size limit with the DB instance parameter track_activity_query_size. This parameter has the following characteristics:

Default text size

On Amazon RDS for PostgreSQL version 9.6, the default setting for the track_activity_query_size parameter is 1,024 bytes. On Amazon RDS for PostgreSQL version 10 or higher, the default is 4,096 bytes.

Maximum text size

The limit for track_activity_query_size is 102,400 bytes for Amazon RDS for PostgreSQL version 12 and lower. The maximum is 1 MB for version 13 and higher.
If the engine returns 1 MB to Performance Insights, the console displays only the first 4 KB. If you download the query, you get the full 1 MB. In this case, viewing and downloading return different numbers of bytes. For more information about the `track_activity_query_size` DB instance parameter, see Run-time Statistics in the PostgreSQL documentation.

To increase the SQL text size, increase the `track_activity_query_size` limit. To modify the parameter, change the parameter setting in the parameter group that is associated with the Amazon RDS for PostgreSQL DB instance.

**To change the setting when the instance uses the default parameter group**
1. Create a new DB instance parameter group for the appropriate DB engine and DB engine version.
2. Set the parameter in the new parameter group.
3. Associate the new parameter group with the DB instance.

For information about setting a DB instance parameter, see Modifying parameters in a DB parameter group (p. 352).

**Viewing and downloading SQL text in the Performance Insights dashboard**

In the Performance Insights dashboard, you can view or download SQL text.

**To view more SQL text in the Performance Insights dashboard**
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance.

   The Performance Insights dashboard is displayed for your DB instance.
4. Scroll down to the Top SQL tab.
5. Choose a SQL statement.

   SQL statements with text larger than 500 bytes look similar to the following image.

6. Scroll down to the SQL text tab.
The Performance Insights dashboard can display up to 4,096 bytes for each SQL statement.

7. (Optional) Choose **Copy** to copy the displayed SQL statement, or choose **Download** to download the SQL statement to view the SQL text up to the DB engine limit.

   **Note**
   To copy or download the SQL statement, disable pop-up blockers.

**Viewing SQL statistics in the Performance Insights dashboard**

In the Performance Insights dashboard, SQL statistics are available in the **Top SQL** tab of the **Database load** chart.

**To view SQL statistics**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the left navigation pane, choose **Performance Insights**.
3. At the top of the page, choose the database whose SQL statistics you want to see.
4. Scroll to the bottom of the page and choose the **Top SQL** tab.
5. Choose an individual statement or digest query.
6. Choose which statistics to display by choosing the gear icon in the upper-right corner of the chart. For descriptions of the SQL statistics for the Amazon RDS engines, see SQL statistics for Performance Insights (p. 830).

The following example shows the statistics preferences for Oracle DB instances.
The following example shows the preferences for MariaDB and MySQL DB instances.

<table>
<thead>
<tr>
<th>Preferences</th>
<th>Columns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Page size</td>
<td>Load by waits (AAS)</td>
</tr>
<tr>
<td></td>
<td>SQL statements</td>
</tr>
<tr>
<td></td>
<td>Support ID</td>
</tr>
<tr>
<td></td>
<td>ID</td>
</tr>
<tr>
<td></td>
<td>executions/sec (executions_per_sec)</td>
</tr>
<tr>
<td></td>
<td>AAE (elapsed_time_per_sec)</td>
</tr>
<tr>
<td></td>
<td>rows processed/sec (rows_processed_per_sec)</td>
</tr>
<tr>
<td></td>
<td>buffer gets/sec (buffer_gets_per_sec)</td>
</tr>
<tr>
<td></td>
<td>physical reads/sec (physical_read_requests_per_sec)</td>
</tr>
<tr>
<td></td>
<td>physical writes/sec (physical_write_requests_per_sec)</td>
</tr>
<tr>
<td></td>
<td>total shareable memory (bytes)/sec (total_sharable_mem_per_sec)</td>
</tr>
</tbody>
</table>
7. Choose Save to save your preferences.

The Top SQL table refreshes.

The following example shows statistics for an Oracle SQL query.

```
<table>
<thead>
<tr>
<th>SQL statements</th>
<th>executions/sec</th>
<th>elapsed time (ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Commit</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Unknown</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>LGWR</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>CKPT</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>DBWO</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>INSERT ALL INTO authors (id,name,email) VALUES ( serial.nextval,'Priya',p[0]...</td>
<td>78.38</td>
<td>0.56</td>
</tr>
<tr>
<td>ARCO</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>
```

### Analyzing Oracle execution plans using the Performance Insights dashboard

When analyzing DB load on an Oracle Database, you might want to know which plans are contributing the most to DB load. For example, the top SQL statements at a given time might be using the plans shown in the following table.
Top SQL | Plan
---|---
SELECT SUM(amount_sold) FROM sales WHERE prod_id = 10 | Plan A
SELECT SUM(amount_sold) FROM sales WHERE prod_id = 521 | Plan B
SELECT SUM(s_total) FROM sales WHERE region = 10 | Plan A
SELECT * FROM emp WHERE emp_id = 1000 | Plan C
SELECT SUM(amount_sold) FROM sales WHERE prod_id = 72 | Plan A

With the plan feature of Performance Insights, you can do the following:

- Find out which plans are used by the top SQL queries.

  For example, you might find out that most of the DB load is generated by queries using plan A and plan B, with only a small percentage using plan C.

- Compare different plans for the same query.

  In the preceding example, three queries are identical except for the product ID. Two queries use plan A, but one query uses plan B. To see the difference in the two plans, you can use Performance Insights.

- Find out when a query switched to a new plan.

  You might see that a query used plan A and then switched to plan B at a certain time. Was there a change in the database at this point? For example, if a table is empty, the optimizer might choose a full table scan. If the table is loaded with a million rows, the optimizer might switch to an index range scan.

- Drill down to the specific steps of a plan with the highest cost.

  For example, for a long-running query might show a missing a join condition in an equijoin. This missing condition forces a Cartesian join, which joins all rows of two tables.

You can perform the preceding tasks by using the plan capture feature of Performance Insights. Just as you can slice Oracle queries by wait events and top SQL, you can slice them by the plan dimension.

For the region, DB engine, and instance class support information for this feature, see Amazon RDS DB engine, Region, and instance class support for Performance Insights features (p. 725)

To analyze Oracle execution plans using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose an Oracle DB instance. The Performance Insights dashboard is displayed for that DB instance.
4. In the Database load (DB load) section, choose Plans next to Slice by.

   The Average active sessions chart shows the plans used by your top SQL statements. The plan hash values appear to the right of the color-coded squares. Each hash value uniquely identifies a plan.
5. Scroll down to the Top SQL tab.

In the following example, the top SQL digest has two plans. You can tell that it's a digest by the question mark in the statement.

6. Choose the digest to expand it into its component statements.

In the following example, the SELECT statement is a digest query. The component queries in the digest use two different plans. The colors of the plans correspond to the database load chart. The total number of plans in the digest is shown in the second column.

7. Scroll down and choose two Plans to compare from Plans for digest query list.
You can view either one or two plans for a query at a time. The following screenshot compares the two plans in the digest, with hash 2032253151 and hash 1117438016. In the following example, 62% of the average active sessions running this digest query are using the plan on the left, whereas 38% are using the plan on the right.

In this example, the plans differ in an important way. Step 2 in plan 2032253151 uses an index scan, whereas plan 1117438016 uses a full table scan. For a table with a large number of rows, a query of a single row is almost always faster with an index scan.

8. (Optional) Choose Copy to copy the plan to the clipboard, or Download to save the plan to your hard drive.

Retrieving metrics with the Performance Insights API

When Performance Insights is turned on, the API provides visibility into instance performance. Amazon CloudWatch Logs provides the authoritative source for vended monitoring metrics for AWS services.

Performance Insights offers a domain-specific view of database load measured as average active sessions (AAS). This metric appears to API consumers as a two-dimensional time-series dataset. The time dimension of the data provides DB load data for each time point in the queried time range. Each time point decomposes overall load in relation to the requested dimensions, such as SQL, Wait-event, User, or Host, measured at that time point.

Amazon RDS Performance Insights monitors your Amazon RDS DB instance so that you can analyze and troubleshoot database performance. One way to view Performance Insights data is in the AWS Management Console. Performance Insights also provides a public API so that you can query your own data. You can use the API to do the following:
To use the Performance Insights API, enable Performance Insights on one of your Amazon RDS DB instances. For information about enabling Performance Insights, see *Turning Performance Insights on and off* (p. 727). For more information about the Performance Insights API, see the Amazon RDS Performance Insights API Reference.

The Performance Insights API provides the following operations.

<table>
<thead>
<tr>
<th>Performance Insights action</th>
<th>AWS CLI command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CreatePerformanceAnalysisReport</td>
<td><code>aws pi create-performance-analysis-report</code></td>
<td>Creates a performance analysis report for a specific time period for the DB instance. The result is AnalysisReportId which is the unique identifier of the report.</td>
</tr>
<tr>
<td>DescribeDimensionKeys</td>
<td><code>aws pi describe-dimension-keys</code></td>
<td>Retrieves the top N dimension keys for a metric for a specific time period.</td>
</tr>
<tr>
<td>GetDimensionKeyDetails</td>
<td><code>aws pi get-dimension-key-details</code></td>
<td>Retrieves the attributes of the specified dimension group for a DB instance or data source. For example, if you specify a SQL ID, and if the dimension details are available, GetDimensionKeyDetails retrieves the full text of the dimension <code>db.sql.statement</code> associated with this ID. This operation is useful because GetResourceMetrics and DescribeDimensionKeys don't support retrieval of large SQL statement text.</td>
</tr>
<tr>
<td>GetPerformanceAnalysisReport</td>
<td><code>aws pi get-performance-analysis-report</code></td>
<td>Retrieves the report including the insights for the report. The result includes the report status, report ID, report time details, insights, and recommendations.</td>
</tr>
<tr>
<td>GetResourceMetadata</td>
<td><code>aws pi get-resource-metadata</code></td>
<td>Retrieve the metadata for different features. For example, the metadata might indicate that a feature is turned on or off on a specific DB instance.</td>
</tr>
<tr>
<td>GetResourceMetrics</td>
<td><code>aws pi get-resource-metrics</code></td>
<td>Retrieves Performance Insights metrics for a set of data sources over a time period. You can</td>
</tr>
<tr>
<td>Performance Insights action</td>
<td>AWS CLI command</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>ListAvailableResourceDimensions</td>
<td><code>aws pi list-available-resource-dimensions</code></td>
<td>Retrieve the dimensions that can be queried for each specified metric type on a specified instance.</td>
</tr>
<tr>
<td>ListAvailableResourceMetrics</td>
<td><code>aws pi list-available-resource-metrics</code></td>
<td>Retrieve all available metrics of the specified metric types that can be queried for a specified DB instance.</td>
</tr>
<tr>
<td>ListPerformanceAnalysisReports</td>
<td><code>aws pi list-performance-analysis-reports</code></td>
<td>Retrieves all the analysis reports available for the DB instance. The reports are listed based on the start time of each report.</td>
</tr>
<tr>
<td>ListTagsForResource</td>
<td><code>aws pi list-tags-for-resource</code></td>
<td>Lists all the metadata tags added to the resource. The list includes the name and value of the tag.</td>
</tr>
<tr>
<td>TagResource</td>
<td><code>aws pi tag-resource</code></td>
<td>Adds metadata tags to the Amazon RDS resource. The tag includes a name and a value.</td>
</tr>
<tr>
<td>UntagResource</td>
<td><code>aws pi untag-resource</code></td>
<td>Removes the metadata tag from the resource.</td>
</tr>
</tbody>
</table>

**Topics**

- AWS CLI for Performance Insights (p. 771)
- Retrieving time-series metrics (p. 771)
- AWS CLI examples for Performance Insights (p. 773)

**AWS CLI for Performance Insights**

You can view Performance Insights data using the AWS CLI. You can view help for the AWS CLI commands for Performance Insights by entering the following on the command line.

```
aws pi help
```

If you don't have the AWS CLI installed, see [Installing the AWS Command Line Interface](#) in the AWS CLI User Guide for information about installing it.

**Retrieving time-series metrics**

The `GetResourceMetrics` operation retrieves one or more time-series metrics from the Performance Insights data. `GetResourceMetrics` requires a metric and time period, and returns a response with a list of data points.

For example, the AWS Management Console uses `GetResourceMetrics` to populate the **Counter Metrics** chart and the **Database Load** chart, as seen in the following image.
All metrics returned by `GetResourceMetrics` are standard time-series metrics, with the exception of `db.load`. This metric is displayed in the **Database Load** chart. The `db.load` metric is different from the other time-series metrics because you can break it into subcomponents called **dimensions**. In the previous image, `db.load` is broken down and grouped by the waits states that make up the `db.load`.

**Note**

`GetResourceMetrics` can also return the `db.sampleload` metric, but the `db.load` metric is appropriate in most cases.

For information about the counter metrics returned by `GetResourceMetrics`, see [Performance Insights counter metrics](p. 814).

The following calculations are supported for the metrics:

- **Average** – The average value for the metric over a period of time. Append `.avg` to the metric name.
- **Minimum** – The minimum value for the metric over a period of time. Append `.min` to the metric name.
- **Maximum** – The maximum value for the metric over a period of time. Append `.max` to the metric name.
- **Sum** – The sum of the metric values over a period of time. Append `.sum` to the metric name.
- **Sample count** – The number of times the metric was collected over a period of time. Append `.sample_count` to the metric name.

For example, assume that a metric is collected for 300 seconds (5 minutes), and that the metric is collected one time each minute. The values for each minute are 1, 2, 3, 4, and 5. In this case, the following calculations are returned:

- **Average** – 3
- **Minimum** – 1
- **Maximum** – 5
- **Sum** – 15
- **Sample count** – 5

For information about using the `get-resource-metrics` AWS CLI command, see [get-resource-metrics](#).
For the `--metric-queries` option, specify one or more queries that you want to get results for. Each query consists of a mandatory `Metric` and optional `GroupBy` and `Filter` parameters. The following is an example of a `--metric-queries` option specification.

```
{
  "Metric": "string",
  "GroupBy": {
    "Group": "string",
    "Dimensions": ["string", ...],
    "Limit": integer
  },
  "Filter": {"string": "string"
  ...
```

AWS CLI examples for Performance Insights

The following examples show how to use the AWS CLI for Performance Insights.

Topics
- Retrieving counter metrics (p. 773)
- Retrieving the DB load average for top wait events (p. 776)
- Retrieving the DB load average for top SQL (p. 777)
- Retrieving the DB load average filtered by SQL (p. 780)
- Retrieving the full text of a SQL statement (p. 783)
- Creating a performance analysis report for a time period (p. 783)
- Retrieving a performance analysis report (p. 784)
- Listing all the performance analysis reports for the DB instance (p. 784)
- Deleting a performance analysis report (p. 785)
- Adding tag to a performance analysis report (p. 785)
- Listing all the tags for a performance analysis report (p. 785)
- Deleting tags from a performance analysis report (p. 786)

Retrieving counter metrics

The following screenshot shows two counter metrics charts in the AWS Management Console.
The following example shows how to gather the same data that the AWS Management Console uses to generate the two counter metric charts.

For Linux, macOS, or Unix:

```bash
aws pi get-resource-metrics
   --service-type RDS
   --identifier db-ID
   --start-time 2018-10-30T00:00:00Z
   --end-time 2018-10-30T01:00:00Z
   --period-in-seconds 60
   --metric-queries '[["Metric": "os.cpuUtilization.user.avg" ],
                    {"Metric": "os.cpuUtilization.idle.avg"]'
```

For Windows:

```bash
aws pi get-resource-metrics ^
   --service-type RDS ^
   --identifier db-ID ^
   --start-time 2018-10-30T00:00:00Z ^
   --end-time 2018-10-30T01:00:00Z ^
   --period-in-seconds 60 ^
   --metric-queries '[["Metric": "os.cpuUtilization.user.avg" ],
                    {"Metric": "os.cpuUtilization.idle.avg"]'
```

You can also make a command easier to read by specifying a file for the --metrics-query option. The following example uses a file called query.json for the option. The file has the following contents.

```
[
  {
    "Metric": "os.cpuUtilization.user.avg"
  },
  {
    "Metric": "os.cpuUtilization.idle.avg"
  }
]
```

Run the following command to use the file.

For Linux, macOS, or Unix:

```bash
aws pi get-resource-metrics
   --service-type RDS
   --identifier db-ID
   --start-time 2018-10-30T00:00:00Z
   --end-time 2018-10-30T01:00:00Z
   --period-in-seconds 60
   --metric-queries file://query.json
```

For Windows:

```bash
aws pi get-resource-metrics ^
   --service-type RDS ^
   --identifier db-ID ^
   --start-time 2018-10-30T00:00:00Z ^
   --end-time 2018-10-30T01:00:00Z ^
   --period-in-seconds 60 ^
   --metric-queries file://query.json
```
The preceding example specifies the following values for the options:

- `--service-type` – RDS for Amazon RDS
- `--identifier` – The resource ID for the DB instance
- `--start-time` and `--end-time` – The ISO 8601 DateTime values for the period to query, with multiple supported formats

It queries for a one-hour time range:

- `--period-in-seconds` – 60 for a per-minute query
- `--metric-queries` – An array of two queries, each just for one metric.

The metric name uses dots to classify the metric in a useful category, with the final element being a function. In the example, the function is `avg` for each query. As with Amazon CloudWatch, the supported functions are `min`, `max`, `total`, and `avg`.

The response looks similar to the following.

```json
{
    "Identifier": "db-XXX",
    "AlignedStartTime": 1540857600.0,
    "AlignedEndTime": 1540861200.0,
    "MetricList": [
        
        //A list of key/datapoints
        "Key": {
            "Metric": "os.cpuUtilization.user.avg" //Metric1
        },
        "DataPoints": [
            //Each list of datapoints has the same timestamps and same number of items
            { "Timestamp": 1540857660.0, //Minute1 "Value": 4.0
            },
            { "Timestamp": 1540857720.0, //Minute2 "Value": 4.0
            },
            { "Timestamp": 1540857780.0, //Minute 3 "Value": 10.0
            }
        ] //... 60 datapoints for the os.cpuUtilization.user.avg metric
    ],
    
    //end of MetricList
} //end of MetricList
```
The response has an Identifier, AlignedStartTime, and AlignedEndTime. If the --period-in-seconds value was 60, the start and end times have been aligned to the minute. If the --period-in-seconds was 3600, the start and end times would have been aligned to the hour.

The MetricList in the response has a number of entries, each with a Key and a DataPoints entry. Each DataPoint has a Timestamp and a Value. Each Datapoints list has 60 data points because the queries are for per-minute data over an hour, with Timestamp1/Minute1, Timestamp2/Minute2, and so on, up to Timestamp60/Minute60.

Because the query is for two different counter metrics, there are two elements in the response MetricList.

**Retrieving the DB load average for top wait events**

The following example is the same query that the AWS Management Console uses to generate a stacked area line graph. This example retrieves the db.load.avg for the last hour with load divided according to the top seven wait events. The command is the same as the command in [Retrieving counter metrics](p. 773). However, the query.json file has the following contents.

```json
[
  {
    "Metric": "db.load.avg",
    "GroupBy": { "Group": "db.wait_event", "Limit": 7 }
  }
]
```

Run the following command.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
  --service-type RDS \
  --identifier db-ID \
  --start-time 2018-10-30T00:00:00Z \
  --end-time 2018-10-30T01:00:00Z \
  --period-in-seconds 60 \
  --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
  --service-type RDS ^
  --identifier db-ID ^
  --start-time 2018-10-30T00:00:00Z ^
  --end-time 2018-10-30T01:00:00Z ^
  --period-in-seconds 60 ^
  --metric-queries file://query.json
```

The example specifies the metric of db.load.avg and a GroupBy of the top seven wait events. For details about valid values for this example, see [DimensionGroup](p. 773) in the [Performance Insights API Reference](p. 773).

The response looks similar to the following.

```json
{
  "Identifier": "db-XXX",
```
In this response, there are eight entries in the MetricList. There is one entry for the total db.load.avg, and seven entries each for the db.load.avg divided according to one of the top seven wait events. Unlike in the first example, because there was a grouping dimension, there must be one key for each grouping of the metric. There can't be only one key for each metric, as in the basic counter metric use case.

Retrieving the DB load average for top SQL

The following example groups db.wait_events by the top 10 SQL statements. There are two different groups for SQL statements:

- db.sql – The full SQL statement, such as select * from customers where customer_id = 123
• `db.sql_tokenized` – The tokenized SQL statement, such as `select * from customers where customer_id = ?`

When analyzing database performance, it can be useful to consider SQL statements that only differ by their parameters as one logic item. So, you can use `db.sql_tokenized` when querying. However, especially when you’re interested in explain plans, sometimes it’s more useful to examine full SQL statements with parameters, and query grouping by `db.sql`. There is a parent-child relationship between tokenized and full SQL, with multiple full SQL (children) grouped under the same tokenized SQL (parent).

The command in this example is similar to the command in [Retrieving the DB load average for top wait events](p. 776). However, the `query.json` file has the following contents.

```
[
  {
    "Metric": "db.load.avg",
    "GroupBy": { "Group": "db.sql_tokenized", "Limit": 10 }
  }
]
```

The following example uses `db.sql_tokenized`.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
  --service-type RDS \
  --identifier db-ID \
  --start-time 2018-10-29T00:00:00Z \
  --end-time 2018-10-30T00:00:00Z \
  --period-in-seconds 3600 \
  --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
  --service-type RDS ^
  --identifier db-ID ^
  --start-time 2018-10-29T00:00:00Z ^
  --end-time 2018-10-30T00:00:00Z ^
  --period-in-seconds 3600 ^
  --metric-queries file://query.json
```

This example queries over 24 hours, with a one hour period-in-seconds.

The example specifies the metric of `db.load.avg` and a `GroupBy` of the top seven wait events. For details about valid values for this example, see `DimensionGroup` in the [Performance Insights API Reference](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/PerformanceInsights_US_Eu.html).

The response looks similar to the following.

```
{
  "AlignedStartTime": 1540771200.0,
  "AlignedEndTime": 1540857600.0,
  "Identifier": "db-XXX",
  "MetricList": [ //11 entries in the MetricList
```
This response has 11 entries in the MetricList (1 total, 10 top tokenized SQL), with each entry having 24 per-hour DataPoints.

For tokenized SQL, there are three entries in each dimensions list:

- `db.sql_tokenized.statement` – The tokenized SQL statement.
- `db.sql_tokenized.db_id` – Either the native database ID used to refer to the SQL, or a synthetic ID that Performance Insights generates for you if the native database ID isn’t available. This example returns the `pi-2372568224` synthetic ID.
- `db.sql_tokenized.id` – The ID of the query inside Performance Insights.

In the AWS Management Console, this ID is called the Support ID. It’s named this because the ID is data that AWS Support can examine to help you troubleshoot an issue with your database. AWS takes the security and privacy of your data extremely seriously, and almost all data is stored encrypted with your AWS KMS customer master key (CMK). Therefore, nobody inside AWS can look at this data. In the example preceding, both the `tokenized.statement` and the `tokenized.db_id` are stored encrypted. If you have an issue with your database, AWS Support can help you by referencing the Support ID.

When querying, it might be convenient to specify a Group in GroupBy. However, for finer-grained control over the data that’s returned, specify the list of dimensions. For example, if all that is needed is the `db.sql_tokenized.statement`, then a Dimensions attribute can be added to the query.json file.

```json
[
  {
    "Metric": "db.load.avg",
    "GroupBy": {
      "Group": "db.sql_tokenized",
      "Dimensions": ["db.sql_tokenized.statement"],
      "Limit": 10
    }
  }
]```
Retrieving the DB load average filtered by SQL

The preceding image shows that a particular query is selected, and the top average active sessions stacked area line graph is scoped to that query. Although the query is still for the top seven overall wait events, the value of the response is filtered. The filter causes it to take into account only sessions that are a match for the particular filter.

The corresponding API query in this example is similar to the command in Retrieving the DB load average for top SQL (p. 777). However, the query.json file has the following contents.

```
[
  {
    "Metric": "db.load.avg",
    "GroupBy": { "Group": "db.wait_event", "Limit": 5 },
    "Filter": { "db.sql_tokenized.id": "AKIAIOSFODNN7EXAMPLE" }
  }
]
```

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
  --service-type RDS \
  --identifier db-ID \
  --start-time 2018-10-30T00:00:00Z \
  --end-time 2018-10-30T01:00:00Z \
  --period-in-seconds 60 \
  --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
  --service-type RDS ^
  --identifier db-ID ^
```
The response looks similar to the following.

```json
{
  "Identifier": "db-XXX",
  "AlignedStartTime": 1556215200.0,
  "MetricList": [
    {
      "Key": {
        "Metric": "db.load.avg"
      },
      "DataPoints": [
        {
          "Timestamp": 1556218800.0,
          "Value": 1.4878117913832196
        },
        {
          "Timestamp": 1556222400.0,
          "Value": 1.192823803967328
        }
      ]
    },
    {
      "Key": {
        "Metric": "db.load.avg",
        "Dimensions": {
          "db.wait_event.type": "io",
          "db.wait_event.name": "wait/io/aurora_redo_log_flush"
        }
      },
      "DataPoints": [
        {
          "Timestamp": 1556218800.0,
          "Value": 1.1360544217687074
        },
        {
          "Timestamp": 1556222400.0,
          "Value": 1.058051341890315
        }
      ]
    },
    {
      "Key": {
        "Metric": "db.load.avg",
        "Dimensions": {
          "db.wait_event.type": "io",
          "db.wait_event.name": "wait/io/table/sql/handler"
        }
      },
      "DataPoints": [
        {
          "Timestamp": 1556218800.0,
          "Value": 0.16241496598639457
        },
        {
          "Timestamp": 1556222400.0,
          "Value": 0.05163360560093349
        }
      ]
    }
  ]
}
```
In this response, all values are filtered according to the contribution of tokenized SQL AKIAIOSFODNN7EXAMPLE specified in the query.json file. The keys also might follow a different order than a query without a filter, because it's the top five wait events that affected the filtered SQL.
Retrieving the full text of a SQL statement

The following example retrieves the full text of a SQL statement for DB instance db-10BCD2EFGHIJ3KL4M5NO6PQRS5. The --group is db.sql, and the --group-identifier is db.sql.id. In this example, my-sql-id represents a SQL ID retrieved by invoking pi get-resource-metrics or pi describe-dimension-keys.

Run the following command.

For Linux, macOS, or Unix:

```bash
aws pi get-dimension-key-details --service-type RDS --identifier db-10BCD2EFGHIJ3KL4M5NO6PQRS5 --group db.sql --group-identifier my-sql-id --requested-dimensions statement
```

For Windows:

```bash
aws pi get-dimension-key-details ^ --service-type RDS ^ --identifier db-10BCD2EFGHIJ3KL4M5NO6PQRS5 ^ --group db.sql ^ --group-identifier my-sql-id ^ --requested-dimensions statement
```

In this example, the dimensions details are available. Thus, Performance Insights retrieves the full text of the SQL statement, without truncating it.

```json
{
  "Dimensions": [ 
    { 
      "Value": "SELECT e.last_name, d.department_name FROM employees e, departments d
WHERE e.department_id=d.department_id",
      "Dimension": "db.sql.statement",
      "Status": "AVAILABLE"
    },
    ...
  ]
}
```

Creating a performance analysis report for a time period

The following example creates a performance analysis report with the 1682969503 start time and 1682979503 end time for the db-loadtest-0 database.

```bash
aws pi-test create-performance-analysis-report --service-type RDS --identifier db-loadtest-0 --start-time 1682969503 --end-time 1682979503 --endpoint-url https://api.titan.pi.a2z.com --region us-west-2
```

The response is the unique identifier report-0234d3ed98e28fb17 for the report.
Retrieving a performance analysis report

The following example retrieves the analysis report details for the report-0d99cc91c4422ee61 report.

```
aws pi-test get-performance-analysis-report \
  --service-type RDS \ 
  --identifier db-loadtest-0 \ 
  --analysis-report-id report-0d99cc91c4422ee61 \ 
  --endpoint-url https://api.titan.pi.a2z.com \ 
  --region us-west-2
```

The response provides the report status, ID, time details, and insights.

```
{
  "AnalysisReport": {
    "Status": "Succeeded",
    "ServiceType": "RDS",
    "Identifier": "db-loadtest-0",
    "StartTime": 1680583486.584,
    "AnalysisReportId": "report-0d99cc91c4422ee61",
    "EndTime": 1680587086.584,
    "CreateTime": 1680587087.139,
    "Insights": [
      ...
    ]
  }
}
```

Listing all the performance analysis reports for the DB instance

The following example lists all the available performance analysis reports for the db-loadtest-0 database.

```
aws pi-test list-performance-analysis-reports \
  --service-type RDS \ 
  --identifier db-loadtest-0 \ 
  --endpoint-url https://api.titan.pi.a2z.com \ 
  --region us-west-2
```

The response lists all the reports with the report ID, status, and time period details.

```
{
  "AnalysisReports": [
    {
      "Status": "Succeeded",
      "EndTime": 1680587086.584,
      "CreationTime": 1680587087.139,
```
Deleting a performance analysis report

The following example deletes the analysis report for the `db-loadtest-0` database.

```
aws pi-test delete-performance-analysis-report \
    --service-type RDS \
    --identifier db-loadtest-0 \
    --analysis-report-id report-0d99cc91c4422ee61 \
    --endpoint-url https://api.titan.pi.a2z.com \
    --region us-west-2
```

Adding tag to a performance analysis report

The following example adds a tag with a key `name` and value `test-tag` to the `report-01ad15f9b88bcbd56` report.

```
aws pi-test tag-resource \
    --service-type RDS \
    --resource-arn arn:aws:pi:us-west-2:356798100956:perf-reports/RDS/db-loadtest-0/report-01ad15f9b88bcbd56 \
    --tags Key=name,Value=test-tag \
    --endpoint-url https://api.titan.pi.a2z.com \
    --region us-west-2
```

Listing all the tags for a performance analysis report

The following example lists all the tags for the `report-01ad15f9b88bcbd56` report.
aws pi-test list-tags-for-resource
--service-type RDS
--endpoint-url https://api.titan.pi.a2z.com
--region us-west-2

The response lists the value and key for all the tags added to the report:

```
{
  "Tags": [
    {
      "Value": "test-tag",
      "Key": "name"
    }
  ]
}
```

Deleting tags from a performance analysis report

The following example deletes the name tag from the report-01ad15f9b88bcbd56 report.

aws pi-test untag-resource
--service-type RDS
--tag-keys name
--endpoint-url https://api.titan.pi.a2z.com
--region us-west-2

After the tag is deleted, calling the list-tags-for-resource API doesn't list this tag.

Logging Performance Insights calls using AWS CloudTrail

Performance Insights runs with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Performance Insights. CloudTrail captures all API calls for Performance Insights as events. This capture includes calls from the Amazon RDS console and from code calls to the Performance Insights API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Performance Insights. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the data collected by CloudTrail, you can determine certain information. This information includes the request that was made to Performance Insights, the IP address the request was made from, who made the request, and when it was made. It also includes additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Working with Performance Insights information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Performance Insights, that activity is recorded in a CloudTrail event along with other AWS service events.
in the CloudTrail console in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History in AWS CloudTrail User Guide.

For an ongoing record of events in your AWS account, including events for Performance Insights, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in AWS CloudTrail User Guide:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

All Performance Insights operations are logged by CloudTrail and are documented in the Performance Insights API Reference. For example, calls to the DescribeDimensionKeys and GetResourceMetrics operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.

Performance Insights log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source. Each event includes information about the requested operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the GetResourceMetrics operation.

```json
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "AKIAIOSFODNN7EXAMPLE",
        "arn": "arn:aws:iam::123456789012:user/johndoe",
        "accountId": "123456789012",
        "accessKeyId": "AKIAI44QH8D8EXAMPLE",
        "userName": "johndoe"
    },
    "eventTime": "2019-12-18T19:28:46Z",
    "eventSource": "pi.amazonaws.com",
    "eventName": "GetResourceMetrics",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "72.21.198.67",
    "userAgent": "aws-cli/1.16.240 Python/3.7.4 Darwin/18.7.0 botocore/1.12.230",
}
```
"requestParameters": {
    "identifier": "db-YTDU5J5V6G7XGCVDVDFD2V3SZM",

Analyzing performance anomalies with Amazon DevOps Guru for Amazon RDS

Amazon DevOps Guru is a fully managed operations service that helps developers and operators improve the performance and availability of their applications. DevOps Guru offloads the tasks associated with identifying operational issues so that you can quickly implement recommendations to improve your application. For more information, see What is Amazon DevOps Guru? in the Amazon DevOps Guru User Guide.

DevOps Guru detects, analyzes, and makes recommendations for existing operational issues for all Amazon RDS DB engines. DevOps Guru for RDS extends this capability by applying machine learning to Performance Insights metrics for RDS for PostgreSQL databases. These monitoring features allow DevOps Guru for RDS to detect and diagnose performance bottlenecks and recommend specific corrective actions. DevOps Guru for RDS can also detect problematic conditions in your RDS for PostgreSQL database before they occur.

The following video is an overview of DevOps Guru for RDS.

For a deep dive on this subject, see Amazon DevOps Guru for RDS under the hood.

Topics

- Benefits of DevOps Guru for RDS (p. 789)
- How DevOps Guru for RDS works (p. 790)
- Setting up DevOps Guru for RDS (p. 791)

Benefits of DevOps Guru for RDS

If you're responsible for RDS for PostgreSQL database, you might not know that an event or regression that is affecting that database is occurring. When you learn about the issue, you might not know why it's occurring or what to do about it. Rather than turning to a database administrator (DBA) for help or relying on third-party tools, you can follow recommendations from DevOps Guru for RDS.

You gain the following advantages from the detailed analysis of DevOps Guru for RDS:

**Fast diagnosis**

DevOps Guru for RDS continuously monitors and analyzes database telemetry. Performance Insights, Enhanced Monitoring, and Amazon CloudWatch collect telemetry data for your database instance. DevOps Guru for RDS uses statistical and machine learning techniques to mine this data and detect anomalies. To learn more about telemetry data, see Monitoring DB load with Performance Insights on Amazon RDS and Monitoring OS metrics with Enhanced Monitoring in the Amazon RDS User Guide.

**Fast resolution**

Each anomaly identifies the performance issue and suggests avenues of investigation or corrective actions. For example, DevOps Guru for RDS might recommend that you investigate specific wait events. Or it might recommend that you tune your application pool settings to limit the number of database connections. Based on these recommendations, you can resolve performance issues more quickly than by troubleshooting manually.

**Proactive insights**

DevOps Guru for RDS uses metrics from your resources to detect potentially problematic behavior before it becomes a bigger problem. For example, it can detect when your database is using an increasing number of on-disk temporary tables, which could start to impact performance.
DevOps Guru then provides recommendations to help you address issues before they become bigger problems.

**Deep knowledge of Amazon engineers and machine learning**

To detect performance issues and help you resolve bottlenecks, DevOps Guru for RDS relies on machine learning (ML) and advanced mathematical formulas. Amazon database engineers contributed to the development of the DevOps Guru for RDS findings, which encapsulate many years of managing hundreds of thousands of databases. By drawing on this collective knowledge, DevOps Guru for RDS can teach you best practices.

### How DevOps Guru for RDS works

DevOps Guru for RDS collects data about your RDS for PostgreSQL databases from Amazon RDS Performance Insights. The most important metric is DBLoad. DevOps Guru for RDS consumes the Performance Insights metrics, analyzes them with machine learning, and publishes insights to the dashboard.

An *insight* is a collection of related anomalies that were detected by DevOps Guru.

In DevOps Guru for RDS, an *anomaly* is a pattern that deviates from what is considered normal performance for your RDS for PostgreSQL database.

#### Proactive insights

A *proactive insight* lets you know about problematic behavior before it occurs. It contains anomalies with related metrics and suggestions to help you address issues in your RDS for PostgreSQL databases before they become bigger problems. These insights are published in the DevOps Guru dashboard.

For example, DevOps Guru might detect that your RDS for PostgreSQL database is creating many on-disk temporary tables. If not addressed, this trend might lead to performance issues. Each proactive insight includes recommendations for corrective behavior and links to relevant topics in Tuning RDS for PostgreSQL with Amazon DevOps Guru proactive insights (p. 2370). For more information, see Working with insights in DevOps Guru in the Amazon DevOps Guru User Guide.

#### Reactive insights

A *reactive insight* identifies anomalous behavior as it occurs. If DevOps Guru for RDS finds performance issues in your RDS for PostgreSQL DB instances, it publishes a reactive insight in the DevOps Guru dashboard. For more information, see Working with insights in DevOps Guru in the Amazon DevOps Guru User Guide.

#### Causal anomalies

A *causal anomaly* is a top-level anomaly within a reactive insight. Database load (DB load) is the causal anomaly for DevOps Guru for RDS.

An anomaly measures performance impact by assigning a severity level of High, Medium, or Low. To learn more, see Key concepts for DevOps Guru for RDS in the Amazon DevOps Guru User Guide.

If DevOps Guru detects a current anomaly on your DB instance, you're alerted in the Databases page of the RDS console. The console also alerts you to anomalies that occurred in the past 24 hours. To go to the anomaly page from the RDS console, choose the link in the alert message. The RDS console also alerts you in the page for your RDS for PostgreSQL DB instance.

#### Contextual anomalies

A *contextual anomaly* is a finding within Database load (DB load) that is related to a reactive insight. Each contextual anomaly describes a specific RDS for PostgreSQL performance issue that requires
investigation. For example, DevOps Guru for RDS might recommend that you consider increasing CPU capacity or investigate wait events that are contributing to DB load.

**Important**
We recommend that you test any changes on a test instance before modifying a production instance. In this way, you understand the impact of the change.

## Setting up DevOps Guru for RDS

To allow DevOps Guru for Amazon RDS to publish insights for a RDS for PostgreSQL database, complete the following tasks.

### Topics
- [Configuring IAM access policies for DevOps Guru for RDS](#) (p. 791)
- [Turning on Performance Insights for your RDS for PostgreSQL DB instances](#) (p. 791)
- [Turning on DevOps Guru and specifying resource coverage](#) (p. 791)

### Configuring IAM access policies for DevOps Guru for RDS

To view alerts from DevOps Guru in the RDS console, your AWS Identity and Access Management (IAM) user or role must have either of the following policies:

- The AWS managed policy `AmazonDevOpsGuruConsoleFullAccess`
- The AWS managed policy `AmazonDevOpsGuruConsoleReadOnlyAccess` and either of the following policies:
  - The AWS managed policy `AmazonRDSFullAccess`
  - A customer managed policy that includes `pi:GetResourceMetrics` and `pi:DescribeDimensionKeys`

For more information, see [Configuring access policies for Performance Insights](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/monitoring-performance-insights.html) (p. 734).

### Turning on Performance Insights for your RDS for PostgreSQL DB instances

DevOps Guru for RDS relies on Performance Insights for its data. Without Performance Insights, DevOps Guru publishes anomalies, but doesn't include the detailed analysis and recommendations.

When you create or modify a RDS for PostgreSQL DB instance, you can turn on Performance Insights. For more information, see [Turning Performance Insights on and off](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/monitoring-performance-insights.html) (p. 727).

### Turning on DevOps Guru and specifying resource coverage

You can turn on DevOps Guru to have it monitor your RDS for PostgreSQL databases in either of the following ways.

### Topics
- [Turning on DevOps Guru in the RDS console](#) (p. 792)
- [Adding RDS for PostgreSQL resources in the DevOps Guru console](#) (p. 795)
- [Adding RDS for PostgreSQL resources using AWS CloudFormation](#) (p. 795)
Turning on DevOps Guru in the RDS console

You can take multiple paths in the Amazon RDS console to turn on DevOps Guru.

Topics

• Turning on DevOps Guru when you create an RDS for PostgreSQL database (p. 792)
• Turning on DevOps Guru from the notification banner (p. 793)
• Responding to a permissions error when you turn on DevOps Guru (p. 794)

Turning on DevOps Guru when you create an RDS for PostgreSQL database

The creation workflow includes a setting that turns on DevOps Guru coverage for your database. This setting is turned on by default when you choose the Production template.

To turn on DevOps Guru when you create an RDS for PostgreSQL database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Follow the steps in Creating a DB instance (p. 303), up to but not including the step where you choose monitoring settings.
3. In Monitoring, choose Turn on Performance Insights. For DevOps Guru for RDS to provide detailed analysis of performance anomalies, Performance Insights must be turned on.
4. Choose Turn on DevOps Guru.
5. Create a tag for your database so that DevOps Guru can monitor it. Do the following:

- In the text field for **Tag key**, enter a name that begins with **Devops-Guru-**.
- In the text field for **Tag value**, enter any value. For example, if you enter `rds-database-1` for the name of your RDS for PostgreSQL database, you can also enter `rds-database-1` as the tag value.

For more information about tags, see "Use tags to identify resources in your DevOps Guru applications" in the *Amazon DevOps Guru User Guide*.

6. Complete the remaining steps in *Creating a DB instance (p. 303)*.

**Turning on DevOps Guru from the notification banner**

If your resources aren't covered by DevOps Guru, Amazon RDS notifies you with a banner in the following locations:

- The **Monitoring** tab of a DB cluster instance
- The Performance Insights dashboard
To turn on DevOps Guru for your RDS for PostgreSQL database

1. In the banner, choose Turn on DevOps Guru for RDS.
2. Enter a tag key name and value. For more information about tags, see "Use tags to identify resources in your DevOps Guru applications" in the Amazon DevOps Guru User Guide.

3. Choose Turn on DevOps Guru.

Responding to a permissions error when you turn on DevOps Guru

If you turn on DevOps Guru from the RDS console when you create a database, RDS might display the following banner about missing permissions.

To respond to a permissions error

1. Grant your IAM user or role the user managed role AmazonDevOpsGuruConsoleFullAccess. For more information, see Configuring IAM access policies for DevOps Guru for RDS (p. 791).
2. Open the RDS console.
3. In the navigation pane, choose Performance Insights.
4. Choose a DB instance in the cluster that you just created.
5. Turn on DevOps Guru for RDS.
6. Choose a tag value. For more information, see "Use tags to identify resources in your DevOps Guru applications" in the Amazon DevOps Guru User Guide.

   **Turn on DevOps Guru for database-15-instance-1**
   DevOps Guru for RDS automatically detects performance anomalies for DB instances and provides recommendations.

   To allow DevOps Guru for RDS to monitor a resource, specify a tag. The tag key must begin with "DevOps-Guru". Learn more

<table>
<thead>
<tr>
<th>Tag key</th>
<th>Tag value</th>
</tr>
</thead>
<tbody>
<tr>
<td>devops-guru-default</td>
<td>database-15-instance-1</td>
</tr>
</tbody>
</table>

   Cost per resource per hour

   $0.0042 Amazon DevOps Guru pricing

   By choosing Turn on DevOps Guru, you agree to the terms related to use of DevOps Guru in the AWS Service Terms.

   Cancel  Turn on DevOps Guru

7. Choose Turn on DevOps Guru.

**Adding RDS for PostgreSQL resources in the DevOps Guru console**

You can specify your DevOps Guru resource coverage on the DevOps Guru console. Follow the step described in Specify your DevOps Guru resource coverage in the Amazon DevOps Guru User Guide. When you edit your analyzed resources, choose one of the following options:

- Choose All account resources to analyze all supported resources, including the RDS for PostgreSQL databases, in your AWS account and Region.
- Choose CloudFormation stacks to analyze the RDS for PostgreSQL databases that are in stacks you choose. For more information, see Use AWS CloudFormation stacks to identify resources in your DevOps Guru applications in the Amazon DevOps Guru User Guide.
- Choose Tags to analyze the RDS for PostgreSQL databases that you have tagged. For more information, see Use tags to identify resources in your DevOps Guru applications in the Amazon DevOps Guru User Guide.

For more information, see Enable DevOps Guru in the Amazon DevOps Guru User Guide.

**Adding RDS for PostgreSQL resources using AWS CloudFormation**

You can use tags to add coverage for your RDS for PostgreSQL resources to your CloudFormation templates. The following procedure assumes that you have a CloudFormation template both for your RDS for PostgreSQL DB instance and DevOps Guru stack.

**To specify an RDS for PostgreSQL DB instance using a CloudFormation tag**

1. In the CloudFormation template for your DB instance, define a tag using a key/value pair.

   The following example assigns the value my-db-instance1 to Devops-guru-cfn-default for an RDS for PostgreSQL DB instance.
MyDBInstance1:
Type: "AWS::RDS::DBInstance"
Properties:
  DBInstanceIdentifier: my-db-instance1
Tags:
  - Key: Devops-guru-cfn-default
    Value: devopsguru-my-db-instance1

2. In the CloudFormation template for your DevOps Guru stack, specify the same tag in your resource collection filter.

The following example configures DevOps Guru to provide coverage for the resource with the tag value my-db-instance1.

DevOpsGuruResourceCollection:
Type: AWS::DevOpsGuru::ResourceCollection
Properties:
  ResourceCollectionFilter:
    Tags:
      - AppBoundaryKey: "Devops-guru-cfn-default"
        TagValues:
          - "devopsguru-my-db-instance1"

The following example provides coverage for all resources within the application boundary Devops-guru-cfn-default.

DevOpsGuruResourceCollection:
Type: AWS::DevOpsGuru::ResourceCollection
Properties:
  ResourceCollectionFilter:
    Tags:
      - AppBoundaryKey: "Devops-guru-cfn-default"
        TagValues:
          - "*"

For more information, see AWS::DevOpsGuru::ResourceCollection and AWS::RDS::DBInstance in the AWS CloudFormation User Guide.
Monitoring OS metrics with Enhanced Monitoring

With Enhanced Monitoring, you can monitor the operating system of your DB instance in real time. When you want to see how different processes or threads use the CPU, Enhanced Monitoring metrics are useful.

Topics
- Overview of Enhanced Monitoring (p. 797)
- Setting up and enabling Enhanced Monitoring (p. 798)
- Viewing OS metrics in the RDS console (p. 802)
- Viewing OS metrics using CloudWatch Logs (p. 805)

Overview of Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view all the system metrics and process information for your RDS DB instances on the console. You can manage which metrics you want to monitor for each instance and customize the dashboard according to your requirements. For descriptions of the Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring (p. 837).

RDS delivers the metrics from Enhanced Monitoring into your Amazon CloudWatch Logs account. You can create metrics filters in CloudWatch from CloudWatch Logs and display the graphs on the CloudWatch dashboard. You can consume the Enhanced Monitoring JSON output from CloudWatch Logs in a monitoring system of your choice. For more information, see Enhanced Monitoring in the Amazon RDS FAQs.

Topics
- Enhanced Monitoring availability (p. 797)
- Differences between CloudWatch and Enhanced Monitoring metrics (p. 797)
- Retention of Enhanced Monitoring metrics (p. 798)
- Cost of Enhanced Monitoring (p. 798)

Enhanced Monitoring availability

Enhanced Monitoring is available for the following database engines:
- MariaDB
- Microsoft SQL Server
- MySQL
- Oracle
- PostgreSQL

Enhanced Monitoring is available for all DB instance classes except for the db.m1.small instance class.

Differences between CloudWatch and Enhanced Monitoring metrics

A hypervisor creates and runs virtual machines (VMs). Using a hypervisor, an instance can support multiple guest VMs by virtually sharing memory and CPU. CloudWatch gathers metrics about CPU
utilization from the hypervisor for a DB instance. In contrast, Enhanced Monitoring gathers its metrics from an agent on the DB instance.

You might find differences between the CloudWatch and Enhanced Monitoring measurements, because the hypervisor layer performs a small amount of work. The differences can be greater if your DB instances use smaller instance classes. In this scenario, more virtual machines (VMs) are probably managed by the hypervisor layer on a single physical instance.

For descriptions of the Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring (p. 837). For more information about CloudWatch metrics, see the Amazon CloudWatch User Guide.

Retention of Enhanced Monitoring metrics

By default, Enhanced Monitoring metrics are stored for 30 days in the CloudWatch Logs. This retention period is different from typical CloudWatch metrics.

To modify the amount of time the metrics are stored in the CloudWatch Logs, change the retention for the RDSOSMetrics log group in the CloudWatch console. For more information, see Change log data retention in CloudWatch logs in the Amazon CloudWatch Logs User Guide.

Cost of Enhanced Monitoring

Enhanced Monitoring metrics are stored in the CloudWatch Logs instead of in CloudWatch metrics. The cost of Enhanced Monitoring depends on the following factors:

- You are charged for Enhanced Monitoring only if you exceed the free tier provided by Amazon CloudWatch Logs. Charges are based on CloudWatch Logs data transfer and storage rates.
- The amount of information transferred for an RDS instance is directly proportional to the defined granularity for the Enhanced Monitoring feature. A smaller monitoring interval results in more frequent reporting of OS metrics and increases your monitoring cost. To manage costs, set different granularities for different instances in your accounts.
- Usage costs for Enhanced Monitoring are applied for each DB instance that Enhanced Monitoring is enabled for. Monitoring a large number of DB instances is more expensive than monitoring only a few.
- DB instances that support a more compute-intensive workload have more OS process activity to report and higher costs for Enhanced Monitoring.

For more information about pricing, see Amazon CloudWatch pricing.

Setting up and enabling Enhanced Monitoring

To use Enhanced Monitoring, you must create an IAM role, and then enable Enhanced Monitoring.

Topics

- Creating an IAM role for Enhanced Monitoring (p. 798)
- Turning Enhanced Monitoring on and off (p. 799)
- Protecting against the confused deputy problem (p. 801)

Creating an IAM role for Enhanced Monitoring

Enhanced Monitoring requires permission to act on your behalf to send OS metric information to CloudWatch Logs. You grant Enhanced Monitoring permissions using an AWS Identity and Access Management (IAM) role. You can either create this role when you enable Enhanced Monitoring or create it beforehand.
Creating the IAM role when you enable Enhanced Monitoring

When you enable Enhanced Monitoring in the RDS console, Amazon RDS can create the required IAM role for you. The role is named `rds-monitoring-role`. RDS uses this role for the specified DB instance, read replica, or Multi-AZ DB cluster.

To create the IAM role when enabling Enhanced Monitoring

1. Follow the steps in _Turning Enhanced Monitoring on and off_ (p. 799).
2. Set _Monitoring Role_ to _Default_ in the step where you choose a role.

Creating the IAM role before you enable Enhanced Monitoring

You can create the required role before you enable Enhanced Monitoring. When you enable Enhanced Monitoring, specify your new role's name. You must create this required role if you enable Enhanced Monitoring using the AWS CLI or the RDS API.

The user that enables Enhanced Monitoring must be granted the _PassRole_ permission. For more information, see Example 2 in _Granting a user permissions to pass a role to an AWS service_ in the IAM User Guide.

To create an IAM role for Amazon RDS enhanced monitoring

2. In the navigation pane, choose _Roles_.
3. Choose _Create role_.
4. Choose the _AWS service_ tab, and then choose _RDS_ from the list of services.
5. Choose _RDS - Enhanced Monitoring_, and then choose _Next_.
6. Ensure that the _Permissions policies_ shows _AmazonRDEnhancedMonitoringRole_, and then choose _Next_.
7. For _Role name_, enter a name for your role. For example, enter _emaccess_.
   - The trusted entity for your role is the AWS service _monitoring.rds.amazonaws.com_.
8. Choose _Create role_.

Turning Enhanced Monitoring on and off

You can turn Enhanced Monitoring on and off using the AWS Management Console, AWS CLI, or RDS API. You choose the RDS DB instances on which you want to turn on Enhanced Monitoring. You can set different granularities for metric collection on each DB instance.

**Console**

You can turn on Enhanced Monitoring when you create a DB instance, Multi-AZ DB cluster, or read replica, or when you modify a DB instance or Multi-AZ DB cluster. If you modify a DB instance to turn on Enhanced Monitoring, you don't need to reboot your DB instance for the change to take effect.

You can turn on Enhanced Monitoring in the RDS console when you do one of the following actions in the _Databases_ page:
• Create a DB instance or Multi-AZ DB cluster – Choose Create database.
• Create a read replica – Choose Actions, then Create read replica.
• Modify a DB instance or Multi-AZ DB cluster – Choose Modify.

To turn Enhanced Monitoring on or off in the RDS console
1. Scroll to Additional configuration.
2. In Monitoring, choose Enable Enhanced Monitoring for your DB instance or read replica. To turn Enhanced Monitoring off, choose Disable Enhanced Monitoring.
3. Set the Monitoring Role property to the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose Default to have RDS create a role for you named rds-monitoring-role.
4. Set the Granularity property to the interval, in seconds, between points when metrics are collected for your DB instance or read replica. The Granularity property can be set to one of the following values: 1, 5, 10, 15, 30, or 60.

The fastest that the RDS console refreshes is every 5 seconds. If you set the granularity to 1 second in the RDS console, you still see updated metrics only every 5 seconds. You can retrieve 1-second metric updates by using CloudWatch Logs.

AWS CLI

To turn on Enhanced Monitoring using the AWS CLI, in the following commands, set the --monitoring-interval option to a value other than 0 and set the --monitoring-role-arn option to the role you created in Creating an IAM role for Enhanced Monitoring (p. 798).

• create-db-instance
• create-db-instance-read-replica
• modify-db-instance
• create-db-cluster (Multi-AZ DB cluster)
• modify-db-cluster (Multi-AZ DB cluster)

The --monitoring-interval option specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values for the option are 0, 1, 5, 10, 15, 30, and 60.

To turn off Enhanced Monitoring using the AWS CLI, set the --monitoring-interval option to 0 in these commands.

Example

The following example turns on Enhanced Monitoring for a DB instance:

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --monitoring-interval 30 \
  --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```bash
aws rds modify-db-instance ^
```
Example

The following example turns on Enhanced Monitoring for a Multi-AZ DB cluster:

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
  --db-cluster-identifier mydbcluster \
  --monitoring-interval 30 \
  --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```
aws rds modify-db-cluster ^
  --db-cluster-identifier mydbcluster ^
  --monitoring-interval 30 ^
  --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

RDS API

To turn on Enhanced Monitoring using the RDS API, set the `MonitoringInterval` parameter to a value other than 0 and set the `MonitoringRoleArn` parameter to the role you created in protecting against the confused deputy problem.

To turn off Enhanced Monitoring using the RDS API, set `MonitoringInterval` to 0.

Protecting against the confused deputy problem

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the calling service) calls another service (the called service). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see the confused deputy problem.

To limit the permissions to the resource that Amazon RDS can give another service, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in a trust policy for your Enhanced Monitoring role. If you use both global condition context keys, they must use the same account ID.
The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. For Amazon RDS, set `aws:SourceArn` to `arn:aws:rds:Region:my-account-id:db:dbname`.

The following example uses the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in a trust policy to prevent the confused deputy problem.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringLike": {
          "aws:SourceArn": "arn:aws:rds:Region:my-account-id:db:dbname"
        },
        "StringEquals": {
          "aws:SourceAccount": "my-account-id"
        }
      }
    }
  ]
}
```

### Viewing OS metrics in the RDS console

You can view OS metrics reported by Enhanced Monitoring in the RDS console by choosing **Enhanced monitoring** for Monitoring.

The following example shows the Enhanced Monitoring page. For descriptions of the Enhanced Monitoring metrics, see [OS metrics in Enhanced Monitoring](p. 837).

Some DB instances use more than one disk for the DB instance's data storage volume. On those DB instances, the **Physical Devices** graphs show metrics for each one of the disks. For example, the following graph shows metrics for four disks.
**Note**
Currently, Physical Devices graphs are not available for Microsoft SQL Server DB instances.

When you are viewing aggregated Disk I/O and File system graphs, the rdsdev device relates to the /rdsdbdata file system, where all database files and logs are stored. The filesystem device relates to the / file system (also known as root), where files related to the operating system are stored.

If the DB instance is a Multi-AZ deployment, you can view the OS metrics for the primary DB instance and its Multi-AZ standby replica. In the Enhanced monitoring view, choose primary to view the OS metrics for the primary DB instance, or choose secondary to view the OS metrics for the standby replica.
For more information about Multi-AZ deployments, see Configuring and managing a Multi-AZ deployment (p. 492).

Note
Currently, viewing OS metrics for a Multi-AZ standby replica is not supported for MariaDB DB instances.

If you want to see details for the processes running on your DB instance, choose OS process list for Monitoring.

The Process List view is shown following.

The Enhanced Monitoring metrics shown in the Process list view are organized as follows:

- **RDS child processes** – Shows a summary of the RDS processes that support the DB instance, for example mysql for MySQL DB instances. Process threads appear nested beneath the parent process. Process threads show CPU utilization only as other metrics are the same for all threads for the process. The console displays a maximum of 100 processes and threads. The results are a combination of the top CPU consuming and memory consuming processes and threads. If there are more than 50 processes and more than 50 threads, the console displays the top 50 consumers in each category. This display helps you identify which processes are having the greatest impact on performance.

- **RDS processes** – Shows a summary of the resources used by the RDS management agent, diagnostics monitoring processes, and other AWS processes that are required to support RDS DB instances.

- **OS processes** – Shows a summary of the kernel and system processes, which generally have minimal impact on performance.
The items listed for each process are:

- **VIRT** – Displays the virtual size of the process.
- **RES** – Displays the actual physical memory being used by the process.
- **CPU%** – Displays the percentage of the total CPU bandwidth being used by the process.
- **MEM%** – Displays the percentage of the total memory being used by the process.

The monitoring data that is shown in the RDS console is retrieved from Amazon CloudWatch Logs. You can also retrieve the metrics for a DB instance as a log stream from CloudWatch Logs. For more information, see Viewing OS metrics using CloudWatch Logs (p. 805).

Enhanced Monitoring metrics are not returned during the following:

- A failover of the DB instance.
- Changing the instance class of the DB instance (scale compute).

Enhanced Monitoring metrics are returned during a reboot of a DB instance because only the database engine is rebooted. Metrics for the operating system are still reported.

### Viewing OS metrics using CloudWatch Logs

After you have enabled Enhanced Monitoring for your DB instance or Multi-AZ DB cluster, you can view the metrics for it using CloudWatch Logs, with each log stream representing a single DB instance or DB cluster being monitored. The log stream identifier is the resource identifier (DbiResourceId) for the DB instance or DB cluster.

**To view Enhanced Monitoring log data**

2. If necessary, choose the AWS Region that your DB instance or Multi-AZ DB cluster is in. For more information, see Regions and endpoints in the Amazon Web Services General Reference.
3. Choose Logs in the navigation pane.
4. Choose **RDSOSMetrics** from the list of log groups.

In a Multi-AZ DB instance deployment, log files with `-secondary` appended to the name are for the Multi-AZ standby replica.

5. Choose the log stream that you want to view from the list of log streams.
Metrics reference for Amazon RDS

In this reference, you can find descriptions of Amazon RDS metrics for Amazon CloudWatch, Performance Insights, and Enhanced Monitoring.

Topics
- Amazon CloudWatch metrics for Amazon RDS (p. 806)
- Amazon CloudWatch dimensions for Amazon RDS (p. 813)
- Amazon CloudWatch metrics for Performance Insights (p. 813)
- Performance Insights counter metrics (p. 814)
- SQL statistics for Performance Insights (p. 830)
- OS metrics in Enhanced Monitoring (p. 837)

Amazon CloudWatch metrics for Amazon RDS

Amazon RDS publishes metrics to Amazon CloudWatch in the AWS/RDS and AWS/Usage namespaces.

Topics
- Amazon CloudWatch instance-level metrics for Amazon RDS (p. 806)
- Amazon CloudWatch usage metrics for Amazon RDS (p. 812)

Amazon CloudWatch instance-level metrics for Amazon RDS

The AWS/RDS namespace in Amazon CloudWatch includes the following instance-level metrics.

**Note**
The Amazon RDS console might display metrics in units that are different from the units sent to Amazon CloudWatch. For example, the Amazon RDS console might display a metric in megabytes (MB), while the metric is sent to Amazon CloudWatch in bytes.

<table>
<thead>
<tr>
<th><strong>Metric</strong></th>
<th><strong>Console name</strong></th>
<th><strong>Description</strong></th>
<th><strong>Applies to</strong></th>
<th><strong>Units</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>BinLogDiskUsage</td>
<td>Binary Log Disk Usage (MB)</td>
<td>The amount of disk space occupied by binary logs. If automatic backups are enabled for MySQL and MariaDB instances, including read replicas, binary logs are created.</td>
<td>MariaDB</td>
<td>Bytes</td>

<td>CPU Credit Balance (Count)</td>
<td>(T2 instances) The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the CPUCreditBalance also includes the number of launch credits that have been accrued. Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits don't count towards the limit. The credits in the CPUCreditBalance are available for the instance to spend to burst beyond its baseline CPU utilization. When an instance is running, credits in the CPUCreditBalance don't expire. When the instance stops, the CPUCreditBalance does not persist, and all accrued credits are lost. CPU credit metrics are available at a five-minute frequency only. Launch credits work the same way in Amazon RDS as they do in Amazon EC2. For more information, see Launch credits in the Amazon Elastic Compute Cloud User Guide for Linux Instances.</td>

</table>
| DatabaseConnections   | DBConnections (Count)         | The number of client network connections to the database instance. The number of database sessions can be higher than the metric value because the metric value doesn't include the following:  
  • Sessions that no longer have a network connection but which the database hasn't cleaned up  
  • Sessions created by the database engine for its own purposes  
  • Sessions created by the database engine's parallel execution capabilities  
  • Sessions created by the database engine job scheduler  
  • Amazon RDS connections | All                     | Count                                          |
<p>| DiskQueueDepth        | Queue Depth (Count)           | The number of outstanding I/Os (read/write requests) waiting to access the disk.                  | All        | Count     |
| EBSByteBalance%       | EBS Byte Balance (Percent)    | The percentage of throughput credits remaining in the burst bucket of your RDS database. This metric is available for basic monitoring only. The metric value is based on the throughput and IOPS of all volumes, including the root volume, rather than on only those volumes containing database files. To find the instance sizes that support this metric, see the instance sizes with an asterisk (*) in the EBS optimized by default table in Amazon EC2 User Guide for Linux Instances. The Sum statistic is not applicable to this metric. | All        | Percentage|</p>

### Amazon CloudWatch usage metrics for Amazon RDS

The AWS/Usage namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. CloudWatch collects usage metrics automatically for all AWS Regions.

For more information, see CloudWatch usage metrics in the Amazon CloudWatch User Guide. For more information about quotas, see Quotas and constraints for Amazon RDS (p. 2737) and Requesting a quota increase in the Service Quotas User Guide.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Units*</th>
</tr>
</thead>
<tbody>
<tr>
<td>AllocatedStorage</td>
<td>The total storage for all DB instances. The sum excludes temporary migration instances.</td>
<td>Gigabytes</td>
</tr>
<tr>

<td>The number of option groups in your AWS account. The count excludes the default option groups.</td>
<td>Count</td>
</tr>
<tr>
<td>ReservedDBInstances</td>
<td>The number of reserved DB instances in your AWS account. The count excludes retired or declined instances.</td>
<td>Count</td>
</tr>
</tbody>
</table>
Amazon RDS doesn't publish units for usage metrics to CloudWatch. The units only appear in the documentation.

**Amazon CloudWatch dimensions for Amazon RDS**

You can filter Amazon RDS metrics data by using any dimension in the following table.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Filters the requested data for . . .</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBInstanceIdentifier</td>
<td>A specific DB instance.</td>
</tr>
<tr>
<td>DatabaseClass</td>
<td>All instances in a database class. For example, you can aggregate metrics for all instances that belong to the database class db.r5.large.</td>
</tr>
<tr>
<td>EngineName</td>
<td>The identified engine name only. For example, you can aggregate metrics for all instances that have the engine name postgres.</td>
</tr>
<tr>
<td>SourceRegion</td>
<td>The specified Region only. For example, you can aggregate metrics for all DB instances in the us-east-1 Region.</td>
</tr>
</tbody>
</table>

**Amazon CloudWatch metrics for Performance Insights**

Performance Insights automatically publishes metrics to Amazon CloudWatch. The same data can be queried from Performance Insights, but having the metrics in CloudWatch makes it easy to add CloudWatch alarms. It also makes it easy to add the metrics to existing CloudWatch Dashboards.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBLoad</td>
<td>The number of active sessions for the DB engine. Typically, you want the data for the average number of active sessions. In Performance Insights, this data is queried as db.load.avg.</td>
</tr>
<tr>
<td>DBLoadCPU</td>
<td>The number of active sessions where the wait event type is CPU. In Performance Insights, this data is queried as db.load.avg, filtered by the wait event type CPU.</td>
</tr>
<tr>
<td>DBLoadNonCPU</td>
<td>The number of active sessions where the wait event type is not CPU.</td>
</tr>
</tbody>
</table>

**Note**

These metrics are published to CloudWatch only if there is load on the DB instance.

You can examine these metrics using the CloudWatch console, the AWS CLI, or the CloudWatch API.

For example, you can get the statistics for the DBLoad metric by running the `get-metric-statistics` command.

```bash
aws cloudwatch get-metric-statistics
```
Counter metrics for Performance Insights

```
--region us-west-2 \
--namespace AWS/RDS \
--metric-name DBLoad \
--period 60 \
--statistics Average \
--start-time 1532035185 \
--end-time 1532036185 \
--dimensions Name=DBInstanceIdentifier,Value=db-loadtest-0
```

This example generates output similar to the following.

```
{
  "Datapoints": [
    {
      "Timestamp": "2021-07-19T21:30:00Z",
      "Unit": "None",
      "Average": 2.1
    },
    {

    {
      "Timestamp": "2021-07-19T21:29:00Z",
      "Unit": "None",
      "Average": 3.0
    },
    {
      "Timestamp": "2021-07-19T21:33:00Z",
      "Unit": "None",
      "Average": 2.4
    }
  ],
  "Label": "DBLoad"
}
```

**Performance Insights counter metrics**

Counter metrics are operating system and database performance metrics in the Performance Insights dashboard. To help identify and analyze performance problems, you can correlate counter metrics with DB load. You can add a statistic function to the metric to get the metric values. For example, the supported functions for `os.memory.active` metric are `.avg`, `.min`, `.max`, `.sum`, and `.sample_count`.
The counter metrics are collected one time each minute. The OS metrics collection depends on whether Enhanced Monitoring is turned on or off. If Enhanced Monitoring is turned off, the OS metrics are collected one time each minute. If Enhanced Monitoring is turned on, the OS metrics are collected for the selected time period. For more information about turning Enhanced Monitoring on or off, see Turning Enhanced Monitoring on and off (p. 799).

**Topics**
- Performance Insights operating system counters (p. 815)
- Performance Insights counters for Amazon RDS for MariaDB and MySQL (p. 820)
- Performance Insights counters for Amazon RDS for Microsoft SQL Server (p. 825)
- Performance Insights counters for Amazon RDS for Oracle (p. 826)
- Performance Insights counters for Amazon RDS for PostgreSQL (p. 828)

**Performance Insights operating system counters**

The following operating system counters, which are prefixed with `os`, are available with Performance Insights for all RDS engines except RDS for SQL Server.

You can use `ListAvailableResourceMetrics` API for the list of available counter metrics for your DB instance. For more information, see `ListAvailableResourceMetrics` in the Amazon RDS Performance Insights API Reference guide.

Non-native counters for Amazon RDS for MariaDB and MySQL

Non-native counter metrics are counters defined by Amazon RDS. A non-native metric can be a metric that you get with a specific query. A non-native metric also can be a derived metric, where two or more native counters are used in calculations for ratios, hit rates, or latencies.

<table>
<thead>
<tr>
<th>Counter</th>
<th>Type</th>
<th>Metric</th>
<th>Description</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>innodb_buffer_pool_hits</td>
<td>Cache</td>
<td>db.Cache.innoDB_buffer_pool_hits</td>
<td>Number of reads that InnoDB could satisfy from the buffer pool.</td>
<td><code>innodb_buffer_pool_read_requests - innodb_buffer_pool_reads</code></td>
</tr>
<tr>
<td>innodb_buffer_pool_hit_rate</td>
<td>Cache</td>
<td>db.Cache.innoDB_buffer_pool_hit_rate</td>
<td>Hit rate percentage of reads that InnoDB could satisfy from the buffer pool.</td>
<td><code>100 * innodb_buffer_pool_read_requests / (innodb_buffer_pool_read_requests + innodb_buffer_pool_reads)</code></td>
</tr>
<tr>
<td>innodb_buffer_pool_usage</td>
<td>Cache</td>
<td>db.Cache.innoDB_buffer_pool_usage</td>
<td>Usage percentage of the InnoDB buffer pool that contains data (pages).</td>
<td><code>Innodb_buffer_pool_pages_data / Innodb_buffer_pool_pages_total * 100.0</code></td>
</tr>
</tbody>
</table>

**Note**
When using compressed tables, this value can vary. For more information, see the information about `Innodb_buffer_pool_pages_data` and `Innodb_buffer_pool_pages_total` in `Server status variables` in the MySQL documentation.

### Performance Insights counters for Amazon RDS for Oracle

The following database counters are available with Performance Insights for RDS for Oracle.

#### Native counters for RDS for Oracle

Native metrics are defined by the database engine and not by Amazon RDS. You can find definitions for these native metrics in [Statistics Descriptions](#) in the Oracle documentation.

**Note**

For the CPU used by this session counter metric, the unit has been transformed from the native centiseconds to active sessions to make the value easier to use. For example, CPU send in the DB Load chart represents the demand for CPU. The counter metric CPU used by this
session represents the amount of CPU used by Oracle sessions. You can compare CPU send to the CPU used by this session counter metric. When demand for CPU is higher than CPU used, sessions are waiting for CPU time.

<table>
<thead>
<tr>
<th>Counter</th>

</tr>
<tr>
<td>checkpoint_write_latency</td>
<td>Checkpoint</td>
<td>db.Checkpoint.checkpoint_write_latency</td>
<td>The total amount of time that has been spent in the portion of checkpoint processing where files are written to disk.</td>
<td>checkpoint_write_time / (checkpoints_timed + checkpoints_req)</td>
</tr>
<tr>
<td>read_latency</td>
<td>I/O</td>
<td>db.IO.read_latency</td>
<td>The time spent reading data file blocks by backends in this instance.</td>
<td>blk_read_time / blks_read</td>
</tr>
</tbody>
</table>
Amazon Relational Database Service User Guide
SQL statistics for Performance Insights

SQL statistics are performance-related metrics about SQL queries that are collected by Performance Insights. Performance Insights gathers statistics for each second that a query is running and for each SQL call. The SQL statistics are an average for the selected time range.

A SQL digest is a composite of all queries having a given pattern but not necessarily having the same literal values. The digest replaces literal values with a question mark. For example, `SELECT * FROM emp WHERE lname= ?`. This digest might consist of the following child queries:

```
SELECT * FROM emp WHERE lname = 'Sanchez'
SELECT * FROM emp WHERE lname = 'Olagappan'
SELECT * FROM emp WHERE lname = 'Wu'
```

All engines support SQL statistics for digest queries.

For the region, DB engine, and instance class support information for this feature, see Amazon RDS DB engine, Region, and instance class support for Performance Insights features (p. 725)

Topics
- SQL statistics for MariaDB and MySQL (p. 830)
- SQL statistics for Oracle (p. 832)
- SQL statistics for SQL Server (p. 834)
- SQL statistics for RDS PostgreSQL (p. 835)

SQL statistics for MariaDB and MySQL

MariaDB and MySQL collect SQL statistics only at the digest level. No statistics are shown at the statement level.

Topics
- Digest statistics for MariaDB and MySQL (p. 830)
- Per-second statistics for MariaDB and MySQL (p. 831)
- Per-call statistics for MariaDB and MySQL (p. 831)

Digest statistics for MariaDB and MySQL

Performance Insights collects SQL digest statistics from the `events_statements_summary_by_digest` table. The `events_statements_summary_by_digest` table is managed by your database.

The digest table doesn't have an eviction policy. When the table is full, the AWS Management Console shows the following message:

```
Performance Insights is unable to collect SQL Digest statistics on new queries because the table events_statements_summary_by_digest is full. Please truncate events_statements_summary_by_digest table to clear the issue. Check the User Guide for more details.
```

In this situation, MariaDB and MySQL don't track SQL queries. To address this issue, Performance Insights automatically truncates the digest table when both of the following conditions are met:

- The table is full.
• Performance Insights manages the Performance Schema automatically.

For automatic management, the `performance_schema` parameter must be set to 0 and the `Source` must not be set to `user`. If Performance Insights isn't managing the Performance Schema automatically, see `Turning on the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL` (p. 731).

In the AWS CLI, check the source of a parameter value by running the `describe-db-parameters` command.

**Per-second statistics for MariaDB and MySQL**

The following SQL statistics are available for MariaDB and MySQL DB instances.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Unit</th>
</tr>
</thead>

### SQL statistics for Oracle

Amazon RDS for Oracle collects SQL statistics both at the statement and digest level. At the statement level, the ID column represents the value of `V$SQL.SQL_ID`. At the digest level, the ID column shows the value of `V$SQL.FORCE_MATCHING_SIGNATURE`.

If the ID is 0 at the digest level, Oracle Database has determined that this statement is not suitable for reuse. In this case, the child SQL statements could belong to different digests. However, the statements are grouped together under the `digest_text` for the first SQL statement collected.

**Topics**
- Per-second statistics for Oracle (p. 832)
- Per-call statistics for Oracle (p. 833)

### Per-second statistics for Oracle

The following metrics provide per-second statistics for an Oracle SQL query.

</tr>
<tr>
<td>db.sql_tokenized.stats.cpu_time_per_exec</td>
<td>CPU time per execution (in ms)</td>
</tr>
</tbody>
</table>
SQL statistics for SQL Server

Amazon RDS for SQL Server collects SQL statistics both at the statement and digest level. At the statement level, the ID column represents the value of `sql_handle`. At the digest level, the ID column shows the value of `query_hash`.

SQL Server returns NULL values for `query_hash` for a few statements. For example, `ALTER INDEX`, `CHECKPOINT`, `UPDATE STATISTICS`, `COMMIT TRANSACTION`, `FETCH NEXT FROM Cursor`, and a few `INSERT` statements, `SELECT @<variable>`, conditional statements, and executable stored procedures. In this case, the `sql_handle` value is displayed as the ID at the digest level for that statement.

### SQL statistics for RDS PostgreSQL

For each SQL call and for each second that a query runs, Performance Insights collects SQL statistics. RDS for PostgreSQL collect SQL statistics only at the digest-level. No statistics are shown at the statement-level.

Following, you can find information about digest-level statistics for RDS for PostgreSQL.

**Topics**

- [Digest statistics for RDS PostgreSQL (p. 835)](#)
- [Per-second digest statistics for RDS PostgreSQL (p. 836)](#)
- [Per-call digest statistics for RDS PostgreSQL (p. 836)](#)

### Digest statistics for RDS PostgreSQL

To view SQL digest statistics, RDS PostgreSQL must load the `pg_stat_statements` library. For PostgreSQL DB instances that are compatible with PostgreSQL 11 or later, the database loads this library by default. For PostgreSQL DB instances that are compatible with PostgreSQL 10 or earlier, enable this library manually. To enable it manually, add `pg_stat_statements` to `shared_preload_libraries` in the DB parameter group associated with the DB instance. Then reboot your DB instance. For more information, see [Working with parameter groups (p. 347)](#).

**Note**

Performance Insights can only collect statistics for queries in `pg_stat_activity` that aren't truncated. By default, PostgreSQL databases truncate queries longer than 1,024 bytes. To increase the query size, change the `track_activity_query_size` parameter in the DB
parameter group associated with your DB instance. When you change this parameter, a DB instance reboot is required.

**Per-second digest statistics for RDS PostgreSQL**

The following SQL digest statistics are available for PostgreSQL DB instances.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.sql_tokenized.stats.calls_per_sec</td>
<td>Calls per second</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.rows_per_sec</td>
<td>Rows per second</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.total_time_per_sec</td>
<td>Average active executions per second (AAE)</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.shared_blks_hit_per_sec</td>
<td>Block hits per second</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.shared_blks_read_per_sec</td>
<td>Block reads per second</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.shared_blks_dirtied_per_sec</td>
<td>Blocks dirtied per second</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.shared_blks_written_per_sec</td>
<td>Block writes per second</td>
</tr>

Monitoring events, logs, and streams in an Amazon RDS DB instance

When you monitor your Amazon RDS databases and your other AWS solutions, your goal is to maintain the following:

- Reliability
- Availability
- Performance
- Security

Monitoring metrics in an Amazon RDS instance (p. 678) explains how to monitor your instance using metrics. A complete solution must also monitor database events, log files, and activity streams. AWS provides you with the following monitoring tools:

- **Amazon EventBridge** is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications, Software-as-a-Service (SaaS) applications, and AWS services. EventBridge routes that data to targets such as AWS Lambda. This way, you can monitor events that happen in services and build event-driven architectures. For more information, see the Amazon EventBridge User Guide.

- **Amazon CloudWatch Logs** provides a way to monitor, store, and access your log files from Amazon RDS instances, AWS CloudTrail, and other sources. Amazon CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the Amazon CloudWatch Logs User Guide.

- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account. CloudTrail delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called AWS, the source IP address from which the calls were made, and when the calls occurred. For more information, see the AWS CloudTrail User Guide.

- **Database Activity Streams** is an Amazon RDS feature that provides a near real-time stream of the activity in your DB instance. Amazon RDS pushes activities to an Amazon Kinesis data stream. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Kinesis Data Firehose and AWS Lambda to consume the stream and store the data.

Topics
- Viewing logs, events, and streams in the Amazon RDS console (p. 846)
- Monitoring Amazon RDS events (p. 850)
- Monitoring Amazon RDS log files (p. 895)
- Monitoring Amazon RDS API calls in AWS CloudTrail (p. 940)
- Monitoring Amazon RDS with Database Activity Streams (p. 944)

Viewing logs, events, and streams in the Amazon RDS console

Amazon RDS integrates with AWS services to show information about logs, events, and database activity streams in the RDS console.
The Logs & events tab for your RDS DB instance shows the following information:

- **Amazon CloudWatch alarms** – Shows any metric alarms that you have configured for the DB instance. If you haven't configured alarms, you can create them in the RDS console. For more information, see Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 706).
- **Recent events** – Shows a summary of events (environment changes) for your RDS DB instance. For more information, see Viewing Amazon RDS events (p. 852).
- **Logs** – Shows database log files generated by a DB instance. For more information, see Monitoring Amazon RDS log files (p. 895).

The Configuration tab displays information about database activity streams.

**To view logs, events, and streams for your DB instance in the RDS console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB instance that you want to monitor.

The database page appears. The following example shows an Oracle database named orclb.

4. Choose Logs & events.

The Logs & events section appears.
5. Choose **Configuration**.

The following example shows the status of the database activity streams for your DB instance.
### Storage
- Encryption: Not enabled
- Storage type: General Purpose SSD (gp2)
- Provisioned IOPS: 1
- Storage: 98 GiB
- Storage autoscaling: Enabled
- Maximum storage threshold: 1000 GiB

### Performance Insights
- Performance Insights enabled: Yes
- AWS KMS key: aws/rds
- Retention period: 731 days

### Published logs
- CloudWatch Logs
  - Alert
  - Audit
  - Listener
  - Trace

### Database activity stream
- Status: Stopped
Monitoring Amazon RDS events

An event indicates a change in an environment. This can be an AWS environment, an SaaS partner service or application, or a custom application or service. For descriptions of the RDS events, see Amazon RDS event categories and event messages (p. 874).

Topics
- Overview of events for Amazon RDS (p. 850)
- Viewing Amazon RDS events (p. 852)
- Working with Amazon RDS event notification (p. 855)
- Creating a rule that triggers on an Amazon RDS event (p. 870)
- Amazon RDS event categories and event messages (p. 874)

Overview of events for Amazon RDS

An RDS event indicates a change in the Amazon RDS environment. For example, Amazon RDS generates an event when the state of a DB instance changes from pending to running. Amazon RDS delivers events to CloudWatch Events and EventBridge in near-real time.

Note
Amazon RDS emits events on a best effort basis. We recommend that you avoid writing programs that depend on the order or existence of notification events, because they might be out of sequence or missing.

Amazon RDS records events that relate to the following resources:

- DB instances
  For a list of DB instance events, see DB instance events (p. 876).
- DB parameter groups
  For a list of DB parameter group events, see DB parameter group events (p. 889).
- DB security groups
  For a list of DB security group events, see DB security group events (p. 890).
- DB snapshots
  For a list of DB snapshot events, see DB snapshot events (p. 890).
- RDS Proxy events
  For a list of RDS Proxy events, see RDS Proxy events (p. 891).
- Blue/green deployment events
  For a list of blue/green deployment events, see Blue/green deployment events (p. 892).

This information includes the following:

- The date and time of the event
- The source name and source type of the event
- A message associated with the event
- Event notifications include tags from when the message was sent and may not reflect tags at the time when the event occurred
Viewing Amazon RDS events

You can retrieve the following event information for your Amazon RDS resources:

- Resource name
- Resource type
- Time of the event
- Message summary of the event

Access the events through the AWS Management Console, which shows events from the past 24 hours. You can also retrieve events by using the `describe-events` AWS CLI command, or the `DescribeEvents` RDS API operation. If you use the AWS CLI or the RDS API to view events, you can retrieve events for up to the past 14 days.

**Note**

If you need to store events for longer periods of time, you can send Amazon RDS events to CloudWatch Events. For more information, see [Creating a rule that triggers on an Amazon RDS event](p. 870)

For descriptions of the Amazon RDS events, see [Amazon RDS event categories and event messages](p. 874).

To access detailed information about events using AWS CloudTrail, including request parameters, see [CloudTrail events](p. 940).

**Console**

**To view all Amazon RDS events for the past 24 hours**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Events**.
   - The available events appear in a list.
3. (Optional) Enter a search term to filter your results.
   - The following example shows a list of events filtered by the characters **stopped**.

![RDS Events](image)

**AWS CLI**

To view all events generated in the last hour, call `describe-events` with no parameters.
aws rds describe-events

The following sample output shows that a DB instance has been stopped.

```
{
  "Events": [
    {
      "EventCategories": [ "notification" ],
      "SourceType": "db-instance",
      "Date": "2022-04-22T21:31:00.681Z",
      "Message": "DB instance stopped",
      "SourceIdentifier": "testinst"
    }
  ]
}
```

To view all Amazon RDS events for the past 10080 minutes (7 days), call the `describe-events` AWS CLI command and set the `--duration` parameter to 10080.

```
aws rds describe-events --duration 10080
```

The following example shows the events in the specified time range for DB instance `test-instance`.

```
aws rds describe-events \
  --source-identifier test-instance \
  --source-type db-instance \
  --start-time 2022-03-13T22:00Z \
  --end-time 2022-03-13T23:59Z
```

The following sample output shows the status of a backup.

```
{
  "Events": [
    {
      "SourceType": "db-instance",
      "SourceIdentifier": "test-instance",
      "EventCategories": [ "backup" ],
      "Message": "Backing up DB instance",
      "Date": "2022-03-13T23:09:23.983Z",
      "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:test-instance"
    },
    {
      "SourceType": "db-instance",
      "SourceIdentifier": "test-instance",
      "EventCategories": [ "backup" ],
      "Message": "Finished DB Instance backup",
      "Date": "2022-03-13T23:15:13.049Z",
      "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:test-instance"
    }
  ]
}
```
You can view all Amazon RDS instance events for the past 14 days by calling the `DescribeEvents` RDS API operation and setting the `Duration` parameter to 20160.
Working with Amazon RDS event notification

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint.

Topics

- Overview of Amazon RDS event notification (p. 855)
- Granting permissions to publish notifications to an Amazon SNS topic (p. 859)
- Subscribing to Amazon RDS event notification (p. 860)
- Amazon RDS event notification tags and attributes (p. 863)
- Listing Amazon RDS event notification subscriptions (p. 864)
- Modifying an Amazon RDS event notification subscription (p. 865)
- Adding a source identifier to an Amazon RDS event notification subscription (p. 866)
- Removing a source identifier from an Amazon RDS event notification subscription (p. 867)
- Listing the Amazon RDS event notification categories (p. 868)
- Deleting an Amazon RDS event notification subscription (p. 869)

Overview of Amazon RDS event notification

Amazon RDS groups events into categories that you can subscribe to so that you can be notified when an event in that category occurs.

Topics

- RDS resources eligible for event subscription (p. 855)
- Basic process for subscribing to Amazon RDS event notifications (p. 856)
- Delivery of RDS event notifications (p. 856)
- Billing for Amazon RDS event notifications (p. 856)
- Examples of Amazon RDS events (p. 856)

RDS resources eligible for event subscription

You can subscribe to an event category for the following resources:

- DB instance
- DB snapshot
- DB parameter group
- DB security group
- RDS Proxy
- Custom engine version

For example, if you subscribe to the backup category for a given DB instance, you're notified whenever a backup-related event occurs that affects the DB instance. If you subscribe to a configuration change category for a DB instance, you're notified when the DB instance is changed. You also receive notification when an event notification subscription changes.

You might want to create several different subscriptions. For example, you might create one subscription that receives all event notifications for all DB instances and another subscription that includes only critical events for a subset of the DB instances. For the second subscription, specify one or more DB instances in the filter.
Basic process for subscribing to Amazon RDS event notifications

The process for subscribing to Amazon RDS event notification is as follows:

1. You create an Amazon RDS event notification subscription by using the Amazon RDS console, AWS CLI, or API.

   Amazon RDS uses the ARN of an Amazon SNS topic to identify each subscription. The Amazon RDS console creates the ARN for you when you create the subscription. Create the ARN by using the Amazon SNS console, the AWS CLI, or the Amazon SNS API.

2. Amazon RDS sends an approval email or SMS message to the addresses you submitted with your subscription.

3. You confirm your subscription by choosing the link in the notification you received.

4. The Amazon RDS console updates the **My Event Subscriptions** section with the status of your subscription.

5. Amazon RDS begins sending the notifications to the addresses that you provided when you created the subscription.

To learn about identity and access management when using Amazon SNS, see [Identity and access management in Amazon SNS](https://docs.aws.amazon.com/sns/latest/dg/sns-security.html) in the *Amazon Simple Notification Service Developer Guide*.

You can use AWS Lambda to process event notifications from a DB instance. For more information, see [Using AWS Lambda with Amazon RDS](https://docs.aws.amazon.com/lambda/latest/dg/with-rds.html) in the *AWS Lambda Developer Guide*.

Delivery of RDS event notifications

Amazon RDS sends notifications to the addresses that you provide when you create the subscription. The notification can include message attributes which provide structured metadata about the message. For more information about message attributes, see [Amazon RDS event categories and event messages](#)

Event notifications might take up to five minutes to be delivered.

**Important**

Amazon RDS doesn't guarantee the order of events sent in an event stream. The event order is subject to change.

When Amazon SNS sends a notification to a subscribed HTTP or HTTPS endpoint, the POST message sent to the endpoint has a message body that contains a JSON document. For more information, see [Amazon SNS message and JSON formats](https://docs.aws.amazon.com/sns/latest/dg/sns-json.html) in the *Amazon Simple Notification Service Developer Guide*.

You can configure SNS to notify you with text messages. For more information, see [Mobile text messaging (SMS)](https://docs.aws.amazon.com/sns/latest/dg/sms-messaging.html) in the *Amazon Simple Notification Service Developer Guide*.

To turn off notifications without deleting a subscription, choose **No** for **Enabled** in the Amazon RDS console. Or you can set the **Enabled** parameter to `false` using the AWS CLI or Amazon RDS API.

Billing for Amazon RDS event notifications

Billing for Amazon RDS event notification is through Amazon SNS. Amazon SNS fees apply when using event notification. For more information about Amazon SNS billing, see [Amazon Simple Notification Service pricing](https://aws.amazon.com/sns/pricing/).

Examples of Amazon RDS events

The following examples illustrate different types of Amazon RDS events in JSON format. For a tutorial that shows you how to capture and view events in JSON format, see [Tutorial: Log DB instance state changes using Amazon EventBridge](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/连忙 GetValue from DB Instance Events in JSON Format).
Example of a DB instance event

The following is an example of a DB instance event in JSON format. The event shows that RDS performed a multi-AZ failover for the instance named `my-db-instance`. The event ID is RDS-EVENT-0049.

```
{
  "version": "0",
  "id": "68f6e973-1a0c-d37b-f2f2-94a7f62ff4d4e",
  "detail-type": "RDS DB Instance Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-09-27T22:36:43Z",
  "region": "us-east-1",
  "resources": ["arn:aws:rds:us-east-1:123456789012:db:my-db-instance"],
  "detail": {
    "EventCategories": ["failover"],
    "SourceType": "DB_INSTANCE",
    "Date": "2018-09-27T22:36:43.292Z",
    "Message": "A Multi-AZ failover has completed.",
    "SourceIdentifier": "rds:my-db-instance",
    "EventID": "RDS-EVENT-0049"
  }
}
```

Example of a DB parameter group event

The following is an example of a DB parameter group event in JSON format. The event shows that the parameter `time_zone` was updated in parameter group `my-db-param-group`. The event ID is RDS-EVENT-0037.

```
{
  "version": "0",
  "id": "844e2571-85d4-695f-b930-0153b71dcb42",
  "detail-type": "RDS DB Parameter Group Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-10-06T12:26:13Z",
  "region": "us-east-1",
  "resources": ["arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group"],

  }
}
```
Example of a DB snapshot event

The following is an example of a DB snapshot event in JSON format. The event shows the deletion of the snapshot named my-db-snapshot. The event ID is RDS-EVENT-0041.

```json
{
    "version": "0",
    "id": "844e2571-85d4-695f-b930-0153b71dcb42",
    "detail-type": "RDS DB Snapshot Event",
    "source": "aws.rds",
    "account": "123456789012",
    "time": "2018-10-06T12:26:13Z",
    "region": "us-east-1",
    "resources": [
    ],
    "detail": {
        "EventCategories": ["deletion"],
        "SourceType": "SNAPSHOT",
        "Date": "2018-10-06T12:26:13.882Z",
        "Message": "Deleted manual snapshot",
        "SourceIdentifier": "rds:my-db-snapshot",
        "EventID": "RDS-EVENT-0041"
    }
}
```
Granting permissions to publish notifications to an Amazon SNS topic

To grant Amazon RDS permissions to publish notifications to an Amazon Simple Notification Service (Amazon SNS) topic, attach an AWS Identity and Access Management (IAM) policy to the destination topic. For more information about permissions, see Example cases for Amazon Simple Notification Service access control in the Amazon Simple Notification Service Developer Guide.

By default, an Amazon SNS topic has a policy allowing all Amazon RDS resources within the same account to publish notifications to it. You can attach a custom policy to allow cross-account notifications, or to restrict access to certain resources.

The following is an example of an IAM policy that you attach to the destination Amazon SNS topic. It restricts the topic to DB instances with names that match the specified prefix. To use this policy, specify the following values:

- **Resource** – The Amazon Resource Name (ARN) for your Amazon SNS topic
- **SourceARN** – Your RDS resource ARN
- **SourceAccount** – Your AWS account ID

To see a list of resource types and their ARNs, see Resources Defined by Amazon RDS in the Service Authorization Reference.

```json
{
  "Version": "2008-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "events.rds.amazonaws.com"
      },
      "Action": [
        "sns:Publish"
      ],
      "Condition": {
        "ArnLike": {
        },
        "StringEquals": {
          "aws:SourceAccount": "123456789012"
        }
      }
    }
  ]
}
```
Subscribing to Amazon RDS event notification

The simplest way to create a subscription is with the RDS console. If you choose to create event notification subscriptions using the CLI or API, you must create an Amazon Simple Notification Service topic and subscribe to that topic with the Amazon SNS console or Amazon SNS API. You will also need to retain the Amazon Resource Name (ARN) of the topic because it is used when submitting CLI commands or API operations. For information on creating an SNS topic and subscribing to it, see Getting started with Amazon SNS in the Amazon Simple Notification Service Developer Guide.

You can specify the type of source you want to be notified of and the Amazon RDS source that triggers the event:

**Source type**

The type of source. For example, Source type might be Instances. You must choose a source type.

**Resources to include**

The Amazon RDS resources that are generating the events. For example, you might choose Select specific instances and then myDBInstance1.

The following table explains the result when you specify or don't specify Resources to include.

<table>
<thead>
<tr>
<th>Resources to include</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specified</td>
<td>RDS notifies you about all events for the specified resource only.</td>
<td>If your Source type is Instances and your resource is myDBInstance1, RDS notifies you about all events for myDBInstance1 only.</td>
</tr>
<tr>
<td>Not specified</td>
<td>RDS notifies you about the events for the specified source type for all your Amazon RDS resources.</td>
<td>If your Source type is Instances, RDS notifies you about all instance-related events in your account.</td>
</tr>
</tbody>
</table>

An Amazon SNS topic subscriber receives every message published to the topic by default. To receive only a subset of the messages, the subscriber must assign a filter policy to the topic subscription. For more information about SNS message filtering, see Amazon SNS message filtering in the Amazon Simple Notification Service Developer Guide.

**Console**

To subscribe to RDS event notification

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In navigation pane, choose Event subscriptions.
3. In the Event subscriptions pane, choose Create event subscription.
4. Enter your subscription details as follows:
   a. For Name, enter a name for the event notification subscription.
   b. For Send notifications to, do one of the following:
      - Choose New email topic. Enter a name for your email topic and a list of recipients. We recommend that you configure the events subscriptions to the same email address as
Choosing an Amazon Resource Name (ARN). Then choose existing Amazon SNS ARN for an Amazon SNS topic.

If you want to use a topic that has been enabled for server-side encryption (SSE), grant Amazon RDS the necessary permissions to access the AWS KMS key. For more information, see Enable compatibility between event sources from AWS services and encrypted topics in the Amazon Simple Notification Service Developer Guide.

c. For **Source type**, choose a source type. For example, choose **Instances** or **Parameter groups**.

d. Choose the event categories and resources that you want to receive event notifications for.

The following example configures event notifications for the DB instance named `testinst`.

```
Source

Source type
Source type of resource this subscription will consume events from

Instances

Instances to include
Instances that this subscription will consume events from

- All instances
- Select specific instances

Specific instances
Select instances

[testinst]

Event categories to include
Event categories that this subscription will consume events from

- All event categories
- Select specific event categories
```

e. Choose **Create**.

The Amazon RDS console indicates that the subscription is being created.

AWS CLI

To subscribe to RDS event notification, use the AWS CLI `create-event-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`
Example

For Linux, macOS, or Unix:

```
aws rds create-event-subscription \
   --subscription-name myeventsubscription \
   --sns-topic-arn arn:aws:sns:us-east-1:123456789012:myawsuser-RDS \
   --enabled
```

For Windows:

```
aws rds create-event-subscription ^
   --subscription-name myeventsubscription ^
   --sns-topic-arn arn:aws:sns:us-east-1:123456789012:myawsuser-RDS ^
   --enabled
```

API

To subscribe to Amazon RDS event notification, call the Amazon RDS API function `CreateEventSubscription`. Include the following required parameters:

- SubscriptionName
- SnsTopicArn
Amazon RDS event notification tags and attributes

When Amazon RDS sends an event notification to Amazon Simple Notification Service (SNS) or Amazon EventBridge, the notification contains message attributes and event tags. RDS sends the message attributes separately along with the message, while the event tags are in the body of the message. Use the message attributes and the Amazon RDS tags to add metadata to your resources. You can modify these tags with your own notations about the DB instances. For more information about tagging Amazon RDS resources, see Tagging Amazon RDS resources (p. 461).

By default, the Amazon SNS and Amazon EventBridge receives every message sent to them. SNS and EventBridge can filter the message and send the notifications to the preferred communication mode, such as an email, a text message, or a call to an HTTP endpoint.

Note
The notification sent in an email or a text message will not have event tags.

The following table shows the message attributes for RDS events sent to the topic subscriber.

<table>
<thead>
<tr>
<th>Amazon RDS event attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EventID</td>
<td>Identifier for the RDS event message, for example, <code>RDS-EVENT-0006</code>.</td>
</tr>
<tr>
<td>Resource</td>
<td>The ARN identifier for the resource emitting the event, for example, <code>arn:aws:rds:ap-southeast-2:123456789012:db:database-1</code>.</td>
</tr>
</tbody>
</table>

The RDS tags provide data about the resource that was affected by the service event. RDS adds the current state of the tags in the message body when the notification is sent to SNS or EventBridge.

For more information about filtering message attributes for SNS, see Amazon SNS message filtering in the Amazon Simple Notification Service Developer Guide.

For more information about filtering event tags for EventBridge, see Content filtering in Amazon EventBridge event patterns in the Amazon EventBridge User Guide.

For more information about filtering payload-based tags for SNS, see https://aws.amazon.com/blogs/compute/introducing-payload-based-message-filtering-for-amazon-sns/
Listing Amazon RDS event notification subscriptions

You can list your current Amazon RDS event notification subscriptions.

**Console**

**To list your current Amazon RDS event notification subscriptions**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Event subscriptions**. The **Event subscriptions** pane shows all your event notification subscriptions.

**AWS CLI**

To list your current Amazon RDS event notification subscriptions, use the AWS CLI `describe-event-subscriptions` command.

**Example**

The following example describes all event subscriptions.

```
aws rds describe-event-subscriptions
```

The following example describes the `myfirsteventssubscription`.

```
aws rds describe-event-subscriptions --subscription-name myfirsteventssubscription
```

**API**

To list your current Amazon RDS event notification subscriptions, call the Amazon RDS API `DescribeEventSubscriptions` action.
Modifying an Amazon RDS event notification subscription

After you have created a subscription, you can change the subscription name, source identifier, categories, or topic ARN.

**Console**

**To modify an Amazon RDS event notification subscription**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Event subscriptions.
3. In the Event subscriptions pane, choose the subscription that you want to modify and choose Edit.
4. Make your changes to the subscription in either the Target or Source section.
5. Choose Edit. The Amazon RDS console indicates that the subscription is being modified.

**AWS CLI**

To modify an Amazon RDS event notification subscription, use the AWS CLI `modify-event-subscription` command. Include the following required parameter:

- `--subscription-name`

**Example**

The following code enables myeventsubscription.

For Linux, macOS, or Unix:

```
aws rds modify-event-subscription \
   --subscription-name myeventsubscription \
   --enabled
```

For Windows:

```
aws rds modify-event-subscription ^
   --subscription-name myeventsubscription ^
   --enabled
```

**API**

To modify an Amazon RDS event, call the Amazon RDS API operation `ModifyEventSubscription`. Include the following required parameter:

- `SubscriptionName`
Adding a source identifier to an Amazon RDS event notification subscription

You can add a source identifier (the Amazon RDS source generating the event) to an existing subscription.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see Modifying an Amazon RDS event notification subscription (p. 865).

AWS CLI

To add a source identifier to an Amazon RDS event notification subscription, use the AWS CLI add-source-identifier-to-subscription command. Include the following required parameters:

• --subscription-name
• --source-identifier

Example

The following example adds the source identifier mysql to the myrdseventsubscription subscription.

For Linux, macOS, or Unix:

```bash
aws rds add-source-identifier-to-subscription \
  --subscription-name myrdseventsubscription \
  --source-identifier mysql
```

For Windows:

```bash
aws rds add-source-identifier-to-subscription ^
  --subscription-name myrdseventsubscription ^
  --source-identifier mysql
```

API

To add a source identifier to an Amazon RDS event notification subscription, call the Amazon RDS API AddSourceIdentifierToSubscription. Include the following required parameters:

• SubscriptionName
• SourceIdentifier
Removing a source identifier from an Amazon RDS event notification subscription

You can remove a source identifier (the Amazon RDS source generating the event) from a subscription if you no longer want to be notified of events for that source.

**Console**

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see [Modifying an Amazon RDS event notification subscription](p. 865).

**AWS CLI**

To remove a source identifier from an Amazon RDS event notification subscription, use the AWS CLI `remove-source-identifier-from-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--source-identifier`

**Example**

The following example removes the source identifier `mysqldb` from the `myrdseventsubscription` subscription.

For Linux, macOS, or Unix:

```
aws rds remove-source-identifier-from-subscription
     --subscription-name myrdseventsubscription \ 
     --source-identifier mysqldb
```

For Windows:

```
aws rds remove-source-identifier-from-subscription ^
     --subscription-name myrdseventsubscription ^
     --source-identifier mysqldb
```

**API**

To remove a source identifier from an Amazon RDS event notification subscription, use the Amazon RDS API `RemoveSourceIdentifierFromSubscription` command. Include the following required parameters:

- `SubscriptionName`
- `SourceIdentifier`
Listing the Amazon RDS event notification categories

All events for a resource type are grouped into categories. To view the list of categories available, use the following procedures.

**Console**

When you create or modify an event notification subscription, the event categories are displayed in the Amazon RDS console. For more information, see [Modifying an Amazon RDS event notification subscription](p. 865).

**AWS CLI**

To list the Amazon RDS event notification categories, use the AWS CLI `describe-event-categories` command. This command has no required parameters.

**Example**

```
aws rds describe-event-categories
```

**API**

To list the Amazon RDS event notification categories, use the Amazon RDS API `DescribeEventCategories` command. This command has no required parameters.
Deleting an Amazon RDS event notification subscription

You can delete a subscription when you no longer need it. All subscribers to the topic will no longer receive event notifications specified by the subscription.

**Console**

**To delete an Amazon RDS event notification subscription**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **DB Event Subscriptions**.
3. In the **My DB Event Subscriptions** pane, choose the subscription that you want to delete.
4. Choose **Delete**.
5. The Amazon RDS console indicates that the subscription is being deleted.

**AWS CLI**

To delete an Amazon RDS event notification subscription, use the AWS CLI `delete-event-subscription` command. Include the following required parameter:

- `--subscription-name`

**Example**

The following example deletes the subscription `myrdssubscription`.

```
aws rds delete-event-subscription --subscription-name myrdssubscription
```

**API**

To delete an Amazon RDS event notification subscription, use the RDS API `DeleteEventSubscription` command. Include the following required parameter:

- `SubscriptionName`
Creating a rule that triggers on an Amazon RDS event

Using Amazon CloudWatch Events and Amazon EventBridge, you can automate AWS services and respond to system events such as application availability issues or resource changes.

Topics

• Creating rules to send Amazon RDS events to CloudWatch Events (p. 870)
• Tutorial: Log DB instance state changes using Amazon EventBridge (p. 871)

Creating rules to send Amazon RDS events to CloudWatch Events

You can write simple rules to indicate which Amazon RDS events interest you and which automated actions to take when an event matches a rule. You can set a variety of targets, such as an AWS Lambda function or an Amazon SNS topic, which receive events in JSON format. For example, you can configure Amazon RDS to send events to CloudWatch Events or Amazon EventBridge whenever a DB instance is created or deleted. For more information, see the Amazon CloudWatch Events User Guide and the Amazon EventBridge User Guide.

To create a rule that triggers on an RDS event:

2. Under Events in the navigation pane, choose Rules.
3. Choose Create rule.
4. For Event Source, do the following:
   a. Choose Event Pattern.
   b. For Service Name, choose Relational Database Service (RDS).
   c. For Event Type, choose the type of Amazon RDS resource that triggers the event. For example, if a DB instance triggers the event, choose RDS DB Instance Event.
5. For Targets, choose Add Target and choose the AWS service that is to act when an event of the selected type is detected.
6. In the other fields in this section, enter information specific to this target type, if any is needed.
7. For many target types, CloudWatch Events needs permissions to send events to the target. In these cases, CloudWatch Events can create the IAM role needed for your event to run:
   • To create an IAM role automatically, choose Create a new role for this specific resource.
   • To use an IAM role that you created before, choose Use existing role.
8. Optionally, repeat steps 5-7 to add another target for this rule.
9. Choose Configure details. For Rule definition, type a name and description for the rule.

The rule name must be unique within this Region.
10. Choose Create rule.

For more information, see Creating a CloudWatch Events Rule That Triggers on an Event in the Amazon CloudWatch User Guide.
Tutorial: Log DB instance state changes using Amazon EventBridge

In this tutorial, you create an AWS Lambda function that logs the state changes for an Amazon RDS instance. You then create a rule that runs the function whenever there is a state change of an existing RDS DB instance. The tutorial assumes that you have a small running test instance that you can shut down temporarily.

**Important**

Don't perform this tutorial on a running production DB instance.

**Topics**

- [Step 1: Create an AWS Lambda function (p. 871)]
- [Step 2: Create a rule (p. 872)]
- [Step 3: Test the rule (p. 872)]

**Step 1: Create an AWS Lambda function**

Create a Lambda function to log the state change events. You specify this function when you create your rule.

**To create a Lambda function**

2. If you’re new to Lambda, you see a welcome page. Choose **Get Started Now**. Otherwise, choose **Create function**.
3. Choose **Author from scratch**.
4. On the **Create function** page, do the following:
   a. Enter a name and description for the Lambda function. For example, name the function **RDSInstanceStateChange**.
   b. In **Runtime**, select **Node.js 16x**.
   c. For **Architecture**, choose **x86_64**.
   d. For **Execution role**, do either of the following:
      - Choose **Create a new role with basic Lambda permissions**.
      - For **Existing role**, choose **Use an existing role**. Choose the role that you want to use.
   e. Choose **Create function**.
5. On the **RDSInstanceStateChange** page, do the following:
   a. In **Code source**, select **index.js**.
   b. In the **index.js** pane, delete the existing code.
   c. Enter the following code:

```javascript
console.log('Loading function');
exports.handler = async (event, context) => {
  console.log('Received event:', JSON.stringify(event));
};
```
   d. Choose **Deploy**.
Step 2: Create a rule

Create a rule to run your Lambda function whenever you launch an Amazon RDS instance.

To create the EventBridge rule

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. In the navigation pane, choose Rules.
3. Choose Create rule.
4. Enter a name and description for the rule. For example, enter RDSInstanceStateChangeRule.
5. Choose Rule with an event pattern, and then choose Next.
6. For Event source, choose AWS events or EventBridge partner events.
7. Scroll down to the Event pattern section.
8. For Event source, choose AWS services.
9. For AWS service, choose Relational Database Service (RDS).
10. For Event type, choose RDS DB Instance Event.
11. Leave the default event pattern. Then choose Next.
12. For Target types, choose AWS service.
13. For Select a target, choose Lambda function.
14. For Function, choose the Lambda function that you created. Then choose Next.
15. In Configure tags, choose Next.
16. Review the steps in your rule. Then choose Create rule.

Step 3: Test the rule

To test your rule, shut down an RDS DB instance. After waiting a few minutes for the instance to shut down, verify that your Lambda function was invoked.

To test your rule by stopping a DB instance

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Stop an RDS DB instance.
3. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
4. In the navigation pane, choose Rules, choose the name of the rule that you created.
5. In Rule details, choose Monitoring.
6. In All metrics, choose the name of the rule that you created.
7. The graph should indicate that the rule was invoked.
8. In the navigation pane, choose Log groups.
9. Choose the name of the log group for your Lambda function (/aws/lambda/function-name).
10. Choose the name of the log stream to view the data provided by the function for the instance that you launched. You should see a received event similar to the following:

```json
{
    "version": "0",
    "id": "12a345b6-78c9-01d2-34e5-123f4ghi5j6k",
    "detail-type": "RDS DB Instance Event",
    "source": "aws.rds",
    "detail": {
        "eventSource": "rds.amazonaws.com",
        "eventName": "dbinstance terminating",
        "instanceId": "db-0123456789",
        "resourceType": "DBInstance",
        "region": "us-west-2"
    }
}
```
For more examples of RDS events in JSON format, see Overview of events for Amazon RDS (p. 850).

10. (Optional) When you're finished, you can open the Amazon RDS console and start the instance that you stopped.
Amazon RDS event categories and event messages

Amazon RDS generates a significant number of events in categories that you can subscribe to using the Amazon RDS Console, AWS CLI, or the API.

Topics
- DB cluster events (p. 874)
- DB instance events (p. 876)
- DB parameter group events (p. 889)
- DB security group events (p. 890)
- DB snapshot events (p. 890)
- DB cluster snapshot events (p. 891)
- RDS Proxy events (p. 891)
- Blue/green deployment events (p. 892)
- Custom engine version events (p. 893)

DB cluster events

The following table shows the event category and a list of events when a DB cluster is the source type.

For more information about Multi-AZ DB cluster deployments, see Multi-AZ DB cluster deployments (p. 499)

<table>
<thead>
<tr>
<th>Category</th>
<th>RDS event ID</th>
<th>Message</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>creation</td>
<td>RDS-EVENT-0170</td>
<td>DB cluster created.</td>
<td></td>
</tr>
<tr>
<td>failover</td>
<td>RDS-EVENT-0069</td>
<td>Cluster failover failed, check the health of your cluster instances and try again.</td>
<td></td>
</tr>
<tr>
<td>failover</td>
<td>RDS-EVENT-0070</td>
<td>Promoting previous primary again: name.</td>
<td></td>
</tr>
<tr>
<td>failover</td>
<td>RDS-EVENT-0071</td>
<td>Completed failover to DB instance: name.</td>
<td></td>
</tr>
<tr>
<td>failover</td>
<td>RDS-EVENT-0072</td>
<td>Started same AZ failover to DB instance: name.</td>
<td></td>
</tr>
<tr>
<td>failover</td>
<td>RDS-EVENT-0073</td>
<td>Started cross AZ failover to DB instance: name.</td>
<td></td>
</tr>
<tr>
<td>global failover</td>
<td>RDS-EVENT-0181</td>
<td>Global switchover to DB cluster name in Region name started.</td>
<td>This event is for a switchover operation (previously called &quot;managed planned failover&quot;). The process can be delayed because other operations are running on the DB cluster.</td>
</tr>
<tr>
<td>global failover</td>
<td>RDS-EVENT-0182</td>
<td>Old primary DB cluster name in Region name successfully shut down.</td>
<td>This event is for a switchover operation (previously called &quot;managed planned failover&quot;).</td>
</tr>
<tr>

</tbody>
</table>
DB security group events

The following table shows the event category and a list of events when a DB security group is the source type.

**Note**

DB security groups are resources for EC2-Classic. EC2-Classic was retired on August 15, 2022. If you haven't migrated from EC2-Classic to a VPC, we recommend that you migrate as soon as possible. For more information, see [Migrate from EC2-Classic to a VPC](#) in the *Amazon EC2 User Guide* and the blog [EC2-Classic Networking is Retiring – Here’s How to Prepare](#).

Monitoring Amazon RDS log files

Every RDS database engine generates logs that you can access for auditing and troubleshooting. The type of logs depends on your database engine.

You can access database logs using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API. You can't view, watch, or download transaction logs.

Topics
• Viewing and listing database log files (p. 895)
• Downloading a database log file (p. 896)
• Watching a database log file (p. 897)
• Publishing database logs to Amazon CloudWatch Logs (p. 898)
• Reading log file contents using REST (p. 900)
• MariaDB database log files (p. 902)
• Microsoft SQL Server database log files (p. 911)
• MySQL database log files (p. 915)
• Oracle database log files (p. 924)
• RDS for PostgreSQL database log files (p. 931)

Viewing and listing database log files

You can view database log files for your Amazon RDS DB engine by using the AWS Management Console. You can list what log files are available for download or monitoring by using the AWS CLI or Amazon RDS API.

Note
If you can't view the list of log files for an existing RDS for Oracle DB instance, reboot the instance to view the list.

Console

To view a database log file
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the Logs & events tab.
5. Scroll down to the Logs section.
6. (Optional) Enter a search term to filter your results.
7. Choose the log that you want to view, and then choose View.

AWS CLI

To list the available database log files for a DB instance, use the AWS CLI describe-db-log-files command.

The following example returns a list of log files for a DB instance named my-db-instance.
Example

```bash
aws rds describe-db-log-files --db-instance-identifier my-db-instance
```

RDS API

To list the available database log files for a DB instance, use the Amazon RDS API `DescribeDBLogFile` action.

Downloading a database log file

You can use the AWS Management Console, AWS CLI, or API to download a database log file.

Console

To download a database log file

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the Logs & events tab.
5. Scroll down to the Logs section.
6. In the Logs section, choose the button next to the log that you want to download, and then choose Download.
7. Open the context (right-click) menu for the link provided, and then choose Save Link As. Enter the location where you want the log file to be saved, and then choose Save.

AWS CLI

To download a database log file, use the AWS CLI command `download-db-log-file-portion`. By default, this command downloads only the latest portion of a log file. However, you can download an entire file by specifying the parameter `--starting-token 0`.

The following example shows how to download the entire contents of a log file called `log/ERROR.4` and store it in a local file called `errorlog.txt`.

Example

For Linux, macOS, or Unix:
aws rds download-db-log-file-portion \
   --db-instance-identifier myexampledb \
   --starting-token 0 --output text \
   --log-file-name log/ERROR.4 > errorlog.txt

For Windows:

aws rds download-db-log-file-portion ^
   --db-instance-identifier myexampledb ^
   --starting-token 0 --output text ^
   --log-file-name log/ERROR.4 > errorlog.txt

**RDS API**

To download a database log file, use the Amazon RDS API [DownloadDBLogFilePortion](https://docs.aws.amazon.com/AmazonRDS/latest/APIReference/API_DownloadDBLogFilePortion.html) action.

**Watching a database log file**

Watching a database log file is equivalent to tailing the file on a UNIX or Linux system. You can watch a log file by using the AWS Management Console. RDS refreshes the tail of the log every 5 seconds.

**To watch a database log file**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.

   ![](image)

5. In the **Logs** section, choose a log file, and then choose **Watch**.

   ![](image)

RDS shows the tail of the log, as in the following MySQL example.
Publishing database logs to Amazon CloudWatch Logs

In an on-premises database, the database logs reside on the file system. Amazon RDS doesn't provide host access to the database logs on the file system of your DB instance. For this reason, Amazon RDS lets you export database logs to Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data. You can also store the data in highly durable storage and manage the data with the CloudWatch Logs Agent.

Topics

- Overview of RDS integration with CloudWatch Logs (p. 898)
- Deciding which logs to publish to CloudWatch Logs (p. 899)
- Specifying the logs to publish to CloudWatch Logs (p. 899)
- Searching and filtering your logs in CloudWatch Logs (p. 899)

Overview of RDS integration with CloudWatch Logs

In CloudWatch Logs, a log stream is a sequence of log events that share the same source. Each separate source of logs in CloudWatch Logs makes up a separate log stream. A log group is a group of log streams that share the same retention, monitoring, and access control settings.

Amazon RDS continuously streams your DB instance log records to a log group. For example, you have a log group /aws/rds/instance/instance_name/log_type for each type of log that you publish. This log group is in the same AWS Region as the database instance that generates the log.

AWS retains log data published to CloudWatch Logs for an indefinite time period unless you specify a retention period. For more information, see Change log data retention in CloudWatch Logs.
Deciding which logs to publish to CloudWatch Logs

Each RDS database engine supports its own set of logs. To learn about the options for your database engine, review the following topics:

- the section called “Publishing MariaDB logs to Amazon CloudWatchLogs” (p. 904)
- the section called “Publishing MySQL logs to Amazon CloudWatchLogs” (p. 918)
- the section called “Publishing Oracle logs to Amazon CloudWatchLogs” (p. 927)
- the section called “Publishing PostgreSQL logs to Amazon CloudWatchLogs” (p. 936)
- the section called “Publishing SQL Server logs to Amazon CloudWatchLogs” (p. 911)

Specifying the logs to publish to CloudWatch Logs

You specify which logs to publish in the console. Make sure that you have a service-linked role in AWS Identity and Access Management (IAM). For more information about service-linked roles, see Using service-linked roles for Amazon RDS (p. 2701).

To specify the logs to publish

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Do either of the following:
   - Choose Create database.
   - Choose a database from the list, and then choose Modify.
4. In Logs exports, choose which logs to publish.

   The following example specifies the audit log, error logs, general log, and slow query log.

   ![Log exports](image)

   The following service-linked role is used for publishing logs to CloudWatch Logs.

   IAM role
   The following service-linked role is used for publishing logs to CloudWatch Logs.

   RDS Service Linked Role

Searching and filtering your logs in CloudWatch Logs

You can search for log entries that meet a specified criteria using the CloudWatch Logs console. You can access the logs either through the RDS console, which leads you to the CloudWatch Logs console, or from the CloudWatch Logs console directly.
To search your RDS logs using the RDS console
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose a DB instance.
4. Choose Configuration.
5. Under Published logs, choose the database log that you want to view.

To search your RDS logs using the CloudWatch Logs console
2. In the navigation pane, choose Log groups.
3. In the filter box, enter /aws/rds.
4. For Log Groups, choose the name of the log group containing the log stream to search.
5. For Log Streams, choose the name of the log stream to search.
6. Under Log events, enter the filter syntax to use.

For more information, see Searching and filtering log data in the Amazon CloudWatch Logs User Guide. For a blog tutorial explaining how to monitor RDS logs, see Build proactive database monitoring for Amazon RDS with Amazon CloudWatch Logs, AWS Lambda, and Amazon SNS.

Reading log file contents using REST
Amazon RDS provides a REST endpoint that allows access to DB instance log files. This is useful if you need to write an application to stream Amazon RDS log file contents.

The syntax is:

```
GET /v13/downloadCompleteLogFile/DBInstanceId/LogFileName HTTP/1.1
Content-type: application/json
host: rds.region.amazonaws.com
```

The following parameters are required:

- **DBInstanceId**—the name of the DB instance that contains the log file you want to download.
- **LogFileName**—the name of the log file to be downloaded.

The response contains the contents of the requested log file, as a stream.

The following example downloads the log file named log/ERROR.6 for the DB instance named sample-sql in the us-west-2 region.

```
GET /v13/downloadCompleteLogFile/sample-sql/log/ERROR.6 HTTP/1.1
host: rds.us-west-2.amazonaws.com
X-Amz-Security-Token: AQoDYXdxEH/--------
wEa0AIrHngC5z9CylR6aobWxK7HR5efnAVN3XvR71wqKYa1Fsn6UyJUfEFTft9n0bql1x4QJ+GVV9cpACkETq=
X-Amz-Date: 20140903T233749Z
X-Amz-Algorith: AWS4-HMAC-SHA256
X-Amz-Credential: AKIADQKE4SARGYLE/20140903/us-west-2/rds/aws4_request
X-Amz-SignedHeaders: host
X-Amz-Content-SHA256: e3b0c44298fc1c229afbf4c8996fb92427ae41e4649b934de495991b7852b855
X-Amz-Expires: 86400
```
If you specify a nonexistent DB instance, the response consists of the following error:

- **DBInstanceNotFound**—`DBInstanceIdentifier` does not refer to an existing DB instance. (HTTP status code: 404)
MariaDB database log files

You can monitor the MariaDB error log, slow query log, and the general log. The MariaDB error log is generated by default; you can generate the slow query and general logs by setting parameters in your DB parameter group. Amazon RDS rotates all of the MariaDB log files; the intervals for each type are given following.

You can monitor the MariaDB logs directly through the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs. You can also access MariaDB logs by directing the logs to a database table in the main database and querying that table. You can use the mysqlbinlog utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files (p. 895).

Topics
- Accessing MariaDB error logs (p. 902)
- Accessing the MariaDB slow query and general logs (p. 902)
- Publishing MariaDB logs to Amazon CloudWatch Logs (p. 904)
- Log file size (p. 906)
- Managing table-based MariaDB logs (p. 906)
- Binary logging format (p. 907)
- Accessing MariaDB binary logs (p. 908)
- Binary log annotation (p. 909)

Accessing MariaDB error logs

The MariaDB error log is written to the <host-name>.err file. You can view this file by using the Amazon RDS console, You can also retrieve the log using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs. The <host-name>.err file is flushed every 5 minutes, and its contents are appended to mysql-error-running.log. The mysql-error-running.log file is then rotated every hour and the hourly files generated during the last 24 hours are retained. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

MariaDB writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server did not encounter an error that resulted in a log entry.

Accessing the MariaDB slow query and general logs

You can write the MariaDB slow query log and general log to a file or database table by setting parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see Working with parameter groups (p. 347). You must set these parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, AWS CLI, or AWS SDKs.

You can control MariaDB logging by using the parameters in this list:
- slow_query_log: To create the slow query log, set to 1. The default is 0.
- general_log: To create the general log, set to 1. The default is 0.
- long_query_time: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query run time to be logged, in seconds. The default is 10 seconds; the
minimum is 0. If log_output = FILE, you can specify a floating point value that goes to microsecond resolution. If log_output = TABLE, you must specify an integer value with second resolution. Only queries whose run time exceeds the long_query_time value are logged. For example, setting long_query_time to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.

- log_queries_not_using_indexes: To log all queries that do not use an index to the slow query log, set this parameter to 1. The default is 0. Queries that do not use an index are logged even if their run time is less than the value of the long_query_time parameter.
- log_output option: You can specify one of the following options for the log_output parameter:
  - TABLE (default)– Write general queries to the mysql.general_log table, and slow queries to the mysql.slow_log table.
  - FILE– Write both general and slow query logs to the file system. Log files are rotated hourly.
  - NONE– Disable logging.

When logging is enabled, Amazon RDS rotates table logs or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. FILE and TABLE logging approach rotation and deletion as follows:

- When FILE logging is enabled, log files are examined every hour and log files older than 24 hours are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 2 percent of a DB instance's allocated space. In these cases, the largest log files are deleted until the log file size no longer exceeds the threshold.
- When TABLE logging is enabled, in some cases log tables are rotated every 24 hours. This rotation occurs if the space used by the table logs is more than 20 percent of the allocated storage space. It also occurs if the size of all logs combined is greater than 10 GB. If the amount of space used for a DB instance is greater than 90 percent of the DB instance's allocated storage space, the thresholds for log rotation are reduced. Log tables are then rotated if the space used by the table logs is more than 10 percent of the allocated storage space. They're also rotated if the size of all logs combined is greater than 5 GB.

When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the mysql.general_log table is named mysql.general_log_backup. The backup log table for the mysql.slow_log table is named mysql.slow_log_backup.

You can rotate the mysql.general_log table by calling the mysql.rds_rotate_general_log procedure. You can rotate the mysql.slow_log table by calling the mysql.rds_rotate_slow_log procedure.

Table logs are rotated during a database version upgrade.

Amazon RDS records both TABLE and FILE log rotation in an Amazon RDS event and sends you a notification.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the log_output parameter to FILE. Like the MariaDB error log, these log files are rotated hourly. The log files that were generated during the previous 24 hours are retained.

For more information about the slow query and general logs, go to the following topics in the MariaDB documentation:

- Slow query log
- General query log
Publishing MariaDB logs to Amazon CloudWatch Logs

You can configure your MariaDB DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each MariaDB database log as a separate database stream in the log group. For example, suppose that you configure the export function to include the slow query log. Then slow query data is stored in a slow query log stream in the /aws/eks/instance/my_instance/slowquery log group.

The error log is enabled by default. The following table summarizes the requirements for the other MariaDB logs.

<table>
<thead>
<tr>
<th>Log</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audit log</td>
<td>The DB instance must use a custom option group with the MARIADB_AUDIT_PLUGIN option.</td>
</tr>
<tr>
<td>General log</td>
<td>The DB instance must use a custom parameter group with the parameter setting general_log = 1 to enable the general log.</td>
</tr>
<tr>
<td>Slow query log</td>
<td>The DB instance must use a custom parameter group with the parameter setting slow_query_log = 1 to enable the slow query log.</td>
</tr>
<tr>
<td>Log output</td>
<td>The DB instance must use a custom parameter group with the parameter setting log_output = FILE to write logs to the file system and publish them to CloudWatch Logs.</td>
</tr>
</tbody>
</table>

Console

To publish MariaDB logs to CloudWatch Logs from the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.
3. Choose Modify.
4. In the Log exports section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose Continue, and then choose Modify DB Instance on the summary page.

AWS CLI

You can publish a MariaDB logs with the AWS CLI. You can call the modify-db-instance command with the following parameters:

• --db-instance-identifier
• --cloudwatch-logs-export-configuration
Note
A change to the --cloudwatch-logs-export-configuration option is always applied to the DB instance immediately. Therefore, the --apply-immediately and --no-apply-immediately options have no effect.

You can also publish MariaDB logs by calling the following AWS CLI commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-instance-identifier`
- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`
- `--engine`

Other options might be required depending on the AWS CLI command you run.

Example

The following example modifies an existing MariaDB DB instance to publish log files to CloudWatch Logs. The --cloudwatch-logs-export-configuration value is a JSON object. The key for this object is EnableLogTypes, and its value is an array of strings with any combination of audit, error, general, and slowquery.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["audit","error","general","slowquery"]}'
```

For Windows:

```bash
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["audit","error","general","slowquery"]}'
```

Example

The following command creates a MariaDB DB instance and publishes log files to CloudWatch Logs. The --enable-cloudwatch-logs-exports value is a JSON array of strings. The strings can be any combination of audit, error, general, and slowquery.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '["audit","error","general","slowquery"]'
```
RDS API

You can publish MariaDB logs with the RDS API. You can call the ModifyDBInstance operation with the following parameters:

- DBInstanceIdentifier
- CloudwatchLogsExportConfiguration

**Note**
A change to the CloudwatchLogsExportConfiguration parameter is always applied to the DB instance immediately. Therefore, the ApplyImmediately parameter has no effect.

You can also publish MariaDB logs by calling the following RDS API operations:

- CreateDBInstance
- RestoreDBInstanceFromDBSnapshot
- RestoreDBInstanceFromS3
- RestoreDBInstanceToPointInTime

Run one of these RDS API operations with the following parameters:

- DBInstanceIdentifier
- EnableCloudwatchLogsExports
- Engine
- DBInstanceClass

Other parameters might be required depending on the AWS CLI command you run.

Log file size

The MariaDB slow query log, error log, and the general log file sizes are constrained to no more than 2 percent of the allocated storage space for a DB instance. To maintain this threshold, logs are automatically rotated every hour and log files older than 24 hours are removed. If the combined log file size exceeds the threshold after removing old log files, then the largest log files are deleted until the log file size no longer exceeds the threshold.

Managing table-based MariaDB logs

You can direct the general and slow query logs to tables on the DB instance. To do so, create a DB parameter group and set the log_output server parameter to TABLE. General queries are then logged
to the mysql.general_log table, and slow queries are logged to the mysql.slow_log table. You
can query the tables to access the log information. Enabling this logging increases the amount of data
written to the database, which can degrade performance.

Both the general log and the slow query logs are disabled by default. In order to enable logging to
tables, you must also set the general_log and slow_query_log server parameters to 1.

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate
parameter to 0. A large amount of data often accumulates over time, which can use up a considerable
percentage of your allocated storage space. Amazon RDS does not allow you to truncate the log tables,
but you can move their contents. Rotating a table saves its contents to a backup table and then creates
a new empty log table. You can manually rotate the log tables with the following command line
procedures, where the command prompt is indicated by PROMPT>:

PROMPT> CALL mysql.rds_rotate_slow_log;
PROMPT> CALL mysql.rds_rotate_general_log;

To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in
succession.

**Binary logging format**

MariaDB on Amazon RDS supports the row-based, statement-based, and mixed binary logging formats.
The default binary logging format is mixed. For details on the different MariaDB binary log formats, see
**Binary log formats** in the MariaDB documentation.

If you plan to use replication, the binary logging format is important. This is because it determines
the record of data changes that is recorded in the source and sent to the replication targets. For
information about the advantages and disadvantages of different binary logging formats for replication,
see [Advantages and disadvantages of statement-based and row-based replication](#) in the MySQL
documentation.

**Important**

Setting the binary logging format to row-based can result in very large binary log files. Large
binary log files reduce the amount of storage available for a DB instance. They also can increase
the amount of time to perform a restore operation of a DB instance.

Statement-based replication can cause inconsistencies between the source DB instance and a
read replica. For more information, see [Unsafe statements for statement-based replication](#) in
the MariaDB documentation.

**To set the MariaDB binary logging format**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://
   console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group that is used by the DB instance that you want to modify.

   You can't modify a default parameter group. If the DB instance is using a default parameter group,
   create a new parameter group and associate it with the DB instance.

   For more information on DB parameter groups, see [Working with parameter groups](#) (p. 347).
4. For Parameter group actions, choose Edit.
5. Set the binlog_format parameter to the binary logging format of your choice (ROW, STATEMENT,
or MIXED).
6. Choose Save changes to save the updates to the DB parameter group.
Accessing MariaDB binary logs

You can use the mysqlbinlog utility to download binary logs in text format from MariaDB DB instances. The binary log is downloaded to your local computer. For more information about using the mysqlbinlog utility, go to Using mysqlbinlog in the MariaDB documentation.

To run the mysqlbinlog utility against an Amazon RDS instance, use the following options:

- Specify the --read-from-remote-server option.
- --host: Specify the DNS name from the endpoint of the instance.
- --port: Specify the port used by the instance.
- --user: Specify a MariaDB user that has been granted the replication slave permission.
- --password: Specify the password for the user, or omit a password value so the utility prompts you for a password.
- --result-file: Specify the local file that receives the output.
- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command SHOW BINARY LOGS.

For more information about mysqlbinlog options, go to mysqlbinlog options in the MariaDB documentation.

The following is an example:

For Linux, macOS, or Unix:

```
mysqlbinlog \
    --read-from-remote-server \
    --host=mariadbinstance1.1234abcd.region.rds.amazonaws.com \
    --port=3306 \
    --user ReplUser \
    --password <password> \
    --result-file=/tmp/binlog.txt
```

For Windows:

```
mysqlbinlog ^
    --read-from-remote-server ^
    --host=mariadbinstance1.1234abcd.region.rds.amazonaws.com ^
    --port=3306 ^
    --user ReplUser ^
    --password <password> ^
    --result-file=/tmp/binlog.txt
```

Amazon RDS normally purges a binary log as soon as possible. However, the binary log must still be available on the instance to be accessed by mysqlbinlog. To specify the number of hours for RDS to retain binary logs, use the mysql.rds_set_configuration stored procedure. Specify a period with enough time for you to download the logs. After you set the retention period, monitor storage usage for the DB instance to ensure that the retained binary logs don't take up too much storage.

The following example sets the retention period to 1 day.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the mysql.rds_show_configuration stored procedure.
call mysql.rds_show_configuration;

**Binary log annotation**

In a MariaDB DB instance, you can use the `Annotate_rows` event to annotate a row event with a copy of the SQL query that caused the row event. This approach provides similar functionality to enabling the `binlog_rows_query_log_events` parameter on an RDS for MySQL DB instance.

You can enable binary log annotations globally by creating a custom parameter group and setting the `binlog_annotate_row_events` parameter to 1. You can also enable annotations at the session level, by calling `SET SESSION binlog_annotate_row_events = 1`. Use the `replicate_annotate_row_events` to replicate binary log annotations to the replica instance if binary logging is enabled on it. No special privileges are required to use these settings.

The following is an example of a row-based transaction in MariaDB. The use of row-based logging is triggered by setting the transaction isolation level to read-committed.

```
CREATE DATABASE IF NOT EXISTS test;
USE test;
CREATE TABLE square(x INT PRIMARY KEY, y INT NOT NULL) ENGINE = InnoDB;
SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED;
BEGIN
  INSERT INTO square(x, y) VALUES(5, 5 * 5);
COMMIT;
```

Without annotations, the binary log entries for the transaction look like the following:

```
BEGIN
  /*!*/;
  # at 1163
  #150922 7:55:57 server id 1855786460  end_log_pos 1209
  Table_map: `test`.`square`
mapped to number 76
  #150922 7:55:57 server id 1855786460  end_log_pos 1247
  Write_rows: table id 76
  flags: STMT_END_F
  ### INSERT INTO `test`.`square`
  ### SET
  ###   @1=5
  ###   @2=25
  # at 1247
  #150922 7:56:01 server id 1855786460  end_log_pos 1274
  Xid = 62
COMMIT/*!*/;
```

The following statement enables session-level annotations for this same transaction, and disables them after committing the transaction:

```
CREATE DATABASE IF NOT EXISTS test;
USE test;
CREATE TABLE square(x INT PRIMARY KEY, y INT NOT NULL) ENGINE = InnoDB;
SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED;
SET SESSION binlog_annotate_row_events = 1;
BEGIN;
  INSERT INTO square(x, y) VALUES(5, 5 * 5);
COMMIT;
SET SESSION binlog_annotate_row_events = 0;
```

With annotations, the binary log entries for the transaction look like the following:

```
BEGIN
  909
```
/*!*/;
# at 423
# at 483
# at 529
#150922 8:04:24 server id 1855786460 end_log_pos 483 Annotate_rows:
#Q> INSERT INTO square(x, y) VALUES(5, 5 * 5)
#150922 8:04:24 server id 1855786460 end_log_pos 529 Table_map: `test`.`square` mapped to number 76
#150922 8:04:24 server id 1855786460 end_log_pos 567 Write_rows: table id 76 flags:
### INSERT INTO `test`.`square`
### SET
###   @1=5
###   @2=25
# at 567
#150922 8:04:26 server id 1855786460 end_log_pos 594 Xid = 88
COMMIT/*!*/;
Microsoft SQL Server database log files

You can access Microsoft SQL Server error logs, agent logs, trace files, and dump files by using the Amazon RDS console, AWS CLI, or RDS API. For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files (p. 895).

Topics

• Retention schedule (p. 911)
• Viewing the SQL Server error log by using the rds_read_error_log procedure (p. 911)
• Publishing SQL Server logs to Amazon CloudWatch Logs (p. 911)

Retention schedule

Log files are rotated each day and whenever your DB instance is restarted. The following is the retention schedule for Microsoft SQL Server logs on Amazon RDS.

<table>
<thead>
<tr>
<th>Log type</th>
<th>Retention schedule</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error logs</td>
<td>A maximum of 30 error logs are retained. Amazon RDS might delete error logs older than 7 days.</td>
</tr>
<tr>
<td>Agent logs</td>
<td>A maximum of 10 agent logs are retained. Amazon RDS might delete agent logs older than 7 days.</td>
</tr>
<tr>
<td>Trace files</td>
<td>Trace files are retained according to the trace file retention period of your DB instance. The default trace file retention period is 7 days. To modify the trace file retention period for your DB instance, see Setting the retention period for trace and dump files (p. 1637).</td>
</tr>
<tr>
<td>Dump files</td>
<td>Dump files are retained according to the dump file retention period of your DB instance. The default dump file retention period is 7 days. To modify the dump file retention period for your DB instance, see Setting the retention period for trace and dump files (p. 1637).</td>
</tr>
</tbody>
</table>

Viewing the SQL Server error log by using the rds_read_error_log procedure

You can use the Amazon RDS stored procedure rds_read_error_log to view error logs and agent logs. For more information, see Viewing error and agent logs (p. 1636).

Publishing SQL Server logs to Amazon CloudWatch Logs

With Amazon RDS for SQL Server, you can publish error and agent log events directly to Amazon CloudWatch Logs. Analyze the log data with CloudWatch Logs, then use CloudWatch to create alarms and view metrics.

With CloudWatch Logs, you can do the following:

• Store logs in highly durable storage space with a retention period that you define.
• Search and filter log data.
• Share log data between accounts.
• Export logs to Amazon S3.
• Stream data to Amazon OpenSearch Service.
• Process log data in real time with Amazon Kinesis Data Streams. For more information, see Working with Amazon CloudWatch Logs in the Amazon Managed Service for Apache Flink for SQL Applications Developer Guide.

Amazon RDS publishes each SQL Server database log as a separate database stream in the log group. For example, if you publish error logs, error data is stored in an error log stream in the /aws/ids/instance/my_instance/error log group.

For Multi-AZ DB instances, Amazon RDS publishes the database log as two separate streams in the log group. For example, if you publish the error logs, the error data is stored in the error log streams /aws/ids/instance/my_instance.node1/error and /aws/ids/instance/my_instance.node2/error respectively. The log streams don't change during a failover and the error log stream of each node can contain error logs from primary or secondary instance.

**Note**
Publishing SQL Server logs to CloudWatch Logs isn't enabled by default. Publishing trace and dump files isn't supported. Publishing SQL Server logs to CloudWatch Logs is supported in all regions, except for Asia Pacific (Hong Kong).

**Console**

**To publish SQL Server DB logs to CloudWatch Logs from the AWS Management Console**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.
3. Choose Modify.
4. In the Log exports section, choose the logs that you want to start publishing to CloudWatch Logs.
    
    You can choose Agent log, Error log, or both.
5. Choose Continue, and then choose Modify DB Instance on the summary page.

**AWS CLI**

To publish SQL Server logs, you can use the modify-db-instance command with the following parameters:

• --db-instance-identifier
• --cloudwatch-logs-export-configuration

**Note**
A change to the --cloudwatch-logs-export-configuration option is always applied to the DB instance immediately. Therefore, the --apply-immediately and --no-apply-immediately options have no effect.

You can also publish SQL Server logs using the following commands:

• create-db-instance
• restore-db-instance-from-db-snapshot
• restore-db-instance-to-point-in-time
Example

The following example creates an SQL Server DB instance with CloudWatch Logs publishing enabled. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings that can include error, agent, or both.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
  --db-instance-identifier mydbinstance \
  --enable-cloudwatch-logs-exports ['"error","agent"'] \
  --db-instance-class db.m4.large \
  --engine sqlserver-se
```

For Windows:

```bash
aws rds create-db-instance ^
  --db-instance-identifier mydbinstance ^
  --enable-cloudwatch-logs-exports "["error","agent"]" ^
  --db-instance-class db.m4.large ^
  --engine sqlserver-se
```

Note

When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

Example

The following example modifies an existing SQL Server DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings that can include error, agent, or both.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --cloudwatch-logs-export-configuration '{"EnableLogTypes":["error","agent"]}'
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --cloudwatch-logs-export-configuration "{"EnableLogTypes":["error","agent"]}"
```

Note

When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

Example

The following example modifies an existing SQL Server DB instance to disable publishing agent log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `DisableLogTypes`, and its value is an array of strings that can include error, agent, or both.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --cloudwatch-logs-export-configuration '{"DisableLogTypes":["error","agent"]}'
```
--db-instance-identifier mydbinstance \
--cloudwatch-logs-export-configuration '{"DisableLogTypes":["agent"]}'

For Windows:

```bash
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--cloudwatch-logs-export-configuration "{"DisableLogTypes":["agent"]}"
```

**Note**

When using the Windows command prompt, you must escape double quotes ("') in JSON code by prefixing them with a backslash (\).
MySQL database log files

You can monitor the MySQL logs directly through the Amazon RDS console, Amazon RDS API, AWS CLI, or AWS SDKs. You can also access MySQL logs by directing the logs to a database table in the main database and querying that table. You can use the mysqlbinlog utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files (p. 895).

Topics

- Overview of RDS for MySQL database logs (p. 915)
- Publishing MySQL logs to Amazon CloudWatch Logs (p. 918)
- Managing table-based MySQL logs (p. 920)
- Configuring MySQL binary logging (p. 921)
- Accessing MySQL binary logs (p. 922)

Overview of RDS for MySQL database logs

You can monitor the following types of RDS for MySQL log files:

- Error log
- Slow query log
- General log
- Audit log

The RDS for MySQL error log is generated by default. You can generate the slow query and general logs by setting parameters in your DB parameter group.

Topics

- RDS for MySQL error logs (p. 915)
- RDS for MySQL slow query and general logs (p. 916)
- MySQL audit log (p. 916)
- Log rotation and retention for RDS for MySQL (p. 916)
- Size limits on redo logs (p. 917)
- Size limits on BLOBs written to the redo log (p. 917)

RDS for MySQL error logs

RDS for MySQL writes errors in the mysql-error.log file. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

RDS for MySQL writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it’s because the server didn’t encounter an error that would result in a log entry.

By design, the error logs are filtered so that only unexpected events such as errors are shown. However, the error logs also contain some additional database information, for example query progress, which isn’t shown. Therefore, even without any actual errors the size of the error logs might increase because of ongoing database activities. And while you might see a certain size in bytes or kilobytes for the error logs in the AWS Management Console, they might have 0 bytes when you download them.
RDS for MySQL writes `mysql-error.log` to disk every 5 minutes. It appends the contents of the log to `mysql-error-running.log`.

RDS for MySQL rotates the `mysql-error-running.log` file every hour. It retains the logs generated during the last two weeks.

**Note**

The log retention period is different between Amazon RDS and Aurora.

### RDS for MySQL slow query and general logs

You can write the RDS for MySQL slow query log and the general log to a file or a database table. To do so, set parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see [Working with parameter groups](p. 347). You must set these parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs.

You can control RDS for MySQL logging by using the parameters in this list:

- `slow_query_log`: To create the slow query log, set to 1. The default is 0.
- `general_log`: To create the general log, set to 1. The default is 0.
- `long_query_time`: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query runtime to be logged, in seconds. The default is 10 seconds; the minimum is 0. If `log_output = FILE`, you can specify a floating point value that goes to microsecond resolution. If `log_output = TABLE`, you must specify an integer value with second resolution. Only queries whose runtime exceeds the `long_query_time` value are logged. For example, setting `long_query_time` to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.
- `log_queries_not_using_indexes`: To log all queries that do not use an index to the slow query log, set to 1. Queries that don't use an index are logged even if their runtime is less than the value of the `long_query_time` parameter. The default is 0.
- `log_output option`: You can specify one of the following options for the `log_output` parameter.
  - `TABLE` (default) – Write general queries to the `mysql.general_log` table, and slow queries to the `mysql.slow_log` table.
  - `FILE` – Write both general and slow query logs to the file system.
  - `NONE` – Disable logging.

For more information about the slow query and general logs, go to the following topics in the MySQL documentation:

- [The slow query log](#)
- [The general query log](#)

### MySQL audit log

To access the audit log, the DB instance must use a custom option group with the `MARIADB_AUDIT_PLUGIN` option. For more information, see [MariaDB Audit Plugin support for MySQL](p. 1749).

### Log rotation and retention for RDS for MySQL

When logging is enabled, Amazon RDS rotates table logs or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. RDS for MySQL handles rotation and deletion as follows:
• The MySQL slow query log, error log, and the general log file sizes are constrained to no more than 2 percent of the allocated storage space for a DB instance. To maintain this threshold, logs are automatically rotated every hour. MySQL removes log files more than two weeks old. If the combined log file size exceeds the threshold after removing old log files, then the oldest log files are deleted until the log file size no longer exceeds the threshold.

• When FILE logging is enabled, log files are examined every hour and log files more than two weeks old are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 2 percent of a DB instance's allocated space. In these cases, the oldest log files are deleted until the log file size no longer exceeds the threshold.

• When TABLE logging is enabled, in some cases log tables are rotated every 24 hours. This rotation occurs if the space used by the table logs is more than 20 percent of the allocated storage space. It also occurs if the size of all logs combined is greater than 10 GB. If the amount of space used for a DB instance is greater than 90 percent of the DB instance's allocated storage space, then the thresholds for log rotation are reduced. Log tables are then rotated if the space used by the table logs is more than 10 percent of the allocated storage space. They're also rotated if the size of all logs combined is greater than 5 GB. You can subscribe to the low_free_storage event to be notified when log tables are rotated to free up space. For more information, see Working with Amazon RDS event notification (p. 855).

When log tables are rotated, the current log table is first copied to a backup log table. Then the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the mysql.general_log table is named mysql.general_log_backup. The backup log table for the mysql.slow_log table is named mysql.slow_log_backup.

You can rotate the mysql.general_log table by calling the mysql.rds_rotate_general_log procedure. You can rotate the mysql.slow_log table by calling the mysql.rds_rotate_slow_log procedure.

Table logs are rotated during a database version upgrade.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the log_output parameter to FILE. Like the MySQL error log, these log files are rotated hourly. The log files that were generated during the previous two weeks are retained. Note that the retention period is different between Amazon RDS and Aurora.

Size limits on redo logs

For RDS for MySQL version 8.0.28 and lower, the innodb_log_file_size parameter determines the size of redo logs. The default value of this parameter is 256 MB. For information about limitations related to this limit, see Size limits on BLOBs written to the redo log (p. 917). For more information on how redo log size is calculated for these versions of MySQL, see innodb_log_file_size in the MySQL documentation.

For RDS for MySQL version 8.0.30 and higher, the innodb_redo_log_capacity parameter is used instead of the innodb_log_file_size parameter. The default value of the innodb_redo_log_capacity parameter is 256 MB. For more information, see Changes in MySQL 8.0.30 in the MySQL documentation.

Size limits on BLOBs written to the redo log

For RDS for MySQL version 8.0.30 and higher, the innodb_redo_log_capacity parameter is used instead of the innodb_log_file_size parameter. The size limit doesn't apply to the innodb_redo_log_capacity parameter. For more information, see Size limits on redo logs (p. 917).
Publishing MySQL logs to Amazon CloudWatch Logs

You can configure your MySQL DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each MySQL database log as a separate database stream in the log group. For example, if you configure the export function to include the slow query log, slow query data is stored in a slow query log stream in the /aws/rds/instance/my_instance/slowquery log group.

The error log is enabled by default. The following table summarizes the requirements for the other MySQL logs.

<table>
<thead>
<tr>
<th>Log</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audit log</td>
<td>The DB instance must use a custom option group with the MARIADB_AUDIT_PLUGIN option.</td>
</tr>
<tr>
<td>General log</td>
<td>The DB instance must use a custom parameter group with the parameter setting general_log = 1 to enable the general log.</td>
</tr>
<tr>
<td>Slow query log</td>
<td>The DB instance must use a custom parameter group with the parameter setting slow_query_log = 1 to enable the slow query log.</td>
</tr>
<tr>
<td>Log output</td>
<td>The DB instance must use a custom parameter group with the parameter setting log_output = FILE to write logs to the file system and publish them to CloudWatch Logs.</td>
</tr>
</tbody>
</table>

**Console**

To publish MySQL logs to CloudWatch Logs using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.
3. Choose Modify.
4. In the Log exports section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose Continue, and then choose Modify DB Instance on the summary page.

**AWS CLI**

You can publish MySQL logs with the AWS CLI. You can call the modify-db-instance command with the following parameters:

- --db-instance-identifier
- --cloudwatch-logs-export-configuration
Note
A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish MySQL logs by calling the following AWS CLI commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-instance-identifier`
- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`
- `--engine`

Other options might be required depending on the AWS CLI command you run.

Example
The following example modifies an existing MySQL DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["audit","error","general","slowquery"]}'
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["audit","error","general","slowquery"]}'
```

Example
The following example creates a MySQL DB instance and publishes log files to CloudWatch Logs. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings. The strings can be any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
  --db-instance-identifier mydbinstance \
  --enable-cloudwatch-logs-exports ['"audit","error","general","slowquery"]' \
  --db-instance-class db.m4.large \
```

Example
The following example modifies an existing MySQL DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["audit","error","general","slowquery"]}'
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["audit","error","general","slowquery"]}'
```
RDS API

You can publish MySQL logs with the RDS API. You can call the ModifyDBInstance action with the following parameters:

- **DBInstanceIdentifier**
- **CloudwatchLogsExportConfiguration**

**Note**
A change to the CloudwatchLogsExportConfiguration parameter is always applied to the DB instance immediately. Therefore, the ApplyImmediately parameter has no effect.

You can also publish MySQL logs by calling the following RDS API operations:

- [CreateDBInstance](#)
- [RestoreDBInstanceFromDBSnapshot](#)
- [RestoreDBInstanceFromS3](#)
- [RestoreDBInstanceToPointInTime](#)

Run one of these RDS API operations with the following parameters:

- **DBInstanceIdentifier**
- **EnableCloudwatchLogsExports**
- **Engine**
- **DBInstanceClass**

Other parameters might be required depending on the AWS CLI command you run.

Managing table-based MySQL logs

You can direct the general and slow query logs to tables on the DB instance by creating a DB parameter group and setting the log_output server parameter to TABLE. General queries are then logged to the mysql.general_log table, and slow queries are logged to the mysql.slow_log table. You can query the tables to access the log information. Enabling this logging increases the amount of data written to the database, which can degrade performance.

Both the general log and the slow query logs are disabled by default. In order to enable logging to tables, you must also set the general_log and slow_query_log server parameters to 1.

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate parameter to 0. A large amount of data often accumulates over time, which can use up a considerable percentage of your allocated storage space. Amazon RDS doesn't allow you to truncate the log tables,
but you can move their contents. Rotating a table saves its contents to a backup table and then creates a new empty log table. You can manually rotate the log tables with the following command line procedures, where the command prompt is indicated by PROMPT>:

```
PROMPT> CALL mysql.rds_rotate_slow_log;
PROMPT> CALL mysql.rds_rotate_general_log;
```

To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in succession.

**Configuring MySQL binary logging**

The binary log is a set of log files that contain information about data modifications made to an MySQL server instance. The binary log contains information such as the following:

- Events that describe database changes such as table creation or row modifications
- Information about the duration of each statement that updated data
- Events for statements that could have updated data but didn’t

The binary log records statements that are sent during replication. It is also required for some recovery operations. For more information, see [The Binary Log](https://dev.mysql.com/doc/refman/8.0/en/log-rotation.html) and [Binary Log Overview](https://dev.mysql.com/doc/refman/8.0/en/log-rotation.html) in the MySQL documentation.

The automated backups feature determines whether binary logging is turned on or off for MySQL. You have the following options:

Turn binary logging on
- Set the backup retention period to a positive nonzero value.

Turn binary logging off
- Set the backup retention period to zero.

For more information, see [Enabling automated backups (p. 593)](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_MySQL.html#CHAP_MySQL.BinaryLog).

MySQL on Amazon RDS supports the **row-based**, **statement-based**, and **mixed** binary logging formats. We recommend mixed unless you need a specific binlog format. For details on the different MySQL binary log formats, see [Binary logging formats](https://dev.mysql.com/doc/refman/8.0/en/log-rotation.html) in the MySQL documentation.

If you plan to use replication, the binary logging format is important because it determines the record of data changes that is recorded in the source and sent to the replication targets. For information about the advantages and disadvantages of different binary logging formats for replication, see [Advantages and disadvantages of statement-based and row-based replication](https://dev.mysql.com/doc/refman/8.0/en/log-rotation.html) in the MySQL documentation.

**Important**

Setting the binary logging format to row-based can result in very large binary log files. Large binary log files reduce the amount of storage available for a DB instance and can increase the amount of time to perform a restore operation of a DB instance. Statement-based replication can cause inconsistencies between the source DB instance and a read replica. For more information, see [Determination of safe and unsafe statements in binary logging](https://dev.mysql.com/doc/refman/8.0/en/log-rotation.html) in the MySQL documentation.

Enabling binary logging increases the number of write disk I/O operations to the DB instance. You can monitor IOPS usage with the WriteIOPS CloudWatch metric.

**To set the MySQL binary logging format**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
In the navigation pane, choose Parameter groups.

Choose the parameter group used by the DB instance you want to modify. You can’t modify a default parameter group. If the DB instance is using a default parameter group, create a new parameter group and associate it with the DB instance.

For more information on parameter groups, see Working with parameter groups (p. 347).

4. From Parameter group actions, choose Edit.

5. Set the binlog_format parameter to the binary logging format of your choice (ROW, STATEMENT, or MIXED).

You can turn off binary logging by setting the backup retention period of a DB instance to zero, but this disables daily automated backups. We recommend that you don’t disable backups. For more information about the Backup retention period setting, see Settings for DB instances (p. 402).

6. Choose Save changes to save the updates to the DB parameter group.

Because the binlog_format parameter is dynamic, you don't need to reboot the DB instance for the changes to apply.

Important
Changing a DB parameter group affects all DB instances that use that parameter group. If you want to specify different binary logging formats for different MySQL DB instances in an AWS Region, the DB instances must use different DB parameter groups. These parameter groups identify different logging formats. Assign the appropriate DB parameter group to each DB instance.

Accessing MySQL binary logs

You can use the mysqlbinlog utility to download or stream binary logs from RDS for MySQL DB instances. The binary log is downloaded to your local computer, where you can perform actions such as replaying the log using the mysql utility. For more information about using the mysqlbinlog utility, see Using mysqlbinlog to back up binary log files in the MySQL documentation.

To run the mysqlbinlog utility against an Amazon RDS instance, use the following options:

- **--read-from-remote-server** – Required.
- **--host** – The DNS name from the endpoint of the instance.
- **--port** – The port used by the instance.
- **--user** – A MySQL user that has been granted the REPLICATION_SLAVE permission.
- **--password** – The password for the MySQL user, or omit a password value so that the utility prompts you for a password.
- **--raw** – Download the file in binary format.
- **--result-file** – The local file to receive the raw output.
- **--stop-never** – Stream the binary log files.
- **--verbose** – When you use the ROW binlog format, include this option to see the row events as pseudo-SQL statements. For more information on the --verbose option, see mysqlbinlog row event display in the MySQL documentation.
- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command SHOW BINARY LOGS.

For more information about mysqlbinlog options, see mysqlbinlog — Utility for processing binary log files in the MySQL documentation.

The following examples show how to use the mysqlbinlog utility.
For Linux, macOS, or Unix:

```bash
mysqlbinlog \
   --read-from-remote-server \
   --host=MySQLInstance1.cg034hpkmjt.region.rds.amazonaws.com \
   --port=3306 \
   --user ReplUser \
   --password \
   --raw \
   --verbose \
   --result-file=/tmp/ \
   binlog.00098
```

For Windows:

```bash
mysqlbinlog ^
   --read-from-remote-server ^
   --host=MySQLInstance1.cg034hpkmjt.region.rds.amazonaws.com ^
   --port=3306 ^
   --user ReplUser ^
   --password ^
   --raw ^
   --verbose ^
   --result-file=/tmp/ ^
   binlog.00098
```

Amazon RDS normally purges a binary log as soon as possible, but the binary log must still be available on the instance to be accessed by mysqlbinlog. To specify the number of hours for RDS to retain binary logs, use the `mysql.rds_set_configuration` (p. 1774) stored procedure and specify a period with enough time for you to download the logs. After you set the retention period, monitor storage usage for the DB instance to ensure that the retained binary logs don't take up too much storage.

The following example sets the retention period to 1 day.

```sql
call mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the `mysql.rds_show_configuration` (p. 1776) stored procedure.

```sql
call mysql.rds_show_configuration;
```
Oracle database log files

You can access Oracle alert logs, audit files, and trace files by using the Amazon RDS console or API. For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files (p. 895).

The Oracle audit files provided are the standard Oracle auditing files. Amazon RDS supports the Oracle fine-grained auditing (FGA) feature. However, log access doesn't provide access to FGA events that are stored in the SYS.FGA_LOG$ table and that are accessible through the DBA_FGA_AUDIT_TRAIL view.

The DescribeDBLogFiles API operation that lists the Oracle log files that are available for a DB instance ignores the MaxRecords parameter and returns up to 1,000 records. The call returns LastWritten as a POSIX date in milliseconds.

Topics
- Retention schedule (p. 924)
- Working with Oracle trace files (p. 924)
- Publishing Oracle logs to Amazon CloudWatch Logs (p. 927)
- Previous methods for accessing alert logs and listener logs (p. 930)

Retention schedule

The Oracle database engine might rotate log files if they get very large. To retain audit or trace files, download them. If you store the files locally, you reduce your Amazon RDS storage costs and make more space available for your data.

The following table shows the retention schedule for Oracle alert logs, audit files, and trace files on Amazon RDS.

<table>
<thead>
<tr>
<th>Log type</th>
<th>Retention schedule</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alert logs</td>
<td>The text alert log is rotated daily with 30-day retention managed by Amazon RDS. The XML alert log is retained for at least seven days. You can access this log by using the ALERTLOG view.</td>
</tr>
<tr>
<td>Audit files</td>
<td>The default retention period for audit files is seven days. Amazon RDS might delete audit files older than seven days.</td>
</tr>
<tr>
<td>Trace files</td>
<td>The default retention period for trace files is seven days. Amazon RDS might delete trace files older than seven days.</td>
</tr>
<tr>
<td>Listener logs</td>
<td>The default retention period for the listener logs is seven days. Amazon RDS might delete listener logs older than seven days.</td>
</tr>
</tbody>
</table>

Note
Audit files and trace files share the same retention configuration.

Working with Oracle trace files

Following, you can find descriptions of Amazon RDS procedures to create, refresh, access, and delete trace files.

Topics
Listing files

You can use either of two procedures to allow access to any file in the background_dump_dest path. The first procedure refreshes a view containing a listing of all files currently in background_dump_dest.

EXEC rdsadmin.manage_tracefiles.refresh_tracefile_listing;

After the view is refreshed, query the following view to access the results.

SELECT * FROM rdsadmin.tracefile_listing;

An alternative to the previous process is to use FROM table to stream nonrelational data in a table-like format to list database directory contents.

SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('BDUMP'));

The following query shows the text of a log file.

SELECT text FROM
    TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP','alert_dbname.log.date'));

On a read replica, get the name of the BDUMP directory by querying V$DATABASE.DB_UNIQUE_NAME. If the unique name is DATABASE_B, then the BDUMP directory is BDUMP_B. The following example queries the BDUMP name on a replica and then uses this name to query the contents of alert_DATABASE.log.2020-06-23.

SELECT 'BDUMP' || (SELECT regexp_replace(DB_UNIQUE_NAME,'.*(_[A-Z])', '1') FROM V$DATABASE) AS BDUMP_VARIABLE FROM DUAL;

BDUMP_VARIABLE
--------------
BDUMP_B

SELECT TEXT FROM
    table(rdsadmin.rds_file_util.read_text_file('BDUMP_B','alert_DATABASE.log.2020-06-23'));

Generating trace files and tracing a session

Because there are no restrictions on ALTER SESSION, many standard methods to generate trace files in Oracle remain available to an Amazon RDS DB instance. The following procedures are provided for trace files that require greater access.

<table>
<thead>
<tr>
<th>Oracle method</th>
<th>Amazon RDS method</th>
</tr>
</thead>
<tbody>
<tr>
<td>oradebug hanganalyze 3</td>
<td>EXEC rdsadmin.manage_tracefiles.hanganalyze;</td>
</tr>
</tbody>
</table>
You can use many standard methods to trace individual sessions connected to an Oracle DB instance in Amazon RDS. To enable tracing for a session, you can run subprograms in PL/SQL packages supplied by Oracle, such as DBMS_SESSION and DBMS_MONITOR. For more information, see Enabling tracing for a session in the Oracle documentation.

**Retrieving trace files**

You can retrieve any trace file in background_dump_dest using a standard SQL query on an Amazon RDS–managed external table. To use this method, you must execute the procedure to set the location for this table to the specific trace file.

For example, you can use the `rdsadmin.tracefile_listing` view mentioned preceding to list all of the trace files on the system. You can then set the `tracefile_table` view to point to the intended trace file using the following procedure.

```sql
EXEC rdsadmin.manage_tracefiles.set_tracefile_table_location('CUST01_ora_3260_SYSTEMSTATE.trc');
```

The following example creates an external table in the current schema with the location set to the file provided. You can retrieve the contents into a local file using a SQL query.

```sql
SPOOL /tmp/tracefile.txt
SELECT * FROM tracefile_table;
SPOOL OFF;
```

**Purging trace files**

Trace files can accumulate and consume disk space. Amazon RDS purges trace files by default and log files that are older than seven days. You can view and set the trace file retention period using the `show_configuration` procedure. You should run the command `SET SERVEROUTPUT ON` so that you can view the configuration results.

The following example shows the current trace file retention period, and then sets a new trace file retention period.

```sql
# Show the current tracefile retention
SQL> EXEC rdsadmin.rdsadmin_util.show_configuration;
NAME:tracefile retention
VALUE:10080
DESCRIPTION:tracefile expiration specifies the duration in minutes before tracefiles in bdump are automatically deleted.

# Set the tracefile retention to 24 hours:
SQL> EXEC rdsadmin.rdsadmin_util.set_configuration('tracefile retention',1440);
SQL> commit;

#show the new tracefile retention
SQL> EXEC rdsadmin.rdsadmin_util.show_configuration;
NAME:tracefile retention
VALUE:1440
DESCRIPTION:tracefile expiration specifies the duration in minutes before tracefiles in bdump are automatically deleted.
```
In addition to the periodic purge process, you can manually remove files from the `background_dump_dest`. The following example shows how to purge all files older than five minutes.

```
EXEC rdsadmin.manage_tracefiles.purge_tracefiles(5);
```

You can also purge all files that match a specific pattern (if you do, don't include the file extension, such as `.trc`). The following example shows how to purge all files that start with `SCHPOC1_ora_5935`.

```
EXEC rdsadmin.manage_tracefiles.purge_tracefiles('SCHPOC1_ora_5935');
```

### Publishing Oracle logs to Amazon CloudWatch Logs

You can configure your Amazon RDS for Oracle DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can analyze the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each Oracle database log as a separate database stream in the log group. For example, if you configure the export function to include the audit log, audit data is stored in an audit log stream in the `/aws/rds/instance/my_instance/audit` log group. RDS for Oracle supports the following logs:

- Alert log
- Trace log
- Audit log
- Listener log
- Oracle Management Agent log

This Oracle Management Agent log consists of the log groups shown in the following table.

<table>
<thead>
<tr>
<th>Log name</th>
<th>CloudWatch log group</th>
</tr>
</thead>
<tbody>
<tr>
<td>emctl.log</td>
<td>oemagent-emctl</td>
</tr>
<tr>
<td>emdctlj.log</td>
<td>oemagent-emdctlj</td>
</tr>
<tr>
<td>gcagent.log</td>
<td>oemagent-gcagent</td>
</tr>
<tr>
<td>gcagent_errors.log</td>
<td>oemagent-gcagent-errors</td>
</tr>
<tr>
<td>emagent.nohup</td>
<td>oemagent-emagent-nohup</td>
</tr>
<tr>
<td>secure.log</td>
<td>oemagent-secure</td>
</tr>
</tbody>
</table>

For more information, see [Locating Management Agent Log and Trace Files](#) in the Oracle documentation.

**Console**

**To publish Oracle DB logs to CloudWatch Logs from the AWS Management Console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

**AWS CLI**

To publish Oracle logs, you can use the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

**Note**
A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish Oracle logs using the following commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

**Example**

The following example creates an Oracle DB instance with CloudWatch Logs publishing enabled. The `--cloudwatch-logs-export-configuration` value is a JSON array of strings. The strings can be any combination of `alert`, `audit`, `listener`, and `trace`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-instance-identifier mydbinstance \
  --cloudwatch-logs-export-configuration \'
  ["trace","audit","alert","listener","oemagent"]\' \
  --db-instance-class db.m5.large \
  --allocated-storage 20 \
  --engine oracle-ee \
  --engine-version 12.1.0.2.v18 \
  --license-model bring-your-own-license \
  --master-username myadmin \
  --manage-master-user-password
```

For Windows:

```
aws rds create-db-instance ^
  --db-instance-identifier mydbinstance ^
  --cloudwatch-logs-export-configuration trace alert audit listener oemagent ^
  --db-instance-class db.m5.large ^
  --allocated-storage 20 ^
  --engine oracle-ee ^
  --engine-version 12.1.0.2.v18 ^
  --license-model bring-your-own-license ^
  --master-username myadmin ^
  --manage-master-user-password
```
Example

The following example modifies an existing Oracle DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `alert`, `audit`, `listener`, and `trace`.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["trace","alert","audit","listener","oemagent"]}'
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --cloudwatch-logs-export-configuration EnableLogTypes="trace","alert","audit","listener","oemagent"
```

Example

The following example modifies an existing Oracle DB instance to disable publishing audit and listener log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `DisableLogTypes`, and its value is an array of strings with any combination of `alert`, `audit`, `listener`, and `trace`.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --cloudwatch-logs-export-configuration '{"DisableLogTypes": ["audit","listener"]}'
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --cloudwatch-logs-export-configuration DisableLogTypes="audit","listener"
```

RDS API

You can publish Oracle DB logs with the RDS API. You can call the `ModifyDBInstance` action with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

Note

A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish Oracle logs by calling the following RDS API operations:

- `CreateDBInstance`
- `RestoreDBInstanceFromDBSnapshot`
- RestoreDBInstanceFromS3
- RestoreDBInstanceToPointInTime

Run one of these RDS API operations with the following parameters:

- DBInstanceIdentifier
- EnableCloudwatchLogsExports
- Engine
- DBInstanceClass

Other parameters might be required depending on the RDS operation that you run.

### Previous methods for accessing alert logs and listener logs

You can view the alert log using the Amazon RDS console. You can also use the following SQL statement to access the alert log.

```sql
SELECT message_text FROM alertlog;
```

The `listenerlog` view contains entries for Oracle Database version 12.1.0.2 and earlier. To access the listener log for these database versions, use the following query.

```sql
SELECT message_text FROM listenerlog;
```

For Oracle Database versions 12.2.0.1 and later, access the listener log using Amazon CloudWatch Logs.

**Note**

Oracle rotates the alert and listener logs when they exceed 10 MB, at which point they are unavailable from Amazon RDS views.
RDS for PostgreSQL database log files

RDS for PostgreSQL logs database activities to the default PostgreSQL log file. For an on-premises PostgreSQL DB instance, these messages are stored locally in `log/postgresql.log`. For an RDS for PostgreSQL DB instance, the log file is available on the Amazon RDS instance. Also, you must use the Amazon RDS Console to view or download its contents. The default logging level captures login failures, fatal server errors, deadlocks, and query failures.

For more information about how you can view, download, and watch file-based database logs, see Monitoring Amazon RDS log files (p. 895). To learn more about PostgreSQL logs, see Working with Amazon RDS and Aurora PostgreSQL logs: Part 1 and Working with Amazon RDS and Aurora PostgreSQL logs: Part 2.

In addition to the standard PostgreSQL logs discussed in this topic, RDS for PostgreSQL also supports the PostgreSQL Audit extension (pgAudit). Most regulated industries and government agencies need to maintain an audit log or audit trail of changes made to data to comply with legal requirements. For information about installing and using pgAudit, see Using pgAudit to log database activity (p. 2379).

Topics

- Parameters that affect logging behavior (p. 931)
- Turning on query logging for your RDS for PostgreSQL DB instance (p. 933)
- Publishing PostgreSQL logs to Amazon CloudWatch Logs (p. 936)

Parameters that affect logging behavior

You can customize the logging behavior for your RDS for PostgreSQL DB instance by modifying various parameters. In the following table you can find the parameters that affect how long the logs are stored, when to rotate the log, and whether to output the log as a CSV (comma-separated value) format. You can also find the text output sent to STDERR, among other settings. To change settings for the parameters that are modifiable, use a custom DB parameter group for your RDS for PostgreSQL instance. For more information, see Working with DB parameter groups (p. 349). As noted in the table, the `log_line_prefix` can't be changed.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_destination</td>
<td>stderr</td>
<td>Sets the output format for the log. The default is stderr but you can also specify comma-separated value (CSV) by adding csvlog to the setting. For more information, see Setting the log destination (stderr, csvlog) (p. 933)</td>
</tr>
<tr>
<td>log_filename</td>
<td>postgresql.log.%Y-%m-%d-%H</td>
<td>Specifies the pattern for the log file name. In addition to the default, this parameter supports postgresql.log.%Y-%m-%d for the filename pattern.</td>
</tr>
<tr>
<td>log_line_prefix</td>
<td>%t:%r:%u%@%d:[%p]</td>
<td>Defines the prefix for each log line that gets written to stderr, to note the time (%t), remote host (%r), user (%u), database (%d), and process ID (%p). You can't modify this parameter.</td>
</tr>
<tr>
<td>log_rotation_age</td>
<td>60</td>
<td>Minutes after which log file is automatically rotated. You can change this value to between 1 and 1440 minutes. For more information, see Setting log file rotation (p. 932).</td>
</tr>
</tbody>
</table>
PostgreSQL database log files

### Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_rotation_size</td>
<td>–</td>
<td>The size (kB) at which the log is automatically rotated. By default, this parameter isn't used because logs are rotated based on the log_rotation_age parameter. To learn more, see [Setting log file rotation](p. 932).</td>
</tr>
<tr>
<td>rds.log_retention_period</td>
<td>4320</td>
<td>PostgreSQL logs that are older than the specified number of minutes are deleted. The default value of 4320 minutes deletes log files after 3 days. For more information, see [Setting the log retention period](p. 932).</td>
</tr>
</tbody>
</table>

To identify application issues, you can look for query failures, login failures, deadlocks, and fatal server errors in the log. For example, suppose that you converted a legacy application from Oracle to Amazon RDS PostgreSQL, but not all queries converted correctly. These incorrectly formatted queries generate error messages that you can find in the logs to help identify problems. For more information about logging queries, see [Turning on query logging for your RDS for PostgreSQL DB instance](p. 933).

In the following topics, you can find information about how to set various parameters that control the basic details for your PostgreSQL logs.

#### Topics

- [Setting the log retention period](p. 932)
- [Setting log file rotation](p. 932)
- [Setting the log destination (stderr, csvlog)](p. 933)
- [Understanding the log_line_prefix parameter](p. 933)

#### Setting the log retention period

The rds.logRetentionPeriod parameter specifies how long your RDS for PostgreSQL DB instance keeps its log files. The default setting is 3 days (4,320 minutes), but you can set this value to anywhere from 1 day (1,440 minutes) to 7 days (10,080 minutes). Be sure that your RDS for PostgreSQL DB instance has sufficient storage to hold the log files for the period of time.

We recommend that you have your logs routinely published to Amazon CloudWatch Logs so that you can view and analyze system data long after the logs have been removed from your RDS for PostgreSQL DB instance. For more information, see [Publishing PostgreSQL logs to Amazon CloudWatch Logs](p. 936).

#### Setting log file rotation

Amazon RDS creates new log files every hour by default. The timing is controlled by the log_rotation_age parameter. This parameter has a default value of 60 (minutes), but you can set it to anywhere from 1 minute to 24 hours (1,440 minutes). When it's time for rotation, a new distinct log file is created. The file is named according to the pattern specified by the log_filename parameter.

Log files can also be rotated according to their size, as specified in the log_rotation_size parameter. This parameter specifies that the log should be rotated when it reaches the specified size (in kilobytes). For an RDS for PostgreSQL DB instance, log_rotation_size is unset, that is, there is no value specified. However, you can set the parameter from 0-2097151 kB (kilobytes).

The log file names are based on the file name pattern specified in the log_filename parameter. The available settings for this parameter are as follows:
• `postgresql.log.%Y-%m-%d` – Default format for the log file name. Includes the year, month, and date in the name of the log file.
• `postgresql.log.%Y-%m-%d-%H` – Includes the hour in the log file name format.

For more information, see `log_rotation_age` and `log_rotation_size` in the PostgreSQL documentation.

**Setting the log destination (stderr, csvlog)**

By default, Amazon RDS PostgreSQL generates logs in standard error (stderr) format. This format is the default setting for the `log_destination` parameter. Each message is prefixed using the pattern specified in the `log_line_prefix` parameter. For more information, see [Understanding the `log_line_prefix` parameter](p. 933).

RDS for PostgreSQL can also generate the logs in `csvlog` format. The `csvlog` is useful for analyzing the log data as comma-separated values (CSV) data. For example, suppose that you use the `log_fdw` extension to work with your logs as foreign tables. The foreign table created on `stderr` log files contains a single column with log event data. By adding `csvlog` to the `log_destination` parameter, you get the log file in the CSV format with demarcations for the multiple columns of the foreign table. You can now sort and analyze your logs more easily. To learn how to use the `log_fdw` with `csvlog`, see [Using the `log_fdw` extension to access the DB log using SQL](p. 2418).

If you specify `csvlog` for this parameter, be aware that both `stderr` and `csvlog` files are generated. Be sure to monitor the storage consumed by the logs, taking into account the `rds.log_retention_period` and other settings that affect log storage and turnover. Using `stderr` and `csvlog` more than doubles the storage consumed by the logs.

If you add `csvlog` to `log_destination` and you want to revert to the `stderr` alone, you need to reset the parameter. To do so, open the Amazon RDS Console and then open the custom DB parameter group for your instance. Choose the `log_destination` parameter, choose `Edit parameter`, and then choose `Reset`.

For more information about configuring logging, see [Working with Amazon RDS and Aurora PostgreSQL logs: Part 1](#).

**Understanding the `log_line_prefix` parameter**

The `stderr` log format prefixes each log message with the details specified by the `log_line_prefix` parameter, as follows.

```
%t:%r:%u@%d:[%p]:t
```

You can't change this setting. Each log entry sent to `stderr` includes the following information.

- `%t` – Time of log entry
- `%r` – Remote host address
- `%u@%d` – User name @ database name
- `[%p]` – Process ID if available

**Turning on query logging for your RDS for PostgreSQL DB instance**

You can collect more detailed information about your database activities, including queries, queries waiting for locks, checkpoints, and many other details by setting some of the parameters listed in the following table. This topic focuses on logging queries.
### PostgreSQL database log files

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_connections</td>
<td>–</td>
<td>Logs each successful connection.</td>
</tr>
<tr>
<td>log_disconnections</td>
<td>–</td>
<td>Logs the end of each session and its duration.</td>
</tr>
<tr>
<td>log_checkpoints</td>
<td>1</td>
<td>Logs each checkpoint.</td>
</tr>
<tr>
<td>log_lock_waits</td>
<td>–</td>
<td>Logs long lock waits. By default, this parameter isn't set.</td>
</tr>
<tr>
<td>log_min_duration_sample</td>
<td>–</td>
<td>(ms) Sets the minimum execution time above which a sample of statements is logged. Sample size is set using the log_statement_sample_rate parameter.</td>
</tr>
<tr>
<td>log_min_duration_statement</td>
<td></td>
<td>Any SQL statement that runs at least for the specified amount of time or longer gets logged. By default, this parameter isn't set. Turning on this parameter can help you find unoptimized queries.</td>
</tr>
<tr>
<td>log_statement</td>
<td>–</td>
<td>Sets the type of statements logged. By default, this parameter isn't set, but you can change it to all, ddl, or mod to specify the types of SQL statements that you want logged. If you specify anything other than none for this parameter, you should also take additional steps to prevent the exposure of passwords in the log files. For more information, see Mitigating risk of password exposure when using query logging (p. 936).</td>
</tr>
<tr>
<td>log_statement_sample_rate</td>
<td></td>
<td>The percentage of statements exceeding the time specified in log_min_duration_sample to be logged, expressed as a floating point value between 0.0 and 1.0.</td>
</tr>
<tr>
<td>log_statement_stats</td>
<td>–</td>
<td>Writes cumulative performance statistics to the server log.</td>
</tr>
</tbody>
</table>

### Using logging to find slow performing queries

You can log SQL statements and queries to help find slow performing queries. You turn on this capability by modifying the settings in the `log_statement` and `log_min_duration` parameters as outlined in this section. Before turning on query logging for your RDS for PostgreSQL DB instance, you should be aware of possible password exposure in the logs and how to mitigate the risks. For more information, see Mitigating risk of password exposure when using query logging (p. 936).

Following, you can find reference information about the `log_statement` and `log_min_duration` parameters.

**log_statement**

This parameter specifies the type of SQL statements that should get sent to the log. The default value is none. If you change this parameter to all, ddl, or mod, be sure to apply recommended actions to mitigate the risk of exposing passwords in the logs. For more information, see Mitigating risk of password exposure when using query logging (p. 936).
Amazon Relational Database Service User Guide

PostgreSQL database log files

all

Logs all statements. This setting is recommended for debugging purposes.
ddl

Logs all data definition language (DDL) statements, such as CREATE, ALTER, DROP, and so on.
mod

Logs all DDL statements and data manipulation language (DML) statements, such as INSERT, UPDATE, and DELETE, which modify the data.
none

No SQL statements get logged. We recommend this setting to avoid the risk of exposing passwords in the logs.

log_min_duration_statement

Any SQL statement that runs at least for the specified amount of time or longer gets logged. By default, this parameter isn’t set. Turning on this parameter can help you find unoptimized queries.

–1–2147483647

The number of milliseconds (ms) of runtime over which a statement gets logged.

To set up query logging

These steps assume that your RDS for PostgreSQL DB instance uses a custom DB parameter group.

1. Set the log_statement parameter to all. The following example shows the information that is written to the postgresql.log file with this parameter setting.

   ```
   2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:LOG: statement: SELECT feedback, s.sentiment,s.confidence FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s ORDER BY s.confidence DESC;
   2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:LOG: QUERY STATISTICS
   2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:LOG: DETAIL: ! system usage stats:
   ! 0.017355 s user, 0.000000 s system, 0.168593 s elapsed
   ! [0.025146 s user, 0.000000 s system total]
   ! 36644 kB max resident size
   ! 0/8 [0/8] filesystem blocks in/out
   ! 0/753 [0/1364] page faults/reclaims, 0 [0] swaps
   ! 0 [0] signals rcvd, 0/0 [0/0] messages rcvd/sent
   ! 19/0 [27/0] voluntary/involuntary context switches
   2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:STATEMENT: SELECT feedback, s.sentiment,s.confidence FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s ORDER BY s.confidence DESC;
   2022-10-05 22:05:56 UTC:52.95.4.1(11335):postgres@labdb:[3639]:ERROR: syntax error at or near "ORDER" at character 1
   2022-10-05 22:05:56 UTC:52.95.4.1(11335):postgres@labdb:[3639]:STATEMENT: ORDER BY s.confidence DESC;
   -------------------------------- END OF LOG --------------------------------
   ```

2. Set the log_min_duration_statement parameter. The following example shows the information that is written to the postgresql.log file when the parameter is set to 1.

935
Queries that exceed the duration specified in the `log_min_duration_statement` parameter are logged. The following shows an example. You can view the log file for your RDS for PostgreSQL DB instance in the Amazon RDS Console.

```
2022-10-05 19:05:19 UTC:52.95.4.1(6461):postgres@labdb:[6144]:LOG: statement: DROP table comments;
2022-10-05 19:05:19 UTC:52.95.4.1(6461):postgres@labdb:[6144]:LOG: duration: 167.754 ms
2022-10-05 19:08:07 UTC:@:[355]:LOG: checkpoint starting: time
2022-10-05 19:08:08 UTC:@:[355]:LOG: checkpoint complete: wrote 11 buffers (0.0%); 0 WAL file(s) added, 0 removed, 0 recycled; write=1.013 s, sync=0.006 s, total=1.033 s; sync files=8, longest=0.004 s, average=0.001 s; distance=131028 kB, estimate=131028 kB
----------------------- END OF LOG ----------------------
```

Mitigating risk of password exposure when using query logging

We recommend that you keep `log_statement` set to `none` to avoid exposing passwords. If you set `log_statement` to `all`, `ddl`, or `mod`, we recommend that you take one or more of the following steps.

- For the client, encrypt sensitive information. For more information, see Encryption Options in the PostgreSQL documentation. Use the ENCRYPTED (and UNENCRYPTED) options of the CREATE and ALTER statements. For more information, see CREATE USER in the PostgreSQL documentation.
- For your RDS for PostgreSQL DB instance, set up and use the PostgreSQL Auditing (pgAudit) extension. This extension redact sensitive information in CREATE and ALTER statements sent to the log. For more information, see Using pgAudit to log database activity (p. 2379).
- Restrict access to the CloudWatch logs.
- Use stronger authentication mechanisms such as IAM.

Publishing PostgreSQL logs to Amazon CloudWatch Logs

To store your PostgreSQL log records in highly durable storage, you can use Amazon CloudWatch Logs. With CloudWatch Logs, you can also perform real-time analysis of log data and use CloudWatch to view metrics and create alarms. For example, if you set `log_statement` to `ddl`, you can set up an alarm to alert you whenever a DDL statement is executed. You can choose to have your PostgreSQL logs uploaded to CloudWatch Logs during the process of creating your RDS for PostgreSQL DB instance. If you chose not to upload logs at that time, you can later modify your instance to start uploading logs from that point forward. In other words, existing logs aren't uploaded. Only new logs are uploaded as they're created on your modified RDS for PostgreSQL DB instance.

All currently available RDS for PostgreSQL versions support publishing log files to CloudWatch Logs. For more information, see Amazon RDS for PostgreSQL updates in the Amazon RDS for PostgreSQL Release Notes.

To work with CloudWatch Logs, configure your RDS for PostgreSQL DB instance to publish log data to a log group.

You can publish the following log types to CloudWatch Logs for RDS for PostgreSQL:

- Postgresql log
- Upgrade log

After you complete the configuration, Amazon RDS publishes the log events to log streams within a CloudWatch log group. For example, the PostgreSQL log data is stored within the log group `/aws/rds/instance/my_instance/postgresql`. To view your logs, open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
Console

To publish PostgreSQL logs to CloudWatch Logs using the console
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to modify, and then choose Modify.
4. In the Log exports section, choose the logs that you want to start publishing to CloudWatch Logs.
   The Log exports section is available only for PostgreSQL versions that support publishing to CloudWatch Logs.
5. Choose Continue, and then choose Modify DB Instance on the summary page.

AWS CLI

You can publish PostgreSQL logs with the AWS CLI. You can call the modify-db-instance command with the following parameters.

- --db-instance-identifier
- --cloudwatch-logs-export-configuration

Note
A change to the --cloudwatch-logs-export-configuration option is always applied to the DB instance immediately. Therefore, the --apply-immediately and --no-apply-immediately options have no effect.

You can also publish PostgreSQL logs by calling the following CLI commands:

- create-db-instance
- restore-db-instance-from-db-snapshot
- restore-db-instance-to-point-in-time

Run one of these CLI commands with the following options:

- --db-instance-identifier
- --enable-cloudwatch-logs-exports
- --db-instance-class
- --engine

Other options might be required depending on the CLI command you run.

Example Modify an instance to publish logs to CloudWatch Logs

The following example modifies an existing PostgreSQL DB instance to publish log files to CloudWatch Logs. The --cloudwatch-logs-export-configuration value is a JSON object. The key for this object is EnableLogTypes, and its value is an array of strings with any combination of postgresql and upgrade.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["postgresql", "upgrade"]}'
```
For Windows:

```bash
aws rds modify-db-instance
   --db-instance-identifier mydbinstance
   --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["postgresql","upgrade"]}'
```

**Example Create an instance to publish logs to CloudWatch Logs**

The following example creates a PostgreSQL DB instance and publishes log files to CloudWatch Logs. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings. The strings can be any combination of `postgresql` and `upgrade`.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance
   --db-instance-identifier mydbinstance
   --enable-cloudwatch-logs-exports '['"postgresql","upgrade"]'
   --db-instance-class db.m4.large
   --engine postgres
```

For Windows:

```bash
aws rds create-db-instance
   --db-instance-identifier mydbinstance
   --enable-cloudwatch-logs-exports '['"postgresql","upgrade"]'
   --db-instance-class db.m4.large
   --engine postgres
```

**RDS API**

You can publish PostgreSQL logs with the RDS API. You can call the `ModifyDBInstance` action with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

**Note**

A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish PostgreSQL logs by calling the following RDS API operations:

- `CreateDBInstance`
- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceToPointInTime`

Run one of these RDS API operations with the following parameters:

- `DBInstanceIdentifier`
- `EnableCloudwatchLogsExports`
• Engine
• DBInstanceClass

Other parameters might be required depending on the operation that you run.
Monitoring Amazon RDS API calls in AWS CloudTrail

AWS CloudTrail is an AWS service that helps you audit your AWS account. AWS CloudTrail is turned on for your AWS account when you create it. For more information about CloudTrail, see the AWS CloudTrail User Guide.

Topics
- CloudTrail integration with Amazon RDS (p. 940)
- Amazon RDS log file entries (p. 940)

CloudTrail integration with Amazon RDS

All Amazon RDS actions are logged by CloudTrail. CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon RDS.

CloudTrail events

CloudTrail captures API calls for Amazon RDS as events. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. Events include calls from the Amazon RDS console and from code calls to the Amazon RDS API operations.

Amazon RDS activity is recorded in a CloudTrail event in Event history. You can use the CloudTrail console to view the last 90 days of recorded API activity and events in an AWS Region. For more information, see Viewing events with CloudTrail event history.

CloudTrail trails

For an ongoing record of events in your AWS account, including events for Amazon RDS, create a trail. A trail is a configuration that enables delivery of events to a specified Amazon S3 bucket. CloudTrail typically delivers log files within 15 minutes of account activity.

Note
If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history.

You can create two types of trails for an AWS account: a trail that applies to all Regions, or a trail that applies to one Region. By default, when you create a trail in the console, the trail applies to all Regions.

Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:

- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple Regions and Receiving CloudTrail log files from multiple accounts

Amazon RDS log file entries

CloudTrail log files contain one or more log entries. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.
The following example shows a CloudTrail log entry that demonstrates the CreateDBInstance action.

```json
{
    "eventVersion": "1.04",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "AKIAIOSFODNN7EXAMPLE",

"copyTagsToSnapshot": false,
"dBInstanceIdentifier": "test-instance",
"licenseModel": "general-public-license",
"iAMDatabaseAuthenticationEnabled": false,
"performanceInsightsEnabled": false,
"vpcSecurityGroups": [
  {
    "status": "active",
    "vpcSecurityGroupId": "sg-f839b688"
  }
],
"requestID": "daf2e3f5-96a3-4df7-a026-863f96db793e",
"eventID": "797163d3-5726-441d-80a7-6eeb7464acd4"}
As shown in the `userIdentity` element in the preceding example, every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information about the `userIdentity`, see the CloudTrail `userIdentity` element. For more information about `CreateDBInstance` and other Amazon RDS actions, see the Amazon RDS API Reference.
Monitoring Amazon RDS with Database Activity Streams

By using Database Activity Streams, you can monitor near real-time streams of database activity.

Topics
- Overview of Database Activity Streams (p. 944)
- Configuring unified auditing for Oracle Database (p. 948)
- Configuring auditing policy for Microsoft SQL Server (p. 949)
- Starting a database activity stream (p. 950)
- Modifying a database activity stream (p. 951)
- Getting the status of a database activity stream (p. 953)
- Stopping a database activity stream (p. 954)
- Monitoring database activity streams (p. 955)
- Managing access to database activity streams (p. 975)

Overview of Database Activity Streams

As an Amazon RDS database administrator, you need to safeguard your database and meet compliance and regulatory requirements. One strategy is to integrate database activity streams with your monitoring tools. In this way, you monitor and set alarms for auditing activity in your database.

Security threats are both external and internal. To protect against internal threats, you can control administrator access to data streams by configuring the Database Activity Streams feature. Amazon RDS DBAs don't have access to the collection, transmission, storage, and processing of the streams.

Topics
- How database activity streams work (p. 944)
- Auditing in Oracle Database and Microsoft SQL Server Database (p. 945)
- Asynchronous mode for database activity streams (p. 947)
- Requirements and limitations for database activity streams (p. 947)
- Region and version availability (p. 947)
- Supported DB instance classes for database activity streams (p. 947)

How database activity streams work

Amazon RDS pushes activities to an Amazon Kinesis data stream in near real time. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Kinesis Data Firehose and AWS Lambda to consume the stream and store the data.

Important
Use of the database activity streams feature in Amazon RDS is free, but Amazon Kinesis charges for a data stream. For more information, see Amazon Kinesis Data Streams pricing.

You can configure applications for compliance management to consume database activity streams. These applications can use the stream to generate alerts and audit activity on your database.

Amazon RDS supports database activity streams in Multi-AZ deployments. In this case, database activity streams audit both the primary and standby instances.
Auditing in Oracle Database and Microsoft SQL Server Database

Auditing is the monitoring and recording of configured database actions. Amazon RDS doesn't capture database activity by default. You create and manage audit policies in your database yourself.

Topics
- Unified auditing in Oracle Database (p. 945)
- Auditing in Microsoft SQL Server (p. 945)
- Non-native audit fields for Oracle Database and SQL Server (p. 946)
- DB parameter group override (p. 946)

Unified auditing in Oracle Database

In an Oracle database, a unified audit policy is a named group of audit settings that you can use to audit an aspect of user behavior. A policy can be as simple as auditing the activities of a single user. You can also create complex audit policies that use conditions.

An Oracle database writes audit records, including SYS audit records, to the unified audit trail. For example, if an error occurs during an INSERT statement, standard auditing indicates the error number and the SQL that was run. The audit trail resides in a read-only table in the AUDSYS schema. To access these records, query the UNIFIED_AUDIT_TRAIL data dictionary view.

Typically, you configure database activity streams as follows:

1. Create an Oracle Database audit policy by using the CREATE AUDIT POLICY command.
   - The Oracle Database generates audit records.
2. Activate the audit policy by using the AUDIT POLICY command.
3. Configure database activity streams.
   - Only activities that match the Oracle Database audit policies are captured and sent to the Amazon Kinesis data stream. When database activity streams are enabled, an Oracle database administrator can't alter the audit policy or remove audit logs.

To learn more about unified audit policies, see About Auditing Activities with Unified Audit Policies and AUDIT in the Oracle Database Security Guide.

Auditing in Microsoft SQL Server

Database Activity Stream uses SQLAudit feature to audit the SQL Server database.

RDS for SQL Server instance contains the following:

- Server audit – The SQL server audit collects a single instance of server or database-level actions, and a group of actions to monitor. The server-level audits RDS_DAS_AUDIT and RDS_DAS_AUDIT_CHANGES are managed by RDS.
- Server audit specification – The server audit specification records the server-level events. You can modify the RDS_DAS_SERVER_AUDIT_SPEC specification. This specification is linked to the server audit RDS_DAS_AUDIT. The RDS_DAS_CHANGES_AUDIT_SPEC specification is managed by RDS.
- Database audit specification – The database audit specification records the database-level events. You can create a database audit specification RDS_DAS_DB_<name> and link it to RDS_DAS_AUDIT server audit.

You can configure database activity streams by using the console or CLI. Typically, you configure database activity streams as follows:
1. (Optional) Create a database audit specification with the CREATE DATABASE AUDIT SPECIFICATION command and link it to RDS_DAS_AUDIT server audit.

2. (Optional) Modify the server audit specification with the ALTER SERVER AUDIT SPECIFICATION command and define the policies.

3. Activate the database and server audit policies. For example:

   ```sql
   ALTER DATABASE AUDIT SPECIFICATION [<Your database specification>] WITH (STATE=ON)
   ```

   ```sql
   ALTER SERVER AUDIT SPECIFICATION [RDS_DAS_SERVER_AUDIT_SPEC] WITH (STATE=ON)
   ```

4. Configure database activity streams.

   Only activities that match the server and database audit policies are captured and sent to the Amazon Kinesis data stream. When database activity streams are enabled and the policies are locked, a database administrator can't alter the audit policy or remove audit logs.

   **Important**
   
   If the database audit specification for a specific database is enabled and the policy is in a locked state, then the database can't be dropped.

For more information about SQL Server auditing, see [SQL Server Audit Components](#) in the [Microsoft SQL Server documentation](#).

**Non-native audit fields for Oracle Database and SQL Server**

When you start a database activity stream, every database event generates a corresponding activity stream event. For example, a database user might run SELECT and INSERT statements. The database audits these events and sends them to an Amazon Kinesis data stream.

The events are represented in the stream as JSON objects. A JSON object contains a `DatabaseActivityMonitoringRecord`, which contains a `databaseActivityEventList` array. Predefined fields in the array include `class`, `clientApplication`, and `command`.

By default, an activity stream doesn't include engine-native audit fields. You can configure Amazon RDS for Oracle and SQL Server so that it includes these extra fields in the `engineNativeAuditFields` JSON object.

In Oracle Database, most events in the unified audit trail map to fields in the RDS data activity stream. For example, the `UNIFIED_AUDIT_TRAIL.SQL_TEXT` field in unified auditing maps to the `commandText` field in a database activity stream. However, Oracle Database audit fields such as `OS_USERNAME` don't map to predefined fields in a database activity stream.

In SQL Server, most of the event's fields that are recorded by the SQLAudit map to the fields in RDS database activity stream. For example, the `code` field from `sys.fn_get_audit_file` in the audit maps to the `commandText` field in a database activity stream. However, SQL Server database audit fields, such as `permission_bitmask`, don't map to predefined fields in a database activity stream.

For more information about `databaseActivityEventList`, see [databaseActivityEventList JSON array](#) (p. 968).

**DB parameter group override**

Typically, you turn on unified auditing in RDS for Oracle by attaching a parameter group. However, Database Activity Streams require additional configuration. To improve your customer experience, Amazon RDS performs the following:

- If you activate an activity stream, RDS for Oracle ignores the auditing parameters in the parameter group.
• If you deactivate an activity stream, RDS for Oracle stops ignoring the auditing parameters.

The database activity stream for SQL Server is independent of any parameters you set in the SQL Audit option.

Asynchronous mode for database activity streams

Activity streams in Amazon RDS are always asynchronous. When a database session generates an activity stream event, the session returns to normal activities immediately. In the background, Amazon RDS makes the activity stream event into a durable record.

If an error occurs in the background task, Amazon RDS generates an event. This event indicates the beginning and end of any time windows where activity stream event records might have been lost. Asynchronous mode favors database performance over the accuracy of the activity stream.

Requirements and limitations for database activity streams

In RDS, database activity streams have the following requirements and limitations:

• Amazon Kinesis is required for database activity streams.
• AWS Key Management Service (AWS KMS) is required for database activity streams because they are always encrypted.
• Applying additional encryption to your Amazon Kinesis data stream is incompatible with database activity streams, which are already encrypted with your AWS KMS key.
• You create and manage audit policies yourself. Unlike Amazon Aurora, RDS for Oracle doesn't capture database activities by default.
• You create and manage audit policies or specifications yourself. Unlike Amazon Aurora, Amazon RDS doesn't capture database activities by default.
• In a Multi-AZ deployment, start the database activity stream only on the primary DB instance. The activity stream audits both the primary and standby DB instances automatically. No additional steps are required during a failover.
• Renaming a DB instance doesn't create a new Kinesis stream.
• CDBs aren't supported for RDS for Oracle.
• Read replicas aren't supported.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with database activity streams, see Database activity streams (p. 121).

Supported DB instance classes for database activity streams

For RDS for Oracle you can use database activity streams with the following DB instance classes:

• db.m4.*large
• db.m5.*large
• db.m5d.*large
• db.m6i.*large
• db.r4.*large
• db.r5.*large
Configuring Oracle unified auditing

For RDS for SQL Server you can use database activity streams with the following DB instance classes:

- db.m4.*large
- db.m5.*large
- db.m5d.*large
- db.m6i.*large
- db.r4.*large
- db.r5.*large
- db.r5b.*large
- db.r5d.*large
- db.r6i.*large
- db.x1e.*large
- db.z1d.*large

For more information about instance class types, see DB instance classes (p. 11).

Configuring unified auditing for Oracle Database

When you configure unified auditing for use with database activity streams, the following situations are possible:

- Unified auditing isn't configured for your Oracle database.

  In this case, create new policies with the CREATE AUDIT POLICY command, then activate them with the AUDIT POLICY command. The following example creates and activates a policy to monitor users with specific privileges and roles.

  ```sql
  CREATE AUDIT POLICY table_pol
  PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE
  ROLES emp_admin, sales_admin;
  AUDIT POLICY table_pol;
  ```

  For complete instructions, see Configuring Audit Policies in the Oracle Database documentation.

- Unified auditing is configured for your Oracle database.

  When you activate a database activity stream, RDS for Oracle automatically clears existing audit data. It also revokes audit trail privileges. RDS for Oracle can no longer do the following:

  - Purge unified audit trail records.
• Add, delete, or modify the unified audit policy.
• Update the last archived timestamp.

**Important**
We strongly recommend that you back up your audit data before activating a database activity stream.

For a description of the UNIFIED_AUDIT_TRAIL view, see [UNIFIED_AUDIT_TRAIL](#). If you have an account with Oracle Support, see [How To Purge The UNIFIED AUDIT TRAIL](#).

### Configuring auditing policy for Microsoft SQL Server

A SQL Server database instance has the server audit RDS_DAS_AUDIT, which is managed by Amazon RDS. You can define the policies to record server events in the server audit specification RDS_DAS_SERVER_AUDIT_SPEC. You can create a database audit specification, such as RDS_DAS_DB_<name>, and define the policies to record database events. For the list of server and database level audit action groups, see [SQL Server Audit Action Groups and Actions](#) in the Microsoft SQL Server documentation.

The default server policy monitors only failed logins and changes to any database or server audit specifications for database activity streams.

Limitations for the audit and audit specifications include the following:

• You can't modify the server or database audit specifications when the database activity stream is in a *locked* state.
• You can't modify the server audit RDS_DAS_AUDIT specification.
• You can't modify the SQL Server audit RDS_DAS_CHANGES or its related server audit specification RDS_DAS_CHANGES_AUDIT_SPEC.
• When creating a database audit specification, you must use the format RDS_DAS_DB_<name> for example, RDS_DAS_DB_databaseActions.

**Important**
For smaller instance classes, we recommend that you don't audit all but only the data that is required. This helps to reduce the performance impact of Database Activity Streams on these instance classes.

The following sample code modifies the server audit specification RDS_DAS_SERVER_AUDIT_SPEC and audits any logout and successful login actions:

```sql
ALTER SERVER AUDIT SPECIFICATION [RDS_DAS_SERVER_AUDIT_SPEC] 
WITH (STATE=OFF);
ALTER SERVER AUDIT SPECIFICATION [RDS_DAS_SERVER_AUDIT_SPEC] 
ADD (LOGOUT_GROUP), 
ADD (SUCCESSFUL_LOGIN_GROUP) 
WITH (STATE = ON );
```

The following sample code creates a database audit specification RDS_DAS_DB_database_spec and attaches it to the server audit RDS_DAS_AUDIT:

```sql
USE testDB;
CREATE DATABASE AUDIT SPECIFICATION [RDS_DAS_DB_database_spec] 
FOR SERVER AUDIT [RDS_DAS_AUDIT] 
ADD ( INSERT, UPDATE, DELETE 
ON testTable BY testUser )
```
When you start an activity stream for the DB instance, each database activity event that you configured in the audit policy generates an activity stream event. SQL commands such as CONNECT and SELECT generate access events. SQL commands such as CREATE and INSERT generate change events.

**Important**

Turning on an activity stream for an Oracle DB instance clears existing audit data. It also revokes audit trail privileges. When the stream is enabled, RDS for Oracle can no longer do the following:

- Purge unified audit trail records.
- Add, delete, or modify the unified audit policy.
- Update the last archived time stamp.

**Console**

**To start a database activity stream**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the Amazon RDS database instance on which you want to start an activity stream. In a Multi-AZ deployment, start the stream on only the primary instance. The activity stream audits both the primary and the standby instances.
4. For **Actions**, choose **Start activity stream**.

   The **Start database activity stream: name** window appears, where *name* is your RDS instance.
5. Enter the following settings:

   - For **AWS KMS key**, choose a key from the list of AWS KMS keys.

     Amazon RDS uses the KMS key to encrypt the key that in turn encrypts database activity. Choose a KMS key other than the default key. For more information about encryption keys and AWS KMS, see [*What is AWS Key Management Service?* in the AWS Key Management Service Developer Guide.](https://docs.aws.amazon.com/kms/latest/developerguide/what-is-kms.html)
   - For **Database activity events**, choose **Enable engine-native audit fields** to include the engine specific audit fields.
   - Choose **Immediately**.

     When you choose **Immediately**, the RDS instance restarts right away. If you choose **During the next maintenance window**, the RDS instance doesn't restart right away. In this case, the database activity stream doesn't start until the next maintenance window.
6. Choose **Start database activity stream**.

   The status for the the database shows that the activity stream is starting.

**Note**

If you get the error *You can't start a database activity stream in this configuration*, check [*Supported DB instance classes for database activity streams*](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_AuditStreams.html) to see whether your RDS instance is using a supported instance class.
AWS CLI

To start database activity streams for a DB instance, configure the database using the `start-activity-stream` AWS CLI command.

- `--resource-arn arn` – Specifies the Amazon Resource Name (ARN) of the DB instance.
- `--kms-key-id key` – Specifies the KMS key identifier for encrypting messages in the database activity stream. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the AWS KMS key.
- `--engine-native-audit-fields-included` – Includes engine-specific auditing fields in the data stream. To exclude these fields, specify `--no-engine-native-audit-fields-included` (default).

The following example starts a database activity stream for a DB instance in asynchronous mode.

For Linux, macOS, or Unix:

```
aws rds start-activity-stream \
    --mode async \
    --kms-key-id my-kms-key-arn \
    --resource-arn my-instance-arn \
    --engine-native-audit-fields-included \
    --apply-immediately
```

For Windows:

```
aws rds start-activity-stream ^
    --mode async ^
    --kms-key-id my-kms-key-arn ^
    --resource-arn my-instance-arn ^
    --engine-native-audit-fields-included ^
    --apply-immediately
```

RDS API

To start database activity streams for a DB instance, configure the instance using the `StartActivityStream` operation.

Call the action with the parameters below:

- Region
- KmsKeyId
- ResourceArn
- Mode
- EngineNativeAuditFieldsIncluded

Modifying a database activity stream

You might want to customize your Amazon RDS audit policy when your activity stream is started. If you don’t want to lose time and data by stopping your activity stream, you can change the `audit policy state` to either of the following settings:

**Locked (default)**

The audit policies in your database are read-only.
Unlocked

The audit policies in your database are read/write.

The basic steps are as follows:
1. Modify the audit policy state to unlocked.
2. Customize your audit policy.
3. Modify the audit policy state to locked.

Console

To modify the audit policy state of your activity stream
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. For Actions, choose Modify database activity stream.

The Modify database activity stream: name window appears, where name is your RDS instance.
4. Choose either of the following options:

Locked

When you lock your audit policy, it becomes read-only. You can’t edit your audit policy unless you unlock the policy or stop the activity stream.

Unlocked

When you unlock your audit policy, it becomes read/write. You can edit your audit policy while the activity stream is started.
5. Choose Modify DB activity stream.

The status for the Amazon RDS database shows Configuring activity stream.
6. (Optional) Choose the DB instance link. Then choose the Configuration tab.

The Audit policy status field shows one of the following values:
- Locked
- Unlocked
- Locking policy
- Unlocking policy

AWS CLI

To modify the activity stream state for the database instance, use the modify-activity-stream AWS CLI command.

<table>
<thead>
<tr>
<th>Option</th>
<th>Required?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--resource-arn my-instance-ARN</td>
<td>Yes</td>
<td>The Amazon Resource Name (ARN) of your RDS database instance.</td>
</tr>
</tbody>
</table>
### Option Required? Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Required?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--audit-policy-state</td>
<td>No</td>
<td>The new state of the audit policy for the database activity stream on your instance: locked or unlocked.</td>
</tr>
</tbody>
</table>

The following example unlocks the audit policy for the activity stream started on `my-instance-ARN`.

For Linux, macOS, or Unix:

```
aws rds modify-activity-stream \
    --resource-arn my-instance-ARN \
    --audit-policy-state unlocked
```

For Windows:

```
aws rds modify-activity-stream ^
    --resource-arn my-instance-ARN ^
    --audit-policy-state unlocked
```

The following example describes the instance `my-instance`. The partial sample output shows that the audit policy is unlocked.

```
aws rds describe-db-instances --db-instance-identifier my-instance

{
    "DBInstances": [
        {
            ...,
            "Engine": "oracle-ee",
            ...,
            "ActivityStreamStatus": "started",
            "ActivityStreamKmsKeyId": "ab12345e-1111-2bc3-12a3-ab1cd12345e",
            "ActivityStreamKinesisStreamName": "aws-rds-das-db-AB1CDEFG23GHIJK4LMNOPQRST",
            "ActivityStreamMode": "async",
            "ActivityStreamEngineNativeAuditFieldsIncluded": true,
            "ActivityStreamPolicyStatus": "unlocked",
            ...
        }
    ]
}
```

### RDS API

To modify the policy state of your database activity stream, use the `ModifyActivityStream` operation.

Call the action with the parameters below:

- AuditPolicyState
- ResourceArn

### Getting the status of a database activity stream

You can get the status of an activity stream for your Amazon RDS database instance using the console or AWS CLI.
Console

To get the status of a database activity stream

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance link.
3. Choose the Configuration tab, and check Database activity stream for status.

AWS CLI

You can get the activity stream configuration for a database instance as the response to a describe-db-instances CLI request.

The following example describes my-instance.

```bash
aws rds --region my-region describe-db-instances --db-instance-identifier my-db
```

The following example shows a JSON response. The following fields are shown:

- ActivityStreamKinesisStreamName
- ActivityStreamKmsKeyId
- ActivityStreamStatus
- ActivityStreamMode
- ActivityStreamPolicyStatus

```
{
    "DBInstances": [
    {
        ...
        "Engine": "oracle-ee",
        ...
        "ActivityStreamStatus": "starting",
        "ActivityStreamKmsKeyId": "ab12345e-1111-2bc3-12a3-ab1cd12345e",
        "ActivityStreamKinesisStreamName": "aws-rds-das-db-AB1CDEFG23GHIJK4LMNOPQRST",
        "ActivityStreamMode": "async",
        "ActivityStreamEngineNativeAuditFieldsIncluded": true,
        "ActivityStreamPolicyStatus": "locked",
        ...
    }
    ...
}
```

RDS API

You can get the activity stream configuration for a database as the response to a DescribeDBInstances operation.

Stopping a database activity stream

You can stop an activity stream using the console or AWS CLI.

If you delete your Amazon RDS database instance, the activity stream is stopped and the underlying Amazon Kinesis stream is deleted automatically.
Console

To turn off an activity stream

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose a database that you want to stop the database activity stream for.
4. For Actions, choose Stop activity stream. The Database Activity Stream window appears.
   a. Choose Immediately.
   When you choose Immediately, the RDS instance restarts right away. If you choose During the next maintenance window, the RDS instance doesn't restart right away. In this case, the database activity stream doesn't stop until the next maintenance window.
   b. Choose Continue.

AWS CLI

To stop database activity streams for your database, configure the DB instance using the AWS CLI command stop-activity-stream. Identify the AWS Region for the DB instance using the --region parameter. The --apply-immediately parameter is optional.

For Linux, macOS, or Unix:

```bash
aws rds --region MY_REGION
   stop-activity-stream
   --resource-arn MY_DB_ARN
   --apply-immediately
```

For Windows:

```bash
aws rds --region MY_REGION
   stop-activity-stream
   --resource-arn MY_DB_ARN
   --apply-immediately
```

RDS API

To stop database activity streams for your database, configure the DB instance using the StopActivityStream operation. Identify the AWS Region for the DB instance using the Region parameter. The ApplyImmediately parameter is optional.

Monitoring database activity streams

Database activity streams monitor and report activities. The stream of activity is collected and transmitted to Amazon Kinesis. From Kinesis, you can monitor the activity stream, or other services and applications can consume the activity stream for further analysis. You can find the underlying Kinesis stream name by using the AWS CLI command describe-db-instances or the RDS API DescribeDBInstances operation.

Amazon RDS manages the Kinesis stream for you as follows:

- Amazon RDS creates the Kinesis stream automatically with a 24-hour retention period.
- Amazon RDS scales the Kinesis stream if necessary.
- If you stop the database activity stream or delete the DB instance, Amazon RDS deletes the Kinesis stream.
The following categories of activity are monitored and put in the activity stream audit log:

- **SQL commands** – All SQL commands are audited, and also prepared statements, built-in functions, and functions in PL/SQL. Calls to stored procedures are audited. Any SQL statements issued inside stored procedures or functions are also audited.

- **Other database information** – Activity monitored includes the full SQL statement, the row count of affected rows from DML commands, accessed objects, and the unique database name. Database activity streams also monitor the bind variables and stored procedure parameters.

  **Important**
  The full SQL text of each statement is visible in the activity stream audit log, including any sensitive data. However, database user passwords are redacted if Oracle can determine them from the context, such as in the following SQL statement.

  ```sql
  ALTER ROLE role-name WITH password
  ```

- **Connection information** – Activity monitored includes session and network information, the server process ID, and exit codes.

If an activity stream has a failure while monitoring your DB instance, you are notified through RDS events.

**Topics**
- Accessing an activity stream from Kinesis (p. 956)
- Audit log contents and examples (p. 957)
- `databaseActivityEventList` JSON array (p. 968)
- Processing a database activity stream using the AWS SDK (p. 975)

### Accessing an activity stream from Kinesis

When you enable an activity stream for a database, a Kinesis stream is created for you. From Kinesis, you can monitor your database activity in real time. To further analyze database activity, you can connect your Kinesis stream to consumer applications. You can also connect the stream to compliance management applications such as IBM's Security Guardium or Imperva's SecureSphere Database Audit and Protection.

You can access your Kinesis stream either from the RDS console or the Kinesis console.

**To access an activity stream from Kinesis using the RDS console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the Amazon RDS database instance on which you started an activity stream.
4. Choose **Configuration**.
5. Under **Database activity stream**, choose the link under **Kinesis stream**.
6. In the Kinesis console, choose **Monitoring** to begin observing the database activity.

**To access an activity stream from Kinesis using the Kinesis console**

2. Choose your activity stream from the list of Kinesis streams.

   An activity stream's name includes the prefix `aws-rds-das-db-` followed by the resource ID of the database. The following is an example.
To use the Amazon RDS console to find the resource ID for the database, choose your DB instance from the list of databases, and then choose the **Configuration** tab.

To use the AWS CLI to find the full Kinesis stream name for an activity stream, use a `describe-db-instances` CLI request and note the value of `ActivityStreamKinesisStreamName` in the response.

3. Choose **Monitoring** to begin observing the database activity.

For more information about using Amazon Kinesis, see [What Is Amazon Kinesis Data Streams?](https://docs.aws.amazon.com/kinesis/latest/dev/what-is-kinesis.html).

## Audit log contents and examples

Monitored events are represented in the database activity stream as JSON strings. The structure consists of a JSON object containing a `DatabaseActivityMonitoringRecord`, which in turn contains a `databaseActivityEventList` array of activity events.

### Topics
- Examples of an audit log for an activity stream (p. 957)
- DatabaseActivityMonitoringRecords JSON object (p. 966)
- `databaseActivityEvents` JSON Object (p. 966)

### Examples of an audit log for an activity stream

Following are sample decrypted JSON audit logs of activity event records.

#### Example Activity event record of a CONNECT SQL statement

The following activity event record shows a login with the use of a `CONNECT` SQL statement (**command**) by a JDBC Thin Client (**clientApplication**) for your Oracle DB.

```json
{
   "class": "Standard",
   "clientApplication": "JDBC Thin Client",
   "command": "LOGON",

DatabaseActivityMonitoringRecords JSON object

The database activity event records are in a JSON object that contains the following information.

<table>
<thead>
<tr>
<th>JSON Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>The type of JSON record. The value is DatabaseActivityMonitoringRecords.</td>
</tr>
<tr>
<td>version</td>
<td>string</td>
<td>The version of the database activity monitoring records. Oracle DB uses version 1.3 and SQL Server uses version 1.4. These engine versions introduce the engineNativeAuditFields JSON object.</td>
</tr>
<tr>
<td>databaseActivityEvents (p. 966)</td>
<td>string</td>
<td>A JSON object that contains the activity events.</td>
</tr>
<tr>
<td>key</td>
<td>string</td>
<td>An encryption key that you use to decrypt the databaseActivityEventList (p. 968)</td>
</tr>
</tbody>
</table>

databaseActivityEvents JSON Object

The databaseActivityEvents JSON object contains the following information.

Top-level fields in JSON record

Each event in the audit log is wrapped inside a record in JSON format. This record contains the following fields.

**type**

This field always has the value DatabaseActivityMonitoringRecords.

**version**

This field represents the version of the database activity stream data protocol or contract. It defines which fields are available.
**databaseActivityEvents**

An encrypted string representing one or more activity events. It’s represented as a base64 byte array. When you decrypt the string, the result is a record in JSON format with fields as shown in the examples in this section.

**key**

The encrypted data key used to encrypt the `databaseActivityEvents` string. This is the same AWS KMS key that you provided when you started the database activity stream.

The following example shows the format of this record.

```json
{
  "type":"DatabaseActivityMonitoringRecords",
  "version":"1.3",
  "databaseActivityEvents":"encrypted audit records",
  "key":"encrypted key"
}
```

```
"type":"DatabaseActivityMonitoringRecords",
"version":"1.4",
"databaseActivityEvents":"encrypted audit records",
"key":"encrypted key"
```

Take the following steps to decrypt the contents of the `databaseActivityEvents` field:

1. Decrypt the value in the key JSON field using the KMS key you provided when starting database activity stream. Doing so returns the data encryption key in clear text.
2. Base64-decode the value in the `databaseActivityEvents` JSON field to obtain the ciphertext, in binary format, of the audit payload.
3. Decrypt the binary ciphertext with the data encryption key that you decoded in the first step.
4. Decompress the decrypted payload.
   - The encrypted payload is in the `databaseActivityEvents` field.
   - The `databaseActivityEventList` field contains an array of audit records. The `type` fields in the array can be record or heartbeat.

The audit log activity event record is a JSON object that contains the following information.

<table>
<thead>
<tr>
<th>JSON Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>type</code></td>
<td>string</td>
<td>The type of JSON record. The value is <code>DatabaseActivityMonitoringRecord</code>.</td>
</tr>
<tr>
<td><code>instanceId</code></td>
<td>string</td>
<td>The DB instance resource identifier. It corresponds to the DB instance attribute <code>DbiResourceId</code>.</td>
</tr>
<tr>
<td><code>databaseActivityEventList</code></td>
<td>string</td>
<td>An array of activity audit records or heartbeat messages.</td>
</tr>
</tbody>
</table>
### databaseActivityEventList JSON array

The audit log payload is an encrypted databaseActivityEventList JSON array. The following table lists alphabetically the fields for each activity event in the decrypted DatabaseActivityEventList array of an audit log.

When unified auditing is enabled in Oracle Database, the audit records are populated in this new audit trail. The UNIFIED_AUDIT_TRAIL view displays audit records in tabular form by retrieving the audit records from the audit trail. When you start a database activity stream, a column in UNIFIED_AUDIT_TRAIL maps to a field in the databaseActivityEventList array.

**Important**
The event structure is subject to change. Amazon RDS might add new fields to activity events in the future. In applications that parse the JSON data, make sure that your code can ignore or take appropriate actions for unknown field names.

### databaseActivityEventList fields for Amazon RDS for Oracle

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Source</th>
<th>Description</th>
</tr>
</thead>
</table>
| class             | string    | AUDIT_TYPE column in UNIFIED_AUDIT_TRAIL | The class of activity event. This corresponds to the AUDIT_TYPE column in the UNIFIED_AUDIT_TRAIL view. Valid values for Amazon RDS for Oracle are the following:
  • Standard
  • FineGrainedAudit
  • XS
  • Database Vault
  • Label Security
  • RMAN_AUDIT
  • Datapump
  • Direct path API
  For more information, see UNIFIED_AUDIT_TRAIL in the Oracle documentation. |
<p>| clientApplication | string    | CLIENT_PROGRAM_NAME in UNIFIED_AUDIT_TRAIL | The application the client used to connect as reported by the client. The client doesn't have to provide this information, so the value can be null. A sample value is JDBC Thin Client. |
| command           | string    | ACTION_NAME column in UNIFIED_AUDIT_TRAIL | Name of the action executed by the user. To understand the complete action, read both the command name and the AUDIT_TYPE value. A sample value is ALTER DATABASE. |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Source</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>commandText</td>
<td>string</td>
<td>SQL_TEXT column in UNIFIED_AUDIT_TRAIL</td>
<td>The SQL statement associated with the event. A sample value is ALTER DATABASE BEGIN BACKUP.</td>
</tr>
<tr>
<td>databaseName</td>
<td>string</td>
<td>NAME column in V$DATABASE</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>dbid</td>
<td>number</td>
<td>DBID column in UNIFIED_AUDIT_TRAIL</td>
<td>Numerical identifier for the database. A sample value is 1559204751.</td>
</tr>
<tr>
<td>dbProtocol</td>
<td>string</td>
<td>N/A</td>
<td>The database protocol. In this beta, the value is oracle.</td>
</tr>
<tr>
<td>dbUserName</td>
<td>string</td>
<td>DBUSERNAME column in UNIFIED_AUDIT_TRAIL</td>
<td>Name of the database user whose actions were audited. A sample value is RDSADMIN.</td>
</tr>
<tr>
<td>endTime</td>
<td>string</td>
<td>N/A</td>
<td>This field isn't used for RDS for Oracle and is always null.</td>
</tr>
<tr>
<td>Field</td>
<td>Data Type</td>
<td>Source</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------</td>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>engineNativeAuditFields</td>
<td>object</td>
<td>UNIFIED_AUDIT_TRAIL</td>
<td>By default, this object is empty. When you start the activity stream with the <code>--engine-native-audit-fields-included</code> option, this object includes the following columns and their values:</td>
</tr>
</tbody>
</table>
|                          |           |                         | ADDITIONAL_INFO
|                          |           |                         | APPLICATION_CONTEXTS
|                          |           |                         | AUDIT_OPTION
|                          |           |                         | AUTHENTICATION_TYPE

</tr>
</tbody>
</table>
### Field | Data Type | Source | Description
---|---|---|---
serverVersion | string | Database Host | The database server version, for example, 15.00.4073.23.v1.R1 for SQL Server 2017.
serviceName | string | Database Host | The name of the service. An example value is sqlserver-ee.
sessionId | integer | sys.fn_get_audit_file.session_id | Unique identifier of the session.
startTime | string | N/A | This field isn't used by Amazon RDS for SQL Server and the value is null.
statementId | string | sys.fn_get_audit_file.sequence_group_id | A unique identifier for the client's SQL statement. The identifier is different for each event that is generated. A sample value is 0x38eaf4156267184094bb82071aaab644.
substatementId | integer | sys.fn_get_audit_file.sequence_number | An identifier to determine the sequence number for a statement. This identifier helps when large records are split into multiple records.
transactionId | integer | sys.fn_get_audit_file.transaction_id | An identifier of a transaction. If there aren't any active transactions, the value is zero.
type | string | Database activity stream generated | The type of event. The values are record or heartbeat.

### Processing a database activity stream using the AWS SDK

You can programmatically process an activity stream by using the AWS SDK.

### Managing access to database activity streams

Any user with appropriate AWS Identity and Access Management (IAM) role privileges for database activity streams can create, start, stop, and modify the activity stream settings for a DB instance. These actions are included in the audit log of the stream. For best compliance practices, we recommend that you don't provide these privileges to DBAs.

You set access to database activity streams using IAM policies. For more information about Amazon RDS authentication, see Identity and access management for Amazon RDS (p. 2623). For more information about creating IAM policies, see Creating and using an IAM policy for IAM database access (p. 2663).

### Example Policy to allow configuring database activity streams

To give users fine-grained access to modify activity streams, use the service-specific operation context keys rds:StartActivityStream and rds:StopActivityStream in an IAM policy. The following IAM policy example allows a user or role to configure activity streams.

```json
{
   "Version":"2012-10-17",
   "Statement":
```
"Statement": [  
  {  
    "Sid": "ConfigureActivityStreams",
    "Effect": "Allow",
    "Action": [  
      "rds:StartActivityStream",
      "rds:StopActivityStream"
    ],
    "Resource": "*",
  }
]

Example Policy to allow starting database activity streams

The following IAM policy example allows a user or role to start activity streams.

{
  "Version": "2012-10-17",
  "Statement": [  
    {  
      "Sid": "AllowStartActivityStreams",
      "Effect": "Allow",
      "Action": "rds:StartActivityStream",
      "Resource": "*"
    }
  ]
}

Example Policy to allow stopping database activity streams

The following IAM policy example allows a user or role to stop activity streams.

{
  "Version": "2012-10-17",
  "Statement": [  
    {  
      "Sid": "AllowStopActivityStreams",
      "Effect": "Allow",
      "Action": "rds:StopActivityStream",
      "Resource": "*"
    }
  ]
}

Example Policy to deny starting database activity streams

The following IAM policy example prevents a user or role from starting activity streams.

{
  "Version": "2012-10-17",
  "Statement": [  
    {  
      "Sid": "DenyStartActivityStreams",
      "Effect": "Deny",
      "Action": "rds:StartActivityStream",
      "Resource": "*"
    }
  ]
}
Example Policy to deny stopping database activity streams

The following IAM policy example prevents a user or role from stopping activity streams.

```
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"DenyStopActivityStreams",
            "Effect":"Deny",
            "Action":"rds:StopActivityStream",
            "Resource":"*"
        }
    ]
}
```
Working with Amazon RDS Custom

Amazon RDS Custom automates database administration tasks and operations. RDS Custom makes it possible for you as a database administrator to access and customize your database environment and operating system. With RDS Custom, you can customize to meet the requirements of legacy, custom, and packaged applications.

For the latest webinars and blogs about RDS Custom, see Amazon RDS Custom resources.

Topics
- Addressing the challenge of database customization (p. 978)
- Management model and benefits for Amazon RDS Custom (p. 979)

- Working with RDS Custom for SQL Server (p. 1087)

Addressing the challenge of database customization

Amazon RDS Custom brings the benefits of Amazon RDS to a market that can't easily move to a fully managed service because of customizations that are required with third-party applications. Amazon RDS Custom saves administrative time, is durable, and scales with your business.

If you need the entire database and operating system to be fully managed by AWS, we recommend Amazon RDS. If you need administrative rights to the database and underlying operating system to make dependent applications available, Amazon RDS Custom is the better choice. If you want full management responsibility and simply need a managed compute service, the best option is self-managing your commercial databases on Amazon EC2.

To deliver a managed service experience, Amazon RDS doesn't let you access the underlying host. Amazon RDS also restricts access to some procedures and objects that require high-level privileges. However, for some applications, you might need to perform operations as a privileged operating system (OS) user.

For example, you might need to do the following:
- Install custom database and OS patches and packages.
- Configure specific database settings.
- Configure file systems to share files directly with their applications.

Previously, if you needed to customize your application, you had to deploy your database on-premises or on Amazon EC2. In this case, you bear most or all of the responsibility for database management, as summarized in the following table.

<table>
<thead>
<tr>
<th>Feature</th>
<th>On-premises responsibility</th>
<th>Amazon EC2 responsibility</th>
<th>Amazon RDS responsibility</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

When you manage database software yourself, you gain more control, but you're also more prone to user errors. For example, when you make changes manually, you might accidentally cause application downtime. You might spend hours checking every change to identify and fix an issue. Ideally, you want a managed database service that automates common DBA tasks, but also supports privileged access to the database and underlying operating system.

Management model and benefits for Amazon RDS Custom

Amazon RDS Custom is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. RDS Custom automates setup, operation, and scaling of databases in the AWS Cloud while granting you access to the database and underlying operating system. With this access, you can configure settings, install patches, and enable native features to meet the dependent application's requirements. With RDS Custom, you can run your database workload using the AWS Management Console or the AWS CLI.

RDS Custom supports only the Oracle Database and Microsoft SQL Server DB engines.

Topics
- Shared responsibility model in RDS Custom (p. 979)
- Support perimeter and unsupported configurations in RDS Custom (p. 981)
- Key benefits of RDS Custom (p. 981)

Shared responsibility model in RDS Custom

With RDS Custom, you use the managed features of Amazon RDS, but you manage the host and customize the OS as you do in Amazon EC2. You take on additional database management
Shared responsibility means the following:

1. You own part of the process when using an RDS Custom feature.
   For example, in RDS Custom for Oracle, you control which Oracle database patches to use and when to apply them to your DB instances.
2. You are responsible for making sure that any customizations to RDS Custom features work correctly.
   To help protect against invalid customization, RDS Custom has automation software that runs outside of your DB instance. If your underlying Amazon EC2 instance becomes impaired, RDS Custom attempts to resolve these problems automatically by either rebooting or replacing the EC2 instance. The only user-visible change is a new IP address. For more information, see Amazon RDS Custom host replacement (p. 983).

The following table details the shared responsibility model for different features of RDS Custom.

<table>

You can create an RDS Custom DB instance using Microsoft SQL Server. In this case:

- You don't manage your own media.
- You don't need to purchase SQL Server licenses separately. AWS holds the license for the SQL Server database software.

You can create an RDS Custom DB instance using Oracle Database. In this case, you do the following:
• Manage your own media.

When using RDS Custom, you upload your own database installation files and patches. You create a custom engine version (CEV) from these files. Then you can create an RDS Custom DB instance by using this CEV.

• Manage your own licenses.

You bring your own Oracle Database licenses and manage licenses by yourself.

Support perimeter and unsupported configurations in RDS Custom

RDS Custom provides a monitoring capability called the support perimeter. This feature ensures that your host and database environment are configured correctly. If you make a change that causes your DB instance to go outside the support perimeter, RDS Custom changes the instance status to unsupported-configuration until you manually fix the configuration problems. For more information, see RDS Custom support perimeter (p. 985).

Key benefits of RDS Custom

With RDS Custom, you can do the following:

• Automate many of the same administrative tasks as Amazon RDS, including the following:
  • Lifecycle management of databases
  • Automated backups and point-in-time recovery (PITR)
  • Monitoring the health of RDS Custom DB instances and observing changes to the infrastructure, operating system, and databases
  • Notification or taking action to fix issues depending on disruption to the DB instance
  • Install third-party applications.

You can install software to run custom applications and agents. Because you have privileged access to the host, you can modify file systems to support legacy applications.

• Install custom patches.

You can apply custom database patches or modify OS packages on your RDS Custom DB instances.

• Stage an on-premises database before moving it to a fully managed service.

If you manage your own on-premises database, you can stage the database to RDS Custom as-is. After you familiarize yourself with the cloud environment, you can migrate your database to a fully managed Amazon RDS DB instance.

• Create your own automation.

You can create, schedule, and run custom automation scripts for reporting, management, or diagnostic tools.

Amazon RDS Custom architecture

Amazon RDS Custom architecture is based on Amazon RDS, with important differences. The following diagram shows the key components of the RDS Custom architecture.
As in Amazon RDS, your RDS Custom DB instance resides in a virtual private cloud (VPC).
Your RDS Custom DB instance consists of the following main components:

- Amazon EC2 instance
- Instance endpoint
- Operating system installed on the Amazon EC2 instance
- Amazon EBS storage, which contains any additional file systems

### RDS Custom automation and monitoring

RDS Custom has automation software that runs outside of the DB instance. This software communicates with agents on the DB instance and with other components within the overall RDS Custom environment.

The RDS Custom monitoring and recovery features offer similar functionality to Amazon RDS. By default, RDS Custom is in full automation mode. The automation software has the following primary responsibilities:

- Collect metrics and send notifications
- Perform automatic instance recovery

An important responsibility of RDS Custom automation is responding to problems with your Amazon EC2 instance. For various reasons, the host might become impaired or unreachable. RDS Custom resolves these problems by either rebooting or replacing the Amazon EC2 instance.

**Topics**

- [Amazon RDS Custom host replacement](p. 983)
- [RDS Custom support perimeter](p. 985)

### Amazon RDS Custom host replacement

If the Amazon EC2 host becomes impaired, RDS Custom attempts to reboot it. If this effort fails, RDS Custom uses the same stop and start feature included in Amazon EC2. The only customer-visible change when a host is replaced is a new public IP address.

**Topics**
Stopping and starting the host

RDS Custom automatically takes the following steps, with no user intervention required:

1. Stops the Amazon EC2 host.
   
   The EC2 instance performs a normal shutdown and stops running. Any Amazon EBS volumes remain attached to the instance, and their data persists. Any data stored in the instance store volumes (not supported on RDS Custom) or RAM of the host computer is gone.
   
   For more information, see Stop and start your instance in the Amazon EC2 User Guide for Linux Instances.

2. Starts the Amazon EC2 host.
   
   The EC2 instance migrates to a new underlying host hardware. In some cases, the RDS Custom DB instance remains on the original host.

Effects of host replacement

In RDS Custom, you have full control over the root device volume and Amazon EBS storage volumes. The root volume can contain important data and configurations that you don't want to lose.

RDS Custom for Oracle retains all database and customer data after the operation, including root volume data. No user intervention is required. On RDS Custom for SQL Server, database data is retained, but any data on the C: drive, including operating system and customer data, is lost.

After the replacement process, the Amazon EC2 host has a new public IP address. The host retains the following:

- Instance ID
- Private IP addresses
- Elastic IP addresses
- Instance metadata
- Data storage volume data
- Root volume data (on RDS Custom for Oracle)

Best practices for Amazon EC2 hosts

The Amazon EC2 host replacement feature covers the majority of Amazon EC2 impairment scenarios. We recommend that you adhere to the following best practices:

- Before you change your configuration or the operating system, back up your data. If the root volume or operating system becomes corrupt, host replacement can't repair it. Your only options are restoring from a DB snapshot or point-in-time recovery.
- Don't manually stop or terminate the physical Amazon EC2 host. Both actions result in the instance being put outside the RDS Custom support perimeter.
- (RDS Custom for SQL Server) If you attach additional volumes to the Amazon EC2 host, configure them to remount upon restart. If the host is impaired, RDS Custom might stop and start the host automatically.
RDS Custom support perimeter

RDS Custom provides additional monitoring capability called the support perimeter. This additional monitoring ensures that your RDS Custom DB instance uses a supported AWS infrastructure, operating system, and database.

The support perimeter checks that your DB instance conforms to the requirements listed in Fixing unsupported configurations in RDS Custom for Oracle (p. 1080) and Fixing unsupported configurations in RDS Custom for SQL Server (p. 1188). If any of these requirements aren’t met, RDS Custom considers your DB instance to be outside of the support perimeter.

Topics
• Unsupported configurations in RDS Custom (p. 985)
• Troubleshooting unsupported configurations (p. 985)

Unsupported configurations in RDS Custom

When your DB instance is outside the support perimeter, RDS Custom changes the DB instance status to unsupported-configuration and sends event notifications. After you fix the configuration problems, RDS Custom changes the DB instance status back to available.

While your DB instance is in the unsupported-configuration state, the following is true:

• Your database is reachable. An exception is when the DB instance is in the unsupported-configuration because the database is shutting down unexpectedly.
• You can’t modify your DB instance.
• You can’t take DB snapshots.
• Automatic backups aren’t created.
• For RDS Custom for SQL Server DB instances only, RDS Custom doesn’t replace the underlying Amazon EC2 instance if it becomes impaired. For more information about host replacement, see Amazon RDS Custom host replacement (p. 983).
• You can delete your DB instance, but most other RDS Custom API operations aren’t available.
• RDS Custom continues to support point-in-time recovery (PITR) by archiving redo log files and uploading them to Amazon S3. PITR in an unsupported-configuration state differs in the following ways:
  • PITR can take a long time to completely restore to a new RDS Custom DB instance. This situation occurs because you can’t take either automated or manual snapshots while the instance is in the unsupported-configuration state.
  • PITR has to replay more redo logs starting from the most recent snapshot taken before the instance entered the unsupported-configuration state.
  • In some cases, the DB instance is in the unsupported-configuration state because you made a change that prevented the uploading of archived redo log files. Examples include stopping the EC2 instance, stopping the RDS Custom agent, and detaching EBS volumes. In such cases, PITR can’t restore the DB instance to the latest restorable time.

Troubleshooting unsupported configurations

RDS Custom provides troubleshooting guidance for the unsupported-configuration state. Although some guidance applies to both RDS Custom for Oracle and RDS Custom for SQL Server, other guidance depends on your DB engine. For engine-specific troubleshooting information, see the following topics:

• Fixing unsupported configurations in RDS Custom for Oracle (p. 1080)
• Fixing unsupported configurations in RDS Custom for SQL Server (p. 1188)
Amazon S3

If you use RDS Custom for Oracle, you upload installation media to a user-created Amazon S3 bucket. RDS Custom for Oracle uses the media in this bucket to create a custom engine version (CEV). A CEV is a binary volume snapshot of a database version and Amazon Machine Image (AMI). From the CEV, you can create an RDS Custom DB instance. For more information, see Working with custom engine versions for Amazon RDS Custom for Oracle (p. 1015).

For both RDS Custom for Oracle and RDS Custom for SQL Server, RDS Custom automatically creates an Amazon S3 bucket prefixed with the string `do-not-delete-rds-custom-`. RDS Custom uses the `do-not-delete-rds-custom-` S3 bucket to store the following types of files:

- AWS CloudTrail logs for the trail created by RDS Custom
- Support perimeter artifacts (see RDS Custom support perimeter (p. 985))
- Database redo log files (RDS Custom for Oracle only)
- Transaction logs (RDS Custom for SQL Server only)
- Custom engine version artifacts (RDS Custom for Oracle only)

RDS Custom creates the `do-not-delete-rds-custom-` S3 bucket when you create either of the following resources:

- Your first CEV for RDS Custom for Oracle
- Your first DB instance for RDS Custom for SQL Server

RDS Custom creates one bucket for each combination of the following:

- AWS account ID
- Engine type (either RDS Custom for Oracle or RDS Custom for SQL Server)
- AWS Region

For example, if you create RDS Custom for Oracle CEVs in a single AWS Region, one `do-not-delete-rds-custom-` bucket exists. If you create multiple RDS Custom for SQL Server instances, and they reside in different AWS Regions, one `do-not-delete-rds-custom-` bucket exists in each AWS Region. If you create one RDS Custom for Oracle instance and two RDS Custom for SQL Server instances in a single AWS Region, two `do-not-delete-rds-custom-` buckets exist.

AWS CloudTrail

RDS Custom automatically creates an AWS CloudTrail trail whose name begins with `do-not-delete-rds-custom-`. The RDS Custom support perimeter relies on the events from CloudTrail to determine whether your actions affect RDS Custom automation. For more information, see Troubleshooting unsupported configurations (p. 985).

RDS Custom creates the trail when you create your first DB instance. RDS Custom creates one trail for each combination of the following:

- AWS account ID
- Engine type (either RDS Custom for Oracle or RDS Custom for SQL Server)
- AWS Region

When you delete an RDS Custom DB instance, the CloudTrail for this instance isn't automatically removed. In this case, your AWS account continues to be billed for the undeleted CloudTrail. RDS Custom
is not responsible for the deletion of this resource. To learn how to remove the CloudTrail manually, see Deleting a trail in the AWS CloudTrail User Guide.
Security in Amazon RDS Custom

Familiarize yourself with the security considerations for RDS Custom.

Topics
- How RDS Custom securely manages tasks on your behalf (p. 988)
- SSL certificates (p. 989)
- Securing your Amazon S3 bucket against the confused deputy problem (p. 989)
- Rotating RDS Custom for Oracle credentials for compliance programs (p. 990)

How RDS Custom securely manages tasks on your behalf

RDS Custom uses the following tools and techniques to securely run operations on your behalf:

**AWSServiceRoleForRDSCustom service-linked role**

A service-linked role is predefined by the service and includes all permissions that the service needs to call other AWS services on your behalf. For RDS Custom, AWSServiceRoleForRDSCustom is a service-linked role that is defined according to the principle of least privilege. RDS Custom uses the permissions in AmazonRDSCustomServiceRolePolicy, which is the policy attached to this role, to perform most provisioning and all off-host management tasks. For more information, see AmazonRDSCustomServiceRolePolicy.

When it performs tasks on the host, RDS Custom automation uses credentials from the service-linked role to run commands using AWS Systems Manager. You can audit the command history through the Systems Manager command history and AWS CloudTrail. Systems Manager connects to your RDS Custom DB instance using your networking setup. For more information, see Step 3: Configure IAM and your Amazon VPC (p. 1003).

**Temporary IAM credentials**

When provisioning or deleting resources, RDS Custom sometimes uses temporary credentials derived from the credentials of the calling IAM principal. These IAM credentials are restricted by the IAM policies attached to that principal and expire after the operation is completed. To learn about the permissions required for IAM principals who use RDS Custom, see Step 4: Grant required permissions to your IAM user or role (p. 1012).

**Amazon EC2 instance profile**

An EC2 instance profile is a container for an IAM role that you can use to pass role information to an EC2 instance. An EC2 instance underlies an RDS Custom DB instance. You provide an instance profile when you create an RDS Custom DB instance. RDS Custom uses EC2 instance profile credentials when it performs host-based management tasks such as backups. For more information, see Create your IAM role and instance profile manually (p. 1007).

**SSH key pair**

When RDS Custom creates the EC2 instance that underlies a DB instance, it creates an SSH key pair on your behalf. The key uses the naming prefix do-not-delete-rds-custom-ssh-privatekey-db-.. AWS Secrets Manager stores this SSH private key as a secret in your AWS account. Amazon RDS doesn't store, access, or use these credentials. For more information, see Amazon EC2 key pairs and Linux instances.

**Note**

RDS Custom
SSL certificates

RDS Custom DB instances don't support managed SSL certificates. If you want to deploy SSL, you can self-manage SSL certificates in your own wallet and create an SSL listener to secure the connections between the client database or for database replication. For more information, see Configuring Transport Layer Security Authentication in the Oracle Database documentation.

Securing your Amazon S3 bucket against the confused deputy problem

When you create an Amazon RDS Custom for Oracle custom engine version (CEV) or an RDS Custom for SQL Server DB instance, RDS Custom creates an Amazon S3 bucket. The S3 bucket stores files such as CEV artifacts, redo (transaction) logs, configuration items for the support perimeter, and AWS CloudTrail logs.

You can make these S3 buckets more secure by using the global condition context keys to prevent the confused deputy problem. For more information, see Preventing cross-service confused deputy problems (p. 2657).

The following RDS Custom for Oracle example shows the use of the aws:SourceArn and aws:SourceAccount global condition context keys in an S3 bucket policy. For RDS Custom for Oracle, make sure to include the Amazon Resource Names (ARNs) for the CEVs and the DB instances. For RDS Custom for SQL Server, make sure to include the ARN for the DB instances.

```json

      }
   }
},
...
```
Rotating RDS Custom for Oracle credentials for compliance programs

Some compliance programs require database user credentials to change periodically, for example, every 90 days. RDS Custom for Oracle automatically rotates credentials for some predefined database users.

Topics

- Automatic rotation of credentials for predefined users (p. 990)
- Guidelines for rotating user credentials (p. 991)
- Rotating user credentials manually (p. 991)

Automatic rotation of credentials for predefined users

If your RDS Custom for Oracle DB instance is hosted in Amazon RDS, credentials for the following predefined Oracle users rotate every 30 days automatically. Credentials for the preceding users reside in AWS Secrets Manager.

Predefined Oracle users

<table>
<thead>
<tr>
<th>Database user</th>
<th>Created by</th>
<th>Supported engine versions</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYS</td>
<td>Oracle</td>
<td>custom-oracle-ee and custom-oracle-ee-cdb</td>
<td></td>
</tr>
<tr>
<td>SYSTEM</td>
<td>Oracle</td>
<td>custom-oracle-ee and custom-oracle-ee-cdb</td>
<td></td>
</tr>
<tr>
<td>RDSADMIN</td>
<td>RDS</td>
<td>custom-oracle-ee</td>
<td></td>
</tr>
<tr>
<td>C##RDSADMIN</td>
<td>RDS</td>
<td>custom-oracle-ee-cdb</td>
<td>Usersnames with a C## prefix exist only in CDBs. For more information about CDBs, see Overview of Amazon RDS Custom for Oracle architecture.</td>
</tr>
<tr>
<td>RDS_DATAGUARD</td>
<td>RDS</td>
<td>custom-oracle-ee</td>
<td>This user exists only in read replicas, source databases for read replicas, and databases that you have physically migrated into RDS Custom using Oracle Data Guard.</td>
</tr>
<tr>
<td>C##RDS_DATAGUARDRDS</td>
<td>custom-oracle-ee-cdb</td>
<td></td>
<td>This user exists only in read replicas, source databases for read replicas, and databases that you have physically migrated into RDS Custom using Oracle Data Guard. Usernames with a C## prefix exist only in CDBs. For more information about CDBs, see Overview of Amazon RDS Custom for Oracle architecture.</td>
</tr>
</tbody>
</table>

An exception to the automatic credential rotation is an RDS Custom for Oracle DB instance that you have manually configured as a standby database. RDS only rotates credentials for read
replicas that you have created using the `create-db-instance-read-replica` CLI command or `CreateDBInstanceReadReplica` API.

**Guidelines for rotating user credentials**

To make sure that your credentials rotate according to your compliance program, note the following guidelines:

- If your DB instance rotates credentials automatically, don't manually change or delete a secret, password file, or password for users listed in [Predefined Oracle users](#). Otherwise, RDS Custom might place your DB instance outside of the support perimeter, which suspends automatic rotation.
- The RDS master user is not predefined, so you are responsible for either changing the password manually or setting up automatic rotation in Secrets Manager. For more information, see [Rotate AWS Secrets Manager secrets](#).

**Rotating user credentials manually**

For the following categories of databases, RDS doesn't automatically rotate the credentials for the users listed in [Predefined Oracle users](#):

- A database that you configured manually to function as a standby database.
- An on-premises database.
- A DB instance that is outside of the support perimeter or in a state in which the RDS Custom automation can't run. In this case, RDS Custom also doesn't rotate keys.

If your database is in any of the preceding categories, you must rotate your user credentials manually.

**To rotate user credentials manually for a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In **Databases**, make sure that RDS isn't currently backing up your DB instance or performing operations such configuring high availability.
3. In the database details page, choose **Configuration** and note the Resource ID for the DB instance. Or you can use the AWS CLI command `describe-db-instances`.
5. In the search box, enter your DB Resource ID and find the secret in the following form:

   ```
   do-not-delete-rds-custom-db-resource-id-numeric-string
   ```

   This secret stores the password for RDSADMIN, SYS, and SYSTEM. The following sample key is for the DB instance with the DB resource ID `db-ABCDEFG12HIJKLNMNOPQRS3TUVWX`:

   ```
   do-not-delete-rds-custom-db-ABCDEFG12HIJKLNMNOPQRS3TUVWX-123456
   ```

   **Important**
   If your DB instance is a read replica and uses the `custom-oracle-ee-cdb` engine, two secrets exist with the suffix `db-resource-id-numeric-string`, one for the master user and the other for RDSADMIN, SYS, and SYSTEM. To find the correct secret, run the following command on the host:
cat /opt/aws/rdscustomagent/config/database_metadata.json | python3 -c "import sys, json; print(json.load(sys.stdin)['dbMonitoringUserPassword'])"

The `dbMonitoringUserPassword` attribute indicates the secret for RDSADMIN, SYS, and SYSTEM.

6. If your DB instance exists in an Oracle Data Guard configuration, find the secret in the following form:

   ```
do-not-delete-rds-custom-db-resource-id-numeric-string-dg
   ```

   This secret stores the password for RDS_DATAGUARD. The following sample key is for the DB instance with the DB resource ID `db-ABCDEFG12HIJKMNOPQRS3TUVWX`:

   ```
do-not-delete-rds-custom-db-ABCDEFG12HIJKMNOPQRS3TUVWX-789012-dg
   ```

7. For all database users listed in Predefined Oracle users (p. 990), update the passwords by following the instructions in Modify an AWS Secrets Manager secret.

8. If your database is a standalone database or a source database in an Oracle Data Guard configuration:

   a. Start your Oracle SQL client and log in as SYS.

   b. Run a SQL statement in the following form for each database user listed in Predefined Oracle users (p. 990):

   ```
   ALTER USER user-name IDENTIFIED BY pwd-from-secrets-manager ACCOUNT UNLOCK;
   ```

   For example, if the new password for RDSADMIN stored in Secrets Manager is `pwd-123`, run the following statement:

   ```
   ALTER USER RDSADMIN IDENTIFIED BY pwd-123 ACCOUNT UNLOCK;
   ```

9. If your DB instance runs Oracle Database 12c Release 1 (12.1) and is managed by Oracle Data Guard, manually copy the password file (`orapw`) from the primary DB instance to each standby DB instance.

   If your DB instance is hosted in Amazon RDS, the password file location is `/rdsdbdata/config/orapw`. For databases that aren't hosted in Amazon RDS, the default location is `$ORACLE_HOME/dbs/orapw$ORACLE_SID` on Linux and UNIX and `%ORACLE_HOME%/database/PWD%ORACLE_SID%/ora` on Windows.
Working with RDS Custom for Oracle

Following, you can find instructions for creating, managing, and maintaining your RDS Custom for Oracle DB instances.

- Configuring a DB instance for Amazon RDS Custom for Oracle (p. 1035)
- Managing an Amazon RDS Custom for Oracle DB instance (p. 1047)
- Working with Oracle replicas for RDS Custom for Oracle (p. 1060)
- Backing up and restoring an Amazon RDS Custom for Oracle DB instance (p. 1065)
- Migrating an on-premises database to RDS Custom for Oracle (p. 1072)
- Upgrading a DB instance for Amazon RDS Custom for Oracle (p. 1073)
- Troubleshooting DB issues for Amazon RDS Custom for Oracle (p. 1078)

RDS Custom for Oracle workflow

The following diagram shows the typical workflow for RDS Custom for Oracle.

The steps are as follows:
1. Upload your database software to your Amazon S3 bucket.
   
   For more information, see Step 3: Upload your installation files to Amazon S3 (p. 1017).

2. Create an RDS Custom for Oracle custom engine version (CEV) from your media.
   
   Choose either the multitenant or non-multitenant architecture. For more information, see Creating a CEV (p. 1026).

3. Create an RDS Custom for Oracle DB instance from a CEV.
   
   For more information, see Creating an RDS Custom for Oracle DB instance (p. 1035).

4. Connect your application to the DB instance endpoint.
   
   For more information, see Connecting to your RDS Custom DB instance using SSH (p. 1041) and Connecting to your RDS Custom DB instance using Session Manager (p. 1040).

5. (Optional) Access the host to customize your software.

6. Monitor notifications and messages generated by RDS Custom automation.

### Database installation files

Your responsibility for media is a key difference between Amazon RDS and RDS Custom. Amazon RDS, which is a fully managed service, supplies the Amazon Machine Image (AMI) and database software. The Amazon RDS database software is preinstalled, so you need only choose a database engine and version, and create your database.

For RDS Custom, you supply your own media. When you create a custom engine version, RDS Custom installs the media that you provide. RDS Custom media contains your database installation files and patches. This service model is called Bring Your Own Media (BYOM).

### Custom engine version

An RDS Custom custom engine version (CEV) is a binary volume snapshot of a database version and AMI. By default, RDS Custom for Oracle uses the most recent AMI that Amazon EC2 makes available. You can also choose to reuse an existing AMI.

### CEV manifest

After you download Oracle database installation files from Oracle, you upload them to an Amazon S3 bucket. When you create your CEV, you specify the file names in a JSON document called a CEV manifest. RDS Custom for Oracle uses the specified files and the AMI to create your CEV.

RDS Custom for Oracle provides JSON manifest templates with our recommended .zip files for each supported Oracle Database release. For example, the following template is for the 19.17.0.0.0 RU.

```json
{
   "mediaImportTemplateVersion": "2020-08-14",
   "databaseInstallationFileNames": [
      "V982063-01.zip"
   ],
   "opatchFileNames": [
      "p6880880_190000_Linux-x86-64.zip"
   ],
   "psuRuPatchFileNames": [
      "p34419443_190000_Linux-x86-64.zip",
      "p3441846_190000_Linux-x86-64.zip"
   ],
   "otherPatchFileNames": [
      "p28852325_190000_Linux-x86-64.zip"
   ]
}
```
You can also specify installation parameters in the JSON manifest. For example, you can set nondefault values for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. For more information, see JSON fields in the CEV manifest (p. 1020).

**CEV naming format**

Name your CEV using a customer-specified string. The name format is the following, depending on your Oracle Database release:

- 19. `customized_string`
- 18. `customized_string`
- 12.2. `customized_string`
- 12.1. `customized_string`

You can use 1–50 alphanumeric characters, underscores, dashes, and periods. For example, you might name your CEV `19.my_cev1`.

**Multitenant architecture**

The multitenant architecture enables an Oracle database to function as a multitenant container database (CDB). A CDB includes zero, one, or many customer-created pluggable databases (PDBs). A PDB is a portable collection of schemas and objects that appears to an application as a non-CDB.

When you create a CEV, you can specify the either the multitenant or non-multitenant architecture. You can create an RDS Custom for Oracle CDB only when the CEV that you used to create it uses the multitenant architecture. For more information, see Working with custom engine versions for Amazon RDS Custom for Oracle (p. 1015).

**Creating a DB instance for RDS Custom for Oracle**

After you create your CEV, it's available for use. You can create multiple CEVs, and you can create multiple RDS Custom for Oracle DB instances from any CEV. You can also change the status of a CEV to make it available or inactive.

You can either create your RDS Custom for Oracle DB instance with the Oracle Multitenant architecture (`custom-oracle-ee-cdb engine type`) or with the traditional non-CDB architecture (`custom-oracle-ee engine type`). When you create a container database (CDB), it contains one pluggable database (PDB) and one PDB seed. You can create additional PDBs manually using Oracle SQL.

To create your RDS Custom for Oracle DB instance, use the `create-db-instance` command. In this command, specify which CEV to use. The procedure is similar to creating an Amazon RDS DB instance. However, some parameters are different. For more information, see Configuring a DB instance for Amazon RDS Custom for Oracle (p. 1035).
Database connection

Like an Amazon RDS DB instance, an RDS Custom DB instance resides in a virtual private cloud (VPC). Your application connects to the Oracle database using an Oracle listener.

If your database is a CDB, you can use the listener L_RDSCDB_001 to connect to the CDB root and to a PDB. If you plug a non-CDB into a CDB, make sure to set USE_SID_AS_SERVICE_LISTENER = ON so that migrated applications keep the same settings.

When you connect to a non-CDB, the master user is the user for the non-CDB. When you connect to a CDB, the master user is the user for the PDB. To connect to the CDB root, log in to the host, start a SQL client, and create an administrative user with SQL commands.

RDS Custom customization

You can access the RDS Custom host to install or customize software. To avoid conflicts between your changes and the RDS Custom automation, you can pause the automation for a specified period. During this period, RDS Custom doesn't perform monitoring or instance recovery. At the end of the period, RDS Custom resumes full automation. For more information, see Pausing and resuming your RDS Custom DB instance (p. 1049).
Database architecture for Amazon RDS Custom for Oracle

RDS Custom for Oracle supports both the multitenant and non-multitenant architecture.

Topics
- Supported Oracle database architectures (p. 997)
- Supported engine types (p. 997)
- Supported features in the multitenant architecture (p. 997)

Supported Oracle database architectures

Oracle Database 19c supports both the multitenant and non-multitenant (non-CDB) architecture. The multitenant architecture enables an Oracle database to function as a container database (CDB). A CDB includes pluggable databases (PDBs). A PDB is a portable collection of schemas and objects that appears to an application as a traditional Oracle database. For more information, see Introduction to the Multitenant Architecture in the Oracle Multitenant Administrator's Guide.

The multitenant and non-multitenant architectures are mutually exclusive. If a database isn't a CDB, it's a non-CDB and so can't contain other databases. In RDS Custom for Oracle, only Oracle Database 19c supports the multitenant architecture. Thus, if you create instances using previous database releases, you can create only non-CDBs.

Supported engine types

When you create an Amazon RDS Custom for Oracle CEV or DB instance, choose either of the following engine types:

- custom-oracle-ee-cdb

  This engine type specifies the multitenant architecture. This option is available only for Oracle Database 19c. When you create an RDS for Oracle DB instance using the multitenant architecture, your CDB includes the following containers:
  - CDB root (CDB$ROOT)
  - PDB seed (PDB$SEED)
  - Initial PDB

  You can create more PDBs using the Oracle SQL command CREATE PLUGGABLE DATABASE. You can't use RDS APIs to create or delete PDBs.

- custom-oracle-ee

  This engine type specifies the traditional non-CDB architecture. A non-CDB can't contain pluggable databases (PDBs).

For more information, see Multitenant architecture considerations (p. 1035).

Supported features in the multitenant architecture

An RDS Custom for Oracle CDB instance supports the following features:

- Backups
- Restoring and point-time-restore (PITR) from backups
• Read replicas
• Minor version upgrades
RDS Custom for Oracle requirements and limitations

In this topic, you can find a summary of the Amazon RDS Custom for Oracle feature availability and requirements for quick reference.

**Topics**
- AWS Region and database version support for RDS Custom for Oracle (p. 999)
- Edition and licensing support for RDS Custom for Oracle (p. 999)
- DB instance class support for RDS Custom for Oracle (p. 999)
- General requirements for RDS Custom for Oracle (p. 1000)
- General limitations for RDS Custom for Oracle (p. 1000)

**AWS Region and database version support for RDS Custom for Oracle**

Feature availability and support vary across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS Custom for Oracle, see RDS Custom (p. 151).

**Edition and licensing support for RDS Custom for Oracle**

RDS Custom for Oracle supports only Enterprise Edition on the BYOL model.

**DB instance class support for RDS Custom for Oracle**

RDS Custom for Oracle supports the following DB instance classes.

<table>
<thead>
<tr>
<th>Type</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.r6i</td>
<td>`db.r6i.large</td>
</tr>
<tr>
<td>db.r5b</td>
<td>`db.r5b.large</td>
</tr>
<tr>
<td>db.r5</td>
<td>`db.r5.large</td>
</tr>
<tr>
<td>db.x2iedn</td>
<td>`db.x2iedn.xlarge</td>
</tr>
<tr>
<td>db.m6i</td>
<td>`db.m6i.large</td>
</tr>
<tr>
<td>db.m5</td>
<td>`db.m5.large</td>
</tr>
<tr>
<td>db.t3</td>
<td>`db.t3.medium</td>
</tr>
</tbody>
</table>
**General requirements for RDS Custom for Oracle**

Make sure to follow these requirements for Amazon RDS Custom for Oracle:

- Use [Oracle Software Delivery Cloud](https://docs.oracle.com/middleware/12211/rdbms/windows/odcsuperportal/oad/index.htm) to download Oracle installation and patch files. For more information, see [Prerequisites for creating an RDS Custom for Oracle DB instance](p. 1002).
- Use the DB instance classes shown in [DB instance class support for RDS Custom for Oracle](p. 999). The DB instances must run Oracle Linux 7 Update 9.
- Specify the gp2, gp3, or io1 solid state drives for storage. The maximum storage limit is 64 TiB.
- Make sure that you have an AWS KMS key to create an RDS Custom DB instance. For more information, see [Step 1: Create or reuse a symmetric encryption AWS KMS key](p. 1003).
- Use only the approved Oracle database installation and patch files. For more information, see [Step 2: Download your database installation files and patches from Oracle Software Delivery Cloud](p. 1016).
- Create an AWS Identity and Access Management (IAM) role and instance profile. For more information, see [Step 3: Configure IAM and your Amazon VPC](p. 1003).
- Make sure to supply a networking configuration that RDS Custom can use to access other AWS services. For specific requirements, see [Step 3: Configure IAM and your Amazon VPC](p. 1003).
- Make sure that the combined number of RDS Custom and Amazon RDS DB instances doesn't exceed your quota limit. For example, if your quota for Amazon RDS is 40 DB instances, you can have 20 RDS Custom for Oracle DB instances and 20 Amazon RDS DB instances.

**General limitations for RDS Custom for Oracle**

The following limitations apply to RDS Custom for Oracle:

- You can't provide your own AMI. You can specify only the default AMI or an AMI that has been previously used by a CEV.
- You can't modify a CEV to use a different AMI.
- You can't modify the DB instance identifier of an existing RDS Custom for Oracle DB instance.
- You can't specify the multitenant architecture for a database release other than Oracle Database 19c.
- You can't create a CDB instance from a CEV that uses the custom-oracle-ee engine. The CEV must use custom-oracle-ee-cdb.
- Not all Amazon RDS options are supported. For example, when you create or modify an RDS Custom for Oracle DB instance, you can't do the following:
  - Change the number of CPU cores and threads per core on the DB instance class.
  - Turn on storage autoscaling.
  - Create a Multi-AZ deployment.

  **Note**
  For an alternative HA solution, see the AWS blog article [Build high availability for Amazon RDS Custom for Oracle using read replicas](https://aws.amazon.com/blogs/database/build-high-availability-for-amazon-rds-custom-for-oracle-using-read-replicas/).

- Set backup retention to 0.
- Configure Kerberos authentication.
- Specify your own DB parameter group or option group.
- Turn on Performance Insights.
- Turn on automatic minor version upgrade.
- You can't specify a DB instance storage size greater than the maximum of 64 TiB.
- You can't create multiple Oracle databases on a single RDS Custom for Oracle DB instance.
- You can't stop your RDS Custom for Oracle DB instance or its underlying Amazon EC2 instance. Billing for an RDS Custom for Oracle DB instance can't be stopped.
• You can't use automatic shared memory management. RDS Custom for Oracle supports only automatic memory management. For more information, see Automatic Memory Management in the Oracle Database Administrator’s Guide.

• Make sure not to change the DB_UNIQUE_NAME for the primary DB instance. Changing the name causes any restore operation to become stuck.

For limitations specific to modifying an RDS Custom for Oracle DB instance, see Modifying your RDS Custom for Oracle DB instance (p. 1052). For replication limitations, see General limitations for RDS Custom for Oracle replication (p. 1062).
Setting up your environment for Amazon RDS Custom for Oracle

Before you create an Amazon RDS Custom for Oracle DB instance, perform the following tasks.

**Topics**

- Prerequisites for creating an RDS Custom for Oracle DB instance (p. 1002)
- Step 1: Create or reuse a symmetric encryption AWS KMS key (p. 1003)
- Step 2: Download and install the AWS CLI (p. 1003)
- Step 3: Configure IAM and your Amazon VPC (p. 1003)
- Step 4: Grant required permissions to your IAM user or role (p. 1012)

**Prerequisites for creating an RDS Custom for Oracle DB instance**

Before creating an RDS Custom for Oracle DB instance, make sure that you meet the following prerequisites:

- You have access to My Oracle Support and Oracle Software Delivery Cloud to download the supported list of installation files and patches for the Enterprise Edition of any of the following Oracle Database releases:
  - Oracle Database 19c
  - Oracle Database 18c
  - Oracle Database 12c Release 2 (12.2)
  - Oracle Database 12c Release 1 (12.1)

  If you use an unknown patch, custom engine version (CEV) creation fails. In this case, contact the RDS Custom support team and ask it to add the missing patch.

  For more information, see Step 2: Download your database installation files and patches from Oracle Software Delivery Cloud (p. 1016).

- You have access to Amazon S3. This service is required for the following reasons:
  - You upload your Oracle installation files to S3 buckets. You use the uploaded installation files to create your RDS Custom CEV.
  - RDS Custom for Oracle uses scripts downloaded from internally defined S3 buckets to perform actions on your DB instances. These scripts are necessary for onboarding and RDS Custom automation.
  - RDS Custom for Oracle uploads certain files to S3 buckets located in your customer account. These buckets use the following naming format: `do-not-delete-rds-custom-account_id-region-six_character_alphanumerics_string`. For example, you might have a bucket named `do-not-delete-rds-custom-123456789012-us-east-1-12a3b4`.

  For more information, see Step 3: Upload your installation files to Amazon S3 (p. 1017) and Creating a CEV (p. 1026).

- You supply your own virtual private cloud (VPC) and security group configuration. For more information, see Step 3: Configure IAM and your Amazon VPC (p. 1003).

- The AWS Identity and Access Management (IAM) user that creates a CEV or RDS Custom DB instance has the required permissions for IAM, CloudTrail, and Amazon S3.

  For more information, see Step 4: Grant required permissions to your IAM user or role (p. 1012).
