    "Resource": "*"
}
```

2. Follow the steps in [Attach a permissions policy to a secret](https://docs.aws.amazon.com/secretmanager/latest/userguide/attach-policy.html) in the *AWS Secrets Manager User Guide*. The permissions policy gives the `secretsmanager:GetSecretValue` action to the `rds.amazonaws.com` service principal.

We recommend that you use the `aws:sourceAccount` and `aws:sourceArn` conditions in the policy to avoid the *confused deputy* problem. Use your AWS account for `aws:sourceAccount` and the option group ARN for `aws:sourceArn`. For more information, see [Preventing cross-service confused deputy problems](https://docs.aws.amazon.com/secretmanager/latest/userguide/preventing-cross-service-confused-deputy-problems.html).

The following example shows a permissions policy.

```
{
    "Version" : "2012-10-17",
    "Statement" : [
        {
            "Effect" : "Allow",
            "Principal" : {
                "Service" : "rds.amazonaws.com"
            },
```

---

**SQL Server Reporting Services**

---

**2823**
"Action" : "secretsmanager:GetSecretValue",
"Resource" : "*",
"Condition" : {
    "StringEquals" : {
        "aws:sourceAccount" : "123456789012"
    },
    "ArnLike" : {
    }
}
}

For more examples, see Permissions policy examples for AWS Secrets Manager in the AWS Secrets Manager User Guide.

**Revoking system-level permissions**

The RDS_SSRS_ROLE system role doesn't have sufficient permissions to delete system-level role assignments. To remove a user or user group from RDS_SSRS_ROLE, use the same stored procedure that you used to grant the role but use the SSRS_REVOKE_PORTAL_PERMISSION task type.

**To revoke access from a domain user for the web portal**

- Use the following stored procedure.

  ```sql
  exec msdb.dbo.rds_msbi_task
  @task_type='SSRS_REVOKE_PORTAL_PERMISSION',
  @ssrs_group_or_username=N'AD_domain\user';
  ```

Doing this deletes the user from the RDS_SSRS_ROLE system role. It also deletes the user from the Content Manager item-level role if the user has it.

**Monitoring the status of a task**

To track the status of your granting or revoking task, call the rds_fn_task_status function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to SSRS. The second parameter accepts a task ID.
To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 42);
```

The `rds_fn_task_status` function returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>task_type</td>
<td>For SSRS, tasks can have the following task types:</td>
</tr>
<tr>
<td></td>
<td>• SSRS_GRANT_PORTAL_PERMISSION</td>
</tr>
<tr>
<td></td>
<td>• SSRS_REVOKE_PORTAL_PERMISSION</td>
</tr>
<tr>
<td>database_name</td>
<td>Not applicable to SSRS tasks.</td>
</tr>
<tr>
<td>% complete</td>
<td>The progress of the task as a percentage.</td>
</tr>
<tr>
<td>duration (mins)</td>
<td>The amount of time spent on the task, in minutes.</td>
</tr>
<tr>
<td>lifecycle</td>
<td>The status of the task. Possible statuses are the following:</td>
</tr>
<tr>
<td></td>
<td>• CREATED – After you call one of the SSRS stored procedures, a task is created and the status is set to CREATED.</td>
</tr>
</tbody>
</table>
|                  | • IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It can take
### Output parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>up to five minutes for the status to change from CREATED to IN_PROGRESS</strong>.</td>
<td></td>
</tr>
<tr>
<td>- <strong>SUCCESS</strong> – After a task completes, the status is set to SUCCESS.</td>
<td></td>
</tr>
<tr>
<td>- <strong>ERROR</strong> – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column.</td>
<td></td>
</tr>
<tr>
<td>- <strong>CANCEL_REQUESTED</strong> – After you call the rds_cancel_task stored procedure, the status of the task is set to CANCEL_REQUESTED.</td>
<td></td>
</tr>
<tr>
<td>- <strong>CANCELLED</strong> – After a task is successfully canceled, the status of the task is set to CANCELLED.</td>
<td></td>
</tr>
</tbody>
</table>

| **task_info**          | Additional information about the task. If an error occurs during processing, this column contains information about the error. |
| **last_updated**       | The date and time that the task status was last updated. |
| **created_at**         | The date and time that the task was created. |
| **S3_object_arn**      | Not applicable to SSRS tasks. |
| **overwrite_S3_backup_file** | Not applicable to SSRS tasks. |
| **KMS_master_key_arn** | Not applicable to SSRS tasks. |
| **filepath**           | Not applicable to SSRS tasks. |
| **overwrite_file**     | Not applicable to SSRS tasks. |
### Turning off SSRS

To turn off SSRS, remove the SSRS option from its option group. Removing the option doesn't delete the SSRS databases. For more information, see [Deleting the SSRS databases](#).

You can turn SSRS on again by adding back the SSRS option. If you have also deleted the SSRS databases, readding the option on the same DB instance creates new report server databases.

#### Console

**To remove the SSRS option from its option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSRS option (`ssrs-se-2017` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSRS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

#### CLI

**To remove the SSRS option from its option group**

- Run one of the following commands.

  **Example**

  For Linux, macOS, or Unix:

  ```bash
  aws rds remove-option-from-option-group \
  --option-group-name ssrs-se-2017 \
  ```
Deleting the SSRS databases

Removing the SSRS option doesn't delete the report server databases. To delete them, use the following stored procedure.

To delete the report server databases, be sure to remove the SSRS option first.

To delete the SSRS databases

- Use the following stored procedure.

```sql
exec msdb.dbo.rds_drop_ssrs_databases
```
Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server

A distributed transaction is a database transaction in which two or more network hosts are involved. RDS for SQL Server supports distributed transactions among hosts, where a single host can be one of the following:

- RDS for SQL Server DB instance
- On-premises SQL Server host
- Amazon EC2 host with SQL Server installed
- Any other EC2 host or RDS DB instance with a database engine that supports distributed transactions

In RDS, starting with SQL Server 2012 (version 11.00.5058.0.v1 and later), all editions of RDS for SQL Server support distributed transactions. The support is provided using Microsoft Distributed Transaction Coordinator (MSDTC). For in-depth information about MSDTC, see Distributed Transaction Coordinator in the Microsoft documentation.

Contents

- Limitations
- Enabling MSDTC
  - Creating the option group for MSDTC
  - Adding the MSDTC option to the option group
  - Creating the parameter group for MSDTC
  - Modifying the parameter for MSDTC
  - Associating the option group and parameter group with the DB instance
- Using distributed transactions
- Using XA transactions
- Using transaction tracing
- Modifying the MSDTC option
- Disabling MSDTC
- Troubleshooting MSDTC for RDS for SQL Server
Limitations

The following limitations apply to using MSDTC on RDS for SQL Server:

- MSDTC isn't supported on instances using SQL Server Database Mirroring. For more information, see Transactions - availability groups and database mirroring.

- The in-doubt xact resolution parameter must be set to 1 or 2. For more information, see Modifying the parameter for MSDTC.

- MSDTC requires all hosts participating in distributed transactions to be resolvable using their host names. RDS automatically maintains this functionality for domain-joined instances. However, for standalone instances make sure to configure the DNS server manually.

- Java Database Connectivity (JDBC) XA transactions are supported for SQL Server 2017 version 14.00.3223.3 and higher, and SQL Server 2019.

- Distributed transactions that depend on client dynamic link libraries (DLLs) on RDS instances aren't supported.

- Using custom XA dynamic link libraries isn't supported.

Enabling MSDTC

Use the following process to enable MSDTC for your DB instance:

1. Create a new option group, or choose an existing option group.

2. Add the MSDTC option to the option group.

3. Create a new parameter group, or choose an existing parameter group.

4. Modify the parameter group to set the in-doubt xact resolution parameter to 1 or 2.

5. Associate the option group and parameter group with the DB instance.

Creating the option group for MSDTC

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of your DB instance.
You can also use an existing option group if it's for the correct SQL Server engine and version.

**Console**

The following procedure creates an option group for SQL Server Standard Edition 2016.

**To create the option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:
   a. For **Name**, enter a name for the option group that is unique within your AWS account, such as `msdtc-se-2016`. The name can contain only letters, digits, and hyphens.
   b. For **Description**, enter a brief description of the option group, such as **MSDTC option group for SQL Server SE 2016**. The description is used for display purposes.
   c. For **Engine**, choose `sqlserver-se`.
   d. For **Major engine version**, choose `13.00`.
5. Choose **Create**.

**CLI**

The following example creates an option group for SQL Server Standard Edition 2016.

**To create the option group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:
Adding the MSDTC option to the option group

Next, use the AWS Management Console or the AWS CLI to add the MSDTC option to the option group.

The following option settings are required:

- **Port** – The port that you use to access MSDTC. Allowed values are 1150–49151 except for 1234, 1434, 3260, 3343, 3389, and 47001. The default value is 5000.

  Make sure that the port you want to use is enabled in your firewall rules. Also, make sure as needed that this port is enabled in the inbound and outbound rules for the security group associated with your DB instance. For more information, see [Can't connect to Amazon RDS DB instance](https://docs.aws.amazon.com/storagegateway/latest/ug/cant-connect-to-rgw-instance.html).

- **Security groups** – The VPC security group memberships for your RDS DB instance.

- **Authentication type** – The authentication mode between hosts. The following authentication types are supported:
  
  - **Mutual** – The RDS instances are mutually authenticated to each other using integrated authentication. If this option is selected, all instances associated with this option group must be domain-joined.
  
  - **None** – No authentication is performed between hosts. We don't recommend using this mode in production environments.
• **Transaction log size** – The size of the MSDTC transaction log. Allowed values are 4–1024 MB. The default size is 4 MB.

The following option settings are optional:

• **Enable inbound connections** – Whether to allow inbound MSDTC connections to instances associated with this option group.

• **Enable outbound connections** – Whether to allow outbound MSDTC connections from instances associated with this option group.

• **Enable XA** – Whether to allow XA transactions. For more information on the XA protocol, see XA specification.

• **Enable SNA LU** – Whether to allow the SNA LU protocol to be used for distributed transactions. For more information on SNA LU protocol support, see Managing IBM CICS LU 6.2 transactions in the Microsoft documentation.

**Console**

**To add the MSDTC option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **MSDTC** for **Option name**.
6. Under **Option settings**:
   a. For **Port**, enter the port number for accessing MSDTC. The default is **5000**.
   b. For **Security groups**, choose the VPC security group to associate with the option.
   c. For **Authentication type**, choose **Mutual** or **None**.
   d. For **Transaction log size**, enter a value from 4–1024. The default is **4**.
7. Under **Additional configuration**, do the following:
   a. For **Connections**, as needed choose **Enable inbound connections** and **Enable outbound connections**.
b. For **Allowed protocols**, as needed choose **Enable XA** and **Enable SNA LU**.

8. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.

9. Choose **Add option**.

   To add this option, no reboot is required.

**CLI**

**To add the MSDTC option**

1. Create a JSON file, for example `msdtc-option.json`, with the following required parameters.

   ```json
   {
     "OptionGroupName": "msdtc-se-2016",
     "OptionsToInclude": [
       {
         "OptionName": "MSDTC",
         "Port": 5000,
         "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
         "OptionSettings": [
           { "Name": "AUTHENTICATION", "Value": "MUTUAL" },
           { "Name": "TRANSACTION_LOG_SIZE", "Value": "4" }
         ]
       },
       "ApplyImmediately": true
     }
   }
   ```

2. Add the MSDTC option to the option group.

   **Example**

   For Linux, macOS, or Unix:

   ```bash
   aws rds add-option-to-option-group \
   --cli-input-json file://msdtc-option.json \
   --apply-immediately
   ```

   For Windows:

   ```bash
   aws rds add-option-to-option-group
   ```
No reboot is required.

Creating the parameter group for MSDTC

Create or modify a parameter group for the in-doubt xact resolution parameter that corresponds to the SQL Server edition and version of your DB instance.

Console

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
4. In the Create parameter group pane, do the following:
   a. For Parameter group family, choose sqlserver-se-13.0.
   b. For Group name, enter an identifier for the parameter group, such as msdtc-sqlserver-se-13.
   c. For Description, enter in-doubt xact resolution.
5. Choose Create.

CLI

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:
Modifying the parameter for MSDTC

Modify the in-doubt xact resolution parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

For MSDTC, set the in-doubt xact resolution parameter to one of the following:

- 1 – Presume commit. Any MSDTC in-doubt transactions are presumed to have committed.
- 2 – Presume abort. Any MSDTC in-doubt transactions are presumed to have stopped.

For more information, see in-doubt xact resolution server configuration option in the Microsoft documentation.

Console

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

**To modify the parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group, such as msdtc-sqlserver-se-13.
4. Under Parameters, filter the parameter list for xact.
5. Choose **in-doubt xact resolution**.
6. Choose **Edit parameters**.
7. Enter 1 or 2.
8. Choose **Save changes**.

**CLI**

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

**To modify the parameter group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
--db-parameter-group-name msdtc-sqlserver-se-13 \
--parameters "ParameterName='in-doubt xact resolution',ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
--db-parameter-group-name msdtc-sqlserver-se-13 ^
--parameters "ParameterName='in-doubt xact resolution',ParameterValue=1,ApplyMethod=immediate"
```

**Associating the option group and parameter group with the DB instance**

You can use the AWS Management Console or the AWS CLI to associate the MSDTC option group and parameter group with the DB instance.

**Console**

You can associate the MSDTC option group and parameter group with a new or existing DB instance.
For a new DB instance, associate them when you launch the instance. For more information, see **Creating an Amazon RDS DB instance**.

For an existing DB instance, associate them by modifying the instance. For more information, see **Modifying an Amazon RDS DB instance**.

**Note**

If you use an domain-joined existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see [Working with AWS Managed Active Directory with RDS for SQL Server](#).

---

**CLI**

You can associate the MSDTC option group and parameter group with a new or existing DB instance.

**Note**

If you use an existing domain-joined DB instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see [Working with AWS Managed Active Directory with RDS for SQL Server](#).

---

**To create a DB instance with the MSDTC option group and parameter group**

- Specify the same DB engine type and major version as you used when creating the option group.

  **Example**

  For Linux, macOS, or Unix:

  ```
  aws rds create-db-instance \
  --db-instance-identifier mydbinstance \
  --db-instance-class db.m5.2xlarge \
  ```
For Windows:

```
aws rds create-db-instance ^
  --db-instance-identifier mydbinstance ^
  --db-instance-class db.m5.2xlarge ^
  --engine sqlserver-se ^
  --engine-version 13.00.5426.0.v1 ^
  --allocated-storage 100 ^
  --master-username admin ^
  --storage-type gp2 ^
  --license-model li ^
  --domain-iam-role-name my-directory-iam-role ^
  --domain my-domain-id ^
  --option-group-name msdtc-se-2016 ^
  --db-parameter-group-name msdtc-sqlserver-se-13
```

To modify a DB instance and associate the MSDTC option group and parameter group

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \n  --db-instance-identifier mydbinstance \n  --option-group-name msdtc-se-2016 \n  --db-parameter-group-name msdtc-sqlserver-se-13
```
For Windows:

```bash
aws rds modify-db-instance
  --db-instance-identifier mydbinstance
  --option-group-name msdtc-se-2016
  --db-parameter-group-name msdtc-sqlserver-se-13
  --apply-immediately
```

**Using distributed transactions**

In Amazon RDS for SQL Server, you run distributed transactions in the same way as distributed transactions running on-premises:

- Using .NET framework `System.Transactions` promotable transactions, which optimizes distributed transactions by deferring their creation until they're needed.

In this case, promotion is automatic and doesn't require you to make any intervention. If there's only one resource manager within the transaction, no promotion is performed. For more information about implicit transaction scopes, see [Implementing an implicit transaction using transaction scope](#) in the Microsoft documentation.

Promotable transactions are supported with these .NET implementations:

- Starting with ADO.NET 2.0, `System.Data.SqlClient` supports promotable transactions with SQL Server. For more information, see [System.Transactions integration with SQL Server](#) in the Microsoft documentation.

- ODP.NET supports `System.Transactions`. A local transaction is created for the first connection opened in the `TransactionsScope` scope to Oracle Database 11g release 1 (version 11.1) and later. When a second connection is opened, this transaction is automatically promoted to a distributed transaction. For more information about distributed transaction support in ODP.NET, see [Microsoft Distributed Transaction Coordinator integration](#) in the Microsoft documentation.

- Using the `BEGIN DISTRIBUTED TRANSACTION` statement. For more information, see [BEGIN DISTRIBUTED TRANSACTION (Transact-SQL)](#) in the Microsoft documentation.
Using XA transactions

Starting from RDS for SQL Server 2017 version 14.00.3223.3, you can control distributed transactions using JDBC. When you set the Enable XA option setting to true in the MSDTC option, RDS automatically enables JDBC transactions and grants the SqlJDBCXAUser role to the guest user. This allows executing distributed transactions through JDBC. For more information, including a code example, see Understanding XA transactions in the Microsoft documentation.

Using transaction tracing

RDS supports controlling MSDTC transaction traces and downloading them from the RDS DB instance for troubleshooting. You can control transaction tracing sessions by running the following RDS stored procedure.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'trace_action',
 [@traceall='0|1'],
 [@traceaborted='0|1'],
 [@tracelong='0|1'];
```

The following parameter is required:

- `trace_action` – The tracing action. It can be START, STOP, or STATUS.

The following parameters are optional:

- `@traceall` – Set to 1 to trace all distributed transactions. The default is 0.
- `@traceaborted` – Set to 1 to trace canceled distributed transactions. The default is 0.
- `@tracelong` – Set to 1 to trace long-running distributed transactions. The default is 0.

Example of START tracing action

To start a new transaction tracing session, run the following example statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'START',
 @traceall='0',
 @traceaborted='1',
 @tracelong='1';
```
Note

Only one transaction tracing session can be active at one time. If a new tracing session START command is issued while a tracing session is active, an error is returned and the active tracing session remains unchanged.

Example of STOP tracing action

To stop a transaction tracing session, run the following statement.

`exec msdb.dbo.rds_msdtc_transaction_tracing 'STOP'`

This statement stops the active transaction tracing session and saves the transaction trace data into the log directory on the RDS DB instance. The first row of the output contains the overall result, and the following lines indicate details of the operation.

The following is an example of a successful tracing session stop.

```
OK: Trace session has been successfully stopped.
Setting log file to: D:\rdsdbdata\MSDTC\Trace\dtctrace.log
Examining D:\rdsdbdata\MSDTC\Trace\msdtctr.mof for message formats, 8 found.
Searching for TMF files on path: (null)
Logfile D:\rdsdbdata\MSDTC\Trace\dtctrace.log:
  OS version    10.0.14393  (Currently running on 6.2.9200)
  Start Time    <timestamp>
  End Time      <timestamp>
  Timezone is   @tzres.dll,-932 (Bias is 0mins)
  BufferSize    16384 B
  Maximum File Size  10 MB
  Buffers Written Not set (Logger may not have been stopped).
  Logger Mode Settings (11000002) (circular paged)
  ProcessorCount 1
  Processing completed Buffers: 1, Events: 3, EventsLost: 0 :: Format Errors: 0, Unknowns: 3
  Event traces dumped to d:\rdsdbdata\Log\msdtc_<timestamp>.log
```

You can use the detailed information to query the name of the generated log file. For more information about downloading log files from the RDS DB instance, see Monitoring Amazon RDS log files.
The trace session logs remain on the instance for 35 days. Any older trace session logs are automatically deleted.

**Example of STATUS tracing action**

To trace the status of a transaction tracing session, run the following statement.

```sql
exec msdb.dbo.rds_msdtc_transaction_tracing 'STATUS'
```

This statement outputs the following as separate rows of the result set.

```
OK
SessionStatus: <Started|Stopped>
TraceAll: <True|False>
TraceAborted: <True|False>
TraceLongLived: <True|False>
```

The first line indicates the overall result of the operation: OK or ERROR with details, if applicable. The subsequent lines indicate details about the tracing session status:

- **SessionStatus** can be one of the following:
  - Started if a tracing session is running.
  - Stopped if no tracing session is running.
- The tracing session flags can be True or False depending on how they were set in the START command.

**Modifying the MSDTC option**

After you enable the MSDTC option, you can modify its settings. For information about how to modify option settings, see [Modifying an option setting](#).

---

**Note**

Some changes to MSDTC option settings require the MSDTC service to be restarted. This requirement can affect running distributed transactions.
Disabling MSDTC

To disable MSDTC, remove the MSDTC option from its option group.

Console

To remove the MSDTC option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the option group with the MSDTC option (msdtc-se-2016 in the previous examples).
4. Choose Delete option.
5. Under Deletion options, choose MSDTC for Options to delete.
6. Under Apply immediately, choose Yes to delete the option immediately, or No to delete it at the next maintenance window.
7. Choose Delete.

CLI

To remove the MSDTC option from its option group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```bash
aws rds remove-option-from-option-group \ 
   --option-group-name msdtc-se-2016 \ 
   --options MSDTC \ 
   --apply-immediately
```

For Windows:

```bash
aws rds remove-option-from-option-group ^
   --option-group-name msdtc-se-2016 ^
   --options MSDTC ^
```
Troubleshooting MSDTC for RDS for SQL Server

In some cases, you might have trouble establishing a connection between MSDTC running on a client computer and the MSDTC service running on an RDS for SQL Server DB instance. If so, make sure of the following:

- The inbound rules for the security group associated with the DB instance are configured correctly. For more information, see Can't connect to Amazon RDS DB instance.
- Your client computer is configured correctly.
- The MSDTC firewall rules on your client computer are enabled.

To configure the client computer

1. Open Component Services.
   Or, in Server Manager, choose Tools, and then choose Component Services.
2. Expand Component Services, expand Computers, expand My Computer, and then expand Distributed Transaction Coordinator.
3. Open the context (right-click) menu for Local DTC and choose Properties.
5. Choose all of the following:
   - Network DTC Access
   - Allow Inbound
   - Allow Outbound
6. Make sure that the correct authentication mode is chosen:
   - Mutual Authentication Required – The client machine is joined to the same domain as other nodes participating in distributed transaction, or there is a trust relationship configured between domains.
   - No Authentication Required – All other cases.
7. Choose OK to save your changes.
8. If prompted to restart the service, choose Yes.
To enable MSDTC firewall rules

1. Open Windows Firewall, then choose Advanced settings.

   Or, in Server Manager, choose Tools, and then choose Windows Firewall with Advanced Security.

   ![Note](image)

   Depending on your operating system, Windows Firewall might be called Windows Defender Firewall.

2. Choose Inbound Rules in the left pane.

3. Enable the following firewall rules, if they are not already enabled:

   - Distributed Transaction Coordinator (RPC)
   - Distributed Transaction Coordinator (RPC)-EPMAP
   - Distributed Transaction Coordinator (TCP-In)

Common DBA tasks for Microsoft SQL Server

This section describes the Amazon RDS-specific implementations of some common DBA tasks for DB instances that are running the Microsoft SQL Server database engine. In order to deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges.

Note

When working with a SQL Server DB instance, you can run scripts to modify a newly created database, but you cannot modify the [model] database, the database used as the model for new databases.

Topics

- Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS
- Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor

- Determining the last failover time
- Disabling fast inserts during bulk loading
- Dropping a Microsoft SQL Server database
- Renaming a Microsoft SQL Server database in a Multi-AZ deployment
- Resetting the db_owner role password
- Restoring license-terminated DB instances
- Transitioning a Microsoft SQL Server database from OFFLINE to ONLINE
- Using change data capture
- Using SQL Server Agent
- Working with Microsoft SQL Server logs
- Working with trace and dump files
Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS

You can access the tempdb database on your Microsoft SQL Server DB instances on Amazon RDS. You can run code on tempdb by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information about connecting to your DB instance, see Connecting to a DB instance running the Microsoft SQL Server database engine.

The master user for your DB instance is granted CONTROL access to tempdb so that this user can modify the tempdb database options. The master user isn't the database owner of the tempdb database. If necessary, the master user can grant CONTROL access to other users so that they can also modify the tempdb database options.

Note
You can't run Database Console Commands (DBCC) on the tempdb database.

Modifying tempdb database options

You can modify the database options on the tempdb database on your Amazon RDS DB instances. For more information about which options can be modified, see tempdb database in the Microsoft documentation.

Database options such as the maximum file size options are persistent after you restart your DB instance. You can modify the database options to optimize performance when importing data, and to prevent running out of storage.

Optimizing performance when importing data

To optimize performance when importing large amounts of data into your DB instance, set the SIZE and FILEGROWTH properties of the tempdb database to large numbers. For more information about how to optimize tempdb, see Optimizing tempdb performance in the Microsoft documentation.

The following example demonstrates setting the size to 100 GB and file growth to 10 percent.

```
alter database[tempdb] modify file (NAME = N'templog', SIZE=100GB, FILEGROWTH = 10%)
```
Preventing storage problems

To prevent the tempdb database from using all available disk space, set the MAXSIZE property. The following example demonstrates setting the property to 2048 MB.

```
alter database [tempdb] modify file (NAME = N'templog', MAXSIZE = 2048MB)
```

Shrinking the tempdb database

There are two ways to shrink the tempdb database on your Amazon RDS DB instance. You can use the `rds_shrink_tempdbfile` procedure, or you can set the SIZE property.

Using the `rds_shrink_tempdbfile` procedure

You can use the Amazon RDS procedure `msdb.dbo.rds_shrink_tempdbfile` to shrink the tempdb database. You can only call `rds_shrink_tempdbfile` if you have CONTROL access to tempdb. When you call `rds_shrink_tempdbfile`, there is no downtime for your DB instance.

The `rds_shrink_tempdbfile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@temp_filename</td>
<td>SYSNAME</td>
<td>—</td>
<td>required</td>
<td>The logical name of the file to shrink.</td>
</tr>
<tr>
<td>@target_size</td>
<td>int</td>
<td>null</td>
<td>optional</td>
<td>The new size for the file, in megabytes.</td>
</tr>
</tbody>
</table>

The following example gets the names of the files for the tempdb database.

```
use tempdb;
GO

select name, * from sys.sysfiles;
GO
```

The following example shrinks a tempdb database file named test_file, and requests a new size of 10 megabytes:

```
```
exec msdb.dbo.rds_shrink_tempdbfile @temp_filename = N'test_file', @target_size = 10;

**Setting the SIZE property**

You can also shrink the tempdb database by setting the SIZE property and then restarting your DB instance. For more information about restarting your DB instance, see [Rebooting a DB instance](#).

The following example demonstrates setting the SIZE property to 1024 MB.

```
alter database [tempdb] modify file (NAME = N'templog', SIZE = 1024MB)
```

**TempDB configuration for Multi-AZ deployments**

If your RDS for SQL Server DB instance is in a Multi-AZ Deployment using Database Mirroring (DBM) or Always On Availability Groups (AGs), keep in mind the following considerations for using the tempdb database.

You can't replicate tempdb data from your primary DB instance to your secondary DB instance.

When you fail over to a secondary DB instance, tempdb on that secondary DB instance will be empty.

You can synchronize the configuration of the tempdb database options, including its file sizing and autogrowth settings, from your primary DB instance to your secondary DB instance. Synchronizing the tempDB configuration is supported on all RDS for SQL Server versions. You can turn on automatic synchronization of the tempdb configuration by using the following stored procedure:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types = 'TempDbFile';
```

⚠️ **Important**

Before using the `rds_set_system_database_sync_objects` stored procedure, ensure you've set your preferred tempdb configuration on your primary DB instance, rather than on your secondary DB instance. If you made the configuration change on your secondary DB instance, your preferred tempdb configuration could be deleted when you turn on automatic synchronization.

You can use the following function to confirm whether automatic synchronization of the tempdb configuration is turned on:
SELECT * from msdb.dbo.rds_fn_get_system_database_sync_objects();

When automatic synchronization of the tempdb configuration is turned on, there will be a return value for the object_class field. When it's turned off, no value is returned.

You can use the following function to find the last time objects were synchronized, in UTC time:

SELECT * from msdb.dbo.rds_fn_server_object_last_sync_time();

For example, if you modified the tempdb configuration at 01:00 and then run the rds_fn_server_object_last_sync_time function, the value returned for last_sync_time should be after 01:00, indicating that an automatic synchronization occurred.

If you are also using SQL Server Agent job replication, you can enable replication for both SQL Agent jobs and the tempdb configuration by providing them in the @object_type parameter:

EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types = 'SQLAgentJob,TempDbFile';

For more information on SQL Server Agent job replication, see Turning on SQL Server Agent job replication.

As an alternative to using the rds_set_system_database_sync_objects stored procedure to ensure that tempdb configuration changes are automatically synchronized, you can use one of the following manual methods:

**Note**

We recommend turning on automatic synchronization of the tempdb configuration by using the rds_set_system_database_sync_objects stored procedure. Using automatic synchronization prevents the need to perform these manual tasks each time you change your tempdb configuration.

- First modify your DB instance and turn Multi-AZ off, then modify tempdb, and finally turn Multi-AZ back on. This method doesn't involve any downtime.

  For more information, see Modifying an Amazon RDS DB instance.
• First modify tempdb in the original primary instance, then fail over manually, and finally modify tempdb in the new primary instance. This method involves downtime.

For more information, see Rebooting a DB instance.

Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor

Database Engine Tuning Advisor is a client application provided by Microsoft that analyzes database workload and recommends an optimal set of indexes for your Microsoft SQL Server databases based on the kinds of queries you run. Like SQL Server Management Studio, you run Tuning Advisor from a client computer that connects to your Amazon RDS DB instance that is running SQL Server. The client computer can be a local computer that you run on premises within your own network or it can be an Amazon EC2 Windows instance that is running in the same region as your Amazon RDS DB instance.

This section shows how to capture a workload for Tuning Advisor to analyze. This is the preferred process for capturing a workload because Amazon RDS restricts host access to the SQL Server instance. For more information, see Database Engine Tuning Advisor in the Microsoft documentation.

To use Tuning Advisor, you must provide what is called a workload to the advisor. A workload is a set of Transact-SQL statements that run against a database or databases that you want to tune. Database Engine Tuning Advisor uses trace files, trace tables, Transact-SQL scripts, or XML files as workload input when tuning databases. When working with Amazon RDS, a workload can be a file on a client computer or a database table on an Amazon RDS for SQL Server DB accessible to your client computer. The file or the table must contain queries against the databases you want to tune in a format suitable for replay.

For Tuning Advisor to be most effective, a workload should be as realistic as possible. You can generate a workload file or table by performing a trace against your DB instance. While a trace is running, you can either simulate a load on your DB instance or run your applications with a normal load.

There are two types of traces: client-side and server-side. A client-side trace is easier to set up and you can watch trace events being captured in real-time in SQL Server Profiler. A server-side trace is more complex to set up and requires some Transact-SQL scripting. In addition, because the trace is written to a file on the Amazon RDS DB instance, storage space is consumed by the trace. It is
important to track of how much storage space a running server-side trace uses because the DB instance could enter a storage-full state and would no longer be available if it runs out of storage space.

For a client-side trace, when a sufficient amount of trace data has been captured in the SQL Server Profiler, you can then generate the workload file by saving the trace to either a file on your local computer or in a database table on a DB instance that is available to your client computer. The main disadvantage of using a client-side trace is that the trace may not capture all queries when under heavy loads. This could weaken the effectiveness of the analysis performed by the Database Engine Tuning Advisor. If you need to run a trace under heavy loads and you want to ensure that it captures every query during a trace session, you should use a server-side trace.

For a server-side trace, you must get the trace files on the DB instance into a suitable workload file or you can save the trace to a table on the DB instance after the trace completes. You can use the SQL Server Profiler to save the trace to a file on your local computer or have the Tuning Advisor read from the trace table on the DB instance.

**Running a client-side trace on a SQL Server DB instance**

**To run a client-side trace on a SQL Server DB instance**

1. Start SQL Server Profiler. It is installed in the Performance Tools folder of your SQL Server instance folder. You must load or define a trace definition template to start a client-side trace.
2. In the SQL Server Profiler File menu, choose **New Trace**. In the **Connect to Server** dialog box, enter the DB instance endpoint, port, master user name, and password of the database you would like to run a trace on.
3. In the **Trace Properties** dialog box, enter a trace name and choose a trace definition template. A default template, TSQL_Replay, ships with the application. You can edit this template to define your trace. Edit events and event information under the **Events Selection** tab of the **Trace Properties** dialog box.
   
   For more information about trace definition templates and using the SQL Server Profiler to specify a client-side trace, see [Database Engine Tuning Advisor](https://docs.microsoft.com) in the Microsoft documentation.
4. Start the client-side trace and watch SQL queries in real-time as they run against your DB instance.
5. Select **Stop Trace** from the **File** menu when you have completed the trace. Save the results as a file or as a trace table on your DB instance.
Running a server-side trace on a SQL Server DB instance

Writing scripts to create a server-side trace can be complex and is beyond the scope of this document. This section contains sample scripts that you can use as examples. As with a client-side trace, the goal is to create a workload file or trace table that you can open using the Database Engine Tuning Advisor.

The following is an abridged example script that starts a server-side trace and captures details to a workload file. The trace initially saves to the file RDSTrace.trc in the D:\RDSDBDATA\Log directory and rolls-over every 100 MB so subsequent trace files are named RDSTrace_1.trc, RDSTrace_2.trc, etc.

```sql
DECLARE @file_name NVARCHAR(245) = 'D:\RDSDBDATA\Log\RDSTrace';
DECLARE @max_file_size BIGINT = 100;
DECLARE @on BIT = 1
DECLARE @rc INT
DECLARE @traceid INT

EXEC @rc = sp_trace_create @traceid OUTPUT, 2, @file_name, @max_file_size
IF (@rc = 0) BEGIN
    EXEC sp_trace_setevent @traceid, 10, 1, @on
    EXEC sp_trace_setevent @traceid, 10, 2, @on
    EXEC sp_trace_setevent @traceid, 10, 3, @on
    ...
    EXEC sp_trace_setfilter @traceid, 10, 0, 7, N'SQL Profiler'
    EXEC sp_trace_setstatus @traceid, 1
END
```

The following example is a script that stops a trace. Note that a trace created by the previous script continues to run until you explicitly stop the trace or the process runs out of disk space.

```sql
DECLARE @traceid INT
SELECT @traceid = traceid FROM ::fn_trace_getinfo(default)
WHERE property = 5 AND value = 1 AND traceid <> 1

IF @traceid IS NOT NULL BEGIN
    EXEC sp_trace_setstatus @traceid, 0
    EXEC sp_trace_setstatus @traceid, 2
END
```
You can save server-side trace results to a database table and use the database table as the workload for the Tuning Advisor by using the fn_trace_gettable function. The following commands load the results of all files named RDSTrace.trc in the D:\rdsdbdata\Log directory, including all rollover files like RDSTrace_1.trc, into a table named RDSTrace in the current database.

```sql
SELECT * INTO RDSTrace
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace.trc', default);
```

To save a specific rollover file to a table, for example the RDSTrace_1.trc file, specify the name of the rollover file and substitute 1 instead of default as the last parameter to fn_trace_gettable.

```sql
SELECT * INTO RDSTrace_1
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace_1.trc', 1);
```

### Running Tuning Advisor with a trace

Once you create a trace, either as a local file or as a database table, you can then run Tuning Advisor against your DB instance. Using Tuning Advisor with Amazon RDS is the same process as when working with a standalone, remote SQL Server instance. You can either use the Tuning Advisor UI on your client machine or use the dta.exe utility from the command line. In both cases, you must connect to the Amazon RDS DB instance using the endpoint for the DB instance and provide your master user name and master user password when using Tuning Advisor.

The following code example demonstrates using the dta.exe command line utility against an Amazon RDS DB instance with an endpoint of `dta.cnazcmklsdei.us-east-1.rds.amazonaws.com`. The example includes the master user name `admin` and the master user password `test`, the example database to tune is named `machine` named `C:\RDSTrace.trc`. The example command line code also specifies a trace session named `RDSTrace1` and specifies output files to the local machine named `RDSTrace.sql` for the SQL output script, `RDSTrace.txt` for a result file, and `RDSTrace.xml` for an XML file of the analysis. There is also an error table specified on the RDSDTA database named `RDSTraceErrors`.

```plaintext
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RDSDTA -i C:\RDSTrace.trc -s RDSTrace1 -o C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\ RDSTrace.xml -e RDSDTA.dbo.RDSTraceErrors
```

Here is the same example command line code except the input workload is a table on the remote Amazon RDS instance named `RDSTrace` which is on the `RDSDTA` database.
Changing the db_owner to the rdsa account for your database

When you create or restore a database in an RDS for SQL Server DB instance, Amazon RDS sets the owner of the database to rdsa. If you have a Multi-AZ deployment using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs), Amazon RDS sets the owner of the database on the secondary DB instance to NT AUTHORITY\SYSTEM. The owner of the secondary database can't be changed until the secondary DB instance is promoted to the primary role. In most cases, setting the owner of the database to NT AUTHORITY\SYSTEM isn't problematic when executing queries, however, can throw errors when executing system stored procedures such as sys.sp_updatestats that require elevated permissions to execute.

You can use the following query to identify the owner of the databases owned by NT AUTHORITY\SYSTEM:

```
SELECT name FROM sys.databases WHERE SUSER_SNAME(owner_sid) = 'NT AUTHORITY\SYSTEM';
```

You can use the Amazon RDS stored procedure rds_changedbowner_to_rdsa to change the owner of the database to rdsa. The following databases are not allowed to be used with rds_changedbowner_to_rdsa: master, model, msdb, rdsadmin, rdsadmin_ReportServer, rdsadmin_ReportServerTempDB, SSISDB.

To change the owner of the database to rdsa, call the rds_changedbowner_to_rdsa stored procedure and provide the name of the database.

**Example usage:**

```
exec msdb.dbo.rds_changedbowner_to_rdsa 'TestDB1';
```

The following parameter is required:

- @db_name – The name of the database to change the owner of the database to rdsa.
Collations and character sets for Microsoft SQL Server

SQL Server supports collations at multiple levels. You set the default server collation when you create the DB instance. You can override the collation in the database, table, or column level.

Topics

• Server-level collation for Microsoft SQL Server
• Database-level collation for Microsoft SQL Server

Server-level collation for Microsoft SQL Server

When you create a Microsoft SQL Server DB instance, you can set the server collation that you want to use. If you don’t choose a different collation, the server-level collation defaults to SQL_Latin1_General_CP1_CI_AS. The server collation is applied by default to all databases and database objects.

⚠️ Note

You can't change the collation when you restore from a DB snapshot.

Currently, Amazon RDS supports the following server collations:

<table>
<thead>
<tr>
<th>Collation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arabic_CI_AS</td>
<td>Arabic, case-insensitive, accent-sensitive,</td>

</tr>
</tbody>
</table>

To choose the collation:

- If you're using the Amazon RDS console, when creating a new DB instance choose **Additional configuration**, then enter the collation in the **Collation** field. For more information, see [Creating an Amazon RDS DB instance](#).
• If you're using the AWS CLI, use the `--character-set-name` option with the `create-db-instance` command. For more information, see `create-db-instance`.

• If you're using the Amazon RDS API, use the `CharacterSetName` parameter with the `CreateDBInstance` operation. For more information, see `CreateDBInstance`.

Database-level collation for Microsoft SQL Server

You can change the default collation at the database, table, or column level by overriding the collation when creating a new database or database object. For example, if your default server collation is `SQL_Latin1_General_CP1_CI_AS`, you can change it to `Mohawk_100_CI_AS` for Mohawk collation support. Even arguments in a query can be type-cast to use a different collation if necessary.

For example, the following query would change the default collation for the `AccountName` column to `Mohawk_100_CI_AS`.

```sql
CREATE TABLE [dbo].[Account]
(
    [AccountID] [nvarchar](10) NOT NULL,
    [AccountName] [nvarchar](100) COLLATE Mohawk_100_CI_AS NOT NULL
) ON [PRIMARY];
```

The Microsoft SQL Server DB engine supports Unicode by the built-in `NCHAR`, `NVARCHAR`, and `NTEXT` data types. For example, if you need CJK support, use these Unicode data types for character storage and override the default server collation when creating your databases and tables. Here are several links from Microsoft covering collation and Unicode support for SQL Server:

• [Working with collations](#)
• [Collation and international terminology](#)
• [Using SQL Server collations](#)
• [International considerations for databases and database engine applications](#)

Creating a database user

You can create a database user for your Amazon RDS for Microsoft SQL Server DB instance by running a T-SQL script like the following example. Use an application such as SQL Server...
Management Suite (SSMS). You log into the DB instance as the master user that was created when you created the DB instance.

```sql
--Initially set context to master database
USE [master];
GO
--Create a server-level login named theirname with password theirpassword
CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';
GO
--Set context to msdb database
USE [msdb];
GO
--Create a database user named theirname and link it to server-level login theirname
CREATE USER [theirname] FOR LOGIN [theirname];
GO
```

For an example of adding a database user to a role, see Adding a user to the SQLAgentUser role.

**Note**

If you get permission errors when adding a user, you can restore privileges by modifying the DB instance master user password. For more information, see Resetting the db_owner role password.

**Determining a recovery model for your Microsoft SQL Server database**

In Amazon RDS, the recovery model, retention period, and database status are linked. It's important to understand the consequences before making a change to one of these settings. Each setting can affect the others. For example:

- If you change a database's recovery model to SIMPLE or BULK_LOGGED while backup retention is enabled, Amazon RDS resets the recovery model to FULL within five minutes. This also results in RDS taking a snapshot of the DB instance.
- If you set backup retention to 0 days, RDS sets the recovery mode to SIMPLE.
- If you change a database's recovery model from SIMPLE to any other option while backup retention is set to 0 days, RDS resets the recovery model to SIMPLE.
**Important**

Never change the recovery model on Multi-AZ instances, even if it seems you can do so—for example, by using ALTER DATABASE. Backup retention, and therefore FULL recovery mode, is required for Multi-AZ. If you alter the recovery model, RDS immediately changes it back to FULL.

This automatic reset forces RDS to completely rebuild the mirror. During this rebuild, the availability of the database is degraded for about 30-90 minutes until the mirror is ready for failover. The DB instance also experiences performance degradation in the same way it does during a conversion from Single-AZ to Multi-AZ. How long performance is degraded depends on the database storage size—the bigger the stored database, the longer the degradation.

For more information on SQL Server recovery models, see [Recovery models (SQL Server)](https://docs.microsoft.com/en-us/sql/database-engine/recovery-models) in the Microsoft documentation.

### Determining the last failover time

To determine the last failover time, use the following stored procedure:

```sql
execute msdb.dbo.rds_failover_time;
```

This procedure returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>errorlog_available_from</td>
<td>Shows the time from when error logs are available in the log directory.</td>
</tr>
<tr>
<td>recent_failover_time</td>
<td>Shows the last failover time if it's available from the error logs. Otherwise it shows null.</td>
</tr>
</tbody>
</table>
Note

The stored procedure searches all of the available SQL Server error logs in the log directory to retrieve the most recent failover time. If the failover messages have been overwritten by SQL Server, then the procedure doesn't retrieve the failover time.

Example of no recent failover

This example shows the output when there is no recent failover in the error logs. No failover has happened since 2020-04-29 23:59:00.01.

<table>
<thead>
<tr>
<th>errorlog_available_from</th>
<th>recent_failover_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-04-29 23:59:00.0100000</td>
<td>null</td>
</tr>
</tbody>
</table>

Example of recent failover

This example shows the output when there is a failover in the error logs. The most recent failover was at 2020-05-05 18:57:51.89.

<table>
<thead>
<tr>
<th>errorlog_available_from</th>
<th>recent_failover_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-04-29 23:59:00.0100000</td>
<td>2020-05-05 18:57:51.8900000</td>
</tr>
</tbody>
</table>

Disabling fast inserts during bulk loading

Starting with SQL Server 2016, fast inserts are enabled by default. Fast inserts leverage the minimal logging that occurs while the database is in the simple or bulk logged recovery model to optimize insert performance. With fast inserts, each bulk load batch acquires new extents, bypassing the allocation lookup for existing extents with available free space to optimize insert performance.

However, with fast inserts bulk loads with small batch sizes can lead to increased unused space consumed by objects. If increasing batch size isn't feasible, enabling trace flag 692 can help reduce
unused reserved space, but at the expense of performance. Enabling this trace flag disables fast inserts while bulk loading data into heap or clustered indexes.

You enable trace flag 692 as a startup parameter using DB parameter groups. For more information, see Working with parameter groups.

Trace flag 692 is supported for Amazon RDS on SQL Server 2016 and later. For more information on trace flags, see DBCC TRACEON - trace flags in the Microsoft documentation.

Dropping a Microsoft SQL Server database

You can drop a database on an Amazon RDS DB instance running Microsoft SQL Server in a Single-AZ or Multi-AZ deployment. To drop the database, use the following command:

```sql
EXECUTE msdb.dbo.rds_drop_database  N'your-database-name'
```

**Note**

Use straight single quotes in the command. Smart quotes will cause an error.

After you use this procedure to drop the database, Amazon RDS drops all existing connections to the database and removes the database’s backup history.

Renaming a Microsoft SQL Server database in a Multi-AZ deployment

To rename a Microsoft SQL Server database instance that uses Multi-AZ, use the following procedure:

1. First, turn off Multi-AZ for the DB instance.
2. Rename the database by running `rdsadmin.dbo.rds_modify_db_name`.
3. Then, turn on Multi-AZ Mirroring or Always On Availability Groups for the DB instance, to return it to its original state.

For more information, see Adding Multi-AZ to a Microsoft SQL Server DB instance.
Note

If your instance doesn't use Multi-AZ, you don't need to change any settings before or after running `rdsadmin.dbo.rds_modify_db_name`.

Example: In the following example, the `rdsadmin.dbo.rds_modify_db_name` stored procedure renames a database from `MOO` to `ZAR`. This is similar to running the statement DDL ALTER DATABASE `[MOO] MODIFY NAME = `[ZAR]`.

```
EXEC rdsadmin.dbo.rds_modify_db_name N'MOO', N'ZAR'
GO
```

Resetting the `db_owner` role password

If you lock yourself out of the `db_owner` role on your Microsoft SQL Server database, you can reset the `db_owner` role password by modifying the DB instance master password. By changing the DB instance master password, you can regain access to the DB instance, access databases using the modified password for the `db_owner`, and restore privileges for the `db_owner` role that may have been accidentally revoked. You can change the DB instance password by using the Amazon RDS console, the AWS CLI command `modify-db-instance`, or by using the `ModifyDBInstance` operation. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

Restoring license-terminated DB instances

Microsoft has requested that some Amazon RDS customers who did not report their Microsoft License Mobility information terminate their DB instance. Amazon RDS takes snapshots of these DB instances, and you can restore from the snapshot to a new DB instance that has the License Included model.

To restore from a SQL Server snapshot after Amazon RDS has created a final snapshot of your instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the snapshot of your SQL Server DB instance. Amazon RDS creates a final snapshot of your DB instance. The name of the terminated instance snapshot is in the format `instance_name-final-snapshot`. For example, if your DB instance name is `mytest.cdxgahslksma.us-east-1.rds.com`, the final snapshot is called `mytest-final-snapshot` and is located in the same AWS Region as the original DB instance.
4. For Actions, choose Restore Snapshot.

   The Restore DB Instance window appears.
5. For License Model, choose license-included.
6. Choose the SQL Server DB engine that you want to use.
7. For DB Instance Identifier, enter the name for the restored DB instance.
8. Choose Restore DB Instance.

For more information about restoring from a snapshot, see [Restoring from a DB snapshot](#).

### Transitioning a Microsoft SQL Server database from OFFLINE to ONLINE

You can transition your Microsoft SQL Server database on an Amazon RDS DB instance from OFFLINE to ONLINE.

<table>
<thead>
<tr>
<th>SQL Server method</th>
<th>Amazon RDS method</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER DATABASE <code>db_name</code> SET ONLINE;</td>
<td>EXEC rdsadmin.dbo.rds_set_database_online <code>db_name</code></td>
</tr>
</tbody>
</table>
Using change data capture

Amazon RDS supports change data capture (CDC) for your DB instances running Microsoft SQL Server. CDC captures changes that are made to the data in your tables. It stores metadata about each change, which you can access later. For more information about how CDC works, see Change data capture in the Microsoft documentation.

Before you use CDC with your Amazon RDS DB instances, enable it in the database by running msdb.dbo.rds_cdc_enable_db. You must have master user privileges to enable CDC in the Amazon RDS DB instance. After CDC is enabled, any user who is db_owner of that database can enable or disable CDC on tables in that database.

⚠️ Important

During restores, CDC will be disabled. All of the related metadata is automatically removed from the database. This applies to snapshot restores, point-in-time restores, and SQL Server Native restores from S3. After performing one of these types of restores, you can re-enable CDC and re-specify tables to track.

To enable CDC for a DB instance, run the msdb.dbo.rds_cdc_enable_db stored procedure.

```
exec msdb.dbo.rds_cdc_enable_db 'database_name'
```

To disable CDC for a DB instance, run the msdb.dbo.rds_cdc_disable_db stored procedure.

```
exec msdb.dbo.rds_cdc_disable_db 'database_name'
```

Topics

- Tracking tables with change data capture
- Change data capture jobs
- Change data capture for Multi-AZ instances

Tracking tables with change data capture

After CDC is enabled on the database, you can start tracking specific tables. You can choose the tables to track by running sys.sp_cdc_enable_table.
--Begin tracking a table
exec sys.sp_cdc_enable_table
    @source_schema = N'source_schema',
    @source_name = N'source_name',
    @role_name = N'role_name'

--The following parameters are optional:
    -- @capture_instance = 'capture_instance'
    -- @supports_net_changes = supports_net_changes
    -- @index_name = 'index_name'
    -- @captured_column_list = 'captured_column_list'
    -- @filegroup_name = 'filegroup_name'
    -- @allow_partition_switch = 'allow_partition_switch'

To view the CDC configuration for your tables, run sys.sp_cdc_help_change_data_capture.

--View CDC configuration
exec sys.sp_cdc_help_change_data_capture

--The following parameters are optional and must be used together.
    -- 'schema_name', 'table_name'

For more information on CDC tables, functions, and stored procedures in SQL Server documentation, see the following:

- Change data capture stored procedures (Transact-SQL)
- Change data capture functions (Transact-SQL)
- Change data capture tables (Transact-SQL)

Change data capture jobs

When you enable CDC, SQL Server creates the CDC jobs. Database owners (db_owner) can view, create, modify, and delete the CDC jobs. However, the RDS system account owns them. Therefore, the jobs aren't visible from native views, procedures, or in SQL Server Management Studio.
To control behavior of CDC in a database, use native SQL Server procedures such as `sp_cdc_enable_table` and `sp_cdc_start_job`. To change CDC job parameters, like `maxtrans` and `maxscans`, you can use `sp_cdc_change_job`.

To get more information regarding the CDC jobs, you can query the following dynamic management views:

- `sys.dm_cdc_errors`
- `sys.dm_cdc_log_scan_sessions`
- `sysjobs`
- `sysjobhistory`

**Change data capture for Multi-AZ instances**

If you use CDC on a Multi-AZ instance, make sure the mirror's CDC job configuration matches the one on the principal. CDC jobs are mapped to the `database_id`. If the database IDs on the secondary are different from the principal, then the jobs won't be associated with the correct database. To try to prevent errors after failover, RDS drops and recreates the jobs on the new principal. The recreated jobs use the parameters that the principal recorded before failover.

Although this process runs quickly, it's still possible that the CDC jobs might run before RDS can correct them. Here are three ways to force parameters to be consistent between primary and secondary replicas:

- Use the same job parameters for all the databases that have CDC enabled.
- Before you change the CDC job configuration, convert the Multi-AZ instance to Single-AZ.
- Manually transfer the parameters whenever you change them on the principal.

To view and define the CDC parameters that are used to recreate the CDC jobs after a failover, use `rds_show_configuration` and `rds_set_configuration`.

The following example returns the value set for `cdc_capture_maxtrans`. For any parameter that is set to `RDS_DEFAULT`, RDS automatically configures the value.

```
-- Show configuration for each parameter on either primary and secondary replicas.
exec rdsadmin.dbo.rds_show_configuration 'cdc_capture_maxtrans';
```
To set the configuration on the secondary, run `rdsadmin.dbo.rds_set_configuration`. This procedure sets the parameter values for all of the databases on the secondary server. These settings are used only after a failover. The following example sets the `maxtrans` for all CDC capture jobs to 1000:

```sql
--To set values on secondary. These are used after failover.
exec rdsadmin.dbo.rds_set_configuration 'cdc_capture_maxtrans', 1000;
```

To set the CDC job parameters on the principal, use `sys.sp_cdc_change_job` instead.

### Using SQL Server Agent

With Amazon RDS, you can use SQL Server Agent on a DB instance running Microsoft SQL Server Enterprise Edition, Standard Edition, or Web Edition. SQL Server Agent is a Microsoft Windows service that runs scheduled administrative tasks that are called jobs. You can use SQL Server Agent to run T-SQL jobs to rebuild indexes, run corruption checks, and aggregate data in a SQL Server DB instance.

When you create a SQL Server DB instance, the master user is enrolled in the `SQLAgentUserRole` role.

SQL Server Agent can run a job on a schedule, in response to a specific event, or on demand. For more information, see [SQL Server Agent](https://docs.microsoft.com/en-us/sql/server-agents/overview) in the Microsoft documentation.

---

#### Note

Avoid scheduling jobs to run during the maintenance and backup windows for your DB instance. The maintenance and backup processes that are launched by AWS could interrupt a job or cause it to be canceled.

In Multi-AZ deployments, SQL Server Agent jobs are replicated from the primary host to the secondary host when the job replication feature is turned on. For more information, see [Turning on SQL Server Agent job replication](https://aws.amazon.com/rds/sql-server-agent/).

Multi-AZ deployments have a limit of 10,000 SQL Server Agent jobs. If you need a higher limit, request an increase by contacting AWS Support. Open the [AWS Support Center](https://aws.amazon.com/support/) page, sign in if necessary, and choose **Create case**. Choose **Service limit increase**. Complete and submit the form.
To view the history of an individual SQL Server Agent job in SQL Server Management Studio (SSMS), open Object Explorer, right-click the job, and then choose View History.

Because SQL Server Agent is running on a managed host in a DB instance, some actions aren't supported:

- Running replication jobs and running command-line scripts by using ActiveX, Windows command shell, or Windows PowerShell aren't supported.
- You can't manually start, stop, or restart SQL Server Agent.
- Email notifications through SQL Server Agent aren't available from a DB instance.
- SQL Server Agent alerts and operators aren't supported.
- Using SQL Server Agent to create backups isn't supported. Use Amazon RDS to back up your DB instance.

**Turning on SQL Server Agent job replication**

You can turn on SQL Server Agent job replication by using the following stored procedure:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types = 'SQLAgentJob';
```

You can run the stored procedure on all SQL Server versions supported by Amazon RDS for SQL Server. Jobs in the following categories are replicated:

- [Uncategorized (Local)]
- [Uncategorized (Multi-Server)]
- [Uncategorized]
- Data Collector
- Database Engine Tuning Advisor
- Database Maintenance
- Full-Text

Only jobs that use T-SQL job steps are replicated. Jobs with step types such as SQL Server Integration Services (SSIS), SQL Server Reporting Services (SSRS), Replication, and PowerShell aren't replicated. Jobs that use Database Mail and server-level objects aren't replicated.
Important

The primary host is the source of truth for replication. Before turning on job replication, make sure that your SQL Server Agent jobs are on the primary. If you don't do this, it could lead to the deletion of your SQL Server Agent jobs if you turn on the feature when newer jobs are on the secondary host.

You can use the following function to confirm whether replication is turned on.

```
SELECT * from msdb.dbo.rds_fn_get_system_database_sync_objects();
```

The T-SQL query returns the following if SQL Server Agent jobs are replicating. If they're not replicating, it returns nothing for `object_class`.

![Image showing the query results]

You can use the following function to find the last time objects were synchronized in UTC time.

```
SELECT * from msdb.dbo.rds_fn_server_object_last_sync_time();
```

For example, suppose that you modify a SQL Server Agent job at 01:00. You expect the most recent synchronization time to be after 01:00, indicating that synchronization has taken place.

After synchronization, the values returned for `date_created` and `date_modified` on the secondary node are expected to match.

![Image showing the query results]

If you are also using tempdb replication, you can enable replication for both SQL Agent jobs and the tempdb configuration by providing them in the `@object_type` parameter:
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types = 'SQLAgentJob,TempDbFile';

For more information on tempdb replication, see TempDB configuration for Multi-AZ deployments.

### Adding a user to the SQLAgentUserRole

To allow an additional login or user to use SQL Server Agent, log in as the master user and do the following:

1. Create another server-level login by using the `CREATE LOGIN` command.
2. Create a user in `msdb` using `CREATE USER` command, and then link this user to the login that you created in the previous step.
3. Add the user to the SQLAgentUserRole using the `sp_addrolemember` system stored procedure.

For example, suppose that your master user name is `admin` and you want to give access to SQL Server Agent to a user named `theirname` with a password `theirpassword`. In that case, you can use the following procedure.

#### To add a user to the SQLAgentUserRole

1. Log in as the master user.
2. Run the following commands:

   ```sql
   --Initially set context to master database
   USE [master];
   GO
   --Create a server-level login named theirname with password theirpassword
   CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';
   GO
   --Set context to msdb database
   USE [msdb];
   GO
   --Create a database user named theirname and link it to server-level login theirname
   CREATE USER [theirname] FOR LOGIN [theirname];
   GO
   --Added database user theirname in msdb to SQLAgentUserRole in msdb
   ```
Deleting a SQL Server Agent job

You use the `sp_delete_job` stored procedure to delete SQL Server Agent jobs on Amazon RDS for Microsoft SQL Server.

You can't use SSMS to delete SQL Server Agent jobs. If you try to do so, you get an error message similar to the following:

```
The EXECUTE permission was denied on the object 'xp_regread', database 'mssqlsystemresource', schema 'sys'.
```

As a managed service, RDS is restricted from running procedures that access the Windows registry. When you use SSMS, it tries to run a process (`xp_regread`) for which RDS isn't authorized.

**Note**

On RDS for SQL Server, only members of the sysadmin role are allowed to update or delete jobs owned by a different login.

To delete a SQL Server Agent job

- Run the following T-SQL statement:

  ```
  EXEC msdb..sp_delete_job @job_name = 'job_name';
  ```

Working with Microsoft SQL Server logs

You can use the Amazon RDS console to view, watch, and download SQL Server Agent logs, Microsoft SQL Server error logs, and SQL Server Reporting Services (SSRS) logs.

**Watching log files**

If you view a log in the Amazon RDS console, you can see its contents as they exist at that moment. Watching a log in the console opens it in a dynamic state so that you can see updates to it in near-real time.
Only the latest log is active for watching. For example, suppose you have the following logs shown:

![Logs table]

Only log/ERROR, as the most recent log, is being actively updated. You can choose to watch others, but they are static and will not update.

Archiving log files

The Amazon RDS console shows logs for the past week through the current day. You can download and archive logs to keep them for reference past that time. One way to archive logs is to load them into an Amazon S3 bucket. For instructions on how to set up an Amazon S3 bucket and upload a file, see Amazon S3 basics in the Amazon Simple Storage Service Getting Started Guide and click Get Started.

Viewing error and agent logs

To view Microsoft SQL Server error and agent logs, use the Amazon RDS stored procedure rds_read_error_log with the following parameters:

- **@index** – the version of the log to retrieve. The default value is 0, which retrieves the current error log. Specify 1 to retrieve the previous log, specify 2 to retrieve the one before that, and so on.
- **@type** – the type of log to retrieve. Specify 1 to retrieve an error log. Specify 2 to retrieve an agent log.

**Example**

The following example requests the current error log.

```sql
EXEC rdsadmin.dbo.rds_read_error_log @index = 0, @type = 1;
```
For more information on SQL Server errors, see Database engine errors in the Microsoft documentation.

Working with trace and dump files

This section describes working with trace files and dump files for your Amazon RDS DB instances running Microsoft SQL Server.

Generating a trace SQL query

```
declare @rc int
declare @TraceID int
declare @maxfilesize bigint

set @maxfilesize = 5

exec @rc = sp_trace_create @TraceID output, 0, N'D:\rdsdbdata\log\rdstest', @maxfilesize, NULL
```

Viewing an open trace

```
select * from ::fn_trace_getinfo(default)
```

Viewing trace contents

```
select * from ::fn_trace_gettable('D:\rdsdbdata\log\rdstest.trc', default)
```

Setting the retention period for trace and dump files

Trace and dump files can accumulate and consume disk space. By default, Amazon RDS purges trace and dump files that are older than seven days.

To view the current trace and dump file retention period, use the rds_show_configuration procedure, as shown in the following example.

```
exec rdsadmin..rds_show_configuration;
```

To modify the retention period for trace files, use the rds_set_configuration procedure and set the tracefile retention in minutes. The following example sets the trace file retention period to 24 hours.
To modify the retention period for dump files, use the `rds_set_configuration` procedure and set the `dumpfile retention` in minutes. The following example sets the dump file retention period to 3 days.

```
exec rdsadmin..rds_set_configuration 'dumpfile retention', 4320;
```

For security reasons, you cannot delete a specific trace or dump file on a SQL Server DB instance. To delete all unused trace or dump files, set the retention period for the files to 0.
Amazon RDS for MySQL

Amazon RDS supports DB instances that run the following versions of MySQL:

- MySQL 8.0
- MySQL 5.7

For more information about minor version support, see MySQL on Amazon RDS versions.

To create an Amazon RDS for MySQL DB instance, use the Amazon RDS management tools or interfaces. You can then do the following:

- Resize your DB instance
- Authorize connections to your DB instance
- Create and restore from backups or snapshots
- Create Multi-AZ secondaries
- Create read replicas
- Monitor the performance of your DB instance

To store and access the data in your DB instance, you use standard MySQL utilities and applications.

Amazon RDS for MySQL is compliant with many industry standards. For example, you can use RDS for MySQL databases to build HIPAA-compliant applications. You can use RDS for MySQL databases to store healthcare related information, including protected health information (PHI) under a Business Associate Agreement (BAA) with AWS. Amazon RDS for MySQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements. In addition, Amazon RDS for MySQL has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see AWS cloud compliance.

For information about the features in each version of MySQL, see The main features of MySQL in the MySQL documentation.

Before creating a DB instance, complete the steps in Setting up for Amazon RDS. When you create a DB instance, the RDS master user gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts.
You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running MySQL inside a virtual private cloud (VPC) based on Amazon VPC. You can also add features to your MySQL DB instance by turning on various options. Amazon RDS supports Multi-AZ deployments for MySQL as a high-availability, failover solution.

⚠️ Important

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced privileges. You can access your database using standard SQL clients such as the mysql client. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

MySQL feature support on Amazon RDS

RDS for MySQL supports most of the features and capabilities of MySQL. Some features might have limited support or restricted privileges.

You can filter new Amazon RDS features on the What's New with Database? page. For Products, choose Amazon RDS. Then search using keywords such as MySQL 2022.

Note
The following lists are not exhaustive.

Topics
- Supported storage engines for RDS for MySQL
- Using memcached and other options with MySQL on Amazon RDS
- InnoDB cache warming for MySQL on Amazon RDS
- MySQL features not supported by Amazon RDS

Supported storage engines for RDS for MySQL

While MySQL supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. Amazon RDS fully supports the InnoDB storage engine for MySQL DB instances. Amazon RDS features such as Point-In-Time restore and snapshot restore require a recoverable storage engine and are supported for the InnoDB storage engine only. For more information, see MySQL memcached support.

The Federated Storage Engine is currently not supported by Amazon RDS for MySQL.

For user-created schemas, the MyISAM storage engine does not support reliable recovery and can result in lost or corrupt data when MySQL is restarted after a recovery, preventing Point-In-Time restore or snapshot restore from working as intended. However, if you still choose to use MyISAM with Amazon RDS, snapshots can be helpful under some conditions.

Note
System tables in the mysql schema can be in MyISAM storage.
If you want to convert existing MyISAM tables to InnoDB tables, you can use the ALTER TABLE command (for example, `alter table TABLE_NAME engine=innodb;`). Bear in mind that MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

MySQL 5.1, 5.5, and 5.6 are no longer supported in Amazon RDS. However, you can restore existing MySQL 5.1, 5.5, and 5.6 snapshots. When you restore a MySQL 5.1, 5.5, or 5.6 snapshot, the DB instance is automatically upgraded to MySQL 5.7.

**Using memcached and other options with MySQL on Amazon RDS**

Most Amazon RDS DB engines support option groups that allow you to select additional features for your DB instance. RDS for MySQL DB instances support the memcached option, a simple, key-based cache. For more information about memcached and other options, see [Options for MySQL DB instances](#). For more information about working with option groups, see [Working with option groups](#).

**InnoDB cache warming for MySQL on Amazon RDS**

InnoDB cache warming can provide performance gains for your MySQL DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This bypasses the need for the buffer pool to "warm up" from normal database use and instead preloads the buffer pool with the pages for known common queries. The file that stores the saved buffer pool information only stores metadata for the pages that are in the buffer pool, and not the pages themselves. As a result, the file does not require much storage space. The file size is about 0.2 percent of the cache size. For example, for a 64 GiB cache, the cache warming file size is 128 MiB. For more information on InnoDB cache warming, see [Saving and restoring the buffer pool state](#) in the MySQL documentation.

RDS for MySQL DB instances support InnoDB cache warming. To enable InnoDB cache warming, set the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group will affect all MySQL DB instances that use that parameter group. To enable InnoDB cache warming for specific MySQL DB instances, you might need to create a new parameter group for those instances. For information on parameter groups, see [Working with parameter groups](#).
InnoDB cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you do not commonly see a significant performance benefit.

⚠️ Important

If your MySQL DB instance does not shut down normally, such as during a failover, then the buffer pool state will not be saved to disk. In this case, MySQL loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might not reflect the most recent state of the buffer pool prior to the restart.

To ensure that you have a recent state of the buffer pool available to warm the InnoDB cache on startup, we recommend that you periodically dump the buffer pool "on demand." You can create an event to dump the buffer pool automatically and on a regular interval. For example, the following statement creates an event named periodic_buffer_pool_dump that dumps the buffer pool every hour.

```
CREATE EVENT periodic_buffer_pool_dump
ON SCHEDULE EVERY 1 HOUR
DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information on MySQL events, see Event syntax in the MySQL documentation.

### Dumping and loading the buffer pool on demand

You can save and load the InnoDB cache "on demand."

- To dump the current state of the buffer pool to disk, call the `mysql.rds_innodb_buffer_pool_dump_now` stored procedure.
- To load the saved state of the buffer pool from disk, call the `mysql.rds_innodb_buffer_pool_load_now` stored procedure.
- To cancel a load operation in progress, call the `mysql.rds_innodb_buffer_pool_load_abort` stored procedure.

### MySQL features not supported by Amazon RDS

Amazon RDS doesn't currently support the following MySQL features:
- Authentication Plugin
- Error Logging to the System Log
- InnoDB Tablespace Encryption
- Password Strength Plugin
- Persisted system variables
- Rewriter Query Rewrite Plugin
- Semisynchronous replication
- Transportable tablespace
- X Plugin

**Note**

Global transaction IDs are supported for all RDS for MySQL 5.7 versions, and for RDS for MySQL 8.0.26 and higher 8.0 versions.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection. When you create a DB instance, you are assigned to the `db_owner` role for all databases on that instance, and you have all database-level permissions except for those used for backups. Amazon RDS manages backups for you.
MySQL on Amazon RDS versions

For MySQL, version numbers are organized as version = X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes—for example, going from version 5.7 to 8.0. A version change is considered minor if only the minor version number changes—for example, going from version 8.0.28 to 8.0.32.

Topics

• Supported MySQL minor versions on Amazon RDS

• Working with the Database Preview environment
• MySQL version 8.2 in the Database Preview environment
• MySQL version 8.1 in the Database Preview environment
• Deprecated versions for Amazon RDS for MySQL

Supported MySQL minor versions on Amazon RDS

Amazon RDS currently supports the following minor versions of MySQL.

<table>
<thead>
<tr>
<th>MySQL engine version</th>
<th>Community release date</th>
<th>RDS release date</th>
<th>RDS end of standard support date</th>
</tr>
</thead>
<tbody>
<tr>
<td>8.0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>8.0.36</td>
<td>16 January 2024</td>
<td>12 February 2024</td>
<td>March 2025</td>
</tr>
<tr>
<td>8.0.35</td>
<td>25 October 2023</td>
<td>9 November 2023</td>
<td>March 2025</td>
</tr>
<tr>
<td>8.0.34</td>
<td>18 July 2023</td>
<td>9 August 2023</td>
<td>September 2024</td>
</tr>
</tbody>
</table>

Note

Dates with only a month and a year are approximate and are updated with an exact date when it’s known.
You can specify any currently supported MySQL version when creating a new DB instance. You can specify the major version (such as MySQL 5.7), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

For example, to list the supported engine versions for RDS for MySQL, run the following CLI command:

```bash
aws rds describe-db-engine-versions --engine mysql --query "[*].
    {Engine:Engine,EngineVersion:EngineVersion}" --output text
```

The default MySQL version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region using the following AWS CLI command:

---

* Amazon RDS Extended Support eligible minor engine version. For more information, see [Using Amazon RDS Extended Support](#).
With Amazon RDS, you control when to upgrade your MySQL instance to a new major version supported by Amazon RDS. You can maintain compatibility with specific MySQL versions, test new versions with your application before deploying in production, and perform major version upgrades at times that best fit your schedule.

When automatic minor version upgrade is enabled, your DB instance will be upgraded automatically to new MySQL minor versions as they are supported by Amazon RDS. This patching occurs during your scheduled maintenance window. You can modify a DB instance to enable or disable automatic minor version upgrades.

If you opt out of automatically scheduled upgrades, you can manually upgrade to a supported minor version release by following the same procedure as you would for a major version update. For information, see Upgrading a DB instance engine version.

Amazon RDS currently supports the major version upgrades from MySQL version 5.6 to version 5.7, and from MySQL version 5.7 to version 8.0. Because major version upgrades involve some compatibility risk, they do not occur automatically; you must make a request to modify the DB instance. You should thoroughly test any upgrade before upgrading your production instances. For information about upgrading a MySQL DB instance, see Upgrading the MySQL DB engine.

You can test a DB instance against a new version before upgrading by creating a DB snapshot of your existing DB instance, restoring from the DB snapshot to create a new DB instance, and then initiating a version upgrade for the new DB instance. You can then experiment safely on the upgraded clone of your DB instance before deciding whether or not to upgrade your original DB instance.
## Supported MySQL major versions on Amazon RDS

RDS for MySQL major versions are available under standard support at least until community end of life for the corresponding community version. You can continue running a major version past its RDS end of standard support date for a fee. For more information, see [Using Amazon RDS Extended Support](#) and [Amazon RDS for MySQL pricing](#).

You can use the following dates to plan your testing and upgrade cycles.

<table>
<thead>
<tr>
<th>MySQL major version</th>
<th>Community release date</th>
<th>RDS release date</th>
<th>Community end of life date</th>
<th>RDS end of standard support date</th>
<th>RDS start of Extended Support year 1 pricing date</th>
<th>RDS start of Extended Support year 3 pricing date</th>
<th>RDS end of Extended Support date</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 8.0</td>
<td>19 April 2018</td>
<td>23 October 2018</td>
<td>April 2026</td>
<td>31 July 2026</td>
<td>1 August 2026</td>
<td>1 August 2028</td>
<td>31 July 2029</td>
</tr>
<tr>
<td>MySQL 5.7*</td>
<td>21 October 2015</td>
<td>22 February 2016</td>
<td>October 2023</td>
<td>29 February 2024</td>
<td>1 March 2024</td>
<td>1 March 2026</td>
<td>28 February 2027</td>
</tr>
</tbody>
</table>

* MySQL 5.7 is now only available under RDS Extended Support. For more information, see [Using Amazon RDS Extended Support](#).

## Working with the Database Preview environment

In July 2023, Oracle announced a new release model for MySQL. This model includes two types of releases: Innovation Releases and LTS releases. Amazon RDS makes MySQL Innovation Releases...
available in the RDS Preview environment. To learn more about the MySQL Innovation releases, see Introducing MySQL Innovation and Long-Term Support (LTS) versions.

RDS for MySQL DB instances in the Database Preview environment are functionally similar to other RDS for MySQL DB instances. However, you can't use the Database Preview environment for production workloads.

Preview environments have the following limitations:

- Amazon RDS deletes all DB instances 60 days after you create them, along with any backups and snapshots.
- You can only use General Purpose SSD and Provisioned IOPS SSD storage.
- You can't get help from AWS Support with DB instances. Instead, you can post your questions to the AWS-managed Q&A community, AWS re:Post.
- You can't copy a snapshot of a DB instance to a production environment.

The following options are supported by the preview.

- You can create DB instances using db.m6i, db.r6i, db.m6g, db.m5, db.t3, db.r6g, and db.r5 DB instance classes. For more information about RDS instance classes, see DB instance classes.
- You can use both single-AZ and multi-AZ deployments.
- You can use standard MySQL dump and load functions to export databases from or import databases to the Database Preview environment.

Features not supported in the Database Preview environment

The following features aren't available in the Database Preview environment:

- Cross-Region snapshot copy
- Cross-Region read replicas

Creating a new DB instance in the Database Preview environment

You can create a DB instance in the Database Preview environment using the AWS Management Console, AWS CLI, or RDS API.
To create a DB instance in the Database Preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Dashboard from the navigation pane.
3. In the Dashboard page, locate the Database Preview Environment section, as shown in the following image.

You can navigate directly to the Database Preview environment. Before you can proceed, you must acknowledge and accept the limitations.
4. To create the RDS for MySQL DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the Console procedure in Creating a DB instance.

AWS CLI

To create a DB instance in the Database Preview environment using the AWS CLI, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

To create the RDS for MySQL DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the AWS CLI procedure in Creating a DB instance.

RDS API

To create a DB instance in the Database Preview environment using the RDS API, use the following endpoint.
To create the RDS for MySQL DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the RDS API procedure in Creating a DB instance.

MySQL version 8.2 in the Database Preview environment

MySQL version 8.2 is now available in the Amazon RDS Database Preview environment. MySQL version 8.2 contains several improvements that are described in Changes in MySQL 8.2.0.

For information on the Database Preview environment, see the section called “The Database Preview environment”. To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.

MySQL version 8.1 in the Database Preview environment

MySQL version 8.1 is now available in the Amazon RDS Database Preview environment. MySQL version 8.1 contains several improvements that are described in Changes in MySQL 8.1.0.

For information on the Database Preview environment, see the section called “The Database Preview environment”. To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.

Deprecated versions for Amazon RDS for MySQL

Amazon RDS for MySQL version 5.1, 5.5, and 5.6 are deprecated.

For information about the Amazon RDS deprecation policy for MySQL, see Amazon RDS FAQs.
Connecting to a DB instance running the MySQL database engine

Before you can connect to a DB instance running the MySQL database engine, you must create a DB instance. For information, see Creating an Amazon RDS DB instance. After Amazon RDS provisions your DB instance, you can use any standard MySQL client application or utility to connect to the instance. In the connection string, you specify the DNS address from the DB instance endpoint as the host parameter, and specify the port number from the DB instance endpoint as the port parameter.

To authenticate to your RDS DB instance, you can use one of the authentication methods for MySQL and AWS Identity and Access Management (IAM) database authentication:

- To learn how to authenticate to MySQL using one of the authentication methods for MySQL, see Authentication method in the MySQL documentation.
- To learn how to authenticate to MySQL using IAM database authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

You can connect to a MySQL DB instance by using tools like the MySQL command-line client. For more information on using the MySQL command-line client, see mysql - the MySQL command-line client in the MySQL documentation. One GUI-based application you can use to connect is MySQL Workbench. For more information, see the Download MySQL Workbench page. For information about installing MySQL (including the MySQL command-line client), see Installing and upgrading MySQL.

Most Linux distributions include the MariaDB client instead of the Oracle MySQL client. To install the MySQL command-line client on Amazon Linux 2023, run the following command:

```
sudo dnf install mariadb105
```

To install the MySQL command-line client on Amazon Linux 2, run the following command:

```
sudo yum install mariadb
```

To install the MySQL command-line client on most DEB-based Linux distributions, run the following command:
apt-get install mariadb-client

To check the version of your MySQL command-line client, run the following command:

mysql --version

To read the MySQL documentation for your current client version, run the following command:

man mysql

To connect to a DB instance from outside of its Amazon VPC, the DB instance must be publicly accessible, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance.

You can use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) encryption on connections to a MySQL DB instance. For information, see Using SSL/TLS with a MySQL DB instance. If you are using AWS Identity and Access Management (IAM) database authentication, make sure to use an SSL/TLS connection. For information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

You can also connect to a DB instance from a web server. For more information, see Tutorial: Create a web server and an Amazon RDS DB instance.

Note
For information on connecting to a MariaDB DB instance, see Connecting to a DB instance running the MariaDB database engine.

Topics
• Finding the connection information for a MySQL DB instance
• Connecting from the MySQL command-line client (unencrypted)
• Connecting from MySQL Workbench
• Connecting with the Amazon Web Services JDBC Driver for MySQL
• Troubleshooting connections to your MySQL DB instance
Finding the connection information for a MySQL DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is mydb.123456789012.us-east-1.rds.amazonaws.com. In this case, the port value is 3306, and the database user is admin. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify mydb.123456789012.us-east-1.rds.amazonaws.com.
- For port, specify 3306.
- For user, specify admin.

To connect to a DB instance, use any client for the MySQL DB engine. For example, you might use the MySQL command-line client or MySQL Workbench.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS CLI describe-db-instances command, or the Amazon RDS API DescribeDBInstances operation to list its details.

Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases to display a list of your DB instances.
3. Choose the name of the MySQL DB instance to display its details.
4. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
5. If you need to find the master user name, choose the Configuration tab and view the Master username value.
AWS CLI

To find the connection information for a MySQL DB instance by using the AWS CLI, call the `describe-db-instances` command. In the call, query for the DB instance ID, endpoint, port, and master user name.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-instances \
  --filters "Name=engine,Values=mysql" \
  --query "[*].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```bash
aws rds describe-db-instances ^
  --filters "Name=engine,Values=mysql" ^
  --query "[*].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```
[
  [
    "mydb1",
    "mydb1.123456789012.us-east-1.rds.amazonaws.com",
    3306,
    "admin"
  ],
  [
    "mydb2",
    "mydb2.123456789012.us-east-1.rds.amazonaws.com",
    3306,
    "admin"
  ]
]
```

RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the `DescribeDBInstances` operation. In the output, find the values for the endpoint address, endpoint port, and master user name.
Important

Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting from the MySQL command-line client with SSL/TLS (encrypted).

To connect to a DB instance using the MySQL command-line client, enter the following command at the command prompt. For the -h parameter, substitute the DNS name (endpoint) for your DB instance. For the -P parameter, substitute the port for your DB instance. For the -u parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com -P 3306 -u mymasteruser -p
```

After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 9738
Server version: 8.0.28 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

Connecting from MySQL Workbench

To connect from MySQL Workbench

1. Download and install MySQL Workbench at Download MySQL Workbench.
2. Open MySQL Workbench.
3. From **Database**, choose **Manage Connections**.

4. In the **Manage Server Connections** window, choose **New**.

5. In the **Connect to Database** window, enter the following information:

   - **Stored Connection** – Enter a name for the connection, such as **MyDB**.
   - **Hostname** – Enter the DB instance endpoint.
   - **Port** – Enter the port used by the DB instance.
   - **Username** – Enter the user name of a valid database user, such as the master user.
   - **Password** – Optionally, choose **Store in Vault** and then enter and save the password for the user.

   The window looks similar to the following:
You can use the features of MySQL Workbench to customize connections. For example, you can use the SSL tab to configure SSL/TLS connections. For information about using MySQL Workbench, see the MySQL Workbench documentation. Encrypting client connections to MySQL DB instances with SSL/TLS, see Encrypting client connections to MySQL DB instances with SSL/TLS.

6. Optionally, choose Test Connection to confirm that the connection to the DB instance is successful.

7. Choose Close.

8. From Database, choose Connect to Database.

9. From Stored Connection, choose your connection.

10. Choose OK.
Connecting with the Amazon Web Services JDBC Driver for MySQL

The AWS JDBC Driver for MySQL is a client driver designed for RDS for MySQL. By default, the driver has settings that are optimized for use with RDS for MySQL. For more information about the driver and complete instructions for using it, see the AWS JDBC Driver for MySQL GitHub repository.

The driver is drop-in compatible with the MySQL Connector/J driver. To install or upgrade your connector, replace the MySQL connector .jar file (located in the application CLASSPATH) with the AWS JDBC Driver for MySQL .jar file, and update the connection URL prefix from `jdbc:mysql://` to `jdbc:mysql:aws://`.

The AWS JDBC Driver for MySQL supports IAM database authentication. For more information, see AWS IAM Database Authentication in the AWS JDBC Driver for MySQL GitHub repository. For more information about IAM database authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

Troubleshooting connections to your MySQL DB instance

Two common causes of connection failures to a new DB instance are:

- The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MySQL application or utility is running. The DB instance must have a VPC security group that authorizes the connections. For more information, see Amazon VPC VPCs and Amazon RDS.
  
  You can add or edit an inbound rule in the security group. For Source, choose My IP. This allows access to the DB instance from the IP address detected in your browser.

- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see Can't connect to Amazon RDS DB instance.
Securing MySQL DB instance connections

You can manage the security of your MySQL DB instances.

Topics

• MySQL security on Amazon RDS
• Using the Password Validation Plugin for RDS for MySQL
• Encrypting client connections to MySQL DB instances with SSL/TLS
• Updating applications to connect to MySQL DB instances using new SSL/TLS certificates
• Using Kerberos authentication for MySQL

MySQL security on Amazon RDS

Security for MySQL DB instances is managed at three levels:

• AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management for Amazon RDS.

• When you create a DB instance, you use a VPC security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance. These connections can be made using Secure Sockets Layer (SSL) and Transport Layer Security (TLS). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.

• To authenticate login and permissions for a MySQL DB instance, you can take either of the following approaches, or a combination of them.

You can take the same approach as with a stand-alone instance of MySQL. Commands such as CREATE USER, RENAME USER, GRANT, REVOKE, and SET PASSWORD work just as they do in on-premises databases, as does directly modifying database schema tables. For information, see Access control and account management in the MySQL documentation.

You can also use IAM database authentication. With IAM database authentication, you authenticate to your DB instance by using an IAM user or IAM role and an authentication token. An authentication token is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control
access to your AWS resources and your databases. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

Another option is Kerberos authentication for RDS for MySQL. The DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users authenticate with a MySQL DB instance joined to the trusting domain, authentication requests are forwarded. Forwarded requests go to the domain directory that you create with AWS Directory Service. For more information, see Using Kerberos authentication for MySQL.

When you create an Amazon RDS DB instance, the master user has the following default privileges:

- alter
- alter routine
- create
- create routine
- create temporary tables
- create user
- create view
- delete
- drop
- event
- execute
- grant option
- index
- insert
- lock tables
- process
- references
- replication client
- replication slave
- select
- show databases
Note

Although it is possible to delete the master user on the DB instance, it is not recommended. To recreate the master user, use the ModifyDBInstance RDS API operation or the modify-db-instance AWS CLI command and specify a new master user password with the appropriate parameter. If the master user does not exist in the instance, the master user is created with the specified password.

To provide management services for each DB instance, the rdsadmin user is created when the DB instance is created. Attempting to drop, rename, change the password, or change privileges for the rdsadmin account will result in an error.

To allow management of the DB instance, the standard kill and kill_query commands have been restricted. The Amazon RDS commands rds_kill and rds_kill_query are provided to allow you to end user sessions or queries on DB instances.

Using the Password Validation Plugin for RDS for MySQL

MySQL provides the validate_password plugin for improved security. The plugin enforces password policies using parameters in the DB parameter group for your MySQL DB instance. The plugin is supported for DB instances running MySQL version 5.7 and 8.0. For more information about the validate_password plugin, see The Password Validation Plugin in the MySQL documentation.

To enable the validate_password plugin for a MySQL DB instance

1. Connect to your MySQL DB instance and run the following command.

```
INSTALL PLUGIN validate_password SONAME 'validate_password.so';
```

2. Configure the parameters for the plugin in the DB parameter group used by the DB instance.
For more information about the parameters, see Password Validation Plugin options and variables in the MySQL documentation.

For more information about modifying DB instance parameters, see Modifying parameters in a DB parameter group.

After installing and enabling the password_validate plugin, reset existing passwords to comply with your new validation policies.

Amazon RDS doesn't validate passwords. The MySQL DB instance performs password validation. If you set a user password with the AWS Management Console, the modify-db-instance AWS CLI command, or the ModifyDBInstance RDS API operation, the change can succeed even if the new password doesn't satisfy your password policies. However, a new password is set in the MySQL DB instance only if it satisfies the password policies. In this case, Amazon RDS records the following event.

"RDS-EVENT-0067" - An attempt to reset the master password for the DB instance has failed.

For more information about Amazon RDS events, see Working with Amazon RDS event notification.

Encrypting client connections to MySQL DB instances with SSL/TLS

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS). Amazon RDS supports SSL/TLS encryption for MySQL DB instances. Using SSL/TLS, you can encrypt a connection between your application client and your MySQL DB instance. SSL/TLS support is available in all AWS Regions for MySQL.

Topics

- Using SSL/TLS with a MySQL DB instance
- Requiring SSL/TLS for all connections to a MySQL DB instance
- Connecting from the MySQL command-line client with SSL/TLS (encrypted)
Using SSL/TLS with a MySQL DB instance

Amazon RDS creates an SSL/TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL/TLS certificate includes the DB instance endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

An SSL/TLS certificate created by Amazon RDS is the trusted root entity and should work in most cases but might fail if your application does not accept certificate chains. If your application does not accept certificate chains, you might need to use an intermediate certificate to connect to your AWS Region. For example, you must use an intermediate certificate to connect to the AWS GovCloud (US) Regions using SSL/TLS.

For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster. For more information about using SSL/TLS with MySQL, see Updating applications to connect to MySQL DB instances using new SSL/TLS certificates.

MySQL uses OpenSSL for secure connections. Amazon RDS for MySQL supports Transport Layer Security (TLS) versions 1.0, 1.1, 1.2, and 1.3. TLS support depends on the MySQL version. The following table shows the TLS support for MySQL versions.

<table>
<thead>
<tr>
<th>MySQL version</th>
<th>TLS 1.0</th>
<th>TLS 1.1</th>
<th>TLS 1.2</th>
<th>TLS 1.3</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 8.0</td>
<td>Not supported</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>MySQL 5.7</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
<td>Not supported</td>
</tr>
</tbody>
</table>

You can require SSL/TLS connections for specific users accounts. For example, you can use one of the following statements, depending on your MySQL version, to require SSL/TLS connections on the user account encrypted_user.

To do so, use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL/TLS connections with MySQL, see the Using encrypted connections in the MySQL documentation.
Requiring SSL/TLS for all connections to a MySQL DB instance

Use the require_secure_transport parameter to require that all user connections to your MySQL DB instance use SSL/TLS. By default, the require_secure_transport parameter is set to OFF. You can set the require_secure_transport parameter to ON to require SSL/TLS for connections to your DB instance.

You can set the require_secure_transport parameter value by updating the DB parameter group for your DB instance. You don’t need to reboot your DB instance for the change to take effect.

When the require_secure_transport parameter is set to ON for a DB instance, a database client can connect to it if it can establish an encrypted connection. Otherwise, an error message similar to the following is returned to the client:

```
MySQL Error 3159 (HY000): Connections using insecure transport are prohibited while --require_secure_transport=ON.
```

For information about setting parameters, see Modifying parameters in a DB parameter group.

For more information about the require_secure_transport parameter, see the MySQL documentation.

Connecting from the MySQL command-line client with SSL/TLS (encrypted)

The mysql client program parameters are slightly different if you are using the MySQL 5.7 version, the MySQL 8.0 version, or the MariaDB version.

To find out which version you have, run the mysql command with the --version option. In the following example, the output shows that the client program is from MariaDB.

```
$ mysql --version
mysql  Ver 15.1 Distrib 10.5.15-MariaDB, for osx10.15 (x86_64) using readline 5.1
```

Most Linux distributions, such as Amazon Linux, CentOS, SUSE, and Debian have replaced MySQL with MariaDB, and the mysql version in them is from MariaDB.

To connect to your DB instance using SSL/TLS, follow these steps:
To connect to a DB instance with SSL/TLS using the MySQL command-line client

1. Download a root certificate that works for all AWS Regions.

   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

2. Use a MySQL command-line client to connect to a DB instance with SSL/TLS encryption. For the -h parameter, substitute the DNS name (endpoint) for your DB instance. For the --ssl-ca parameter, substitute the SSL/TLS certificate file name. For the -P parameter, substitute the port for your DB instance. For the -u parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

   The following example shows how to launch the client using the --ssl-ca parameter using the MySQL 5.7 client or later:

   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=REQUIRED -P 3306 -u myadmin -p

   To require that the SSL/TLS connection verifies the DB instance endpoint against the endpoint in the SSL/TLS certificate, enter the following command:

   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=VERIFY_IDENTITY -P 3306 -u myadmin -p

   The following example shows how to launch the client using the --ssl-ca parameter using the MariaDB client:

   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem -ssl -P 3306 -u myadmin -p

3. Enter the master user password when prompted.

   You will see output similar to the following.

   Welcome to the MySQL monitor. Commands end with ; or \g.
   Your MySQL connection id is 9738
   Server version: 8.0.28 Source distribution
   Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
Updating applications to connect to MySQL DB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances. If they do, you can further check whether those applications require certificate verification to connect.

### Note

Some applications are configured to connect to MySQL DB instances only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.

You can specify the following SSL modes: disabled, preferred, and required. When you use the preferred SSL mode and the CA certificate doesn't exist or isn't up to date, the connection falls back to not using SSL and connects without encryption.

Because these later versions use the OpenSSL protocol, an expired server certificate doesn't prevent successful connections unless the required SSL mode is specified. We recommend avoiding preferred mode. In preferred mode, if the connection encounters an invalid certificate, it stops using encryption and proceeds unencrypted.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate](#). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#). For information about using SSL/TLS with MySQL DB instances, see [Using SSL/TLS with a MySQL DB instance](#).
Topics

- Determining whether any applications are connecting to your MySQL DB instance using SSL
- Determining whether a client requires certificate verification to connect
- Updating your application trust store
- Example Java code for establishing SSL connections

Determining whether any applications are connecting to your MySQL DB instance using SSL

If you are using Amazon RDS for MySQL version 5.7 or 8.0 and the Performance Schema is enabled, run the following query to check if connections are using SSL/TLS. For information about enabling the Performance Schema, see [Performance Schema quick start](#) in the MySQL documentation.

```sql
mysql> SELECT id, user, host, connection_type
    FROM performance_schema.threads pst
    INNER JOIN information_schema.processlist isp
    ON pst.processlist_id = isp.id;
```

In this sample output, you can see both your own session (admin) and an application logged in as webapp1 are using SSL.

```
+----+-----------------+------------------+-----------------+
<table>
<thead>
<tr>
<th>id</th>
<th>user</th>
<th>host</th>
<th>connection_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>admin</td>
<td>10.0.4.249:42590</td>
<td>SSL/TLS</td>
</tr>
<tr>
<td>4</td>
<td>event_scheduler</td>
<td>localhost</td>
<td>NULL</td>
</tr>
<tr>
<td>10</td>
<td>webapp1</td>
<td>159.28.1.1:42189</td>
<td>SSL/TLS</td>
</tr>
</tbody>
</table>
+----+-----------------+------------------|-----------------+
3 rows in set (0.00 sec)
```

Determining whether a client requires certificate verification to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.
The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see Configuration properties in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the server CA certificate if your connection properties have sslMode set to VERIFY_CA or VERIFY_IDENTITY, as in the following example.

Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);

### Note

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see Client-side configuration for encrypted connections in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the --ssl-mode option you specify VERIFY_CA or VERIFY_IDENTITY, as in the following example.
When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the `--ssl-verify-server-cert` option, as in the following example.

```bash
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-mode=VERIFY_CA
```

### Updating your application trust store

For information about updating the trust store for MySQL applications, see [Installing SSL certificates](#) in the MySQL documentation.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

For sample scripts that import certificates, see [Sample script for importing certificates into your trust store](#).

**Note**

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

If you are using the mysql JDBC driver in an application, set the following properties in the application.

```java
System.setProperty("javax.net.ssl.trustStore", "certs");
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

When you start the application, set the following properties.
Note

Specify a password other than the prompt shown here as a security best practice.

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection that validates the server certificate using JDBC.

```java
public class MySQLSSLTest {

    private static final String DB_USER = "username";
    private static final String DB_PASSWORD = "password";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
    private static final String KEY_STORE_PASS = "keystore-password";

    public static void test(String[] args) throws Exception {
        Class.forName("com.mysql.jdbc.Driver");

        System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);

        Properties properties = new Properties();
        properties.setProperty("sslMode", "VERIFY_IDENTITY");
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);

        Connection connection = null;
        Statement stmt = null;
        ResultSet rs = null;
        try {
```

Using new SSL/TLS certificates
connection = DriverManager.getConnection("jdbc:mysql://mydatabase.123456789012.us-east-1.rds.amazonaws.com:3306",properties);
    stmt = connection.createStatement();
    rs=stmt.executeQuery("SELECT 1 from dual");
} finally {
    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException e) {
        }
    }
    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException e) {
        }
    }
    if (connection != null) {
        try {
            connection.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
    return;
}
Using Kerberos authentication for MySQL

You can use Kerberos authentication to authenticate users when they connect to your MySQL DB instance. The DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users authenticate with a MySQL DB instance joined to the trusting domain, authentication requests are forwarded. Forwarded requests go to the domain directory that you create with AWS Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. With this approach, you have a centralized place for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with Kerberos authentication, see Kerberos authentication.

Overview of Setting up Kerberos authentication for MySQL DB instances

To set up Kerberos authentication for a MySQL DB instance, complete the following general steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service to create the directory. For details about doing so, see Create your AWS Managed Microsoft AD directory in the AWS Directory Service Administration Guide.

2. Create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess. The role allows Amazon RDS to make calls to your directory.

   For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS managed Microsoft AD in the AWS Directory Service Administration Guide.
4. Create or modify a MySQL DB instance. If you use either the CLI or RDS API in the create request, specify a domain identifier with the Domain parameter. Use the d-* identifier that was generated when you created your directory and the name of the role that you created.

If you modify an existing MySQL DB instance to use Kerberos authentication, set the domain and IAM role parameters for the DB instance. Locate the DB instance in the same VPC as the domain directory.

5. Use the Amazon RDS master user credentials to connect to the MySQL DB instance. Create the user in MySQL using the `CREATE USER` clause `IDENTIFIED WITH 'auth_pam'`. Users that you create this way can log in to the MySQL DB instance using Kerberos authentication.

### Setting up Kerberos authentication for MySQL DB instances

You use AWS Managed Microsoft AD to set up Kerberos authentication for a MySQL DB instance. To set up Kerberos authentication, you take the following steps.

#### Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

\[\text{Note}\]

Be sure to save this password. AWS Directory Service doesn't store it. You can reset it, but you can't retrieve it.

- Creates a security group for the directory controllers.
When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you created your directory and is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

To create a directory with AWS Managed Microsoft AD

2. In the navigation pane, choose **Directories** and choose **Set up Directory**.
3. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

   **Directory DNS name**

   The fully qualified name for the directory, such as `corp.example.com`.
Directory NetBIOS name

The short name for the directory, such as CORP.

Directory description

(Optional) A description for the directory.

Admin password

The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password and can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Non-alphanumeric characters (~!@#$%^&*_-+=`\{|}[]:;"'<>,.?/)

Confirm password

The administrator password retyped.

5. Choose Next.

6. Enter the following information in the Networking section and then choose Next:

   VPC

   The VPC for the directory. Create the MySQL DB instance in this same VPC.

   Subnets

   Subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Review the directory information and make any necessary changes. When the information is correct, choose Create directory.
It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory name in the directory listing. Note the **Directory ID** value because you need this value when you create or modify your MySQL DB instance.
Step 2: Create the IAM role for use by Amazon RDS

For Amazon RDS to call AWS Directory Service for you, an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess` is required. This role allows Amazon RDS to make calls to the AWS Directory Service.

When a DB instance is created using the AWS Management Console and the console user has the `iam:CreateRole` permission, the console creates this role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, you must create the
IAM role manually. When you create this IAM role, choose Directory Service, and attach the AWS managed policy AmazonRDSDirectoryServiceAccess to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

**Note**

The IAM role used for Windows Authentication for RDS for SQL Server can't be used for RDS for MySQL.

Optionally, you can create policies with the required permissions instead of using the managed IAM policy AmazonRDSDirectoryServiceAccess. In this case, the IAM role must have the following IAM trust policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ],
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The role must also have the following IAM role policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",
        "rds:CreateDBCluster",
        "rds:DescribeDBClusters","
      ],
      "Effect": "Allow",
      "Resource": ["*"]
    }
  ]
}
```
Step 3: Create and configure users

You can create users with the Active Directory Users and Computers tool. This tool is part of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to an Amazon EC2 instance based on Microsoft Windows. This instance must be a member of the AWS Directory Service directory and be logged in as a user that has privileges to create users. For more information, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

Step 4: Create or modify a MySQL DB instance

Create or modify a MySQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new MySQL DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.
  
  For instructions, see Creating an Amazon RDS DB instance.

- Modify an existing MySQL DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation.
  
  For instructions, see Modifying an Amazon RDS DB instance.

- Restore a MySQL DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.
  
  For instructions, see Restoring from a DB snapshot.

- Restore a MySQL DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation.
Kerberos authentication is only supported for MySQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows egress within the directory's VPC so the DB instance can communicate with the directory.

When you use the console to create, modify, or restore a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Choose **Browse Directory** and then select the directory, or choose **Create a new directory**.

When you use the AWS CLI or RDS API, associate a DB instance with a directory. The following parameters are required for the DB instance to use the domain directory you created:

- For the **--domain** parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the **--domain-iam-role-name** parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:
aws rds modify-db-instance \
   --db-instance-identifier mydbinstance \
   --domain d-ID \
   --domain-iam-role-name role-name

For Windows:

aws rds modify-db-instance ^
   --db-instance-identifier mydbinstance ^
   --domain d-ID ^
   --domain-iam-role-name role-name

⚠️ Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Step 5: Create Kerberos authentication MySQL logins

Use the Amazon RDS master user credentials to connect to the MySQL DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision MySQL logins and users from the Active Directory users in your domain. Database permissions are managed through standard MySQL permissions that are granted to and revoked from these logins.

You can allow an Active Directory user to authenticate with MySQL. To do this, first use the Amazon RDS master user credentials to connect to the MySQL DB instance as with any other DB instance. After you're logged in, create an externally authenticated user with PAM (Pluggable Authentication Modules) in MySQL as shown following.

CREATE USER 'testuser'@'%' IDENTIFIED WITH 'auth_pam';

Replace testuser with the user name. Users (both humans and applications) from your domain can now connect to the DB instance from a domain joined client machine using Kerberos authentication.
Important

We strongly recommend that clients use SSL/TLS connections when using PAM authentication. If they don't use SSL/TLS connections, the password might be sent as clear text in some cases. To require an SSL/TLS encrypted connection for your AD user, run the following command:

```
UPDATE mysql.user SET ssl_type = 'any' WHERE ssl_type = '' AND PLUGIN = 'auth_pam' and USER = 'testuser';
FLUSH PRIVILEGES;
```

For more information, see Using SSL/TLS with a MySQL DB instance.

Managing a DB instance in a domain

You can use the CLI or the RDS API to manage your DB instance and its relationship with your managed Active Directory. For example, you can associate an Active Directory for Kerberos authentication and disassociate an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Active Directory to another.

For example, using the Amazon RDS API, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the ModifyDBInstance API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the ModifyDBInstance API operation and specify the current membership's directory ID and the new IAM role.
- To disable Kerberos authentication on a DB instance, use the ModifyDBInstance API operation and specify none as the domain parameter.
- To move a DB instance from one domain to another, use the ModifyDBInstance API operation and specify the domain identifier of the new domain as the domain parameter.
- To list membership for each DB instance, use the DescribeDBInstances API operation.
Understanding domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership for the DB instance by running the `describe-db-instances` CLI command. The status of the DB instance can be one of the following:

- **kerberos-enabled** – The DB instance has Kerberos authentication enabled.
- **enabling-kerberos** – AWS is in the process of enabling Kerberos authentication on this DB instance.
- **pending-enable-kerberos** – The enabling of Kerberos authentication is pending on this DB instance.
- **pending-maintenance-enable-kerberos** – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- **pending-disable-kerberos** – The disabling of Kerberos authentication is pending on this DB instance.
- **pending-maintenance-disable-kerberos** – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- **enable-kerberos-failed** – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Check and fix your configuration before reissuing the DB instance modify command.
- **disabling-kerberos** – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. For example, suppose that you create a DB instance or modify an existing DB instance and the attempt to enable Kerberos authentication fails. If this happens, re-issue the modify command or modify the newly created DB instance to join the domain.

Connecting to MySQL with Kerberos authentication

To connect to MySQL with Kerberos authentication, you must log in using the Kerberos authentication type.

To create a database user that you can connect to using Kerberos authentication, use an IDENTIFIED WITH clause on the CREATE USER statement. For instructions, see Step 5: Create Kerberos authentication MySQL logins.
To avoid errors, use the MariaDB `mysql` client. You can download MariaDB software at https://downloads.mariadb.org/.

At a command prompt, connect to one of the endpoints associated with your MySQL DB instance. Follow the general procedures in Connecting to a DB instance running the MySQL database engine. When you're prompted for the password, enter the Kerberos password associated with that user name.

**Restoring a MySQL DB instance and adding it to a domain**

You can restore a DB snapshot or complete a point-in-time restore for a MySQL DB instance and then add it to a domain. After the DB instance is restored, modify the DB instance using the process explained in Step 4: Create or modify a MySQL DB instance to add the DB instance to a domain.

**Kerberos authentication MySQL limitations**

The following limitations apply to Kerberos authentication for MySQL:

- Only an AWS Managed Microsoft AD is supported. However, you can join RDS for MySQL DB instances to shared Managed Microsoft AD domains owned by different accounts in the same AWS Region.
- You must reboot the DB instance after enabling the feature.
- The domain name length can't be longer than 61 characters.
- You can't enable Kerberos authentication and IAM authentication at the same time. Choose one authentication method or the other for your MySQL DB instance.
- Don't modify the DB instance port after enabling the feature.
- Don't use Kerberos authentication with read replicas.
- If you have auto minor version upgrade turned on for a MySQL DB instance that is using Kerberos authentication, you must turn off Kerberos authentication and then turn it back on after an automatic upgrade. For more information about auto minor version upgrades, see Automatic minor version upgrades for MySQL.
- To delete a DB instance with this feature enabled, first disable the feature. To do so, use the `modify-db-instance` CLI command for the DB instance and specify none for the `--domain` parameter.

  If you use the CLI or RDS API to delete a DB instance with this feature enabled, expect a delay.
You can't set up a forest trust relationship between your on-premises or self-hosted Microsoft Active Directory and the AWS Managed Microsoft AD.
Improving query performance for RDS for MySQL with Amazon RDS Optimized Reads

You can achieve faster query processing for RDS for MySQL with Amazon RDS Optimized Reads. An RDS for MySQL DB instance or Multi-AZ DB cluster that uses RDS Optimized Reads can achieve up to 2x faster query processing compared to a DB instance or cluster that doesn't use it.

Topics
- Overview of RDS Optimized Reads
- Use cases for RDS Optimized Reads
- Best practices for RDS Optimized Reads
- Using RDS Optimized Reads
- Monitoring DB instances that use RDS Optimized Reads
- Limitations for RDS Optimized Reads

Overview of RDS Optimized Reads

When you use an RDS for MySQL DB instance or Multi-AZ DB cluster that has RDS Optimized Reads turned on, it achieves faster query performance through the use of an instance store. An instance store provides temporary block-level storage for your DB instance or Multi-AZ DB cluster. The storage is located on Non-Volatile Memory Express (NVMe) solid state drives (SSDs) that are physically attached to the host server. This storage is optimized for low latency, high random I/O performance, and high sequential read throughput.

RDS Optimized Reads is turned on by default when a DB instance or Multi-AZ DB cluster uses a DB instance class with an instance store, such as db.m5d or db.m6gd. With RDS Optimized Reads, some temporary objects are stored on the instance store. These temporary objects include internal temporary files, internal on-disk temp tables, memory map files, and binary log (binlog) cache files. For more information about the instance store, see Amazon EC2 instance store in the Amazon Elastic Compute Cloud User Guide for Linux Instances.

The workloads that generate temporary objects in MySQL for query processing can take advantage of the instance store for faster query processing. This type of workload includes queries involving sorts, hash aggregations, high-load joins, Common Table Expressions (CTEs), and queries on unindexed columns. These instance store volumes provide higher IOPS and performance,
regardless of the storage configurations used for persistent Amazon EBS storage. Because RDS Optimized Reads offloads operations on temporary objects to the instance store, the input/output operations per second (IOPS) or throughput of the persistent storage (Amazon EBS) can now be used for operations on persistent objects. These operations include regular data file reads and writes, and background engine operations, such as flushing and insert buffer merges.

Both manual and automated RDS snapshots only contain engine files for persistent objects. The temporary objects created in the instance store aren't included in RDS snapshots.

Use cases for RDS Optimized Reads

If you have workloads that rely heavily on temporary objects, such as internal tables or files, for their query execution, then you can benefit from turning on RDS Optimized Reads. The following use cases are candidates for RDS Optimized Reads:

- Applications that run analytical queries with complex common table expressions (CTEs), derived tables, and grouping operations
- Read replicas that serve heavy read traffic with unoptimized queries
- Applications that run on-demand or dynamic reporting queries that involve complex operations, such as queries with GROUP BY and ORDER BY clauses
- Workloads that use internal temporary tables for query processing

You can monitor the engine status variable `created_tmp_disk_tables` to determine the number of disk-based temporary tables created on your DB instance.

- Applications that create large temporary tables, either directly or in procedures, to store intermediate results
- Database queries that perform grouping or ordering on non-indexed columns

Best practices for RDS Optimized Reads

Use the following best practices for RDS Optimized Reads:

- Add retry logic for read-only queries in case they fail because the instance store is full during the execution.
• Monitor the storage space available on the instance store with the CloudWatch metric FreeLocalStorage. If the instance store is reaching its limit because of workload on the DB instance, modify the DB instance to use a larger DB instance class.

• When your DB instance or Multi-AZ DB cluster has sufficient memory but is still reaching the storage limit on the instance store, increase the binlog_cache_size value to maintain the session-specific binlog entries in memory. This configuration prevents writing the binlog entries to temporary binlog cache files on disk.

The binlog_cache_size parameter is session-specific. You can change the value for each new session. The setting for this parameter can increase the memory utilization on the DB instance during peak workload. Therefore, consider increasing the parameter value based on the workload pattern of your application and available memory on the DB instance.

• Use the default value of MIXED for the binlog_format. Depending on the size of the transactions, setting binlog_format to ROW can result in large binlog cache files on the instance store.

• Set the internal_tmp_mem_storage_engine parameter to TempTable, and set the temptable_max_mmap parameter to match the size of the available storage on the instance store.

• Avoid performing bulk changes in a single transaction. These types of transactions can generate large binlog cache files on the instance store and can cause issues when the instance store is full. Consider splitting writes into multiple small transactions to minimize storage use for binlog cache files.

• Use the default value of ABORT_SERVER for the binlog_error_action parameter. Doing so avoids issues with the binary logging on DB instances with backups enabled.

Using RDS Optimized Reads

When you provision an RDS for MySQL DB instance with one of the following DB instance classes in a Single-AZ DB instance deployment, Multi-AZ DB instance deployment, or Multi-AZ DB cluster deployment, the DB instance automatically uses RDS Optimized Reads.

To turn on RDS Optimized Reads, do one of the following:

• Create an RDS for MySQL DB instance or Multi-AZ DB cluster using one of these DB instance classes. For more information, see Creating an Amazon RDS DB instance.
• Modify an existing RDS for MySQL DB instance or Multi-AZ DB cluster to use one of these DB instance classes. For more information, see Modifying an Amazon RDS DB instance.

RDS Optimized Reads is available in all AWS Regions RDS where one or more of the DB instance classes with local NVMe SSD storage are supported. For information about DB instance classes, see the section called “DB instance classes”.

DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see the section called “Determining DB instance class support in AWS Regions”.

If you don't want to use RDS Optimized Reads, modify your DB instance or Multi-AZ DB cluster so that it doesn't use a DB instance class that supports the feature.

**Monitoring DB instances that use RDS Optimized Reads**

You can monitor DB instances that use RDS Optimized Reads with the following CloudWatch metrics:

- FreeLocalStorage
- ReadIOPSLocalStorage
- ReadLatencyLocalStorage
- ReadThroughputLocalStorage
- WriteIOPSLocalStorage
- WriteLatencyLocalStorage
- WriteThroughputLocalStorage

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS.

**Limitations for RDS Optimized Reads**

The following limitations apply to RDS Optimized Reads:

- RDS Optimized Reads is supported for RDS for MySQL version 8.0.28 and higher. For information about RDS for MySQL versions, see MySQL on Amazon RDS versions.
• You can't change the location of temporary objects to persistent storage (Amazon EBS) on the DB instance classes that support RDS Optimized Reads.

• When binary logging is enabled on a DB instance, the maximum transaction size is limited by the size of the instance store. In MySQL, any session that requires more storage than the value of `binlog_cache_size` writes transaction changes to temporary binlog cache files, which are created on the instance store.

• Transactions can fail when the instance store is full.
Improving write performance with RDS Optimized Writes for MySQL

You can improve the performance of write transactions with RDS Optimized Writes for MySQL. When your RDS for MySQL database uses RDS Optimized Writes, it can achieve up to two times higher write transaction throughput.

Topics

• Overview of RDS Optimized Writes
• Using RDS Optimized Writes
• Enabling RDS Optimized Writes on an existing database
• Limitations for RDS Optimized Writes

Overview of RDS Optimized Writes

When you turn on RDS Optimized Writes, your RDS for MySQL databases write only once when flushing data to durable storage without the need for the doublewrite buffer. The databases continue to provide ACID property protections for reliable database transactions, along with improved performance.

Relational databases, like MySQL, provide the ACID properties of atomicity, consistency, isolation, and durability for reliable database transactions. To help provide these properties, MySQL uses a data storage area called the doublewrite buffer that prevents partial page write errors. These errors occur when there is a hardware failure while the database is updating a page, such as in the case of a power outage. A MySQL database can detect partial page writes and recover with a copy of the page in the doublewrite buffer. While this technique provides protection, it also results in extra write operations. For more information about the MySQL doublewrite buffer, see Doublewrite Buffer in the MySQL documentation.

With RDS Optimized Writes turned on, RDS for MySQL databases write only once when flushing data to durable storage without using the doublewrite buffer. RDS Optimized Writes is useful if you run write-heavy workloads on your RDS for MySQL databases. Examples of databases with write-heavy workloads include ones that support digital payments, financial trading, and gaming applications.
These databases run on DB instance classes that use the AWS Nitro System. Because of the hardware configuration in these systems, the database can write 16-KiB pages directly to data files reliably and durably in one step. The AWS Nitro System makes RDS Optimized Writes possible.

You can set the new database parameter `rds.optimized_writes` to control the RDS Optimized Writes feature for RDS for MySQL databases. Access this parameter in the DB parameter groups of RDS for MySQL version 8.0. Set the parameter using the following values:

- **AUTO** – Turn on RDS Optimized Writes if the database supports it. Turn off RDS Optimized Writes if the database doesn't support it. This setting is the default.
- **OFF** – Turn off RDS Optimized Writes even if the database supports it.

If you have an existing database with an engine version, DB instance class, and/or file system format that doesn't support RDS Optimized Writes, you can enable the feature by creating a blue/green deployment. For more information, see the section called “Enabling on an existing database”.

If you migrate an RDS for MySQL database that is configured to use RDS Optimized Writes to a DB instance class that doesn't support the feature, RDS automatically turns off RDS Optimized Writes for the database.

When RDS Optimized Writes is turned off, the database uses the MySQL doublewrite buffer.

To determine whether an RDS for MySQL database is using RDS Optimized Writes, view the current value of the `innodb_doublewrite` parameter for the database. If the database is using RDS Optimized Writes, this parameter is set to `FALSE (0)`.

**Using RDS Optimized Writes**

You can turn on RDS Optimized Writes when you create an RDS for MySQL database with the RDS console, the AWS CLI, or the RDS API. RDS Optimized Writes is turned on automatically when both of the following conditions apply during database creation:

- You specify a DB engine version and DB instance class that support RDS Optimized Writes.
- RDS Optimized Writes is supported for RDS for MySQL version 8.0.30 and higher. For information about RDS for MySQL versions, see [MySQL on Amazon RDS versions](#).
- db.m7g
- db.m6g
- db.m6gd
- db.m6i
- db.m5
- db.m5d
- db.r7g
- db.r6g
- db.r6gd
- db.r6i
- db.r5
- db.r5b
- db.r5d
- db.x2idn
- db.x2iedn

For information about DB instance classes, see the section called “DB instance classes”.

DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see the section called “Determining DB instance class support in AWS Regions”.

To upgrade your database to a DB instance class that supports RDS Optimized Writes, you can create a blue/green deployment. For more information, see the section called “Enabling on an existing database”.

- In the parameter group associated with the database, the rds.optimized_writes parameter is set to AUTO. In default parameter groups, this parameter is always set to AUTO.

If you want to use a DB engine version and DB instance class that support RDS Optimized Writes, but you don’t want to use this feature, then specify a custom parameter group when you create the database. In this parameter group, set the rds.optimized_writes parameter to OFF. If you want the database to use RDS Optimized Writes later, you can set the parameter to AUTO to turn it on. For information about creating custom parameter groups and setting parameters, see Working with parameter groups.
For information about creating a DB instance, see Creating an Amazon RDS DB instance.

**Console**

When you use the RDS console to create an RDS for MySQL database, you can filter for the DB engine versions and DB instance classes that support RDS Optimized Writes. After you turn on the filters, you can choose from the available DB engine versions and DB instance classes.

To choose a DB engine version that supports RDS Optimized Writes, filter for the RDS for MySQL DB engine versions that support it in **Engine version**, and then choose a version.
In the **Instance configuration** section, filter for the DB instance classes that support RDS Optimized Writes, and then choose a DB instance class.
After you make these selections, you can choose other settings that meet your requirements and finish creating the RDS for MySQL database with the console.

AWS CLI

To create a DB instance by using the AWS CLI, use the create-db-instance command. Make sure the --engine-version and --db-instance-class values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the rds.optimized_writes parameter set to AUTO. This example associates the default parameter group with the DB instance.

Example Creating a DB instance that uses RDS Optimized Writes

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
  --db-instance-identifier mydbinstance \
  --engine mysql \
  --engine-version 8.0.30 \
  --db-instance-class db.r5b.large \
  --manage-master-user-password \
  --master-username admin \
  --allocated-storage 200
```

For Windows:

```bash
aws rds create-db-instance ^
  --db-instance-identifier mydbinstance ^
  --engine mysql ^
```
RDS API

You can create a DB instance using the CreateDBInstance operation. When you use this operation, make sure the EngineVersion and DBInstanceClass values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the rds.optimized_writes parameter set to AUTO.

Enabling RDS Optimized Writes on an existing database

In order to modify an existing RDS for MySQL database to turn on RDS Optimized Writes, the database must have been created with a supported DB engine version and DB instance class. In addition, the database must have been created after RDS Optimized Writes was released on November 27, 2022, as the required underlying file system configuration is incompatible with that of databases created before it was released. If these conditions are met, you can turn on RDS Optimized Writes by setting the rds.optimized_writes parameter to AUTO.

If your database was not created with a supported engine version, instance class, or file system configuration, you can use RDS Blue/Green Deployments to migrate to a supported configuration. While creating the blue/green deployment, do the following:

- Select Enable Optimized Writes on green database, then specify an engine version and DB instance class that supports RDS Optimized Writes. For a list of supported engine versions and instance classes, see Using RDS Optimized Writes.

- Under Storage, choose Upgrade storage file system configuration. This option upgrades the database to a compatible underlying file system configuration.

When you create the blue/green deployment, if the rds.optimized_writes parameter is set to AUTO, RDS Optimized Writes will be automatically enabled on the green environment. You can then switch over the blue/green deployment, which promotes the green environment to be the new production environment.

For more information, see the section called “Creating a blue/green deployment”.

Enabling on an existing database
Limitations for RDS Optimized Writes

When you're restoring an RDS for MySQL database from a snapshot, you can only turn on RDS Optimized Writes for the database if all of the following conditions apply:

- The snapshot was created from a database that supports RDS Optimized Writes.
- The snapshot was created from a database that was created after RDS Optimized Writes was released.
- The snapshot is restored to a database that supports RDS Optimized Writes.
- The restored database is associated with a parameter group that has the `rds.optimized_writes` parameter set to AUTO.
Upgrading the MySQL DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MySQL databases: major version upgrades and minor version upgrades.

**Major version upgrades**

*Major version upgrades* can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. Before you perform a major version upgrade, we recommend that you follow the instructions in *Major version upgrades for MySQL*.

For major version upgrades of Multi-AZ DB instance deployments, Amazon RDS simultaneously upgrades both the primary and standby replicas. Your DB instance won't be available until the upgrade completes. Currently, Amazon RDS doesn't support major version upgrades for Multi-AZ DB cluster deployments.

Tip

You can minimize the downtime required for a major version upgrade by using a blue/green deployment. For more information, see *Using Amazon RDS Blue/Green Deployments for database updates*.

**Minor version upgrades**

*Minor version upgrades* include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or, you can enable the *Auto minor version upgrade* option when creating or modifying a DB instance. Doing so means that Amazon RDS automatically upgrades your DB instance after testing and approving the new version. For information about performing an upgrade, see *Upgrading a DB instance engine version*.

When you perform a minor version upgrade of a Multi-AZ DB cluster, Amazon RDS upgrades the reader DB instances one at a time. Then, one of the reader DB instances switches to be the new writer DB instance. Amazon RDS then upgrades the old writer instance (which is now a reader instance).
### Note

The downtime for a minor version upgrade of a Multi-AZ DB instance deployment can last for several minutes. Multi-AZ DB clusters typically reduce the downtime of minor version upgrades to approximately 35 seconds. When used with RDS Proxy, you can further reduce downtime to one second or less. For more information, see [Using RDS Proxy](#). Alternately, you can use an open source database proxy such as ProxySQL, PgBouncer, or the AWS JDBC Driver for MySQL.

If your MySQL DB instance uses read replicas, then you must upgrade all of the read replicas before upgrading the source instance.

#### Topics
- **Overview of upgrading**
- **MySQL version numbers**
- **RDS version number**
- **Major version upgrades for MySQL**
- **Testing an upgrade**
- **Upgrading a MySQL DB instance**
- **Automatic minor version upgrades for MySQL**
- **Using a read replica to reduce downtime when upgrading a MySQL database**

#### Overview of upgrading

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
    --engine mysql
    --engine-version version-number
    --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```
For Windows:

```bash
aws rds describe-db-engine-versions ^
   --engine mysql ^
   --engine-version version-number ^
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For example, to identify the valid upgrade targets for a MySQL version 8.0.28 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
   --engine mysql \
   --engine-version 8.0.28 \
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
   --engine mysql ^
   --engine-version 8.0.28 ^
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

Amazon RDS takes two or more DB snapshots during the upgrade process. Amazon RDS takes up to two snapshots of the DB instance before making any upgrade changes. If the upgrade doesn't work for your databases, you can restore one of these snapshots to create a DB instance running the old version. Amazon RDS takes another snapshot of the DB instance when the upgrade completes. Amazon RDS takes these snapshots regardless of whether AWS Backup manages the backups for the DB instance.

**Note**

Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see [Modifying an Amazon RDS DB instance](#).
After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance uses read replication, then you must upgrade all of the read replicas before upgrading the source instance.

**MySQL version numbers**

The version numbering sequence for the RDS for MySQL database engine is either in the form of major.minor.patch.YYYYMMDD or major.minor.patch, for example, 8.0.33.R2.20231201 or 5.7.44. The format used depends on the MySQL engine version. For information about RDS Extended Support version numbering, see [Amazon RDS Extended Support version naming](#).

**major**

The major version number is both the integer and the first fractional part of the version number, for example, 8.0. A major version upgrade increases the major part of the version number. For example, an upgrade from 5.7.44 to 8.0.33 is a major version upgrade, where 5.7 and 8.0 are the major version numbers.

**minor**

The minor version number is the third part of the version number, for example, the 33 in 8.0.33.

**patch**

The patch is the fourth part of the version number, for example, the R2 in 8.0.33.R2. An RDS patch version includes important bug fixes added to a minor version after its release.

**YYYYMMDD**

The date is the fifth part of the version number, for example, the 20231201 in 8.0.33.R2.20231201. An RDS date version is a security patch that includes important security fixes added to a minor version after its release. It doesn't include any fixes that might change an engine's behavior.
### RDS version number

RDS version numbers use either the `major.minor.patch` or the `major.minor.patch.YYMMDD` naming scheme. An RDS patch version includes important bug fixes added to a minor version after its release. An RDS date version (`YYMMDD`) is a security patch. A security patch doesn't include any fixes that might change the engine's behavior. For information about RDS Extended Support version numbering, see Amazon RDS Extended Support version naming.

To identify the Amazon RDS version number of your database, you must first create the `rds_tools` extension by using the following command:

```
CREATE EXTENSION rds_tools;
```

You can find out the RDS version number of your RDS for MySQL database with the following SQL query:

```
mysql> select mysql.rds_version();
```
For example, querying an RDS for MySQL 8.0.34 database returns the following output:

```
+---------------------+
| mysql.rds_version() |
+---------------------+
| 8.0.34.R2.20231201  |
+---------------------+
1 row in set (0.01 sec)
```

### Major version upgrades for MySQL

Amazon RDS supports the following in-place upgrades for major versions of the MySQL database engine:

- MySQL 5.6 to MySQL 5.7
- MySQL 5.7 to MySQL 8.0

**Note**

You can only create MySQL version 5.7 and 8.0 DB instances with latest-generation and current-generation DB instance classes, in addition to the db.m3 previous-generation DB instance class.

In some cases, you want to upgrade a MySQL version 5.6 DB instance running on a previous-generation DB instance class (other than db.m3) to a MySQL version 5.7 DB instance. In these cases, first modify the DB instance to use a latest-generation or current-generation DB instance class. After you do this, you can then modify the DB instance to use the MySQL version 5.7 database engine. For information on Amazon RDS DB instance classes, see [DB instance classes](#).

### Topics

- [Overview of MySQL major version upgrades](#)
- [Upgrades to MySQL version 5.7 might be slow](#)
- [Prechecks for upgrades from MySQL 5.7 to 8.0](#)
- [Rollback after failure to upgrade from MySQL 5.7 to 8.0](#)
Overview of MySQL major version upgrades

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically; you must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.

To perform a major version upgrade for a MySQL version 5.6 DB instance on Amazon RDS to MySQL version 5.7 or later, first perform any available OS updates. After OS updates are complete, upgrade to each major version: 5.6 to 5.7 and then 5.7 to 8.0. MySQL DB instances created before April 24, 2014, show an available OS update until the update has been applied. For more information on OS updates, see Applying updates for a DB instance.

During a major version upgrade of MySQL, Amazon RDS runs the MySQL binary `mysql_upgrade` to upgrade tables, if necessary. Also, Amazon RDS empties the `slow_log` and `general_log` tables during a major version upgrade. To preserve log information, save the log contents before the major version upgrade.

MySQL major version upgrades typically complete in about 10 minutes. Some upgrades might take longer because of the DB instance class size or because the instance doesn't follow certain operational guidelines in Best practices for Amazon RDS. If you upgrade a DB instance from the Amazon RDS console, the status of the DB instance indicates when the upgrade is complete. If you upgrade using the AWS Command Line Interface (AWS CLI), use the `describe-db-instances` command and check the Status value.

Upgrades to MySQL version 5.7 might be slow

MySQL version 5.6.4 introduced a new date and time format for the `datetime`, `time`, and `timestamp` columns that allows fractional components in date and time values. When upgrading a DB instance to MySQL version 5.7, MySQL forces the conversion of all date and time column types to the new format.

Because this conversion rebuilds your tables, it might take a considerable amount of time to complete the DB instance upgrade. The forced conversion occurs for any DB instances that are running a version before MySQL version 5.6.4. It also occurs for any DB instances that were upgraded from a version before MySQL version 5.6.4 to a version other than 5.7.

If your DB instance runs a version before MySQL version 5.6.4, or was upgraded from a version before 5.6.4, we recommend an extra step. In these cases, we recommend that you convert the
datetime, time, and timestamp columns in your database before upgrading your DB instance to MySQL version 5.7. This conversion can significantly reduce the amount of time required to upgrade the DB instance to MySQL version 5.7. To upgrade your date and time columns to the new format, issue the `ALTER TABLE <table_name> FORCE;` command for each table that contains date or time columns. Because altering a table locks the table as read-only, we recommend that you perform this update during a maintenance window.

To find all tables in your database that have datetime, time, or timestamp columns and create an `ALTER TABLE <table_name> FORCE;` command for each table, use the following query.

```
SET show_old_temporals = ON;
SELECT table_schema, table_name, column_name, column_type
FROM information_schema.columns
WHERE column_type LIKE '%/* 5.5 binary format */';
SET show_old_temporals = OFF;
```

**Prechecks for upgrades from MySQL 5.7 to 8.0**

MySQL 8.0 includes a number of incompatibilities with MySQL 5.7. These incompatibilities can cause problems during an upgrade from MySQL 5.7 to MySQL 8.0. So, some preparation might be required on your database for the upgrade to be successful. The following is a general list of these incompatibilities:

- There must be no tables that use obsolete data types or functions.
- There must be no orphan *.frm files.
- Triggers must not have a missing or empty definer or an invalid creation context.
- There must be no partitioned table that uses a storage engine that does not have native partitioning support.
- There must be no keyword or reserved word violations. Some keywords might be reserved in MySQL 8.0 that were not reserved previously.

For more information, see [Keywords and reserved words](#) in the MySQL documentation.

- There must be no tables in the MySQL 5.7 `mysql` system database that have the same name as a table used by the MySQL 8.0 data dictionary.
- There must be no obsolete SQL modes defined in your `sql_mode` system variable setting.
- There must be no tables or stored procedures with individual ENUM or SET column elements that exceed 255 characters or 1020 bytes in length.
Before upgrading to MySQL 8.0.13 or higher, there must be no table partitions that reside in shared InnoDB tablespaces.

There must be no queries and stored program definitions from MySQL 8.0.12 or lower that use `ASC` or `DESC` qualifiers for `GROUP BY` clauses.

Your MySQL 5.7 installation must not use features that are not supported in MySQL 8.0.

For more information, see [Features removed in MySQL 8.0](http://example.com) in the MySQL documentation.

There must be no foreign key constraint names longer than 64 characters.

For improved Unicode support, consider converting objects that use the `utf8mb3` charset to use the `utf8mb4` charset. The `utf8mb3` character set is deprecated. Also, consider using `utf8mb4` for character set references instead of `utf8`, because currently `utf8` is an alias for the `utf8mb3` charset.

For more information, see [The utf8mb3 character set (3-byte UTF-8 unicode encoding)](http://example.com) in the MySQL documentation.

When you start an upgrade from MySQL 5.7 to 8.0, Amazon RDS runs prechecks automatically to detect these incompatibilities. For information about upgrading to MySQL 8.0, see [Upgrading MySQL](http://example.com) in the MySQL documentation.

These prechecks are mandatory. You can't choose to skip them. The prechecks provide the following benefits:

- They enable you to avoid unplanned downtime during the upgrade.
- If there are incompatibilities, Amazon RDS prevents the upgrade and provides a log for you to learn about them. You can then use the log to prepare your database for the upgrade to MySQL 8.0 by reducing the incompatibilities. For detailed information about removing incompatibilities, see [Preparing your installation for upgrade](http://example.com) in the MySQL documentation and [Upgrading to MySQL 8.0? Here is what you need to know...](http://example.com) on the MySQL Server Blog.

The prechecks include some that are included with MySQL and some that were created specifically by the Amazon RDS team. For information about the prechecks provided by MySQL, see [Upgrade checker utility](http://example.com).

The prechecks run before the DB instance is stopped for the upgrade, meaning that they don't cause any downtime when they run. If the prechecks find an incompatibility, Amazon RDS
automatically cancels the upgrade before the DB instance is stopped. Amazon RDS also generates an event for the incompatibility. For more information about Amazon RDS events, see Working with Amazon RDS event notification.

Amazon RDS records detailed information about each incompatibility in the log file PrePatchCompatibility.log. In most cases, the log entry includes a link to the MySQL documentation for correcting the incompatibility. For more information about viewing log files, see Viewing and listing database log files.

Due to the nature of the prechecks, they analyze the objects in your database. This analysis results in resource consumption and increases the time for the upgrade to complete.

Note
Amazon RDS runs all of these prechecks only for an upgrade from MySQL 5.7 to MySQL 8.0. For an upgrade from MySQL 5.6 to MySQL 5.7, prechecks are limited to confirming that there are no orphan tables and that there is enough storage space to rebuild tables. Prechecks aren't run for upgrades to releases lower than MySQL 5.7.

Rollback after failure to upgrade from MySQL 5.7 to 8.0

When you upgrade a DB instance from MySQL version 5.7 to MySQL version 8.0, the upgrade can fail. In particular, it can fail if the data dictionary contains incompatibilities that weren't captured by the prechecks. In this case, the database fails to start up successfully in the new MySQL 8.0 version. At this point, Amazon RDS rolls back the changes performed for the upgrade. After the rollback, the MySQL DB instance is running MySQL version 5.7. When an upgrade fails and is rolled back, Amazon RDS generates an event with the event ID RDS-EVENT-0188.

Typically, an upgrade fails because there are incompatibilities in the metadata between the databases in your DB instance and the target MySQL version. When an upgrade fails, you can view the details about these incompatibilities in the upgradeFailure.log file. Resolve the incompatibilities before attempting to upgrade again.

During an unsuccessful upgrade attempt and rollback, your DB instance is restarted. Any pending parameter changes are applied during the restart and persist after the rollback.

For more information about upgrading to MySQL 8.0, see the following topics in the MySQL documentation:

Major version upgrades
Preparing Your Installation for Upgrade

Upgrading to MySQL 8.0? Here is what you need to know...

Note
Currently, automatic rollback after upgrade failure is supported only for MySQL 5.7 to 8.0 major version upgrades.

Testing an upgrade

Before you perform a major version upgrade on your DB instance, thoroughly test your database for compatibility with the new version. In addition, thoroughly test all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.

To test a major version upgrade

1. Review the upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications:
   - Changes in MySQL 5.6
   - Changes in MySQL 5.7
   - Changes in MySQL 8.0
2. If your DB instance is a member of a custom DB parameter group, create a new DB parameter group with your existing settings that is compatible with the new major version. Specify the new DB parameter group when you upgrade your test instance, so your upgrade testing ensures that it works correctly. For more information about creating a DB parameter group, see Working with parameter groups.
3. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot for a Single-AZ DB instance.
4. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring from a DB snapshot.
5. Modify this new test DB instance to upgrade it to the new version, using one of the methods detailed following. If you created a new parameter group in step 2, specify that parameter group.
6. Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage.

7. Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version. Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1. Test all stored procedures and functions. Direct test versions of your applications to the upgraded DB instance.

8. If all tests pass, then perform the upgrade on your production DB instance. We recommend that you don't allow write operations to the DB instance until you confirm that everything is working correctly.

**Upgrading a MySQL DB instance**

For information about manually or automatically upgrading a MySQL DB instance, see [Upgrading a DB instance engine version](#).

**Automatic minor version upgrades for MySQL**

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.

In the AWS Management Console, these settings are under **Additional configuration**. The following image shows the **Auto minor version upgrade** setting.
For more information about these settings, see Settings for DB instances.

For some RDS for MySQL major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window.

RDS doesn’t automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the MySQL community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified MySQL minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
   --engine mysql
   --engine-version minor-version
   --region region
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].
   {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}"`
```
For Windows:

```bash
aws rds describe-db-engine-versions ^
  --engine mysql ^
  --engine-version minor-version ^
  --region region ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].
  {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
  --output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MySQL minor version 8.0.11 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \\
  --engine mysql \\
  --engine-version 8.0.11 \\
  --region us-east-2 \\
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].
  {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \\
  --output table
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
  --engine mysql ^
  --engine-version 8.0.11 ^
  --region us-east-2 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].
  {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
  --output table
```

Your output is similar to the following.

```
----------------------------------
|    DescribeDBEngineVersions     |
+--------------+-----------------+------------------+
| Automatic minor version upgrades | 2958             |
```

Automatic minor version upgrades
### AutoUpgrade vs. EngineVersion Table

<table>
<thead>
<tr>
<th>AutoUpgrade</th>
<th>EngineVersion</th>
</tr>
</thead>
<tbody>
<tr>
<td>False</td>
<td>8.0.15</td>
</tr>
<tr>
<td>False</td>
<td>8.0.16</td>
</tr>
<tr>
<td>False</td>
<td>8.0.17</td>
</tr>
<tr>
<td>False</td>
<td>8.0.19</td>
</tr>
<tr>
<td>False</td>
<td>8.0.20</td>
</tr>
<tr>
<td>False</td>
<td>8.0.21</td>
</tr>
<tr>
<td>True</td>
<td>8.0.23</td>
</tr>
<tr>
<td>False</td>
<td>8.0.25</td>
</tr>
</tbody>
</table>

In this example, the **AutoUpgrade** value is **True** for MySQL version 8.0.23. So, the automatic minor upgrade target is MySQL version 8.0.23, which is highlighted in the output.

A MySQL DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see [Automatically upgrading the minor engine version](#).

## Using a read replica to reduce downtime when upgrading a MySQL database

In most cases, a blue/green deployment is the best option to reduce downtime when upgrading a MySQL DB instance. For more information, see [Using Amazon RDS Blue/Green Deployments for database updates](#).

If you can't use a blue/green deployment and your MySQL DB instance is currently in use with a production application, you can use the following procedure to upgrade the database version for your DB instance. This procedure can reduce the amount of downtime for your application.

By using a read replica, you can perform most of the maintenance steps ahead of time and minimize the necessary changes during the actual outage. With this technique, you can test and prepare the new DB instance without making any changes to your existing DB instance.
The following procedure shows an example of upgrading from MySQL version 5.7 to MySQL version 8.0. You can use the same general steps for upgrades to other major versions.

**Note**

When you are upgrading from MySQL version 5.7 to MySQL version 8.0, complete the prechecks before performing the upgrade. For more information, see [Prechecks for upgrades from MySQL 5.7 to 8.0](https://console.aws.amazon.com/rds/).

To upgrade a MySQL database while a DB instance is in use

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Create a read replica of your MySQL 5.7 DB instance. This process creates an upgradable copy of your database. Other read replicas of the DB instance might also exist.
   a. In the console, choose **Databases**, and then choose the DB instance that you want to upgrade.
   b. For **Actions**, choose **Create read replica**.
   c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MySQL 5.7 DB instance.
   d. Choose **Create read replica**.
3. (Optional) When the read replica has been created and **Status** shows **Available**, convert the read replica into a Multi-AZ deployment and enable backups.

   By default, a read replica is created as a Single-AZ deployment with backups disabled. Because the read replica ultimately becomes the production DB instance, it is a best practice to configure a Multi-AZ deployment and enable backups now.
   a. In the console, choose **Databases**, and then choose the read replica that you just created.
   b. Choose **Modify**.
   c. For **Multi-AZ deployment**, choose **Create a standby instance**.
   d. For **Backup Retention Period**, choose a positive nonzero value, such as 3 days, and then choose **Continue**.
   e. For **Scheduling of modifications**, choose **Apply immediately**.
f. Choose **Modify DB instance**.

4. When the read replica **Status** shows **Available**, upgrade the read replica to MySQL 8.0:

   a. In the console, choose **Databases**, and then choose the read replica that you just created.
   
   b. Choose **Modify**.
   
   c. For **DB engine version**, choose the MySQL 8.0 version to upgrade to, and then choose **Continue**.
   
   d. For **Scheduling of modifications**, choose **Apply immediately**.
   
   e. Choose **Modify DB instance** to start the upgrade.

5. When the upgrade is complete and **Status** shows **Available**, verify that the upgraded read replica is up-to-date with the source MySQL 5.7 DB instance. To verify, connect to the read replica and run the `SHOW REPLICA STATUS` command. If the `Seconds_Behind_Master` field is 0, then replication is up-to-date.

   **Note**

   Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

6. **(Optional) Create a read replica of your read replica.**

   If you want the DB instance to have a read replica after it is promoted to a standalone DB instance, you can create the read replica now.

   a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.
   
   b. For **Actions**, choose **Create read replica**.
   
   c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MySQL 5.7 DB instance.
   
   d. Choose **Create read replica**.

7. **(Optional) Configure a custom DB parameter group for the read replica.**

   If you want the DB instance to use a custom parameter group after it is promoted to a standalone DB instance, you can create the DB parameter group now and associate it with the read replica.
a. Create a custom DB parameter group for MySQL 8.0. For instructions, see [Creating a DB parameter group](#).

b. Modify the parameters that you want to change in the DB parameter group you just created. For instructions, see [Modifying parameters in a DB parameter group](#).

c. In the console, choose **Databases**, and then choose the read replica.

d. Choose **Modify**.

e. For **DB parameter group**, choose the MySQL 8.0 DB parameter group you just created, and then choose **Continue**.

f. For **Scheduling of modifications**, choose **Apply immediately**.

g. Choose **Modify DB instance** to start the upgrade.

8. Make your MySQL 8.0 read replica a standalone DB instance.

---

**Important**

When you promote your MySQL 8.0 read replica to a standalone DB instance, it is no longer a replica of your MySQL 5.7 DB instance. We recommend that you promote your MySQL 8.0 read replica during a maintenance window when your source MySQL 5.7 DB instance is in read-only mode and all write operations are suspended. When the promotion is completed, you can direct your write operations to the upgraded MySQL 8.0 DB instance to ensure that no write operations are lost.

In addition, we recommend that, before promoting your MySQL 8.0 read replica, you perform all necessary data definition language (DDL) operations on your MySQL 8.0 read replica. An example is creating indexes. This approach avoids negative effects on the performance of the MySQL 8.0 read replica after it has been promoted. To promote a read replica, use the following procedure.

---

a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.

b. For **Actions**, choose **Promote**.

c. Choose **Yes** to enable automated backups for the read replica instance. For more information, see [Introduction to backups](#).

d. Choose **Continue**.

e. Choose **Promote Read Replica**.
9. You now have an upgraded version of your MySQL database. At this point, you can direct your applications to the new MySQL 8.0 DB instance.
Upgrading a MySQL DB snapshot engine version

With Amazon RDS, you can create a storage volume DB snapshot of your MySQL DB instance. When you create a DB snapshot, the snapshot is based on the engine version used by your DB instance. In addition to upgrading the DB engine version of your DB instance, you can also upgrade the engine version for your DB snapshots. For RDS for MySQL, you can upgrade a version 5.7 snapshot to version 8.0. You can upgrade encrypted or unencrypted DB snapshots.

The following versions support MySQL DB snapshot upgrade:

- You can upgrade from RDS for MySQL snapshot version 5.7.16 and higher 5.7 versions.
- You can upgrade to RDS for MySQL snapshot version 8.0.28 and higher, except for versions 8.0.29, 8.0.30, and 8.0.31.

You can't upgrade versions 5.7.40, 5.7.41, and 5.7.42 to version 8.0.28, but you can upgrade these versions to version 8.0.32 and higher.

After restoring a DB snapshot upgraded to a new engine version, make sure to test that the upgrade was successful. For more information about a major version upgrade, see the section called “Upgrading the MySQL DB engine”.

To learn how to restore a DB snapshot, see the section called “Restoring from a DB snapshot”.

Note

You can't upgrade automated DB snapshots that were created during the automated backup process.

You can upgrade a DB snapshot using the AWS Management Console, AWS CLI, or RDS API.

Console

To upgrade a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the snapshot that you want to upgrade.
4. For Actions, choose Upgrade snapshot. The Upgrade snapshot page appears.

5. Choose the New engine version to upgrade to.

6. Choose Save changes to upgrade the snapshot.

During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from Available to Upgrading, and then changes to Active upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to Unavailable. You can't recover the snapshot from this state.

Note

If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade a DB snapshot to a new database engine version, use the AWS CLI modify-db-snapshot command.

Options

- --db-snapshot-identifier – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Working with Amazon Resource Names (ARNs) in Amazon RDS.

- --engine-version – The engine version to upgrade the DB snapshot to.

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-snapshot \
  --db-snapshot-identifier my_db_snapshot \n  --engine-version new_version
```

For Windows:

```bash
aws rds modify-db-snapshot ^
```
RDS API

To upgrade a DB snapshot to a new database engine version, call the RDS API ModifyDBSnapshot operation.

Parameters

- **DBSnapshotIdentifier** – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see [Working with Amazon Resource Names (ARNs) in Amazon RDS](#).

- **EngineVersion** – The engine version to upgrade the DB snapshot to.
Importing data into a MySQL DB instance

You can use several different techniques to import data into an RDS for MySQL DB instance. The best approach depends on the source of the data, the amount of data, and whether the import is done one time or is ongoing. If you are migrating an application along with the data, also consider the amount of downtime that you are willing to experience.

Overview

Find techniques to import data into an RDS for MySQL DB instance in the following table.

<table>
<thead>
<tr>
<th>Source</th>
<th>Amount of data</th>
<th>One time or ongoing</th>
<th>Application downtime</th>
<th>Technique</th>
<th>More information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Existing MySQL database on premises or on Amazon EC2</td>
<td>Any</td>
<td>One time</td>
<td>Some</td>
<td>Create a backup of your on-premises database, store it on Amazon S3, and then restore the backup file to a new Amazon RDS DB instance running MySQL.</td>
<td><a href="#">Restoring a backup into a MySQL DB instance</a></td>
</tr>
<tr>
<td>Any existing database</td>
<td>Any</td>
<td>One time or ongoing</td>
<td>Minimal</td>
<td>Use AWS Database Migration Service to migrate the database with minimal downtime and, for many database DB engines, continue ongoing replication.</td>
<td><a href="#">What is AWS Database Migration Service</a> and <a href="#">Using a MySQL-compatible database as a target</a></td>
</tr>

<td>Configuring binary log file position replication with an external source instance Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime</td>
</tr>
</tbody>
</table>

**Note**

The 'mysql' system database contains authentication and authorization information required to log in to your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the 'mysql' database in your DB instance can result in error and might render the DB instance and your data inaccessible. If this occurs, you can restore the DB instance from a snapshot using the AWS CLI `restore-db-`
instance-from-db-snapshot command. You can recover the DB instance using the AWS CLI restore-db-instance-to-point-in-time command.

**Importing data considerations**

Following, you can find additional technical information related to loading data into MySQL. This information is intended for advanced users who are familiar with the MySQL server architecture. All comments related to LOAD DATA LOCAL INFILE also apply to mysqlimport.

**Binary log**

Data loads incur a performance penalty and require additional free disk space (up to four times more) when binary logging is enabled versus loading the same data with binary logging turned off. The severity of the performance penalty and the amount of free disk space required is directly proportional to the size of the transactions used to load the data.

**Transaction size**

Transaction size plays an important role in MySQL data loads. It has a major influence on resource consumption, disk space utilization, resume process, time to recover, and input format (flat files or SQL). This section describes how transaction size affects binary logging and makes the case for disabling binary logging during large data loads. As noted earlier, binary logging is enabled and disabled by setting the Amazon RDS automated backup retention period. Non-zero values enable binary logging, and zero disables it. We also describe the impact of large transactions on InnoDB and why it's important to keep transaction sizes small.

**Small transactions**

For small transactions, binary logging doubles the number of disk writes required to load the data. This effect can severely degrade performance for other database sessions and increase the time required to load the data. The degradation experienced depends in part upon the upload rate, other database activity taking place during the load, and the capacity of your Amazon RDS DB instance.

The binary logs also consume disk space roughly equal to the amount of data loaded until they are backed up and removed. Fortunately, Amazon RDS minimizes this by backing up and removing binary logs on a frequent basis.
**Large transactions**

Large transactions incur a 3X penalty for IOPS and disk consumption with binary logging enabled. This is due to the binary log cache spilling to disk, consuming disk space and incurring additional IO for each write. The cache cannot be written to the binlog until the transaction commits or rolls back, so it consumes disk space in proportion to the amount of data loaded. When the transaction commits, the cache must be copied to the binlog, creating a third copy of the data on disk.

Because of this, there must be at least three times as much free disk space available to load the data compared to loading with binary logging disabled. For example, 10 GiB of data loaded as a single transaction consumes at least 30 GiB disk space during the load. It consumes 10 GiB for the table + 10 GiB for the binary log cache + 10 GiB for the binary log itself. The cache file remains on disk until the session that created it terminates or the session fills its binary log cache again during another transaction. The binary log must remain on disk until backed up, so it might be some time before the extra 20 GiB is freed.

If the data was loaded using LOAD DATA LOCAL INFILE, yet another copy of the data is created if the database has to be recovered from a backup made before the load. During recovery, MySQL extracts the data from the binary log into a flat file. MySQL then runs LOAD DATA LOCAL INFILE, just as in the original transaction. However, this time the input file is local to the database server. Continuing with the example preceding, recovery fails unless there is at least 40 GiB free disk space available.

**Disable binary logging**

Whenever possible, disable binary logging during large data loads to avoid the resource overhead and addition disk space requirements. In Amazon RDS, disabling binary logging is as simple as setting the backup retention period to zero. If you do this, we recommend that you take a DB snapshot of the database instance immediately before the load. By doing this, you can quickly and easily undo changes made during loading if you need to.

After the load, set the backup retention period back to an appropriate (no zero) value.

You can't set the backup retention period to zero if the DB instance is a source DB instance for read replicas.

**InnoDB**

The information in this section provides a strong argument for keeping transaction sizes small when using InnoDB.
Undo

InnoDB generates undo to support features such as transaction rollback and MVCC. Undo is stored in the InnoDB system tablespace (usually ibdata1) and is retained until removed by the purge thread. The purge thread cannot advance beyond the undo of the oldest active transaction, so it is effectively blocked until the transaction commits or completes a rollback. If the database is processing other transactions during the load, their undo also accumulates in the system tablespace and cannot be removed even if they commit and no other transaction needs the undo for MVCC. In this situation, all transactions (including read-only transactions) that access any of the rows changed by any transaction (not just the load transaction) slow down. The slowdown occurs because transactions scan through undo that could have been purged if not for the long-running load transaction.

Undo is stored in the system tablespace, and the system tablespace never shrinks in size. Thus, large data load transactions can cause the system tablespace to become quite large, consuming disk space that you can't reclaim without recreating the database from scratch.

Rollback

InnoDB is optimized for commits. Rolling back a large transaction can take a very, very long time. In some cases, it might be faster to perform a point-in-time recovery or restore a DB snapshot.

Input data format

MySQL can accept incoming data in one of two forms: flat files and SQL. This section points out some key advantages and disadvantages of each.

Flat files

Loading flat files with LOAD DATA LOCAL INFILE can be the fastest and least costly method of loading data as long as transactions are kept relatively small. Compared to loading the same data with SQL, flat files usually require less network traffic, lowering transmission costs and load much faster due to the reduced overhead in the database.

One big transaction

LOAD DATA LOCAL INFILE loads the entire flat file as one transaction. This isn't necessarily a bad thing. If the size of the individual files can be kept small, this has a number of advantages:
• Resume capability – Keeping track of which files have been loaded is easy. If a problem arises during the load, you can pick up where you left off with little effort. Some data might have to be retransmitted to Amazon RDS, but with small files, the amount retransmitted is minimal.

• Load data in parallel – If you've got IOPS and network bandwidth to spare with a single file load, loading in parallel might save time.

• Throttle the load rate – Data load having a negative impact on other processes? Throttle the load by increasing the interval between files.

Be careful

The advantages of LOAD DATA LOCAL INFILE diminish rapidly as transaction size increases. If breaking up a large set of data into smaller ones isn't an option, SQL might be the better choice.

SQL

SQL has one main advantage over flat files: it's easy to keep transaction sizes small. However, SQL can take significantly longer to load than flat files and it can be difficult to determine where to resume the load after a failure. For example, mysqldump files are not restartable. If a failure occurs while loading a mysqldump file, the file requires modification or replacement before the load can resume. The alternative is to restore to the point in time before the load and replay the file after the cause of the failure has been corrected.

Take checkpoints using Amazon RDS snapshots

If you have a load that's going to take several hours or even days, loading without binary logging isn't a very attractive prospect unless you can take periodic checkpoints. This is where the Amazon RDS DB snapshot feature comes in very handy. A DB snapshot creates a point-in-time consistent copy of your database instance which can be used restore the database to that point in time after a crash or other mishap.

To create a checkpoint, simply take a DB snapshot. Any previous DB snapshots taken for checkpoints can be removed without affecting durability or restore time.

Snapshots are fast too, so frequent checkpointing doesn't add significantly to load time.

Decreasing load time

Here are some additional tips to reduce load times:
• Create all secondary indexes before loading. This is counter-intuitive for those familiar with other databases. Adding or modifying a secondary index causes MySQL to create a new table with the index changes, copy the data from the existing table to the new table, and drop the original table.

• Load data in PK order. This is particularly helpful for InnoDB tables, where load times can be reduced by 75–80 percent and data file size cut in half.

• Disable foreign key constraints foreign_key_checks=0. For flat files loaded with LOAD DATA LOCAL INFILE, this is required in many cases. For any load, disabling FK checks provides significant performance gains. Just be sure to enable the constraints and verify the data after the load.

• Load in parallel unless already near a resource limit. Use partitioned tables when appropriate.

• Use multi-value inserts when loading with SQL to minimize overhead when running statements. When using mysqldump, this is done automatically.

• Reduce InnoDB log IO innodb_flush_log_at_trx_commit=0

• If you are loading data into a DB instance that does not have read replicas, set the sync_binlog parameter to 0 while loading data. When data loading is complete, set the sync_binlog parameter to back to 1.

• Load data before converting the DB instance to a Multi-AZ deployment. However, if the DB instance already uses a Multi-AZ deployment, switching to a Single-AZ deployment for data loading is not recommended, because doing so only provides marginal improvements.

Note
Using innodb_flush_log_at_trx_commit=0 causes InnoDB to flush its logs every second instead of at each commit. This provides a significant speed advantage, but can lead to data loss during a crash. Use with caution.

Topics
• Restoring a backup into a MySQL DB instance
• Importing data from an external MariaDB or MySQL database to an RDS for MariaDB or RDS for MySQL DB instance
• Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime
• Importing data from any source to a MariaDB or MySQL DB instance
Restoring a backup into a MySQL DB instance

Amazon RDS supports importing MySQL databases by using backup files. You can create a backup of your database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL.

The scenario described in this section restores a backup of an on-premises database. You can use this technique for databases in other locations, such as Amazon EC2 or non-AWS cloud services, as long as the database is accessible.

You can find the supported scenario in the following diagram.

```
<table>
<thead>
<tr>
<th>Corporate data center</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL database</td>
</tr>
</tbody>
</table>

AWS Cloud

Database backup

Amazon S3 bucket

MySQL DB instance
```

Importing backup files from Amazon S3 is supported for MySQL in all AWS Regions.

We recommend that you import your database to Amazon RDS by using backup files if your on-premises database can be offline while the backup file is created, copied, and restored. If your database can’t be offline, you can use binary log (binlog) replication to update your database after you have migrated to Amazon RDS through Amazon S3 as explained in this topic. For more information, see Configuring binary log file position replication with an external source instance. You can also use the AWS Database Migration Service to migrate your database to Amazon RDS. For more information, see What is AWS Database Migration Service?

Limitations and recommendations for importing backup files from Amazon S3 to Amazon RDS

The following are some limitations and recommendations for importing backup files from Amazon S3:
• You can only import your data to a new DB instance, not an existing DB instance.
• You must use Percona XtraBackup to create the backup of your on-premises database.
• You can't import data from a DB snapshot export to Amazon S3.
• You can't migrate from a source database that has tables defined outside of the default MySQL data directory.
• You must import your data to the default minor version of your MySQL major version in your AWS Region. For example, if your major version is MySQL 8.0, and the default minor version for your AWS Region is 8.0.28, then you must import your data into a MySQL version 8.0.28 DB instance. You can upgrade your DB instance after importing. For information about determining the default minor version, see MySQL on Amazon RDS versions.
• Backward migration is not supported for both major versions and minor versions. For example, you can't migrate from version 8.0 to version 5.7, and you can't migrate from version 8.0.32 to version 8.0.31.
• You can't import a MySQL 5.5 or 5.6 database.
• You can't import an on-premises MySQL database from one major version to another. For example, you can't import a MySQL 5.7 database to an RDS for MySQL 8.0 database. You can upgrade your DB instance after you complete the import.
• You can't restore from an encrypted source database, but you can restore to an encrypted Amazon RDS DB instance.
• You can't restore from an encrypted backup in the Amazon S3 bucket.
• You can't restore from an Amazon S3 bucket in a different AWS Region than your Amazon RDS DB instance.
• Importing from Amazon S3 is not supported on the db.t2.micro DB instance class. However, you can restore to a different DB instance class, and change the DB instance class later. For more information about instance classes, see Hardware specifications for DB instance classes.
• Amazon S3 limits the size of a file uploaded to an Amazon S3 bucket to 5 TB. If a backup file exceeds 5 TB, then you must split the backup file into smaller files.
• When you restore the database, the backup is copied and then extracted on your DB instance. Therefore, provision storage space for your DB instance that is equal to or greater than the sum of the backup size, plus the original database's size on disk.
• Amazon RDS limits the number of files uploaded to an Amazon S3 bucket to 1 million. If the backup data for your database, including all full and incremental backups, exceeds 1 million files, use a Gzip (.gz), tar (.tar.gz), or Percona xbstream (.xbstream) file to store full and incremental
backup files in the Amazon S3 bucket. Percona XtraBackup 8.0 only supports Percona xbstream for compression.

- User accounts are not imported automatically. Save your user accounts from your source database and add them to your new DB instance later.
- Functions are not imported automatically. Save your functions from your source database and add them to your new DB instance later.
- Stored procedures are not imported automatically. Save your stored procedures from your source database and add them to your new DB instance later.
- Time zone information is not imported automatically. Record the time zone information for your source database, and set the time zone of your new DB instance later. For more information, see Local time zone for MySQL DB instances.
- The `innodb_data_file_path` parameter must be configured with only one data file that uses the default data file name "ibdata1:12M:autoextend". Databases with two data files, or with a data file with a different name, can't be migrated using this method.

The following are examples of file names that are not allowed:

```
"innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend" and
"innodb_data_file_path=ibdata01:50M:autoextend".
```

- The maximum size of the restored database is the maximum database size supported minus the size of the backup. So, if the maximum database size supported is 64 TiB, and the size of the backup is 30 TiB, then the maximum size of the restored database is 34 TiB, as in the following example:

```
64 TiB - 30 TiB = 34 TiB
```

For information about the maximum database size supported by Amazon RDS for MySQL, see General Purpose SSD storage and Provisioned IOPS SSD storage.

### Overview of setting up to import backup files from Amazon S3 to Amazon RDS

These are the components you need to set up to import backup files from Amazon S3 to Amazon RDS:

- An Amazon S3 bucket to store your backup files.
- A backup of your on-premises database created by Percona XtraBackup.
- An AWS Identity and Access Management (IAM) role to allow Amazon RDS to access the bucket.
If you already have an Amazon S3 bucket, you can use that. If you don't have an Amazon S3 bucket, you can create a new one. If you want to create a new bucket, see "Creating a bucket."

Use the Percona XtraBackup tool to create your backup. For more information, see "Creating your database backup."

If you already have an IAM role, you can use that. If you don't have an IAM role, you can create a new one manually. Alternatively, you can choose to have a new IAM role created for you in your account by the wizard when you restore the database by using the AWS Management Console. If you want to create a new IAM role manually, or attach trust and permissions policies to an existing IAM role, see "Creating an IAM role manually. If you want to have a new IAM role created for you, follow the procedure in "Console."

Creating your database backup

Use the Percona XtraBackup software to create your backup. We recommend that you use the latest version of Percona XtraBackup. You can install Percona XtraBackup from "Download Percona XtraBackup."

⚠️ Warning
When creating a database backup, XtraBackup might save credentials in the xtrabackup_info file. Make sure you examine that file so that the tool_command setting in it doesn't contain any sensitive information.

📝 Note
For MySQL 8.0 migration, you must use Percona XtraBackup 8.0. Percona XtraBackup 8.0.12 and higher versions support migration of all versions of MySQL. If you are migrating to RDS for MySQL 8.0.20 or higher, you must use Percona XtraBackup 8.0.12 or higher.
For MySQL 5.7 migrations, you can also use Percona XtraBackup 2.4. For migrations of earlier MySQL versions, you can also use Percona XtraBackup 2.3 or 2.4.

You can create a full backup of your MySQL database files using Percona XtraBackup. Alternatively, if you already use Percona XtraBackup to back up your MySQL database files, you can upload your existing full and incremental backup directories and files.
For more information about backing up your database with Percona XtraBackup, see Percona XtraBackup - documentation and The xtrabackup binary on the Percona website.

Creating a full backup with Percona XtraBackup

To create a full backup of your MySQL database files that can be restored from Amazon S3, use the Percona XtraBackup utility (xtrabackup) to back up your database.

For example, the following command creates a backup of a MySQL database and stores the files in the folder /on-premises/s3-restore/backup folder.

```bash
xtrabackup --backup --user=<myuser> --password=<password> --target-dir=/on-premises/s3-restore/backup
```

If you want to compress your backup into a single file (which can be split later, if needed), you can save your backup in one of the following formats:

- Gzip (.gz)
- tar (.tar)
- Percona xbstream (.xbstream)

Note

Percona XtraBackup 8.0 only supports Percona xbstream for compression.

The following command creates a backup of your MySQL database split into multiple Gzip files.

```bash
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar --target-dir=/on-premises/s3-restore/backup | gzip - | split -d --bytes=500MB - /on-premises/s3-restore/backup/backup.tar.gz
```

The following command creates a backup of your MySQL database split into multiple tar files.

```bash
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar --target-dir=/on-premises/s3-restore/backup | split -d --bytes=500MB - /on-premises/s3-restore/backup/backup.tar
```
The following command creates a backup of your MySQL database split into multiple xbstream files.

```bash
xtrabackup --backup --user=<myuser> --password=<password> --stream=xbstream \
    --target-dir=/on-premises/s3-restore/backup | split -d --bytes=500MB \
    - /on-premises/s3-restore/backup/backup.xbstream
```

**Note**

If you see the following error, it might be caused by mixing file formats in your command:

```
ERROR:/bin/tar: This does not look like a tar archive
```

**Using incremental backups with Percona XtraBackup**

If you already use Percona XtraBackup to perform full and incremental backups of your MySQL database files, you don't need to create a full backup and upload the backup files to Amazon S3. Instead, you can save a significant amount of time by copying your existing backup directories and files to your Amazon S3 bucket. For more information about creating incremental backups using Percona XtraBackup, see [Incremental backup](#).

When copying your existing full and incremental backup files to an Amazon S3 bucket, you must recursively copy the contents of the base directory. Those contents include the full backup and also all incremental backup directories and files. This copy must preserve the directory structure in the Amazon S3 bucket. Amazon RDS iterates through all files and directories. Amazon RDS uses the `xtrabackup-checkpoints` file that is included with each incremental backup to identify the base directory, and to order incremental backups by log sequence number (LSN) range.

**Backup considerations for Percona XtraBackup**

Amazon RDS consumes your backup files based on the file name. Name your backup files with the appropriate file extension based on the file format—for example, `.xbstream` for files stored using the Percona xbstream format.

Amazon RDS consumes your backup files in alphabetical order and also in natural number order. Use the `split` option when you issue the `xtrabackup` command to ensure that your backup files are written and named in the proper order.
Amazon RDS doesn't support partial backups created using Percona XtraBackup. You can't use the following options to create a partial backup when you back up the source files for your database: --tables, --tables-exclude, --tables-file, --databases, --databases-exclude, or --databases-file.

Amazon RDS supports incremental backups created using Percona XtraBackup. For more information about creating incremental backups using Percona XtraBackup, see Incremental backup.

Creating an IAM role manually

If you don't have an IAM role, you can create a new one manually. Alternatively, you can choose to have a new IAM role created for you by the wizard when you restore the database by using the AWS Management Console. If you want to have a new IAM role created for you, follow the procedure in Console.

To manually create a new IAM role for importing your database from Amazon S3, create a role to delegate permissions from Amazon RDS to your Amazon S3 bucket. When you create an IAM role, you attach trust and permissions policies. To import your backup files from Amazon S3, use trust and permissions policies similar to the examples following. For more information about creating the role, see Creating a role to delegate permissions to an AWS service.

Alternatively, you can choose to have a new IAM role created for you by the wizard when you restore the database by using the AWS Management Console. If you want to have a new IAM role created for you, follow the procedure in Console.

The trust and permissions policies require that you provide an Amazon Resource Name (ARN). For more information about ARN formatting, see Amazon Resource Names (ARNs) and AWS service namespaces.

Example Trust policy for importing from Amazon S3

```json
{
    "Version": "2012-10-17",
    "Statement":
    [
    {
        "Effect": "Allow",
        "Principal": {"Service": "rds.amazonaws.com"},
        "Action": "sts:AssumeRole"
    ]
}
```
Example Permissions policy for importing from Amazon S3 — IAM user permissions

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowS3AccessRole",
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws:iam::IAM User ID:role/S3Access"
        }
    ]
}
```

Example Permissions policy for importing from Amazon S3 — role permissions

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:GetBucketLocation"
            ],
            "Resource": "arn:aws:s3:::bucket_name"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": "arn:aws:s3:::bucket_name/prefix*"
        }
    ]
}
```
Note

If you include a file name prefix, include the asterisk (*) after the prefix. If you don't want to specify a prefix, specify only an asterisk.

Importing data from Amazon S3 to a new MySQL DB instance

You can import data from Amazon S3 to a new MySQL DB instance using the AWS Management Console, AWS CLI, or RDS API.

Console

To import data from Amazon S3 to a new MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the top right corner of the Amazon RDS console, choose the AWS Region in which to create your DB instance. Choose the same AWS Region as the Amazon S3 bucket that contains your database backup.
3. In the navigation pane, choose Databases.
4. Choose Restore from S3.

The Create database by restoring from S3 page appears.
5. **Under S3 destination:**

   a. Choose the **S3 bucket** that contains the backup.
b. (Optional) For **S3 folder path prefix**, enter a file path prefix for the files stored in your Amazon S3 bucket.

If you don't specify a prefix, then RDS creates your DB instance using all of the files and folders in the root folder of the S3 bucket. If you do specify a prefix, then RDS creates your DB instance using the files and folders in the S3 bucket where the path for the file begins with the specified prefix.

For example, suppose that you store your backup files on S3 in a subfolder named backups, and you have multiple sets of backup files, each in its own directory (gzip_backup1, gzip_backup2, and so on). In this case, you specify a prefix of backups/ gzip_backup1 to restore from the files in the gzip_backup1 folder.

6. Under **Engine options**:

   a. For **Engine type**, choose **MySQL**.

   b. For **Source engine version**, choose the MySQL major version of your source database.

   c. For **Version**, choose the default minor version of your MySQL major version in your AWS Region.

   In the AWS Management Console, only the default minor version is available. You can upgrade your DB instance after importing.

7. For **IAM role**, you can choose an existing IAM role.

8. (Optional) You can also have a new IAM role created for you by choosing **Create a new role** and entering the **IAM role name**.

9. Specify your DB instance information. For information about each setting, see [Settings for DB instances](#).

   **Note**

   Be sure to allocate enough memory for your new DB instance so that the restore operation can succeed.

   You can also choose **Enable storage autoscaling** to allow for future growth automatically.

10. Choose additional settings as needed.

11. Choose **Create database**.
AWS CLI

To import data from Amazon S3 to a new MySQL DB instance by using the AWS CLI, call the `restore-db-instance-from-s3` command with the following parameters. For information about each setting, see the Settings for DB instances.

**Note**
Be sure to allocate enough memory for your new DB instance so that the restore operation can succeed.
You can also use the `--max-allocated-storage` parameter to enable storage autoscaling and allow for future growth automatically.

- `--allocated-storage`
- `--db-instance-identifier`
- `--db-instance-class`
- `--engine`
- `--master-username`
- `--manage-master-user-password`
- `--s3-bucket-name`
- `--s3-ingestion-role-arn`
- `--s3-prefix`
- `--source-engine`
- `--source-engine-version`

**Example**

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-s3 \
   --allocated-storage 250 \
   --db-instance-identifier myidentifier \
   --db-instance-class db.m5.large \
   --engine mysql \
   --master-username admin \
   --manage-master-user-password
```
---s3-bucket-name mybucket \
---s3-ingestion-role-arn arn:aws:iam::account-number:role/rolename \
---s3-prefix bucketprefix \
---source-engine mysql \
---source-engine-version 8.0.32 \
---max-allocated-storage 1000

For Windows:

aws rds restore-db-instance-from-s3 ^
  --allocated-storage 250 ^
  --db-instance-identifier myidentifier ^
  --db-instance-class db.m5.large ^
  --engine mysql ^
  --master-username admin ^
  --manage-master-user-password ^
  --s3-bucket-name mybucket ^
  --s3-ingestion-role-arn arn:aws:iam::account-number:role/rolename ^
  --s3-prefix bucketprefix ^
  --source-engine mysql ^
  --source-engine-version 8.0.32 ^
  --max-allocated-storage 1000

RDS API

To import data from Amazon S3 to a new MySQL DB instance by using the Amazon RDS API, call the RestoreDBInstanceFromS3 operation.

Importing data from an external MariaDB or MySQL database to an RDS for MariaDB or RDS for MySQL DB instance

You can also import data from an existing MariaDB or MySQL database to a MySQL or MariaDB DB instance. You do so by copying the database with mysql dump and piping it directly into the MariaDB or MySQL DB instance. The mysql dump command line utility is commonly used to make backups and transfer data from one MariaDB or MySQL server to another. It's included with MySQL and MariaDB client software.

Note

If you are importing or exporting large amounts of data with a MySQL DB instance, it's more reliable and faster to move data in and out of Amazon RDS by using xtrabackup.
backup files and Amazon S3. For more information, see [Restoring a backup into a MySQL DB instance](#).

A typical `mysqldump` command to move data from an external database to an Amazon RDS DB instance looks similar to the following.

```bash
mysqldump -u local_user \
   --databases database_name \
   --single-transaction \
   --compress \
   --order-by-primary \ 
   -p local_password | mysql -u RDS_user \
      --port=port_number \
      --host=host_name \
   -pRDS_password
```

**Important**

Make sure not to leave a space between the `-p` option and the entered password. Specify credentials other than the prompts shown here as a security best practice.

Make sure that you're aware of the following recommendations and considerations:

- Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The `mysqldump` utility excludes these schemas by default.  
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the `pt-show-grants` utility.  
- To perform the import, make sure the user doing so has access to the DB instance. For more information, see [Controlling access with security groups](#).

The parameters used are as follows:

- `-u local_user` – Use to specify a user name. In the first usage of this parameter, you specify the name of a user account on the local MariaDB or MySQL database identified by the `--databases` parameter.
• **--databases database_name** – Use to specify the name of the database on the local MariaDB or MySQL instance that you want to import into Amazon RDS.

• **--single-transaction** – Use to ensure that all of the data loaded from the local database is consistent with a single point in time. If there are other processes changing the data while mysqldump is reading it, using this parameter helps maintain data integrity.

• **--compress** – Use to reduce network bandwidth consumption by compressing the data from the local database before sending it to Amazon RDS.

• **--order-by-primary** – Use to reduce load time by sorting each table’s data by its primary key.

• **-p local_password** – Use to specify a password. In the first usage of this parameter, you specify the password for the user account identified by the first -u parameter.

• **-u RDS_user** – Use to specify a user name. In the second usage of this parameter, you specify the name of a user account on the default database for the MariaDB or MySQL DB instance identified by the --host parameter.

• **-p port_number** – Use to specify the port for your MariaDB or MySQL DB instance. By default, this is 3306 unless you changed the value when creating the instance.

• **--host host_name** – Use to specify the Domain Name System (DNS) name from the Amazon RDS DB instance endpoint, for example, myinstance.123456789012.us-east-1.rds.amazonaws.com. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

• **-p RDS_password** – Use to specify a password. In the second usage of this parameter, you specify the password for the user account identified by the second -u parameter.

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when you run mysqldump. To do so, include the following parameters with your mysqldump command: **--routines=0 --triggers=0 --events=0**.

The following example copies the world sample database on the local host to a MySQL DB instance.

For Linux, macOS, or Unix:

```
sudo mysqldump -u localuser \
  --databases world \
  --single-transaction \
  --compress \
```

Importing data from an external database
--order-by-primary \
--routines=0 \
--triggers=0 \
--events=0 \
-"localpassword" | mysql -u rdsuser \
   --port=3306 \
   --host=myinstance.123456789012.us-east-1.rds.amazonaws.com \
   -"rdspassword"

For Windows, run the following command in a command prompt that has been opened by right-clicking **Command Prompt** on the Windows programs menu and choosing **Run as administrator**:

```bash
mysqldump -u localuser ^
   --databases world ^
   --single-transaction ^
   --compress ^
   --order-by-primary ^
   --routines=0 ^
   --triggers=0 ^
   --events=0 ^
   -"localpassword" | mysql -u rdsuser ^
      --port=3306 ^
      --host=myinstance.123456789012.us-east-1.rds.amazonaws.com ^
      -"rdspassword"
```

**Note**
Specify credentials other than the prompts shown here as a security best practice.

### Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime

In some cases, you might need to import data from an external MariaDB or MySQL database that supports a live application to a MariaDB DB instance, a MySQL DB instance, or a MySQL Multi-AZ DB cluster. Use the following procedure to minimize the impact on availability of applications. This procedure can also help if you are working with a very large database. Using this procedure, you can reduce the cost of the import by reducing the amount of data that is passed across the network to AWS.
In this procedure, you transfer a copy of your database data to an Amazon EC2 instance and import the data into a new Amazon RDS database. You then use replication to bring the Amazon RDS database up-to-date with your live external instance, before redirecting your application to the Amazon RDS database. Configure MariaDB replication based on global transaction identifiers (GTIDs) if the external instance is MariaDB 10.0.24 or higher and the target instance is RDS for MariaDB. Otherwise, configure replication based on binary log coordinates. We recommend GTID-based replication if your external database supports it because GTID-based replication is a more reliable method. For more information, see [Global transaction ID](#) in the MariaDB documentation.

**Note**

If you want to import data into a MySQL DB instance and your scenario supports it, we recommend moving data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see [Restoring a backup into a MySQL DB instance](#).

**Note**

We don’t recommend that you use this procedure with source MySQL databases from MySQL versions earlier than version 5.5 because of potential replication issues. For
Create a copy of your existing database

The first step in the process of migrating a large amount of data to an RDS for MariaDB or RDS for MySQL database with minimal downtime is to create a copy of the source data.

You can use the mysqldump utility to create a database backup in either SQL or delimited-text format. We recommend that you do a test run with each format in a non-production environment to see which method minimizes the amount of time that mysqldump runs.

We also recommend that you weigh mysqldump performance against the benefit offered by using the delimited-text format for loading. A backup using delimited-text format creates a tab-separated text file for each table being dumped. To reduce the amount of time required to import your database, you can load these files in parallel using the LOAD DATA LOCAL INFILE command. For more information about choosing a mysqldump format and then loading the data, see Using mysqldump for backups in the MySQL documentation.

Before you start the backup operation, make sure to set the replication options on the MariaDB or MySQL database that you are copying to Amazon RDS. The replication options include turning...
on binary logging and setting a unique server ID. Setting these options causes your server to start logging database transactions and prepares it to be a source replication instance later in this process.

Note

Use the --single-transaction option with mysqldump because it dumps a consistent state of the database. To ensure a valid dump file, don't run data definition language (DDL) statements while mysqldump is running. You can schedule a maintenance window for these operations.

Exclude the following schemas from the dump file: sys, performance_schema, and information_schema. The mysqldump utility excludes these schemas by default.

To migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the pt-show-grants utility.

To set replication options

1. Edit the my.cnf file (this file is usually under /etc).

```
sudo vi /etc/my.cnf
```

Add the log_bin and server_id options to the [mysqld] section. The log_bin option provides a file name identifier for binary log files. The server_id option provides a unique identifier for the server in source-replica relationships.

The following example shows the updated [mysqld] section of a my.cnf file.

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

For more information, see the MySQL documentation.

2. For replication with a Multi-AZ DB cluster, set the ENFORCE_GTID_CONSISTENCY and the GTID_MODE parameter to ON.

```
mysql> SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = ON;
```
mysql> SET @@GLOBAL.GTID_MODE = ON;

These settings aren't required for replication with a DB instance.

3. Restart the mysql service.

    sudo service mysqld restart

To create a backup copy of your existing database

1. Create a backup of your data using the mysqldump utility, specifying either SQL or delimited-text format.

    Specify --master-data=2 to create a backup file that can be used to start replication between servers. For more information, see the _mysqldump_ documentation.

    To improve performance and ensure data integrity, use the --order-by-primary and --single-transaction options of mysqldump.

    To avoid including the MySQL system database in the backup, do not use the --all-databases option with mysqldump. For more information, see _Creating a data snapshot using mysqldump_ in the MySQL documentation.

    Use chmod if necessary to make sure that the directory where the backup file is being created is writeable.

    **Important**

    On Windows, run the command window as an administrator.

    - To produce SQL output, use the following command.

        For Linux, macOS, or Unix:

        ```
        sudo mysqldump \
        --databases database_name \
        --master-data=2 \
        --single-transaction \
        ```
my sqldump ^
   --databases database_name ^
   --master-data=2 ^
   --single-transaction ^
   --order-by-primary ^
   -r backup.sql ^
   -u local_user ^
   -p password

Note
Specify credentials other than the prompts shown here as a security best practice.

For Windows:

my sqldump ^
   --databases database_name ^
   --master-data=2 ^
   --single-transaction ^
   --order-by-primary ^
   -r backup.sql ^
   -u local_user ^
   -p password

Note
Specify credentials other than the prompts shown here as a security best practice.

To produce delimited-text output, use the following command.

For Linux, macOS, or Unix:

sudo my sqldump ^
   --tab=target_directory ^
   --fields-terminated-by ',' ^
   --fields-enclosed-by '' ^
   --lines-terminated-by 0x0d0a ^
   database_name ^
   --master-data=2 ^
   --single-transaction ^
   --order-by-primary ^
   -p password
For Windows:

mysqldump ^
   --tab=target_directory ^
   --fields-terminated-by "," ^
   --fields-enclosed-by """" ^
   --lines-terminated-by 0x0d0a ^
   database_name ^
   --master-data=2 ^
   --single-transaction ^
   --order-by-primary ^
   -p password

**Note**

Specify credentials other than the prompts shown here as a security best practice. Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, exclude them when you run mysqldump. To do so, include the following arguments with your mysqldump command: --routines=0 --triggers=0 --events=0.

When using the delimited-text format, a CHANGE MASTER TO comment is returned when you run mysqldump. This comment contains the master log file name and position. If the external instance is other than MariaDB version 10.0.24 or higher, note the values for MASTER_LOG_FILE and MASTER_LOG_POS. You need these values when setting up replication.

-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031',
MASTER_LOG_POS=107;

If you are using SQL format, you can get the master log file name and position in the CHANGE MASTER TO comment in the backup file. If the external instance is MariaDB version 10.0.24 or higher, you can get the GTID in the next step.
2. If the external instance you are using is MariaDB version 10.0.24 or higher, you use GTID-based replication. Run `SHOW MASTER STATUS` on the external MariaDB instance to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance.

```sql
SELECT BINLOG_GTID_POS('binary log file name', binary log file position);
```

Note the GTID returned; you need it to configure replication.

3. Compress the copied data to reduce the amount of network resources needed to copy your data to the Amazon RDS database. Note the size of the backup file. You need this information when determining how large an Amazon EC2 instance to create. When you are done, compress the backup file using GZIP or your preferred compression utility.

- To compress SQL output, use the following command.

```bash
gzip backup.sql
```

- To compress delimited-text output, use the following command.

```bash
tar -zcvf backup.tar.gz target_directory
```

**Create an Amazon EC2 instance and copy the compressed database**

Copying your compressed database backup file to an Amazon EC2 instance takes fewer network resources than doing a direct copy of uncompressed data between database instances. After your data is in Amazon EC2, you can copy it from there directly to your MariaDB or MySQL database. For you to save on the cost of network resources, your Amazon EC2 instance must be in the same AWS Region as your Amazon RDS DB instance. Having the Amazon EC2 instance in the same AWS Region as your Amazon RDS database also reduces network latency during the import.
To create an Amazon EC2 instance and copy your data

1. In the AWS Region where you plan to create the RDS database, create a virtual private cloud (VPC), a VPC security group, and a VPC subnet. Ensure that the inbound rules for your VPC security group allow the IP addresses required for your application to connect to AWS. You can specify a range of IP addresses (for example, 203.0.113.0/24), or another VPC security group. You can use the Amazon VPC Management Console to create and manage VPCs, subnets, and security groups. For more information, see Getting started with Amazon VPC in the Amazon Virtual Private Cloud Getting Started Guide.

2. Open the Amazon EC2 Management Console and choose the AWS Region to contain both your Amazon EC2 instance and your Amazon RDS database. Launch an Amazon EC2 instance using the VPC, subnet, and security group that you created in Step 1. Ensure that you select an instance type with enough storage for your database backup file when it is uncompressed. For details on Amazon EC2 instances, see Getting started with Amazon EC2 Linux instances in the Amazon Elastic Compute Cloud User Guide for Linux.

3. To connect to your Amazon RDS database from your Amazon EC2 instance, edit your VPC security group. Add an inbound rule specifying the private IP address of your EC2 instance. You can find the private IP address on the Details tab of the Instance pane in the EC2 console window. To edit the VPC security group and add an inbound rule, choose Security Groups in the EC2 console navigation pane, choose your security group, and then add an inbound rule for
MySQL or Aurora specifying the private IP address of your EC2 instance. To learn how to add an inbound rule to a VPC security group, see Adding and removing rules in the Amazon VPC User Guide.

4. Copy your compressed database backup file from your local system to your Amazon EC2 instance. Use chmod if necessary to make sure that you have write permission for the target directory of the Amazon EC2 instance. You can use scp or a Secure Shell (SSH) client to copy the file. The following is an example.

```bash
$ scp -r -i key_pair.pem backup.sql.gz ec2-user@EC2 DNS:/target_directory/
backup.sql.gz
```

⚠️ Important

Be sure to copy sensitive data using a secure network transfer protocol.

5. Connect to your Amazon EC2 instance and install the latest updates and the MySQL client tools using the following commands.

```
sudo yum update -y
sudo yum install mysql -y
```

For more information, see Connect to your instance in the Amazon Elastic Compute Cloud User Guide for Linux.

⚠️ Important

This example installs the MySQL client on an Amazon Machine Image (AMI) for an Amazon Linux distribution. To install the MySQL client on a different distribution, such as Ubuntu or Red Hat Enterprise Linux, this example doesn't work. For information about installing MySQL, see Installing and Upgrading MySQL in the MySQL documentation.

6. While connected to your Amazon EC2 instance, decompress your database backup file. The following are examples.

- To decompress SQL output, use the following command.

  ```
gzip backup.sql.gz -d
  ```

- To decompress delimited-text output, use the following command.
Create a MySQL or MariaDB database and import data from your Amazon EC2 instance

By creating a MariaDB DB instance, a MySQL DB instance, or a MySQL Multi-AZ DB cluster in the same AWS Region as your Amazon EC2 instance, you can import the database backup file from EC2 faster than over the internet.

To create a MariaDB or MySQL database and import your data

1. Determine which DB instance class and what amount of storage space is required to support the expected workload for this Amazon RDS database. As part of this process, decide what is sufficient space and processing capacity for your data load procedures. Also decide what is required to handle the production workload. You can estimate this based on the size and resources of the source MariaDB or MySQL database. For more information, see DB instance classes.

2. Create a DB instance or Multi-AZ DB cluster in the AWS Region that contains your Amazon EC2 instance.
To create a MySQL Multi-AZ DB cluster, follow the instructions in Creating a Multi-AZ DB cluster.

To create a MariaDB or MySQL DB instance, follow the instructions in Creating an Amazon RDS DB instance and use the following guidelines:

- Specify a DB engine version that is compatible with your source DB instance, as follows:
  - If your source instance is MySQL 5.5.x, the Amazon RDS DB instance must be MySQL.
  - If your source instance is MySQL 5.6.x or 5.7.x, the Amazon RDS DB instance must be MySQL or MariaDB.
  - If your source instance is MySQL 8.0.x, the Amazon RDS DB instance must be MySQL 8.0.x.
  - If your source instance is MariaDB 5.5 or higher, the Amazon RDS DB instance must be MariaDB.
- Specify the same virtual private cloud (VPC) and VPC security group as for your Amazon EC2 instance. This approach ensures that your Amazon EC2 instance and your Amazon RDS instance are visible to each other over the network. Make sure your DB instance is publicly accessible. To set up replication with your source database as described later, your DB instance must be publicly accessible.
- Don't configure multiple Availability Zones, backup retention, or read replicas until after you have imported the database backup. When that import is completed, you can configure Multi-AZ and backup retention for the production instance.

3. Review the default configuration options for the Amazon RDS database. If the default parameter group for the database doesn't have the configuration options that you want, find a different one that does or create a new parameter group. For more information on creating a parameter group, see Working with parameter groups.

4. Connect to the new Amazon RDS database as the master user. Create the users required to support the administrators, applications, and services that need to access the instance. The hostname for the Amazon RDS database is the Endpoint value for this instance without including the port number. An example is mysamp1eddb.123456789012.us-west-2.rds.amazonaws.com. You can find the endpoint value in the database details in the Amazon RDS Management Console.

5. Connect to your Amazon EC2 instance. For more information, see Connect to your instance in the Amazon Elastic Compute Cloud User Guide for Linux.
6. Connect to your Amazon RDS database as a remote host from your Amazon EC2 instance using the `mysql` command. The following is an example.

   ```
   mysql -h host_name -P 3306 -u db_master_user -p
   ```

   The hostname is the Amazon RDS database endpoint.

7. At the `mysql` prompt, run the `source` command and pass it the name of your database dump file to load the data into the Amazon RDS DB instance:

   - For SQL format, use the following command.
     ```
     mysql> source backup.sql;
     ```

   - For delimited-text format, first create the database, if it isn't the default database you created when setting up the Amazon RDS database.
     ```
     mysql> create database database_name;
     $ mysql> use database_name;
     ```

     Then create the tables.

     ```
     mysql> source table1.sql
     $ mysql> source table2.sql
     etc...
     ```

     Then import the data.

     ```
     mysql> LOAD DATA LOCAL INFILE 'table1.txt' INTO TABLE table1 FIELDS TERMINATED BY ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
     $ mysql> LOAD DATA LOCAL INFILE 'table2.txt' INTO TABLE table2 FIELDS TERMINATED BY ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
     etc...
     ```

   To improve performance, you can perform these operations in parallel from multiple connections so that all of your tables are created and then loaded at the same time.
Note

If you used any data-formatting options with mysqldump when you initially dumped the table, make sure to use the same options with mysqlimport or LOAD DATA LOCAL INFILE to ensure proper interpretation of the data file contents.

8. Run a simple SELECT query against one or two of the tables in the imported database to verify that the import was successful.

If you no longer need the Amazon EC2 instance used in this procedure, terminate the EC2 instance to reduce your AWS resource usage. To terminate an EC2 instance, see Terminating an instance in the Amazon EC2 User Guide.

Replicate between your external database and new Amazon RDS database

Your source database was likely updated during the time that it took to copy and transfer the data to the MariaDB or MySQL database. Thus, you can use replication to bring the copied database up-to-date with the source database.

The permissions required to start replication on an Amazon RDS database are restricted and not available to your Amazon RDS master user. Because of this, make sure to use either the
Amazon RDS mysql.rds_set_external_master command or the mysql.rds_set_external_master_gtid command to configure replication, and the mysql.rds_start_replication command to start replication between your live database and your Amazon RDS database.

To start replication

Earlier, you turned on binary logging and set a unique server ID for your source database. Now you can set up your Amazon RDS database as a replica with your live database as the source replication instance.

1. In the Amazon RDS Management Console, add the IP address of the server that hosts the source database to the VPC security group for the Amazon RDS database. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

   You might also need to configure your local network to permit connections from the IP address of your Amazon RDS database, so that it can communicate with your source instance. To find the IP address of the Amazon RDS database, use the host command.

   host  rds_db_endpoint

   The hostname is the DNS name from the Amazon RDS database endpoint, for example myinstance.123456789012.us-east-1.rds.amazonaws.com. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

2. Using the client of your choice, connect to the source instance and create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

   **MySQL 5.5, 5.6, and 5.7**

   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';

   **MySQL 8.0**

   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
3. For the source instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain, issue the following command.

**MySQL 5.5, 5.6, and 5.7**

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY 'password';
```

**MySQL 8.0**

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

4. If you used SQL format to create your backup file and the external instance is not MariaDB 10.0.24 or higher, look at the contents of that file.

```
cat backup.sql
```

The file includes a `CHANGE MASTER TO` comment that contains the master log file name and position. This comment is included in the backup file when you use the `--master-data` option with `mysqldump`. Note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`.

```
--
-- Position to start replication or point-in-time recovery from
--

-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```
If you used delimited text format to create your backup file and the external instance isn't MariaDB 10.0.24 or higher, you should already have binary log coordinates from step 1 of the procedure at "To create a backup copy of your existing database" in this topic.

If the external instance is MariaDB 10.0.24 or higher, you should already have the GTID from which to start replication from step 2 of the procedure at "To create a backup copy of your existing database" in this topic.

5. Make the Amazon RDS database the replica. If the external instance isn't MariaDB 10.0.24 or higher, connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the `mysql.rds_set_external_master` command. Use the master log file name and master log position that you determined in the previous step if you have a SQL format backup file. Or use the name and position that you determined when creating the backup files if you used delimited-text format. The following is an example.

```sql
CALL mysql.rds_set_external_master ('myserver.mydomain.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

**Note**

Specify credentials other than the prompts shown here as a security best practice.

If the external instance is MariaDB 10.0.24 or higher, connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the `mysql.rds_set_external_master_gtid` command. Use the GTID that you determined in step 2 of the procedure at "To create a backup copy of your existing database" in this topic. The following is an example.

```sql
CALL mysql.rds_set_external_master_gtid ('source_server_ip_address', 3306, 'ReplicationUser', 'password', 'GTID', 0);
```

The `source_server_ip_address` is the IP address of source replication instance. An EC2 private DNS address is currently not supported.
6. On the Amazon RDS database, issue the `mysql.rds_start_replication` command to start replication.

```
CALL mysql.rds_start_replication;
```

7. On the Amazon RDS database, run the `SHOW REPLICA STATUS` command to determine when the replica is up-to-date with the source replication instance. The results of the `SHOW REPLICA STATUS` command include the `Seconds_Behind_Master` field. When the `Seconds_Behind_Master` field returns 0, then the replica is up-to-date with the source replication instance.

**Note**

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

For a MariaDB 10.5, 10.6, or 10.11 DB instance, run the `mysql.rds_replica_status` procedure instead of the MySQL command.

8. After the Amazon RDS database is up-to-date, turn on automated backups so you can restore that database if needed. You can turn on or modify automated backups for your Amazon RDS database using the Amazon RDS Management Console. For more information, see Introduction to backups.

**Redirect your live application to your Amazon RDS instance**

After the MariaDB or MySQL database is up-to-date with the source replication instance, you can now update your live application to use the Amazon RDS instance.
To redirect your live application to your MariaDB or MySQL database and stop replication

1. To add the VPC security group for the Amazon RDS database, add the IP address of the server that hosts the application. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

2. Verify that the Seconds_Behind_Master field in the `SHOW REPLICA STATUS` command results is 0, which indicates that the replica is up-to-date with the source replication instance.

   ```
   SHOW REPLICA STATUS;
   ```

   **Note**
   
   Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

   For a MariaDB 10.5, 10.6, or 10.11 DB instance, run the `mysql.rds_replica_status` procedure instead of the MySQL command.

3. Close all connections to the source when their transactions complete.
4. Update your application to use the Amazon RDS database. This update typically involves changing the connection settings to identify the hostname and port of the Amazon RDS database, the user account and password to connect with, and the database to use.

5. Connect to the DB instance.

   For a Multi-AZ DB cluster, connect to the writer DB instance.

6. Stop replication for the Amazon RDS instance using the `mysql.rds_stop_replication` command.

   ```
   CALL mysql.rds_stop_replication;
   ```

7. Run the `mysql.rds_reset_external_master` command on your Amazon RDS database to reset the replication configuration so this instance is no longer identified as a replica.

   ```
   CALL mysql.rds_reset_external_master;
   ```

8. Turn on additional Amazon RDS features such as Multi-AZ support and read replicas. For more information, see [Configuring and managing a Multi-AZ deployment](#) and [Working with DB instance read replicas](#).

**Importing data from any source to a MariaDB or MySQL DB instance**

If you have more than 1 GiB of data to load, or if your data is coming from somewhere other than a MariaDB or MySQL database, we recommend creating flat files and loading them with `mysqlimport`. The `mysqlimport` utility is another command line utility bundled with the MySQL and MariaDB client software. Its purpose is to load flat files into MySQL or MariaDB. For information about `mysqlimport`, see [mysqlimport - a data import program](#) in the MySQL documentation.

We also recommend creating DB snapshots of the target Amazon RDS DB instance before and after the data load. Amazon RDS DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. When you initiate a DB snapshot, I/O operations to your DB instance are momentarily suspended while your database is backed up.

Creating a DB snapshot immediately before the load makes it possible for you to restore the database to its state before the load, if you need to. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap and can also be used to seed new database instances.

The following list shows the steps to take. Each step is discussed in more detail following.
1. Create flat files containing the data to be loaded.
2. Stop any applications accessing the target DB instance.
3. Create a DB snapshot.
4. Consider turning off Amazon RDS automated backups.
5. Load the data using mysqlimport.
6. Enable automated backups again.

Step 1: Create flat files containing the data to be loaded

Use a common format, such as comma-separated values (CSV), to store the data to be loaded. Each table must have its own file; you can’t combine data for multiple tables in the same file. Give each file the same name as the table it corresponds to. The file extension can be anything you like. For example, if the table name is sales, the file name might be sales.csv or sales.txt, but not sales_01.csv.

Whenever possible, order the data by the primary key of the table being loaded. Doing this drastically improves load times and minimizes disk storage requirements.

The speed and efficiency of this procedure depends on keeping the size of the files small. If the uncompressed size of any individual file is larger than 1 GiB, split it into multiple files and load each one separately.

On Unix-like systems (including Linux), use the split command. For example, the following command splits the sales.csv file into multiple files of less than 1 GiB, splitting only at line breaks (-C 1024m). The new files are named sales.part_00, sales.part_01, and so on.

```
split -C 1024m -d sales.csv sales.part_
```

Similar utilities are available for other operating systems.

Step 2: Stop any applications accessing the target DB instance

Before starting a large load, stop all application activity accessing the target DB instance that you plan to load to. We recommend this particularly if other sessions will be modifying the tables being loaded or tables that they reference. Doing this reduces the risk of constraint violations occurring during the load and improves load performance. It also makes it possible to restore the DB instance to the point just before the load without losing changes made by processes not involved in the load.
Of course, this might not be possible or practical. If you can't stop applications from accessing the DB instance before the load, take steps to ensure the availability and integrity of your data. The specific steps required vary greatly depending upon specific use cases and site requirements.

**Step 3: Create a DB snapshot**

If you plan to load data into a new DB instance that contains no data, you can skip this step. Otherwise, creating a DB snapshot of your DB instance makes it possible for you to restore the DB instance to the point just before the load, if it becomes necessary. As previously mentioned, when you initiate a DB snapshot, I/O operations to your DB instance are suspended for a few minutes while the database is backed up.

The example following uses the AWS CLI `create-db-snapshot` command to create a DB snapshot of the AcmeRDS instance and give the DB snapshot the identifier "preload".

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
    --db-instance-identifier AcmeRDS \
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds create-db-snapshot ^
    --db-instance-identifier AcmeRDS ^
    --db-snapshot-identifier preload
```

You can also use the restore from DB snapshot functionality to create test DB instances for dry runs or to undo changes made during the load.

Keep in mind that restoring a database from a DB snapshot creates a new DB instance that, like all DB instances, has a unique identifier and endpoint. To restore the DB instance without changing the endpoint, first delete the DB instance so that you can reuse the endpoint.

For example, to create a DB instance for dry runs or other testing, you give the DB instance its own identifier. In the example, AcmeRDS-2 is the identifier. The example connects to the DB instance using the endpoint associated with AcmeRDS-2.

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
```
For Windows:

```
aws rds restore-db-instance-from-db-snapshot
    --db-instance-identifier AcmeRDS-2
    --db-snapshot-identifier preload
```

To reuse the existing endpoint, first delete the DB instance and then give the restored database the same identifier.

For Linux, macOS, or Unix:

```
aws rds delete-db-instance
    --db-instance-identifier AcmeRDS
    --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot
    --db-instance-identifier AcmeRDS
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds delete-db-instance
    --db-instance-identifier AcmeRDS
    --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot
    --db-instance-identifier AcmeRDS
    --db-snapshot-identifier preload
```

The preceding example takes a final DB snapshot of the DB instance before deleting it. This is optional but recommended.

**Step 4: Consider turning off Amazon RDS automated backups**

⚠️ **Warning**

Do not turn off automated backups if you need to perform point-in-time recovery.
Turning off automated backups erases all existing backups, so point-in-time recovery isn't possible after automated backups have been turned off. Disabling automated backups is a performance optimization and isn't required for data loads. Manual DB snapshots aren't affected by turning off automated backups. All existing manual DB snapshots are still available for restore.

Turning off automated backups reduces load time by about 25 percent and reduces the amount of storage space required during the load. If you plan to load data into a new DB instance that contains no data, turning off backups is an easy way to speed up the load and avoid using the additional storage needed for backups. However, in some cases you might plan to load into a DB instance that already contains data. If so, weigh the benefits of turning off backups against the impact of losing the ability to perform point-in-time-recovery.

DB instances have automated backups turned on by default (with a one day retention period). To turn off automated backups, set the backup retention period to zero. After the load, you can turn backups back on by setting the backup retention period to a nonzero value. To turn on or turn off backups, Amazon RDS shuts the DB instance down and restarts it to turn MariaDB or MySQL logging on or off.

Use the AWS CLI modify-db-instance command to set the backup retention to zero and apply the change immediately. Setting the retention period to zero requires a DB instance restart, so wait until the restart has completed before proceeding.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
   --db-instance-identifier AcmeRDS \
   --apply-immediately \
   --backup-retention-period 0
```

For Windows:

```
aws rds modify-db-instance ^
   --db-instance-identifier AcmeRDS ^
   --apply-immediately ^
   --backup-retention-period 0
```

You can check the status of your DB instance with the AWS CLI describe-db-instances command. The following example displays the DB instance status of the AcmeRDS DB instance.
When the DB instance status is available, you're ready to proceed.

Step 5: Load the data

Use the mysqlimport utility to load the flat files into Amazon RDS. The following example tells
mysqlimport to load all of the files named "sales" with an extension starting with "part_". This is a
convenient way to load all of the files created in the "split" example.

Use the --compress option to minimize network traffic. The --fields-terminated-by=',' option is
used for CSV files, and the --local option specifies that the incoming data is located on the client.
Without the --local option, the Amazon RDS DB instance looks for the data on the database host,
so always specify the --local option. For the --host option, specify the DB instance endpoint of the
RDS for MySQL DB instance.

In the following examples, replace master_user with the master username for your DB instance.

Replace hostname with the endpoint for your DB instance. An example of a DB instance endpoint
is my-db-instance.123456789012.us-west-2.rds.amazonaws.com.

For RDS for MySQL version 8.0.15 and higher, run the following statement before using the
mysqlimport utility.

GRANT SESSION_VARIABLES_ADMIN ON *.* TO master_user;

For Linux, macOS, or Unix:

mysqlimport --local "
   --compress "
   --user=master_user "
   --password "
   --host=hostname "
   --fields-terminated-by=',' Acme sales.part_*

For Windows:

mysqlimport --local ^
   --compress ^
For very large data loads, take additional DB snapshots periodically between loading files and note which files have been loaded. If a problem occurs, you can easily resume from the point of the last DB snapshot, avoiding lengthy reloads.

**Step 6: Turn Amazon RDS automated backups back on**

After the load is finished, turn Amazon RDS automated backups on by setting the backup retention period back to its preload value. As noted earlier, Amazon RDS restarts the DB instance, so be prepared for a brief outage.

The following example uses the AWS CLI `modify-db-instance` command to turn on automated backups for the AcmeRDS DB instance and set the retention period to one day.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance
  --db-instance-identifier AcmeRDS
  --backup-retention-period 1
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance
  --db-instance-identifier AcmeRDS
  --backup-retention-period 1
  --apply-immediately
```
Working with MySQL replication in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see [Working with DB instance read replicas](#). For specific information about working with read replicas on Amazon RDS for MySQL, see [Working with MySQL read replicas](#).

You can use global transaction identifiers (GTIDs) for replication with RDS for MySQL. For more information, see [Using GTID-based replication for Amazon RDS for MySQL](#).

You can also set up replication between an RDS for MySQL DB instance and a MariaDB or MySQL instance that is external to Amazon RDS. For information about configuring replication with an external source, see [Configuring binary log file position replication with an external source instance](#).

For any of these replication options, you can use either row-based replication, statement-based, or mixed replication. Row-based replication only replicates the changed rows that result from a SQL statement. Statement-based replication replicates the entire SQL statement. Mixed replication uses statement-based replication when possible, but switches to row-based replication when SQL statements that are unsafe for statement-based replication are run. In most cases, mixed replication is recommended. The binary log format of the DB instance determines whether replication is row-based, statement-based, or mixed. For information about setting the binary log format, see [Configuring MySQL binary logging](#).

**Note**

You can configure replication to import databases from a MariaDB or MySQL instance that is external to Amazon RDS, or to export databases to such instances. For more information, see [Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime](#) and [Exporting data from a MySQL DB instance by using replication](#).

Working with MySQL read replicas

Following, you can find specific information about working with read replicas on RDS for MySQL. For general information about read replicas and instructions for using them, see Working with DB instance read replicas.

Topics

• Configuring read replicas with MySQL
• Configuring replication filters with MySQL
• Configuring delayed replication with MySQL
• Updating read replicas with MySQL
• Working with Multi-AZ read replica deployments with MySQL
• Using cascading read replicas with RDS for MySQL
• Monitoring MySQL read replicas
• Starting and stopping replication with MySQL read replicas
• Troubleshooting a MySQL read replica problem

Configuring read replicas with MySQL

Before a MySQL DB instance can serve as a replication source, make sure to enable automatic backups on the source DB instance. To do this, set the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica. Automatic backups are supported for read replicas running any version of MySQL. You can configure replication based on binary log coordinates for a MySQL DB instance.

On RDS for MySQL version 5.7.43 and higher MySQL 5.7 versions and RDS for MySQL 8.0.28 and higher 8.0 versions, you can configure replication using global transaction identifiers (GTIDs). For more information, see Using GTID-based replication for Amazon RDS for MySQL.

You can create up to 15 read replicas from one DB instance within the same Region. For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

RDS for MySQL supports cascading read replicas. To learn how to configure cascading read replicas, see Using cascading read replicas with RDS for MySQL.
You can run multiple read replica create and delete actions at the same time that reference the same source DB instance. When you perform these actions, stay within the limit of 15 read replicas for each source instance.

A read replica of a MySQL DB instance can't use a lower DB engine version than its source DB instance.

**Preparing MySQL DB instances that use MyISAM**

If your MySQL DB instance uses a nontransactional engine such as MyISAM, you need to perform the following steps to successfully set up your read replica. These steps are required to make sure that the read replica has a consistent copy of your data. These steps are not required if all of your tables use a transactional engine such as InnoDB.

1. Stop all data manipulation language (DML) and data definition language (DDL) operations on non-transactional tables in the source DB instance and wait for them to complete. SELECT statements can continue running.
2. Flush and lock the tables in the source DB instance.
3. Create the read replica using one of the methods in the following sections.
4. Check the progress of the read replica creation using, for example, the `DescribeDBInstances` API operation. Once the read replica is available, unlock the tables of the source DB instance and resume normal database operations.

**Configuring replication filters with MySQL**

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB instance that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.
Note

You can also use replication filters to specify which databases and tables are replicated with a primary MySQL DB instance that is configured as a replica in an inbound replication topology. For more information about this configuration, see Configuring binary log file position replication with an external source instance.

Topics

- Setting replication filtering parameters for RDS for MySQL
- Replication filtering limitations for RDS for MySQL
- Replication filtering examples for RDS for MySQL
- Viewing the replication filters for a read replica

Setting replication filtering parameters for RDS for MySQL

To configure replication filters, set the following replication filtering parameters on the read replica:

- `replicate-do-db` – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- `replicate-ignore-db` – Don't replicate changes to the specified databases. When the `replicate-do-db` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-do-table` – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-ignore-table` – Don't replicate changes to the specified tables. When the `replicate-do-table` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-wild-do-table` – Replicate tables based on the specified database and table name patterns. The `%` and `_` wildcard characters are supported. When the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-wild-ignore-table` – Don't replicate tables based on the specified database and table name patterns. The `%` and `_` wildcard characters are supported. When the `replicate-do-
table or replicate-wild-do-table parameter is set for a read replica, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MySQL documentation:

- For general information, see Replica Server Options and Variables.
- For information about how database replication filtering parameters are evaluated, see Evaluation of Database-Level Replication and Binary Logging Options.
- For information about how table replication filtering parameters are evaluated, see Evaluation of Table-Level Replication Options.

By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the % and _ wildcard characters in the replicate-wild-do-table and replicate-wild-ignore-table parameters. The % wildcard matches any number of characters, and the _ wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the binlog_format parameter determines whether the replication is row-based or statement-based. For more information, see Configuring MySQL binary logging.

**Note**

All data definition language (DDL) statements are replicated as statements, regardless of the binlog_format setting on the source DB instance.

**Replication filtering limitations for RDS for MySQL**

The following limitations apply to replication filtering for RDS for MySQL:

- Each replication filtering parameter has a 2,000-character limit.
• Commas aren't supported in replication filters for parameter values. In a list of parameters, commas can only be used as value separators. For example, `ParameterValue='a,b'` isn't supported, but `ParameterValue='a,b'` is.

• The MySQL `--binlog-do-db` and `--binlog-ignore-db` options for binary log filtering aren't supported.

• Replication filtering doesn't support XA transactions.

For more information, see [Restrictions on XA Transactions](#) in the MySQL documentation.

**Replication filtering examples for RDS for MySQL**

To configure replication filtering for a read replica, modify the replication filtering parameters in the parameter group associated with the read replica.

**Note**

You can't modify a default parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB parameter groups, see [Working with parameter groups](#).

You can set parameters in a parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see [Modifying parameters in a DB parameter group](#). When you set parameters in a parameter group, all of the DB instances associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a parameter group, make sure that the parameter group is associated only with read replicas. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set `ApplyMethod` to `pending-reboot`.

The following examples set replication filters:

- [Including databases in replication](#)
- [Including tables in replication](#)
- [Including tables in replication with wildcard characters](#)
• Excluding databases from replication
• Excluding tables from replication
• Excluding tables from replication using wildcard characters

Example Including databases in replication

The following example includes the mydb1 and mydb2 databases in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name myparametergroup \
   --parameters "ParameterName=replicate-do-db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
   --db-parameter-group-name myparametergroup ^
   --parameters "ParameterName=replicate-do-db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"
```

Example Including tables in replication

The following example includes the table1 and table2 tables in database mydb1 in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name myparametergroup \
   --parameters "ParameterName=replicate-do-table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
   --db-parameter-group-name myparametergroup ^
```
Example Including tables in replication using wildcard characters

The following example includes tables with names that begin with order and return in database mydb in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order %,mydb.return%',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order %,mydb.return%',ApplyMethod=immediate"
```

Example Excluding databases from replication

The following example excludes the mydb5 and mydb6 databases from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-ignore-db,ParameterValue='mydb5,mydb6',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
```
Example Excluding tables from replication

The following example excludes tables `table1` in database `mydb5` and `table2` in database `mydb6` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-ignore-table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-ignore-table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with `order` and `return` in database `mydb7` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order%,mydb7.return%',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order%,mydb7.return%',ApplyMethod=immediate"
```
Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.
  
  For instructions, see [Viewing parameter values for a DB parameter group](#).

- In a MySQL client, connect to the read replica and run the `SHOW REPLICA STATUS` statement.
  
  In the output, the following fields show the replication filters for the read replica:

  - `Replicate_Do_DB`
  - `Replicate_Ignore_DB`
  - `Replicate_Do_Table`
  - `Replicate_Ignore_Table`
  - `Replicate_Wild_Do_Table`
  - `Replicate_Wild_Ignore_Table`

  For more information about these fields, see [Checking Replication Status](#) in the MySQL documentation.

  **Note**

  Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

Configuring delayed replication with MySQL

You can use delayed replication as a strategy for disaster recovery. With delayed replication, you specify the minimum amount of time, in seconds, to delay replication from the source to the read replica. In the event of a disaster, such as a table deleted unintentionally, you complete the following steps to recover from the disaster quickly:

- Stop replication to the read replica before the change that caused the disaster is sent to it.

  Use the `mysql.rds_stop_replication` stored procedure to stop replication.

- Start replication and specify that replication stops automatically at a log file location.
You specify a location just before the disaster using the `mysql.rds_start_replication_until` stored procedure.

- Promote the read replica to be the new source DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance](#).

**Note**

- On RDS for MySQL 8.0, delayed replication is supported for MySQL 8.0.28 and higher. On RDS for MySQL 5.7, delayed replication is supported for MySQL 5.7.43 and higher.
- Use stored procedures to configure delayed replication. You can't configure delayed replication with the AWS Management Console, the AWS CLI, or the Amazon RDS API.
- On RDS for MySQL 5.7.43 and higher MySQL 5.7 versions and RDS for MySQL 8.0.28 and higher 8.0 versions, you can use replication based on global transaction identifiers (GTIDs) in a delayed replication configuration. If you use GTID-based replication, use the `mysql.rds_start_replication_until_gtid` stored procedure instead of the `mysql.rds_start_replication_until` stored procedure. For more information about GTID-based replication, see [Using GTID-based replication for Amazon RDS for MySQL](#).

**Topics**

- [Configuring delayed replication during read replica creation](#)
- [Modifying delayed replication for an existing read replica](#)
- [Setting a location to stop replication to a read replica](#)
- [Promoting a read replica](#)

**Configuring delayed replication during read replica creation**

To configure delayed replication for any future read replica created from a DB instance, run the `mysql.rds_set_configuration` stored procedure with the `target` delay parameter.

**To configure delayed replication during read replica creation**

1. Using a MySQL client, connect to the MySQL DB instance to be the source for read replicas as the master user.
2. Run the `mysql.rds_set_configuration` stored procedure with the `target delay` parameter.

   For example, run the following stored procedure to specify that replication is delayed by at least one hour (3,600 seconds) for any read replica created from the current DB instance.

   ```
call mysql.rds_set_configuration('target delay', 3600);
```

   **Note**
   After running this stored procedure, any read replica you create using the AWS CLI or Amazon RDS API is configured with replication delayed by the specified number of seconds.

---

**Modifying delayed replication for an existing read replica**

To modify delayed replication for an existing read replica, run the `mysql.rds_set_source_delay` stored procedure.

**To modify delayed replication for an existing read replica**

1. Using a MySQL client, connect to the read replica as the master user.
2. Use the `mysql.rds_stop_replication` stored procedure to stop replication.
3. Run the `mysql.rds_set_source_delay` stored procedure.

   For example, run the following stored procedure to specify that replication to the read replica is delayed by at least one hour (3600 seconds).

   ```
call mysql.rds_set_source_delay(3600);
```
4. Use the `mysql.rds_start_replication` stored procedure to start replication.

**Setting a location to stop replication to a read replica**

After stopping replication to the read replica, you can start replication and then stop it at a specified binary log file location using the `mysql.rds_start_replication_until` stored procedure.
To start replication to a read replica and stop replication at a specific location

1. Using a MySQL client, connect to the source MySQL DB instance as the master user.
2. Run the `mysql.rds_start_replication_until` stored procedure.

The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file. In a disaster recovery scenario, assume that location 120 is just before the disaster.

```sql
call mysql.rds_start_replication_until(
    'mysql-bin-changelog.000777',
    120);
```

Replication stops automatically when the stop point is reached. The following RDS event is generated: Replication has been stopped since the replica reached the stop point specified by the `rds_start_replication_until` stored procedure.

Promoting a read replica

After replication is stopped, in a disaster recovery scenario, you can promote a read replica to be the new source DB instance. For information about promoting a read replica, see Promoting a read replica to be a standalone DB instance.

Updating read replicas with MySQL

Read replicas are designed to support read queries, but you might need occasional updates. For example, you might need to add an index to optimize the specific types of queries accessing the replica.

Although you can enable updates by setting the `read_only` parameter to 0 in the DB parameter group for the read replica, we recommend that you don't do so because it can cause problems if the read replica becomes incompatible with the source DB instance. For maintenance operations, we recommend that you use blue/green deployments. For more information, see Using Blue/Green Deployments for database updates.

If you disable read-only on a read replica, change the value of the `read_only` parameter back to 1 as soon as possible.
Working with Multi-AZ read replica deployments with MySQL

You can create a read replica from either single-AZ or Multi-AZ DB instance deployments. You use Multi-AZ deployments to improve the durability and availability of critical data, but you can't use the Multi-AZ secondary to serve read-only queries. Instead, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. If the source instance of a Multi-AZ deployment fails over to the secondary, any associated read replicas automatically switch to use the secondary (now primary) as their replication source. For more information, see Configuring and managing a Multi-AZ deployment.

You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

Using cascading read replicas with RDS for MySQL

RDS for MySQL supports cascading read replicas. With cascading read replicas, you can scale reads without adding overhead to your source RDS for MySQL DB instance.

With cascading read replicas, your RDS for MySQL DB instance sends data to the first read replica in the chain. That read replica then sends data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for MySQL DB instance, but without the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for MySQL DB instance. For example, suppose that you have an RDS for MySQL DB instance, mysql-main. You can do the following:

- Starting with mysql-main, create the first read replica in the chain, read-replica-1.
- Next, from read-replica-1, create the next read replica in the chain, read-replica-2.
- Finally, from read-replica-2, create the third read replica in the chain, read-replica-3.

You can't create another read replica beyond this third cascading read replica in the series for mysql-main. A complete series of instances from an RDS for MySQL source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, each source RDS for MySQL DB instance must have automated backups turned on. To turn on automatic backups on a read replica, first create the read replica,
and then modify the read replica to turn on automatic backups. For more information, see Creating a read replica.

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload from your mysql-main DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote read-replica-2. The chain is affected as follows:

- Promoting read-replica-2 removes it from the replication chain.
  - It is now a full read/write DB instance.
  - It continues replicating to read-replica-3, just as it was doing before promotion.
- Your mysql-main continues replicating to read-replica-1.

For more information about promoting read replicas, see Promoting a read replica to be a standalone DB instance.

**Monitoring MySQL read replicas**

For MySQL read replicas, you can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric. The ReplicaLag metric reports the value of the Seconds_Behind_Master field of the SHOW REPLICA STATUS command.

⚠️ Note

Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

Common causes for replication lag for MySQL are the following:

- A network outage.
- Writing to tables that have different indexes on a read replica. If the read_only parameter is set to 0 on the read replica, replication can break if the read replica becomes incompatible with the source DB instance. After you've performed maintenance tasks on the read replica, we recommend that you set the read_only parameter back to 1.
Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MySQL.

When the ReplicaLag metric reaches 0, the replica has caught up to the source DB instance. If the ReplicaLag metric returns -1, then replication is currently not active. ReplicaLag = -1 is equivalent to Seconds_Behind_Master = NULL.

**Starting and stopping replication with MySQL read replicas**

You can stop and restart the replication process on an Amazon RDS DB instance by calling the system stored procedures `mysql.rds_stop_replication` and `mysql.rds_start_replication`. You can do this when replicating between two Amazon RDS instances for long-running operations such as creating large indexes. You also need to stop and start replication when importing or exporting databases. For more information, see [Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime](#) and [Exporting data from a MySQL DB instance by using replication](#).

If replication is stopped for more than 30 consecutive days, either manually or due to a replication error, Amazon RDS terminates replication between the source DB instance and all read replicas. It does so to prevent increased storage requirements on the source DB instance and long failover times. The read replica DB instance is still available. However, replication can't be resumed because the binary logs required by the read replica are deleted from the source DB instance after replication is terminated. You can create a new read replica for the source DB instance to reestablish replication.

**Troubleshooting a MySQL read replica problem**

For MySQL DB instances, in some cases read replicas present replication errors or data inconsistencies (or both) between the read replica and its source DB instance. This problem occurs when some binary log (binlog) events or InnoDB redo logs aren't flushed during a failure of the read replica or the source DB instance. In these cases, manually delete and recreate the read replicas. You can reduce the chance of this happening by setting the following parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`. These settings might reduce performance, so test their impact before implementing the changes in a production environment.

⚠️ **Warning**

In the parameter group associated with the source DB instance, we recommend keeping these parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`. 

---

*Working with MySQL read replicas*
These parameters are dynamic. If you don't want to use these settings, we recommend temporarily setting those values before executing any operation on the source DB instance that might cause it to restart. These operations include, but are not limited to, rebooting, rebooting with failover, upgrading the database version, and changing the DB instance class or its storage. The same recommendation applies to creating new read replicas for the source DB instance. Failure to follow this guidance increases the risk of read replicas presenting replication errors or data inconsistencies (or both) between the read replica and its source DB instance.

The replication technologies for MySQL are asynchronous. Because they are asynchronous, occasional BinLogDiskUsage increases on the source DB instance and ReplicaLag on the read replica are to be expected. For example, a high volume of write operations to the source DB instance can occur in parallel. In contrast, write operations to the read replica are serialized using a single I/O thread, which can lead to a lag between the source instance and read replica. For more information about read-only replicas in the MySQL documentation, see Replication implementation details.

You can do several things to reduce the lag between updates to a source DB instance and the subsequent updates to the read replica, such as the following:

- Sizing a read replica to have a storage size and DB instance class comparable to the source DB instance.
- Ensuring that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the max_allowed_packet parameter later in this section.

Amazon RDS monitors the replication status of your read replicas and updates the Replication State field of the read replica instance to Error if replication stops for any reason. An example might be if DML queries run on your read replica conflict with the updates made on the source DB instance.

You can review the details of the associated error thrown by the MySQL engine by viewing the Replication Error field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045, RDS-EVENT-0046, and RDS-EVENT-0047. For more information about events and subscribing to events, see Working with Amazon RDS event notification. If a MySQL error message is returned, review the error number in the MySQL error message documentation.
One common issue that can cause replication errors is when the value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance. The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. You use `max_allowed_packet` to specify the maximum size of DML code that can be run on the database. In some cases, the `max_allowed_packet` value in the DB parameter group associated with a read replica is smaller than the `max_allowed_packet` value in the DB parameter group associated with the source DB instance. In these cases, the replication process can throw the error `Packet bigger than 'max_allowed_packet' bytes` and stop replication. To fix the error, have the source DB instance and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

Other common situations that can cause replication errors include the following:

- Writing to tables on a read replica. In some cases, you might create indexes on a read replica that are different from the indexes on the source DB instance. If you do, set the `read_only` parameter to 0 to create the indexes. If you write to tables on the read replica, it might break replication if the read replica becomes incompatible with the source DB instance. After you perform maintenance tasks on the read replica, we recommend that you set the `read_only` parameter back to 1.

- Using a non-transactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the InnoDB storage engine on MySQL.

- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see Determination of safe and unsafe statements in binary logging.

If you decide that you can safely skip an error, you can follow the steps described in the section Skipping the current replication error. Otherwise, you can first delete the read replica. Then you create an instance using the same DB instance identifier so that the endpoint remains the same as that of your old read replica. If a replication error is fixed, the Replication State changes to replicating.

**Using GTID-based replication for Amazon RDS for MySQL**

Following, you can learn how to use global transaction identifiers (GTIDs) with binary log (binlog) replication among Amazon RDS for MySQL DB instances.
If you use binlog replication and aren't familiar with GTID-based replication with MySQL, see Replication with global transaction identifiers in the MySQL documentation for background.

GTID-based replication is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL version 8.0.26 and higher MySQL 8.0 versions. All MySQL DB instances in a replication configuration must meet this requirement.

Topics
- Overview of global transaction identifiers (GTIDs)
- Parameters for GTID-based replication
- Configuring GTID-based replication for new read replicas
- Configuring GTID-based replication for existing read replicas
- Disabling GTID-based replication for a MySQL DB instance with read replicas

Overview of global transaction identifiers (GTIDs)

*Global transaction identifiers (GTIDs)* are unique identifiers generated for committed MySQL transactions. You can use GTIDs to make binlog replication simpler and easier to troubleshoot.

MySQL uses two different types of transactions for binlog replication:

- *GTID transactions* – Transactions that are identified by a GTID.
- *Anonymous transactions* – Transactions that don't have a GTID assigned.

In a replication configuration, GTIDs are unique across all DB instances. GTIDs simplify replication configuration because when you use them, you don't have to refer to log file positions. GTIDs also make it easier to track replicated transactions and determine whether the source instance and replicas are consistent.

You can use GTID-based replication to replicate data with RDS for MySQL read replicas. You can configure GTID-based replication when you are creating new read replicas, or you can convert existing read replicas to use GTID-based replication.

You can also use GTID-based replication in a delayed replication configuration with RDS for MySQL. For more information, see Configuring delayed replication with MySQL.
Parameters for GTID-based replication

Use the following parameters to configure GTID-based replication.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
</table>
| gtid_mode          | OFF, OFF_PERMISSIVE, ON_PERMISSIVE, ON | OFF specifies that new transactions are anonymous transactions (that is, don't have GTIDs), and a transaction must be anonymous to be replicated.  
OFF_PERMISSIVE specifies that new transactions are anonymous transactions, but all transactions can be replicated.  
ON_PERMISSIVE specifies that new transactions are GTID transactions, but all transactions can be replicated.  
ON specifies that new transactions are GTID transactions, and a transaction must be a GTID transaction to be replicated. |
| enforce_gtid_consistency | OFF, ON, WARN                | OFF allows transactions to violate GTID consistency.  
ON prevents transactions from violating GTID consistency.  
WARN allows transactions to violate GTID consistency but generates a warning when a violation occurs. |

⚠️ Note

In the AWS Management Console, the gtid_mode parameter appears as gtid-mode.
For GTID-based replication, use these settings for the parameter group for your DB instance or read replica:

- **ON** and **ON_PERMISSIVE** apply only to outgoing replication from an RDS DB instance. Both of these values cause your RDS DB instance to use GTIDs for transactions that are replicated. **ON** requires that the target database also use GTID-based replication. **ON_PERMISSIVE** makes GTID-based replication optional on the target database.

- **OFF_PERMISSIVE**, if set, means that your RDS DB instances can accept incoming replication from a source database. They can do this regardless of whether the source database uses GTID-based replication.

- **OFF**, if set, means that your RDS DB instance only accepts incoming replication from source databases that don't use GTID-based replication.

For more information about parameter groups, see [Working with parameter groups](#).

### Configuring GTID-based replication for new read replicas

When GTID-based replication is enabled for an RDS for MySQL DB instance, GTID-based replication is configured automatically for read replicas of the DB instance.

**To enable GTID-based replication for new read replicas**

1. Make sure that the parameter group associated with the DB instance has the following parameter settings:
   - **gtid_mode** – ON or ON_PERMISSIVE
   - **enforce_gtid_consistency** – ON

   For more information about setting configuration parameters using parameter groups, see [Working with parameter groups](#).

2. If you changed the parameter group of the DB instance, reboot the DB instance. For more information on how to do so, see [Rebooting a DB instance](#).

3. Create one or more read replicas of the DB instance. For more information on how to do so, see [Creating a read replica](#).
Amazon RDS attempts to establish GTID-based replication between the MySQL DB instance and the read replicas using the MASTER_AUTO_POSITION. If the attempt fails, Amazon RDS uses log file positions for replication with the read replicas. For more information about the MASTER_AUTO_POSITION, see [GTID auto-positioning](#) in the MySQL documentation.

### Configuring GTID-based replication for existing read replicas

For an existing MySQL DB instance with read replicas that doesn't use GTID-based replication, you can configure GTID-based replication between the DB instance and the read replicas.

#### To enable GTID-based replication for existing read replicas

1. If the DB instance or any read replica is using an 8.0 version of RDS for MySQL version lower than 8.0.26, upgrade the DB instance or read replica to 8.0.26 or a higher MySQL 8.0 version. All RDS for MySQL 5.7 versions support GTID-based replication.

   For more information, see [Upgrading the MySQL DB engine](#).

2. (Optional) Reset the GTID parameters and test the behavior of the DB instance and read replicas:
   
   a. Make sure that the parameter group associated with the DB instance and each read replica has the enforce_gtid_consistency parameter set to WARN.

      For more information about setting configuration parameters using parameter groups, see [Working with parameter groups](#).

   b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.

      For more information, see [Rebooting a DB instance](#).

   c. Run your DB instance and read replicas with your normal workload and monitor the log files.

      If you see warnings about GTID-incompatible transactions, adjust your application so that it only uses GTID-compatible features. Make sure that the DB instance is not generating any warnings about GTID-incompatible transactions before proceeding to the next step.

3. Reset the GTID parameters for GTID-based replication that allows anonymous transactions until the read replicas have processed all of them.
a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:

- gtid_mode – ON_PERMISSIVE
- enforce_gtid_consistency – ON

b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.

4. Wait for all of your anonymous transactions to be replicated. To check that these are replicated, do the following:

a. Run the following statement on your source DB instance.

   ```
   SHOW MASTER STATUS;
   ```

   Note the values in the File and Position columns.

b. On each read replica, use the file and position information from its source instance in the previous step to run the following query.

   ```
   SELECT MASTER_POS_WAIT('file', position);
   ```

   For example, if the file name is `mysql-bin-changelog.000031` and the position is 107, run the following statement.

   ```
   SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
   ```

   If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. Proceed to the next step when the query returns for all read replicas.

5. Reset the GTID parameters for GTID-based replication only.

a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:

   - gtid_mode – ON
   - enforce_gtid_consistency – ON

b. Reboot the DB instance and each read replica.

6. On each read replica, run the following procedure.
Disabling GTID-based replication for a MySQL DB instance with read replicas

You can disable GTID-based replication for a MySQL DB instance with read replicas.

To disable GTID-based replication for a MySQL DB instance with read replicas

1. On each read replica, run the following procedure.

   CALL mysql.rds_set_master_auto_position(1);

2. Reset the gtid_mode to ON_PERMISSIVE.

   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has gtid_mode set to ON_PERMISSIVE.

      For more information about setting configuration parameters using parameter groups, see Working with parameter groups.

   b. Reboot the MySQL DB instance and each read replica. For more information about rebooting, see Rebooting a DB instance.

3. Reset the gtid_mode to OFF_PERMISSIVE:

   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has gtid_mode set to OFF_PERMISSIVE.

   b. Reboot the MySQL DB instance and each read replica.

4. Wait for all of the GTID transactions to be applied on all of the read replicas. To check that these are applied, do the following:

   Wait for all of the GTID transactions to be applied on the Aurora primary instance. To check that these are applied, do the following:

   a. On the MySQL DB instance, run the SHOW MASTER STATUS command.

      Your output should be similar to the following.
Note the file and position in your output.

b. On each read replica, use the file and position information from its source instance in the previous step to run the following query.

```sql
SELECT MASTER_POS_WAIT('file', position);
```

For example, if the file name is `mysql-bin-changelog.000031` and the position is 107, run the following statement.

```sql
SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
```

If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. When the query returns for all read replicas, go to the next step.

5. Reset the GTID parameters to disable GTID-based replication:

   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has the following parameter settings:

     - `gtid_mode` – OFF
     - `enforce_gtid_consistency` – OFF

   b. Reboot the MySQL DB instance and each read replica.

### Configuring binary log file position replication with an external source instance

You can set up replication between an RDS for MySQL or MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS using binary log file replication.

**Topics**

- [Before you begin](#)
- [Configuring binary log file position replication with an external source instance](#)
Before you begin

You can configure replication using the binary log file position of replicated transactions.

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure that you use the Amazon RDS `mysql.rds_set_external_master` and `mysql.rds_start_replication` commands to set up replication between your live database and your Amazon RDS database.

To set the binary logging format for a MySQL or MariaDB database, update the `binlog_format` parameter. If your DB instance uses the default DB instance parameter group, create a new DB parameter group to modify `binlog_format` settings. We recommend that you use the default setting for `binlog_format`, which is MIXED. However, you can also set `binlog_format` to ROW or STATEMENT if you need a specific binary log (binlog) format. Reboot your DB instance for the change to take effect.

For information about setting the `binlog_format` parameter, see Configuring MySQL binary logging. For information about the implications of different MySQL replication types, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

Configuring binary log file position replication with an external source instance

Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

- Monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification.

- Maintain the binlogs on your source instance until you have verified that they have been applied to the replica. This maintenance makes sure that you can restore your source instance in the event of a failure.

- Turn on automated backups on your Amazon RDS DB instance. Turning on automated backups makes sure that you can restore your replica to a particular point in time if you need to re-synchronize your source instance and replica. For information on backups and point-in-time restore, see Backing up, restoring, and exporting data.
To configure binary log file replication with an external source instance

1. Make the source MySQL or MariaDB instance read-only.

   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SET GLOBAL read_only = ON;

2. Run the `SHOW MASTER STATUS` command on the source MySQL or MariaDB instance to determine the binlog location.

   You receive output similar to the following example.

   File                        Position
   ------------------------------------
   mysql-bin-changelog.000031      107
   ------------------------------------

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`. For very large databases, you might want to use the procedure in Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime.

   For Linux, macOS, or Unix:

   ```
   mysqldump --databases database_name 
   --single-transaction 
   --compress 
   --order-by-primary 
   -u local_user 
   -plocal_password | mysql 
   --host=hostname 
   --port=3306 
   -u RDS_user_name 
   -pRDS_password
   ```

   For Windows:

   ```
   mysqldump --databases database_name 
   --single-transaction ^
   --compress ^
   --order-by-primary ^
   -u local_user ^
   -plocal_password | mysql ^
   ```
To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the --host, --user (-u), --port and -p options in the mysql command. The host name is the Domain Name Service (DNS) name from the Amazon RDS DB instance endpoint, for example myinstance.123456789012.us-east-1.rds.amazonaws.com. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

```sql
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see the MySQL documentation.

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the virtual private cloud (VPC) security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can
Communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the host command.

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication and restrict it to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

**Note**

Specify a password other than the prompt shown here as a security best practice.

7. For the external instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the source instance by using the `mysql.rds_set_external_master` command. Use the master log file name and master log position that you determined in step 2. The following is an example.

```
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

**Note**

On RDS for MySQL, you can choose to use delayed replication by running the `mysql.rds_set_external_master_with_delay` stored procedure instead. On RDS for MySQL, one reason to use delayed replication is to turn on disaster recovery with the `mysql.rds_start_replication_until` stored procedure. Currently,
RDS for MariaDB supports delayed replication but doesn't support the `mysql.rds_start_replication_until` procedure.

9. On the Amazon RDS DB instance, issue the `mysql.rds_start_replication` command to start replication.

```
CALL mysql.rds_start_replication;
```

## Configuring multi-source-replication for RDS for MySQL

With multi-source replication, you can set up an Amazon RDS for MySQL DB instance as a replica that receives binary log events from more than one RDS for MySQL source DB instance. Multi-source replication is supported for RDS for MySQL DB instances running the following engine versions:

- 8.0.35 and higher minor versions
- 5.7.44 and higher minor versions

For information about MySQL multi-source replication, see [MySQL Multi-Source Replication](#) in the MySQL documentation. The MySQL documentation contains detailed information about this feature, while this topic describes how to configure and manage the multi-source replication channels on your RDS for MySQL DB instances.

### Topics
- Use cases for multi-source replication
- Considerations and best practices for multi-source replication
- Prerequisites for multi-source replication
- Configuring multi-source replication channels on RDS for MySQL DB instances
- Using filters with multi-source replication
- Monitoring multi-source replication channels
- Limitations for multi-source replication on RDS for MySQL

### Use cases for multi-source replication

The following cases are good candidates for using multi-source replication on RDS for MySQL:
• Applications that need to merge or combine multiple shards on separate DB instances into a single shard.

• Applications that need to generate reports from data consolidated from multiple sources.

• Requirements to create consolidated long-term backups of data that's distributed among multiple RDS for MySQL DB instances.

Considerations and best practices for multi-source replication

Before you use multi-source replication on RDS for MySQL, review the following considerations and best practices:

• Make sure that a DB instance configured as a multi-source replica has sufficient resources such as throughput, memory, CPU, and IOPS to handle the workload from multiple source instances.

• Regularly monitor resource utilization on your multi-source replica and adjust the storage or instance configuration to handle the workload without straining resources.

• You can configure multi-threaded replication on a multi-source replica by setting the system variable `replica_parallel_workers` or `slave_parallel_workers` to a value greater than 0. In this case, the number of threads allocated to each channel is the value of this variable, plus one coordinator thread to manage the applier threads.

• Configure replication filters appropriately to avoid conflicts. You can configure `replica_rewrite_db` to replicate an entire database to another database on a replica. For example, all tables in database A can be replicated to database B on a replica instance. This approach can be helpful when all source instances are using the same schema naming convention.

• To avoid replication errors, avoid writing to the replica. We recommended that you enable the `read_only` parameter on multi-source replicas to block write operations. Doing so helps to eliminate replication issues caused by conflicting write operations.

• To increase the performance of read operations such as sorts and high-load joins that are executed on the multi-source replica, consider using RDS Optimized Reads. This feature can help with queries that depend on large temporary tables or sort files. For more information, see the section called “Improving query performance with RDS Optimized Reads”.

• To minimize replication lag and improve the performance of a multi-source replica, consider enabling optimized writes. For more information, see the section called “Improving write performance with RDS Optimized Writes for MySQL”.

Configuring multi-source replication
• Perform management operations (such as changing configuration) on one channel at a time, and avoid performing changes to multiple channels from multiple connections. These practices can lead to conflicts in replication operations. For example, simultaneously executing \texttt{rds\_skip\_repl\_error\_for\_channel} and \texttt{rds\_start\_replication\_for\_channel} procedures from multiple connections can cause skipping of events on a different channel than intended.

• You can enable backups on a multi-source replication instance and export data from that instance to an Amazon S3 bucket to store it for long-term purposes. However, it's important to also configure backups with appropriate retention on the individual source instances. For information about exporting snapshot data to Amazon S3, see the section called “Exporting DB snapshot data to Amazon S3”.

• To distribute the read workload on a multi-source replica, you can create read replicas from a multi-source replica. You can locate these read replicas in different AWS Regions based on your application's requirements. For more information about read replicas, see the section called “Working with MySQL read replicas”.

**Prerequisites for multi-source replication**

Before you configure multi-source replication, complete the following prerequisites.

• Make sure that each source RDS for MySQL DB instance has automatic backups enabled. Enabling automatic backups enables binary logging. To learn how to enable automatic backups, see the section called “Enabling automated backups”.

• To avoid replication errors, we recommended that you block write operations to the source DB instances. You can do so by setting the \texttt{read-only} parameter to \texttt{ON} in a custom parameter group attached to the RDS for MySQL source DB instance. You can use the AWS Management Console or the AWS CLI to create a new custom parameter group or to modify an existing one. For more information, see the section called “Creating a DB parameter group” and the section called “Modifying parameters in a DB parameter group”.

• For each source DB instance, add the IP address of the instance to the Amazon virtual private cloud (VPC) security group for the multi-source DB instance. To identify the IP address of a source DB instance, you can run the command \texttt{dig RDS Endpoint}. Run the command from an Amazon EC2 instance in the same VPC as the destination multi-source DB instance.

• For each source DB instance, use a client to connect to the DB instance and create a database user with the required privileges for replication, as in the following example.
CREATE USER 'repl_user' IDENTIFIED BY 'password';

GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user';

Configuring multi-source replication channels on RDS for MySQL DB instances

Configuring multi-source replication channels is similar to configuring single source replication. For multi-source replication, you first turn on binary logging on the source instance. Then, you import data from the sources to the multi-source replica. Then, you start replication from each source by using the binary log coordinates or by using GTID auto-positioning.

To configure an RDS for MySQL DB instance as a multi-source replica of two or more RDS for MySQL DB instances, perform the following steps.

**Topics**

- [Step 1: Import data from the source DB instances to the multi-source replica](#)
- [Step 2: Start replication from the source DB instances to the multi-source replica](#)

### Step 1: Import data from the source DB instances to the multi-source replica

Perform the following steps on each source DB instance.

Before you import the data from a source to the multi-source replica, determine the current binary log file and position by running the `SHOW MASTER STATUS` command. Take note of these details for use in the next step. In this example output, the file is `mysql-bin-changelog.000031` and the position is 107.

<table>
<thead>
<tr>
<th>File</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-bin-changelog.000031</td>
<td>107</td>
</tr>
</tbody>
</table>

Now copy the database from the source DB instance to the multi-source replica by using `mysqldump`, as in the following example.

```
mysqldump --databases database_name \n   --single-transaction \n```
After copying the database, you can set the read-only parameter to OFF on the source DB instance.

**Step 2: Start replication from the source DB instances to the multi-source replica**

For each source DB instance, use the master user credentials to connect to the instance, and run the following two stored procedures. These stored procedures configure replication on a channel and start replication. This example uses the binlog file name and position from the example output in the previous step.

```
CALL mysql.rds_set_external_source_for_channel('mysourcehost.example.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0, 'channel_1');
CALL mysql.rds_start_replication_for_channel('channel_1');
```

For more information about using these stored procedures and others to set up and manage your replication channels, see the section called "Managing multi-source replication".

**Using filters with multi-source replication**

You can use replication filters to specify which databases and tables are replicated with in multi-source replica. Replication filters can include databases and tables in replication or exclude them from replication. For more information on replication filters, see the section called “Configuring replication filters with MySQL”.

With multi-source replication, you can configure replication filters globally or at the channel level. Channel-level filtering is available only with supported DB instances running version 8.0. The following examples show how to configure filters globally or at the channel level.

Note the following requirements and behavior with filtering in multi-source replication:

- Back quotes (```) around the channel names are required.
• If you change replication filters in the parameter group, the multi-source replica's `sql_thread` for all channels with updates are restarted to apply the changes dynamically. If an update involves a global filter, then all replication channels in the running state are restarted.

• All global filters are applied before any channel-specific filters.

• If a filter is applied globally and at the channel level, then only the channel-level filter is applied. For example, if the filters are `replicate_ignore_db="db1, `channel_22`:db2"`, then `replicate_ignore_db` set to `db1` is applied to all channels except for `channel_22`, and only `channel_22` ignores changes from `db2`.

Example 1: Setting a global filter

In the following example, the `temp_data` database is excluded from replication in every channel.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \  --db-parameter-group-name myparametergroup \  --parameters "ParameterName=replicate-ignore-db,ParameterValue='temp_data',ApplyMethod=immediate"
```

Example 2: Setting a channel-level filter

In the following example, changes from the `sample22` database are only included in channel `channel_22`. Similarly, changes from the `sample99` database are only included in channel `channel_99`.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \  --db-parameter-group-name myparametergroup \  --parameters "ParameterName=replicate-do-db,ParameterValue='`channel_22`:sample22, `channel_99`:sample99',ApplyMethod=immediate"
```

**Monitoring multi-source replication channels**

You can monitor individual channels in a multi-source replica by using the following methods:

• To monitor the status of all channels or a specific channel, connect to the multi-source replica and run the `SHOW REPLICA STATUS` or `SHOW REPLICA STATUS FOR CHANNEL`
'channel_name' command. For more information, see Checking Replication Status in the MySQL documentation.

- To receive notification when a replication channel is started, stopped, or removed, use RDS event notification. For more information, see the section called “Working with Amazon RDS event notification”.

- To monitor the lag for a specific channel, check the ReplicationChannelLag metric for it. Data points for this metric have a period of 60 seconds (1 minute) are available for 15 days. To locate the replication channel lag for a channel, use the instance identifier and the replication channel name. To receive notification when this lag exceeds a particular threshold, you can set up a CloudWatch alarm. For more information, see the section called “Monitoring RDS with CloudWatch”.

Limitations for multi-source replication on RDS for MySQL

The following limitations apply to multi-source replication on RDS for MySQL:

- Currently, RDS for MySQL supports configuring a maximum of 15 channels for a multi-source replica.

- A read replica instance can't be configured as a multi-source replica.

- To configure multi-source replication on RDS for MySQL running engine version 5.7, Performance Schema must be enabled on the replica instance. Enabling Performance Schema is optional on RDS for MySQL running engine version 8.0.

- For RDS for MySQL running engine version 5.7, replication filters apply to all replication channels. For RDS for MySQL running engine version 8.0, you can configure filters that apply to all replication channels or to individual channels.

- Restoring an RDS snapshot or performing a Point-in-time-Restore (PITR) doesn't restore multi-source replica channel configurations.

- When you create a read replica of a multi-source replica, it only replicates data from the multi-source instance. It doesn't restore any channel configuration.

- MySQL doesn't support setting up a different number of parallel workers for each channel. Every channel gets the same number of parallel workers based on the replica_parallel_workers value.

The following additional limitations apply if your multi-source replication target is a Multi-AZ DB cluster:
• A channel must be configured for a source RDS for MySQL instance before any writes to that instance occur.

• Each source RDS for MySQL instance must have GTID-based replication enabled.

• A failover event on the DB cluster removes the multi-source replication configuration. Restoring that configuration requires repeating the configuration steps.
Configuring active-active clusters for RDS for MySQL

You can set up an active-active cluster for RDS for MySQL by using the MySQL Group Replication plugin. The Group Replication plugin is supported for RDS for MySQL DB instances running version 8.0.35 and higher minor versions.

For information about MySQL Group Replication, see [Group Replication](#) in the MySQL documentation. The MySQL documentation contains detailed information about this feature, while this topic describes how to configure and manage the plugin on your RDS for MySQL DB instances.

**Note**

For the sake of brevity, all mentions of "active-active" cluster in this topic refer to active-active clusters using the MySQL Group Replication plugin.

Topics

- Use cases for active-active clusters
- Considerations and best practices for active-active clusters
- Prerequisites for a cross-VPC active-active cluster
- Required parameter settings for active-active clusters
- Converting an existing DB instance to an active-active cluster
- Setting up an active-active cluster with new DB instances
- Adding a DB instance to an active-active cluster
- Monitoring active-active clusters
- Stopping Group Replication on a DB instance in an active-active cluster
- Renaming a DB instance in an active-active cluster
- Removing a DB instance from an active-active cluster
- Limitations for RDS for MySQL active-active clusters

Use cases for active-active clusters

The following cases are good candidates for using active-active clusters:
Applications that need all of the DB instances in the cluster to support write operations. The Group Replication plugin keeps the data consistent on each DB instance in the active-active cluster. For more information about how this works, see [Group Replication](#) in the MySQL documentation.

Applications that require continuous availability of the database. With an active-active cluster, the data is retained on all of the DB instances in the cluster. If one DB instance fails, the application can reroute traffic to another DB instance in the cluster.

Applications that might need to split read and write operations among different DB instances in the cluster for load balancing purposes. With an active-active cluster, your applications can send read traffic to specific DB instances and write traffic to others. You can also switch which DB instances to send reads or writes to at any time.

### Considerations and best practices for active-active clusters

Before you use RDS for MySQL active-active clusters, review the following considerations and best practices:

- Active-active clusters can't have more than nine DB instances.
- With the Group Replication plugin, you can control the transaction consistency guarantees of the active-active cluster. For more information, see [Transaction Consistency Guarantees](#) in the MySQL documentation.
- Conflicts are possible when different DB instances update the same row in an active-active cluster. For information about conflicts and conflict resolution, see [Group Replication](#) in the MySQL documentation.
- For fault tolerance, include at least three DB instances in your active-active cluster. It is possible to configure an active-active cluster with only one or two DB instances, but the cluster won't be fault tolerant. For information about fault tolerance, see [Fault-tolerance](#) in the MySQL documentation.
- When a DB instance joins an existing active-active cluster and is running the same engine version as the lowest engine version in the cluster, the DB instance joins in read-write mode.
- When a DB instance joins an existing active-active cluster and is running a higher engine version than the lowest engine version in the cluster, the DB instance must remain in read-only mode.
- If you enable Group Replication for a DB instance by setting its `rds.group_replication_enabled` parameter to 1 in the DB parameter group, but replication hasn't started or has failed to start, the DB instance is placed in super-read-only mode to
prevent data inconsistencies. For information about super-read-only mode, see the MySQL documentation.

- You can upgrade a DB instance in an active-active cluster, but the DB instance is read-only until all of the other DB instances in the active-active cluster are upgraded to the same engine version or a higher engine version. When you upgrade a DB instance, the DB instance automatically joins the same active-active cluster when the upgrade completes. To avoid an unintended switch to read-only mode for a DB instance, disable automatic minor version upgrades for it. For information about upgrading a MySQL DB instance, see Upgrading the MySQL DB engine.

- You can add a DB instance in a Multi-AZ DB instance deployment to an existing active-active cluster. You can also convert a Single-AZ DB instance in an active-active cluster to a Multi-AZ DB instance deployment. If a primary DB instance in a Multi-AZ deployment fails, that primary instance fails over to the standby instance. The new primary DB instance automatically joins the same cluster after failover completes. For more information about Multi-AZ DB instance deployments, see Multi-AZ DB instance deployments.

- We recommend that the DB instances in an active-active cluster have different time ranges for their maintenance windows. This practice avoids multiple DB instances in the cluster going offline for maintenance at the same time. For more information, see The Amazon RDS maintenance window.

- Active-active clusters can use SSL for connections between DB instances. To configure SSL connections, set the group_replication_recovery_use_ssl and group_replication_ssl_mode parameters. The values for these parameters must match for all DB instances in the active-active cluster.

  Currently, active-active clusters don't support certificate authority (CA) verification for connections between AWS Regions. So, the group_replication_ssl_mode parameter must be set to DISABLED (the default) or REQUIRED for cross-Region clusters.

- An RDS for MySQL active-active cluster runs in multi-primary mode. The default value of the group_replication_enforce_update_everywhere_checks is ON and the parameter is static. When this parameter is set to 0N, applications can't insert into a table that has cascading foreign key constraints.

- An RDS for MySQL active-active cluster uses the MySQL communication stack for connection security instead of XCOM. For more information, see Communication Stack for Connection Security Management in the MySQL documentation.
• When a DB parameter group is associated with a DB instance in an active-active cluster, we recommend only associating this DB parameter group with other DB instances that are in the cluster.

• Active-active clusters only support RDS for MySQL DB instances. These DB instances must be running supported versions of the DB engine.

• When a DB instance in an active-active cluster has an unexpected failure, RDS starts recovery of the DB instance automatically. If the DB instance doesn't recover, we recommend replacing it with a new DB instance by performing a point-in-time recovery with a healthy DB instance in the cluster. For instructions, see Adding a DB instance to an active-active cluster using point-in-time recovery.

• You can delete a DB instance in an active-active cluster without affecting the other DB instances in the cluster. For information about deleting a DB instance, see Deleting a DB instance.

Prerequisites for a cross-VPC active-active cluster

You can configure an active-active cluster with DB instances in more than one VPC. The VPCs can be in the same AWS Region or different AWS Regions.

Note

Sending traffic between multiple AWS Regions might incur additional costs. For more information, see Overview of Data Transfer Costs for Common Architectures.

If you are configuring an active-active cluster in a single VPC, you can skip these steps and move on to Setting up an active-active cluster with new DB instances.

To prepare for an active-active cluster with DB instances in more than one VPC

1. Make sure the IPv4 address ranges in the CIDR blocks meet the following requirements:

   • The IPv4 address ranges in the CIDR blocks of the VPCs can't overlap.

   • All of the IPv4 address ranges in the CIDR blocks either must be lower than 128.0.0.0/subnet_mask or higher than 128.0.0.0/subnet_mask.

   The following ranges illustrate these requirements:
• 10.1.0.0/16 in one VPC and 10.2.0.0/16 in the other VPC is supported.
• 172.1.0.0/16 in one VPC and 172.2.0.0/16 in the other VPC is supported.
• 10.1.0.0/16 in one VPC and 10.1.0.0/16 in the other VPC is not supported because the ranges overlap.
• 10.1.0.0/16 in one VPC and 172.1.0.0/16 in the other VPC is not supported because one is below 128.0.0.0/16/subnet_mask and the other is above 128.0.0.0/16/subnet_mask.

For information about CIDR blocks, see VPC CIDR blocks in the Amazon VPC User Guide.

2. In each VPC, make sure DNS resolution and DNS hostnames are both enabled.

   For instructions, see View and update DNS attributes for your VPC in the Amazon VPC User Guide.

3. Configure the VPCs so that you can route traffic between them in one of the following ways:

   • Create a VPC peering connection between the VPCs.

     For instructions, see Create a VPC peering connection in the Amazon VPC Peering Guide. In each VPC, make sure there are inbound rules for your security groups that reference security groups in the peered VPC. Doing so allows traffic to flow to and from instances that are associated with the referenced security group in the peered VPC. For instructions, see Update your security groups to reference peer security groups in the Amazon VPC Peering Guide.

   • Create a transit gateway between the VPCs.

     For instructions, see Getting started with transit gateways in Amazon VPC TransitGateways. In each VPC, make sure there are inbound rules for your security groups that allow traffic from the other VPC, such as inbound rules that specify the CIDR of the other VPC. Doing so allows traffic to flow to and from instances that are associated with the referenced security group in the active-active cluster. For more information, see Control traffic to your AWS resources using security groups in the Amazon VPC User Guide.

Required parameter settings for active-active clusters

The following parameter settings are required when you are setting up an RDS for MySQL active-active cluster.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Required setting</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>binlog_format</strong></td>
<td>Sets the binary logging format. The default value for RDS for MySQL is MIXED. For more information, see the MySQL documentation.</td>

Converting an existing DB instance to an active-active cluster

The DB engine version of the DB instance you want to migrate to an active-active cluster must be MySQL 8.0.35 or higher. If you need to upgrade the engine version, see Upgrading the MySQL DB engine.

If you are setting up an active-active cluster with DB instances in more than one VPC, make sure you complete the prerequisites in Prerequisites for a cross-VPC active-active cluster.

Complete the following steps to migrate an existing DB instance to an active-active cluster for RDS for MySQL.

Topics

• Step 1: Set the active-active cluster parameters in one or more custom parameter groups
• Step 2: Associate the DB instance with a DB parameter group that has the required Group Replication parameters set
• Step 3: Create the active-active cluster
• Step 4: Create additional RDS for MySQL DB instances for the active-active cluster
• Step 5: Initialize the group on the DB instance you are converting
• Step 6: Start replication on the other DB instances in the active-active cluster
• Step 7: (Recommended) Check the status of the active-active cluster

Step 1: Set the active-active cluster parameters in one or more custom parameter groups

The RDS for MySQL DB instances in an active-active cluster must be associated with a custom parameter group that has the correct setting for required parameters. For information about the parameters and the required setting for each one, see Required parameter settings for active-active clusters.

You can set these parameters in new parameter groups or in existing parameter groups. However, to avoid accidentally affecting DB instances that aren't part of the active-active cluster, we strongly recommend that you create a new custom parameter group. The DB instances in an active-active cluster can be associated with the same DB parameter group or with different DB parameter groups.
You can use the AWS Management Console or the AWS CLI to create a new custom parameter group. For more information, see Creating a DB parameter group. The following example runs the create-db-parameter-group AWS CLI command to create a custom DB parameter group named myactivepg:

For Linux, macOS, or Unix:

```bash
aws rds create-db-parameter-group
  --db-parameter-group-name myactivepg
  --db-parameter-group-family mysql8.0
  --description "Parameter group for active-active clusters"
```

For Windows:

```bash
aws rds create-db-parameter-group
  --db-parameter-group-name myactivepg
  --db-parameter-group-family mysql8.0
  --description "Parameter group for active-active clusters"
```

You can also use the AWS Management Console or the AWS CLI to set the parameters in the custom parameter group. For more information, see Modifying parameters in a DB parameter group.

The following example runs the modify-db-parameter-group AWS CLI command to set the parameters:

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group
  --db-parameter-group-name myactivepg
  --parameters
    "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-reboot"
    "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-reboot"
    "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-reboot"
    "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-reboot"
```

Converting a DB instance to an active-active cluster
"ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" \ 
"ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate" \ 
"ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-555555555555',ApplyMethod=pending-reboot"

For Windows:

```bash
aws rds modify-db-parameter-group ^
   --db-parameter-group-name myactivepg ^
   --parameters
   "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-reboot" ^
   "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-reboot" ^
   "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-reboot" ^
      "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-reboot" ^
   "ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" ^
   "ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate" ^
   "ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-555555555555',ApplyMethod=pending-reboot"
```

**Step 2: Associate the DB instance with a DB parameter group that has the required Group Replication parameters set**

Associate the DB instance with a parameter group you created or modified in the previous step. For instructions, see [Associating a DB parameter group with a DB instance](#).

Reboot the DB instance for the new parameter settings to take effect. For instructions, see [Rebooting a DB instance](#).
**Step 3: Create the active-active cluster**

In the DB parameter group associated with the DB instance, set the `group_replication_group_seeds` parameter to the endpoint of the DB instance you are converting.

You can use the AWS Management Console or the AWS CLI to set the parameter. You don’t need to reboot the DB instance after setting this parameter. For more information about setting parameters, see [Modifying parameters in a DB parameter group](#).

The following example runs the `modify-db-parameter-group` AWS CLI command to set the parameters:

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
  --db-parameter-group-name myactivepg \
  --parameters
  "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --parameters
  "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

**Step 4: Create additional RDS for MySQL DB instances for the active-active cluster**

To create additional DB instances for the active-active cluster, perform point-in-time recovery on the DB instance you are converting. For instructions, see [Adding a DB instance to an active-active cluster using point-in-time recovery](#).

An active-active cluster can have up to nine DB instances. Perform point-in-time recovery on the DB instance until you have the number of DB instances you want for the cluster. When you perform point-in-recovery, make sure you associate the DB instance you are adding with a DB parameter group that has `rds.group_replication_enabled` set to 1. Otherwise, Group Replication won’t start on the newly added DB instance.
Step 5: Initialize the group on the DB instance you are converting

Initialize the group and start replication:

1. Connect to that DB instance you are converting in a SQL client. For more information about connecting to an RDS for MySQL DB instance, see Connecting to a DB instance running the MySQL database engine.

2. In the SQL client, run the following stored procedures and replace group_replication_user_password with the password for the rdsgrprepladmin user. The rdsgrprepladmin user is reserved for Group Replication connections in an active-active cluster. The password for this user must be the same on all of the DB instances in an active-active cluster.

   ```sql
   call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
   call mysql.rds_group_replication_create_user('group_replication_user_password');
   call mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
   call mysql.rds_group_replication_start(1);
   ```

   This example sets the binlog retention hours value to 168, which means that binary log files are retained for seven days on the DB instance. You can adjust this value to meet your requirements.

   This example specifies 1 in the mysql.rds_group_replication_start stored procedure to initialize a new group with the current DB instance.

   For more information about the stored procedures called in the example, see Managing active-active clusters.

Step 6: Start replication on the other DB instances in the active-active cluster

For each of the DB instances in the active-active cluster, use a SQL client to connect to the instance, and run the following stored procedures. Replace group_replication_user_password with the password for the rdsgrprepladmin user.

```sql
   call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
   call mysql.rds_group_replication_create_user('group_replication_user_password');
   call mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
   ```
call mysql.rds_group_replication_start(0);

This example sets the binlog retention hours value to 168, which means that binary log files are retained for seven days on each DB instance. You can adjust this value to meet your requirements.

This example specifies 0 in the mysql.rds_group_replication_start stored procedure to join the current DB instance to an existing group.

Tip

Make sure you run these stored procedures on all of the other DB instances in the active-active cluster.

Step 7: (Recommended) Check the status of the active-active cluster

To make sure each member of the cluster is configured correctly, check the status of the cluster by connecting to a DB instance in the active-active cluster, and running the following SQL command:

```
SELECT * FROM performance_schema.replication_group_members;
```

Your output should show ONLINE for the MEMBER_STATE of each DB instance, as in the following sample output:

```
+---------------------------+--------------------------------------+
+----------------+-------------+--------------+-------------+----------------
| CHANNEL_NAME | MEMBER_ID | MEMBER_HOST   | MEMBER_PORT |
| MEMBER_STATE | MEMBER_ROLE | MEMBER_VERSION | MEMBER_COMMUNICATION_STACK|
+---------------------------+--------------------------------------+
| group_replication_applier | 9854d4a2-5d7f-11ee-b8ec-0ec88c43c251 | ip-10-15-3-137 | 3306 | ONLINE | PRIMARY | 8.0.35 | MySQL |
| group_replication_applier | 9e2e9c28-5d7f-11ee-8039-0e5d58f05fef | ip-10-15-3-225 | 3306 | ONLINE | PRIMARY | 8.0.35 | MySQL |
| group_replication_applier | a6ba332d-5d7f-11ee-a025-0a5c6971197d | ip-10-15-1-83 | 3306 | ONLINE | PRIMARY | 8.0.35 | MySQL |
```

Converting a DB instance to an active-active cluster
For information about the possible MEMBER_STATE values, see [Group Replication Server States](#) in the MySQL documentation.

### Setting up an active-active cluster with new DB instances

Complete the following steps to set up an active-active cluster using new RDS for MySQL DB instances.

If you are setting up an active-active cluster with DB instances in more than one VPC, make sure you complete the prerequisites in [Prerequisites for a cross-VPC active-active cluster](#).

**Topics**

- [Step 1: Set the active-active cluster parameters in one or more custom parameter groups](#)
- [Step 2: Create new RDS for MySQL DB instances for the active-active cluster](#)
- [Step 4: Specify the DB instances in the active-active cluster](#)
- [Step 5: Initialize the group on a DB instance and start replication](#)
- [Step 6: Start replication on the other DB instances in the active-active cluster](#)
- [Step 7: (Recommended) Check the status of the active-active cluster](#)
- [Step 8: (Optional) Import data into a DB instance in the active-active cluster](#)

**Step 1: Set the active-active cluster parameters in one or more custom parameter groups**

The RDS for MySQL DB instances in an active-active cluster must be associated with a custom parameter group that has the correct setting for required parameters. For information about the parameters and the required setting for each one, see [Required parameter settings for active-active clusters](#).

You can set these parameters in new parameter groups or in existing parameter groups. However, to avoid accidentally affecting DB instances that aren’t part of the active-active cluster, we strongly recommend that you create a new custom parameter group. The DB instances in an active-active
cluster can be associated with the same DB parameter group or with different DB parameter
groups.

You can use the AWS Management Console or the AWS CLI to create a new custom parameter
group. For more information, see Creating a DB parameter group. The following example runs the
create-db-parameter-group AWS CLI command to create a custom DB parameter group named
myactivepg:

For Linux, macOS, or Unix:

```sh
aws rds create-db-parameter-group
    --db-parameter-group-name myactivepg
    --db-parameter-group-family mysql8.0
    --description "Parameter group for active-active clusters"
```

For Windows:

```sh
aws rds create-db-parameter-group
    --db-parameter-group-name myactivepg
    --db-parameter-group-family mysql8.0
    --description "Parameter group for active-active clusters"
```

You can also use the AWS Management Console or the AWS CLI to set the parameters in the
custom parameter group. For more information, see Modifying parameters in a DB parameter
group.

The following example runs the modify-db-parameter-group AWS CLI command to set the
parameters:

For Linux, macOS, or Unix:

```sh
aws rds modify-db-parameter-group
    --db-parameter-group-name myactivepg
    --parameters
    "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-reboot" \\
    "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-reboot" \\
    "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-reboot"
```
"ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-reboot" \ 
"ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" \ 
"ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate" \ 
"ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-555555555555',ApplyMethod=pending-reboot"

For Windows:

aws rds modify-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --parameters
  "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-reboot" ^
  "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-reboot" ^
  "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-reboot" ^
    "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-reboot" ^
  "ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" ^
  "ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate" ^
  "ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-555555555555',ApplyMethod=pending-reboot"

Step 2: Create new RDS for MySQL DB instances for the active-active cluster

Active-active clusters are supported for version 8.0.35 and higher RDS for MySQL DB instances. You can create up to nine new DB instances for the cluster.

You can use the AWS Management Console or the AWS CLI to create new DB instances. For more information about creating a DB instance, see Creating an Amazon RDS DB instance. When you
create the DB instance, associate it with a DB parameter group that you created or modified in the previous step.

**Step 4: Specify the DB instances in the active-active cluster**

In the DB parameter group associated with each DB instance, set the `group_replication_group_seeds` parameter to the endpoints of the DB instances you want to include in the cluster.

You can use the AWS Management Console or the AWS CLI to set the parameter. You don't need to reboot the DB instance after setting this parameter. For more information about setting parameters, see [Modifying parameters in a DB parameter group](#).

The following example runs the `modify-db-parameter-group` AWS CLI command to set the parameters:

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
  --db-parameter-group-name myactivepg \
  --parameters
  "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-east-1.rds.amazonaws.com:3306,myactivedb2.123456789012.us-east-1.rds.amazonaws.com:3306,myactivedb3.123456789012.us-east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --parameters
  "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-east-1.rds.amazonaws.com:3306,myactivedb2.123456789012.us-east-1.rds.amazonaws.com:3306,myactivedb3.123456789012.us-east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

**Tip**

Make sure you set the `group_replication_group_seeds` parameter in each DB parameter group that is associated with a DB instance in the active-active cluster.
Step 5: Initialize the group on a DB instance and start replication

You can choose any new DB to initialize the group and start replication. To do so, complete the following steps:

1. Choose a DB instance in the active-active cluster, and connect to that DB instance in a SQL client. For more information about connecting to an RDS for MySQL DB instance, see Connecting to a DB instance running the MySQL database engine.

2. In the SQL client, run the following stored procedures and replace group_replication_user_password with the password for the rdsgrprepladmin user. The rdsgrprepladmin user is reserved for Group Replication connections in an active-active cluster. The password for this user must be the same on all of the DB instances in an active-active cluster.

   ```sql
   call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
   call mysql.rds_group_replication_create_user('group_replication_user_password');
   call mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
   call mysql.rds_group_replication_start(1);
   ```

   This example sets the binlog retention hours value to 168, which means that binary log files are retained for seven days on the DB instance. You can adjust this value to meet your requirements.

   This example specifies 1 in the mysql.rds_group_replication_start stored procedure to initialize a new group with the current DB instance.

   For more information about the stored procedures called in the example, see Managing active-active clusters.

Step 6: Start replication on the other DB instances in the active-active cluster

For each of the DB instances in the active-active cluster, use a SQL client to connect to the instance, and run the following stored procedures. Replace group_replication_user_password with the password for the rdsgrprepladmin user.

```sql
   call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
   call mysql.rds_group_replication_create_user('group_replication_user_password');
   ```
call
  mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
call mysql.rds_group_replication_start(0);

This example sets the binlog retention hours value to 168, which means that binary log files are retained for seven days on each DB instance. You can adjust this value to meet your requirements.

This example specifies 0 in the mysql.rds_group_replication_start stored procedure to join the current DB instance to an existing group.

Tip

Make sure you run these stored procedures on all of the other DB instances in the active-active cluster.

Step 7: (Recommended) Check the status of the active-active cluster

To make sure each member of the cluster is configured correctly, check the status of the cluster by connecting to a DB instance in the active-active cluster, and running the following SQL command:

SELECT * FROM performance_schema.replication_group_members;

Your output should show ONLINE for the MEMBER_STATE of each DB instance, as in the following sample output:

<table>
<thead>
<tr>
<th>CHANNEL_NAME</th>
<th>MEMBER_ID</th>
<th>MEMBER_HOST</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_replication_applier</td>
<td>9e2e9c28-5d7f-11ee-8039-0e5d58f05fef</td>
<td>ip-10-15-3-225</td>
</tr>
<tr>
<td>3306</td>
<td>ONLINE</td>
<td>PRIMARY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>8.0.35</td>
</tr>
<tr>
<td></td>
<td></td>
<td>MySQL</td>
</tr>
</tbody>
</table>
For information about the possible MEMBER_STATE values, see [Group Replication Server States](#) in the MySQL documentation.

**Step 8: (Optional) Import data into a DB instance in the active-active cluster**

You can import data from a MySQL database into a DB instance in the active-active cluster. After the data is imported, Group Replication replicates it to the other DB instances in the cluster.

For information about importing data, see [Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime](#).

**Adding a DB instance to an active-active cluster**

You can add a DB instance to an active-active cluster by restoring a DB snapshot or by restoring a DB instance to a point in time. An active-active cluster can include up to nine DB instances.

When you recover a DB instance to a point in time, it usually includes more recent transactions than a DB instance that was restored from a DB snapshot. When the DB instance has more recent transactions, fewer transactions need to be applied when you start replication. So, using point-in-time recovery to add a DB instance to a cluster is usually faster than restoring from a DB snapshot.

**Topics**

- [Adding a DB instance to an active-active cluster using point-in-time recovery](#)
- [Adding a DB instance to an active-active cluster using a DB snapshot](#)

**Adding a DB instance to an active-active cluster using point-in-time recovery**

You can add a DB instance to an active-active cluster by performing point-in-time recovery on a DB instance in the cluster.

For information about recovering a DB instance to a point in time in a different AWS Region, see [Replicating automated backups to another AWS Region](#).
To add a DB instance to an active-active cluster using point-in-time recovery

1. Create a new DB instance by performing point-in-time recovery on a DB instance in the active-active cluster.

   You can perform point-in-time recovery on any DB instance in the cluster to create the new DB instance. For instructions, see [Restoring a DB instance to a specified time](#).

   **Important**

   During point-in-time-recovery, associate the new DB instance with a DB parameter group that has the active-active cluster parameters set. Otherwise, Group Replication won't start on the new DB instance. For information about the parameters and the required setting for each one, see [Required parameter settings for active-active clusters](#).

   **Tip**

   If you take a snapshot of the DB instance before you start point-in-time recovery, you might be able to reduce the amount of time required to apply transactions on the new DB instance.

2. Add the DB instance to the `group_replication_group_seeds` parameter in each DB parameter group associated with a DB instance in the active-active cluster, including the DB parameter group that you associated with the new DB instance.

   For more information about setting parameters, see [Modifying parameters in a DB parameter group](#).

3. In a SQL client, connect to the new DB instance, and call the `mysql.rds_group_replication_set_recovery_channel` stored procedure. Replace `group_replication_user_password` with the password for the `rdsgrprepladmin` user.

   ```
   call mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
   ```

4. Using the SQL client, call the `mysql.rds_group_replication_start` stored procedure to start replication:
Adding a DB instance to an active-active cluster using a DB snapshot

You can add a DB instance to an active-active cluster by creating a DB snapshot of a DB instance in the cluster and then restoring the DB snapshot.

For information about copying a snapshot to a different AWS Region, see the section called “Cross-Region copying”.

To add a DB instance to an active-active cluster using a DB snapshot

1. Create a DB snapshot of a DB instance in the active-active cluster.

   You can create a DB snapshot of any DB instance in the cluster. For instructions, see Creating a DB snapshot for a Single-AZ DB instance.

2. Restore a DB instance from the DB snapshot.

   During the snapshot restore operation, associate the new DB instance with a DB parameter group that has the active-active cluster parameters set. For information about the parameters and the required setting for each one, see Required parameter settings for active-active clusters.

   For information about restoring a DB instance from a DB snapshot, see Restoring from a DB snapshot.

3. Add the DB instance to the group_replication_group_seeds parameter in each DB parameter group associated with a DB instance in the active-active cluster, including the DB parameter group that you associated with the new DB instance.

   For more information about setting parameters, see Modifying parameters in a DB parameter group.

4. In a SQL client, connect to the new DB instance, and call the mysql.rds_group_replication_set_recovery_channel stored procedure. Replace group_replication_user_password with the password for the rdsgrprepladmin user.

   call mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
5. Using the SQL client, call the `mysql.rds_group_replication_start` stored procedure to start replication:

```sql
call mysql.rds_group_replication_start(0);
```

### Monitoring active-active clusters

You can monitor your active-active cluster by connecting to a DB instance in the cluster, and running the following SQL command:

```sql
SELECT * FROM performance_schema.replication_group_members;
```

Your output should show `ONLINE` for the `MEMBER_STATE` of each DB instance, as in the following sample output:

```
+---------------------------+--------------------------------------+
| CHANNEL_NAME | MEMBER_ID | MEMBER_HOST                  |
| MEMBER_PORT | MEMBER_STATE | MEMBER_ROLE | MEMBER_VERSION | MEMBER_COMMUNICATION_STACK |
+---------------------------+--------------------------------------+
| group_replication_applier | 9854d4a2-5d7f-11ee-b8ec-0ec88c43c251 | ip-10-15-3-137 | 3306 | ONLINE       | PRIMARY     | 8.0.35 | MySQL |
| group_replication_applier | 9e2e9c28-5d7f-11ee-8039-0e5d5f05fedef | ip-10-15-3-225 | 3306 | ONLINE       | PRIMARY     | 8.0.35 | MySQL |
| group_replication_applier | a6ba332d-5d7f-11ee-a025-0a5c6971197d | ip-10-15-1-83 | 3306 | ONLINE       | PRIMARY     | 8.0.35 | MySQL |
+---------------------------+--------------------------------------+
3 rows in set (0.00 sec)
```

For information about the possible `MEMBER_STATE` values, see [Group Replication Server States](#) in the MySQL documentation.
Stopping Group Replication on a DB instance in an active-active cluster

You can stop Group Replication on a DB instance in an active-active cluster. When you stop Group Replication, the DB instance is placed in super-read-only mode until replication is restarted or that DB instance is removed from the active-active cluster. For information about super-read-only mode, see the MySQL documentation.

To stop Group Replication temporarily for an active-active cluster

1. Connect to a DB instance in the active-active cluster using a SQL client.

   For more information about connecting to an RDS for MySQL DB instance, see Connecting to a DB instance running the MySQL database engine.

2. In the SQL client, call the mysql.rds_group_replication_stop stored procedure:

   ```sql
   call mysql.rds_group_replication_stop();
   ```

Renaming a DB instance in an active-active cluster

You can change the name of a DB instance in an active-active cluster. To rename more than one DB instance in an active-active cluster, do so one DB instance at a time. So, rename one DB instance and rejoin it to the cluster before you rename the next DB instance.

To rename a DB instance in an active-active cluster

1. Connect to the DB instance in a SQL client, and call the mysql.rds_group_replication_stop stored procedure:

   ```sql
   call mysql.rds_group_replication_stop();
   ```

2. Rename the DB instance by following the instructions in Renaming a DB instance.

3. Modify the group_replication_group_seeds parameter in each DB parameter group associated with a DB instance in the active-active cluster.

   In the parameter setting, replace the old DB instance endpoint with the new DB instance endpoint. For more information about setting parameters, see Modifying parameters in a DB parameter group.
4. Connect to the DB instance in a SQL client, and call the `mysql.rds_group_replication_start` stored procedure:

```
call mysql.rds_group_replication_start(0);
```

### Removing a DB instance from an active-active cluster

When you remove a DB instance from an active-active cluster, it reverts to a standalone DB instance.

**To remove a DB instance from an active-active cluster**

1. Connect to the DB instance in a SQL client, and call the `mysql.rds_group_replication_stop` stored procedure:

```
call mysql.rds_group_replication_stop();
```

2. Modify the `group_replication_group_seeds` parameter for the DB instances that will remain in the active-active cluster.

   In the `group_replication_group_seeds` parameter, delete the DB instance that you are removing from the active-active cluster. For more information about setting parameters, see [Modifying parameters in a DB parameter group](#).

3. Modify the parameters of the DB instance you are removing from the active-active cluster so that it is no longer part of the cluster.

   You can either associate the DB instance with a different parameter group, or modify the parameters in the DB parameter group associated with the DB instance. The parameters to modify include `group_replication_group_name`, `rds.group_replication_enabled`, and `group_replication_group_seeds`. For more information about active-active cluster parameters, see [Required parameter settings for active-active clusters](#).

   If you modify the parameters in a DB parameter group, make sure the DB parameter group isn't associated with other DB instances in the active-active cluster.

4. Reboot the DB instance you removed from the active-active cluster for the new parameter settings to take effect.

   For instructions, see [Rebooting a DB instance](#).
Limitations for RDS for MySQL active-active clusters

The following limitations apply to active-active clusters for RDS for MySQL:

- The master user name can't be `rdsgrprepladmin` for DB instances in an active-active cluster. This user name is reserved for Group Replication connections.
- For DB instances with read replicas in active-active clusters, a prolonged replication status other than `Replicating` can cause log files to exceed storage limits. For information about the status of read replicas, see `Monitoring read replication`.
- Blue/green deployments aren't supported for DB instances in an active-active cluster. For more information, see `Using Amazon RDS Blue/Green Deployments for database updates`.
- Kerberos authentication isn't supported for DB instances in an active-active cluster. For more information, see `Using Kerberos authentication for MySQL`.
- The DB instances in a Multi-AZ DB cluster can't be added to an active-active cluster. However, the DB instances in a Multi-AZ DB instance deployment can be added to an active-active cluster.

For more information, see `Configuring and managing a Multi-AZ deployment`.

- Tables that don't have a primary key aren't replicated in an active-active cluster because writes are rejected by the Group Replication plugin.
- Non-InnoDB tables aren't replicated in an active-active cluster.
- Active-active clusters don't support concurrent DML and DDL statements on different DB instances in the cluster.
- You can't configure an active-active cluster to use single-primary mode for the group's replication mode. For this configuration, we recommend using a Multi-AZ DB cluster instead. For more information, see `Multi-AZ DB cluster deployments`.
- Multi-source replication isn't supported for DB instances in an active-active cluster.
- A cross-Region active-active cluster can't enforce certificate authority (CA) verification for Group Replication connections.
Exporting data from a MySQL DB instance by using replication

To export data from an RDS for MySQL DB instance to a MySQL instance running external to Amazon RDS, you can use replication. In this scenario, the MySQL DB instance is the source MySQL DB instance, and the MySQL instance running external to Amazon RDS is the external MySQL database.

The external MySQL database can run either on-premises in your data center, or on an Amazon EC2 instance. The external MySQL database must run the same version as the source MySQL DB instance, or a later version.

Replication to an external MySQL database is only supported during the time it takes to export a database from the source MySQL DB instance. The replication should be terminated when the data has been exported and applications can start accessing the external MySQL instance.

The following list shows the steps to take. Each step is discussed in more detail in later sections.

1. Prepare an external MySQL DB instance.
2. Prepare the source MySQL DB instance for replication.
3. Use the mysqldump utility to transfer the database from the source MySQL DB instance to the external MySQL database.
4. Start replication to the external MySQL database.
5. After the export completes, stop replication.

Prepare an external MySQL database

Perform the following steps to prepare the external MySQL database.

To prepare the external MySQL database

1. Install the external MySQL database.
2. Connect to the external MySQL database as the master user. Then create the users required to support the administrators, applications, and services that access the database.
3. Follow the directions in the MySQL documentation to prepare the external MySQL database as a replica. For more information, see the MySQL documentation.
4. Configure an egress rule for the external MySQL database to operate as a read replica during the export. The egress rule allows the external MySQL database to connect to the source...
Prepare the source MySQL DB instance as the replication source.

**To prepare the source MySQL DB instance**

1. Ensure that your client computer has enough disk space available to save the binary logs while setting up replication.

2. Connect to the source MySQL DB instance, and create a replication account by following the directions in [Creating a user for replication](#) in the MySQL documentation.

3. Configure ingress rules on the system running the source MySQL DB instance to allow the external MySQL database to connect during replication. Specify an ingress rule that allows TCP connections to the port used by the source MySQL DB instance from the IP address of the external MySQL database.

4. Configure egress rules to allow Transmission Control Protocol (TCP) connections to the port and IP address of the source MySQL DB instance.

5. If the external MySQL database is running in a VPC, configure rules for the VPC access control list (ACL) rules in addition to the security group egress rule:

   - Configure an ACL ingress rule allowing TCP traffic to ports 1024–65535 from the IP address of the source MySQL DB instance.
   - Configure an ACL egress rule allowing outbound TCP traffic to the port and IP address of the source MySQL DB instance.

   For more information about Amazon VPC network ACLs, see [Network ACLs](#) in Amazon VPC User Guide.

6. (Optional) Set the `max_allowed_packet` parameter to the maximum size to avoid replication errors. We recommend this setting.
4. Specify the egress rules:

- If the source MySQL DB instance is running in a VPC, specify the ingress rules in a VPC security group. For more information, see [Controlling access with security groups](#).

5. If source MySQL DB instance is running in a VPC, configure VPC ACL rules in addition to the security group ingress rule:

- Configure an ACL ingress rule to allow TCP connections to the port used by the Amazon RDS instance from the IP address of the external MySQL database.
- Configure an ACL egress rule to allow TCP connections from ports 1024–65535 to the IP address of the external MySQL database.

For more information about Amazon VPC network ACLs, see [Network ACLs](#) in the [Amazon VPC User Guide](#).

6. Ensure that the backup retention period is set long enough that no binary logs are purged during the export. If any of the logs are purged before the export has completed, you must restart replication from the beginning. For more information about setting the backup retention period, see [Introduction to backups](#).

7. Use the `mysql.rds_set_configuration` stored procedure to set the binary log retention period long enough that the binary logs aren't purged during the export. For more information, see [Accessing MySQL binary logs](#).

8. Create an Amazon RDS read replica from the source MySQL DB instance to further ensure that the binary logs of the source MySQL DB instance are not purged. For more information, see [Creating a read replica](#).

9. After the Amazon RDS read replica has been created, call the `mysql.rds_stop_replication` stored procedure to stop the replication process. The source MySQL DB instance no longer purges its binary log files, so they are available for the replication process.

10. (Optional) Set both the `max_allowed_packet` parameter and the `slave_max_allowed_packet` parameter to the maximum size to avoid replication errors. The maximum size for both parameters is 1 GB. We recommend this setting for both parameters. For information about setting parameters, see [Modifying parameters in a DB parameter group](#).
Copy the database

Perform the following steps to copy the database.

To copy the database

1. Connect to the RDS read replica of the source MySQL DB instance, and run the MySQL SHOW REPLICA STATUS\G statement. Note the values for the following:
   - Master_Host
   - Master_Port
   - Master_Log_File
   - Exec_Master_Log_Pos

   Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

2. Use the mysqldump utility to create a snapshot, which copies the data from Amazon RDS to your local client computer. Ensure that your client computer has enough space to hold the mysqldump files from the databases to be replicated. This process can take several hours for very large databases. Follow the directions in Creating a data snapshot using mysqldump in the MySQL documentation.

   The following example runs mysqldump on a client and writes the dump to a file.

For Linux, macOS, or Unix:

```
mysqldump -h source_MySQL_DB_instance_endpoint \
   -u user \n   -ppassword \n   --port=3306 \n   --single-transaction \n   --routines \n   --triggers \n   --databases database database2 > path/rds-dump.sql
```
For Windows:

```bash
mysqldump -h source_MySQL_DB_instance_endpoint ^
  -u user ^
  -ppassword ^
  --port=3306 ^
  --single-transaction ^
  --routines ^
  --triggers ^
  --databases database database2 > path\rds-dump.sql
```

You can load the backup file into the external MySQL database. For more information, see the MySQL documentation. You can run another utility to load the data into the external MySQL database.

**Complete the export**

Perform the following steps to complete the export.

**To complete the export**

1. Use the MySQL CHANGE MASTER statement to configure the external MySQL database. Specify the ID and password of the user granted REPLICATION SLAVE permissions. Specify the Master_Host, Master_Port, Relay_Master_Log_File, and Exec_Master_Log_Pos values that you got from the MySQL SHOW REPLICA STATUS\G statement that you ran on the RDS read replica. For more information, see the MySQL documentation.

   🔄 **Note**
   
   Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

2. Use the MySQL START REPLICA command to initiate replication from the source MySQL DB instance to the external MySQL database.

   Doing this starts replication from the source MySQL DB instance and exports all source changes that have occurred after you stopped replication from the Amazon RDS read replica.
3. Run the MySQL SHOW REPLICA STATUS\G command on the external MySQL database to verify that it is operating as a read replica. For more information about interpreting the results, see the MySQL documentation.

4. After replication on the external MySQL database has caught up with the source MySQL DB instance, use the MySQL STOP REPLICA command to stop replication from the source MySQL DB instance.

5. On the Amazon RDS read replica, call the `mysql.rds_start_replication` stored procedure. Doing this allows Amazon RDS to start purging the binary log files from the source MySQL DB instance.
Options for MySQL DB instances

Following, you can find a description of options, or additional features, that are available for Amazon RDS instances running the MySQL DB engine. To enable these options, you can add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see Working with option groups.

Amazon RDS supports the following options for MySQL:

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>
<th>Engine versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB Audit Plugin support for MySQL</td>
<td>MARIADB_AUDIT_PLUGIN</td>
<td>MySQL 8.0.28 and higher 8.0 versions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>All MySQL 5.7 versions</td>
</tr>
<tr>
<td>MySQL memcached support</td>
<td>MEMCACHED</td>
<td>All MySQL 5.7 and 8.0 versions</td>
</tr>
</tbody>
</table>
MariaDB Audit Plugin support for MySQL

Amazon RDS offers an audit plugin for MySQL database instances based on the open source MariaDB Audit Plugin. For more information, see the [Audit Plugin for MySQL Server GitHub repository](https://github.com/MariaDB/MariaDB-Audit-Plugin).

**Note**
The audit plugin for MySQL is based on the MariaDB Audit Plugin. Throughout this article, we refer to it as MariaDB Audit Plugin.

The MariaDB Audit Plugin records database activity, including users logging on to the database and queries run against the database. The record of database activity is stored in a log file.

**Note**
Currently, the MariaDB Audit Plugin is only supported for the following RDS for MySQL versions:

- MySQL 8.0.28 and higher 8.0 versions
- All MySQL 5.7 versions

Audit Plugin option settings

Amazon RDS supports the following settings for the MariaDB Audit Plugin option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERVER_AUDIT_FILE_PATH</td>
<td>/rdsdbdata/log/audit/</td>
<td>/rdsdbdata/log/audit/</td>
<td>The location of the log file. The log file contains the record of the activity specified in SERVER_AUDIT_EVENTS. For more information, see <a href="https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_AuditPlugin.html">Viewing and listing database log files</a> and <a href="https://dev.mysql.com/doc/refman/8.0/en/server-audit-events.html">MySQL database log files</a>.</td>
</tr>
<tr>
<td>Option setting</td>
<td>Valid values</td>
<td>Default value</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>--------------</td>
<td>---------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SERVER_AUDIT_FILE_ROTATE_SIZE</td>
<td>1–10000000000</td>
<td>1000000</td>
<td>The size in bytes that when reached, causes the file to rotate. For more information, see <a href="#">Overview of RDS for MySQL database logs</a>.</td>
</tr>
<tr>
<td>SERVER_AUDIT_FILE_ROTATIONS</td>
<td>0–100</td>
<td>9</td>
<td>The number of log rotations to save when <code>server_audit_output_type=file</code>. If set to 0, then the log file never rotates. For more information, see <a href="#">Overview of RDS for MySQL database logs</a> and <a href="#">Downloading a database log file</a>.</td>
</tr>
<tr>
<td>Option setting</td>
<td>Valid values</td>
<td>Default value</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------</td>
<td>----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SERVER_AUDIT_EVENTS</td>
<td>CONNECT, QUERY, QUERY_DDL, QUERY_DML, QUERY_DML_NO_SELECT, QUERY_DCL</td>
<td>CONNECT, QUERY</td>
<td>The types of activity to record in the log. Installing the MariaDB Audit Plugin is itself logged.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• CONNECT: Log successful and unsuccessful connections to the database, and disconnections from the database.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• QUERY: Log the text of all queries run against the database.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• QUERY_DDL: Similar to the QUERY event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• QUERY_DML: Similar to the QUERY event, but returns only data manipulation language (DML) queries (INSERT, UPDATE, and so on, and also SELECT).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• QUERY_DML_NO_SELECT: Similar to the QUERY_DML event, but doesn't log SELECT queries.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The QUERY_DML_NO_SELECT setting is supported only for RDS for MySQL 5.7.34 and higher 5.7 versions, and 8.0.25 and higher 8.0 versions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• QUERY_DCL: Similar to the QUERY event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For MySQL, TABLE is not supported.</td>
</tr>
<tr>
<td>Option setting</td>
<td>Valid values</td>
<td>Default value</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------</td>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SERVER_AUDIT_INCL_USERS</td>
<td>Multiple comma-separated values</td>
<td>None</td>
<td>Include only activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_INCL_USERS, make sure no values are added to SERVER_AUDIT_EXCL_USERS.</td>
</tr>
<tr>
<td>SERVER_AUDIT_EXCL_USERS</td>
<td>Multiple comma-separated values</td>
<td>None</td>
<td>Exclude activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_EXCL_USERS, make sure no values are added to SERVER_AUDIT_INCL_USERS. The rdsadmin user queries the database every second to check the health of the database. Depending on your other settings, this activity can possibly cause the size of your log file to grow very large, very quickly. If you don't need to record this activity, add the rdsadmin user to the SERVER_AUDIT_EXCL_USERS list.</td>
</tr>
</tbody>
</table>

**Note**

CONNECT activity is always recorded for all users, even if the user is specified for this option setting.
<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERVER_AUDIT_LOGGING</td>
<td>ON</td>
<td>ON</td>
<td>Logging is active. The only valid value is ON. Amazon RDS does not support deactivating logging. If you want to deactivate logging, remove the MariaDB Audit Plugin. For more information, see <a href="#">Removing the MariaDB Audit Plugin</a>.</td>
</tr>
<tr>
<td>SERVER_AUDIT_QUERY_LOG_LIMIT</td>
<td>0–2147483647</td>
<td>1024</td>
<td>The limit on the length of the query string in a record.</td>
</tr>
</tbody>
</table>

### Adding the MariaDB Audit Plugin

The general process for adding the MariaDB Audit Plugin to a DB instance is the following:

- Create a new option group, or copy or modify an existing option group
- Add the option to the option group
- Associate the option group with the DB instance

After you add the MariaDB Audit Plugin, you don't need to restart your DB instance. As soon as the option group is active, auditing begins immediately.

⚠️ **Important**

Adding the MariaDB Audit Plugin to a DB instance might cause an outage. We recommend adding the MariaDB Audit Plugin during a maintenance window or during a time of low database workload.

### To add the MariaDB Audit Plugin

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step.
Otherwise, create a custom DB option group. Choose **mysql** for **Engine**, and choose 5.7 or 8.0 for **Major engine version**. For more information, see *Creating an option group*.

2. Add the **MARIADB_AUDIT_PLUGIN** option to the option group, and configure the option settings. For more information about adding options, see *Adding an option to an option group*. For more information about each setting, see *Audit Plugin option settings*.

3. Apply the option group to a new or existing DB instance.
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see *Creating an Amazon RDS DB instance*.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see *Modifying an Amazon RDS DB instance*.

**Audit log format**

Log files are represented as comma-separated variable (CSV) files in UTF-8 format.

---

**Tip**

Log file entries are not in sequential order. To order the entries, use the timestamp value. To see the latest events, you might have to review all log files. For more flexibility in sorting and searching the log data, turn on the setting to upload the audit logs to CloudWatch and view them using the CloudWatch interface.

To view audit data with more types of fields and with output in JSON format, you can also use the Database Activity Streams feature. For more information, see *Monitoring Amazon RDS with Database Activity Streams*.

---

The audit log files include the following comma-delimited information in rows, in the specified order:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp</td>
<td>The YYYYMMDD followed by the HH:MI:SS (24-hour clock) for the logged event.</td>
</tr>
<tr>
<td>serverhost</td>
<td>The name of the instance that the event is logged for.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>username</td>
<td>The connected user name of the user.</td>
</tr>
<tr>
<td>host</td>
<td>The host that the user connected from.</td>
</tr>
<tr>
<td>connectionid</td>
<td>The connection ID number for the logged operation.</td>
</tr>
<tr>
<td>queryid</td>
<td>The query ID number, which can be used for finding the relational table events and related queries. For TABLE events, multiple lines are added.</td>
</tr>
<tr>
<td>operation</td>
<td>The recorded action type. Possible values are: CONNECT, QUERY, READ, WRITE, CREATE, ALTER, RENAME, and DROP.</td>
</tr>
<tr>
<td>database</td>
<td>The active database, as set by the USE command.</td>
</tr>
<tr>
<td>object</td>
<td>For QUERY events, this value indicates the query that the database performed. For TABLE events, it indicates the table name.</td>
</tr>
<tr>
<td>retcode</td>
<td>The return code of the logged operation.</td>
</tr>
</tbody>
</table>
| connection_type | The security state of the connection to the server. Possible values are:  
|              | • 0 – Undefined  
|              | • 1 – TCP/IP  
|              | • 2 – Socket  
|              | • 3 – Named pipe  
|              | • 4 – SSL/TLS  
|              | • 5 – Shared memory  
|              | This field is included only for RDS for MySQL version 5.7.34 and higher 5.7 versions, and all 8.0 versions.                                                                                             |

**Viewing and downloading the MariaDB Audit Plugin log**

After you enable the MariaDB Audit Plugin, you access the results in the log files the same way you access any other text-based log files. The audit log files are located at `/rdsdbdata/log/audit/`. 
For information about viewing the log file in the console, see Viewing and listing database log files. For information about downloading the log file, see Downloading a database log file.

Modifying MariaDB Audit Plugin settings

After you enable the MariaDB Audit Plugin, you can modify the settings. For more information about how to modify option settings, see Modifying an option setting. For more information about each setting, see Audit Plugin option settings.

Removing the MariaDB Audit Plugin

Amazon RDS doesn't support turning off logging in the MariaDB Audit Plugin. However, you can remove the plugin from a DB instance. When you remove the MariaDB Audit Plugin, the DB instance is restarted automatically to stop auditing.

To remove the MariaDB Audit Plugin from a DB instance, do one of the following:

- Remove the MariaDB Audit Plugin option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- Modify the DB instance and specify a different option group that doesn't include the plugin. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.
MySQL memcached support

Amazon RDS supports using the memcached interface to InnoDB tables that was introduced in MySQL 5.6. The memcached API enables applications to use InnoDB tables in a manner similar to NoSQL key-value data stores.

The memcached interface is a simple, key-based cache. Applications use memcached to insert, manipulate, and retrieve key-value data pairs from the cache. MySQL 5.6 introduced a plugin that implements a daemon service that exposes data from InnoDB tables through the memcached protocol. For more information about the MySQL memcached plugin, see InnoDB integration with memcached.

To enable memcached support for an RDS for MySQL DB instance

1. Determine the security group to use for controlling access to the memcached interface. If the set of applications already using the SQL interface are the same set that will access the memcached interface, you can use the existing VPC security group used by the SQL interface. If a different set of applications will access the memcached interface, define a new VPC or DB security group. For more information about managing security groups, see Controlling access with security groups.

2. Create a custom DB option group, selecting MySQL as the engine type and version. For more information about creating an option group, see Creating an option group.

3. Add the MEMCACHED option to the option group. Specify the port that the memcached interface will use, and the security group to use in controlling access to the interface. For more information about adding options, see Adding an option to an option group.

4. Modify the option settings to configure the memcached parameters, if necessary. For more information about how to modify option settings, see Modifying an option setting.

5. Apply the option group to an instance. Amazon RDS enables memcached support for that instance when the option group is applied:

   • You enable memcached support for a new instance by specifying the custom option group when you launch the instance. For more information about launching a MySQL instance, see Creating an Amazon RDS DB instance.

   • You enable memcached support for an existing instance by specifying the custom option group when you modify the instance. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.
6. Specify which columns in your MySQL tables can be accessed through the memcached interface. The memcached plug-in creates a catalog table named `containers` in a dedicated database named `innodb_memcache`. You insert a row into the `containers` table to map an InnoDB table for access through memcached. You specify a column in the InnoDB table that is used to store the memcached key values, and one or more columns that are used to store the data values associated with the key. You also specify a name that a memcached application uses to refer to that set of columns. For details on inserting rows in the `containers` table, see InnoDB memcached plugin internals. For an example of mapping an InnoDB table and accessing it through memcached, see Writing applications for the InnoDB memcached plugin.

7. If the applications accessing the memcached interface are on different computers or EC2 instances than the applications using the SQL interface, add the connection information for those computers to the VPC security group associated with the MySQL instance. For more information about managing security groups, see Controlling access with security groups.

You turn off the memcached support for an instance by modifying the instance and specifying the default option group for your MySQL version. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

MySQL memcached security considerations

The memcached protocol does not support user authentication. For more information about MySQL memcached security considerations, see Security Considerations for the InnoDB memcached Plugin in the MySQL documentation.

You can take the following actions to help increase the security of the memcached interface:

- Specify a different port than the default of 11211 when adding the `MEMCACHED` option to the option group.
- Ensure that you associate the memcached interface with a VPC security group that limits access to known, trusted client addresses and EC2 instances. For more information about managing security groups, see Controlling access with security groups.

MySQL memcached connection information

To access the memcached interface, an application must specify both the DNS name of the Amazon RDS instance and the memcached port number. For example, if an instance has a DNS name of `my-memcached`
cache-instance.cg034hpkmjt.region.rds.amazonaws.com and the memcached interface is using port 11212, the connection information specified in PHP would be:

```php
<?php
$cache = new Memcache;
$cache->connect('my-cache-instance.cg034hpkmjt.region.rds.amazonaws.com',11212);
?>
```

To find the DNS name and memcached port of a MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the top right corner of the AWS Management Console, select the region that contains the DB instance.
3. In the navigation pane, choose Databases.
4. Choose the MySQL DB instance name to display its details.
5. In the Connect section, note the value of the Endpoint field. The DNS name is the same as the endpoint. Also, note that the port in the Connect section is not used to access the memcached interface.
6. In the Details section, note the name listed in the Option Group field.
7. In the navigation pane, choose Option groups.
8. Choose the name of the option group used by the MySQL DB instance to show the option group details. In the Options section, note the value of the Port setting for the MEMCACHED option.

MySQL memcached option settings

Amazon RDS exposes the MySQL memcached parameters as option settings in the Amazon RDS MEMCACHED option.

MySQL memcached parameters

- DAEMON_MEMCACHED_R_BATCH_SIZE – an integer that specifies how many memcached read operations (get) to perform before doing a COMMIT to start a new transaction. The allowed
values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.

- **DAEMON_MEMCACHED_W_BATCH_SIZE** – an integer that specifies how many memcached write operations, such as add, set, or incr, to perform before doing a COMMIT to start a new transaction. The allowed values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.

- **INNODB_API_BK_COMMIT_INTERVAL** – an integer that specifies how often to auto-commit idle connections that use the InnoDB memcached interface. The allowed values are 1 to 1073741824; the default is 5. The option takes effect immediately, without requiring that you restart the instance.

- **INNODB_API_DISABLE_ROWLOCK** – a Boolean that disables (1 (true)) or enables (0 (false)) the use of row locks when using the InnoDB memcached interface. The default is 0 (false). The option does not take effect until the instance is restarted.

- **INNODB_API_ENABLE_MDL** – a Boolean that when set to 0 (false) locks the table used by the InnoDB memcached plugin, so that it cannot be dropped or altered by DDL through the SQL interface. The default is 0 (false). The option does not take effect until the instance is restarted.

- **INNODB_API_TRX_LEVEL** – an integer that specifies the transaction isolation level for queries processed by the memcached interface. The allowed values are 0 to 3. The default is 0. The option does not take effect until the instance is restarted.

Amazon RDS configures these MySQL memcached parameters, and they cannot be modified: **DAEMON_MEMCACHED_LIB_NAME**, **DAEMON_MEMCACHED_LIB_PATH**, and **INNODB_API_ENABLE_BINLOG**. The parameters that MySQL administrators set by using daemon_memcached_options are available as individual MEMCACHED option settings in Amazon RDS.

**MySQL daemon_memcached_options parameters**

- **BINDING_PROTOCOL** – a string that specifies the binding protocol to use. The allowed values are auto, ascii, or binary. The default is auto, which means the server automatically negotiates the protocol with the client. The option does not take effect until the instance is restarted.

- **BACKLOG_QUEUE_LIMIT** – an integer that specifies how many network connections can be waiting to be processed by memcached. Increasing this limit may reduce errors received by a client that is not able to connect to the memcached instance, but does not improve the performance of the server. The allowed values are 1 to 2048; the default is 1024. The option does not take effect until the instance is restarted.
• CAS_DISABLED – a Boolean that enables (1 (true)) or disables (0 (false)) the use of compare and swap (CAS), which reduces the per-item size by 8 bytes. The default is 0 (false). The option does not take effect until the instance is restarted.

• CHUNK_SIZE – an integer that specifies the minimum chunk size, in bytes, to allocate for the smallest item's key, value, and flags. The allowed values are 1 to 48. The default is 48 and you can significantly improve memory efficiency with a lower value. The option does not take effect until the instance is restarted.

• CHUNK_SIZE_GROWTH_FACTOR – a float that controls the size of new chunks. The size of a new chunk is the size of the previous chunk times CHUNK_SIZE_GROWTH_FACTOR. The allowed values are 1 to 2; the default is 1.25. The option does not take effect until the instance is restarted.

• ERROR_ON_MEMORY_EXHAUSTED – a Boolean that when set to 1 (true) specifies that memcached will return an error rather than evicting items when there is no more memory to store items. If set to 0 (false), memcached will evict items if there is no more memory. The default is 0 (false). The option does not take effect until the instance is restarted.

• MAX_SIMULTANEOUS_CONNECTIONS – an integer that specifies the maximum number of concurrent connections. Setting this value to anything under 10 prevents MySQL from starting. The allowed values are 10 to 1024; the default is 1024. The option does not take effect until the instance is restarted.

• VERBOSITY – a string that specifies the level of information logged in the MySQL error log by the memcached service. The default is v. The option does not take effect until the instance is restarted. The allowed values are:
  • v – Logs errors and warnings while running the main event loop.
  • vv – In addition to the information logged by v, also logs each client command and the response.
  • vvv – In addition to the information logged by vv, also logs internal state transitions.

Amazon RDS configures these MySQL DAEMON_MEMCACHED_OPTIONS parameters, they cannot be modified: DAEMON_PROCESS, LARGE_MEMORY_PAGES, MAXIMUM_CORE_FILE_LIMIT, MAX_ITEM_SIZE, LOCK_DOWN_PAGE_MEMORY, MASK, IDFILE, REQUESTS_PER_EVENT, SOCKET, and USER.
Parameters for MySQL

By default, a MySQL DB instance uses a DB parameter group that is specific to a MySQL database. This parameter group contains parameters for the MySQL database engine. For information about working with parameter groups and setting parameters, see Working with parameter groups.

RDS for MySQL parameters are set to the default values of the storage engine that you have selected. For more information about MySQL parameters, see the MySQL documentation. For more information about MySQL storage engines, see Supported storage engines for RDS for MySQL.

You can view the parameters available for a specific RDS for MySQL version using the RDS console or the AWS CLI. For information about viewing the parameters in a MySQL parameter group in the RDS console, see Viewing parameter values for a DB parameter group.

Using the AWS CLI, you can view the parameters for an RDS for MySQL version by running the describe-engine-default-parameters command. Specify one of the following values for the --db-parameter-group-family option:

- mysql8.0
- mysql5.7

For example, to view the parameters for RDS for MySQL version 8.0, run the following command.

```bash
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0
```

Your output looks similar to the following.

```json
{
  "EngineDefaults": {
    "Parameters": [
      {
        "ParameterName": "activate_all_roles_on_login",
        "ParameterValue": "0",
        "Description": "Automatically set all granted roles as active after the user has authenticated successfully.",
        "Source": "engine-default",
        "ApplyType": "dynamic",
        "DataType": "boolean",
        "AllowedValues": "0,1",
        "IsModifiable": true
      }
    ]
  }
}
```
To list only the modifiable parameters for RDS for MySQL version 8.0, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0 --query 'EngineDefaults.Parameters[?IsModifiable==`true`]'
```

For Windows:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0 --query "EngineDefaults.Parameters[?IsModifiable==`true`]"
```
Common DBA tasks for MySQL DB instances

In the following content, you can find descriptions of the Amazon RDS-specific implementations of some common DBA tasks for DB instances running the MySQL database engine. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Also, it restricts access to certain system procedures and tables that require advanced privileges.

For information about working with MySQL log files on Amazon RDS, see MySQL database log files.

Topics

- Understanding predefined users
- Ending a session or query
- Skipping the current replication error
- Working with InnoDB tablespaces to improve crash recovery times
- Managing the Global Status History

Understanding predefined users

Amazon RDS automatically creates several predefined users with new RDS for MySQL DB instances. Predefined users and their privileges can't be changed. You can't drop, rename, or modify privileges for these predefined users. Attempting to do so results in an error.

- **rdsadmin** – A user that's created to handle many of the management tasks that the administrator with superuser privileges would perform on a standalone MySQL database. This user is used internally by RDS for MySQL for many management tasks.

- **rdsrepladmin** – A user that's used internally by Amazon RDS to support replication activities on RDS for MySQL DB instances and clusters.

Ending a session or query

You can end user sessions or queries on DB instances by using the `rds_kill` and `rds_kill_query` commands. First connect to your MySQL DB instance, then issue the appropriate command as shown following. For more information, see Connecting to a DB instance running the MySQL database engine.

```
call mysql.rds_kill(thread-ID)
```
CALL mysql.rds_kill_query(thread-ID)

For example, to end the session that is running on thread 99, you would type the following:

CALL mysql.rds_kill(99);

To end the query that is running on thread 99, you would type the following:

CALL mysql.rds_kill_query(99);

Skipping the current replication error

You can skip an error on your read replica if the error is causing your read replica to stop responding and the error doesn't affect the integrity of your data.

Note

First verify that the error in question can be safely skipped. In a MySQL utility, connect to the read replica and run the following MySQL command.

SHOW REPLICA STATUS\G

For information about the values returned, see the MySQL documentation.

Previous versions of and MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

You can skip an error on your read replica in the following ways.

Topics

- Calling the mysql.rds_skip_repl_error procedure
- Setting the slave_skip_errors parameter

Calling the mysql.rds_skip_repl_error procedure

Amazon RDS provides a stored procedure that you can call to skip an error on your read replicas. First connect to your read replica, then issue the appropriate commands as shown following. For more information, see Connecting to a DB instance running the MySQL database engine.
To skip the error, issue the following command.

```
CALL mysql.rds_skip_repl_error;
```

This command has no effect if you run it on the source DB instance, or on a read replica that hasn’t encountered a replication error.

For more information, such as the versions of MySQL that support `mysql.rds_skip_repl_error`, see `mysql.rds_skip_repl_error`.

⚠️ **Important**
If you attempt to call `mysql.rds_skip_repl_error` and encounter the following error: ERROR 1305 (42000): PROCEDURE mysql.rds_skip_repl_error does not exist, then upgrade your MySQL DB instance to the latest minor version or one of the minimum minor versions listed in `mysql.rds_skip_repl_error`.

### Setting the `slave_skip_errors` parameter

To skip one or more errors, you can set the `slave_skip_errors` static parameter on the read replica. You can set this parameter to skip one or more specific replication error codes. Currently, you can set this parameter only for RDS for MySQL 5.7 DB instances. After you change the setting for this parameter, make sure to reboot your DB instance for the new setting to take effect. For information about setting this parameter, see the MySQL documentation.

We recommend setting this parameter in a separate DB parameter group. You can associate this DB parameter group only with the read replicas that need to skip errors. Following this best practice reduces the potential impact on other DB instances and read replicas.

⚠️ **Important**
Setting a nondefault value for this parameter can lead to replication inconsistency. Only set this parameter to a nondefault value if you have exhausted other options to resolve the problem and you are sure of the potential impact on your read replica's data.
Every table in MySQL consists of a table definition, data, and indexes. The MySQL storage engine InnoDB stores table data and indexes in a *tablespace*. InnoDB creates a global shared tablespace that contains a data dictionary and other relevant metadata, and it can contain table data and indexes. InnoDB can also create separate tablespaces for each table and partition. These separate tablespaces are stored in files with a .ibd extension and the header of each tablespace contains a number that uniquely identifies it.

Amazon RDS provides a parameter in a MySQL parameter group called `innodb_file_per_table`. This parameter controls whether InnoDB adds new table data and indexes to the shared tablespace (by setting the parameter value to 0) or to individual tablespaces (by setting the parameter value to 1). Amazon RDS sets the default value for `innodb_file_per_table` parameter to 1, which allows you to drop individual InnoDB tables and reclaim storage used by those tables for the DB instance. In most use cases, setting the `innodb_file_per_table` parameter to 1 is the recommended setting.

You should set the `innodb_file_per_table` parameter to 0 when you have a large number of tables, such as over 1000 tables when you use standard (magnetic) or general purpose SSD storage or over 10,000 tables when you use Provisioned IOPS storage. When you set this parameter to 0, individual tablespaces are not created and this can improve the time it takes for database crash recovery.

MySQL processes each metadata file, which includes tablespaces, during the crash recovery cycle. The time it takes MySQL to process the metadata information in the shared tablespace is negligible compared to the time it takes to process thousands of tablespace files when there are multiple tablespaces. Because the tablespace number is stored within the header of each file, the aggregate time to read all the tablespace files can take up to several hours. For example, a million InnoDB tablespaces on standard storage can take from five to eight hours to process during a crash recovery cycle. In some cases, InnoDB can determine that it needs additional cleanup after a crash recovery cycle so it will begin another crash recovery cycle, which will extend the recovery time. Keep in mind that a crash recovery cycle also entails rolling-back transactions, fixing broken pages, and other operations in addition to the processing of tablespace information.

Since the `innodb_file_per_table` parameter resides in a parameter group, you can change the parameter value by editing the parameter group used by your DB instance without having to reboot the DB instance. After the setting is changed, for example, from 1 (create individual tables) to 0 (use shared tablespace), new InnoDB tables will be added to the shared tablespace while
existing tables continue to have individual tablespaces. To move an InnoDB table to the shared
tablespace, you must use the ALTER TABLE command.

**Migrating multiple tablespaces to the shared tablespace**

You can move an InnoDB table's metadata from its own tablespace to the shared tablespace,
which will rebuild the table metadata according to the innodb_file_per_table parameter
setting. First connect to your MySQL DB instance, then issue the appropriate commands as shown
following. For more information, see [Connecting to a DB instance running the MySQL database
engine](#).

```
ALTER TABLE table_name ENGINE = InnoDB, ALGORITHM=COPY;
```

For example, the following query returns an ALTER TABLE statement for every InnoDB table that
is not in the shared tablespace.

**For MySQL 5.7 DB instances:**

```
SELECT CONCAT('ALTER TABLE `',
REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '', '``'), '`.`',
REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '', '``'), ` ENGINE=InnoDB,
ALGORITHM=COPY;') AS Query
FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ('mysql', '');
```

**For MySQL 8.0 DB instances:**

```
SELECT CONCAT('ALTER TABLE `',
REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '', '``'), '`.`',
REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '', '``'), ` ENGINE=InnoDB,
ALGORITHM=COPY;') AS Query
FROM INFORMATION_SCHEMA.INNODB_TABLES
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ('mysql', '');
```

Rebuilding a MySQL table to move the table's metadata to the shared tablespace requires
additional storage space temporarily to rebuild the table, so the DB instance must have storage
space available. During rebuilding, the table is locked and inaccessible to queries. For small tables
or tables not frequently accessed, this might not be an issue. For large tables or tables frequently
accessed in a heavily concurrent environment, you can rebuild tables on a read replica.
You can create a read replica and migrate table metadata to the shared tablespace on the read replica. While the ALTER TABLE statement blocks access on the read replica, the source DB instance is not affected. The source DB instance will continue to generate its binary logs while the read replica lags during the table rebuilding process. Because the rebuilding requires additional storage space and the replay log file can become large, you should create a read replica with storage allocated that is larger than the source DB instance.

To create a read replica and rebuild InnoDB tables to use the shared tablespace, take the following steps:

1. Make sure that backup retention is enabled on the source DB instance so that binary logging is enabled.

2. Use the AWS Management Console or AWS CLI to create a read replica for the source DB instance. Because the creation of a read replica involves many of the same processes as crash recovery, the creation process can take some time if there is a large number of InnoDB tablespaces. Allocate more storage space on the read replica than is currently used on the source DB instance.

3. When the read replica has been created, create a parameter group with the parameter settings read_only = 0 and innodb_file_per_table = 0. Then associate the parameter group with the read replica.

4. Issue the following SQL statement for all tables that you want migrated on the replica:

   ```sql
   ALTER TABLE name ENGINE = InnoDB
   ```

5. When all of your ALTER TABLE statements have completed on the read replica, verify that the read replica is connected to the source DB instance and that the two instances are in sync.

6. Use the console or CLI to promote the read replica to be the instance. Make sure that the parameter group used for the new standalone DB instance has the innodb_file_per_table parameter set to 0. Change the name of the new standalone DB instance, and point any applications to the new standalone DB instance.
Managing the Global Status History

Tip
To analyze database performance, you can also use Performance Insights on Amazon RDS. For more information, see Monitoring DB load with Performance Insights on Amazon RDS.

MySQL maintains many status variables that provide information about its operation. Their value can help you detect locking or memory issues on a DB instance. The values of these status variables are cumulative since last time the DB instance was started. You can reset most status variables to 0 by using the `FLUSH STATUS` command.

To allow for monitoring of these values over time, Amazon RDS provides a set of procedures that will snapshot the values of these status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure, called Global Status History (GoSH), is installed on all MySQL DB instances starting with versions 5.5.23. GoSH is disabled by default.

To enable GoSH, you first enable the event scheduler from a DB parameter group by setting the parameter `event_scheduler` to ON. For MySQL DB instances running MySQL 5.7, also set the parameter `show_compatibility_56` to 1. For information about creating and modifying a DB parameter group, see Working with parameter groups. For information about the side effects of enabling this parameter, see `show_compatibility_56` in the MySQL 5.7 Reference Manual.

You can then use the procedures in the following table to enable and configure GoSH. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see Connecting to a DB instance running the MySQL database engine. For each procedure, type the following:

```
CALL procedure-name;
```

Where `procedure-name` is one of the procedures in the table.

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysql.rds_enable_gsh_collector</code></td>
<td>Enables GoSH to take default snapshots at intervals specified by <code>rds_set_gsh_collector</code>.</td>
</tr>
<tr>
<td>Procedure</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>mysql.rds_set_gsh_collector</td>
<td>Specifies the interval, in minutes, between snapshots. Default value is 5.</td>
</tr>
<tr>
<td>mysql.rds_disable_gsh_collector</td>
<td>Disables snapshots.</td>
</tr>
<tr>
<td>mysql.rds_collect_global_status_history</td>
<td>Takes a snapshot on demand.</td>
</tr>
<tr>
<td>mysql.rds_enable_gsh_rotation</td>
<td>Enables rotation of the contents of the mysql.rds_global_status_history table to mysql.rds_global_status_history_old at intervals specified by rds_set_gsh_rotation.</td>
</tr>
<tr>
<td>mysql.rds_set_gsh_rotation</td>
<td>Specifies the interval, in days, between table rotations. Default value is 7.</td>
</tr>
<tr>
<td>mysql.rds_disable_gsh_rotation</td>
<td>Disables table rotation.</td>
</tr>
<tr>
<td>mysql.rds_rotate_global_status_history</td>
<td>Rotates the contents of the mysql.rds_global_status_history table to mysql.rds_global_status_history_old on demand.</td>
</tr>
</tbody>
</table>

When GoSH is running, you can query the tables that it writes to. For example, to query the hit ratio of the Innnodb buffer pool, you would issue the following query:

```sql
SELECT a.collection_end, a.collection_start, (( a.variable_Delta - b.variable_delta) / a.variable_delta) * 100 AS "HitRatio"
FROM mysql.rds_global_status_history AS a JOIN mysql.rds_global_status_history AS b
ON a.collection_end = b.collection_end
WHERE a.variable_name = 'Innodb_buffer_pool_read_requests' AND b.variable_name = 'Innodb_buffer_pool_reads'
```
Local time zone for MySQL DB instances

By default, the time zone for a MySQL DB instance is Universal Time Coordinated (UTC). You can set the time zone for your DB instance to the local time zone for your application instead.

To set the local time zone for a DB instance, set the `time_zone` parameter in the parameter group for your DB instance to one of the supported values listed later in this section. When you set the `time_zone` parameter for a parameter group, all DB instances and read replicas that are using that parameter group change to use the new local time zone. For information on setting parameters in a parameter group, see Working with parameter groups.

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

You can set a different local time zone for a DB instance and one or more of its read replicas. To do this, use a different parameter group for the DB instance and the replica or replicas and set the `time_zone` parameter in each parameter group to a different local time zone.

If you are replicating across AWS Regions, then the source DB instance and the read replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the `time_zone` parameter in the instance's and read replica's parameter groups.

When you restore a DB instance from a DB snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB instance to a point in time, then the local time zone for the restored DB instance is the time zone setting from the parameter group of the restored DB instance.

The Internet Assigned Numbers Authority (IANA) publishes new time zones at https://www.iana.org/time-zones several times a year. Every time RDS releases a new minor maintenance release of MySQL, it ships with the latest time zone data at the time of the release. When you use the latest RDS for MySQL versions, you have recent time zone data from RDS. To ensure that your DB instance has recent time zone data, we recommend upgrading to a higher DB engine version. Alternatively, you can modify the time zone tables in MariaDB DB instances manually. To do so, you can use SQL commands or run the `mysql_tzinfo_to_sql` tool in a SQL client. After updating the time zone data manually, reboot your DB instance so that the changes take effect. RDS doesn't modify or reset the time zone data of running DB instances. New time zone data is installed only when you perform a database engine version upgrade.
You can set your local time zone to one of the following values.

<table>
<thead>
<tr>
<th>Local time zone</th>
<th>Time zone</th>

</table>
Known issues and limitations for Amazon RDS for MySQL

Known issues and limitations for working with Amazon RDS for MySQL are as follows.

Topics

• **InnoDB reserved word**
• **Storage-full behavior for Amazon RDS for MySQL**
• **Inconsistent InnoDB buffer pool size**
• **Index merge optimization returns incorrect results**
• **MySQL parameter exceptions for Amazon RDS DB instances**
• **MySQL file size limits in Amazon RDS**
• **MySQL Keyring Plugin not supported**
• **Custom ports**
• **MySQL stored procedure limitations**
• **GTID-based replication with an external source instance**
• **MySQL default authentication plugin**

InnoDB reserved word

InnoDB is a reserved word for RDS for MySQL. You can't use this name for a MySQL database.

Storage-full behavior for Amazon RDS for MySQL

When storage becomes full for a MySQL DB instance, there can be metadata inconsistencies, dictionary mismatches, and orphan tables. To prevent these issues, Amazon RDS automatically stops a DB instance that reaches the storage-full state.

A MySQL DB instance reaches the storage-full state in the following cases:

• The DB instance has less than 20,000 MiB of storage, and available storage reaches 200 MiB or less.
• The DB instance has more than 102,400 MiB of storage, and available storage reaches 1024 MiB or less.
• The DB instance has between 20,000 MiB and 102,400 MiB of storage, and has less than 1% of storage available.
After Amazon RDS stops a DB instance automatically because it reached the storage-full state, you can still modify it. To restart the DB instance, complete at least one of the following:

- Modify the DB instance to enable storage autoscaling.
  
  For more information about storage autoscaling, see Managing capacity automatically with Amazon RDS storage autoscaling.

- Modify the DB instance to increase its storage capacity.
  
  For more information about increasing storage capacity, see Increasing DB instance storage capacity.

After you make one of these changes, the DB instance is restarted automatically. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

**Inconsistent InnoDB buffer pool size**

For MySQL 5.7, there is currently a bug in the way that the InnoDB buffer pool size is managed. MySQL 5.7 might adjust the value of the innodb_buffer_pool_size parameter to a large value that can result in the InnoDB buffer pool growing too large and using up too much memory. This effect can cause the MySQL database engine to stop running or can prevent it from starting. This issue is more common for DB instance classes that have less memory available.

To resolve this issue, set the value of the innodb_buffer_pool_size parameter to a multiple of the product of the innodb_buffer_pool_instances parameter value and the innodb_buffer_pool_chunk_size parameter value. For example, you might set the innodb_buffer_pool_size parameter value to a multiple of eight times the product of the innodb_buffer_pool_instances and innodb_buffer_pool_chunk_size parameter values, as shown in the following example.

```
innodb_buffer_pool_chunk_size = 536870912
innodb_buffer_pool_instances = 4
innodb_buffer_pool_size = (536870912 * 4) * 8 = 17179869184
```

For details on this MySQL 5.7 bug, see https://bugs.mysql.com/bug.php?id=79379 in the MySQL documentation.
Index merge optimization returns incorrect results

Queries that use index merge optimization might return incorrect results due to a bug in the MySQL query optimizer that was introduced in MySQL 5.5.37. When you issue a query against a table with multiple indexes, the optimizer scans ranges of rows based on the multiple indexes, but does not merge the results together correctly. For more information on the query optimizer bug, see http://bugs.mysql.com/bug.php?id=72745 and http://bugs.mysql.com/bug.php?id=68194 in the MySQL bug database.

For example, consider a query on a table with two indexes where the search arguments reference the indexed columns.

```
SELECT * FROM table1
WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';
```

In this case, the search engine will search both indexes. However, due to the bug, the merged results are incorrect.

To resolve this issue, you can do one of the following:

- Set the optimizer_switch parameter to index_merge=off in the DB parameter group for your MySQL DB instance. For information on setting DB parameter group parameters, see Working with parameter groups.
- Upgrade your MySQL DB instance to MySQL version 5.7 or 8.0. For more information, see Upgrading the MySQL DB engine.
- If you cannot upgrade your instance or change the optimizer_switch parameter, you can work around the bug by explicitly identifying an index for the query, for example:

```
SELECT * FROM table1
USE INDEX covering_index
WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';
```

For more information, see Index merge optimization in the MySQL documentation.

MySQL parameter exceptions for Amazon RDS DB instances

Some MySQL parameters require special considerations when used with an Amazon RDS DB instance.
lower_case_table_names

Because Amazon RDS uses a case-sensitive file system, setting the value of the lower_case_table_names server parameter to 2 (names stored as given but compared in lowercase) is not supported. The following are the supported values for Amazon RDS for MySQL DB instances:

- 0 (names stored as given and comparisons are case-sensitive) is supported for all RDS for MySQL versions.
- 1 (names stored in lowercase and comparisons are not case-sensitive) is supported for RDS for MySQL version 5.7 and version 8.0.28 and higher 8.0 versions.

Set the lower_case_table_names parameter in a custom DB parameter group before creating a DB instance. Then, specify the custom DB parameter group when you create the DB instance.

When a parameter group is associated with a MySQL DB instance with a version lower than 8.0, we recommend that you avoid changing the lower_case_table_names parameter in the parameter group. Changing it could cause inconsistencies with point-in-time recovery backups and read replica DB instances.

When a parameter group is associated with a version 8.0 MySQL DB instance, you can't modify the lower_case_table_names parameter in the parameter group.

Read replicas should always use the same lower_case_table_names parameter value as the source DB instance.

long_query_time

You can set the long_query_time parameter to a floating point value so that you can log slow queries to the MySQL slow query log with microsecond resolution. You can set a value such as 0.1 seconds, which would be 100 milliseconds, to help when debugging slow transactions that take less than one second.

MySQL file size limits in Amazon RDS

For MySQL DB instances, the maximum provisioned storage limit constrains the size of a table to a maximum size of 16 TB when using InnoDB file-per-table tablespaces. This limit also constrains the system tablespace to a maximum size of 16 TB. InnoDB file-per-table tablespaces (with tables each in their own tablespace) is set by default for MySQL DB instances.
Note

Some existing DB instances have a lower limit. For example, MySQL DB instances created before April 2014 have a file and table size limit of 2 TB. This 2 TB file size limit also applies to DB instances or read replicas created from DB snapshots taken before April 2014, regardless of when the DB instance was created.

There are advantages and disadvantages to using InnoDB file-per-table tablespaces, depending on your application. To determine the best approach for your application, see File-per-table tablespaces in the MySQL documentation.

We don't recommend allowing tables to grow to the maximum file size. In general, a better practice is to partition data into smaller tables, which can improve performance and recovery times.

One option that you can use for breaking up a large table into smaller tables is partitioning. Partitioning distributes portions of your large table into separate files based on rules that you specify. For example, if you store transactions by date, you can create partitioning rules that distribute older transactions into separate files using partitioning. Then periodically, you can archive the historical transaction data that doesn't need to be readily available to your application. For more information, see Partitioning in the MySQL documentation.

Because there is no single system table or view that provides the size of all the tables and the InnoDB system tablespace, you must query multiple tables to determine the size of the tablespaces.

To determine the size of the InnoDB system tablespace and the data dictionary tablespace

- Use the following SQL command to determine if any of your tablespaces are too large and are candidates for partitioning.

  ```sql
  select FILE_NAME, TABLESPACE_NAME, ROUND(((TOTAL_EXTENTS*EXTENT_SIZE) /1024/1024/1024), 2) as "File Size (GB)" from information_schema.FILES
  ```

  Note

  The data dictionary tablespace is specific to MySQL 8.0.
To determine the size of InnoDB user tables outside of the InnoDB system tablespace (for MySQL 5.7 versions)

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

```sql
SELECT SPACE, NAME, ROUND((ALLOCATED_SIZE / 1024 / 1024 / 1024), 2) as "Tablespace Size (GB)"
FROM information_schema.INNODB_SYS_TABLESPACES ORDER BY 3 DESC;
```

To determine the size of InnoDB user tables outside of the InnoDB system tablespace (for MySQL 8.0 versions)

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

```sql
SELECT SPACE, NAME, ROUND((ALLOCATED_SIZE / 1024 / 1024 / 1024), 2) as "Tablespace Size (GB)"
FROM information_schema.INNODB_TABLESPACES ORDER BY 3 DESC;
```

To determine the size of non-InnoDB user tables

- Use the following SQL command to determine if any of your non-InnoDB user tables are too large.

```sql
SELECT TABLE_SCHEMA, TABLE_NAME, round(((DATA_LENGTH + INDEX_LENGTH + DATA_FREE) / 1024 / 1024 / 1024), 2) As "Approximate size (GB)"
FROM information_schema.TABLES
WHERE TABLE_SCHEMA NOT IN ('mysql', 'information_schema', 'performance_schema')
and ENGINE<>'InnoDB';
```

To enable InnoDB file-per-table tablespaces

- Set the `innodb_file_per_table` parameter to 1 in the parameter group for the DB instance.
To disable InnoDB file-per-table tablespaces

- Set the `innodb_file_per_table` parameter to 0 in the parameter group for the DB instance.

For information on updating a parameter group, see [Working with parameter groups](#).

When you have enabled or disabled InnoDB file-per-table tablespaces, you can issue an ALTER TABLE command to move a table from the global tablespace to its own tablespace, or from its own tablespace to the global tablespace as shown in the following example:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

**MySQL Keyring Plugin not supported**

Currently, Amazon RDS for MySQL doesn't support the MySQL `keyring_aws` Amazon Web Services Keyring Plugin.

**Custom ports**

Amazon RDS blocks connections to custom port 33060 for the MySQL engine. Choose a different port for your MySQL engine.

**MySQL stored procedure limitations**

The `mysql.rds_kill` and `mysql.rds_kill_query` stored procedures can't terminate sessions or queries owned by MySQL users with usernames longer than 16 characters on the following RDS for MySQL versions:

- 8.0.32 and lower 8 versions
- 5.7.41 and lower 5.7 versions

**GTID-based replication with an external source instance**

Amazon RDS doesn't support replication based on global transaction identifiers (GTIDs) from an external MySQL instance into an Amazon RDS for MySQL DB instance that requires setting `GTID_PURGED` during configuration.
MySQL default authentication plugin

RDS for MySQL version 8.0.34 and higher use the mysql_native_password plugin. You can't change the default_authentication_plugin setting.
RDS for MySQL stored procedure reference

These topics describe system stored procedures that are available for Amazon RDS instances running the MySQL DB engine. The master user must run these procedures.

Topics

- Configuring
- Ending a session or query
- Logging
- Managing active-active clusters
- Managing multi-source replication
- Managing the Global Status History
- Replicating
- Warming the InnoDB cache
Configuring

The following stored procedures set and show configuration parameters, such as for binary log file retention.

Topics

• `mysql.rds_set_configuration`
• `mysql.rds_show_configuration`

`mysql.rds_set_configuration`

Specifies the number of hours to retain binary logs or the number of seconds to delay replication.

Syntax

```
CALL mysql.rds_set_configuration(name, value);
```

Parameters

`name`

The name of the configuration parameter to set.

`value`

The value of the configuration parameter.

Usage notes

The `mysql.rds_set_configuration` procedure supports the following configuration parameters:

• `binlog retention hours`
• `source delay`
• `target delay`

The configuration parameters are stored permanently and survive any DB instance reboot or failover.
**binlog retention hours**

The binlog retention hours parameter is used to specify the number of hours to retain binary log files. Amazon RDS normally purges a binary log as soon as possible, but the binary log might still be required for replication with a MySQL database external to RDS.

The default value of binlog retention hours is NULL. For RDS for MySQL, NULL means binary logs aren't retained (0 hours).

To specify the number of hours to retain binary logs on a DB instance, use the mysql.rds_set_configuration stored procedure and specify a period with enough time for replication to occur, as shown in the following example.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

**Note**

You can't use the value 0 for binlog retention hours.

For MySQL DB instances, the maximum binlog retention hours value is 168 (7 days).

After you set the retention period, monitor storage usage for the DB instance to make sure that the retained binary logs don't take up too much storage.

**source delay**

Use the source delay parameter in a read replica to specify the number of seconds to delay replication from the read replica to its source DB instance. Amazon RDS normally replicates changes as soon as possible, but you might want some environments to delay replication. For example, when replication is delayed, you can roll forward a delayed read replica to the time just before a disaster. If a table is dropped accidentally, you can use delayed replication to quickly recover it. The default value of target delay is 0 (don't delay replication).

When you use this parameter, it runs `mysql.rds_set_source_delay` and applies CHANGE primary TO MASTER_DELAY = input value. If successful, the procedure saves the source delay parameter to the mysql.rds_configuration table.

To specify the number of seconds for Amazon RDS to delay replication to a source DB instance, use the mysql.rds_set_configuration stored procedure and specify the number of seconds to
delay replication. In the following example, the replication is delayed by at least one hour (3,600 seconds).

call mysql.rds_set_configuration('source delay', 3600);

The procedure then runs `mysql.rds_set_source_delay(3600)`.

The limit for the `source delay` parameter is one day (86400 seconds).

Note

The `source delay` parameter isn't supported for RDS for MySQL version 8.0 or MariaDB versions below 10.2.

target delay

Use the `target delay` parameter to specify the number of seconds to delay replication between a DB instance and any future RDS-managed read replicas created from this instance. This parameter is ignored for non-RDS-managed read replicas. Amazon RDS normally replicates changes as soon as possible, but you might want some environments to delay replication. For example, when replication is delayed, you can roll forward a delayed read replica to the time just before a disaster. If a table is dropped accidentally, you can use delayed replication to recover it quickly. The default value of `target delay` is 0 (don't delay replication).

For disaster recovery, you can use this configuration parameter with the `mysql.rds_start_replication_until` stored procedure or the `mysql.rds_start_replication_until_gtid` stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_configuration` procedure with this parameter set. After the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

To use the `mysql.rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the `mysql.rds_skip_transaction_with_gtid` stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication for Amazon RDS for MySQL.
To specify the number of seconds for Amazon RDS to delay replication to a read replica, use the `mysql.rds_set_configuration` stored procedure and specify the number of seconds to delay replication. The following example specifies that replication is delayed by at least one hour (3,600 seconds).

call mysql.rds_set_configuration('target delay', 3600);

The limit for the `target delay` parameter is one day (86400 seconds).

Note

The `target delay` parameter isn't supported for RDS for MySQL version 8.0 or MariaDB versions earlier than 10.2.

### `mysql.rds_show_configuration`

The number of hours that binary logs are retained.

#### Syntax

```
CALL mysql.rds_show_configuration;
```

#### Usage notes

To verify the number of hours that Amazon RDS retains binary logs, use the `mysql.rds_show_configuration` stored procedure.

#### Examples

The following example displays the retention period:

```
call mysql.rds_show_configuration;
```

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>binlog retention hours</td>
<td>24</td>
<td>binlog retention hours specifies the duration in hours before binary logs are automatically deleted.</td>
</tr>
</tbody>
</table>
Ending a session or query

The following stored procedures end a session or query.

Topics

- mysql.rds_kill
- mysql.rds_kill_query

mysql.rds_kill

Ends a connection to the MySQL server.

Syntax

CALL mysql.rds_kill(processID);

Parameters

processID

The identity of the connection thread to be ended.

Usage notes

Each connection to the MySQL server runs in a separate thread. To end a connection, use the mysql.rds_kill procedure and pass in the thread ID of that connection. To obtain the thread ID, use the MySQL SHOW PROCESSLIST command.

For information about limitations, see MySQL stored procedure limitations.

Examples

The following example ends a connection with a thread ID of 4243:

CALL mysql.rds_kill(4243);

mysql.rds_kill_query

Ends a query running against the MySQL server.
Syntax

CALL mysql.rds_kill_query(processID);

Parameters

processID

The identity of the process or thread that is running the query to be ended.

Usage notes

To stop a query running against the MySQL server, use the mysql_rds_kill_query procedure and pass in the connection ID of the thread that is running the query. The procedure then terminates the connection.

To obtain the ID, query the MySQL INFORMATION_SCHEMA PROCESSLIST table or use the MySQL SHOW PROCESSLIST command. The value in the ID column from SHOW PROCESSLIST or SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST is the processID.

For information about limitations, see MySQL stored procedure limitations.

Examples

The following example stops a query with a query thread ID of 230040:

CALL mysql.rds_kill_query(230040);
Logging

The following stored procedures rotate MySQL logs to backup tables. For more information, see MySQL database log files.

Topics

• `mysql.rds_rotate_general_log`
• `mysql.rds_rotate_slow_log`

`mysql.rds_rotate_general_log`

Rotates the `mysql.general_log` table to a backup table.

Syntax

```
CALL mysql.rds_rotate_general_log;
```

Usage notes

You can rotate the `mysql.general_log` table to a backup table by calling the `mysql.rds_rotate_general_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`.

You can run this procedure only when the `log_output` parameter is set to `TABLE`.

`mysql.rds_rotate_slow_log`

Rotates the `mysql.slow_log` table to a backup table.

Syntax

```
CALL mysql.rds_rotate_slow_log;
```
Usage notes

You can rotate the `mysql.slow_log` table to a backup table by calling the `mysql.rds_rotate_slow_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup.

You can query the backup log table if needed. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`. 
Managing active-active clusters

The following stored procedures set up and manage RDS for MySQL active-active clusters. For more information, see the section called “Configuring active-active clusters”.

These stored procedures are only available with RDS for MySQL DB instances running version 8.0.35 and higher minor versions.

Topics

- `mysql.rds_group_replication_advance_gtid`
- `mysql.rds_group_replication_create_user`
- `mysql.rds_group_replication_set_recovery_channel`
- `mysql.rds_group_replication_start`
- `mysql.rds_group_replication_stop`

`mysql.rds_group_replication_advance_gtid`

Creates placeholder GTIDs on the current DB instance.

Syntax

```sql
CALL mysql.rds_group_replication_advance_gtid(
  begin_id
  , end_id
  , server_uuid
);
```

Parameters

`begin_id`

The start transaction ID to be created.

`end_id`

The end transaction ID to be created.
**begin_id**

The `group_replication_group_name` for the transaction to be created. The `group_replication_group_name` is specified as a UUID in the DB parameter group associated with the DB instance.

**Usage notes**

In an active-active cluster, for a DB instance to join a group, all GTID transactions executed on the new DB instance must exist on the other members in the cluster. In unusual cases, a new DB instance might have more transactions when transactions are executed before joining the instance to group. In this case, you can't remove any existing transactions, but you can use this procedure to create the corresponding placeholder GTIDs on the other DB instances in the group. Before doing so, verify that the transactions *don't affect the replicated data*.

When you call this procedure, GTID transactions of `server_uuid:begin_id-end_id` are created with empty content. To avoid replication issues, don't use this procedure under any other conditions.

⚠️ **Important**

Avoid calling this procedure when the active-active cluster is functioning normally. Don't call this procedure unless you understand the possible consequences of the transactions you are creating. Calling this procedure might result in inconsistent data.

**Example**

The following example creates placeholder GTIDs on current DB instance:

```sql
CALL mysql.rds_group_replication_advance_gtid(5, 6, '11111111-2222-3333-4444-555555555555');
```

**mysql.rds_group_replication_create_user**

Creates the replication user `rdsgrp repladmin` for group replication on the DB instance.

**Syntax**

```sql
CALL mysql.rds_group_replication_create_user(
```
replication_user_password
);

Parameters

replication_user_password

The password of the replication user rdsgrprepladmin.

Usage notes

• The password of the replication user rdsgrprepladmin must be the same on all of the DB instances in an active-active cluster.

• The rdsgrprepladmin user name is reserved for group replication connections. No other user, including the master user, can have this user name.

Example

The following example creates the replication user rdsgrprepladmin for group replication on the DB instance:

CALL mysql.rds_group_replication_create_user('password');

mysql.rds_group_replication_set_recovery_channel

Sets the group_replication_recovery channel for an active-active cluster. The procedure uses the reserved rdsgrprepladmin user to configure the channel.

Syntax

CALL mysql.rds_group_replication_set_recovery_channel(
replication_user_password);

Parameters

replication_user_password

The password of the replication user rdsgrprepladmin.
Usage notes

The password of the replication user `rdsgrprepladmin` must be the same on all of the DB instances in an active-active cluster. A call to the `mysql.rds_group_replication_create_user` specifies the password.

Example

The following example sets the `group_replication_recovery` channel for an active-active cluster:

```sql
CALL mysql.rds_group_replication_set_recovery_channel('password');
```

`mysql.rds_group_replication_start`

Starts group replication on the current DB instance.

Syntax

```sql
CALL mysql.rds_group_replication_start(
    bootstrap
);
```

Parameters

`bootstrap`

A value that specifies whether to initialize a new group or join an existing group. 1 initializes a new group with the current DB instance. 0 joins the current DB instance to an existing group by connecting to the endpoints defined in the `group_replication_group_seeds` parameter in the DB parameter group associated with the DB instance.

Example

The following example initializes a new group with the current DB instance:

```sql
CALL mysql.rds_group_replication_start(1);
```

`mysql.rds_group_replication_stop`

Stops group replication on the current DB instance.
Syntax

CALL mysql.rds_group_replication_stop();

Usage notes

When you stop replication on a DB instance, it doesn't affect any other DB instance in the active-active cluster.
Managing multi-source replication

The following stored procedures set up and manage replication channels on a RDS for MySQL multi-source replica. For more information, see the section called “Configuring multi-source replication”.

These stored procedures are only available with RDS for MySQL DB instances running the following engine versions:

- 8.0.35 and higher minor versions
- 5.7.44 and higher minor versions

**Note**

Although this documentation refers to source DB instances as RDS for MySQL DB instances, these procedures also work for MySQL instances running external to Amazon RDS.

Topics

- `mysql.rds_next_source_log_for_channel`
- `mysql.rds_reset_external_source_for_channel`
- `mysql.rds_set_external_source_for_channel`
- `mysql.rds_set_external_source_with_auto_position_for_channel`
- `mysql.rds_set_external_source_with_delay_for_channel`
- `mysql.rds_set_source_auto_position_for_channel`
- `mysql.rds_set_source_delay_for_channel`
- `mysql.rds_skip_repl_error_for_channel`
- `mysql.rds_start_replication_for_channel`
- `mysql.rds_start_replication_until_for_channel`
- `mysql.rds_start_replication_until_gtid_for_channel`
- `mysql.rds_stop_replication_for_channel`
**mysql.rds_next_source_log_for_channel**

Changes the source DB instance log position to the start of the next binary log on the source DB instance for the channel. Use this procedure only if you are receiving replication I/O error 1236 on a multi-source replica.

**Syntax**

```sql
CALL mysql.rds_next_source_log_for_channel(
    curr_master_log,
    channel_name
);```

**Parameters**

**curr_master_log**

The index of the current source log file. For example, if the current file is named `mysql-bin-changelog.012345`, then the index is 12345. To determine the current source log file name, run the `SHOW REPLICA STATUS FOR CHANNEL 'channel_name'` command and view the `Source_Log_File` field.

**Note**

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

**channel_name**

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

**Usage notes**

The master user must run the `mysql.rds_next_source_log_for_channel` procedure. If there is an IO_Thread error, for example, you can use this procedure to skip all the events in the current
binary log file and resume the replication from the next binary log file for the channel specified in channel_name.

**Example**

Assume replication fails on a channel on a multi-source replica. Running `SHOW REPLICA STATUS FOR CHANNEL 'channel_1'` on the multi-source replica returns the following result:

```sql
mysql> SHOW REPLICA STATUS FOR CHANNEL 'channel_1'
*************************** 1. row ***************************
Replica_IO_State: Waiting for source to send event
Source_Host: myhost.XXXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com
Source_User: ReplicationUser
Source_Port: 3306
Connect_Retry: 60
Source_Log_File: mysql-bin-changelog.012345
Read_Source_Log_Pos: 1219393
Relay_Log_File: replica-relay-bin.000003
Relay_Log_Pos: 30223388
Relay_Source_Log_File: mysql-bin-changelog.012345
Replica_IO_Running: No
Replica_SQL_Running: Yes
Replicate_Do_DB:.
.
Last_IO_Errno: 1236
Last_IO_Error: Got fatal error 1236 from master when reading data from binary log: 'Client requested master to start replication from impossible position; the first event 'mysql-bin-changelog.013406' at 1219393, the last event read from '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4, the last byte read from '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4.'
Last_SQL_Errno: 0
Last_SQL_Error:
.
.
Channel_name: channel_1
.
.
-- Some fields are omitted in this example output
```

The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Source_Log_File` field shows that the file name is `mysql-bin-changelog.012345`,...
which means that the log file index is 12345. To resolve the error, you can call `mysql.rds_next_source_log_for_channel` with the following parameters:

```
CALL mysql.rds_next_source_log_for_channel(12345,'channel_1');
```

**Note**

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

`mysql.rds_reset_external_source_for_channel`

Stops the replication process on the specified channel, and removes the channel and associated configurations from the multi-source replica.

**Important**

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group](#).

**Syntax**

```
CALL mysql.rds_reset_external_source_for_channel (channel_name);
```

**Parameters**

`channel_name`

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.
Usage notes

The master user must run the `mysql.rds_reset_external_source_for_channel` procedure. This procedure deletes all relay logs that belong to the channel being removed.

**mysql.rds_set_external_source_for_channel**

Configures a replication channel on an RDS for MySQL DB instance to replicate the data from another RDS for MySQL DB instance.

⚠️ **Important**

To run this procedure, autocommit must be enabled. To enable it, set the `autocommit` parameter to `1`. For information about modifying parameters, see [Modifying parameters in a DB parameter group](#).

💡 **Note**

You can use the [section called “mysql.rds_set_external_source_with_delay_for_channel”](#) stored procedure instead to configure this channel with delayed replication.

**Syntax**

```
CALL mysql.rds_set_external_source_for_channel (  
  host_name  
  , host_port  
  , replication_user_name  
  , replication_user_password  
  , mysql_binary_log_file_name  
  , mysql_binary_log_file_location  
  , ssl_encryption  
  , channel_name  
);  
```
Parameters

**host_name**

The host name or IP address of the RDS for MySQL source DB instance.

**host_port**

The port used by the RDS for MySQL source DB instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

**replication_user_name**

The ID of a user with `REPLICATION_CLIENT` and `REPLICATION_SLAVE` permissions on the RDS for MySQL source DB instance. We recommend that you provide an account that is used solely for replication with the source DB instance.

**replication_user_password**

The password of the user ID specified in `replication_user_name`.

**mysql_binary_log_file_name**

The name of the binary log on the source DB instance that contains the replication information.

**mysql_binary_log_file_location**

The location in the `mysql_binary_log_file_name` binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source DB instance.

**ssl_encryption**

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

---

**Note**

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.
**channel_name**

The name of the replication channel. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

**Usage notes**

The master user must run the `mysql.rds_set_external_source_for_channel` procedure. This procedure must be run on the target RDS for MySQL DB instance on which you're creating the replication channel.

Before you run `mysql.rds_set_external_source_for_channel`, configure a replication user on the source DB instance with the privileges required for the multi-source replica. To connect the multi-source replica to the source DB instance, you must specify `replication_user_name` and `replication_user_password` values of a replication user that has **REPLICATION CLIENT** and **REPLICATION SLAVE** permissions on the source DB instance.

**To configure a replication user on the source DB instance**

1. Using the MySQL client of your choice, connect to the source DB instance and create a user account to be used for replication. The following is an example.

   ```sql
   Important
   As a security best practice, specify a password other than the placeholder value shown in the following examples.
   
   MySQL 8.0
   ```
   ```sql
   CREATE USER 'repl_user'@'example.com' IDENTIFIED WITH mysql_native_password BY 'password';
   ```

   MySQL 5.7
   ```sql
   CREATE USER 'repl_user'@'example.com' IDENTIFIED BY 'password';
   ```
2. On the source DB instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'example.com';
```

To use encrypted replication, configure the source DB instance to use SSL connections.

After calling `mysql.rds_set_external_source_for_channel` to configure this replication channel, you can call `mysql.rds_start_replication_for_channel` on the replica to start the replication process on the channel. You can call the section called “mysql.rds_reset_external_source_for_channel” to stop replication on the channel and remove the channel configuration from the replica.

When you call `mysql.rds_set_external_source_for_channel`, Amazon RDS records the time, user, and an action of set channel source in the `mysql.rds_history` table without channel-specific details, and in the `mysql.rds_replication_status` table, with the channel name. This information is recorded only for internal usage and monitoring purposes. To record the complete procedure call for auditing purpose, consider enabling audit logs or general logs, based on the specific requirements of your application.

**Examples**

When run on a RDS for MySQL DB instance, the following example configures a replication channel named `channel_1` on this DB instance to replicate data from the source specified by host `sourcedb.example.com` and port 3306.

```sql
call mysql.rds_set_external_source_for_channel(
    'sourcedb.example.com',
    3306,
    'repl_user',
    'password',
    'mysql-bin-changelog.0777',
    120,
    0,
    'channel_1');
```
mysql.rds_set_external_source_with_auto_position_for_channel

Configures a replication channel on an RDS for MySQL DB instance with an optional replication delay. The replication is based on global transaction identifiers (GTIDs).

⚠️ Important
To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group.

Syntax

```
CALL mysql.rds_set_external_source_with_auto_position_for_channel (
   host_name
   , host_port
   , replication_user_name
   , replication_user_password
   , ssl_encryption
   , delay
   , channel_name
);
```

Parameters

**host_name**

The host name or IP address of the RDS for MySQL source DB instance.

**host_port**

The port used by the RDS for MySQL source DB instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

**replication_user_name**

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the RDS for MySQL source DB instance. We recommend that you provide an account that is used solely for replication with the source DB instance.
replication_user_password

The password of the user ID specified in replication_user_name.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source DB instance.

The limit for this parameter is one day (86,400 seconds).

channel_name

The name of the replication channel. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the mysql.rds_set_external_source_with_auto_position_for_channel procedure. This procedure must be run on the target RDS for MySQL DB instance on which you're creating the replication channel.

Before you run rds_set_external_source_with_auto_position_for_channel, configure a replication user on the source DB instance with the privileges required for the multi-source replica. To connect the multi-source replica to the source DB instance, you must specify replication_user_name and replication_user_password values of a replication user that has REPLICATION_CLIENT and REPLICATION_SLAVE permissions on the source DB instance.
To configure a replication user on the source DB instance

1. Using the MySQL client of your choice, connect to the source DB instance and create a user account to be used for replication. The following is an example.

   **Important**
   As a security best practice, specify a password other than the placeholder value shown in the following examples.

   **MySQL 8.0**
   ```
   CREATE USER 'repl_user'@'example.com' IDENTIFIED WITH mysql_native_password BY 'password';
   ```

   **MySQL 5.7**
   ```
   CREATE USER 'repl_user'@'example.com' IDENTIFIED BY 'password';
   ```

2. On the source DB instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'example.com';
   ```

To use encrypted replication, configure the source DB instance to use SSL connections.

After calling `mysql.rds_set_external_source_with_auto_position_for_channel` to configure an Amazon RDS DB instance as a read replica on a specific channel, you can call the section called “mysql.rds_start_replication_for_channel” on the read replica to start the replication process on that channel.

After calling `mysql.rds_set_external_source_with_auto_position_for_channel` to configure this replication channel, you can call `mysql.rds_start_replication_for_channel` on the replica to start the replication process on the channel. You can call the section called “mysql.rds_reset_external_source_for_channel” to stop replication on the channel and remove the channel configuration from the replica.
Examples

When run on a RDS for MySQL DB instance, the following example configures a replication channel named `channel_1` on this DB instance to replicate data from the source specified by host `sourcedb.example.com` and port 3306. It sets the minimum replication delay to one hour (3,600 seconds). This means that a change from the source RDS for MySQL DB instance isn't applied on the multi-source replica for at least one hour.

```sql
call mysql.rds_set_external_source_with_auto_position_for_channel(
    'sourcedb.example.com',
    3306,
    'repl_user',
    'password',
    0,
    3600,
    'channel_1');
```

**mysql.rds_set_external_source_with_delay_for_channel**

Configures a replication channel on an RDS for MySQL DB instance with a specified replication delay.

⚠️ **Important**

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group](#).

**Syntax**

```sql
CALL mysql.rds_set_external_source_with_delay_for_channel (    host_name    , host_port    , replication_user_name    , replication_user_password    , mysql_binary_log_file_name    , mysql_binary_log_file_location    , ssl_encryption
```

Managing multi-source replication
Parameters

**host_name**

The host name or IP address of the RDS for MySQL source DB instance.

**host_port**

The port used by the RDS for MySQL source DB instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

**replication_user_name**

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the RDS for MySQL source DB instance. We recommend that you provide an account that is used solely for replication with the source DB instance.

**replication_user_password**

The password of the user ID specified in replication_user_name.

**mysql_binary_log_file_name**

The name of the binary log on the source DB instance contains the replication information.

**mysql_binary_log_file_location**

The location in the mysql_binary_log_file_name binary log at which replication will start reading the replication information.

You can determine the binlog file name and location by running SHOW MASTER STATUS on the source database instance.

**ssl_encryption**

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.
### Note

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

---

**delay**

The minimum number of seconds to delay replication from source DB instance.

The limit for this parameter is one day (86400 seconds).

**channel_name**

The name of the replication channel. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

---

**Usage notes**

The master user must run the `mysql.rds_set_external_source_with_delay_for_channel` procedure. This procedure must be run on the target RDS for MySQL DB instance on which you're creating the replication channel.

Before you run `mysql.rds_set_external_source_with_delay_for_channel`, configure a replication user on the source DB instance with the privileges required for the multi-source replica. To connect the multi-source replica to the source DB instance, you must specify `replication_user_name` and `replication_user_password` values of a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the source DB instance.

**To configure a replication user on the source DB instance**

1. Using the MySQL client of your choice, connect to the source DB instance and create a user account to be used for replication. The following is an example.

   ```sql
   Important
   As a security best practice, specify a password other than the placeholder value shown in the following examples.
   ```
MySQL 8.0

CREATE USER 'repl_user'@'example.com' IDENTIFIED WITH mysql_native_password BY 'password';

MySQL 5.7

CREATE USER 'repl_user'@'example.com' IDENTIFIED BY 'password';

2. On the source DB instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'example.com';

To use encrypted replication, configure the source DB instance to use SSL connections.

After calling `mysql.rds_set_external_source_with_delay_for_channel` to configure this replication channel, you can call `mysql.rds_start_replication_for_channel` on the replica to start the replication process on the channel. You can call the section called “`mysql.rds_reset_external_source_for_channel`” to stop replication on the channel and remove the channel configuration from the replica.

When you call `mysql.rds_set_external_source_with_delay_for_channel`, Amazon RDS records the time, user, and an action of set channel source in the `mysql.rds_history` table without channel-specific details, and in the `mysql.rds_replication_status` table, with the channel name. This information is recorded only for internal usage and monitoring purposes. To record the complete procedure call for auditing purpose, consider enabling audit logs or general logs, based on the specific requirements of your application.

Examples

When run on a RDS for MySQL DB instance, the following example configures a replication channel named `channel_1` on this DB instance to replicate data from the source specified by host `sourcedb.example.com` and port `3306`. It sets the minimum replication delay to one hour (3,600 seconds). This means that a change from the source RDS for MySQL DB instance isn't applied on the multi-source replica for at least one hour.
call mysql.rds_set_external_source_with_delay_for_channel('sourcedb.example.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000777', 120, 0, 3600, 'channel_1');

**mysql.rds_set_source_auto_position_for_channel**

Sets the replication mode for the specified channel to be based on either binary log file positions or on global transaction identifiers (GTIDs).

**Syntax**

```sql
CALL mysql.rds_set_source_auto_position_for_channel (auto_position_mode, channel_name);
```

**Parameters**

**auto_position_mode**

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.

**channel_name**

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.
Usage notes

The master user must run the `mysql.rds_set_source_auto_position_for_channel` procedure. This procedure restarts replication on the specified channel to apply the specified auto position mode.

Examples

The following example sets the auto position mode for channel_1 to use the GTID-based replication method.

```sql
CALL mysql.rds_set_source_auto_position_for_channel(1,'channel_1');
```

`mysql.rds_set_source_delay_for_channel`

Sets the minimum number of seconds to delay replication from the source database instance to the multi-source replica for the specified channel.

Syntax

```sql
CALL mysql.rds_set_source_delay_for_channel(delay, channel_name);
```

Parameters

`delay`

The minimum number of seconds to delay replication from the source DB instance.

The limit for this parameter is one day (86400 seconds).

`channel_name`

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_set_source_delay_for_channel` procedure. To use this procedure, first call `mysql.rds_stop_replication_for_channel` to stop the replication. Then, call this procedure to set the replication delay value. When the delay is set, call `mysql.rds_start_replication_for_channel` to restart the replication.
### Examples

The following example sets the delay for replication from the source database instance on channel_1 of the multi-source replica for at least one hour (3,600 seconds).

```sql
CALL mysql.rds_set_source_delay_for_channel(3600,'channel_1');
```

### mysql.rds_skip_repl_error_for_channel

Skips a binary log event and deletes a replication error on a MySQL DB multi-source replica for the specified channel.

#### Syntax

```sql
CALL mysql.rds_skip_repl_error_for_channel(channel_name);
```

#### Parameters

- **channel_name**

  The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

#### Usage notes

The master user must run the `mysql.rds_skip_repl_error_for_channel` procedure on a read replica. You can use this procedure in a similar way `mysql.rds_skip_repl_error` is used to skip an error on a read replica. For more information, see [Calling the mysql.rds_skip_repl_error procedure](#).

#### Note

To skip errors in GTID-based replication, we recommend that you use the procedure [the section called “mysql.rds_skip_transaction_with_gtid”](#) instead.

To determine if there are errors, run the MySQL `SHOW REPLICA STATUS FOR CHANNEL 'channel_name'` command. If a replication error isn't critical, you can run
mysql.rds_skip_repl_error_for_channel to skip the error. If there are multiple errors, mysql.rds_skip_repl_error_for_channel deletes the first error on the specified replication channel, then warns that others are present. You can then use SHOW REPLICA STATUS FOR CHANNEL 'channel_name'\G to determine the correct course of action for the next error. For information about the values returned, see SHOW REPLICA STATUS statement in the MySQL documentation.

**mysql.rds_start_replication_for_channel**

Initiates replication from an RDS for MySQL DB instance to a multi-source replica on the specified channel.

### Note

You can use the [mysql.rds_start_replication_until_for_channel](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/rds-mysql-reference.html#rds-mysql-reference.rds_start_replication_until_for_channel) or [mysql.rds_start_replication_until_gtid_for_channel](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/rds-mysql-reference.html#rds-mysql-reference.rds_start_replication_until_gtid_for_channel) stored procedure to initiate replication from an RDS for MySQL DB instance and stop replication at the specified binary log file location.

### Syntax

```
CALL mysql.rds_start_replication_for_channel(channel_name);
```

### Parameters

- **channel_name**

  The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

### Usage notes

The master user must run the `mysql.rds_start_replication_for_channel` procedure. After you import the data from the source RDS for MySQL DB instance, run this command on the multi-source replica to start replication on the specified channel.
Examples

The following example starts replication on channel_1 of the multi-source replica.

CALL mysql.rds_start_replication_for_channel('channel_1');

**mysql.rds_start_replication_until_for_channel**

Initiates replication from an RDS for MySQL DB instance on the specified channel and stops replication at the specified binary log file location.

**Syntax**

CALL mysql.rds_start_replication_until_for_channel (  
  replication_log_file  
  , replication_stop_point  
  , channel_name  
);  

**Parameters**

*replication_log_file*

The name of the binary log on the source DB instance contains the replication information.

*replication_stop_point*

The location in the replication_log_file binary log at which replication will stop.

*channel_name*

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

**Usage notes**

The master user must run the mysql.rds_start_replication_until_for_channel procedure. With this procedure, replication starts and then stops when the specified binlog file
position is reached. For version 8.0, the procedure stops only the SQL_Thread. For version 5.7, the procedure stops both the SQL_Thread and the IO_Thread.

The file name specified for the replication_log_file parameter must match the source DB instance binlog file name.

When the replication_stop_point parameter specifies a stop location that's in the past, replication is stopped immediately.

**Examples**

The following example initiates replication on channel_1, and replicates changes until it reaches location 120 in the mysql-bin-changelog.000777 binary log file.

```sql
call mysql.rds_start_replication_until_for_channel('mysql-bin-changelog.000777', 120, 'channel_1');
```

**mysql.rds_start_replication_until_gtid_for_channel**

Initiates replication on the specified channel from an RDS for MySQL DB instance and stops replication at the specified global transaction identifier (GTID).

**Syntax**

```sql
CALL mysql.rds_start_replication_until_gtid_for_channel(gtid, channel_name);
```

**Parameters**

`gtid`

The GTID after which to stop replication.

`channel_name`

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.
Usage notes

The master user must run the `mysql.rds_start_replication_until_gtid_for_channel` procedure. The procedure starts replication on the specified channel and applies all changes up to the specified GTID value. Then, it stops replication on the channel.

When the `gtid` parameter specifies a transaction that has already been run by the replica, replication is stopped immediately.

Before you run this procedure, you must disable multi-threaded replication by setting the value of `replica_parallel_workers` or `slave_parallel_workers` to 0.

Examples

The following example initiates replication on `channel_1`, and replicates changes until it reaches GTID `3E11FA47-71CA-11E1-9E33-C80AA9429562:23`.

```sql
call mysql.rds_start_replication_until_gtid_for_channel('3E11FA47-71CA-11E1-9E33-C80AA9429562:23','channel_1');
```

`mysql.rds_stop_replication_for_channel`

Stops replication from a MySQL DB instance on the specified channel.

Syntax

```sql
CALL mysql.rds_stop_replication_for_channel(channel_name);
```

Parameters

`channel_name`

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_stop_replication_for_channel` procedure.
Examples

The following example stops replication on channel_1 of the multi-source replica.

```sql
CALL mysql.rds_stop_replication_for_channel('channel_1');
```
Managing the Global Status History

Amazon RDS provides a set of procedures that take snapshots of the values of status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure is called Global Status History. For more information, see Managing the Global Status History.

The following stored procedures manage how the Global Status History is collected and maintained.

Topics

- `mysql.rds_collect_global_status_history`
- `mysql.rds_disable_gsh_collector`
- `mysql.rds_disable_gsh_rotation`
- `mysql.rds_enable_gsh_collector`
- `mysql.rds_enable_gsh_rotation`
- `mysql.rds_rotate_global_status_history`
- `mysql.rds_set_gsh_collector`
- `mysql.rds_set_gsh_rotation`

`mysql.rds_collect_global_status_history`

Takes a snapshot on demand for the Global Status History.

**Syntax**

```sql
CALL mysql.rds_collect_global_status_history;
```

`mysql.rds_disable_gsh_collector`

Turns off snapshots taken by the Global Status History.

**Syntax**

```sql
CALL mysql.rds_disable_gsh_collector;
```
**mysql.rds_disable_gsh_rotation**

Turns off rotation of the `mysql.global_status_history` table.

**Syntax**

```sql
CALL mysql.rds_disable_gsh_rotation;
```

**mysql.rds_enable_gsh_collector**

Turns on the Global Status History to take default snapshots at intervals specified by `rds_set_gsh_collector`.

**Syntax**

```sql
CALL mysql.rds_enable_gsh_collector;
```

**mysql.rds_enable_gsh_rotation**

Turns on rotation of the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` at intervals specified by `rds_set_gsh_rotation`.

**Syntax**

```sql
CALL mysql.rds_enable_gsh_rotation;
```

**mysql.rds_rotate_global_status_history**

Rotates the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` on demand.

**Syntax**

```sql
CALL mysql.rds_rotate_global_status_history;
```

**mysql.rds_set_gsh_collector**

Specifies the interval, in minutes, between snapshots taken by the Global Status History.
Syntax

CALL mysql.rds_set_gsh_collector(intervalPeriod);

Parameters

intervalPeriod

The interval, in minutes, between snapshots. Default value is 5.

mysql.rds_set_gsh_rotation

Specifies the interval, in days, between rotations of the mysql.global_status_history table.

Syntax

CALL mysql.rds_set_gsh_rotation(intervalPeriod);

Parameters

intervalPeriod

The interval, in days, between table rotations. Default value is 7.
Replicating

The following stored procedures control how transactions are replicated from an external database into RDS for MySQL, or from RDS for MySQL to an external database. To learn how to use replication based on global transaction identifiers (GTIDs) with RDS for MySQL, see Using GTID-based replication for Amazon RDS for MySQL.

Topics

- `mysql.rds_next_master_log`
- `mysql.rds_reset_external_master`
- `mysql.rds_set_external_master`
- `mysql.rds_set_external_master_with_auto_position`
- `mysql.rds_set_external_master_with_delay`
- `mysql.rds_set_master_auto_position`
- `mysql.rds_set_source_delay`
- `mysql.rds_skip_transaction_with_gtid`
- `mysql.rds_skip_repl_error`
- `mysql.rds_start_replication`
- `mysql.rds_start_replication_until`
- `mysql.rds_start_replication_until_gtid`
- `mysql.rds_stop_replication`

`mysql.rds_next_master_log`

Changes the source database instance log position to the start of the next binary log on the source database instance. Use this procedure only if you are receiving replication I/O error 1236 on a read replica.

**Syntax**

```sql
CALL mysql.rds_next_master_log(
    curr_master_log
);
```
Parameters

`curr_master_log`

The index of the current master log file. For example, if the current file is named `mysql-bin-changelog.012345`, then the index is 12345. To determine the current master log file name, run the `SHOW REPLICA STATUS` command and view the `Master_Log_File` field.

Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

Usage notes

The master user must run the `mysql.rds_next_master_log` procedure.

Warning

Call `mysql.rds_next_master_log` only if replication fails after a failover of a Multi-AZ DB instance that is the replication source, and the `Last_IO_Errno` field of `SHOW REPLICA STATUS` reports I/O error 1236.

Calling `mysql.rds_next_master_log` can result in data loss in the read replica if transactions in the source instance were not written to the binary log on disk before the failover event occurred.

You can reduce the chance of this happening by setting the source instance parameters `sync_binlog` and `innodb_support_xa` to 1, although this might reduce performance.

For more information, see Troubleshooting a MySQL read replica problem.

Examples

Assume replication fails on an RDS for MySQL read replica. Running `SHOW REPLICA STATUS\G` on the read replica returns the following result:

```
*************************** 1. row ***************************
Replica_IO_State:
  Source_HOST: myhost.XXXXXXXXXXXrrrr-1.rds.amazonaws.com
```

Source_SSL_Verify_Server_Cert: No
Last_IO_Errno: 1236
Last_IO_Error: Got fatal error 1236 from master when reading data from binary log: 'Client requested master to start replication from impossible position; the first event 'mysql-bin-changelog.013406' at 1219393, the last event read from '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4, the last byte read from '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4.'
Last_SQL_Errno: 0
Last_SQL_Error:
Replicate_Ignore_Server_Ids:
Source_Server_Id: 67285976
The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Master_Log_File` field shows that the file name is `mysql-bin-changelog.012345`, which means that the log file index is 12345. To resolve the error, you can call `mysql.rds_next_master_log` with the following parameter:

```sql
CALL mysql.rds_next_master_log(12345);
```

---

### Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

---

### mysql.rds_reset_external_master

Reconfigures an RDS for MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS.

---

#### Important

To run this procedure, autocommit must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group](#).

---

### Syntax

```sql
CALL mysql.rds_reset_external_master;
```

### Usage notes

The master user must run the `mysql.rds_reset_external_master` procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.
We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas.

For more information about using replication to import data from an instance of MySQL running external to Amazon RDS, see Configuring binary log file position replication with an external source instance.

**mysql.rds_set_external_master**

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

**Important**

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group.

**Note**

You can use the mysql.rds_set_external_master_with_delay stored procedure to configure an external source database instance and delayed replication.

**Syntax**

```
CALL mysql.rds_set_external_master (host_name)
```
Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in replication_user_name.

mysql_binary_log_file_name

The name of the binary log on the source database instance that contains the replication information.

mysql_binary_log_file_location

The location in the mysql_binary_log_file_name binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running SHOW MASTER STATUS on the source database instance.
ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

Usage notes

The master user must run the mysql.rds_set_external_master procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run mysql.rds_set_external_master, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify replication_user_name and replication_user_password values that indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

MySQL 5.7

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

MySQL 8.0

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
```
Note
Specify a password other than the prompt shown here as a security best practice.

2. On the external instance of MySQL, grant REPLICATION_CLIENT and REPLICATION_SLAVE privileges to your replication user. The following example grants REPLICATION_CLIENT and REPLICATION_SLAVE privileges on all databases for the 'repl_user' user for your domain.

MySQL 5.7

```
GRANT REPLICATION_CLIENT, REPLICATION_SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY 'password';
```

MySQL 8.0

```
GRANT REPLICATION_CLIENT, REPLICATION_SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

To use encrypted replication, configure source database instance to use SSL connections.

Note
We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see [Working with DB instance read replicas](#).

After calling `mysql.rds_set_external_master` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` on the read replica to start the replication process. You can call `mysql.rds_resetExternalMaster` to remove the read replica configuration.

When `mysql.rds_set_external_master` is called, Amazon RDS records the time, user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.
Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

call mysql.rds_set_external_master(
    'Externaldb.some.com',
    3306,
    'repl_user',
    'password',
    'mysql-bin-changelog.0777',
    120,
    0);

mysql.rds_set_external_master_with_auto_position

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. This procedure also configures delayed replication and replication based on global transaction identifiers (GTIDs).

⚠️ Important

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group.

Syntax

CALL mysql.rds_set_external_master_with_auto_position ( host_name, host_port, replication_user_name, replication_user_password, ssl_encryption, delay );
Parameters

*host_name*

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

*host_port*

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

*replication_user_name*

The ID of a user with `REPLICATION_CLIENT` and `REPLICATION_SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

*replication_user_password*

The password of the user ID specified in `replication_user_name`.

*ssl_encryption*

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

**Note**

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

*delay*

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86,400 seconds).
Usage notes

The master user must run the `mysql.rds_set_external_master_with_auto_position` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

Before you run `mysql.rds_set_external_master_with_auto_position`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
   ```

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the `repl_user` user for your domain.

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'SomePassW0rd'
   ```

For more information, see Configuring binary log file position replication with an external source instance.

Note

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored
After calling `mysql.rds_set_external_master_with_auto_position` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` on the read replica to start the replication process. You can call `mysql.rds_reset_external_master` to remove the read replica configuration.

When you call `mysql.rds_set_external_master_with_auto_position`, Amazon RDS records the time, the user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_master_with_auto_position` procedure. After the `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the `mysql.rds_skip_transaction_with_gtid` stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication for Amazon RDS for MySQL.

**Examples**

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

```sql
call mysql.rds_set_external_master_with_auto_position(
    'Externaldb.some.com',
    3306,
    'repl_user',
...)
mysql.rds_set_external_master_with_delay

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS and configures delayed replication.

⚠️ Important

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group.

Syntax

```
CALL mysql.rds_set_external_master_with_delay (    
    host_name    
, host_port    
, replication_user_name    
, replication_user_password    
, mysql_binary_log_file_name    
, mysql_binary_log_file_location    
, ssl_encryption    
, delay    
);    
```

Parameters

**host_name**

The host name or IP address of the MySQL instance running external to Amazon RDS that will become the source database instance.

**host_port**

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.
replication_user_name

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in replication_user_name.

mysql_binary_log_file_name

The name of the binary log on the source database instance contains the replication information.

mysql_binary_log_file_location

The location in the mysql_binary_log_file_name binary log at which replication will start reading the replication information.

You can determine the binlog file name and location by running SHOW MASTER STATUS on the source database instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86400 seconds).
Usage notes

The master user must run the `mysql.rds_set_external_master_with_delay` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run `mysql.rds_set_external_master_with_delay`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has `REPLICATION_CLIENT` and `REPLICATION_SLAVE` permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   ```sql
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
   ```

2. On the external instance of MySQL, grant `REPLICATION_CLIENT` and `REPLICATION_SLAVE` privileges to your replication user. The following example grants `REPLICATION_CLIENT` and `REPLICATION_SLAVE` privileges on all databases for the 'repl_user' user for your domain.

   ```sql
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'SomePassW0rd'
   ```

For more information, see [Configuring binary log file position replication with an external source instance](#).

Note

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to
After calling `mysql.rds_set_external_master_with_delay` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` on the read replica to start the replication process. You can call `mysql.rds_reset_external_master` to remove the read replica configuration.

When you call `mysql.rds_set_external_master_with_delay`, Amazon RDS records the time, the user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_master_with_delay` procedure. After the `mysql.rds_start_replication_until` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance](#).

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the `mysql.rds_skip_transaction_with_gtid` stored procedure. For more information about working with GTID-based replication, see [Using GTID-based replication for Amazon RDS for MySQL](#).

The `mysql.rds_set_external_master_with_delay` procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

### Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source
database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

call mysql.rds_set_external_master_with_delay(
    'Externaldb.some.com',
    3306,
    'repl_user',
    'SomePassW0rd',
    'mysql-bin-changelog.000777',
    120,
    0,
    3600);

mysql.rds_set_master_auto_position

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

Syntax

CALL mysql.rds_set_master_auto_position ( 
    auto_position_mode
);

Parameters

auto_position_mode

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.

Usage notes

The master user must run the mysql.rds_set_master_auto_position procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.
**mysql.rds_set_source_delay**

Sets the minimum number of seconds to delay replication from source database instance to the current read replica. Use this procedure when you are connected to a read replica to delay replication from its source database instance.

**Syntax**

```sql
CALL mysql.rds_set_source_delay(
    delay
);
```

**Parameters**

*delay*

The minimum number of seconds to delay replication from the source database instance.

The limit for this parameter is one day (86400 seconds).

**Usage notes**

The master user must run the `mysql.rds_set_source_delay` procedure.

For disaster recovery, you can use this procedure with the `mysql.rds_start_replication_until` stored procedure or the `mysql.rds_start_replication_until_gtid` stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_source_delay` procedure. After the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the `mysql.rds_skip_transaction_with_gtid` stored procedure. For more information on GTID-based replication, see Using GTID-based replication for Amazon RDS for MySQL.

The `mysql.rds_set_source_delay` procedure is available in these versions of RDS for MySQL:
**Examples**

To delay replication from source database instance to the current read replica for at least one hour (3,600 seconds), you can call `mysql.rds_set_source_delay` with the following parameter:

```sql
CALL mysql.rds_set_source_delay(3600);
```

### mysql.rds_skip_transaction_with_gtid

Skips replication of a transaction with the specified global transaction identifier (GTID) on a MySQL DB instance.

You can use this procedure for disaster recovery when a specific GTID transaction is known to cause a problem. Use this stored procedure to skip the problematic transaction. Examples of problematic transactions include transactions that disable replication, delete important data, or cause the DB instance to become unavailable.

**Syntax**

```sql
CALL mysql.rds_skip_transaction_with_gtid (gtid_to_skip);
```

**Parameters**

`gtid_to_skip`

The GTID of the replication transaction to skip.

**Usage notes**

The master user must run the `mysql.rds_skip_transaction_with_gtid` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.
Examples

The following example skips replication of the transaction with the GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23.

```
CALL mysql.rds_skip_transaction_with_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

mysql.rds_skip_repl_error

Skips and deletes a replication error on a MySQL DB read replica.

Syntax

```
CALL mysql.rds_skip_repl_error;
```

Usage notes

The master user must run the mysql.rds_skip_repl_error procedure on a read replica. For more information about this procedure, see Calling the mysql.rds_skip_repl_error procedure.

To determine if there are errors, run the MySQL SHOW REPLICA STATUS\G command. If a replication error isn’t critical, you can run mysql.rds_skip_repl_error to skip the error. If there are multiple errors, mysql.rds_skip_repl_error deletes the first error, then warns that others are present. You can then use SHOW REPLICA STATUS\G to determine the correct course of action for the next error. For information about the values returned, see SHOW REPLICA STATUS statement in the MySQL documentation.

Note

Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

For more information about addressing replication errors with Amazon RDS, see Troubleshooting a MySQL read replica problem.

Replication stopped error

When you call the mysql.rds_skip_repl_error procedure, you might receive an error message stating that the replica is down or disabled.
This error message appears if you run the procedure on the primary instance instead of the read replica. You must run this procedure on the read replica for the procedure to work.

This error message might also appear if you run the procedure on the read replica, but replication can't be restarted successfully.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log (binlog) files. In this case, you might encounter a fatal error due to binlog files being purged before they have been replayed on the read replica. This purge causes replication to stop, and you can no longer call the mysql.rds_skip_repl_error command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binlog files are retained on your source database instance. After you have increased the binlog retention time, you can restart replication and call the mysql.rds_skip_repl_error command as needed.

To set the binlog retention time, use the mysql.rds_set_configuration procedure and specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster. The following example sets the retention period for binlog files to 48 hours.

```sql
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

**mysql.rds_start_replication**

Initiates replication from an RDS for MySQL DB instance.

 réuss 

You can use the mysql.rds_start_replication_until or mysql.rds_start_replication_until_gtid stored procedure to initiate replication from an RDS for MySQL DB instance and stop replication at the specified binary log file location.

**Syntax**

```sql
CALL mysql.rds_start_replication;
```
Usage notes

The master user must run the `mysql.rds_start_replication` procedure.

To import data from an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` on the read replica to start the replication process after you call `mysql.rds_set_external_master` to build the replication configuration. For more information, see [Restoring a backup into a MySQL DB instance](#).

To export data to an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see [Exporting data from a MySQL DB instance by using replication](#).

You can also call `mysql.rds_start_replication` on the read replica to restart any replication process that you previously stopped by calling `mysql.rds_stop_replication`. For more information, see [Working with DB instance read replicas](#).

### `mysql.rds_start_replication_until`

Initiates replication from an RDS for MySQL DB instance and stops replication at the specified binary log file location.

**Syntax**

```sql
CALL mysql.rds_start_replication_until ( replication_log_file , replication_stop_point ) ;
```

**Parameters**

- `replication_log_file`
  
  The name of the binary log on the source database instance that contains the replication information.

- `replication_stop_point`
  
  The location in the `replication_log_file` binary log at which replication will stop.
Usage notes

The master user must run the `mysql.rds_start_replication_until` procedure.

The `mysql.rds_start_replication_until` procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

You can use this procedure with delayed replication for disaster recovery. If you have delayed replication configured, you can use this procedure to roll forward changes to a delayed read replica to the time just before a disaster. After this procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

You can configure delayed replication using the following stored procedures:

- `mysql.rds_set_configuration`
- `mysql.rds_set_external_master_with_delay`
- `mysql.rds_set_source_delay`

The file name specified for the `replication_log_file` parameter must match the source database instance binlog file name.

When the `replication_stop_point` parameter specifies a stop location that is in the past, replication is stopped immediately.

Examples

The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file.

```sql
call mysql.rds_start_replication_until(
    'mysql-bin-changelog.000777',
    120);
```
mysql.rds_start_replication_until_gtid

Initiates replication from an RDS for MySQL DB instance and stops replication immediately after the specified global transaction identifier (GTID).

Syntax

```
CALL mysql.rds_start_replication_until_gtid(gtid);
```

Parameters

`gtid`

The GTID after which replication is to stop.

Usage notes

The master user must run the `mysql.rds_start_replication_until_gtid` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

You can use this procedure with delayed replication for disaster recovery. If you have delayed replication configured, you can use this procedure to roll forward changes to a delayed read replica to the time just before a disaster. After this procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance](#).

You can configure delayed replication using the following stored procedures:

- `mysql.rds_set_configuration`
- `mysql.rds_set_external_master_with_delay`
- `mysql.rds_set_source_delay`

When the `gtid` parameter specifies a transaction that has already been run by the replica, replication is stopped immediately.
Examples

The following example initiates replication and replicates changes until it reaches GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23.

```
call mysql.rds_start_replication_until_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

**mysql.rds_stop_replication**

Stops replication from a MySQL DB instance.

**Syntax**

```
CALL mysql.rds_stop_replication;
```

**Usage notes**

The master user must run the `mysql.rds_stop_replication` procedure.

If you are configuring replication to import data from an instance of MySQL running external to Amazon RDS, you call `mysql.rds_stop_replication` on the read replica to stop the replication process after the import has completed. For more information, see [Restoring a backup into a MySQL DB instance](#).

If you are configuring replication to export data to an instance of MySQL external to Amazon RDS, you call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see [Exporting data from a MySQL DB instance by using replication](#).

You can also use `mysql.rds_stop_replication` to stop replication between two Amazon RDS DB instances. You typically stop replication to perform a long running operation on the read replica, such as creating a large index on the read replica. You can restart any replication process that you stopped by calling `mysql.rds_start_replication` on the read replica. For more information, see [Working with DB instance read replicas](#).
Warming the InnoDB cache

The following stored procedures save, load, or cancel loading the InnoDB buffer pool on RDS for MySQL DB instances. For more information, see InnoDB cache warming for MySQL on Amazon RDS.

Topics

• mysql.rds_innodb_buffer_pool_dump_now
• mysql.rds_innodb_buffer_pool_load_abort
• mysql.rds_innodb_buffer_pool_load_now

mysql.rds_innodb_buffer_pool_dump_now

Dumps the current state of the buffer pool to disk.

Syntax

CALL mysql.rds_innodb_buffer_pool_dump_now();

Usage notes

The master user must run the mysql.rds_innodb_buffer_pool_dump_now procedure.

mysql.rds_innodb_buffer_pool_load_abort

Cancels a load of the saved buffer pool state while in progress.

Syntax

CALL mysql.rds_innodb_buffer_pool_load_abort();

Usage notes

The master user must run the mysql.rds_innodb_buffer_pool_load_abort procedure.

mysql.rds_innodb_buffer_pool_load_now

Loads the saved state of the buffer pool from disk.
Syntax

CALL mysql.rds_innodb_buffer_pool_load_now();

Usage notes

The master user must run the `mysql.rds_innodb_buffer_pool_load_now` procedure.
Amazon RDS for Oracle

Amazon RDS supports DB instances that run the following versions and editions of Oracle Database:

- Oracle Database 21c (21.0.0.0)
- Oracle Database 19c (19.0.0.0)

**Note**
Oracle Database 11g, Oracle Database 12c, and Oracle Database 18c are legacy versions that are no longer supported in Amazon RDS.

Before creating a DB instance, complete the steps in the Setting up for Amazon RDS section of this guide. When you create a DB instance using your master account, the account gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts. You can't use SYS, SYSTEM, or other Oracle-supplied administrative accounts.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running Oracle inside a VPC. You can also add features to your Oracle DB instance by enabling various options. Amazon RDS supports Multi-AZ deployments for Oracle as a high-availability, failover solution.

**Important**
To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced privileges. You can access your database using standard SQL clients such as
Oracle SQL*Plus. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

Overview of Oracle on Amazon RDS

You can read the following sections to get an overview of RDS for Oracle.

Topics

• RDS for Oracle features
• RDS for Oracle releases
• RDS for Oracle licensing options
• RDS for Oracle users and privileges
• RDS for Oracle instance classes
• RDS for Oracle database architecture
• RDS for Oracle parameters
• RDS for Oracle character sets
• RDS for Oracle limitations
RDS for Oracle features

Amazon RDS for Oracle supports most of the features and capabilities of Oracle Database. Some features might have limited support or restricted privileges. Some features are only available in Enterprise Edition, and some require additional licenses. For more information about Oracle Database features for specific Oracle Database versions, see the *Oracle Database Licensing Information User Manual* for the version you're using.

You can filter new Amazon RDS features on the [What's New with Database?](#) page. For Products, choose Amazon RDS. Then search using keywords such as *Oracle 2022*.

### Note

The following lists are not exhaustive.

**Topics**

- New features in RDS for Oracle
- Supported features in RDS for Oracle
- Unsupported features in RDS for Oracle

### New features in RDS for Oracle

To see new features in RDS for Oracle, use the following techniques:

- Search [Document history](#) for the keyword *Oracle*.
- Filter new Amazon RDS features on the [What's New with Database?](#) page. For Products, choose Amazon RDS. Then search for *Oracle YYYY*, where *YYYY* is a year such as 2024.

### Supported features in RDS for Oracle

Amazon RDS for Oracle supports the following Oracle Database features:

- Advanced Compression
- Application Express (APEX)

For more information, see [Oracle Application Express (APEX)](#).
• Automatic Memory Management
• Automatic Undo Management
• Automatic Workload Repository (AWR)

For more information, see Generating performance reports with Automatic Workload Repository (AWR).

• Active Data Guard with Maximum Performance in the same AWS Region or across AWS Regions

For more information, see Working with read replicas for Amazon RDS for Oracle.

• Blockchain tables (Oracle Database 21c and higher)

For more information, see Managing Blockchain Tables in the Oracle Database documentation.

• Continuous Query Notification (version 12.1.0.2.v7 and higher)

For more information, see Using Continuous Query Notification (CQN) in the Oracle documentation.

• Data Redaction

• Database Change Notification

For more information, see Database Change Notification in the Oracle documentation.

Note

This feature changes to Continuous Query Notification in Oracle Database 12c Release 1 (12.1) and higher.

• Database In-Memory (Oracle Database 12c and higher)

• Distributed Queries and Transactions

• Edition-Based Redefinition

For more information, see Setting the default edition for a DB instance.

• EM Express (12c and higher)

For more information, see Oracle Enterprise Manager.

• Fine-Grained Auditing

• Flashback Table, Flashback Query, Flashback Transaction Query

• Gradual password rollover for applications (Oracle Database 21c and higher)
For more information, see Managing Gradual Database Password Rollover for Applications in the Oracle Database documentation.

- **HugePages**

  For more information, see Turning on HugePages for an RDS for Oracle instance.

- **Import/export (legacy and Data Pump) and SQL*Loader**

  For more information, see Importing data into Oracle on Amazon RDS.

- **Java Virtual Machine (JVM)**

  For more information, see Oracle Java virtual machine.

- **JavaScript (Oracle Database 21c and higher)**

  For more information, see DBMS_MLE in the Oracle Database documentation.

- **Label Security (Oracle Database 12c and higher)**

  For more information, see Oracle Label Security.

- **Locator**

  For more information, see Oracle Locator.

- **Materialized Views**

- **Multimedia**

  For more information, see Oracle Multimedia.

- **Multitenant**

  The Oracle multitenant architecture is supported for all Oracle Database 19c and higher releases. For more information, see Working with CDBs in RDS for Oracle.

- **Network encryption**

  For more information, see Oracle native network encryption and Oracle Secure Sockets Layer.

- **Partitioning**

- **Real Application Testing**

  To use the full capture and replay capabilities, you must use Amazon Elastic File System (Amazon EFS) to access files generated by Oracle Real Application Testing. For more information, see
Amazon EFS integration and the blog post Use Oracle Real Application Testing features with Amazon RDS for Oracle.

- Sharding at the application level (but not the Oracle Sharding feature)
- Spatial and Graph
  For more information, see Oracle Spatial.
- Star Query Optimization
- Streams and Advanced Queuing
- Summary Management – Materialized View Query Rewrite
- Text (File and URL data store types are not supported)
- Total Recall
- Transparent Data Encryption (TDE)
  For more information, see Oracle Transparent Data Encryption.
- Unified Auditing, Mixed Mode
  For more information, see Mixed mode auditing in the Oracle documentation.
- XML DB (without the XML DB Protocol Server)
  For more information, see Oracle XML DB.
- Virtual Private Database

Unsupported features in RDS for Oracle

Amazon RDS for Oracle doesn't support the following Oracle Database features:

- Automatic Storage Management (ASM)
- Database Vault
- Flashback Database

Note
For alternative solutions, see the AWS Database Blog entry Alternatives to the Oracle flashback database feature in Amazon RDS for Oracle.

- FTP and SFTP
• Hybrid partitioned tables
• Messaging Gateway
• Oracle Enterprise Manager Cloud Control Management Repository
• Real Application Clusters (Oracle RAC)
• Real Application Security (RAS)
• Unified Auditing, Pure Mode
• Workspace Manager (WMSYS) schema

⚠️ **Note**
The preceding list is not exhaustive.

⚠️ **Warning**
In general, Amazon RDS doesn't prevent you from creating schemas for unsupported features. However, if you create schemas for Oracle features and components that require SYSDBA privileges, you can damage the data dictionary and affect the availability of your DB instance. Use only supported features and schemas that are available in Adding options to Oracle DB instances.

**RDS for Oracle releases**

Amazon RDS for Oracle supports multiple Oracle Database releases.

⚠️ **Note**
For information about upgrading your releases, see Upgrading the RDS for Oracle DB engine.

**Topics**

• [Oracle Database 19c with Amazon RDS](#)
Oracle Database 21c with Amazon RDS

Amazon RDS supports Oracle Database 21c, which includes Oracle Enterprise Edition and Oracle Standard Edition 2. Oracle Database 21c (21.0.0.0) includes many new features and updates from the previous version. A key change is that Oracle Database 21c supports only the multitenant architecture: you can no longer create a database as a traditional non-CDB. To learn more about the differences between CDBs and non-CDBs, see Limitations of RDS for Oracle CDBs.

In this section, you can find the features and changes important to using Oracle Database 21c (21.0.0.0) on Amazon RDS. For a complete list of the changes, see the Oracle database 21c documentation. For a complete list of features supported by each Oracle Database 21c edition, see Permitted features, options, and management packs by Oracle database offering in the Oracle documentation.

Amazon RDS parameter changes for Oracle Database 21c (21.0.0.0)

Oracle Database 21c (21.0.0.0) includes several new parameters and parameters with new ranges and new default values.

Topics

- New parameters
- Changes for the compatible parameter
- Removed parameters

New parameters

The following table shows the new Amazon RDS parameters for Oracle Database 21c (21.0.0.0).

<table>
<thead>
<tr>
<th>Name</th>
<th>Range of values</th>
<th>Default value</th>
<th>Modifiable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>blockchain_table_max_no_drop</td>
<td>NONE</td>
<td>0</td>
<td>NONE</td>
<td>Y</td>
</tr>
<tr>
<td>Name</td>
<td>Range of values</td>
<td>Default value</td>
<td>Modifiable</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------------</td>
<td>---------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>dbnest_enable</td>
<td>NONE</td>
<td>CDB_RESOURCE_PDB_ALL</td>
<td>NONE</td>
<td>N</td>
</tr>
<tr>
<td>dbnest_pdb_fs_conf</td>
<td>NONE</td>
<td>pathname</td>
<td>NONE</td>
<td>N</td>
</tr>
<tr>
<td>diagnostics_control</td>
<td>ERROR</td>
<td>WARNING</td>
<td>IGNORE</td>
<td>Y</td>
</tr>
<tr>
<td>drcp_dedicated_opt</td>
<td>YES</td>
<td>NO</td>
<td>YES</td>
<td>Y</td>
</tr>
<tr>
<td>enable_per_pdb_drcp</td>
<td>true</td>
<td>false</td>
<td>true</td>
<td>N</td>
</tr>
<tr>
<td>inmemory_deep_vectorization</td>
<td>true</td>
<td>false</td>
<td>true</td>
<td>Y</td>
</tr>
<tr>
<td>Name</td>
<td>Range of values</td>
<td>Default value</td>
<td>Modifiable</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-----------------</td>
<td>---------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>mandatory_user_profile</td>
<td>profile_name</td>
<td>N/A</td>
<td>N</td>
<td>Specifies the mandatory user profile for a CDB or PDB.</td>
</tr>
<tr>
<td>optimizer_capture_sql_quarantine</td>
<td>true</td>
<td>false</td>
<td>Y</td>
<td>Enables or disables the deep vectorization framework.</td>
</tr>
<tr>
<td>optimizer_use_sql_quarantine</td>
<td>true</td>
<td>false</td>
<td>Y</td>
<td>Enables or disables the automatic creation of SQL Quarantine configurations.</td>
</tr>
<tr>
<td>result_cache_execution_threshold</td>
<td>0 to 36 687194767</td>
<td>2</td>
<td>Y</td>
<td>Specifies the maximum number of times a PL/SQL function can be executed before its result is stored in the result cache.</td>
</tr>
<tr>
<td>result_cache_max_temp_result</td>
<td>0 to 100</td>
<td>5</td>
<td>Y</td>
<td>Specifies the percentage of RESULT_CACHE_MAX_TEMP_SIZE that any single cached query result can consume.</td>
</tr>
<tr>
<td>result_cache_max_temp_size</td>
<td>0 to 219902325 5552</td>
<td>RESULT_CACHE_SIZE * 10</td>
<td>Y</td>
<td>Specifies the maximum amount of temporary tablespace (in bytes) that can be consumed by the result cache.</td>
</tr>
<tr>
<td>Name</td>
<td>Range of values</td>
<td>Default value</td>
<td>Modifiable</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>----------------------------------------------------------------------------------</td>
<td>---------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sga_min_size</td>
<td>0 to 5552 (maximum value is 50% of sga_target)</td>
<td>0</td>
<td>Y</td>
<td>Indicates a possible minimum value for SGA usage of a pluggable database (PDB).</td>
</tr>
<tr>
<td>tablespace_encrypt ion_default_algorithm</td>
<td>GOST256</td>
<td>SEED128</td>
<td>ARIA256</td>
<td>ARIA192</td>
</tr>
</tbody>
</table>

**Changes for the compatible parameter**

The compatible parameter has a new maximum value for Oracle Database 21c (21.0.0.0) on Amazon RDS. The following table shows the new default value.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Oracle Database 21c (21.0.0.0) maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>compatible</td>
<td>21.0.0</td>
</tr>
</tbody>
</table>

**Removed parameters**

The following parameters were removed in Oracle Database 21c (21.0.0.0):

- remote_os_authent
Amazon RDS parameter changes for Oracle Database 19c (19.0.0.0)

Oracle Database 19c (19.0.0.0) includes several new parameters and parameters with new ranges and new default values.

Topics

- **New parameters**
- **Changes to the compatible parameter**
- **Removed parameters**

New parameters

The following table shows the new Amazon RDS parameters for Oracle Database 19c (19.0.0.0).

<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Modifi</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_signature_enable</td>
<td>TRUE, FALSE (default)</td>
<td>Y</td>
<td>Enables or disables the LOB locator signature feature.</td>
</tr>
<tr>
<td>max_datapump_parallel_per_job</td>
<td>1 to 1024, or AUTO</td>
<td>Y</td>
<td>Specifies the maximum number of parallel processes allowed for each Oracle Data Pump job.</td>
</tr>
</tbody>
</table>
Changes to the compatible parameter

The compatible parameter has a new maximum value for Oracle Database 19c (19.0.0.0) on Amazon RDS. The following table shows the new default value.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Oracle Database 19c (19.0.0.0) maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>compatible</td>
<td>19.0.0</td>
</tr>
</tbody>
</table>

Removed parameters

The following parameters were removed in Oracle Database 19c (19.0.0.0):

- exafusion_enabled
- max_connections
- o7_dictionary_access

Oracle Database 12c with Amazon RDS

Amazon RDS has deprecated support for Oracle Database 12c on both Oracle Enterprise Edition and Oracle Standard Edition 2.

Topics

- Oracle Database 12c Release 2 (12.2.0.1) with Amazon RDS
- Oracle Database 12c Release 1 (12.1.0.2) with Amazon RDS

Oracle Database 12c Release 2 (12.2.0.1) with Amazon RDS

On March 31, 2022, Oracle Corporation deprecated support for Oracle Database 12c Release 2 (12.2.0.1) for BYOL and LI. On this date, the release moved from Oracle Extended Support to Oracle Sustaining Support, indicating the end of support for this release. For more information, see the end of support timeline on AWS re:Post.

<table>
<thead>
<tr>
<th>Date</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>April 1, 2022</td>
<td>Amazon RDS began automatic upgrades of your Oracle Database 12c Release 2 (12.2.0.1) instances to Oracle Database 19c.</td>
</tr>
</tbody>
</table>
Amazon RDS began automatic upgrades to Oracle Database 19c for any Oracle Database 12c Release 2 (12.2.0.1) DB instances restored from snapshots. The automatic upgrade occurs during maintenance windows. If maintenance windows aren't available when the upgrade needs to occur, Amazon RDS upgrades the engine immediately.

<table>
<thead>

</tr>
</tbody>
</table>

**Oracle Database 12c Release 1 (12.1.0.2) with Amazon RDS**

On July 31, 2022, Amazon RDS deprecated support for Oracle Database 12c Release 1 (12.1.0.2) for BYOL and LI. The release moved from Oracle Extended Support to Oracle Sustaining Support, indicating that Oracle Support will no longer release critical patch updates for this release. For more information, see the end of support timeline on [AWS re:Post](https://aws.amazon.com/repost/guides/).

<table>
<thead>
<tr>
<th>Date</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>August 1, 2022</td>
<td>Amazon RDS began automatic upgrades of your Oracle Database 12c Release 1 (12.1.0.2) instances to the latest Release Update (RU) for Oracle Database 19c. The automatic upgrade occurs during maintenance windows. If maintenance windows aren't available when the upgrade needs to occur, Amazon RDS upgrades the engine immediately.</td>
</tr>
<tr>

<td>Amazon RDS began automatic upgrades to Oracle Database 19c for any Oracle Database 12c Release 1 (12.1.0.2) DB instances restored from snapshots.</td>
</tr>
</tbody>
</table>

**RDS for Oracle licensing options**

Amazon RDS for Oracle has two licensing options: License Included (LI) and Bring Your Own License (BYOL). After you create an Oracle DB instance on Amazon RDS, you can change the licensing model by modifying the DB instance. For more information, see [Modifying an Amazon RDS DB instance](https://docs.aws.amazon.com/AmazonRDS/latest/OracleUserGuide/rds-ora-modify-instance-ls).
Important

Make sure that you have the appropriate Oracle Database license, with Software Update License and Support, for your DB instance class and Oracle Database edition. Also make sure that you have licenses for any separately licensed Oracle Database features.

Topics

- **License Included**
- **Bring Your Own License (BYOL)**
- **Licensing Oracle Multi-AZ deployments**

License Included

In the License Included model, you don't need to purchase Oracle Database licenses separately. AWS holds the license for the Oracle database software. In this model, if you have an AWS Support account with case support, contact AWS Support for both Amazon RDS and Oracle Database service requests. The License Included model is only supported on Amazon RDS for Oracle Database Standard Edition 2 (SE2). Your use of RDS for Oracle the LI option is subject to Section 10.3.1 of the [AWS Service Terms](#).

Bring Your Own License (BYOL)

In the BYOL model, you can use your existing Oracle Database licenses to deploy databases on Amazon RDS. Make sure that you have the appropriate Oracle Database license (with Software Update License and Support) for the DB instance class and Oracle Database edition you wish to run. You must also follow Oracle's policies for licensing Oracle Database software in the cloud computing environment. For more information on Oracle's licensing policy for Amazon EC2, see [Licensing Oracle software in the cloud computing environment](#).

In this model, you continue to use your active Oracle support account, and you contact Oracle directly for Oracle Database service requests. If you have an AWS Support account with case support, you can contact AWS Support for Amazon RDS issues. Amazon Web Services and Oracle have a multi-vendor support process for cases that require assistance from both organizations.

Amazon RDS supports the BYOL model only for Oracle Database Enterprise Edition (EE) and Oracle Database Standard Edition 2 (SE2).
Integrating with AWS License Manager

To make it easier to monitor Oracle license usage in the BYOL model, AWS License Manager integrates with Amazon RDS for Oracle. License Manager supports tracking of RDS for Oracle engine editions and licensing packs based on virtual cores (vCPUs). You can also use License Manager with AWS Organizations to manage all of your organizational accounts centrally.

The following table shows the product information filters for RDS for Oracle.

<table>
<thead>
<tr>
<th>Filter</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Engine Edition</td>
<td>oracle-ee</td>
<td>Oracle Database Enterprise Edition (EE)</td>
</tr>
<tr>

<td>sqlt</td>
<td>See <a href="https://docs.oracle.com/en/database/oracle-11g/oracle-11g-database/sqlt.html">Oracle SQLT</a></td>
</tr>
<tr>
<td></td>
<td>tuning pack</td>
<td>See <a href="https://docs.oracle.com/en/database/oracle-11g/oracle-11g-database/sqlt.html">Oracle SQLT</a></td>
</tr>
</tbody>
</table>

To track license usage of your Oracle DB instances, you can create a license configuration. In this case, RDS for Oracle resources that match the product information filter are automatically associated with the license configuration. Discovery of Oracle DB instances can take up to 24 hours.

**Console**

**To create a license configuration to track the license usage of your Oracle DB instances**

2. Create a license configuration.

   For instructions, see [Create a license configuration](https://docs.aws.amazon.com/licenseriments/latest/userguide/) in the AWS License Manager User Guide.
Add a rule for an **RDS Product Information Filter** in the **Product Information** panel.

For more information, see [ProductInformation](#) in the *AWS License Manager API Reference*.

**AWS CLI**

To create a license configuration by using the AWS CLI, call the `create-license-configuration` command. Use the `--cli-input-json` or `--cli-input-yaml` parameters to pass the parameters to the command.

**Example**

The following code creates a license configuration for Oracle Enterprise Edition.

```bash
aws license-manager create-license-configuration -cli-input-json file://rds-oracle-ee.json
```

The following is the sample `rds-oracle-ee.json` file used in the example.

```json
{
    "Name": "rds-oracle-ee",
    "Description": "RDS Oracle Enterprise Edition",
    "LicenseCountingType": "vCPU",
    "LicenseCountHardLimit": false,
    "ProductInformationList": [
        {
            "ResourceType": "RDS",
            "ProductInformationFilterList": [
                {
                    "ProductInformationFilterName": "Engine Edition",
                    "ProductInformationFilterValue": ["oracle-ee"],
                    "ProductInformationFilterComparator": "EQUALS"
                }
            ]
        }
    ]
}
```

For more information about product information, see [Automated discovery of resource inventory](#) in the *AWS License Manager User Guide*. 

---

*Oracle licensing*
Migrating between Oracle editions

If you have an unused BYOL Oracle license appropriate for the edition and class of DB instance that you plan to run, you can migrate from Standard Edition 2 (SE2) to Enterprise Edition (EE). You can't migrate from Enterprise Edition to other editions.

To change the edition and retain your data

1. Create a snapshot of the DB instance.
   
   For more information, see Creating a DB snapshot for a Single-AZ DB instance.

2. Restore the snapshot to a new DB instance, and select the Oracle database edition you want to use.

   For more information, see Restoring from a DB snapshot.

3. (Optional) Delete the old DB instance, unless you want to keep it running and have the appropriate Oracle Database licenses for it.

   For more information, see Deleting a DB instance.

Licensing Oracle Multi-AZ deployments

Amazon RDS supports Multi-AZ deployments for Oracle as a high-availability, failover solution. We recommend Multi-AZ for production workloads. For more information, see Configuring and managing a Multi-AZ deployment.

If you use the Bring Your Own License model, you must have a license for both the primary DB instance and the standby DB instance in a Multi-AZ deployment.

RDS for Oracle users and privileges

When you create an Amazon RDS for Oracle DB instance, the default master user has most of the maximum user permissions on the DB instance. Use the master user account for any administrative tasks, such as creating additional user accounts in your database. Because RDS is a managed service, you aren't allowed to log in as SYS and SYSTEM, and thus don't have SYSDBA privileges.

Topics
Limitations for Oracle DBA privileges

In the database, a role is a collection of privileges that you can grant to or revoke from a user. An Oracle database uses roles to provide security. For more information, see Configuring Privilege and Role Authorization in the Oracle Database documentation.

The predefined role DBA normally allows all administrative privileges on an Oracle database. When you create a DB instance, your master user account gets DBA privileges (with some limitations). To deliver a managed experience, an RDS for Oracle database doesn't provide the following privileges for the DBA role:

- ALTER DATABASE
- ALTER SYSTEM
- CREATE ANY DIRECTORY
- DROP ANY DIRECTORY
- GRANT ANY PRIVILEGE
- GRANT ANY ROLE

For more RDS for Oracle system privilege and role information, see Master user account privileges.

How to manage privileges on SYS objects

You can manage privileges on SYS objects by using the rdsadmin.rdsadmin_util package. For example, if you create the database user myuser, you could use the rdsadmin.rdsadmin_util.grant_sys_object procedure to grant SELECT privileges on V_$SQLAREA to myuser. For more information, see the following topics:

- Granting SELECT or EXECUTE privileges to SYS objects
- Revoking SELECT or EXECUTE privileges on SYS objects
- Granting privileges to non-master users
RDS for Oracle instance classes

The computation and memory capacity of an RDS for Oracle DB instance is determined by its instance class. The DB instance class you need depends on your processing power and memory requirements.

Supported RDS for Oracle instance classes

The supported RDS for Oracle instance classes are a subset of the RDS DB instance classes. For the complete list of RDS instance classes, see [DB instance classes](#).

RDS for Oracle memory-optimized instance classes

RDS for Oracle also offers instance classes that are optimized for workloads that require additional memory, storage, and I/O per vCPU. These instance classes use the following naming convention:

```
db.r5b.instance_size.tpcthreads_per_core.memratio
```

```
db.r5.instance_size.tpcthreads_per_core.memratio
```

The following is an example of a supported instance class:

```
db.r5b.4xlarge.tpc2.mem2x
```

The components of the preceding instance class name are as follows:

- `db.r5b.4xlarge` – The name of the instance class.
- `tpc2` – The threads per core. A value of 2 means that multithreading is turned on. If the value is 1, multithreading is turned off.
- `mem2x` – The ratio of additional memory to the standard memory for the instance class. In this example, the optimization provides twice as much memory as a standard `db.r5.4xlarge` instance.

Supported edition, instance class, and licensing combinations in RDS for Oracle

If you're using the RDS console, you can find out whether a specific edition, instance class, and license combination is supported by choosing [Create database](#) and specifying different option. In the AWS CLI, you can run the following command:
The following table lists all editions, instance classes, and license types supported for RDS for Oracle. Oracle Database 12c Release 1 (12.1.0.2) and Oracle Database 12c Release 2 (12.2.0.2) are listed in the table, but support for these releases is deprecated. For information about the memory attributes of each type, see RDS for Oracle instance types. For information about pricing, see Amazon RDS for Oracle pricing models.

**Note**

We encourage all BYOL customers to consult their licensing agreement to assess the impact of Amazon RDS for Oracle deprecations. For more information on the compute capacity of DB instance classes supported by RDS for Oracle, see [DB instance classes](#) and [Configuring the processor for a DB instance class in RDS for Oracle](#).

**Note**

If you have DB snapshots of DB instances that were using deprecated DB instance classes, you can choose a DB instance class that is not deprecated when you restore the DB snapshots. For more information, see [Restoring from a DB snapshot](#).

### Deprecated RDS for Oracle DB instance classes

The following DB instance classes are deprecated for RDS for Oracle:

- db.m1, db.m2, db.m3, db.m4
• db.t3.micro (supported only on 12.1.0.2, which is deprecated)
• db.t1, db.t2
• db.r1, db.r2, db.r3, db.r4

The preceding DB instance classes have been replaced by better performing DB instance classes that are generally available at a lower cost. If you have DB instances that use deprecated DB instance classes, you have the following options:

• Allow Amazon RDS to modify each DB instance automatically to use a comparable non-deprecated DB instance class. For deprecation timelines, see [DB instance class types](#).

• Change the DB instance class yourself by modifying the DB instance. For more information, see [Modifying an Amazon RDS DB instance](#).

If you have DB snapshots of DB instances that were using deprecated DB instance classes, you can choose a DB instance class that is not deprecated when you restore the DB snapshots. For more information, see [Restoring from a DB snapshot](#).

### RDS for Oracle database architecture

The *Oracle multitenant architecture*, also known as the *CDB architecture*, enables an Oracle database to function as a *multitenant container database (CDB)*. A CDB can include customer-created *pluggable databases (PDBs)*. A *non-CDB* is an Oracle database that uses the traditional architecture, which can't contain PDBs. For more information about the multitenant architecture, see [Oracle Multitenant Administrator’s Guide](#).

For Oracle Database 19c and higher, you can create an RDS for Oracle DB instance that uses the CDB architecture. Your client applications connect at the PDB level rather than the CDB level. RDS for Oracle supports the following configurations of the CDB architecture:

#### Multi-tenant configuration

This RDS platform feature allows an RDS for Oracle CDB instance to contain between 1–30 tenant databases, depending on the database edition and any required option licenses tenant databases (PDBs). The multi-tenant configuration doesn't support application PDBs or proxy PDBs. You can use RDS APIs to add, modify, and remove tenant databases.
Note
The Amazon RDS feature is called "multi-tenant" rather than "multitenant" because it is a capability of the RDS platform, not just the Oracle DB engine. The term "Oracle multitenant" refers exclusively to the Oracle database architecture, which is compatible with both on-premises and RDS deployments.

Single-tenant configuration

This RDS platform feature limits an RDS for Oracle CDB instance to 1 tenant database (PDB). You can't add more PDBs using RDS APIs. The single-tenant configuration uses the same RDS APIs as the non-CDB architecture. Thus, the experience of working with a CDB in the single-tenant configuration is mostly the same as working with a non-CDB.

You can convert a CDB that uses the single-tenant configuration to the multi-tenant configuration, thus allowing you to add PDBs to your CDB. This architecture change is permanent and irreversible. For more information, see Converting the single-tenant configuration to multi-tenant.

Note
You can't access the CDB itself.

In Oracle Database 21c and higher, all databases are CDBs. In contrast, you can create an Oracle Database 19c DB instance as either a CDB or non-CDB. You can't upgrade a non-CDB to a CDB, but you convert an Oracle Database 19c non-CDB to a CDB, and then upgrade it. You can't convert a CDB to a non-CDB.

For more information, see the following resources:

- Working with CDBs in RDS for Oracle
- Limitations of RDS for Oracle CDBs
- Creating an Amazon RDS DB instance
RDS for Oracle parameters

In Amazon RDS, you manage parameters using parameter groups. For more information, see Working with parameter groups. To view the supported parameters for a specific Oracle Database edition and version, run the AWS CLI command describe-engine-default-parameters.

For example, to view the supported parameters for the Enterprise Edition of Oracle Database 19c, run the following command.

```
aws rds describe-engine-default-parameters \
   --db-parameter-group-family oracle-ee-19
```

RDS for Oracle character sets

RDS for Oracle supports two types of character sets: the DB character set and national character set.

DB character set

The Oracle database character set is used in the CHAR, VARCHAR2, and CLOB data types. The database also uses this character set for metadata such as table names, column names, and SQL statements. The Oracle database character set is typically referred to as the DB character set.

You set the character set when you create a DB instance. You can't change the DB character set after you create the database.

Supported DB character sets

The following table lists the Oracle DB character sets that are supported in Amazon RDS. You can use a value from this table with the --character-set-name parameter of the AWS CLI create-db-instance command or with the CharacterSetName parameter of the Amazon RDS API CreateDBInstance operation.

Note

The character set for a CDB is always AL32UTF8. You can set a different character set for the PDB only.

**NLS_LANG environment variable**

A *locale* is a set of information addressing linguistic and cultural requirements that corresponds to a given language and country. Setting the NLS_LANG environment variable in your client's environment is the simplest way to specify locale behavior for Oracle. This variable sets the language and territory used by the client application and the database server. It also indicates the client's character set, which corresponds to the character set for data entered or displayed by a client application. For more information on NLS_LANG and character sets, see [What is a character set or code page?](#) in the Oracle documentation.

**NLS initialization parameters**

You can also set the following National Language Support (NLS) initialization parameters at the instance level for an Oracle DB instance in Amazon RDS:

- NLS_DATE_FORMAT
- NLS_LENGTH_SEMANTICS
- NLS_NCHAR_CONV_EXCP
- NLS_TIME_FORMAT
- NLS_TIME_TZ_FORMAT
- NLS_TIMESTAMP_FORMAT
- NLS_TIMESTAMP_TZ_FORMAT

For information about modifying instance parameters, see [Working with parameter groups](#).

You can set other NLS initialization parameters in your SQL client. For example, the following statement sets the NLS_LANGUAGE initialization parameter to GERMAN in a SQL client that is connected to an Oracle DB instance:

```
ALTER SESSION SET NLS_LANGUAGE=GERMAN;
```
For information about connecting to an Oracle DB instance with a SQL client, see Connecting to your RDS for Oracle DB instance.

National character set

The national character set is used in the NCHAR, NVARCHAR2, and NCLOB data types. The national character set is typically referred to as the NCHAR character set. Unlike the DB character set, the NCHAR character set doesn't affect database metadata.

The NCHAR character set supports the following character sets:

- AL16UTF16 (default)
- UTF8

You can specify either value with the --nchar-character-set-name parameter of the `create-db-instance` command (AWS CLI version 2 only). If you use the Amazon RDS API, specify the NcharCharacterSetName parameter of `CreateDBInstance` operation. You can't change the national character set after you create the database.

For more information about Unicode in Oracle databases, see Supporting multilingual databases with unicode in the Oracle documentation.

RDS for Oracle limitations

In the following sections, you can find important limitations of using RDS for Oracle. For limitations specific to CDBs, see Limitations of RDS for Oracle CDBs.

Note

This list is not exhaustive.

Topics

- Oracle file size limits in Amazon RDS
- Public synonyms for Oracle-supplied schemas
- Schemas for unsupported features
- Limitations for Oracle DBA privileges
- Deprecation of TLS 1.0 and 1.1 Transport Layer Security
Oracle file size limits in Amazon RDS

The maximum size of a single file on RDS for Oracle DB instances is 16 TiB (tebibytes). This limit is imposed by the ext4 filesystem used by the instance. Thus, Oracle bigfile data files are limited to 16 TiB. If you try to resize a data file in a bigfile tablespace to a value over the limit, you receive an error such as the following.

ORA-01237: cannot extend datafile 6
ORA-01110: data file 6: '/rdsdbdata/db/mydir/datafile/myfile.dbf'
ORA-27059: could not reduce file size
Linux-x86_64 Error: 27: File too large
Additional information: 2

Public synonyms for Oracle-supplied schemas

Don't create or modify public synonyms for Oracle-supplied schemas, including SYS, SYSTEM, and RDSADMIN. Such actions might result in invalidation of core database components and affect the availability of your DB instance.

You can create public synonyms referencing objects in your own schemas.

Schemas for unsupported features

In general, Amazon RDS doesn't prevent you from creating schemas for unsupported features. However, if you create schemas for Oracle features and components that require SYS privileges, you can damage the data dictionary and affect your instance availability. Use only supported features and schemas that are available in Adding options to Oracle DB instances.

Limitations for Oracle DBA privileges

In the database, a role is a collection of privileges that you can grant to or revoke from a user. An Oracle database uses roles to provide security.

The predefined role DBA normally allows all administrative privileges on an Oracle database. When you create a DB instance, your master user account gets DBA privileges (with some limitations). To deliver a managed experience, an RDS for Oracle database doesn't provide the following privileges for the DBA role:

- ALTER DATABASE
- ALTER SYSTEM
- CREATE ANY DIRECTORY
- DROP ANY DIRECTORY
- GRANT ANY PRIVILEGE
- GRANT ANY ROLE

Use the master user account for administrative tasks such as creating additional user accounts in the database. You can't use SYS, SYSTEM, and other Oracle-supplied administrative accounts.

**Deprecation of TLS 1.0 and 1.1 Transport Layer Security**

Transport Layer Security protocol versions 1.0 and 1.1 (TLS 1.0 and TLS 1.1) are deprecated. In accordance with security best practices, Oracle has deprecated the use of TLS 1.0 and TLS 1.1. To meet your security requirements, RDS for Oracle strongly recommends that you use TLS 1.2 instead.
Connecting to your RDS for Oracle DB instance

After Amazon RDS provisions your Oracle DB instance, you can use any standard SQL client application to log in to your DB instance. Because RDS is a managed service, you can't log in as SYS or SYSTEM. For more information, see RDS for Oracle users and privileges.

In this topic, you learn how to use Oracle SQL Developer or SQL*Plus to connect to an RDS for Oracle DB instance. For an example that walks you through the process of creating and connecting to a sample DB instance, see Creating and connecting to an Oracle DB instance.

Topics

- Finding the endpoint of your RDS for Oracle DB instance
- Connecting to your DB instance using Oracle SQL developer
- Connecting to your DB instance using SQL*Plus
- Considerations for security groups
- Considerations for process architecture
- Troubleshooting connections to your Oracle DB instance
- Modifying connection properties using sqlnet.ora parameters

Finding the endpoint of your RDS for Oracle DB instance

Each Amazon RDS DB instance has an endpoint, and each endpoint has the DNS name and port number for the DB instance. To connect to your DB instance using a SQL client application, you need the DNS name and port number for your DB instance.

You can find the endpoint for a DB instance using the Amazon RDS console or the AWS CLI.

Note

If you are using Kerberos authentication, see Connecting to Oracle with Kerberos authentication.
Console

To find the endpoint using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the upper-right corner of the console, choose the AWS Region of your DB instance.

3. Find the DNS name and port number for your DB instance.
   
   a. Choose **Databases** to display a list of your DB instances.
   
   b. Choose the Oracle DB instance name to display the instance details.
   
   c. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
AWS CLI

To find the endpoint of an Oracle DB instance by using the AWS CLI, call the `describe-db-instances` command.

**Example To find the endpoint using the AWS CLI**

```
aws rds describe-db-instances
```

Search for `Endpoint` in the output to find the DNS name and port number for your DB instance. The `Address` line in the output contains the DNS name. The following is an example of the JSON endpoint output.

```json
"Endpoint": {
    "HostedZoneId": "Z1PVIF0B656C1W",
    "Port": 3306,
    "Address": "myinstance.123456789012.us-west-2.rds.amazonaws.com"
},
```

**Note**
The output might contain information for multiple DB instances.

Connecting to your DB instance using Oracle SQL developer

In this procedure, you connect to your DB instance by using Oracle SQL Developer. To download a standalone version of this utility, see the [Oracle SQL developer downloads page](#).

To connect to your DB instance, you need its DNS name and port number. For information about finding the DNS name and port number for a DB instance, see [Finding the endpoint of your RDS for Oracle DB instance](#).

**To connect to a DB instance using SQL developer**

1. Start Oracle SQL Developer.
2. On the **Connections** tab, choose the add (+) icon.
3. In the **New/Select Database Connection** dialog box, provide the information for your DB instance:

- For **Connection Name**, enter a name that describes the connection, such as *Oracle-RDS*.
- For **Username**, enter the name of the database administrator for the DB instance.
- For **Password**, enter the password for the database administrator.
- For **Hostname**, enter the DNS name of the DB instance.
- For **Port**, enter the port number.
- For **SID**, enter the DB name. You can find the DB name on the **Configuration** tab of your database details page.

The completed dialog box should look similar to the following.
4. Choose **Connect**.

5. You can now start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your DB instance, do the following:

   a. In the **Worksheet** tab for your connection, enter the following SQL query.

   ```sql
   SELECT NAME FROM V$DATABASE;
   ```

   b. Choose the **execute** icon to run the query.

   SQL Developer returns the database name.
Connecting to your DB instance using SQL*Plus

You can use a utility like SQL*Plus to connect to an Amazon RDS DB instance running Oracle. To download Oracle Instant Client, which includes a standalone version of SQL*Plus, see Oracle Instant Client Downloads.

To connect to your DB instance, you need its DNS name and port number. For information about finding the DNS name and port number for a DB instance, see Finding the endpoint of your RDS for Oracle DB instance.

Example To connect to an Oracle DB instance using SQL*Plus

In the following examples, substitute the user name of your DB instance administrator. Also, substitute the DNS name for your DB instance, and then include the port number and the Oracle SID. The SID value is the name of the DB instance's database that you specified when you created the DB instance, and not the name of the DB instance.

For Linux, macOS, or Unix:
sqlplus 'user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))(CONNECT_DATA=(SID=database_name)))'

For Windows:

sqlplus user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))(CONNECT_DATA=(SID=database_name)))

You should see output similar to the following.

SQL*Plus: Release 12.1.0.2.0 Production on Mon Aug 21 09:42:20 2017

After you enter the password for the user, the SQL prompt appears.

SQL>

**Note**

The shorter format connection string (EZ Connect), such as sqlplus USER/PASSWORD@longer-than-63-chars-rds-endpoint-here:1521/database-identifier, might encounter a maximum character limit, so you we recommend that you don't use it to connect.

**Considerations for security groups**

For you to connect to your DB instance, it must be associated with a security group that contains the necessary IP addresses and network configuration. Your DB instance might use the default security group. If you assigned a default, nonconfigured security group when you created the DB instance, the firewall prevents connections. For information about creating a new security group, see [Controlling access with security groups](#).

After you create the new security group, you modify your DB instance to associate it with the security group. For more information, see [Modifying an Amazon RDS DB instance](#).

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see [Oracle Secure Sockets Layer](#).
Considerations for process architecture

Server processes handle user connections to an Oracle DB instance. By default, the Oracle DB instance uses dedicated server processes. With dedicated server processes, each server process services only one user process. You can optionally configure shared server processes. With shared server processes, each server process can service multiple user processes.

You might consider using shared server processes when a high number of user sessions are using too much memory on the server. You might also consider shared server processes when sessions connect and disconnect very often, resulting in performance issues. There are also disadvantages to using shared server processes. For example, they can strain CPU resources, and they are more complicated to configure and administer.

For more information about dedicated and shared server processes, see About dedicated and shared server processes in the Oracle documentation. For more information about configuring shared server processes on an RDS for Oracle DB instance, see How do I configure Amazon RDS for Oracle database to work with shared servers? in the Knowledge Center.

Troubleshooting connections to your Oracle DB instance

The following are issues you might encounter when you try to connect to your Oracle DB instance.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unable to connect to your DB instance.</td>
<td>For a newly created DB instance, the DB instance has a status of creating until it is ready to use. When the state changes to available, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB instance is available.</td>
</tr>
<tr>
<td>Unable to connect to your DB instance.</td>
<td>If you can't send or receive communications over the port that you specified when you created the DB instance, you can't connect to the DB instance. Check with your network administrator to verify that the port you specified for your DB instance allows inbound and outbound communication.</td>
</tr>
<tr>
<td>Unable to connect to your DB instance.</td>
<td>The access rules enforced by your local firewall and the IP addresses you authorized to access your DB instance in the</td>
</tr>
<tr>
<td>Issue</td>
<td>Troubleshooting suggestions</td>
</tr>
<tr>
<td>----------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Connect failed because target host or object does not exist – Oracle, Error: ORA-12545</td>
<td>Make sure that you specified the server name and port number correctly. For <strong>Server name</strong>, enter the DNS name from the console. For information about finding the DNS name and port number for a DB instance, see <a href="#">Finding the endpoint of your RDS for Oracle DB instance</a>.</td>
</tr>
<tr>
<td>Invalid username/password; logon denied – Oracle, Error: ORA-01017</td>
<td>You were able to reach the DB instance, but the connection was refused. This is usually caused by providing an incorrect user name or password. Verify the user name and password, and then retry.</td>
</tr>
<tr>
<td>TNS:listener does not currently know of SID given in connect descriptor - Oracle, ERROR: ORA-12505</td>
<td>Ensure the correct SID is entered. The SID is the same as your DB name. Find the DB name in the <strong>Configuration</strong> tab of the <strong>Databases</strong> page for your instance. You can also find the DB name using the AWS CLI: aws rds describe-db-instances --query 'DBInstances[*].[DBInstanceIdentifier,DBName]' --output text</td>
</tr>
</tbody>
</table>
Modifying connection properties using sqlnet.ora parameters

The sqlnet.ora file includes parameters that configure Oracle Net features on Oracle database servers and clients. Using the parameters in the sqlnet.ora file, you can modify properties for connections in and out of the database.

For more information about why you might set sqlnet.ora parameters, see Configuring profile parameters in the Oracle documentation.

Setting sqlnet.ora parameters

Amazon RDS for Oracle parameter groups include a subset of sqlnet.ora parameters. You set them in the same way that you set other Oracle parameters. The sqlnetora. prefix identifies which parameters are sqlnet.ora parameters. For example, in an Oracle parameter group in Amazon RDS, the default_sdu_size sqlnet.ora parameter is sqlnetora.default_sdu_size.

For information about managing parameter groups and setting parameter values, see Working with parameter groups.

Supported sqlnet.ora parameters

Amazon RDS supports the following sqlnet.ora parameters. Changes to dynamic sqlnet.ora parameters take effect immediately.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid values</th>
<th>Static/Dynamic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqlnetora.default_sdu_size</td>
<td>Oracle 12c – 512 to 209715</td>
<td>Dynamic</td>
<td>The session data unit (SDU) size, in bytes. The SDU is the amount of data that is put in a buffer and sent across the network at one time.</td>
</tr>
<tr>
<td>sqlnetora.diag_adr_enabled</td>
<td>ON, OFF</td>
<td>Dynamic</td>
<td>A value that enables or disables Automatic Diagnostic Repository (ADR) tracing.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Valid values</td>
<td>Static/Dynamic</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>--------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sqlnetora.recv_buf_size</td>
<td>8192 to 268435</td>
<td>Dynamic</td>
<td>The buffer space limit for receive operations of sessions, supported by the TCP/IP, TCP/IP with SSL, and SDP protocols.</td>
</tr>
<tr>
<td>sqlnetora.send_buf_size</td>
<td>8192 to 268435</td>
<td>Dynamic</td>
<td>The buffer space limit for send operations of sessions, supported by the TCP/IP, TCP/IP with SSL, and SDP protocols.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.allowed_logon_version_client</td>
<td>8, 10, 11, 12</td>
<td>Dynamic</td>
<td>Minimum authentication protocol version allowed for clients, and servers acting as clients, to establish a connection to Oracle DB instances.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.allowed_logon_version_server</td>
<td>8, 9, 10, 11, 12, 12a</td>
<td>Dynamic</td>
<td>Minimum authentication protocol version allowed to establish a connection to Oracle DB instances.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Valid values</td>
<td>Static/Dynamic</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>--------------</td>
<td>----------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.expire_time</td>
<td>0 to 1440</td>
<td>Dynamic</td>
<td>Time interval, in minutes, to send a check to verify that client-server connections are active.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.inbound_connect_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a client to connect with the database server and provide the necessary authentication information.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.outbound_connect_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a client to establish an Oracle Net connection to the DB instance.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.recv_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a database server to wait for client data after establishing a connection.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.send_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a database server to complete a send operation to clients after establishing a connection.</td>
</tr>
<tr>
<td>sqlnetora.tcp.connect_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a client to establish a TCP connection to the database server.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Valid values</td>
<td>Static/Dynamic</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>--------------</td>
<td>----------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sqlnetora.trace_level_server</td>
<td>0, 4, 10, 16, OFF, USER, ADMIN, SUPPORT</td>
<td>Dynamic</td>
<td>For non-ADR tracing, turns server tracing on at a specified level or turns it off.</td>
</tr>
</tbody>
</table>

The default value for each supported sqlnet.ora parameter is the Oracle default for the release. For information about default values for Oracle Database 12c, see [Parameters for the sqlnet.ora file](#) in the Oracle Database 12c documentation.

**Viewing sqlnet.ora parameters**

You can view sqlnet.ora parameters and their settings using the AWS Management Console, the AWS CLI, or a SQL client.

**Viewing sqlnet.ora parameters using the console**

For information about viewing parameters in a parameter group, see [Working with parameter groups](#).

In Oracle parameter groups, the `sqlnetora.` prefix identifies which parameters are sqlnet.ora parameters.

**Viewing sqlnet.ora parameters using the AWS CLI**

To view the sqlnet.ora parameters that were configured in an Oracle parameter group, use the AWS CLI `describe-db-parameters` command.

To view the all of the sqlnet.ora parameters for an Oracle DB instance, call the AWS CLI `download-db-log-file-portion` command. Specify the DB instance identifier, the log file name, and the type of output.
Example

The following code lists all of the sqlnet.ora parameters for mydbinstance.

For Linux, macOS, or Unix:

```bash
aws rds download-db-log-file-portion
   --db-instance-identifier mydbinstance
   --log-file-name trace/sqlnet-parameters
   --output text
```

For Windows:

```bash
aws rds download-db-log-file-portion ^
   --db-instance-identifier mydbinstance ^
   --log-file-name trace/sqlnet-parameters ^
   --output text
```

Viewing sqlnet.ora parameters using a SQL client

After you connect to the Oracle DB instance in a SQL client, the following query lists the sqlnet.ora parameters.

```sql
SELECT * FROM TABLE
   (rdsadmin.rds_file_util.read_text_file(
       p_directory => 'BDUMP',
       p_filename  => 'sqlnet-parameters'));
```

For information about connecting to an Oracle DB instance in a SQL client, see Connecting to your RDS for Oracle DB instance.
Securing Oracle DB instance connections

Amazon RDS for Oracle supports SSL/TLS encrypted connections and also the Oracle Native Network Encryption (NNE) option to encrypt connections between your application and your Oracle DB instance. For more information about the Oracle Native Network Encryption option, see Oracle native network encryption.

Topics

- Using SSL with an RDS for Oracle DB instance
- Updating applications to connect to Oracle DB instances using new SSL/TLS certificates
- Using native network encryption with an RDS for Oracle DB instance
- Configuring Kerberos authentication for Amazon RDS for Oracle
- Configuring UTL_HTTP access using certificates and an Oracle wallet

Using SSL with an RDS for Oracle DB instance

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS), but we still often refer to the protocol as SSL. Amazon RDS supports SSL encryption for Oracle DB instances. Using SSL, you can encrypt a connection between your application client and your Oracle DB instance. SSL support is available in all AWS Regions for Oracle.

To enable SSL encryption for an Oracle DB instance, add the Oracle SSL option to the option group associated with the DB instance. Amazon RDS uses a second port, as required by Oracle, for SSL connections. Doing this allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and an Oracle client. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

For more information, see Oracle Secure Sockets Layer.

Note

You can't use both SSL and Oracle native network encryption (NNE) on the same DB instance. Before you can use SSL encryption, you must disable any other connection encryption.
Updating applications to connect to Oracle DB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances.

⚠️ Important
When you change the certificate for an Amazon RDS for Oracle DB instance, only the database listener is restarted. The DB instance isn't restarted. Existing database connections are unaffected, but new connections will encounter errors for a brief period while the listener is restarted.

حذر
لاستخدام SSL/TLS لاتصل إلى DB instances، يجب تحديث حافظة الثقة في تطبيقك لاستضافة yeni CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster. For information about using SSL/TLS with Oracle DB instances, see Oracle Secure Sockets Layer.

Topics
- Finding out whether applications connect using SSL
- Updating your application trust store
- Example Java code for establishing SSL connections
Finding out whether applications connect using SSL

If your Oracle DB instance uses an option group with the SSL option added, you might be using SSL. Check this by following the instructions in Listing the options and option settings for an option group. For information about the SSL option, see Oracle Secure Sockets Layer.

Check the listener log to determine whether there are SSL connections. The following is sample output in a listener log.

```
date time * (CONNECT_DATA=(CID=(PROGRAM=program) (HOST=host)(USER=user))(SID=sid)) *
(ADDRESS=(PROTOCOL=tcps)(HOST=host)(PORT=port)) * establish * ORCL * 0
```

When PROTOCOL has the value tcps for an entry, it shows an SSL connection. However, when HOST is 127.0.0.1, you can ignore the entry. Connections from 127.0.0.1 are a local management agent on the DB instance. These connections aren't external SSL connections. Therefore, you have applications connecting using SSL if you see listener log entries where PROTOCOL is tcps and HOST is not 127.0.0.1.

To check the listener log, you can publish the log to Amazon CloudWatch Logs. For more information, see Publishing Oracle logs to Amazon CloudWatch Logs.

Updating your application trust store

You can update the trust store for applications that use SQL*Plus or JDBC for SSL/TLS connections.

Updating your application trust store for SQL*Plus

You can update the trust store for applications that use SQL*Plus for SSL/TLS connections.

### Note

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

To update the trust store for SQL*Plus applications

1. Download the new root certificate that works for all AWS Regions and put the file in the ssl_wallet directory.
For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

2. Run the following command to update the Oracle wallet.

```
prompt> orapki wallet add -wallet $ORACLE_HOME/ssl_wallet -trusted_cert -cert $ORACLE_HOME/ssl_wallet/ssl-cert.pem -auto_login_only
```

Replace the file name with the one that you downloaded.

3. Run the following command to confirm that the wallet was updated successfully.

```
prompt> orapki wallet display -wallet $ORACLE_HOME/ssl_wallet
```

Your output should contain the following.

```
Trusted Certificates:
Subject: CN=Amazon RDS Root 2019 CA,OU=Amazon RDS,O=Amazon Web Services,L=Seattle,ST=Washington,C=US
```

Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

For sample scripts that import certificates, see Sample script for importing certificates into your trust store.

**Example Java code for establishing SSL connections**

The following code example shows how to set up the SSL connection using JDBC.

```java
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.util.Properties;

public class OracleSslConnectionTest {
    private static final String DB_SERVER_NAME = "<dns-name-provided-by-amazon-rds>";
```
private static final Integer SSL_PORT = "<ssl-option-port-configured-in-option-group>";
private static final String DB_SID = "<oracle-sid>";
private static final String DB_USER = "<user name>";
private static final String DB_PASSWORD = "<password>";
// This key store has only the prod root ca.
private static final String KEY_STORE_FILE_PATH = "<file-path-to-keystore>";
private static final String KEY_STORE_PASS = "<keystore-password>";

public static void main(String[] args) throws SQLException {
    final Properties properties = new Properties();
    final String connectionString = String.format("jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))(CONNECT_DATA=(SID=%s))))",
        DB_SERVER_NAME, SSL_PORT, DB_SID);
    properties.put("user", DB_USER);
    properties.put("password", DB_PASSWORD);
    properties.put("oracle.jdbc.J2EE13Compliant", "true");
    properties.put("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
    properties.put("javax.net.ssl.trustStoreType", "JKS");
    properties.put("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
    final Connection connection = DriverManager.getConnection(connectionString,
        properties);
    // If no exception, that means handshake has passed, and an SSL connection can be opened
}

⚠️ Important
After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance or cluster.

Using native network encryption with an RDS for Oracle DB instance

Oracle Database offers two ways to encrypt data over the network: native network encryption (NNE) and Transport Layer Security (TLS). NNE is a proprietary Oracle security feature, whereas TLS is an industry standard. RDS for Oracle supports NNE for all editions of Oracle Database.
NNE has the following advantages over TLS:

- You can control NNE on the client and server using settings in the NNE option:
  - SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS and SQLNET.ALLOW_WEAK_CRYPTO
  - SQLNET.CRYPTO_CHECKSUM_CLIENT and SQLNET.CRYPTO_CHECKSUM_SERVER
  - SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT and SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER
  - SQLNET.ENCRYPTION_CLIENT and SQLNET.ENCRYPTION_SERVER
  - SQLNET.ENCRYPTION_TYPES_CLIENT and SQLNET.ENCRYPTION_TYPES_SERVER

- In most cases, you don't need to configure your client or server. In contrast, TLS requires you to configure both client and server.

- No certificates are required. In TLS, the server requires a certificate (which eventually expires), and the client requires a trusted root certificate for the certificate authority that issued the server's certificate.

To enable NNE encryption for an Oracle DB instance, add the Oracle NNE option to the option group associated with the DB instance. For more information, see Oracle native network encryption.

**Note**

You can't use both NNE and TLS on the same DB instance.

### Configuring Kerberos authentication for Amazon RDS for Oracle

You can use Kerberos authentication to authenticate users when they connect to your Amazon RDS for Oracle DB instance. In this configuration, your DB instance works with AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD. When users authenticate with an RDS for Oracle DB instance joined to the trusting domain, authentication requests are forwarded to the directory that you create with AWS Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized place for storing and managing credentials for multiple database instances. A directory can also improve your overall security profile.
Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS for Oracle with Kerberos authentication, see Kerberos authentication.

Note

Kerberos authentication isn't supported for DB instance classes that are deprecated for RDS for Oracle DB instances. For more information, see RDS for Oracle instance classes.

Topics

• Setting up Kerberos authentication for Oracle DB instances
• Managing a DB instance in a domain
• Connecting to Oracle with Kerberos authentication

Setting up Kerberos authentication for Oracle DB instances

Use AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to set up Kerberos authentication for an Oracle DB instance. To set up Kerberos authentication, complete the following steps:

• Step 1: Create a directory using the AWS Managed Microsoft AD
• Step 2: Create a trust
• Step 3: Configure IAM permissions for Amazon RDS
• Step 4: Create and configure users
• Step 5: Enable cross-VPC traffic between the directory and the DB instance
• Step 6: Create or modify an Oracle DB instance
• Step 7: Create Kerberos authentication Oracle logins
• Step 8: Configure an Oracle client
Note
During the setup, RDS creates an Oracle database user named managed_service_user@example.com with the CREATE SESSION privilege, where example.com is your domain name. This user corresponds to the user that Directory Service creates inside your Managed Active Directory. Periodically, RDS uses the credentials provided by the Directory Service to log in to your Oracle database. Afterwards, RDS immediately destroys the ticket cache.

Step 1: Create a directory using the AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

• Sets up an Active Directory within the VPC.
• Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

Note
Be sure to save this password. AWS Directory Service doesn't store it. You can reset it, but you can't retrieve it.

• Creates a security group for the directory controllers.

When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you created your directory and is located in the domain root. The domain root is owned and managed by AWS.
The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

To create the directory, use the AWS Management Console, the AWS CLI, or the AWS Directory Service API. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the Oracle DB instance.

To create a directory with AWS Managed Microsoft AD

2. In the navigation pane, choose Directories and choose Set up Directory.
3. Choose AWS Managed Microsoft AD. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

   **Directory DNS name**

   The fully qualified name for the directory, such as corp.example.com.

   **Directory NetBIOS name**

   The short name for the directory, such as CORP.
**Directory description**

(Optional) A description for the directory.

**Admin password**

The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password and can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Non-alphanumeric characters (~!@#$%^&*_-+=`|(){}[]:"'<>,.?/)  

**Confirm password**

The administrator password retyped.

5. Choose **Next**.

6. Enter the following information in the **Networking** section and then choose **Next**:

**VPC**

The VPC for the directory. Create the Oracle DB instance in this same VPC.

**Subnets**

Subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Review the directory information and make any necessary changes. When the information is correct, choose **Create directory**.
It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory name in the directory listing. Note the **Directory ID** value because you need this value when you create or modify your Oracle DB instance.
Step 2: Create a trust

If you plan to use AWS Managed Microsoft AD only, move on to Step 3: Configure IAM permissions for Amazon RDS.

To get Kerberos authentication using an on-premises or self-hosted Microsoft Active Directory, create a forest trust or external trust. The trust can be one-way or two-way. For more information about setting up forest trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.
**Step 3: Configure IAM permissions for Amazon RDS**

To call AWS Directory Service for you, Amazon RDS requires an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. This role allows Amazon RDS to make calls to the AWS Directory Service.

**Note**

For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see [Activating and deactivating AWS STS in an AWS Region](https://docs.aws.amazon.com/iam/userguide/idpsts.html) in the *IAM User Guide*.

**Creating an IAM role**

When you create a DB instance using the AWS Management Console, and the console user has the `iam:CreateRole` permission, the console creates `rds-directoryservice-kerberos-access-role` automatically. Otherwise, you must create the IAM role manually. When you create an IAM role manually, choose Directory Service, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see [Creating a role to delegate permissions to an AWS service](https://docs.aws.amazon.com/iam/userguide/idpcreaterole.html) in the *IAM User Guide*.

**Note**

The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for RDS for Oracle.

**Creating an IAM trust policy manually**

Optionally, you can create resource policies with the required permissions instead of using the managed IAM policy `AmazonRDSDirectoryServiceAccess`. Specify both `directoryservice.rds.amazonaws.com` and `rds.amazonaws.com` as principals.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in...
resource policies. The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of an Amazon RDS resource. For more information, see [Preventing cross-service confused deputy problems](#).

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "directoryservice.rds.amazonaws.com",
                    "rds.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"
                },
                "StringEquals": {
                    "aws:SourceAccount": "123456789012"
                }
            }
        }
    ]
}
```

The role must also have the following IAM policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ds:DescribeDirectories",
                "ds:AuthorizeApplication",
                "ds:UnauthorizeApplication"
            ]
        }
    ]
}
```
Step 4: Create and configure users

You can create users with the Active Directory Users and Computers tool, which is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. In this case, users are individual people or entities that have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that is a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information about creating users in your Microsoft Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 6: Create or modify an Oracle DB instance.

If you plan to locate the directory and the DB instance in different AWS accounts or VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway. The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the Amazon Virtual Private Cloud Peering Guide.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance's security group can receive inbound traffic from the directory's security group. For more information, see Best practices for AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.
To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join in the AWS Directory Service Administration Guide.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the Directory ID value. You use this directory ID to join the DB instance to the domain.

Step 6: Create or modify an Oracle DB instance

Create or modify an Oracle DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

• Create a new Oracle DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.

  For instructions, see Creating an Amazon RDS DB instance.

• Modify an existing Oracle DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation.

  For instructions, see Modifying an Amazon RDS DB instance.

• Restore an Oracle DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.

  For instructions, see Restoring from a DB snapshot.

• Restore an Oracle DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation.

  For instructions, see Restoring a DB instance to a specified time.

Kerberos authentication is only supported for Oracle DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. When you create or modify the DB instance, do the following:

• Provide the domain identifier (d-* identifier) that was generated when you created your directory.
• Provide the name of the IAM role that you created.
• Ensure that the DB instance security group can receive inbound traffic from the directory security group and send outbound traffic to the directory.

When you use the console to create a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Choose **Browse Directory** and then select the directory, or choose **Create a new directory**.

When you use the console to modify or restore a DB instance, choose the directory in the **Kerberos authentication** section, or choose **Create a new directory**.

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:
• For the --domain parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.

• For the --domain-iam-role-name parameter, use the role you created that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --domain d-ID \
  --domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --domain d-ID ^
  --domain-iam-role-name role-name
```

⚠️ Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

>Note

`MANAGED_SERVICE_USER` is a service account whose name is randomly generated by Directory Service for RDS. During the Kerberos authentication setup, RDS for Oracle creates a user with the same name and assigns it the CREATE SESSION privilege. The Oracle DB user is identified externally as `MANAGED_SERVICE_USER@EXAMPLE.COM`, where `EXAMPLE.COM` is the name of your domain. Periodically, RDS uses the credentials provided by the Directory Service to log in to your Oracle database. Afterward, RDS immediately destroys the ticket cache.
Step 7: Create Kerberos authentication Oracle logins

Use the Amazon RDS master user credentials to connect to the Oracle DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision Oracle logins and users from the Microsoft Active Directory users and groups in your domain. To manage database permissions, you grant and revoke standard Oracle permissions to these logins.

To allow a Microsoft Active Directory user to authenticate with Oracle

1. Connect to the Oracle DB instance using your Amazon RDS master user credentials.
2. Create an externally authenticated user in Oracle database.

In the following example, replace `KRBUSER@CORP.EXAMPLE.COM` with the user name and domain name.

```
CREATE USER "KRBUSER@CORP.EXAMPLE.COM" IDENTIFIED EXTERNALLY;
GRANT CREATE SESSION TO "KRBUSER@CORP.EXAMPLE.COM";
```

Users (both humans and applications) from your domain can now connect to the Oracle DB instance from a domain joined client machine using Kerberos authentication.

Step 8: Configure an Oracle client

To configure an Oracle client, meet the following requirements:

- Create a configuration file named krb5.conf (Linux) or krb5.ini (Windows) to point to the domain. Configure the Oracle client to use this configuration file.
- Verify that traffic can flow between the client host and AWS Directory Service over DNS port 53 over TCP/UDP, Kerberos ports (88 and 464 for managed AWS Directory Service) over TCP, and LDAP port 389 over TCP.
- Verify that traffic can flow between the client host and the DB instance over the database port.

Following is sample content for AWS Managed Microsoft AD.

```
[libdefaults]
  default_realm = EXAMPLE.COM
[realms]
```
EXAMPLE.COM = {
    kdc = example.com
    admin_server = example.com
}
[domain_realm]
.example.com = CORP.EXAMPLE.COM
example.com = CORP.EXAMPLE.COM

Following is sample content for on-premise Microsoft AD. In your krb5.conf or krb5.ini file, replace `on-prem-ad-server-name` with the name of your on-premises AD server.

[libdefaults]
default_realm = ONPREM.COM
[realms]
AWSAD.COM = {
    kdc = awsad.com
    admin_server = awsad.com
}
ONPREM.COM = {
    kdc = `on-prem-ad-server-name`
    admin_server = `on-prem-ad-server-name`
}
[domain_realm]
.awsad.com = AWSAD.COM
awsad.com = AWSAD.COM
.onprem.com = ONPREM.COM
onprem.com = ONPREM.COM

Note
After you configure your krb5.ini or krb5.conf file, we recommend that you reboot the server.

The following is sample sqlnet.ora content for a SQL*Plus configuration:

SQLNET.AUTHENTICATION_SERVICES=(KERBEROS5PRE, KERBEROS5)
SQLNET.KERBEROS5_CONF=\path_to_krb5.conf_file

For an example of a SQL Developer configuration, see Document 1609359.1 from Oracle Support.
Managing a DB instance in a domain

You can use the console, the CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate a Microsoft Active Directory to enable Kerberos authentication. You can also disassociate a Microsoft Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the `modify-db-instance` CLI command and specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the `modify-db-instance` CLI command and specify none for the `--domain` option.
- To move a DB instance from one domain to another, use the `modify-db-instance` CLI command and specify the domain identifier of the new domain for the `--domain` option.

Viewing the status of domain membership

After you create or modify your DB instance, the DB instance becomes a member of the domain. You can view the status of the domain membership for the DB instance in the console or by running the `describe-db-instances` CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
• **enable-kerberos-failed** – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.

• **disabling-kerberos** – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. If the attempt to enable Kerberos authentication fails when you create or modify a DB instance, make sure that you're using the correct IAM role. Then modify the DB instance to join the domain.

**Note**

Only Kerberos authentication with Amazon RDS for Oracle sends traffic to the domain's DNS servers. All other DNS requests are treated as outbound network access on your DB instances running Oracle. For more information about outbound network access with Amazon RDS for Oracle, see [Setting up a custom DNS server](#).

### Force-rotating Kerberos keys

A secret key is shared between AWS Managed Microsoft AD and Amazon RDS for Oracle DB instance. This key is rotated automatically every 45 days. You can use the following Amazon RDS procedure to force the rotation of this key.

```
SELECT rdsadmin.rdsadmin_kerberos_auth_tasks.rotate_kerberos_keytab AS TASK_ID FROM DUAL;
```

**Note**

In a read replica configuration, this procedure is available only on the source DB instance and not on the read replica.

The `SELECT` statement returns the ID of the task in a VARCHAR2 data type. You can view the status of an ongoing task in a bdump file. The bdump files are located in the `/rdsdbdata/log/trace` directory. Each bdump file name is in the following format.
dbtask-\textit{task-id}.log

You can view the result by displaying the task's output file.

\quad \texttt{SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-\textit{task-id}.log'));}

Replace \textit{task-id} with the task ID returned by the procedure.

\begin{itemize}
  \item \textbf{Note}
  \end{itemize}

Tasks are executed asynchronously.

**Connecting to Oracle with Kerberos authentication**

This section assumes that you have set up your Oracle client as described in \textit{Step 8: Configure an Oracle client}. To connect to the Oracle DB with Kerberos authentication, log in using the Kerberos authentication type. For example, after launching Oracle SQL Developer, choose \textbf{Kerberos Authentication} as the authentication type, as shown following.
To connect to Oracle with Kerberos authentication with SQL*Plus:

1. At a command prompt, run the following command:

   \texttt{kinit \textit{username}}

   Replace \textit{username} with the user name and, at the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. Open SQL*Plus and connect using the DNS name and port number for the Oracle DB instance.

   For more information about connecting to an Oracle DB instance in SQL*Plus, see \texttt{Connecting to your DB instance using SQL*Plus}.

### Configuring UTL_HTTP access using certificates and an Oracle wallet

Amazon RDS supports outbound network access on your RDS for Oracle DB instances. To connect your DB instance to the network, you can use the following PL/SQL packages:

**UTL_HTTP**

This package makes HTTP calls from SQL and PL/SQL. You can use it to access data on the Internet over HTTP. For more information, see \texttt{UTL_HTTP} in the Oracle documentation.

**UTL_TCP**

This package provides TCP/IP client-side access functionality in PL/SQL. This package is useful to PL/SQL applications that use Internet protocols and email. For more information, see \texttt{UTL_TCP} in the Oracle documentation.

**UTL_SMTP**

This package provides interfaces to the SMTP commands that enable a client to dispatch emails to an SMTP server. For more information, see \texttt{UTL_SMTP} in the Oracle documentation.

By completing the following tasks, you can configure \texttt{UTL_HTTP REQUEST} to work with websites that require client authentication certificates during the SSL handshake. You can also configure password authentication for \texttt{UTL_HTTP} access to websites by modifying the Oracle wallet generation commands and the \texttt{DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACE} procedure. For more information, see \texttt{DBMS_NETWORK_ACL_ADMIN} in the Oracle Database documentation.
### Considerations when configuring UTL_HTTP access

Before configuring access, consider the following:

- You can use SMTP with the UTL_MAIL option. For more information, see Oracle UTL_MAIL.
- The Domain Name Server (DNS) name of the remote host can be any of the following:
  - Publicly resolvable.
  - The endpoint of an Amazon RDS DB instance.
  - Resolvable through a custom DNS server. For more information, see Setting up a custom DNS server.
- The private DNS name of an Amazon EC2 instance in the same VPC or a peered VPC. In this case, make sure that the name is resolvable through a custom DNS server. Alternatively, to use the DNS provided by Amazon, you can enable the enableDnsSupport attribute in the VPC settings and enable DNS resolution support for the VPC peering connection. For more information, see DNS support in your VPC and Modifying your VPC peering connection.
- To connect securely to remote SSL/TLS resources, we recommend that you create and upload customized Oracle wallets. By using the Amazon S3 integration with Amazon RDS for Oracle feature, you can download a wallet from Amazon S3 into Oracle DB instances. For information about Amazon S3 integration for Oracle, see Amazon S3 integration.
• You can establish database links between Oracle DB instances over an SSL/TLS endpoint if the Oracle SSL option is configured for each instance. No further configuration is required. For more information, see Oracle Secure Sockets Layer.

Step 1: Get the root certificate for a website

For the RDS for Oracle DB instance to make secure connections to a website, add the root CA certificate. Amazon RDS uses the root certificate to sign the website certificate to the Oracle wallet.

You can get the root certificate in various ways. For example, you can do the following:

1. Use a web server to visit the website secured by the certificate.
2. Download the root certificate that was used for signing.

For AWS services, root certificates typically reside in the Amazon trust services repository.

Step 2: Create an Oracle wallet

Create an Oracle wallet that contains both the web server certificates and the client authentication certificates. The RDS Oracle instance uses the web server certificate to establish a secure connection to the website. The website needs the client certificate to authenticate the Oracle database user.

You might want to configure secure connections without using client certificates for authentication. In this case, you can skip the Java keystore steps in the following procedure.

To create an Oracle wallet

1. Place the root and client certificates in a single directory, and then change into this directory.
2. Convert the .p12 client certificate to the Java keystore.

Note

If you're not using client certificates for authentication, you can skip this step.

The following example converts the client certificate named client_certificate.p12 to the Java keystore named client_keystore.jks. The keystore is then included in the Oracle wallet. The keystore password is P12PASSWORD.
3. Create a directory for your Oracle wallet that is different from the certificate directory.

   The following example creates the directory /tmp/wallet.

   ```bash
   mkdir -p /tmp/wallet
   ```

4. Create an Oracle wallet in your wallet directory.

   The following example sets the Oracle wallet password to `P12PASSWORD`, which is the same password used by the Java keystore in a previous step. Using the same password is convenient, but not necessary. The `-auto_login` parameter turns on the automatic login feature, so that you don’t need to specify a password every time you want to access it.

   ```bash
   Note
   Specify a password other than the prompt shown here as a security best practice.
   ```

   ```bash
   orapki wallet create -wallet /tmp/wallet -pwd P12PASSWORD -auto_login
   ```

5. Add the Java keystore to your Oracle wallet.

   ```bash
   Note
   If you're not using client certificates for authentication, you can skip this step.
   ```

   The following example adds the keystore `client_keystore.jks` to the Oracle wallet named `/tmp/wallet`. In this example, you specify the same password for the Java keystore and the Oracle wallet.

   ```bash
   orapki wallet jks_to_pkcs12 -wallet /tmp/wallet -pwd P12PASSWORD -keystore ./client_keystore.jks -jkspwd P12PASSWORD
   ```

6. Add the root certificate for your target website to the Oracle wallet.
The following example adds a certificate named `Root_CA.cer`.

```
orapki wallet add -wallet /tmp/wallet -trusted_cert -cert ./Root_CA.cer -pwd P12PASSWORD
```

7. Add any intermediate certificates.

The following example adds a certificate named `Intermediate.cer`. Repeat this step as many times as need to load all intermediate certificates.

```
orapki wallet add -wallet /tmp/wallet -trusted_cert -cert ./Intermediate.cer -pwd P12PASSWORD
```

8. Confirm that your newly created Oracle wallet has the required certificates.

```
orapki wallet display -wallet /tmp/wallet -pwd P12PASSWORD
```

**Step 3: Download your Oracle wallet to your RDS for Oracle instance**

In this step, you upload your Oracle wallet to Amazon S3, and then download the wallet from Amazon S3 to your RDS for Oracle instance.

**To download your Oracle wallet to your RDS for Oracle DB instance**

1. Complete the prerequisites for Amazon S3 integration with Oracle, and add the S3_INTEGRATION option to your Oracle DB instance. Ensure that the IAM role for the option has access to the Amazon S3 bucket you are using.

   For more information, see [Amazon S3 integration](#).

2. Log in to your DB instance as the master user, and then create an Oracle directory to hold the Oracle wallet.

   The following example creates an Oracle directory named `WALLET_DIR`.

   ```
   EXEC rdsadmin.rdsadmin_util.create_directory('WALLET_DIR');
   ```

   For more information, see [Creating and dropping directories in the main data storage space](#).

3. Upload the Oracle wallet to your Amazon S3 bucket.
You can use any supported upload technique.

4. If you're re-uploading an Oracle wallet, delete the existing wallet. Otherwise, skip to the next step.

The following example removes the existing wallet, which is named `cwallet.sso`.

```sql
EXEC UTL_FILE.FREMOVE ('WALLET_DIR','cwallet.sso');
```

5. Download the Oracle wallet from your Amazon S3 bucket to the Oracle DB instance.

The following example downloads the wallet named `cwallet.sso` from the Amazon S3 bucket named `my_s3_bucket` to the DB instance directory named `WALLET_DIR`.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name => 'my_s3_bucket',
    p_s3_prefix => 'cwallet.sso',
    p_directory_name => 'WALLET_DIR')
AS TASK_ID FROM DUAL;
```

6. (Optional) Download a password-protected Oracle wallet.

Download this wallet only if you want to require a password for every use of the wallet. The following example downloads password-protected wallet `ewallet.p12`.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name => 'my_s3_bucket',
    p_s3_prefix => 'ewallet.p12',
    p_directory_name => 'WALLET_DIR')
AS TASK_ID FROM DUAL;
```

7. Check the status of your DB task.

Substitute the task ID returned from the preceding steps for `dbtask-1234567890123-4567.log` in the following example.

```sql
SELECT TEXT FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-1234567890123-4567.log'));
```

8. Check the contents of the directory that you're using to store the Oracle wallet.
Step 4: Grant user permissions for the Oracle wallet

You can either create a new database user or configure an existing user. In either case, you must configure the user to access the Oracle wallet for secure connections and client authentication using certificates.

To grant user permissions for the Oracle wallet

1. Log in your RDS for Oracle DB instance as the master user.
2. If you don't want to configure an existing database user, create a new user. Otherwise, skip to the next step.

The following example creates a database user named `my-user`.

```
CREATE USER my-user IDENTIFIED BY my-user-pwd;
GRANT CONNECT TO my-user;
```

3. Grant permission to your database user on the directory containing your Oracle wallet.

The following example grants read access to user `my-user` on directory `WALLET_DIR`.

```
GRANT READ ON DIRECTORY WALLET_DIR TO my-user;
```

4. Grant permission to your database user to use the UTL_HTTP package.

The following PL/SQL program grants UTL_HTTP access to user `my-user`.

```
BEGIN
    rdsadmin.rdsadmin_util.grant_sys_object('UTL_HTTP', UPPER('my-user'));
END;
/
```

5. Grant permission to your database user to use the UTL_FILE package.

The following PL/SQL program grants UTL_FILE access to user `my-user`.

For more information, see [Listing files in a DB instance directory](#).
Step 5: Configure access to a website from your DB instance

In this step, you configure your Oracle database user so that it can connect to your target website using UTL_HTTP, your uploaded Oracle Wallet, and the client certificate. For more information, see Configuring Access Control to an Oracle Wallet in the Oracle Database documentation.

To configure access to a website from your RDS for Oracle DB instance

1. Log in your RDS for Oracle DB instance as the master user.
2. Create a Host Access Control Entry (ACE) for your user and the target website on a secure port.

The following example configures my-user to access secret.encrypted-website.com on secure port 443.

```
BEGIN
    DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
        host       => 'secret.encrypted-website.com',
        lower_port => 443,
        upper_port => 443,
        ace        => xs$ace_type(privilege_list => xs$name_list('http'),
                                  principal_name => 'my-user',
                                  principal_type => xs_acl.ptype_db));
    -- If the program unit results in PLS-00201, set
    -- the principal_type parameter to 2 as follows:
    -- principal_type => 2));
END;
/
```

⚠️ Important

The preceding program unit can result in the following error: PLS-00201: identifier 'XS_ACL' must be declared. If this error is returned, replace the

```
BEGIN
    rdsadmin.rdsadmin_util.grant_sys_object('UTL_FILE', UPPER('my-user'));
END;
/
```
line that assigns a value to principal_type with the following line, and then rerun the program unit:

```sql
principal_type => 2));
```

For more information about constants in the PL/SQL package XS_ACL, see `Real Application Security Administrator's and Developer's Guide` in the Oracle Database documentation.

For more information, see `Configuring Access Control for External Network Services` in the Oracle Database documentation.

3. (Optional) Create an ACE for your user and target website on the standard port.

You might need to use the standard port if some web pages are served from the standard web server port (80) instead of the secure port (443).

```sql
BEGIN
    DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
        host       => 'secret.encrypted-website.com',
        lower_port => 80,
        upper_port => 80,
        ace        => xs$ace_type(privilege_list => xs$name_list('http'),
                                   principal_name => 'my-user',
                                   principal_type => xs_acl.ptype_db));
-- If the program unit results in PLS-00201, set
-- the principal_type parameter to 2 as follows:
-- principal_type => 2));
END;
```

4. Confirm that the access control entries exist.

```sql
SET LINESIZE 150
COLUMN HOST FORMAT A40
COLUMN ACL FORMAT A50

SELECT HOST, LOWER_PORT, UPPER_PORT, ACL
FROM DBA_NETWORK_ACLS
ORDER BY HOST;
```
5. **Grant permission to your database user to use the UTL_HTTP package.**

The following PL/SQL program grants UTL_HTTP access to user `my-user`.

```
BEGIN
   rdsadmin.rdsadmin_util.grant_sys_object('UTL_HTTP', UPPER('my-user'));
END;
/
```

6. **Confirm that related access control lists exist.**

```
SET LINESIZE 150
COLUMN ACL FORMAT A50
COLUMN PRINCIPAL FORMAT A20
COLUMN PRIVILEGE FORMAT A10

SELECT ACL, PRINCIPAL, PRIVILEGE, IS_GRANT,
     TO_CHAR(START_DATE, 'DD-MON-YYYY') AS START_DATE,
     TO_CHAR(END_DATE, 'DD-MON-YYYY') AS END_DATE
FROM DBA_NETWORK_ACL_PRIVILEGES
ORDER BY ACL, PRINCIPAL, PRIVILEGE;
```

7. **Grant permission to your database user to use certificates for client authentication and your Oracle wallet for connections.**

**Note**

If you're not using client certificates for authentication, you can skip this step.

```
DECLARE
   l_wallet_path all_directories.directory_path%type;
BEGIN
   SELECT DIRECTORY_PATH
   INTO l_wallet_path
   FROM ALL_DIRECTORIES
   WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
   DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACE(
      wallet_path => 'file:' || l_wallet_path,
      ace         => `xs$ace_type(privilege_list => `xs$name_list('use_client_certificates'),
                     principal_name => 'my-user',
```
Step 6: Test connections from your DB instance to a website

In this step, you configure your database user so that it can connect to the website using UTL_HTTP, your uploaded Oracle Wallet, and the client certificate.

To configure access to a website from your RDS for Oracle DB instance

1. Log in your RDS for Oracle DB instance as a database user with UTL_HTTP permissions.
2. Confirm that a connection to your target website can resolve the host address.

   The following example gets the host address from `secret.encrypted-website.com`.

   ```sql
   SELECT UTL_INADDR.GET_HOST_ADDRESS(host => 'secret.encrypted-website.com')
   FROM DUAL;
   ```

3. Test a failed connection.

   The following query fails because UTL_HTTP requires the location of the Oracle wallet with the certificates.

   ```sql
   SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
   ```

4. Test website access by using UTL_HTTP.SET_WALLET and selecting from DUAL.

   ```sql
   DECLARE
       l_wallet_path all_directories.directory_path%type;
   BEGIN
       SELECT DIRECTORY_PATH
       INTO l_wallet_path
       FROM ALL_DIRECTORIES
       WHERE UPPER(DIRECTORY_NAME)= 'WALLET_DIR';
       UTL_HTTP.SET_WALLET('file://' || l_wallet_path);
   END;
   /
5. (Optional) Test website access by storing your query in a variable and using EXECUTE IMMEDIATE.

```
DECLARE
  l_wallet_path all_directories.directory_path%type;
  v_webpage_sql VARCHAR2(1000);
  v_results     VARCHAR2(32767);
BEGIN
  SELECT DIRECTORY_PATH
    INTO l_wallet_path
    FROM ALL_DIRECTORIES
    WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
  v_webpage_sql := 'SELECT UTL_HTTP.REQUEST('''secret.encrypted-website.com''', '''',
    'file://' ||l_wallet_path||'') FROM DUAL';
  DBMS_OUTPUT.PUT_LINE(v_webpage_sql);
  EXECUTE IMMEDIATE v_webpage_sql INTO v_results;
  DBMS_OUTPUT.PUT_LINE(v_results);
END;
/
```

6. (Optional) Find the file system location of your Oracle wallet directory.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'WALLET_DIR'));
```

Use the output from the previous command to make an HTTP request. For example, if the directory is `rdsdbdata/userdirs/01`, run the following query.

```
SELECT UTL_HTTP.REQUEST('https://secret.encrypted-website.com/', '',
  'file://rdsdbdata/userdirs/01')
FROM   DUAL;
```
Working with CDBs in RDS for Oracle

In the Oracle multitenant architecture, a container database (CDB) can include customer-created pluggable databases (PDBs). For more information about CDBs, see Introduction to the Multitenant Architecture in the Oracle Database documentation.

Topics

- Overview of RDS for Oracle CDBs

- Backing up and restoring a CDB
- Converting an RDS for Oracle non-CDB to a CDB
- Converting the single-tenant configuration to multi-tenant
- Adding an RDS for Oracle tenant database to your CDB instance
- Modifying an RDS for Oracle tenant database
- Deleting an RDS for Oracle tenant database from your CDB
- Viewing tenant database details
- Upgrading your CDB

Overview of RDS for Oracle CDBs

You can create an RDS for Oracle DB instance as a container database (CDB) when you run Oracle Database 19c or higher. Starting with Oracle Database 21c, all databases are CDBs. A CDB differs from a non-CDB because it can contain pluggable databases (PDBs), which are called tenant databases in RDS for Oracle. A PDB is a portable collection of schemas and objects that appears to an application as a separate database.

You create your initial tenant database (PDB) when you create your CDB instance. In RDS for Oracle, your client application interacts with a PDB rather than the CDB. Your experience with a PDB is mostly identical to your experience with a non-CDB.

Topics

- Multi-tenant configuration of the CDB architecture
- Single-tenant configuration of the CDB architecture
- Creation and conversion options for CDBs
Multi-tenant configuration of the CDB architecture

RDS for Oracle supports the *multi-tenant configuration* of the Oracle multitenant architecture, also called the *CDB architecture*. In this configuration, your RDS for Oracle CDB instance can contain 1–30 tenant databases, depending on the database edition and any required option licenses. In Oracle database, a tenant database is a PDB. Your DB instance must use Oracle database release 19.0.0.0.ru-2022-01.rur-2022.r1 or higher.

**Note**

The Amazon RDS feature is called "multi-tenant" rather than "multitenant" because it is a capability of the RDS platform, not just the Oracle DB engine. The term "Oracle multitenant" refers exclusively to the Oracle database architecture, which is compatible with both on-premises and RDS deployments.

You can configure the following settings:

- Tenant database name
- Tenant database master username
- Tenant database master password
- Tenant database character set
- Tenant database national character set

The tenant database character set can be different from the CDB character set. The same applies to the national character set. After you create your initial tenant database, you can create, modify, or delete tenant databases using RDS APIs. The CDB name defaults to RDSCDB and can't be changed. For more information, see Settings for DB instances and Modifying an RDS for Oracle tenant database.
Single-tenant configuration of the CDB architecture

RDS for Oracle supports a legacy configuration of the Oracle multitenant architecture called the *single-tenant configuration*. In this configuration, an RDS for Oracle CDB instance can contain only one tenant (PDB). You can't create more PDBs later.

Creation and conversion options for CDBs

Oracle Database 21c supports only CDBs, whereas Oracle Database 19c supports both CDBs and non-CDBs. All RDS for Oracle CDB instances support both the multi-tenant and single-tenant configurations.

Creation, conversion, and upgrade options for the Oracle database architecture

The following table shows the different architecture options for creating and upgrading RDS for Oracle databases.

<table>
<thead>
<tr>
<th>Release</th>
<th>Database creation options</th>
<th>Architecture conversion options</th>
<th>Major version upgrade targets</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Database 21c</td>
<td>CDB architecture only</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Oracle Database 19c</td>
<td>CDB or non-CDB architecture</td>
<td>Non-CDB to CDB architecture (April 2021 RU or higher)</td>
<td>21c CDB</td>
</tr>
<tr>
<td>Oracle Database 12c (deprecated)</td>
<td>Non-CDB architecture only</td>
<td>N/A</td>
<td>19c non-CDB</td>
</tr>
</tbody>
</table>

As shown in the preceding table, you can't directly upgrade a non-CDB to a CDB in a new major database version. But you can convert an Oracle Database 19c non-CDB to an Oracle Database 19c CDB, and then upgrade the Oracle Database 19c CDB to an Oracle Database 21c CDB. For more information, see [Converting an RDS for Oracle non-CDB to a CDB](#).

Conversion options for CDB architecture configurations

The following table shows the different options for converting the architecture configuration of an RDS for Oracle DB instance.
<table>
<thead>
<tr>
<th>Current architecture and configuration</th>
<th>Conversion to the single-tenant configuration of the CDB architecture</th>
<th>Conversion to the multi-tenant configuration of the CDB architecture</th>
<th>Conversion to the non-CDB architecture</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-CDB</td>
<td>Supported</td>
<td>Supported*</td>
<td>N/A</td>
</tr>
<tr>
<td>CDB using the single-tenant configuration</td>
<td>N/A</td>
<td>Supported</td>
<td>Not supported</td>
</tr>
<tr>
<td>CDB using the multi-tenant configuration</td>
<td>Not supported</td>
<td>N/A</td>
<td>Not supported</td>
</tr>
</tbody>
</table>

* You can't convert a non-CDB to the multi-tenant configuration in a single operation. When you convert a non-CDB to a CDB, the CDB is in the single-tenant configuration. You can then convert the single-tenant to the multi-tenant configuration in a separate operation.

User accounts and privileges in a CDB

In the Oracle multitenant architecture, all user accounts are either common users or local users. A CDB common user is a database user whose single identity and password are known in the CDB root and in every existing and future PDB. In contrast, a local user exists only in a single PDB.

The RDS master user is a local user account in the PDB, which you name when you create your DB instance. If you create new user accounts, these users will also be local users residing in the PDB. You can't use any user accounts to create new PDBs or modify the state of the existing PDB.

The rdsadmin user is a common user account. You can run RDS for Oracle packages that exist in this account, but you can't log in as rdsadmin. For more information, see About Common Users and Local Users in the Oracle documentation.

Parameter group families in a CDB

CDBs have their own parameter group families and default parameter values. The CDB parameter group families are as follows:

- oracle-ee-cdb-21
Limitations of RDS for Oracle CDBs

RDS for Oracle supports a subset of features available in an on-premises CDB.

CDB limitations

The following limitations apply to RDS for Oracle CDBs:

- You can't connect to a CDB. You always connect to the tenant database (PDB) rather than the CDB. Specify the endpoint for the PDB just as for a non-CDB. The only difference is that you specify `pdb_name` for the database name, where `pdb_name` is the name you chose for your PDB.
- You can't convert a CDB in the multi-tenant configuration to a CDB in the single-tenant conversion. Conversion to the multi-tenant configuration is one-way and irreversible.
- You can't enable or convert to the multi-tenant configuration if your DB instance uses an Oracle database release lower than 19.0.0.0.ru-2022-01.rur-2022.r1.
- You can't use an RDS for Oracle CDB with ORDS v22 and higher. As a workaround, you can either use a lower version of ORDS or use an Oracle Database 19c non-CDB.
- You can't use an RDS for Oracle CDB with ORDS v22 and higher. As a workaround, you can either use a lower version of ORDS or use an Oracle Database 19c non-CDB.

Support for the following features depends on the architecture configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Supported in single-tenant</th>
<th>Supported in multi-tenant</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Data Guard</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Oracle Label Security</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Oracle Enterprise Manager (OEM)</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>OEM Agent</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Feature</td>
<td>Supported in single-tenant</td>
<td>Supported in multi-tenant</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>Database Activity Streams</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

**Tenant database (PDB) limitations**

The following limitations apply to tenant databases in the RDS for Oracle multi-tenant configuration:

- You can't defer tenant database operations to the maintenance window. All changes occur immediately.
- You can't add a tenant database to a CDB that uses the single-tenant configuration.
- You can't add or modify multiple tenant databases in a single operation. You can only add or modify them one at a time.
- You can't modify a tenant database to be named CDB$ROOT or PDB$SEED.
- You can't delete a tenant database if it is the only tenant in the CDB.
- Not all DB instance class types have sufficient resources to support multiple PDBs in an RDS for Oracle CDB instance. An increased PDB count affects the performance and stability of the smaller instance classes and increases the time of most instance-level operations, for example, database upgrades.
- You can't use multiple AWS accounts to create PDBs in the same CDB. PDBs must be owned by the same account as the DB instance that the PDBs are hosted on.
- All PDBs in a CDB use the same endpoint and database listener.
- The following operations aren't supported at the PDB level but are supported at the CDB level:
  - Backup and recovery
  - Database upgrades
  - Maintenance actions
- The following features aren't supported at the PDB level but are supported at the CDB level:
  - Performance Insights
  - Option groups (options are installed on all PDBs on your CDB instance)
  - Parameter groups (all parameters are derived from the parameter group associated with your CDB instance)
• PDB-level operations that are supported in the on-premises CDB architecture but aren't supported in an RDS for Oracle CDB include the following:

   ![Note]
   The following list is not exhaustive.

   • Application PDBs
   • Proxy PDBs
   • Starting and stopping a PDB
   • Unplugging and plugging in PDBs

   To move data into or out of your CDB, use the same techniques as for a non-CDB. For more information about migrating data, see Importing data into Oracle on Amazon RDS.

   • Setting options at the PDB level

   The PDB inherits options settings from the CDB option group. For more information about setting options, see Working with parameter groups. For best practices, see Working with DB parameter groups.

   • Configuring parameters in a PDB

   The PDB inherits parameter settings from the CDB. For more information about setting option, see Adding options to Oracle DB instances.

   • Configuring different listeners for PDBs in the same CDB
   • Oracle Flashback features
   • Auditing information from within a PDB

### Configuring an RDS for Oracle CDB

Configuring a CDB is similar to configuring a non-CDB.

**Topics**

• Creating an RDS for Oracle CDB instance
• Connecting to a PDB in your RDS for Oracle CDB
Creating an RDS for Oracle CDB instance

In RDS for Oracle, creating a CDB is almost identical to creating a non-CDB. The difference is that you choose the Oracle multitenant architecture when creating your DB instance and also choose an architecture configuration: multi-tenant or single-tenant. If you create tags when you create a CDB in the multi-tenant configuration, RDS propagates the tags to the initial tenant database. To create a CDB, use the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a CDB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the CDB instance.
3. In the navigation pane, choose Databases.
4. Choose Create database.
5. In Choose a database creation method, select Standard Create.
6. In Engine options, choose Oracle.
7. For Database management type, choose Amazon RDS.
8. For Architecture settings, choose Oracle multitenant architecture.
9. For Architecture configuration, do either of the following:
   - Choose Multi-tenant configuration and proceed to the next step.
   - Choose Single-tenant configuration and skip to Step 11.
10. (Multi-tenant configuration) For Tenant database settings, make the following changes:
   - For Tenant database name, enter the name of your initial PDB. The PDB name must be different from the CDB name, which defaults to RDSCDB.
   - For Tenant database master username, enter the master username of your PDB. You can’t use the tenant database master username to log in to the CDB itself.
   - Either enter a password in Tenant database master password or choose Auto generate a password.
   - For Tenant database character set, choose a character set for the PDB. You can choose a tenant database character set that is different from the CDB character set.
The default PDB character set is AL32UTF8. If you choose a non-default PDB character set, CDB creation might be slower.

**Note**
You can't create multiple tenant databases as part of the CDB creation process. You can only add PDBs to an already existing CDB.

11. (Single-tenant configuration) Choose the settings that you want based on the options listed in Settings for DB instances. Note the following:

- For Master username, enter the name for a local user in your PDB. You can't use the master username to log in to the CDB root.
- For Initial database name, enter the name of your PDB. You can't name the CDB, which has the default name RDSCDB.

12. Choose Create database.

**AWS CLI**

To create a CDB in the multi-tenant configuration, use the create-db-instance command with the following parameters:

- --db-instance-identifier
- --db-instance-class
- --engine { oracle-ee-cdb | oracle-se2-cdb }
- --master-username
- --master-user-password
- --multi-tenant (for the single-tenant configuration, either don't specify multi-tenant or specify --no-multi-tenant)
- --allocated-storage
- --backup-retention-period

For information about each setting, see Settings for DB instances.
This following example creates an RDS for Oracle DB instance named *my-cdb-inst* in the multi-tenant configuration. If you specify `--no-multi-tenant` or don't specify `--multi-tenant`, the default CDB configuration is single-tenant. The engine is `oracle-ee-cdb`: a command that specifies `oracle-ee` and `--multi-tenant` fails with an error. The initial tenant database is named *mypdb*.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
   --engine oracle-ee-cdb \
   --db-instance-identifier my-cdb-inst \
   --multi-tenant \
   --db-name mypdb \
   --allocated-storage 250 \
   --db-instance-class db.t3.large \
   --master-username pdb_admin \
   --master-user-password pdb_admin_password \
   --backup-retention-period 3
```

For Windows:

```bash
aws rds create-db-instance ^
   --engine oracle-ee-cdb ^
   --db-instance-identifier my-cdb-inst ^
   --multi-tenant ^
   --db-name mypdb ^
   --allocated-storage 250 ^
   --db-instance-class db.t3.large ^
   --master-username pdb_admin ^
   --master-user-password pdb_admin_password ^
   --backup-retention-period 3
```

**Note**

Specify a password other than the prompt shown here as a security best practice.
This command produces output similar to the following. The database name, character set, national character set, and master user aren't included in the output. You can view this information by using the CLI command describe-tenant-databases.

```json
{
  "DBInstance": {
    "DBInstanceIdentifier": "my-cdb-inst",
    "DBInstanceClass": "db.t3.large",
    "MultiTenant": true,
    "Engine": "oracle-ee-cdb",
    "DBResourceID": "db-ABCDEFGJIJKLMNOPQRSTUVWXYZ",
    "DBInstanceStatus": "creating",
    "AllocatedStorage": 250,
    "PreferredBackupWindow": "04:59-05:29",
    "BackupRetentionPeriod": 3,
    "DBSecurityGroups": [],
    "VpcSecurityGroups": [
      {
        "VpcSecurityGroupId": "sg-0a1bcd2e",
        "Status": "active"
      }
    ],
    "DBParameterGroups": [
      {
        "DBParameterGroupName": "default.oracle-ee-cdb-19",
        "ParameterApplyStatus": "in-sync"
      }
    ],
    "DBSubnetGroup": {
      "DBSubnetGroupName": "default",
      "DBSubnetGroupDescription": "default",
      "VpcId": "vpc-1234567a",
      "SubnetGroupStatus": "Complete",
      ...
    }
  }
}
```

**RDS API**

To create a DB instance by using the Amazon RDS API, call the `CreateDBInstance` operation.

For information about each setting, see [Settings for DB instances](#).
Connecting to a PDB in your RDS for Oracle CDB

You can use a utility like SQL*Plus to connect to a PDB. To download Oracle Instant Client, which includes a standalone version of SQL*Plus, see Oracle Instant Client Downloads.

To connect SQL*Plus to your PDB, you need the following information:

- PDB name
- Database user name and password
- Endpoint for your DB instance
- Port number

For information about finding the preceding information, see Finding the endpoint of your RDS for Oracle DB instance.

Example To connect to your PDB using SQL*Plus

In the following examples, substitute your master user for master_user_name. Also, substitute the endpoint for your DB instance, and then include the port number and the Oracle SID. The SID value is the name of the PDB that you specified when you created your DB instance, and not the DB instance identifier.

For Linux, macOS, or Unix:

sqlplus 'master_user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=endpoint)(PORT=port))(CONNECT_DATA=(SID=pdb_name)))'

For Windows:

sqlplus master_user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=endpoint)(PORT=port))(CONNECT_DATA=(SID=pdb_name)))

You should see output similar to the following.

SQL*Plus: Release 19.0.0.0.0 Production on Mon Aug 21 09:42:20 2021

After you enter the password for the user, the SQL prompt appears.

SQL>
Note

The shorter format connection string (Easy connect or EZCONNECT), such as
sqlplus `username/password@LONGER-TAN-63-CHARS-RDS-ENDPOINT-HERE:1521/database-identifier`, might encounter a maximum character limit and should not be used to connect.

Backing up and restoring a CDB

You can back up and restore your CDB using either RDS DB snapshots or Recovery Manager (RMAN).

Backing up and restoring a CDB using DB snapshots

DB snapshots work similarly in the CDB and non-CDB architectures. The principal differences are as follows:

- When you restore a DB snapshot of a CDB, you can't rename the CDB. The CDB is named RDSCDB and can't be changed.
- When you restore a DB snapshot of a CDB, you can't rename PDBs. You can modify the PDB name by using the `modify-tenant-database` command.
- To find tenant databases in a snapshot, use the CLI command `describe-db-snapshot-tenant-databases`.
- You can't directly interact with the tenant databases in a CDB snapshot that uses the multi-tenant architecture configuration. If you restore the DB snapshot, you restore all its tenant databases.
- RDS for Oracle implicitly copies tags on a tenant database to the tenant database in a DB snapshot. When you restore a tenant database, the tags appear in the restored database.
- If you restore a DB snapshot and specify new tags using the `--tags` parameter, the new tags overwrite all existing tags.
- If you take a DB snapshot of a CDB instance that has tags, and you specify `--copy-tags-to-snapshot`, RDS for Oracle copies tags from the tenant databases to the tenant databases in the snapshot.

For more information, see [Oracle Database considerations](#).
Backing up and restoring a CDB using RMAN

To learn how to back up and restore a CDB or individual tenant database using RMAN, see Performing common RMAN tasks for Oracle DB instances.

Converting an RDS for Oracle non-CDB to a CDB

You can change the architecture of an Oracle database from the non-CDB architecture to the Oracle multitenant architecture, also called the CDB architecture, with the modify-db-instance command. In most cases, this technique is preferable to creating a new CDB and importing data. The conversion operation incurs downtime.

When you upgrade your database engine version, you can't change the database architecture in the same operation. Therefore, to upgrade an Oracle Database 19c non-CDB to an Oracle Database 21c CDB, you first need to convert the non-CDB to a CDB in one step, and then upgrade the 19c CDB to a 21c CDB in a separate step.

The non-CDB conversion operation has the following requirements:

- You must specify oracle-ee-cdb or oracle-se2-cdb for the DB engine type. These are the only supported values.
- Your DB engine must use Oracle Database 19c with an April 2021 or later release update (RU).

The operation has the following limitations:

- You can't convert a CDB to a non-CDB. You can only convert a non-CDB to a CDB.
- You can't convert a non-CDB to the multi-tenant configuration in a single modify-db-instance call. After you convert a non-CDB to a CDB, your CDB is in the single-tenant configuration. To convert the single-tenant configuration to the multi-tenant configuration, run modify-db-instance again. For more information, see Converting the single-tenant configuration to multi-tenant.
- You can't convert a primary or replica database that has Oracle Data Guard enabled. To convert a non-CDB that has read replicas, first delete all read replicas.
- You can't upgrade the DB engine version and convert a non-CDB to a CDB in the same operation.
- The considerations for option and parameter groups are the same as for upgrading the DB engine. For more information, see Considerations for Oracle DB upgrades.
Console

To convert a non-CDB to a CDB

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where your DB instance resides.

3. In the navigation pane, choose Databases, and then choose the non-CDB instance that you want to convert to a CDB instance.

4. Choose Modify.

5. For Architecture settings, select Oracle multitenant architecture. After conversion, your CDB will be in the single-tenant configuration.

6. (Optional) For DB parameter group, choose a new parameter group for your CDB instance. The same parameter group considerations apply when converting a DB instance as when upgrading a DB instance. For more information, see Parameter group considerations.

7. (Optional) For Option group, choose a new option group for your CDB instance. The same option group considerations apply when converting a DB instance as when upgrading a DB instance. For more information, see Option group considerations.

8. When all the changes are as you want them, choose Continue and check the summary of modifications.

9. (Optional) Choose Apply immediately to apply the changes immediately. Choosing this option can cause downtime in some cases. For more information, see Using the Apply Immediately setting.

10. On the confirmation page, review your changes. If they are correct, choose Modify DB instance.

    Or choose Back to edit your changes or Cancel to cancel your changes.

AWS CLI

To convert the non-CDB on your DB instance to a CDB in the single-tenant configuration, set --engine to oracle-ee-cdb or oracle-se2-cdb in the AWS CLI command modify-db-instance. For more information, see Settings for DB instances.
The following example converts the DB instance named `my-non-cdb` and specifies a custom option group and parameter group.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
   --db-instance-identifier my-non-cdb \
   --engine oracle-ee-cdb \
   --option-group-name custom-option-group \
   --db-parameter-group-name custom-parameter-group
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier my-non-cdb ^
   --engine oracle-ee-cdb ^
   --option-group-name custom-option-group ^
   --db-parameter-group-name custom-parameter-group
```

**RDS API**

To convert a non-CDB to a CDB, specify Engine in the RDS API operation [ModifyDBInstance](#).

**Converting the single-tenant configuration to multi-tenant**

You can modify the architecture of an RDS for Oracle CDB from the single-tenant configuration to the multi-tenant configuration. Before and after the conversion, your CDB contains a single tenant database (PDB).

During the conversion, RDS for Oracle migrates the following metadata to the new tenant database:

- The master username
- The database name
- The character set
- The national character set
Before the conversion, you could view the preceding information by using the describe-db-instances command. After the conversion, you view the information by using the describe-tenant-database command.

The conversion has the following requirements and limitations:

- After you convert the single-tenant architecture configuration to the multi-tenant configuration, you can't later convert the architecture back to the single-tenant configuration. The operation is irreversible.
- The tags for the DB instance propagate to the initial tenant DB created during the conversion.
- You can't convert a primary or replica database that has Oracle Data Guard enabled.
- You can't upgrade the DB engine version and convert to the multi-tenant configuration in the same operation.
- Your IAM policy must have permission to create a tenant database.

**Console**

**To convert a CDB using the single-tenant configuration to the multi-tenant configuration**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where your DB instance resides.
3. In the navigation pane, choose **Databases**, and then choose the non-CDB instance that you want to convert to a CDB instance.
4. Choose **Modify**.
5. For **Architecture settings**, select **Oracle multitenant architecture**.
6. For **Architecture configuration**, select **Multi-tenant configuration**.
7. (Optional) For **DB parameter group**, choose a new parameter group for your CDB instance. The same parameter group considerations apply when converting a DB instance as when upgrading a DB instance.
8. (Optional) For **Option group**, choose a new option group for your CDB instance. The same option group considerations apply when converting a DB instance as when upgrading a DB instance.
9. When all the changes are as you want them, choose Continue and check the summary of modifications.

10. Choose Apply immediately. This option is required when you switch to a multi-tenant configuration. Note that this option can cause downtime in some cases.

11. On the confirmation page, review your changes. If they are correct, choose Modify DB instance.

    Or choose Back to edit your changes or Cancel to cancel your changes.

AWS CLI

To convert a CDB using the single-tenant configuration to the multi-tenant configuration, specify --multi-tenant in the AWS CLI command modify-db-instance.

The following example converts the DB instance named my-st-cdb from the single-tenant configuration to the multi-tenant configuration. The --apply-immediately option is required.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance --region us-east-1
    --db-instance-identifier my-st-cdb
    --multi-tenant
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance --region us-east-1
    --db-instance-identifier my-st-cdb
    --multi-tenant
    --apply-immediately
```

The output looks something like the following.

```
{
    "DBInstance": {
        "DBInstanceIdentifier": "my-st-cdb",
        "DBInstanceClass": "db.r5.large",
    }
}
```
Adding an RDS for Oracle tenant database to your CDB instance

In the RDS for Oracle multi-tenant configuration, a tenant database is a PDB. To add a tenant database, make sure you meet the following prerequisites:

- Your CDB has the multi-tenant configuration enabled. For more information, see Multi-tenant configuration of the CDB architecture.
- You have the necessary IAM permissions to create the tenant database.

You can add a tenant database using the AWS Management Console, the AWS CLI, or the RDS API. You can't add multiple tenant databases in a single operation: you must add them one at a time. If the CDB has backup retention enabled, Amazon RDS backs up the DB instance before and after it adds a new tenant database.
### Console

**To add a tenant database to your DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the tenant database.
3. In the navigation pane, choose **Databases**.
4. Choose the CDB instance to which you want to add a tenant database. Your DB instance must use the multi-tenant configuration of the CDB architecture.
5. Choose **Actions** and then **Add tenant database**.
6. For **Tenant database settings**, do the following:
   - For **Tenant database name**, enter the name of your new PDB.
   - For **Tenant database master username**, enter the name of the master user for your PDB. This master user is different from the master user of the CDB.
   - Either enter a password in **Tenant database master password** or select **Auto generate a password**.
   - For **Tenant database character set**, choose a character set for the PDB. The default is **AL32UTF8**. You can choose a PDB character set that is different from the CDB character set.
   - For **Tenant database national character set**, choose a national character set for the PDB. The default is **AL32UTF8**. The national character set specifies the encoding only for columns that use the NCHAR data type (NCHAR, NVARCHAR2, and NCLOB) and doesn't affect database metadata.

   For more information about the preceding settings, see [Settings for DB instances](#).
7. Choose **Add tenant**.

### AWS CLI

To add a tenant database to your CDB with the AWS CLI, use the command `create-tenant-database` with the following required parameters:

- `--db-instance-identifier`
• --tenant-db-name
• --master-username
• --master-user-password

This following example creates a tenant database named `mypdb2` in the RDS for Oracle CDB instance named `my-cdb-inst`. The PDB character set is UTF-16.

Example

For Linux, macOS, or Unix:

```
aws rds create-tenant-database --region us-east-1 \
    --db-instance-identifier my-cdb-inst \
    --tenant-db-name mypdb2 \
    --master-username mypdb2-admin \
    --master-user-password mypdb2-pwd \
    --character-set-name UTF-16
```

For Windows:

```
aws rds create-tenant-database --region us-east-1 \
    --db-instance-identifier my-cdb-inst ^
    --tenant-db-name mypdb2 ^
    --master-username mypdb2-admin ^
    --master-user-password mypdb2-pwd ^
    --character-set-name UTF-16
```

The output looks similar to the following.

```
...}
    "TenantDatabase" :
    {
        "DbiResourceId" : "db-abc123",
        "TenantDatabaseResourceId" : "tdb-bac567",
        "DBInstanceIdentifier" : "my-cdb-inst",
        "TenantDBName" : "mypdb2",
        "Status" : "creating",
        "MasterUsername" : "mypdb2",
```
Modifying an RDS for Oracle tenant database

You can modify only the PDB name and the master user password of a tenant database in your CDB. Note the following requirements and limitations:

- To modify the settings of a tenant database in your DB instance, the tenant database must exist.
- You can't modify multiple tenant databases in a single operation. You can only modify one tenant database at a time.
- You can't change the name of a tenant database to CDB$ROOT or PDB$SEED.

You can modify PDBs using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To modify the PDB name or master password of a tenant database**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the tenant database.
3. In the navigation pane, choose **Databases**.
4. Choose the tenant database whose database name or master user password you want to modify.
5. Choose **Modify**.
6. For **Tenant database settings**, do any of the following:
   - For **Tenant database name**, enter the new name of your new PDB.
   - For **Tenant database master password**, enter a new password.
7. Choose **Modify tenant**.
AWS CLI

To modify a tenant database using the AWS CLI, call the `modify-tenant-database` command with the following parameters:

- `--db-instance-identifier value`
- `--tenant-db-name value`
- `[--new-tenant-db-name value]`
- `[--master-user-password value]`

The following example renames tenant database `pdb1` to `pdb-hr` on DB instance `my-cdb-inst`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-tenant-database --region us-east-1 \
   --db-instance-identifier my-cdb-inst \
   --tenant-db-name pdb1 \
   --new-tenant-db-name pdb-hr
```

For Windows:

```bash
aws rds modify-tenant-database --region us-east-1 ^
   --db-instance-identifier my-cdb-inst ^
   --tenant-db-name pdb1 ^
   --new-tenant-db-name pdb-hr
```

This command produces output similar to the following.

```json
{
   "TenantDatabase" : {
      "DbiResourceId" : "db-abc123",
      "TenantDatabaseResourceId" : "tdb-bac567",
      "DBInstanceIdentifier" : "my-cdb-inst",
      "TenantDBName" : "pdb1",
      "Status" : "modifying",
      "MasterUsername" : "tenant-admin-user"
   }
}
```
Deleting an RDS for Oracle tenant database from your CDB

You can delete a tenant database (PDB) using the AWS Management Console, the AWS CLI, or the RDS API. Consider the following prerequisites and limitations:

- The tenant database and DB instance must exist.
- For the deletion to succeed, one of the following situations must exist:
  - The tenant database and DB instance are available.
  - The tenant database is being created.
  - The DB instance is modifying the tenant database.
  - You can't delete multiple tenant databases in a single operation.
  - You can't delete a tenant database if it is the only tenant in the CDB.

Note

You can take a final snapshot, but only if the tenant database and DB instance were in an available state before you issued the delete-tenant-database command.
To delete a tenant database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the tenant database that you want to delete.
3. For Actions, choose Delete.
4. To create a final DB snapshot for the DB instance, choose Create final snapshot?.
5. If you chose to create a final snapshot, enter the Final snapshot name.
6. Enter delete me in the box.
7. Choose Delete.

AWS CLI

To delete a tenant database using the AWS CLI, call the delete-tenant-database command with the following parameters:

- --db-instance-identifier value
- --tenant-db-name value
- [--skip-final-snapshot | --no-skip-final-snapshot]
- [--final-snapshot-identifier value]

This following example deletes the tenant database named pdb-test from the CDB named my-cdb-inst. By default, the operation creates a final snapshot.

Example

For Linux, macOS, or Unix:

```bash
aws rds delete-tenant-database --region us-east-1 "
    --db-instance-identifier my-cdb-inst "
    --tenant-db-name pdb-test "
    --final-snapshot-identifier final-snap-pdb-test
```
For Windows:

```
aws rds delete-tenant-database --region us-east-1
   --db-instance-identifier my-cdb-inst
   --tenant-db-name pdb-test
   --final-snapshot-identifier final-snap-pdb-test
```

This command produces output similar to the following.

```
{
   "TenantDatabase" : {
      "DbiResourceId" : "db-abc123",
      "TenantDatabaseResourceId" : "tdb-bac456",
      "DBInstanceIdentifier" : "my-cdb-inst",
      "TenantDBName" : "pdb-test",
      "Status" : "deleting",
      "MasterUsername" : "pdb-test-admin",
      "Port" : "6555",
      "CharacterSetName" : "UTF-16",
      "MaxAllocatedStorage" : "1000",
      "ParameterGroups" : [
         {
            "ParameterGroupName" : "tenant-1-params",
            "ParameterApplyStatus" : "in-sync"
         }
      ],
      "OptionGroupMemberships" : [
         {
            "OptionGroupName" : "tenant-1-options",
            "Status" : "in-sync"
         }
      ]
   }
}
```

### Viewing tenant database details

You can view details about a tenant database in the same way that you can for a non-CDB or CDB.
To view details about a tenant database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where your DB instance resides.
3. In the navigation pane, choose Databases.

In the preceding image, the sole tenant database (PDB) appears as a child of the DB instance.

4. Choose the name of a tenant database.
AWS CLI

To see details about your PDBs, use the AWS CLI command `describe-tenant-databases`.

This following example describes all tenant databases in the specified Region.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds describe-tenant-databases --region us-east-1
```

For Windows:

```bash
aws rds describe-tenant-databases --region us-east-1
```

This command produces output similar to the following.

```json
"TenantDatabases" : [
    {
        "DBInstanceIdentifier" : "my-cdb-inst",
        "TenantDBName" : "pdb-test",
        "Status" : "available",
        "MasterUsername" : "pdb-test-admin",
        "DbiResourceId" : "db-abc123",
        "TenantDatabaseResourceId" : "tdb-bac456",
        "CharacterSetName" : "AL32UTF8",
        "NcharCharacterSetName" : "AL16UTF16",
        "DeletionProtection" : false,
        "PendingModifiedValues" : {
            "MasterUserPassword" : "****"
        },
        "TagList" : []
    },
    {
        "DBInstanceIdentifier" : "my-cdb-inst2",
        "TenantDBName" : "pdb-dev",
        "Status" : "modifying",
        "MasterUsername" : "masterrdsuser"
    }
]
```
The following example describes the tenant databases on DB instance my-cdb-inst in the specified Region.

Example

For Linux, macOS, or Unix:

```
aws rds describe-tenant-databases --region us-east-1 --db-instance-identifier my-cdb-inst
```

For Windows:

```
aws rds describe-tenant-databases --region us-east-1 --db-instance-identifier my-cdb-inst
```

This command produces output similar to the following.

```
{
"TenantDatabase": {
"TenantDatabaseCreateTime": "2023-10-19T23:55:30.046Z",
"DBInstanceIdentifier": "my-cdb-inst",
"TenantDBName": "pdb-hr",
"Status": "creating",
"MasterUsername": "tenant-admin-user",
"DbiResourceId": "db-abc123",
"TenantDatabaseResourceId": "tdb-bac567",

... other truncated data
```
The following example describes tenant database pdb1 on DB instance my-cdb-inst in the US East (N. Virginia) Region.

Example

For Linux, macOS, or Unix:

```
aws rds describe-tenant-databases --region us-east-1 \
--db-instance-identifier my-cdb-inst \
--tenant-db-name pdb1
```

For Windows:

```
aws rds describe-tenant-databases --region us-east-1 ^
--db-instance-identifier my-cdb-inst ^
--tenant-db-name pdb1
```

This command produces output similar to the following.

```json
{
    "TenantDatabases" : [
        {
            "DbiResourceId" : "db-abc123",
            "TenantDatabaseResourceId" : "tdb-bac567",
            "DBInstanceIdentifier" : "my-cdb-inst",
        }
    ]
}
```
You can upgrade a CDB to a different Oracle Database release. For example, you can upgrade an Oracle Database 19c CDB to an Oracle Database 21c CDB. You can't change the database architecture during an upgrade. Thus, you can't upgrade a non-CDB to a CDB or upgrade a CDB to a non-CDB.

The procedure for upgrading a CDB to a CDB is the same as for upgrading a non-CDB to a non-CDB. For more information, see [Upgrading the RDS for Oracle DB engine](#).
Administering your RDS for Oracle DB instance

Following are the common management tasks that you perform with an RDS for Oracle DB instance. Some tasks are the same for all RDS DB instances. Other tasks are specific to RDS for Oracle.

The following tasks are common to all RDS databases, but Oracle Database has special considerations. For example, you connect to an Oracle database using the Oracle clients SQL*Plus and SQL Developer.

<table>

Following, you can find a description for Amazon RDS–specific implementations of common DBA tasks for RDS Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Also, RDS restricts access to certain system procedures and tables that require advanced privileges. In many of the tasks, you run the `rdsadmin` package, which is an Amazon RDS–specific tool that enables you to administer your database.

The following are common DBA tasks for DB instances running Oracle:
## System tasks

### Oracle Scheduler tasks

- **Modifying DBMS_SCHEDULER jobs**
  - Amazon RDS method: dbms_scheduler.set_attribute
  - Oracle method: `dbms_scheduler.set_attribute`

- **Modifying AutoTask maintenance windows**
  - Amazon RDS method: dbms_scheduler.set_attribute
  - Oracle method: `dbms_scheduler.set_attribute`

- **Setting the time zone for Oracle Scheduler jobs**
  - Amazon RDS method: dbms_scheduler.set_scheduler_attribute
  - Oracle method: `dbms_scheduler.set_scheduler_attribute`
| Turning off Oracle Scheduler jobs owned by SYS | Amazon RDS method: rdsadmin.rdsadmin_dbms_scheduler.disable  
Oracle method: dbms_scheduler.disable |
|-----------------------------------------------|------------------------------------------------------------------|
| Turning on Oracle Scheduler jobs owned by SYS  | Amazon RDS method: rdsadmin.rdsadmin_dbms_scheduler.enable  
Oracle method: dbms_scheduler.enable |
| Modifying the Oracle Scheduler repeat interval for jobs of CALENDAR type | Amazon RDS method: rdsadmin.rdsadmin_dbms_scheduler.set_attribute  
Oracle method: dbms_scheduler.set_attribute |
| Modifying the Oracle Scheduler repeat interval for jobs of NAMED type   | Amazon RDS method: rdsadmin.rdsadmin_dbms_scheduler.set_attribute  
Oracle method: dbms_scheduler.set_attribute |
### Turning off autocommit for Oracle Scheduler job creation

Amazon RDS method: `rdsadmin.rdsadmin_dbms_scheduler.set_no_commit_flag`

Oracle method: `dbms_ischeduler.set_no_commit_flag`

---

### Diagnostic tasks

- **Listing incidents**
  - Amazon RDS method: `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents`
  - Oracle method: ADRCI command `show incident`

- **Listing problems**
  - Amazon RDS method: `rdsadmin.rdsadmin_adrci_util.list_adrci_problem`
  - Oracle method: ADRCI command `show problem`

- **Creating incident packages**
  - Amazon RDS method: `rdsadmin.rdsadmin_adrci_util.create_adrci_package`
  - Oracle method: ADRCI command `ips create package`
## Showing trace files

<table>
<thead>
<tr>
<th>Amazon RDS method:</th>
<th>Oracle method: ADRCI command <code>show tracefile</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile</code></td>
<td></td>
</tr>
</tbody>
</table>

## Other tasks

**Creating and dropping directories in the main data storage space**

<table>
<thead>
<tr>
<th>Amazon RDS method:</th>
<th>Oracle method: CREATE DIRECTORY</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rdsadmin.rdsadmin_util.create_directory</code></td>
<td></td>
</tr>
<tr>
<td><code>rdsadmin.rdsadmin_util.drop_directory</code></td>
<td>DROP DIRECTORY</td>
</tr>
</tbody>
</table>

**Listing files in a DB instance directory**

<table>
<thead>
<tr>
<th>Amazon RDS method:</th>
<th>Oracle method: —</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rdsadmin.rds_file_util.listdir</code></td>
<td></td>
</tr>
</tbody>
</table>
| Reading files in a DB instance directory | Amazon RDS method: rdsadmin.rds_file_util.read_text_file  
Oracle method: — |
|------------------------------------------|------------------------------------------------------------------|
| Accessing Opatch files                   | Amazon RDS method: rdsadmin.rds_file_util.read_text_file or rdsadmin.tracefile_listing  
Oracle method: opatch |
| Setting parameters for advisor tasks     | Amazon RDS method: rdsadmin.rdsadmin_util.advisor_task_set_parameter  
Oracle method: Various stored package procedures |
| Disabling AUTO_STATS_ADVISOR_TASK        | Amazon RDS method: rdsadmin.rdsadmin_util.advisor_task_drop  
Oracle method: — |
| Re-enabling AUTO_STATS_ADVISOR_TASK      | Amazon RDS method: rdsadmin.rdsadmin_util.dbms_stats_init  
Oracle method: — |
You can also use Amazon RDS procedures for Amazon S3 integration with Oracle and for running OEM Management Agent database tasks. For more information, see Amazon S3 integration and Performing database tasks with the Management Agent.

**Performing common system tasks for Oracle DB instances**

Following, you can find how to perform certain common DBA tasks related to the system on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

**Topics**

- Disconnecting a session
- Terminating a session
- Canceling a SQL statement in a session
- Enabling and disabling restricted sessions
- Flushing the shared pool
- Flushing the buffer cache
- Flushing the database smart flash cache
- Granting SELECT or EXECUTE privileges to SYS objects
- Revoking SELECT or EXECUTE privileges on SYS objects
- Managing RDS_X$ views for Oracle DB instances
- Granting privileges to non-master users
- Creating custom functions to verify passwords
- Setting up a custom DNS server
- Setting and unsetting system diagnostic events

**Disconnecting a session**

To disconnect the current session by ending the dedicated server process, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.disconnect`. The disconnect procedure has the following parameters.
The following example disconnects a session.

```
begin
    rdsadmin.rdsadmin_util.disconnect(
        sid   => sid,
        serial => serial_number);
end;
/
```

To get the session identifier and the session serial number, query the V$SESSION view. The following example gets all sessions for the user AWSUSER.

```
SELECT SID, SERIAL#, STATUS FROM V$SESSION WHERE USERNAME = 'AWSUSER';
```

The database must be open to use this method. For more information about disconnecting a session, see `ALTER SYSTEM` in the Oracle documentation.

**Terminating a session**

To terminate a session, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.kill`. The `kill` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sid</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The session identifier.</td>
</tr>
<tr>
<td>serial</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The serial number of the session.</td>
</tr>
</tbody>
</table>

Valid values are 'IMMEDIATE' or 'POST_TRANSACTION'.
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>serial</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The serial number of the session.</td>
</tr>
<tr>
<td>method</td>
<td>varchar</td>
<td>null</td>
<td>No</td>
<td>Valid values are 'IMMEDIATE' or 'PROCESS'. If you specify IMMEDIATE, it has the same effect as running the following statement:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>ALTER SYSTEM KILL SESSION 'sid,serial#' IMMEDIATE</td>
</tr>
</tbody>
</table>

If you specify PROCESS, you terminate the processes associated with a session. Only specify PROCESS if terminating the session using IMMEDIATE was unsuccessful.

To get the session identifier and the session serial number, query the V$SESSION view. The following example gets all sessions for the user AWSUSER.

```
SELECT SID, SERIAL#, STATUS FROM V$SESSION WHERE USERNAME = 'AWSUSER';
```

The following example terminates a session.

```
BEGIN
    rdsadmin.rdsadmin_util.kill(
        sid => sid,
        serial => serial_number,
        method => 'IMMEDIATE');
END
```
The following example terminates the processes associated with a session.

```sql
BEGIN
  rdsadmin.rdsadmin_util.kill(
    sid => sid,
    serial => serial_number,
    method => 'PROCESS');
END;
/
```

**Canceling a SQL statement in a session**

To cancel a SQL statement in a session, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.cancel`.

---

**Note**

This procedure is supported for Oracle Database 19c (19.0.0) and all higher major and minor versions of RDS for Oracle.

---

The `cancel` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sid</code></td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The session identifier.</td>
</tr>
<tr>
<td><code>serial</code></td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The serial number of the session.</td>
</tr>
<tr>
<td><code>sql_id</code></td>
<td>varchar2</td>
<td>null</td>
<td>No</td>
<td>The SQL identifier of the SQL statement.</td>
</tr>
</tbody>
</table>

The following example cancels a SQL statement in a session.

```sql
begin
```
To get the session identifier, the session serial number, and the SQL identifier of a SQL statement, query the V$SESSION view. The following example gets all sessions and SQL identifiers for the user AWSUSER.

```
select SID, SERIAL#, SQL_ID, STATUS from V$SESSION where USERNAME = 'AWSUSER';
```

**Enabling and disabling restricted sessions**

To enable and disable restricted sessions, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.restricted_session`. The `restricted_session` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Yes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_enable</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to enable restricted sessions, false to disable restricted sessions.</td>
</tr>
</tbody>
</table>

The following example shows how to enable and disable restricted sessions.

```
/* Verify that the database is currently unrestricted. */

SELECT LOGINS FROM V$INSTANCE;

LOGINS
-------
ALLOWED

/* Enable restricted sessions */

EXEC rdsadmin.rdsadmin_util.restricted_session(p_enable => true);
```
/* Verify that the database is now restricted. */

SELECT LOGINS FROM V$INSTANCE;

LOGINS
-------
RESTRICTED

/* Disable restricted sessions */

EXEC rdsadmin.rdsadmin_util.restricted_session(p_enable => false);

/* Verify that the database is now unrestricted again. */

SELECT LOGINS FROM V$INSTANCE;

LOGINS
-------
ALLOWED

## Flushing the shared pool

To flush the shared pool, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_shared_pool`. The `flush_shared_pool` procedure has no parameters.

The following example flushes the shared pool.

```sql
EXEC rdsadmin.rdsadmin_util.flush_shared_pool;
```

## Flushing the buffer cache

To flush the buffer cache, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_buffer_cache`. The `flush_buffer_cache` procedure has no parameters.

The following example flushes the buffer cache.

```sql
EXEC rdsadmin.rdsadmin_util.flush_buffer_cache;
```
Flush the database smart flash cache

To flush the database smart flash cache, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_flash_cache`. The `flush_flash_cache` procedure has no parameters. The following example flushes the database smart flash cache.

```
EXEC rdsadmin.rdsadmin_util.flush_flash_cache;
```

For more information about using the database smart flash cache with RDS for Oracle, see [Storing temporary data in an RDS for Oracle instance store](#).

Granting SELECT or EXECUTE privileges to SYS objects

Usually you transfer privileges by using roles, which can contain many objects. To grant privileges to a single object, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.grant_sys_object`. The procedure grants only privileges that the master user has already been granted through a role or direct grant.

The `grant_sys_object` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_obj_name</code></td>
<td><code>varchar2</code></td>
<td></td>
<td>Yes</td>
<td>The name of the object to grant privileges for. The object can be a directory, function, package, procedure, sequence, table, or view. Object names must be spelled exactly as they appear in the database.</td>
</tr>
</tbody>
</table>

Important

For all parameter values, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run `CREATE USER myuser` or `CREATE USER MYUSER`, the data dictionary stores `MYUSER`. However, if you use double quotes in `CREATE USER "MyUser"`, the data dictionary stores `MyUser`. 

System tasks
### Parameters

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_grantee</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the object to grant privileges to. The object can be a schema or a role.</td>
</tr>
<tr>
<td>p_privilege</td>
<td>varchar2</td>
<td>null</td>
<td>Yes</td>
<td>—</td>
</tr>
<tr>
<td>p_grant_option</td>
<td>boolean</td>
<td>false</td>
<td>No</td>
<td>Set to true to use the with grant option. The p_grant_option parameter is supported for 12.1.0.2.v4 and later, all 12.2.0.1 versions, and all 19.0.0 versions.</td>
</tr>
</tbody>
</table>

The following example grants select privileges on an object named V_$SESSION to a user named USER1.

```sql
begin
    rdsadmin.rdsadmin_util.grant_sys_object(
        p_obj_name  => 'V_$SESSION',
        p_grantee   => 'USER1',
        p_privilege => 'SELECT');
end;
/
```

The following example grants select privileges on an object named V_$SESSION to a user named USER1 with the grant option.

```sql
begin
    rdsadmin.rdsadmin_util.grant_sys_object(
        p_obj_name  => 'V_$SESSION',
        p_grantee   => 'USER1',
        p_privilege => 'SELECT',
        p_grant_option => true);
end;
/
```
To be able to grant privileges on an object, your account must have those privileges granted to it directly with the grant option, or via a role granted using with admin option. In the most common case, you may want to grant SELECT on a DBA view that has been granted to the SELECT_CATALOG_ROLE role. If that role isn't already directly granted to your user using with admin option, then you can't transfer the privilege. If you have the DBA privilege, then you can grant the role directly to another user.

The following example grants the SELECT_CATALOG_ROLE and EXECUTE_CATALOG_ROLE to USER1. Since the with admin option is used, USER1 can now grant access to SYS objects that have been granted to SELECT_CATALOG_ROLE.

```sql
GRANT SELECT_CATALOG_ROLE TO USER1 WITH ADMIN OPTION;
GRANT EXECUTE_CATALOG_ROLE TO USER1 WITH ADMIN OPTION;
```

Objects already granted to PUBLIC do not need to be re-granted. If you use the grant_sys_object procedure to re-grant access, the procedure call succeeds.

**Revoking SELECT or EXECUTE privileges on SYS objects**

To revoke privileges on a single object, use the Amazon RDS procedure `rdsadmin.util.revoke_sys_object`. The procedure only revokes privileges that the master account has already been granted through a role or direct grant.

The `revoke_sys_object` procedure has the following parameters:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_obj_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the object to revoke privileges for. The object can be a directory, function,</td>
</tr>
</tbody>
</table>
The following example revokes select privileges on an object named V_$SESSION from a user named USER1.

```sql
begin
    rdsadmin.rdsadmin_util.revoke_sys_object(
        p_obj_name  => 'V_$SESSION',
        p_revokee   => 'USER1',
        p_privilege => 'SELECT');
end;
/```

**Managing RDS_X$ views for Oracle DB instances**

You might need to access SYS.X$ fixed tables, which are only accessible by SYS. To create SYS.RDS_X$ views on eligible X$ tables, use the procedures in the rdsadmin.rdsadmin_util package. Your master user is automatically granted the privilege SELECT ... WITH GRANT OPTION on the RDS_X$ views.

The rdsadmin.rdsadmin_util procedures are available in the following database engine versions:
• 21.0.0.0.ru-2023-10.rur-2023-10.r1 and higher Oracle Database 21c versions
• 19.0.0.0.ru-2023-10.rur-2023-10.r1 and higher Oracle Database 19c versions

**Important**

Internally, the `rdsadmin.rdsadmin_util` package creates views on `X$` tables. The `X$` tables are internal system objects that aren’t described in the Oracle Database documentation. We recommend that you test specific views in your non-production database and only create views in your production database under the guidance of Oracle Support.

**List X$ fixed tables eligible for use in RDS_X$ views**

To list `X$` tables that are eligible for use in RDS_X$ views, use the RDS procedure `rdsadmin.rdsadmin_util.list_allowed_sys_x$.views`. This procedure accepts no parameters. The following statements lists all eligible `X$` tables (sample output included).

```
SQL> SET SERVEROUTPUT ON
SQL> SELECT * FROM TABLE(rdsadmin.rdsadmin_util.list_allowed_sys_x$.views);

'X$BH'
'X$K2GTE'
'X$KCBWBPBD'
'X$KCBWDS'
'X$KGLLK'
'X$KLOGB'
'X$KGPLN'
'X$KSLHOT'
'X$KSMSP'
'X$KSPPCV'
'X$KSPII'
'X$KSPPSV'
'X$KSEQE'
'X$KSQRS'
'X$KTUXE'
'X$KQRFP'
```

The list of eligible `X$` tables can change over time. To make sure that your list of eligible `X$` fixed tables is current, rerun `list_allowed_sys_x$.views` periodically.
Creating SYS.RDS_X$ views

To create an RDS_X$ view on an eligible X$ table, use the RDS procedure `rdsadmin.rdsadmin_util.create_sys_x$_view`. You can only create views for the tables listed in the output of `rdsadmin.rdsadmin_util.list_allowed_sys_x$_views`. The `create_sys_x$_view` procedure accepts the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_x$_tbl</td>
<td>varchar2</td>
<td>Null</td>
<td>Yes</td>
<td>A valid X$ table name. The value must be one of the X$ tables reported by <code>list_allowed_sys_x$_views</code>.</td>
</tr>
<tr>
<td>p_force_creation</td>
<td>Boolean</td>
<td>FALSE</td>
<td>No</td>
<td>A value indicating whether to force creation of an RDS_X$ view that already exists for an X$ table. By default, RDS won't create a view if it already exists. To force creation, set this parameter to TRUE.</td>
</tr>
</tbody>
</table>

The following example creates the SYS.RDS_X$KGLOB view on the table X$KGLOB. The format for the view name is **RDS_X$tablename**.

```sql
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.create_sys_x$_view('X$KGLOB');
PL/SQL procedure successfully completed.
```

The following data dictionary query lists the view SYS.RDS_X$KGLOB and shows its status. Your master user is automatically granted the privilege SELECT ... WITH GRANT OPTION on this view.

```
SQL> SET SERVEROUTPUT ON
```
SQL> COL OWNER FORMAT A30
SQL> COL OBJECT_NAME FORMAT A30
SQL> COL STATUS FORMAT A30
SQL> SET LINESIZE 200
SQL> SELECT OWNER, OBJECT_NAME, STATUS
FROM DBA_OBJECTS
WHERE OWNER = 'SYS' AND OBJECT_NAME = 'RDS_X$KGLOB';

<table>
<thead>
<tr>
<th>OWNER</th>
<th>OBJECT_NAME</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RDS_X$KGLOB</td>
<td>VALID</td>
</tr>
</tbody>
</table>

⚠️ Important

$X$ tables aren't guaranteed to stay the same before and after an upgrade. RDS for Oracle drops and recreates the RDS_X$ views on $X$ tables during an engine upgrade. Then it grants the SELECT ... WITH GRANT OPTION privilege to the master user. After an upgrade, grant privileges to database users as needed on the corresponding RDS_X$ views.

Listing SYS.RDS_X$ views

To list existing RDS_X$ views, use the RDS procedure

`rdsadmin.rdsadmin_util.list_created_sys_x$_views`. The procedure lists only views that were created by the procedure `create_sys_x$_view`. The following example lists $X$ tables that have corresponding RDS_X$ views (sample output included).

SQL> SET SERVEROUTPUT ON
SQL> COL XD_TBL_NAME FORMAT A30
SQL> COL STATUS FORMAT A30
SQL> SET LINESIZE 200
SQL> SELECT * FROM TABLE(rdsadmin.rdsadmin_util.list_created_sys_x$_views);

<table>
<thead>
<tr>
<th>XD_TBL_NAME</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>X$BH</td>
<td>VALID</td>
</tr>
<tr>
<td>X$K2GTE</td>
<td>VALID</td>
</tr>
<tr>
<td>X$KCBWBPD</td>
<td>VALID</td>
</tr>
</tbody>
</table>

3 rows selected.
Dropping RDS_X$ views

To drop a SYS.RDS_X$ view, use the RDS procedure rdsadmin.rdsadmin_util.drop_sys_x$$_view. You can only drop views listed in the output of rdsadmin.rdsadmin_util.list_allowed_sys_x$$_views. The drop_sys_x$$_view procedure accepts the following parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_x$$_tbl</td>
<td>varchar2</td>
<td>Null</td>
<td>Yes</td>
<td>A valid X$ fixed table name. The value must be one of the X$ fixed tables reported by list_created_sys_x$$_views.</td>
</tr>
</tbody>
</table>

The following example drops the RDS_X$KGLOB view, which was created on the table X$KGLOB.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.drop_sys_x$$_view('X$KGLOB');
PL/SQL procedure successfully completed.
```

The following example shows that the view SYS.RDS_X$KGLOB has been dropped (sample output included).

```
SQL> SET SERVEROUTPUT ON
SQL> COL OWNER FORMAT A30
SQL> COL OBJECT_NAME FORMAT A30
SQL> COL STATUS FORMAT A30
SQL> SET LINESIZE 200
SQL> SELECT OWNER, OBJECT_NAME, STATUS
FROM DBA_OBJECTS
WHERE OWNER = 'SYS' AND OBJECT_NAME = 'RDS_X$KGLOB';
no rows selected
```
Granting privileges to non-master users

You can grant select privileges for many objects in the SYS schema by using the SELECT_CATALOG_ROLE role. The SELECT_CATALOG_ROLE role gives users SELECT privileges on data dictionary views. The following example grants the role SELECT_CATALOG_ROLE to a user named user1.

```
GRANT SELECT_CATALOG_ROLE TO user1;
```

You can grant EXECUTE privileges for many objects in the SYS schema by using the EXECUTE_CATALOG_ROLE role. The EXECUTE_CATALOG_ROLE role gives users EXECUTE privileges for packages and procedures in the data dictionary. The following example grants the role EXECUTE_CATALOG_ROLE to a user named user1.

```
GRANT EXECUTE_CATALOG_ROLE TO user1;
```

The following example gets the permissions that the roles SELECT_CATALOG_ROLE and EXECUTE_CATALOG_ROLE allow.

```
SELECT *
  FROM ROLE_TAB_PRIVS
 WHERE ROLE IN ('SELECT_CATALOG_ROLE','EXECUTE_CATALOG_ROLE')
ORDER BY ROLE, TABLE_NAME ASC;
```

The following example creates a non-master user named user1, grants the CREATE SESSION privilege, and grants the SELECT privilege on a database named sh.sales.

```
CREATE USER user1 IDENTIFIED BY PASSWORD;
GRANT CREATE SESSION TO user1;
GRANT SELECT ON sh.sales TO user1;
```

Creating custom functions to verify passwords

You can create a custom password verification function in the following ways:

- To use standard verification logic, and to store your function in the SYS schema, use the create_verify_function procedure.
- To use custom verification logic, or to avoid storing your function in the SYS schema, use the create_passthrough_verify_fcn procedure.
The create_verify_function procedure

You can create a custom function to verify passwords by using the Amazon RDS procedure `rdsadmin.rdsadmin_password_verify.create_verify_function`. The `create_verify_function` procedure is supported for version 12.1.0.2.v5 and all higher major and minor versions of RDS for Oracle.

The `create_verify_function` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_verify_function_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name for your custom function. This function is created for you in the SYS schema. You assign this function to user profiles.</td>
</tr>
<tr>
<td>p_min_length</td>
<td>number</td>
<td>8</td>
<td>No</td>
<td>The minimum number of characters required.</td>
</tr>
<tr>
<td>p_max_length</td>
<td>number</td>
<td>256</td>
<td>No</td>
<td>The maximum number of characters allowed.</td>
</tr>
<tr>
<td>p_min_letters</td>
<td>number</td>
<td>1</td>
<td>No</td>
<td>The minimum number of letters required.</td>

<tr>
<td>p_disallow_simple_strings</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to disallow simple strings as the password.</td>
</tr>
<tr>
<td>p_disallow_whitespace</td>
<td>boolean</td>
<td>false</td>
<td>No</td>
<td>Set to true to disallow white space characters in the password.</td>
</tr>
<tr>
<td>p_disallow_at_sign</td>
<td>boolean</td>
<td>false</td>
<td>No</td>
<td>Set to true to disallow the @ character in the password.</td>
</tr>
</tbody>
</table>

You can create multiple password verification functions.
There are restrictions on the name of your custom function. Your custom function can't have the same name as an existing system object. The name can be no more than 30 characters long. Also, the name must include one of the following strings: PASSWORD, VERIFY, COMPLEXITY, ENFORCE, or STRENGTH.

The following example creates a function named CUSTOM_PASSWORD_FUNCTION. The function requires that a password has at least 12 characters, 2 uppercase characters, 1 digit, and 1 special character, and that the password disallows the @ character.

```sql
begin
    rdsadmin.rdsadmin_password_verify.create_verify_function(
        p_verify_function_name => 'CUSTOM_PASSWORD_FUNCTION',
        p_min_length           => 12,
        p_min_uppercase        => 2,
        p_min_digits           => 1,
        p_min_special          => 1,
        p_disallow_at_sign     => true);
end;
/
```

To see the text of your verification function, query DBA_SOURCE. The following example gets the text of a custom password function named CUSTOM_PASSWORD_FUNCTION.

```sql
COL TEXT FORMAT a150

SELECT TEXT
    FROM DBA_SOURCE
    WHERE OWNER = 'SYS'
    AND NAME = 'CUSTOM_PASSWORD_FUNCTION'
ORDER BY LINE;
```

To associate your verification function with a user profile, use alter profile. The following example associates a verification function with the DEFAULT user profile.

```sql
ALTER PROFILE DEFAULT LIMIT PASSWORD_VERIFY_FUNCTION CUSTOM_PASSWORD_FUNCTION;
```

To see what user profiles are associated with what verification functions, query DBA_PROFILES. The following example gets the profiles that are associated with the custom verification function named CUSTOM_PASSWORD_FUNCTION.
The following example gets all profiles and the password verification functions that they are associated with.

```
SELECT * FROM DBA_PROFILES WHERE RESOURCE_NAME = 'PASSWORD_VERIFY_FUNCTION';
```

<table>
<thead>
<tr>
<th>PROFILE</th>
<th>RESOURCE_NAME</th>
<th>RESOURCE</th>
<th>LIMIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>PASSWORD_VERIFY_FUNCTION</td>
<td>PASSWORD</td>
<td></td>
</tr>
<tr>
<td>CUSTOM_PASSWORD_FUNCTION</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RDSADMIN</td>
<td>PASSWORD_VERIFY_FUNCTION</td>
<td>PASSWORD</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The `create_passthrough_verify_fcn` procedure

The `create_passthrough_verify_fcn` procedure is supported for version 12.1.0.2.v7 and all higher major and minor versions of RDS for Oracle.

You can create a custom function to verify passwords by using the Amazon RDS procedure `rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn`. The `create_passthrough_verify_fcn` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_verify_function_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name for your custom verification function. This is a wrapper function that is created for you in the SYS schema, and</td>
</tr>
</tbody>
</table>
## Parameter Details

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_target_owner</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The schema owner for your custom verification function.</td>
</tr>
<tr>
<td>p_target_function_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of your existing custom function that contains the verification logic. Your custom function must return a boolean. Your function should return <code>true</code> if the password is valid and <code>false</code> if the password is invalid.</td>
</tr>
</tbody>
</table>

It doesn't contain any verification logic. You assign this function to user profiles.

The following example creates a password verification function that uses the logic from the function named `PASSWORD_LOGIC_EXTRA_STRONG`.

```sql
begin
    rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn(
        p_verify_function_name => 'CUSTOM_PASSWORD_FUNCTION',
        p_target_owner         => 'TEST_USER',
        p_target_function_name => 'PASSWORD_LOGIC_EXTRA_STRONG');
end;
/
```

To associate the verification function with a user profile, use alter profile. The following example associates the verification function with the DEFAULT user profile.

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_VERIFY_FUNCTION CUSTOM_PASSWORD_FUNCTION;
```
Setting up a custom DNS server

Amazon RDS supports outbound network access on your DB instances running Oracle. For more information about outbound network access, including prerequisites, see Configuring UTL_HTTP access using certificates and an Oracle wallet.

Amazon RDS Oracle allows Domain Name Service (DNS) resolution from a custom DNS server owned by the customer. You can resolve only fully qualified domain names from your Amazon RDS DB instance through your custom DNS server.

After you set up your custom DNS name server, it takes up to 30 minutes to propagate the changes to your DB instance. After the changes are propagated to your DB instance, all outbound network traffic requiring a DNS lookup queries your DNS server over port 53.

To set up a custom DNS server for your Amazon RDS for Oracle DB instance, do the following:

- From the DHCP options set attached to your virtual private cloud (VPC), set the domain-name-servers option to the IP address of your DNS name server. For more information, see DHCP options sets.

  Note
  The domain-name-servers option accepts up to four values, but your Amazon RDS DB instance uses only the first value.

- Ensure that your DNS server can resolve all lookup queries, including public DNS names, Amazon EC2 private DNS names, and customer-specific DNS names. If the outbound network traffic contains any DNS lookups that your DNS server can't handle, your DNS server must have appropriate upstream DNS providers configured.
- Configure your DNS server to produce User Datagram Protocol (UDP) responses of 512 bytes or less.
- Configure your DNS server to produce Transmission Control Protocol (TCP) responses of 1024 bytes or less.
- Configure your DNS server to allow inbound traffic from your Amazon RDS DB instances over port 53. If your DNS server is in an Amazon VPC, the VPC must have a security group that contains inbound rules that permit UDP and TCP traffic on port 53. If your DNS server is not in an Amazon VPC, it must have appropriate firewall allow-listing to permit UDP and TCP inbound traffic on port 53.
For more information, see Security groups for your VPC and Adding and removing rules.

- Configure the VPC of your Amazon RDS DB instance to allow outbound traffic over port 53. Your VPC must have a security group that contains outbound rules that allow UDP and TCP traffic on port 53.

  For more information, see Security groups for your VPC and Adding and removing rules.

- The routing path between the Amazon RDS DB instance and the DNS server has to be configured correctly to allow DNS traffic.
  - If the Amazon RDS DB instance and the DNS server are not in the same VPC, a peering connection has to be set up between them. For more information, see What is VPC peering?

### Setting and unsetting system diagnostic events

To set and unset diagnostic events at the session level, you can use the Oracle SQL statement ALTER SESSION SET EVENTS. However, to set events at the system level you can't use Oracle SQL. Instead, use the system event procedures in the `rdsadmin.rdsadmin_util` package. The system event procedures are available in the following engine versions:

- All Oracle Database 21c versions
- 19.0.0.0.ru-2020-10.rur-2020-10.r1 and higher Oracle Database 19c versions

  For more information, see Version 19.0.0.0.ru-2020-10.rur-2020-10.r1 in the Amazon RDS for Oracle Release Notes.

- 12.2.0.1.ru-2020-10.rur-2020-10.r1 and higher Oracle Database 12c Release 2 (12.2.0.1) versions

  For more information, see Version 12.2.0.1.ru-2020-10.rur-2020-10.r1 in the Amazon RDS for Oracle Release Notes.

- 12.1.0.2.V22 and higher Oracle Database 12c Release 1 (12.1.0.2) versions

  For more information, see Version 12.1.0.2.v22 in the Amazon RDS for Oracle Release Notes.
Important

Internally, the `rdsadmin.rdsadmin_util` package sets events by using the `ALTER SYSTEM SET EVENTS` statement. This `ALTER SYSTEM` statement isn't documented in the Oracle Database documentation. Some system diagnostic events can generate large amounts of tracing information, cause contention, or affect database availability. We recommend that you test specific diagnostic events in your nonproduction database, and only set events in your production database under guidance of Oracle Support.

Listing allowed system diagnostic events

To list the system events that you can set, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.list_allowed_system_events`. This procedure accepts no parameters.

The following example lists all system events that you can set.

```
SET SERVEROUTPUT ON
EXEC rdsadmin.rdsadmin_util.list_allowed_system_events;
```

The following sample output lists event numbers and their descriptions. Use the Amazon RDS procedures `set_system_event` to set these events and `unset_system_event` to unset them.

<table>
<thead>
<tr>
<th>Event Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>604</td>
<td>error occurred at recursive SQL level</td>
</tr>
<tr>
<td>942</td>
<td>table or view does not exist</td>
</tr>
<tr>
<td>1401</td>
<td>inserted value too large for column</td>
</tr>
<tr>
<td>1403</td>
<td>no data found</td>
</tr>
<tr>
<td>1410</td>
<td>invalid ROWID</td>
</tr>
<tr>
<td>1422</td>
<td>exact fetch returns more than requested number of rows</td>
</tr>
<tr>
<td>1426</td>
<td>numeric overflow</td>
</tr>
<tr>
<td>1427</td>
<td>single-row subquery returns more than one row</td>
</tr>
<tr>
<td>1476</td>
<td>divisor is equal to zero</td>
</tr>
<tr>
<td>1483</td>
<td>invalid length for DATE or NUMBER bind variable</td>
</tr>
<tr>
<td>1489</td>
<td>result of string concatenation is too long</td>
</tr>
<tr>
<td>1652</td>
<td>unable to extend temp segment by in tablespace</td>
</tr>
<tr>
<td>1858</td>
<td>a non-numeric character was found where a numeric was expected</td>
</tr>
<tr>
<td>4031</td>
<td>unable to allocate bytes of shared memory (&quot;&quot;,&quot;&quot;,&quot;&quot;,&quot;&quot;)</td>
</tr>
<tr>
<td>6502</td>
<td>PL/SQL: numeric or value error</td>
</tr>
<tr>
<td>10027</td>
<td>Specify Deadlock Trace Information to be Dumped</td>
</tr>
</tbody>
</table>
10046 - enable SQL statement timing
10053 - CBO Enable optimizer trace
10173 - Dynamic Sampling time-out error
10442 - enable trace of kst for ORA-01555 diagnostics
12008 - error in materialized view refresh path
12012 - error on auto execute of job
12504 - TNS:listener was not given the SERVICE_NAME in CONNECT_DATA
14400 - inserted partition key does not map to any partition
31693 - Table data object failed to load/unload and is being skipped due to error:

### Note

The list of the allowed system events can change over time. To make sure that you have the most recent list of eligible events, use `rdsadmin.rdsadmin_util.list_allowed_system_events`.

### Setting system diagnostic events

To set a system event, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.set_system_event`. You can only set events listed in the output of `rdsadmin.rdsadmin_util.list_allowed_system_events`. The `set_system_event` procedure accepts the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
</table>
| p_event        | number    | —       | Yes      | The system event number. The value must be one of the event numbers reported by `list_allowed_system_events`.
| p_level        | number    | —       | Yes      | The event level. See the Oracle Database documentation or Oracle Support for descriptions of different level values. |
The procedure set_system_event constructs and runs the required ALTER SYSTEM SET EVENTS statements according to the following principles:

- The event type (context or errorstack) is determined automatically.
- A statement in the form ALTER SYSTEM SET EVENTS 'event LEVEL event_level' sets the context events. This notation is equivalent to ALTER SYSTEM SET EVENTS 'event TRACE NAME CONTEXT FOREVER, LEVEL event_level'.
- A statement in the form ALTER SYSTEM SET EVENTS 'event ERRORSTACK (event_level)' sets the error stack events. This notation is equivalent to ALTER SYSTEM SET EVENTS 'event TRACE NAME ERRORSTACK LEVEL event_level'.

The following example sets event 942 at level 3, and event 10442 at level 10. Sample output is included.

```sql
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.set_system_event(942,3);
Setting system event 942 with: alter system set events '942 errorstack (3)'
PL/SQL procedure successfully completed.

SQL> EXEC rdsadmin.rdsadmin_util.set_system_event(10442,10);
Setting system event 10442 with: alter system set events '10442 level 10'
PL/SQL procedure successfully completed.
```

Listing system diagnostic events that are set

To list the system events that are currently set, use the Amazon RDS procedure rdsadmin.rdsadmin_util.list_set_system_events. This procedure reports only events set at system level by set_system_event.

The following example lists the active system events.

```sql
SET SERVEROUTPUT ON
EXEC rdsadmin.rdsadmin_util.list_set_system_events;
```

The following sample output shows the list of events, the event type, the level at which the events are currently set, and the time when the event was set.
PL/SQL procedure successfully completed.

Unsetting system diagnostic events

To unset a system event, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.unset_system_event`. You can only unset events listed in the output of `rdsadmin.rdsadmin_util.list_allowed_system_events`. The `unset_system_event` procedure accepts the following parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
</table>
| p_event        | number    | —       | Yes      | The system event number. The value must be one of the event numbers reported by `list_allowed_system_events`.

The following example unsets events 942 and 10442. Sample output is included.

```sql
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.unset_system_event(942);
Unsetting system event 942 with: alter system set events '942 off'

PL/SQL procedure successfully completed.

SQL> EXEC rdsadmin.rdsadmin_util.unset_system_event(10442);
Unsetting system event 10442 with: alter system set events '10442 off'

PL/SQL procedure successfully completed.
```

Performing common database tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to databases on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS
Amazon Relational Database Service doesn't provide shell access to DB instances. Amazon RDS also restricts access to some system procedures and tables that require advanced privileges.

**Topics**

- Changing the global name of a database
- Creating and sizing tablespaces
- Setting the default tablespace
- Setting the default temporary tablespace
- Creating a temporary tablespace on the instance store
- Adding a tempfile to the instance store on a read replica
- Dropping tempfiles on a read replica
- Checkpointing a database
- Setting distributed recovery
- Setting the database time zone
- Working with Oracle external tables
- Generating performance reports with Automatic Workload Repository (AWR)
- Adjusting database links for use with DB instances in a VPC
- Setting the default edition for a DB instance
- Enabling auditing for the SYS.AUD$ table
- Disabling auditing for the SYS.AUD$ table
- Cleaning up interrupted online index builds
- Skipping corrupt blocks
- Resizing tablespaces, data files, and temp files
- Purging the recycle bin
- Setting the default displayed values for full redaction

**Changing the global name of a database**

To change the global name of a database, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.rename_global_name`. The `rename_global_name` procedure has the following parameters.
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_new_global_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The new global name for the database.</td>
</tr>
</tbody>
</table>

The database must be open for the name change to occur. For more information about changing the global name of a database, see [ALTER DATABASE](#) in the Oracle documentation.

The following example changes the global name of a database to `new_global_name`.

```sql
EXEC rdsadmin.rdsadmin_util.rename_global_name(p_new_global_name => 'new_global_name');
```

## Creating and sizing tablespaces

Amazon RDS only supports Oracle Managed Files (OMF) for data files, log files, and control files. When you create data files and log files, you can't specify the physical file names.

By default, if you don't specify a data file size, tablespaces are created with the default of `AUTOEXTEND ON`, and no maximum size. In the following example, the tablespace `users1` is autoextensible.

```sql
CREATE TABLESPACE users1;
```

Because of these default settings, tablespaces can grow to consume all allocated storage. We recommend that you specify an appropriate maximum size on permanent and temporary tablespaces, and that you carefully monitor space usage.

The following example creates a tablespace named `users2` with a starting size of 1 gigabyte. Because a data file size is specified, but `AUTOEXTEND ON` isn't specified, the tablespace isn't autoextensible.

```sql
CREATE TABLESPACE users2 DATAFILE SIZE 1G;
```

The following example creates a tablespace named `users3` with a starting size of 1 gigabyte, autoextend turned on, and a maximum size of 10 gigabytes.

```sql
CREATE TABLESPACE users3 DATAFILE SIZE 1G AUTOEXTEND ON MAXSIZE 10G;
```
The following example creates a temporary tablespace named `temp01`.

```
CREATE TEMPORARY TABLESPACE temp01;
```

We recommend that you don't use smallfile tablespaces because you can't resize smallfile tablespaces with RDS for Oracle. However, you can add a data file to a smallfile tablesapce. To determine whether a tablespace is bigfile or smallfile, query `DBA_TABLESPACES` as follows.

```
SELECT TABLESPACE_NAME, BIGFILE FROM DBA_TABLESPACES;
```

You can resize a bigfile tablespace by using `ALTER TABLESPACE`. You can specify the size in kilobytes (K), megabytes (M), gigabytes (G), or terabytes (T). The following example resizes a bigfile tablespace named `users_bf` to 200 MB.

```
ALTER TABLESPACE users_bf RESIZE 200M;
```

The following example adds an additional data file to a smallfile tablespace named `users_sf`.

```
ALTER TABLESPACE users_sf ADD DATAFILE SIZE 100000M AUTOEXTEND ON NEXT 250m MAXSIZE UNLIMITED;
```

### Setting the default tablespace

To set the default tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_tablespace`. The `alter_default_tablespace` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tablespace_name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the default tablespace.</td>
</tr>
</tbody>
</table>

The following example sets the default tablespace to `users2`:

```
EXEC rdsadmin.rdsadmin_util.alter_default_tablespace(tablespace_name => 'users2');
```
Setting the default temporary tablespace

To set the default temporary tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_temp_tablespace`. The `alter_default_temp_tablespace` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tablespace_name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the default temporary tablespace.</td>
</tr>
</tbody>
</table>

The following example sets the default temporary tablespace to `temp01`.

```
EXEC rdsadmin.rdsadmin_util.alter_default_temp_tablespace(tablespace_name => 'temp01');
```

Creating a temporary tablespace on the instance store

To create a temporary tablespace on the instance store, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace`. The `create_inst_store_tmp_tblspace` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tablespace_name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the temporary tablespace.</td>
</tr>
</tbody>
</table>

The following example creates the temporary tablespace `temp01` in the instance store.

```
EXEC rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace(p_tablespace_name => 'temp01');
```

⚠️ Important

When you run `rdsadmin_util.create_inst_store_tmp_tblspace`, the newly created temporary tablespace is not automatically set as the default temporary tablespace. To set it as the default, see Setting the default temporary tablespace.
For more information, see Storing temporary data in an RDS for Oracle instance store.

**Adding a tempfile to the instance store on a read replica**

When you create a temporary tablespace on a primary DB instance, the read replica doesn’t create tempfiles. Assume that an empty temporary tablespace exists on your read replica for either of the following reasons:

- You dropped a tempfile from the tablespace on your read replica. For more information, see Dropping tempfiles on a read replica.
- You created a new temporary tablespace on the primary DB instance. In this case, RDS for Oracle synchronizes the metadata to the read replica.

You can add a tempfile to the empty temporary tablespace, and store the tempfile in the instance store. To create a tempfile in the instance store, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_inst_store_tempfile`. You can use this procedure only on a read replica. The procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tablespace_name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the temporary tablespace on your read replica.</td>
</tr>
</tbody>
</table>

In the following example, the empty temporary tablespace `temp01` exists on your read replica. Run the following command to create a tempfile for this tablespace, and store it in the instance store.

EXEC rdsadmin.rdsadmin_util.add_inst_store_tempfile(p_tablespace_name => 'temp01');

For more information, see Storing temporary data in an RDS for Oracle instance store.

**Dropping tempfiles on a read replica**

You can't drop an existing temporary tablespace on a read replica. You can change the tempfile storage on a read replica from Amazon EBS to the instance store, or from the instance store to Amazon EBS. To achieve these goals, do the following:

1. Drop the current tempfiles in the temporary tablespace on the read replica.
2. Create new tempfiles on different storage.

To drop the tempfiles, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_replica_tempfiles`. You can use this procedure only on read replicas. The `drop_replica_tempfiles` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tablespace_name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the temporary tablespace on your read replica.</td>
</tr>
</tbody>
</table>

Assume that a temporary tablespace named `temp01` resides in the instance store on your read replica. Drop all tempfiles in this tablespace by running the following command.

```
EXEC rdsadmin.rdsadmin_util.drop_replica_tempfiles(p_tablespace_name => 'temp01');
```

For more information, see [Storing temporary data in an RDS for Oracle instance store](#).

### Checkpointing a database

To checkpoint the database, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.checkpoint`. The checkpoint procedure has no parameters.

The following example checkpoints the database.

```
EXEC rdsadmin.rdsadmin_util.checkpoint;
```

### Setting distributed recovery

To set distributed recovery, use the Amazon RDS procedures `rdsadmin.rdsadmin_util.enable_distr_recovery` and `disable_distr_recovery`. The procedures have no parameters.

The following example enables distributed recovery.

```
EXEC rdsadmin.rdsadmin_util.enable_distr_recovery;
```
The following example disables distributed recovery.

```sql
EXEC rdsadmin.rdsadmin_util.disable_distr_recovery;
```

**Setting the database time zone**

You can set the time zone of your Amazon RDS Oracle database in the following ways:

- **The Timezone option**

  The Timezone option changes the time zone at the host level and affects all date columns and values such as SYSDATE. For more information, see [Oracle time zone](#).

- **The Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_db_time_zone`**

  The `alter_db_time_zone` procedure changes the time zone for only certain data types, and doesn't change SYSDATE. There are additional restrictions on setting the time zone listed in the [Oracle documentation](#).

  **Note**

  You can also set the default time zone for Oracle Scheduler. For more information, see [Setting the time zone for Oracle Scheduler jobs](#).

The `alter_db_time_zone` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_new_tz</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The new time zone as a named region or an absolute offset from Coordinated Universal Time (UTC). Valid offsets range from -12:00 to +14:00.</td>
</tr>
</tbody>
</table>

The following example changes the time zone to UTC plus three hours.
The following example changes the time zone to the Africa/Algiers time zone.

```sql
EXEC rdsadmin.rdsadmin_util.alter_db_time_zone(p_new_tz => 'Africa/Algiers');
```

After you alter the time zone by using the `alter_db_time_zone` procedure, reboot your DB instance for the change to take effect. For more information, see Rebooting a DB instance. For information about upgrading time zones, see Time zone considerations.

**Working with Oracle external tables**

*Oracle external tables* are tables with data that is not in the database. Instead, the data is in external files that the database can access. By using external tables, you can access data without loading it into the database. For more information about external tables, see Managing external tables in the Oracle documentation.

With Amazon RDS, you can store external table files in directory objects. You can create a directory object, or you can use one that is predefined in the Oracle database, such as the DATA_PUMP_DIR directory. For information about creating directory objects, see Creating and dropping directories in the main data storage space. You can query the ALL_DIRECTORIES view to list the directory objects for your Amazon RDS Oracle DB instance.

**Note**

Directory objects point to the main data storage space (Amazon EBS volume) used by your instance. The space used—along with data files, redo logs, audit, trace, and other files—counts against allocated storage.

You can move an external data file from one Oracle database to another by using the `DBMS_FILE_TRANSFER` package or the `UTL_FILE` package. The external data file is moved from a directory on the source database to the specified directory on the destination database. For information about using `DBMS_FILE_TRANSFER`, see Importing using Oracle Data Pump.

After you move the external data file, you can create an external table with it. The following example creates an external table that uses the `emp_xt_file1.txt` file in the USER_DIR1 directory.
CREATE TABLE emp_xt (  emp_id      NUMBER,  first_name  VARCHAR2(50),  last_name   VARCHAR2(50),  user_name   VARCHAR2(20)  )  ORGANIZATION EXTERNAL (  TYPE ORACLE_LOADER  DEFAULT DIRECTORY USER_DIR1  ACCESS PARAMETERS (    RECORDS DELIMITED BY NEWLINE    FIELDS TERMINATED BY ',',    MISSING FIELD VALUES ARE NULL    (emp_id,first_name,last_name,user_name)  )  LOCATION ('emp_xt_file1.txt')  )  PARALLEL  REJECT LIMIT UNLIMITED;

Suppose that you want to move data that is in an Amazon RDS Oracle DB instance into an external data file. In this case, you can populate the external data file by creating an external table and selecting the data from the table in the database. For example, the following SQL statement creates the orders_xt external table by querying the orders table in the database.

CREATE TABLE orders_xt  ORGANIZATION EXTERNAL  (  TYPE ORACLE_DATAPUMP  DEFAULT DIRECTORY DATA_PUMP_DIR  LOCATION ('orders_xt.dmp')  )  AS SELECT * FROM orders;

In this example, the data is populated in the orders_xt.dmp file in the DATA_PUMP_DIR directory.

**Generating performance reports with Automatic Workload Repository (AWR)**

To gather performance data and generate reports, Oracle recommends Automatic Workload Repository (AWR). AWR requires Oracle Database Enterprise Edition and a license for the
Diagnostics and Tuning packs. To enable AWR, set the `CONTROL_MANAGEMENT_PACK_ACCESS` initialization parameter to either `DIAGNOSTIC` or `DIAGNOSTIC+TUNING`.

**Working with AWR reports in RDS**

To generate AWR reports, you can run scripts such as `awrrpt.sql`. These scripts are installed on the database host server. In Amazon RDS, you don't have direct access to the host. However, you can get copies of SQL scripts from another installation of Oracle Database.

You can also use AWR by running procedures in the `SYS.DBMS_WORKLOAD_REPOSITORY` PL/SQL package. You can use this package to manage baselines and snapshots, and also to display ASH and AWR reports. For example, to generate an AWR report in text format run the `DBMS_WORKLOAD_REPOSITORY.AWR_REPORT_TEXT` procedure. However, you can't reach these AWR reports from the AWS Management Console.

When working with AWR, we recommend using the `rdsadmin.rdsadmin_diagnostic_util` procedures. You can use these procedures to generate the following:

- AWR reports
- Active Session History (ASH) reports
- Automatic Database Diagnostic Monitor (ADDM) reports
- Oracle Data Pump Export dump files of AWR data

The `rdsadmin_diagnostic_util` procedures save the reports to the DB instance file system. You can access these reports from the console. You can also access reports using the `rdsadmin.rds_file_util` procedures, and you can access reports that are copied to Amazon S3 using the S3 Integration option. For more information, see [Reading files in a DB instance directory](#) and [Amazon S3 integration](#).

You can use the `rdsadmin_diagnostic_util` procedures in the following Amazon RDS for Oracle DB engine versions:

- All Oracle Database 21c versions
- 19.0.0.0.ru-2020-04.rur-2020-04.r1 and higher Oracle Database 19c versions
- 12.2.0.1.ru-2020-04.rur-2020-04.r1 and higher Oracle Database 12c Release 2 (12.2) versions
- 12.1.0.2.v20 and higher Oracle Database 12c Release 1 (12.1) versions
For a blog that explains how to work with diagnostic reports in a replication scenario, see [Generate AWR reports for Amazon RDS for Oracle read replicas](#).

## Common parameters for the diagnostic utility package

You typically use the following parameters when managing AWR and ADDM with the `rdsadmin_diagnostic_util` package.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>begin_sna</code></td>
<td>NUMBEF</td>
<td>—</td>
<td>Yes</td>
<td>The ID of the beginning snapshot.</td>
</tr>
<tr>
<td><code>p_id</code></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>end_sna</code></td>
<td>NUMBEF</td>
<td>—</td>
<td>Yes</td>
<td>The ID of the ending snapshot.</td>
</tr>
<tr>
<td><code>p_id</code></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>dump_directory</code></td>
<td>VARCHAR2</td>
<td>BDUMF</td>
<td>No</td>
<td>The directory to write the report or export file to. If you specify a nondefault directory, the user that runs the <code>rdsadmin_diagnostic_util</code> procedures must have write permissions for the directory.</td>
</tr>
<tr>
<td><code>p_tag</code></td>
<td>VARCHAR2</td>
<td>—</td>
<td>No</td>
<td>A string that can be used to distinguish between backups to indicate the purpose or usage of backups, such as incremental or daily.</td>
</tr>
</tbody>
</table>

You can specify up to 30 characters. Valid characters are a-z, A-Z, 0-9, an underscore (_), a dash (-), and a period (.). The tag is not case-sensitive. RMAN always stores tags in uppercase, regardless of the case used when entering them.

Tags don't need to be unique, so multiple backups can have the same tag. If you don't specify a tag, RMAN assigns a default tag automatically using the format `TAGYYYYMMDDTHHMMSS`, where YYYY is the year, MM is the month, DD is the day, HH is the hour (in 24-hour format), MM is the minutes, and SS is the seconds. The date and time indicate when RMAN started the backup.
### Parameter: p_tag

**Data type:** VARCHAR2

**Default:** HTML

**Required:** No

**Description:**

For example, a backup with the default tag `TAG20190927T214517` indicates a backup that started on 2019-09-27 at 21:45:17.

The `p_tag` parameter is supported for the following RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0), using 19.0.0.0.
- ru-2021-10.rur-2021-10.r1 and higher
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.
- ru-2021-10.rur-2021-10.r1 and higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.
- V26 and higher

### Parameter: report_type

**Data type:** VARCHAR2

**Default:** HTML

**Required:** No

**Description:**

The format of the report. Valid values are TEXT and HTML.

### Parameter: dbid

**Data type:** NUMBER

**Default:** —

**Required:** No

**Description:**

A valid database identifier (DBID) shown in the `DBA_HIST_DATABASE_INSTANCE` view for Oracle. If this parameter is not specified, RDS uses the current DBID, which is shown in the `V$DATABASE,DBID` view.

You typically use the following parameters when managing ASH with the `rdsadmin_diagnostic_util` package.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>begin_time</td>
<td>DATE</td>
<td>—</td>
<td>Yes</td>
<td>The beginning time of the ASH analysis.</td>
</tr>
<tr>
<td>end_time</td>
<td>DATE</td>
<td>—</td>
<td>Yes</td>
<td>The ending time of the ASH analysis.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
<td>---------</td>
<td>----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>slot_width</td>
<td>NUMBER</td>
<td>0</td>
<td>No</td>
<td>The duration of the slots (in seconds) used in the &quot;Top Activity&quot; section of the ASH report. If this parameter isn't specified, the time interval between begin_time and end_time uses no more than 10 slots.</td>
</tr>
<tr>
<td>sid</td>
<td>NUMBER</td>
<td>Null</td>
<td>No</td>
<td>The session ID.</td>
</tr>
<tr>
<td>sql_id</td>
<td>VARCHAR2</td>
<td>Null</td>
<td>No</td>
<td>The SQL ID.</td>
</tr>
<tr>
<td>wait_class</td>
<td>VARCHAR2</td>
<td>Null</td>
<td>No</td>
<td>The wait class name.</td>
</tr>
<tr>
<td>service_hash</td>
<td>NUMBER</td>
<td>Null</td>
<td>No</td>
<td>The service name hash.</td>
</tr>
<tr>
<td>module_name</td>
<td>VARCHAR2</td>
<td>Null</td>
<td>No</td>
<td>The module name.</td>
</tr>
<tr>
<td>action_name</td>
<td>VARCHAR2</td>
<td>Null</td>
<td>No</td>
<td>The action name.</td>
</tr>
<tr>
<td>client_id</td>
<td>VARCHAR2</td>
<td>Null</td>
<td>No</td>
<td>The application-specific ID of the database session.</td>
</tr>
<tr>
<td>plsql_entry</td>
<td>VARCHAR2</td>
<td>Null</td>
<td>No</td>
<td>The PL/SQL entry point.</td>
</tr>
</tbody>
</table>

**Generating an AWR report**

To generate an AWR report, use the `rdsadmin.rdsadmin_diagnostic_util.awr_report` procedure.

The following example generates a AWR report for the snapshot range 101–106. The output text file is named `awrpt_101_106.txt`. You can access this report from the AWS Management Console.
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_report(101,106,'TEXT');

The following example generates an HTML report for the snapshot range 63–65. The output HTML file is named awrrpt_63_65.html. The procedure writes the report to the nondefault database directory named AWR_RPT_DUMP.

EXEC rdsadmin.rdsadmin_diagnostic_util.awr_report(63,65,'HTML','AWR_RPT_DUMP');

**Extracting AWR data into a dump file**

To extract AWR data into a dump file, use the rdsadmin.rdsadmin_diagnostic_util.awr_extract procedure.

The following example extracts the snapshot range 101–106. The output dump file is named awrextract_101_106.dmp. You can access this file through the console.

EXEC rdsadmin.rdsadmin_diagnostic_util.awr_extract(101,106);

The following example extracts the snapshot range 63–65. The output dump file is named awrextract_63_65.dmp. The file is stored in the nondefault database directory named AWR_RPT_DUMP.

EXEC rdsadmin.rdsadmin_diagnostic_util.awr_extract(63,65,'AWR_RPT_DUMP');

**Generating an ADDM report**

To generate an ADDM report, use the rdsadmin.rdsadmin_diagnostic_util.addm_report procedure.

The following example generates an ADDM report for the snapshot range 101–106. The output text file is named addmrpt_101_106.txt. You can access the report through the console.

EXEC rdsadmin.rdsadmin_diagnostic_util.addm_report(101,106);

The following example generates an ADDM report for the snapshot range 63–65. The output text file is named addmrpt_63_65.txt. The file is stored in the nondefault database directory named ADDM_RPT_DUMP.

EXEC rdsadmin.rdsadmin_diagnostic_util.addm_report(63,65,'ADDM_RPT_DUMP');
Generating an ASH report

To generate an ASH report, use the `rdsadmin.rdsadmin_diagnostic_util.ash_report` procedure.

The following example generates an ASH report that includes the data from 14 minutes ago until the current time. The name of the output file uses the format `ashrptbegin_timeend_time.txt`, where `begin_time` and `end_time` use the format `YYYYMMDDHH24MISS`. You can access the file through the console.

```
BEGIN
    rdsadmin.rdsadmin_diagnostic_util.ash_report(
        begin_time => SYSDATE-14/1440,
        end_time => SYSDATE,
        report_type => 'TEXT');
END;
/
```

The following example generates an ASH report that includes the data from November 18, 2019, at 6:07 PM through November 18, 2019, at 6:15 PM. The name of the output HTML report is `ashrpt_20190918180700_20190918181500.html`. The report is stored in the nondefault database directory named `AWR_RPT_DUMP`.

```
BEGIN
    rdsadmin.rdsadmin_diagnostic_util.ash_report(
        begin_time => TO_DATE('2019-09-18 18:07:00', 'YYYY-MM-DD HH24:MI:SS'),
        end_time => TO_DATE('2019-09-18 18:15:00', 'YYYY-MM-DD HH24:MI:SS'),
        report_type => 'html',
        dump_directory => 'AWR_RPT_DUMP');
END;
/
```

Accessing AWR reports from the console or CLI

To access AWR reports or export dump files, you can use the AWS Management Console or AWS CLI. For more information, see [Downloading a database log file](#).

Adjusting database links for use with DB instances in a VPC

To use Oracle database links with Amazon RDS DB instances inside the same virtual private cloud (VPC) or peered VPCs, the two DB instances should have a valid route between them. Verify the
valid route between the DB instances by using your VPC routing tables and network access control list (ACL).

The security group of each DB instance must allow ingress to and egress from the other DB instance. The inbound and outbound rules can refer to security groups from the same VPC or a peered VPC. For more information, see [Updating your security groups to reference peered VPC security groups](#).

If you have configured a custom DNS server using the DHCP Option Sets in your VPC, your custom DNS server must be able to resolve the name of the database link target. For more information, see [Setting up a custom DNS server](#).

For more information about using database links with Oracle Data Pump, see [Importing using Oracle Data Pump](#).

### Setting the default edition for a DB instance

You can redefine database objects in a private environment called an edition. You can use edition-based redefinition to upgrade an application's database objects with minimal downtime.

You can set the default edition of an Amazon RDS Oracle DB instance using the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_edition`.

The following example sets the default edition for the Amazon RDS Oracle DB instance to `RELEASE_V1`.

```
EXEC rdsadmin.rdsadmin_util.alter_default_edition('RELEASE_V1');
```

The following example sets the default edition for the Amazon RDS Oracle DB instance back to the Oracle default.

```
EXEC rdsadmin.rdsadmin_util.alter_default_edition('ORA$BASE');
```

For more information about Oracle edition-based redefinition, see [About editions and edition-based redefinition](#) in the Oracle documentation.

### Enabling auditing for the SYS.AUD$ table

To enable auditing on the database audit trail table SYS.AUD$, use the Amazon RDS procedure `rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table`. The only supported audit property is ALL. You can't audit or not audit individual statements or operations.
Enabling auditing is supported for Oracle DB instances running the following versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1.0.2.v14) and later

The audit_all_sys_aud_table procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_by_access</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to audit BY ACCESS. Set to false to audit BY SESSION.</td>
</tr>
</tbody>
</table>

**Note**

In a single-tenant CDB, the following operations work, but no customer-visible mechanism can detect the current status of the operations. Auditing information isn't available from within the PDB. For more information, see Limitations of RDS for Oracle CDBs.

The following query returns the current audit configuration for SYS.AUD$ for a database.

```
SELECT * FROM DBA_OBJ_AUDIT_OPTS WHERE OWNER='SYS' AND OBJECT_NAME='AUD$';
```

The following commands enable audit of ALL on SYS.AUD$ BY ACCESS.

```
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table;
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table(p_by_access => true);
```

The following command enables audit of ALL on SYS.AUD$ BY SESSION.

```
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table(p_by_access => false);
```
For more information, see [AUDIT (traditional auditing)](https://oracle.com) in the Oracle documentation.

**Disabling auditing for the SYS.AUD$ table**

To disable auditing on the database audit trail table SYS.AUD$, use the Amazon RDS procedure `rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table`. This procedure takes no parameters.

The following query returns the current audit configuration for SYS.AUD$ for a database:

```sql
SELECT * FROM DBA_OBJ_AUDIT_OPTS WHERE OWNER='SYS' AND OBJECT_NAME='AUD$';
```

The following command disables audit of ALL on SYS.AUD$.

```sql
EXEC rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table;
```

For more information, see [NOAUDIT (traditional auditing)](https://oracle.com) in the Oracle documentation.

**Cleaning up interrupted online index builds**

To clean up failed online index builds, use the Amazon RDS procedure `rdsadmin.rdsadmin_dbms_repair.online_index_clean`.

The `online_index_clean` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_id</td>
<td>binary integer</td>
<td>ALL_INDEX_ID</td>
<td>No</td>
<td>The object ID of the index. Typically, you can use the object ID from the ORA-08104 error text.</td>
</tr>
<tr>
<td>wait_for_lock</td>
<td>binary integer</td>
<td>rdsadmin.rdsadmin_dbms_repair.lock_wait</td>
<td>No</td>
<td>Specify rdsadmin.rdsadmin_dbms_repair.lock_wait, the default, to try to get a lock on the underlying database.</td>
</tr>
</tbody>
</table>
The following example cleans up a failed online index build:

```sql
declare
   is_clean boolean;
begin
   is_clean := rdsadmin.rdsadmin_dbms_repair.online_index_clean(
       object_id     => 1234567890,
       wait_for_lock => rdsadmin.rdsadmin_dbms_repair.lock_nowait
   );
end;
/
```

For more information, see [ONLINE_INDEX_CLEAN function](#) in the Oracle documentation.

### Skipping corrupt blocks

To skip corrupt blocks during index and table scans, use the `rdsadmin.rdsadmin_dbms_repair` package.

The following procedures wrap the functionality of the `sys.dbms_repair.admin_table` procedure and take no parameters:

- `rdsadmin.rdsadmin_dbms_repair.create_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.create_orphan_keys_table`
- `rdsadmin.rdsadmin_dbms_repair.drop_repair_table`
rdsadmin.rdsadmin_dbms_repair.drop_orphan_keys_table
rdsadmin.rdsadmin_dbms_repair.purge_repair_table
rdsadmin.rdsadmin_dbms_repair.purge_orphan_keys_table

The following procedures take the same parameters as their counterparts in the DBMS_REPAIR package for Oracle databases:

rdsadmin.rdsadmin_dbms_repair.check_object
rdsadmin.rdsadmin_dbms_repair.dump_orphan_keys
rdsadmin.rdsadmin_dbms_repair.fix_corrupt_blocks
rdsadmin.rdsadmin_dbms_repair.rebuild_freelists
rdsadmin.rdsadmin_dbms_repair.segment_fix_status
rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks

For more information about handling database corruption, see DBMS_REPAIR in the Oracle documentation.

Example Responding to corrupt blocks

This example shows the basic workflow for responding to corrupt blocks. Your steps will depend on the location and nature of your block corruption.

Important
Before attempting to repair corrupt blocks, review the DBMS_REPAIR documentation carefully.

To skip corrupt blocks during index and table scans

1. Run the following procedures to create repair tables if they don't already exist.

   EXEC rdsadmin.rdsadmin_dbms_repair.create_repair_table;
   EXEC rdsadmin.rdsadmin_dbms_repair.create_orphan_keys_table;

2. Run the following procedures to check for existing records and purge them if appropriate.
3. Run the following procedure to check for corrupt blocks.

```sql
SET SERVEROUTPUT ON
DECLARE v_num_corrupt INT;
BEGIN
  v_num_corrupt := 0;
  rdsadmin.rdsadmin_dbms_repair.check_object (
    schema_name => '&corruptionOwner',
    object_name => '&corruptionTable',
    corrupt_count => v_num_corrupt
  );
  dbms_output.put_line('number corrupt: ' || to_char(v_num_corrupt));
END;
/

COL CORRUPT_DESCRIPTION FORMAT a30
COL REPAIR_DESCRIPTION FORMAT a30

SELECT OBJECT_NAME, BLOCK_ID, CORRUPT_TYPE, MARKED_CORRUPT,
  CORRUPT_DESCRIPTION, REPAIR_DESCRIPTION
FROM   SYS.REPAIR_TABLE;

SELECT SKIP_CORRUPT
FROM   DBA_TABLES
WHERE  OWNER = '&corruptionOwner'
AND    TABLE_NAME = '&corruptionTable';
```

4. Use the skip_corrupt_blocks procedure to enable or disable corruption skipping for affected tables. Depending on the situation, you may also need to extract data to a new table, and then drop the table containing the corrupt block.

Run the following procedure to enable corruption skipping for affected tables.

```sql
begin
```
Run the following procedure to disable corruption skipping.

```
begin
    rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks (
        schema_name => '&corruptionOwner',
        object_name => '&corruptionTable',
        object_type => rdsadmin.rdsadmin_dbms_repair.table_object,
        flags => rdsadmin.rdsadmin_dbms_repair.noskip_flag);
end;
/
```

5. When you have completed all repair work, run the following procedures to drop the repair tables.

```
EXEC rdsadmin.rdsadmin_dbms_repair.drop_repair_table;
EXEC rdsadmin.rdsadmin_dbms_repair.drop_orphan_keys_table;
```

**Resizing tablespaces, data files, and temp files**

By default, Oracle tablespaces are created with auto-extend turned on and no maximum size. Because of these default settings, tablespaces can sometimes grow too large. We recommend that you specify an appropriate maximum size on permanent and temporary tablespaces, and that you carefully monitor space usage.

**Resizing permanent tablespaces**

To resize a permanent tablespace in an RDS for Oracle DB instance, use any of the following Amazon RDS procedures:
The `rdsadmin.rdsadmin_util.resize_datafile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_data_file_id</code></td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The identifier of the data file to resize.</td>
</tr>
<tr>
<td><code>p_size</code></td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The size of the data file. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
</tbody>
</table>

The `rdsadmin.rdsadmin_util.autoextend_datafile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_data_file_id</code></td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The identifier of the data file to resize.</td>
</tr>
<tr>
<td><code>p_autoextend_state</code></td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The state of the autoextension feature. Specify ON to extend the data file automatically and OFF to turn off autoextension.</td>
</tr>
<tr>
<td><code>p_next</code></td>
<td>varchar2</td>
<td>—</td>
<td>No</td>
<td>The size of the next data file increment. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------</td>
<td>---------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>p_maxsize</td>
<td>varchar2</td>
<td>—</td>
<td>No</td>
<td>The maximum disk space allowed for automatic extension. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G). You can specify UNLIMITED to remove the file size limit.</td>
</tr>
</tbody>
</table>

The following example resizes data file 4 to 500 MB.

```sql
EXEC rdsadmin.rdsadmin_util.resize_datafile(4,'500M');
```

The following example turns off autoextension for data file 4. It also turns on autoextension for data file 5, with an increment of 128 MB and no maximum size.

```sql
EXEC rdsadmin.rdsadmin_util.autoextend_datafile(4,'OFF');
EXEC rdsadmin.rdsadmin_util.autoextend_datafile(5,'ON','128M','UNLIMITED');
```

**Resizing temporary tablespaces**

To resize a temporary tablespaces in an RDS for Oracle DB instance, including a read replica, use any of the following Amazon RDS procedures:

- `rdsadmin.rdsadmin_util.resize_temp_tablespace`
- `rdsadmin.rdsadmin_util.resize_tempfile`
- `rdsadmin.rdsadmin_util.autoextend_tempfile`

The `resize_temp_tablespace` procedure has the following parameters.
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_temp_tablespace_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the temporary tablespace to resize.</td>
</tr>
<tr>
<td>p_size</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The size of the tablespace. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
</tbody>
</table>

The `resize_tempfile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_temp_file_id</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The identifier of the temp file to resize.</td>
</tr>
<tr>
<td>p_size</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The size of the temp file. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
</tbody>
</table>

The `autoextend_tempfile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_temp_file_id</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The identifier of the temp file to resize.</td>
</tr>
<tr>
<td>p_autoextend_state</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The state of the autoextension feature. Specify ON to extend the temp file automatic.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>---------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>p_next</td>
<td>varchar2</td>
<td>—</td>
<td>No</td>
<td>The size of the next temp file increment. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
<tr>
<td>p_maxsize</td>
<td>varchar2</td>
<td>—</td>
<td>No</td>
<td>The maximum disk space allowed for automatic extension. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G). You can specify UNLIMITED to remove the file size limit.</td>
</tr>
</tbody>
</table>

The following examples resize a temporary tablespace named TEMP to the size of 4 GB.

```sql
EXEC rdsadmin.rdsadmin_util.resize_temp_tablespace('TEMP','4G');
EXEC rdsadmin.rdsadmin_util.resize_temp_tablespace('TEMP','4096000000');
```

The following example resizes a temporary tablespace based on the temp file with the file identifier 1 to the size of 2 MB.

```sql
EXEC rdsadmin.rdsadmin_util.resize_tempfile(1,'2M');
```

The following example turns off autoextension for temp file 1. It also sets the maximum autoextension size of temp file 2 to 10 GB, with an increment of 100 MB.

```sql
EXEC rdsadmin.rdsadmin_util.autoextend_tempfile(1,'OFF');
```
Purging the recycle bin

When you drop a table, your Oracle database doesn't immediately remove its storage space. The database renames the table and places it and any associated objects in a recycle bin. Purging the recycle bin removes these items and releases their storage space.

To purge the entire recycle bin, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.purge_dba_recyclebin`. However, this procedure can't purge the recycle bin of SYS and RDSADMIN objects. If you need to purge these objects, contact AWS Support.

The following example purges the entire recycle bin.

```
EXEC rdsadmin.rdsadmin_util.purge_dba_recyclebin;
```

Setting the default displayed values for full redaction

To change the default displayed values for full redaction on your Amazon RDS Oracle instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val`. Note that you create a redaction policy with the DBMS_REDACT PL/SQL package, as explained in the Oracle Database documentation. The `dbms_redact_upd_full_rdct_val` procedure specifies the characters to display for different data types affected by an existing policy.

The `dbms_redact_upd_full_rdct_val` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_number_val</td>
<td>number</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NUMBER data type.</td>
</tr>
<tr>
<td>p_binfloat_val</td>
<td>binary_float</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the</td>
</tr>
</tbody>
</table>

For more information about read replicas for Oracle DB instances see [Working with read replicas for Amazon RDS for Oracle](#).
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_bindouble_val</td>
<td>binary_double</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the BINARY_DOUBLE data type.</td>
</tr>
<tr>
<td>p_char_val</td>
<td>char</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the CHAR data type.</td>
</tr>
<tr>
<td>p_varchar_val</td>
<td>varchar2</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the VARCHAR2 data type.</td>
</tr>
<tr>
<td>p_nchar_val</td>
<td>nchar</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NCHAR data type.</td>
</tr>
<tr>
<td>p_nvarchar_val</td>
<td>nvarchar2</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NVARCHAR2 data type.</td>
</tr>
<tr>
<td>p_date_val</td>
<td>date</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the DATE data type.</td>
</tr>
<tr>
<td>p_ts_val</td>
<td>timestamp</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the TIMESTAMP data type.</td>
</tr>
<tr>
<td>p_tswtz_val</td>
<td>timestamp with time zone</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the TIMESTAMP WITH TIME_ZONE data type.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>---------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>p_blob_val</td>
<td>blob</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the BLOB data type.</td>
</tr>
<tr>
<td>p_clob_val</td>
<td>clob</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the CLOB data type.</td>
</tr>
<tr>
<td>p_nclob_val</td>
<td>nclob</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NCLOB data type.</td>
</tr>
</tbody>
</table>

The following example changes the default redacted value to * for the CHAR data type:

```sql
EXEC rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val(p_char_val => '*');
```

The following example changes the default redacted values for NUMBER, DATE, and CHAR data types:

```sql
BEGIN
rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val(
  p_number_val=>1,
  p_date_val=>to_date('1900-01-01','YYYY-MM-DD'),
  p_varchar_val=>'X');
END;
/
```

After you alter the default values for full redaction with the `dbms_redact_upd_full_rdct_val` procedure, reboot your DB instance for the change to take effect. For more information, see [Rebooting a DB instance](#).

## Performing common log-related tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to logging on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS
doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

For more information, see Oracle database log files.

Topics

- Setting force logging
- Setting supplemental logging
- Switching online log files
- Adding online redo logs
- Dropping online redo logs
- Resizing online redo logs
- Retaining archived redo logs
- Accessing online and archived redo logs
- Downloading archived redo logs from Amazon S3

Setting force logging

In force logging mode, Oracle logs all changes to the database except changes in temporary tablespaces and temporary segments (NOLLOGGING clauses are ignored). For more information, see Specifying FORCE LOGGING mode in the Oracle documentation.

To set force logging, use the Amazon RDS procedure rdsadmin.rdsadmin_util.force_logging. The force_logging procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Yes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_enable</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to put the database in force logging mode, false to remove the database from force logging mode.</td>
</tr>
</tbody>
</table>

The following example puts the database in force logging mode.
EXEC rdsadmin.rdsadmin_util.force_logging(p_enable => true);

### Setting supplemental logging

If you enable supplemental logging, LogMiner has the necessary information to support chained rows and clustered tables. For more information, see [Supplemental logging](#) in the Oracle documentation.

Oracle Database doesn't enable supplemental logging by default. To enable and disable supplemental logging, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_supplemental_logging`. For more information about how Amazon RDS manages the retention of archived redo logs for Oracle DB instances, see [Retaining archived redo logs](#).

The `alter_supplemental_logging` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_action</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>'ADD' to add supplemental logging, 'DROP' to drop supplemental logging.</td>
</tr>
<tr>
<td>p_type</td>
<td>varchar2</td>
<td>null</td>
<td>No</td>
<td>The type of supplemental logging. Valid values are 'ALL', 'FOREIGN KEY', 'PRIMARY KEY', 'UNIQUE', or PROCEDURAL.</td>
</tr>
</tbody>
</table>

The following example enables supplemental logging.

```sql
begin
  rdsadmin.rdsadmin_util.alter_supplemental_logging(
    p_action => 'ADD');
end;
/
```
The following example enables supplemental logging for all fixed-length maximum size columns.

```
begin
    rdsadmin.rdsadmin_util.alter_supplemental_logging(
        p_action    => 'ADD',
        p_type      => 'ALL');
end;
/
```

The following example enables supplemental logging for primary key columns.

```
begin
    rdsadmin.rdsadmin_util.alter_supplemental_logging(
        p_action    => 'ADD',
        p_type      => 'PRIMARY KEY');
end;
/
```

**Switching online log files**

To switch log files, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.switch_logfile`. The `switch_logfile` procedure has no parameters.

The following example switches log files.

```
EXEC rdsadmin.rdsadmin_util.switch_logfile;
```

**Adding online redo logs**

An Amazon RDS DB instance running Oracle starts with four online redo logs, 128 MB each. To add additional redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_logfile`.

The `add_logfile` procedure has the following parameters.

⚠ **Note**

The parameters are mutually exclusive.
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bytes</td>
<td>positive</td>
<td>null</td>
<td>No</td>
<td>The size of the log file in bytes.</td>
</tr>
<tr>
<td>p_size</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The size of the log file. You can specify the size in kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
</tbody>
</table>

The following command adds a 100 MB log file.

```sql
EXEC rdsadmin.rdsadmin_util.add_logfile(p_size => '100M');
```

### Dropping online redo logs

To drop redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_logfile`. The `drop_logfile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grp</td>
<td>positive</td>
<td>—</td>
<td>Yes</td>
<td>The group number of the log.</td>
</tr>
</tbody>
</table>

The following example drops the log with group number 3.

```sql
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 3);
```

You can only drop logs that have a status of unused or inactive. The following example gets the statuses of the logs.

```sql
SELECT GROUP#, STATUS FROM V$LOG;
```

<table>
<thead>
<tr>
<th>GROUP#</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>CURRENT</td>
</tr>
</tbody>
</table>
Resizing online redo logs

An Amazon RDS DB instance running Oracle starts with four online redo logs, 128 MB each. The following example shows how you can use Amazon RDS procedures to resize your logs from 128 MB each to 512 MB each.

```sql
/* Query V$LOG to see the logs. */
/* You start with 4 logs of 128 MB each. */

SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#  BYTES      STATUS
-------- ---------- ----------------
 1       134217728  INACTIVE
 2       134217728  CURRENT
 3       134217728  INACTIVE
 4       134217728  INACTIVE

/* Add four new logs that are each 512 MB */

EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);

/* Query V$LOG to see the logs. */
/* Now there are 8 logs. */

SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#  BYTES      STATUS
-------- ---------- ----------------
 1       134217728  INACTIVE
 2       134217728  CURRENT
 3       134217728  INACTIVE
 4       134217728  INACTIVE
 5       536870912  UNUSED
```
/* Drop each inactive log using the group number. */

EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 1);
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 3);
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 4);

/* Query V$LOG to see the logs. */
/* Now there are 5 logs. */

select GROUP#, BYTES, STATUS from V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
2          134217728  CURRENT
5          536870912  UNUSED
6          536870912  UNUSED
7          536870912  UNUSED
8          536870912  UNUSED

/* Switch logs so that group 2 is no longer current. */

EXEC rdsadmin.rdsadmin_util.switch_logfile;

/* Query V$LOG to see the logs. */
/* Now one of the new logs is current. */

SQL>SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
2          134217728  ACTIVE
5          536870912  CURRENT
6          536870912  UNUSED
7          536870912  UNUSED
8          536870912  UNUSED
/* If the status of log 2 is still "ACTIVE", issue a checkpoint to clear it to "INACTIVE". */
EXEC rdsadmin.rdsadmin_util.checkpoint;

/* Query V$LOG to see the logs.       */
/* Now the final original log is inactive. */

SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP# | BYTES      | STATUS       
-------| -----------|--------------
   2   | 134217728  | INACTIVE     
   5   | 536870912  | CURRENT      
   6   | 536870912  | UNUSED       
   7   | 536870912  | UNUSED       
   8   | 536870912  | UNUSED       

# Drop the final inactive log.
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 2);

/* Query V$LOG to see the logs. */
/* Now there are four 512 MB logs. */

SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP# | BYTES      | STATUS       
-------| -----------|--------------
   5   | 536870912  | CURRENT      
   6   | 536870912  | UNUSED       
   7   | 536870912  | UNUSED       
   8   | 536870912  | UNUSED       

Retaining archived redo logs

You can retain archived redo logs locally on your DB instance for use with products like Oracle LogMiner (DBMS_LOGMNR). After you have retained the redo logs, you can use LogMiner to
analyze the logs. For more information, see Using LogMiner to analyze redo log files in the Oracle documentation.

To retain archived redo logs, use the Amazon RDS procedure rdsadmin.rdsadmin_util.set_configuration. The set_configuration procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the configuration to update.</td>
</tr>
<tr>
<td>value</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The value for the configuration.</td>
</tr>
</tbody>
</table>

The following example retains 24 hours of redo logs.

```
begin
    rdsadmin.rdsadmin_util.set_configuration(
        name  => 'archivelog retention hours',
        value => '24');
end;
/
commit;
```

ℹ️ **Note**

The commit is required for the change to take effect.

To view how long archived redo logs are kept for your DB instance, use the Amazon RDS procedure rdsadmin.rdsadmin_util.show_configuration.

The following example shows the log retention time.

```
set serveroutput on
EXEC rdsadmin.rdsadmin_util.show_configuration;
```
The output shows the current setting for archivelog retention hours. The following output shows that archived redo logs are kept for 48 hours.

```
NAME: archivelog retention hours
VALUE: 48
DESCRIPTION: ArchiveLog expiration specifies the duration in hours before archive/redo log files are automatically deleted.
```

Because the archived redo logs are retained on your DB instance, ensure that your DB instance has enough allocated storage for the retained logs. To determine how much space your DB instance has used in the last X hours, you can run the following query, replacing X with the number of hours.

```
SELECT SUM(BLOCKS * BLOCK_SIZE) bytes
FROM V$ARCHIVED_LOG
WHERE FIRST_TIME >= SYSDATE-(X/24) AND DEST_ID=1;
```

RDS for Oracle only generates archived redo logs when the backup retention period of your DB instance is greater than zero. By default the backup retention period is greater than zero.

When the archived log retention period expires, RDS for Oracle removes the archived redo logs from your DB instance. To support restoring your DB instance to a point in time, Amazon RDS retains the archived redo logs outside of your DB instance based on the backup retention period. To modify the backup retention period, see [Modifying an Amazon RDS DB instance](#).

**Note**

In some cases, you might be using JDBC on Linux to download archived redo logs and experience long latency times and connection resets. In such cases, the issues might be caused by the default random number generator setting on your Java client. We recommend setting your JDBC drivers to use a nonblocking random number generator.

### Accessing online and archived redo logs

You might want to access your online and archived redo log files for mining with external tools such as GoldenGate, Attunity, Informatica, and others. To access these files, do the following:

1. Create directory objects that provide read-only access to the physical file paths.
Use `rdsadmin.rdsadmin_master_util.create_archivelog_dir` and `rdsadmin.rdsadmin_master_util.create_onlinelog_dir`.

2. Read the files using PL/SQL.

You can read the files by using PL/SQL. For more information about reading files from directory objects, see [Listing files in a DB instance directory](#) and [Reading files in a DB instance directory](#).

Accessing transaction logs is supported for the following releases:

- Oracle Database 21c
- Oracle Database 19c
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1)

The following code creates directories that provide read-only access to your online and archived redo log files:

```
EXEC rdsadmin.rdsadmin_master_util.create_archivelog_dir;
EXEC rdsadmin.rdsadmin_master_util.create_onlinelog_dir;
```

Important

This code also revokes the `DROP ANY DIRECTORY` privilege.

```
EXEC rdsadmin.rdsadmin_master_util.drop_archivelog_dir;
EXEC rdsadmin.rdsadmin_master_util.drop_onlinelog_dir;
```

The following code grants and revokes the `DROP ANY DIRECTORY` privilege.

```
EXEC rdsadmin.rdsadmin_master_util.revoke_drop_any_directory;
EXEC rdsadmin.rdsadmin_master_util.grant_drop_any_directory;
```
Amazon Relational Database Service
User Guide

Downloading archived redo logs from Amazon S3

You can download archived redo logs on your DB instance using the rdsadmin.rdsadmin_archive_log_download package. If archived redo logs are no longer on your DB instance, you might want to download them again from Amazon S3. Then you can mine the logs or use them to recover or replicate your database.

Note
You can't download archived redo logs on read replica instances.

Downloading archived redo logs: basic steps

The availability of your archived redo logs depends on the following retention policies:

- Backup retention policy – Logs inside of this policy are available in Amazon S3. Logs outside of this policy are removed.
- Archived log retention policy – Logs inside of this policy are available on your DB instance. Logs outside of this policy are removed.

If logs aren't on your instance but are protected by your backup retention period, use rdsadmin.rdsadmin_archive_log_download to download them again. RDS for Oracle saves the logs to the /rdsdbdata/log/arch directory on your DB instance.

To download archived redo logs from Amazon S3

1. Configure your retention period to ensure your downloaded archived redo logs are retained for the duration you need them. Make sure to COMMIT your change.
   RDS retains your downloaded logs according to the archived log retention policy, starting from the time the logs were downloaded. To learn how to set the retention policy, see Retaining archived redo logs.
2. Wait up to 5 minutes for the archived log retention policy change to take effect.
3. Download the archived redo logs from Amazon S3 using rdsadmin.rdsadmin_archive_log_download.
   For more information, see Downloading a single archived redo log and Downloading a series of archived redo logs.
4. Confirm that the logs were downloaded from Amazon S3 successfully.

You can view the status of your download task in a bdump file. The bdump files have the path name /rdsdbdata/log/trace/dbtask-<task-id>.log. In the preceding download step, you run a SELECT statement that returns the task ID in a VARCHAR2 data type. For more information, see similar examples in Monitoring the status of a file transfer.

Downloading a single archived redo log

To download a single archived redo log to the /rdsdbdata/log/arch directory, use rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum. This procedure has the following parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seqnum</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The sequence number of the archived redo log.</td>
</tr>
</tbody>
</table>

The following example downloads the log with sequence number 20.

```sql
SELECT rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum(seqnum => 20) AS TASK_ID
FROM   DUAL;
```

Downloading a series of archived redo logs

To download a series of archived redo logs to the /rdsdbdata/log/arch directory, use download_logs_in_seqnum_range. Your download is limited to 300 logs per request. The download_logs_in_seqnum_range procedure has the following parameters.

Note
RDS automatically checks the available storage before downloading. If the requested logs consume a high percentage of space, you receive an alert.
The following example downloads the logs from sequence 50 to 100.

```sql
SELECT rdsadmin.rdsadmin_archive_log_download.download_logs_in_seqnum_range(start_seq => 50, end_seq => 100)
  AS TASK_ID
FROM   DUAL;
```

### Performing common RMAN tasks for Oracle DB instances

In the following section, you can find how you can perform Oracle Recovery Manager (RMAN) DBA tasks on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges.

Use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to perform RMAN backups of your Amazon RDS for Oracle database to disk. The `rdsadmin.rdsadmin_rman_util` package supports full and incremental database file backups, tablespace backups, and archived redo log backups.

After an RMAN backup has finished, you can copy the backup files off the Amazon RDS for Oracle DB instance host. You might do this for the purpose of restoring to a non-RDS host or for long-term storage of backups. For example, you can copy the backup files to an Amazon S3 bucket. For more information, see using Amazon S3 integration.

The backup files for RMAN backups remain on the Amazon RDS DB instance host until you remove them manually. You can use the `UTL_FILE.FREMOVE` Oracle procedure to remove files from a directory. For more information, see FREMOVE procedure in the Oracle Database documentation.

You can't use the RMAN to restore RDS for Oracle DB instances. However, you can use RMAN to restore a backup to an on-premises or Amazon EC2 instance. For more information, see the blog article Restore an Amazon RDS for Oracle instance to a self-managed instance.
Note

For backing up and restoring to another Amazon RDS for Oracle DB instance, you can continue to use the Amazon RDS backup and restore features. For more information, see Backing up, restoring, and exporting data.

Topics

- Prerequisites for RMAN backups
- Common parameters for RMAN procedures
- Validating database files in RDS for Oracle
- Enabling and disabling block change tracking
- Crosschecking archived redo logs
- Backing up archived redo log files
- Performing a full database backup
- Performing a full backup of a tenant database
- Performing an incremental database backup
- Performing an incremental backup of a tenant database
- Backing up a tablespace
- Backing up a control file
- Performing block media recovery

Prerequisites for RMAN backups

Before backing up your database using the rdsadmin.rdsadmin_rman_util package, make sure that you meet the following prerequisites:

- Make sure that your RDS for Oracle database is in ARCHIVELOG mode. To enable this mode, set the backup retention period to a non-zero value.

- When backing up archived redo logs or performing a full or incremental backup that includes archived redo logs, and when backing up the database, make sure that redo log retention is set to a nonzero value. Archived redo logs are required to make database files consistent during recovery. For more information, see Retaining archived redo logs.
- Make sure that your DB instance has sufficient free space to hold the backups. When backing up your database, you specify an Oracle directory object as a parameter in the procedure call. RMAN places the files in the specified directory. You can use default directories, such as DATA_PUMP_DIR, or create a new directory. For more information, see [Creating and dropping directories in the main data storage space](#).

You can monitor the current free space in an RDS for Oracle instance using the CloudWatch metric FreeStorageSpace. We recommend that your free space exceeds the current size of the database, though RMAN backs up only formatted blocks and supports compression.

### Common parameters for RMAN procedures

You can use procedures in the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to perform tasks with RMAN. Several parameters are common to the procedures in the package. The package has the following common parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory_name</td>
<td>varchar</td>
<td>A valid database directory name.</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory to contain the backup files.</td>
</tr>
<tr>
<td>p_label</td>
<td>varchar</td>
<td>a-z, A-Z, 0-9, __, _-, _\ .</td>
<td>—</td>
<td>No</td>
<td>A unique string that is included in the backup file names.</td>
</tr>
</tbody>
</table>

**Note**

The limit is 30 characters.

<p>| p_owner | varchar | A valid owner of the directory specified in | — | Yes | The owner of the directory to contain the backup files. |</p>
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Datatype</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory_name</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Valid values</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>------------</td>
<td>--------------</td>
<td>---------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>p_tag</td>
<td>varchar</td>
<td>a-z, A-Z, 0-9, ' ', '_'</td>
<td>NULL</td>
<td>No</td>
<td>A string that can be used to distinguish between backups to indicate the purpose or usage of backups, such as daily, weekly, or incremental-level backups. The limit is 30 characters. The tag is not case-sensitive. Tags are always stored in uppercase, regardless of the case used when entering them. Tags don't need to be unique, so multiple backups can have the same tag. If you don't specify a tag, then RMAN assigns a default tag automatically using the format TAGYYYYMMDDTHHMMSS, where YYYY is the year, MM is the month, DD is the day, HH is the hour (in 24-hour format), MM is the minutes, and SS is the seconds. The date and time refer to when RMAN started the backup. For example, a backup might receive a tag TAG20190927T214517 for a backup that started on 2019-09-27 at 21:45:17. The p_tag parameter is supported for the following Amazon RDS for Oracle DB engine versions: • Oracle Database 21c (21.0.0)</td>
</tr>
<tr>

**Note:**
- **RMAN tasks:** Refer to the Amazon Relational Database Service (Amazon RDS) User Guide for more information about RMAN tasks.
### Parameter name | Data type | Valid values | Default | Required | Description
---|---|---|---|---|---
`p_rman_to_dbms_output` | boolean | TRUE, FALSE | FALSE | No | When TRUE, the RMAN output is sent to the DBMS_OUTPUT package in addition to a file in the BDUMP directory. In SQL*Plus, use SET SERVEROUTPUT ON to see the output. When FALSE, the RMAN output is only sent to a file in the BDUMP directory.

`p_section_size_mb` | number | A valid integer | NULL | No | The section size in megabytes (MB). Validates in parallel by dividing each file into the specified section size. When NULL, the parameter is ignored.

`p_validation_type` | varchar | 'PHYSICAL', 'PHYSICAL+LOGICAL' | 'PHYSICAL' | No | The level of corruption detection. Specify 'PHYSICAL' to check for physical corruption. An example of physical corruption is a block with a mismatch in the header and footer. Specify 'PHYSICAL+LOGICAL' to check for logical inconsistencies in addition to physical corruption. An example of logical corruption is a corrupt block.

---

### Validating database files in RDS for Oracle

You can use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to validate Amazon RDS for Oracle database files, such as data files, tablespaces, control files, and server parameter files (SPFILEs).
For more information about RMAN validation, see [Validating database files and backups](#) and [VALIDATE](#) in the Oracle documentation.

**Topics**

- Validating a database
- Validating a tenant database
- Validating a tablespace
- Validating a control file
- Validating an SPFILE
- Validating an Oracle data file

**Validating a database**

To validate all of the relevant files used by an Oracle database in RDS for Oracle, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_database`.

This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures](#).

The following example validates the database using the default values for the parameters.

```
EXEC rdsadmin.rdsadmin_rman_util.validate_database;
```

The following example validates the database using the specified values for the parameters.

```
BEGIN
   rdsadmin.rdsadmin_rman_util.validate_database(
      p_validation_type => 'PHYSICAL+LOGICAL',
      p_parallel        => 4,
      p_section_size_mb => 10,
      p_rman_to_dbms_output => FALSE);
```

RMAN tasks
When the `p_rman_to_dbms_output` parameter is set to FALSE, the RMAN output is written to a file in the BDUMP directory.

To view the files in the BDUMP directory, run the following SELECT statement.

```
SELECT * FROM table(rdsadmin.rds_file_util.listdir('BDUMP')) order by mtime;
```

To view the contents of a file in the BDUMP directory, run the following SELECT statement.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','rds-rman-validate-nnn.txt'));
```

Replace the file name with the name of the file you want to view.

**Validating a tenant database**

To validate the data files of the tenant database in a container database (CDB), use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_tenant`.

This procedure applies only to the current tenant database and uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures](#). This procedure is supported for the following DB engine versions:

- Oracle Database 21c (21.0.0) CDB
- Oracle Database 19c (19.0.0) CDB

The following example validates the current tenant database using the default values for the parameters.
The following example validates the current tenant database using the specified values for the parameters.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.validate_tenant(
    p_validation_type => 'PHYSICAL+LOGICAL',
    p_parallel => 4,
    p_section_size_mb => 10,
    p_rman_to_dbms_output => FALSE);
END;
/
```

When the `p_rman_to_dbms_output` parameter is set to FALSE, the RMAN output is written to a file in the BDUMP directory.

To view the files in the BDUMP directory, run the following SELECT statement.

```
SELECT * FROM table(rdsadmin.rds_file_util.listdir('BDUMP')) order by mtime;
```

To view the contents of a file in the BDUMP directory, run the following SELECT statement.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','rds-rman-validate-nnn.txt'));
```

Replace the file name with the name of the file you want to view.

**Validating a tablespace**

To validate the files associated with a tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`.

This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`
For more information, see [Common parameters for RMAN procedures](#).

This procedure also uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tablespace_name</td>
<td>varchar2</td>
<td>A valid tablespace name</td>
<td>—</td>
<td>Yes</td>
<td>The name of the tablespace.</td>
</tr>
</tbody>
</table>

### Validating a control file

To validate only the control file used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_current_controlfile`.

This procedure uses the following common parameter for RMAN tasks:

- `p_validation_type`
- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures](#).

### Validating an SPFILE

To validate only the server parameter file (SPFILE) used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_spfile`.

This procedure uses the following common parameter for RMAN tasks:

- `p_validation_type`
- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures](#).

### Validating an Oracle data file

To validate a data file, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_datafile`.

---

RMAN tasks
This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures](#).

This procedure also uses the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_datafile</code></td>
<td>varchar2</td>
<td>A valid datafile ID number or a valid datafile name including complete path</td>
<td>—</td>
<td>Yes</td>
<td>The datafile ID number (from <code>v $datafile.file#</code>) or the full datafile name including the path (from <code>v $datafile.name</code>).</td>
</tr>
<tr>
<td><code>p_from_block</code></td>
<td>number</td>
<td>A valid integer</td>
<td>NULL</td>
<td>No</td>
<td>The number of the block where the validation starts within the data file. When this is NULL, 1 is used.</td>
</tr>
<tr>
<td><code>p_to_block</code></td>
<td>number</td>
<td>A valid integer</td>
<td>NULL</td>
<td>No</td>
<td>The number of the block where the validation ends within the data file. When this is NULL,</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Valid values</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>--------------</td>
<td>---------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>the maximum block in the data file is used.</td>
</tr>
</tbody>
</table>

### Enabling and disabling block change tracking

Block changing tracking records changed blocks in a tracking file. This technique can improve the performance of RMAN incremental backups. For more information, see [Using Block Change Tracking to Improve Incremental Backup Performance](#) in the Oracle Database documentation.

RMAN features aren't supported in a read replica. However, as part of your high availability strategy, you might choose to enable block tracking in a read-only replica using the procedure `rdsadmin.rdsadmin_rman_util.enable_block_change_tracking`. If you promote this read-only replica to a source DB instance, block change tracking is enabled for the new source instance. Thus, your instance can benefit from fast incremental backups.

Block change tracking procedures are supported in Enterprise Edition only for the following DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher (deprecated)
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher (deprecated)

#### Note

In a single-tenant CDB, the following operations work, but no customer-visible mechanism can detect the current status of the operations. See also [Limitations of RDS for Oracle CDBs](#).
To enable block change tracking for a DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.enable_block_change_tracking`. To disable block change tracking, use `disable_block_change_tracking`. These procedures take no parameters.

To determine whether block change tracking is enabled for your DB instance, run the following query.

```
SELECT STATUS, FILENAME FROM V$BLOCK_CHANGE_TRACKING;
```

The following example enables block change tracking for a DB instance.

```
EXEC rdsadmin.rdsadmin_rman_util.enable_block_change_tracking;
```

The following example disables block change tracking for a DB instance.

```
EXEC rdsadmin.rdsadmin_rman_util.disable_block_change_tracking;
```

**Crosschecking archived redo logs**

You can crosscheck archived redo logs using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.crosscheck_archivelog`.

You can use this procedure to crosscheck the archived redo logs registered in the control file and optionally delete the expired logs records. When RMAN makes a backup, it creates a record in the control file. Over time, these records increase the size of the control file. We recommend that you remove expired records periodically.

⚠️ **Note**

Standard Amazon RDS backups don't use RMAN and therefore don't create records in the control file.

This procedure uses the common parameter `p_rman_to_dbms_output` for RMAN tasks.

For more information, see [Common parameters for RMAN procedures](#).

This procedure also uses the following additional parameter.
## Parameter name | Data type | Valid values | Default | Required | Description
--- | --- | --- | --- | --- | ---
p_delete_expired | boolean | TRUE, FALSE | TRUE | No | When TRUE, delete expired archived redo log records from the control file. When FALSE, retain the expired archived redo log records in the control file.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

The following example marks archived redo log records in the control file as expired, but does not delete the records.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.crosscheck_archivelog(
    p_delete_expired => FALSE,
    p_rman_to_dbms_output => FALSE);
END;
/
```

The following example deletes expired archived redo log records from the control file.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.crosscheck_archivelog(
    p_delete_expired => TRUE,
    p_rman_to_dbms_output => FALSE);
END;
```
Backing up archived redo log files

You can use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to back up archived redo logs for an Amazon RDS Oracle DB instance.

The procedures for backing up archived redo logs are supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

**Topics**

- [Backing up all archived redo logs](#backspping-up-all-archived-redo-logs)
- [Backing up an archived redo log from a date range](#backspping-up-an-archived-redo-log-from-a-date-range)
- [Backing up an archived redo log from an SCN range](#backspping-up-an-archived-redo-log-from-an-scn-range)
- [Backing up an archived redo log from a sequence number range](#backspping-up-an-archived-redo-log-from-a-sequence-number-range)

**Backing up all archived redo logs**

To back up all of the archived redo logs for an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_all`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
For more information, see Common parameters for RMAN procedures.

The following example backs up all archived redo logs for the DB instance.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_archivelog_all(
    p_owner               => 'SYS',
    p_directory_name      => 'MYDIRECTORY',
    p_parallel            => 4,
    p_tag                 => 'MY_LOG_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

### Backing up an archived redo log from a date range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a date range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_date`. The date range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameters.
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_from_date</td>
<td>date</td>
<td>A date that is between the start_date and next_date of an archived redo log that exists on disk. The value must be less than or equal to the value specified for p_to_date.</td>
<td>—</td>
<td>Yes</td>
<td>The starting date for the archived log backups.</td>
</tr>
<tr>
<td>p_to_date</td>
<td>date</td>
<td>A date that is between the start_date and next_date of an archived redo log that exists on disk.</td>
<td>—</td>
<td>Yes</td>
<td>The ending date for the archived log backups.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Valid values</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>--------------</td>
<td>---------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_date.</td>
<td></td>
<td>redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_date.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following example backs up archived redo logs in the date range for the DB instance.

```sql
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_archivelog_date(
    p_owner => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_from_date => '03/01/2019 00:00:00',
    p_to_date => '03/02/2019 00:00:00',
    p_parallel => 4,
    p_tag => 'MY_LOG_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

**Backing up an archived redo log from an SCN range**

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a system change number (SCN) range, use the Amazon RDS procedure
rdsadmin.rdsadmin_rman_util.backup_archivelog_scn. The SCN range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
- p_parallel
- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_from_scn</td>
<td>number</td>
<td>An SCN of an archived redo log that exists on disk. The value must be less than or equal to the value specified for p_to_scn.</td>
<td>—</td>
<td>Yes</td>
<td>The starting SCN for the archived log backups.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Valid values</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------</td>
<td>-------------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>p_to_scn</td>
<td>number</td>
<td>An SCN of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_scn.</td>
<td>—</td>
<td>Yes</td>
<td>The ending SCN for the archived log backups.</td>
</tr>
</tbody>
</table>

The following example backs up archived redo logs in the SCN range for the DB instance.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_archivelog_scn(
    p_owner           => 'SYS',
    p_directory_name  => 'MYDIRECTORY',
    p_from_scn        => 1533835,
    p_to_scn          => 1892447,
    p_parallel        => 4,
    p_tag             => 'MY_LOG_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/```

RMAN tasks
Backing up an archived redo log from a sequence number range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a sequence number range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_sequence`. The sequence number range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

This procedure also uses the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_from_sequence</code></td>
<td>number</td>
<td>A sequence number an archived redo log that exists on disk. The value must be less than</td>
<td>—</td>
<td>Yes</td>
<td>The starting sequence number for the archived log backups.</td>
</tr>
</tbody>
</table>
### Parameter name | Data type | Valid values | Default | Required | Description
--- | --- | --- | --- | --- | ---
| p_to_sequence | number | or equal to the value specified for p_to_sequence. | — | Yes | The ending sequence number for the archived log backups.

The following example backs up archived redo logs in the sequence number range for the DB instance.

```sql
BEGIN
   rdsadmin.rdsadmin_rman_util.backup_archivelog_sequence(
      p_owner => 'SYS',
   )
END
```
Performing a full database backup

You can perform a backup of all blocks of data files included in the backup using Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_database_full`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example performs a full backup of the DB instance using the specified values for the parameters.
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_database_full(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_tag                 => 'FULL_DB_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/

Performing a full backup of a tenant database

You can perform a backup of all data blocks included a tenant database in a container database (CDB). Use the Amazon RDS procedure rdsadmin.rdsadmin_rman_util.backup_tenant_full. This procedure applies only to the current database backup and uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
- p_parallel
- p_section_size_mb
- p_include_archive_logs
- p_optimize
- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures.

The rdsadmin_rman_util.backup_tenant_full procedure is supported for the following RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0) CDB
- Oracle Database 19c (19.0.0) CDB
The following example performs a full backup of the current tenant database using the specified values for the parameters.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_tenant_full(
    p_owner               => 'SYS',
    p_directory_name      => 'MYDIRECTORY',
    p_parallel            => 4,
    p_section_size_mb     => 10,
    p_tag                 => 'FULL_TENANT_DB_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

**Performing an incremental database backup**

You can perform an incremental backup of your DB instance using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_database_incremental`.

For more information about incremental backups, see [Incremental backups](#) in the Oracle documentation.

This procedure uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
- p_parallel
- p_section_size_mb
- p_include_archive_logs
- p_include_controlfile
- p_optimize
- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see [Common parameters for RMAN procedures](#).
This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

This procedure also uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_level</td>
<td>number</td>
<td>0, 1</td>
<td>0</td>
<td>No</td>
<td>Specify 0 to enable a full incremental backup. Specify 1 to enable a non-cumulative incremental backup.</td>
</tr>
</tbody>
</table>

The following example performs an incremental backup of the DB instance using the specified values for the parameters.

```sql
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_database_incremental(
    p_owner => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_level => 1,
    p_parallel => 4,
    p_section_size_mb => 10,
    p_tag => 'MY_INCREMENTAL_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/```
Performing an incremental backup of a tenant database

You can perform an incremental backup of the current tenant database in your CDB. Use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_tenant_incremental`.

For more information about incremental backups, see [Incremental backups](#) in the Oracle Database documentation.

This procedure applies only to the current tenant database and uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_include_controlfile`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0) CDB
- Oracle Database 19c (19.0.0) CDB

This procedure also uses the following additional parameter.
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_level</td>
<td>number</td>
<td>0, 1</td>
<td>0</td>
<td>No</td>
<td>Specify 0 to enable a full incremental backup. Specify 1 to enable a non-cumulative incremental backup.</td>
</tr>
</tbody>
</table>

The following example performs an incremental backup of the current tenant database using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_tenant_incremental(
        p_owner => 'SYS',
        p_directory_name => 'MYDIRECTORY',
        p_level => 1,
        p_parallel => 4,
        p_section_size_mb => 10,
        p_tag => 'MY_INCREMENTAL_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

**Backing up a tablespace**

You can back up a tablespace using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_tablespace`.

This procedure uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
- p_parallel
- p_section_size_mb
• p_include_archive_logs
• p_include_controlfile
• p_optimize
• p_compress
• p_rman_to_dbms_output
• p_tag

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tablespace_name</td>
<td>varchar2</td>
<td>A valid tablespace name.</td>
<td>—</td>
<td>Yes</td>
<td>The name of the tablespace to back up.</td>
</tr>
</tbody>
</table>

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

• Oracle Database 21c (21.0.0)
• Oracle Database 19c (19.0.0)
• Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.ru-2019-01.r1 or higher
• Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

The following example performs a tablespace backup using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_tablespace(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_tablespace_name     => 'MYTABLESPACE',
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_tag                 => 'MYTABLESPACE_BACKUP',
    );
```

Backing up a control file

You can back up a control file using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_current_controlfile`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

The following example backs up a control file using the specified values for the parameters.

```sql
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_current_controlfile(
        p_owner => 'SYS',
        p_directory_name => 'MYDIRECTORY',
        p_tag => 'CONTROL_FILE_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```
Performing block media recovery

You can recovery individual data blocks, known as block media recovery, using the Amazon RDS procedures rdsadmin.rdsadmin_rman_util.recover_datafile_block. You can use this overloaded procedure to recover either an individual data block or a range of data blocks.

This procedure uses the following common parameter for RMAN tasks:

- p_rman_to_dbms_output

For more information, see Common parameters for RMAN procedures.

This procedure uses the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
</table>
| p_datafile     | NUMBER    | A valid data file ID number. | —       | Yes      | The data file containin g the corrupt blocks. Specify the data file in either of the following ways:  
  - The data file ID number, which is located in V$DATAFILE.FILE#  
  - The full data file name, including the path, located in V $DATAFILE.NAME |
| p_block        | NUMBER    | A valid integer. | —       | Yes      | The number of an individual block to be recovered.  
  The following parameters are mutually exclusive:
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_from_block</td>
<td>NUMBER</td>
<td>A valid integer.</td>
<td>—</td>
<td>Yes</td>
<td>The first block number in a range of blocks to be recovered. The following parameters are mutually exclusive: • p_block • p_from_block and p_to_block</td>
</tr>
<tr>
<td>p_to_block</td>
<td>NUMBER</td>
<td>A valid integer.</td>
<td>—</td>
<td>Yes</td>
<td>The last block number in a range of blocks to be recovered. The following parameters are mutually exclusive: • p_block • p_from_block and p_to_block</td>
</tr>
</tbody>
</table>

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example recovers block 100 in data file 5.

```sql
BEGIN
  rdsadmin.rdsadmin_rman_util.recover_datafile_block
```
The following example recovers blocks 100 to 150 in data file 5.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.recover_datafile_block(
        p_datafile => 5,
        p_from_block => 100,
        p_to_block => 150,
        p_rman_to_dbms_output => TRUE);
END;
/
```

### Performing common scheduling tasks for Oracle DB instances

Some scheduler jobs owned by SYS can interfere with normal database operations. Oracle Support recommends you disable these jobs or modify the schedule. To perform tasks for Oracle Scheduler jobs owned by SYS, use the Amazon RDS package `rdsadmin.rdsadmin_dbms_scheduler`.

The `rdsadmin.rdsadmin_dbms_scheduler` procedures are supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c
- Oracle Database 12c Release 2 (12.2) on 12.2.0.2.ru-2019-07.rur-2019-07.r1 or higher 12.2 versions
- Oracle Database 12c Release 1 (12.1) on 12.1.0.2.v17 or higher 12.1 versions

### Common parameters for Oracle Scheduler procedures

To perform tasks with Oracle Scheduler, use procedures in the Amazon RDS package `rdsadmin.rdsadmin_dbms_scheduler`. Several parameters are common to the procedures in the package. The package has the following common parameters.
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>varchar2</td>
<td>'SYS.BSLN_MAINTAIN_STATS_JOB', 'SYS.CLEAN_UP_ONLINE_IND_BUILD'</td>
<td>—</td>
<td>Yes</td>
<td>The name of the job to modify.</td>
</tr>
</tbody>
</table>

**Note**
Currently, you can only modify SYS.CLEAN_UP_ONLINE_IND_BUILD and SYS.BSLN_MAINTAIN_STATS_JOB jobs.

<table>
<thead>
<tr>
<th>attribute</th>
<th>varchar2</th>
<th>'REPEAT_INTERVAL', 'SCHEDULE_NAME'</th>
<th>—</th>
<th>Yes</th>
<th>Attribute to modify.</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>varchar2</td>
<td>A valid schedule interval or schedule</td>
<td>—</td>
<td>Yes</td>
<td>The new value of the attribute.</td>
</tr>
</tbody>
</table>

To modify the repeat interval for the job, specify 'REPEAT_INTERVAL'.
To modify the schedule name for the job, specify 'SCHEDULE_NAME'.
### Modifying DBMS_SCHEDULER jobs

To modify certain components of Oracle Scheduler, use the Oracle procedure `dbms_scheduler.set_attribute`. For more information, see [DBMS_SCHEDULER](https://docs.oracle.com/en/database/oracle/database/121/121.1.0/dbsched.html) and [SET_ATTRIBUTE procedure](https://docs.oracle.com/en/database/oracle/database/121/121.1.0/dbsched.html) in the Oracle documentation.

When working with Amazon RDS DB instances, prepend the schema name SYS to the object name. The following example sets the resource plan attribute for the Monday window object.

```sql
BEGIN
    DBMS_SCHEDULER.SET_ATTRIBUTE(
        name => 'SYS.MONDAY_WINDOW',
        attribute => 'RESOURCE_PLAN',
        value => 'resource_plan_1');
END;
/
```

### Modifying AutoTask maintenance windows

Amazon RDS for Oracle instances are created with default settings for maintenance windows. Automated maintenance tasks such as optimizer statistics collection run during these windows. By default, the maintenance windows turn on Oracle Database Resource Manager.

To modify the window, use the `DBMS_SCHEDULER` package. You might need to modify the maintenance window settings for the following reasons:

- You want maintenance jobs to run at a different time, with different settings, or not at all. For example, might want to modify the window duration, or change the repeat time and interval.
- You want to avoid the performance impact of enabling Resource Manager during maintenance. For example, if the default maintenance plan is specified, and if the maintenance window opens

---

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name, depending on attribute used.</td>
<td>name, depending on attribute used.</td>
<td>name, depending on attribute used.</td>
<td>name, depending on attribute used.</td>
<td>name, depending on attribute used.</td>
<td>name, depending on attribute used.</td>
</tr>
</tbody>
</table>
while the database is under load, you might see wait events such as `resmgr:cpu quantum`. This wait event is related to Database Resource Manager. You have the following options:

- Ensure that maintenance windows are active during off-peak times for your DB instance.
- Disable the default maintenance plan by setting the `resource_plan` attribute to an empty string.
- Set the `resource_manager_plan` parameter to `FORCE:` in your parameter group. If your instance uses Enterprise Edition, this setting prevents Database Resource Manager plans from activating.

To modify your maintenance window settings

1. Connect to your database using an Oracle SQL client.
2. Query the current configuration for a scheduler window.

The following example queries the configuration for MONDAY_WINDOW.

```
SELECT ENABLED, RESOURCE_PLAN, DURATION, REPEAT_INTERVAL
FROM   DBA_SCHEDULER_WINDOWS
WHERE  WINDOW_NAME='MONDAY_WINDOW';
```

The following output shows that the window is using the default values.

```
<table>
<thead>
<tr>
<th>ENABLED</th>
<th>RESOURCE_PLAN</th>
<th>DURATION</th>
<th>REPEAT_INTERVAL</th>
</tr>
</thead>
</table>
| TRUE    | DEFAULT_MAINTENANCE_PLAN  | +000 04:00:00 | freq=daily;byday=MON;byhour=22
|         |                           |          |                         |
|         |                           |          | ;byminute=0;             |
|         |                           |          | bysecond=0               |
```

3. Modify the window using the `DBMS_SCHEDULER` package.

The following example sets the resource plan to null so that the Resource Manager won't run during the maintenance window.

```
BEGIN
   -- disable the window to make changes
   DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"',force=>TRUE);
END;
```
The following example sets the maximum duration of the window to 2 hours.

```sql
BEGIN
    DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"',force=>TRUE);
    DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"',
                                   attribute=>'DURATION', value=>'0 2:00:00');
    DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/
```

The following example sets the repeat interval to every Monday at 10 AM.

```sql
BEGIN
    DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"',force=>TRUE);
    DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"',
                                   attribute=>'REPEAT_INTERVAL',
                                   value=>'freq=daily;byday=MON;byhour=10;byminute=0;bysecond=0');
    DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/
```

### Setting the time zone for Oracle Scheduler jobs

To modify the time zone for Oracle Scheduler, you can use the Oracle procedure `dbms_scheduler.set_scheduler_attribute`. For more information about the `dbms_scheduler` package, see [DBMS_SCHEDULER](https://docs.oracle.com/en/database/oracle/database/19/adb/Oracle-Scheduler-api.html) and [SET_SCHEDULER_ATTRIBUTE](https://docs.oracle.com/en/database/oracle/database/19/adb/Oracle-Scheduler-api.html) in the Oracle documentation.
To modify the current time zone setting

1. Connect to the database using a client such as SQL Developer. For more information, see Connecting to your DB instance using Oracle SQL developer.

2. Set the default time zone as following, substituting your time zone for `time_zone_name`.

   ```sql
   BEGIN
   DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE(
       attribute => 'default_timezone',
       value => 'time_zone_name'
   );
   END;
   /
   ``

   In the following example, you change the time zone to Asia/Shanghai.

   Start by querying the current time zone, as shown following.

   ```sql
   SELECT VALUE FROM DBA_SCHEDULER_GLOBAL_ATTRIBUTE WHERE ATTRIBUTE_NAME='DEFAULT_TIMEZONE';
   ``

   The output shows that the current time zone is ETC/UTC.

   ```text
   VALUE
   --------
   Etc/UTC
   ``

   Then you set the time zone to Asia/Shanghai.

   ```sql
   BEGIN
   DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE(
       attribute => 'default_timezone',
       value => 'Asia/Shanghai'
   );
   END;
   /
   ``

   For more information about changing the system time zone, see Oracle time zone.
**Turning off Oracle Scheduler jobs owned by SYS**

To disable an Oracle Scheduler job owned by the SYS user, use the `rdsadmin.rdsadmin_dbms_scheduler.disable` procedure.

This procedure uses the name common parameter for Oracle Scheduler tasks. For more information, see [Common parameters for Oracle Scheduler procedures](#).

The following example disables the `SYS.CLEANUP_ONLINE_IND_BUILD` Oracle Scheduler job.

```sql
BEGIN
    rdsadmin.rdsadmin_dbms_scheduler.disable('SYS.CLEANUP_ONLINE_IND_BUILD');
END;
/
```

**Turning on Oracle Scheduler jobs owned by SYS**

To turn on an Oracle Scheduler job owned by SYS, use the `rdsadmin.rdsadmin_dbms_scheduler.enable` procedure.

This procedure uses the name common parameter for Oracle Scheduler tasks. For more information, see [Common parameters for Oracle Scheduler procedures](#).

The following example enables the `SYS.CLEANUP_ONLINE_IND_BUILD` Oracle Scheduler job.

```sql
BEGIN
    rdsadmin.rdsadmin_dbms_scheduler.enable('SYS.CLEANUP_ONLINE_IND_BUILD');
END;
/
```

**Modifying the Oracle Scheduler repeat interval for jobs of CALENDAR type**

To modify the repeat interval to modify a SYS-owned Oracle Scheduler job of CALENDAR type, use the `rdsadmin.rdsadmin_dbms_scheduler.disable` procedure.

This procedure uses the following common parameters for Oracle Scheduler tasks:

- name
- attribute
The following example modifies the repeat interval of the SYS.CLEANUP_ONLINE_IND_BUILD Oracle Scheduler job.

```sql
BEGIN
    rdsadmin.rdsadmin_dbms_scheduler.set_attribute(
        name => 'SYS.CLEANUP_ONLINE_IND_BUILD',
        attribute => 'repeat_interval',
        value => 'freq=daily;byday=FRI,SAT;byhour=20;byminute=0;bysecond=0');
END;
/
```

### Modifying the Oracle Scheduler repeat interval for jobs of NAMED type

Some Oracle Scheduler jobs use a schedule name instead of an interval. For this type of jobs, you must create a new named schedule in the master user schema. Use the standard Oracle `sys.dbms_scheduler.create_schedule` procedure to do this. Also, use the `rdsadmin.rdsadmin_dbms_scheduler.set_attribute` procedure to assign the new named schedule to the job.

This procedure uses the following common parameter for Oracle Scheduler tasks:

- **name**
- **attribute**
- **value**

For more information, see [Common parameters for Oracle Scheduler procedures](#).

The following example modifies the repeat interval of the SYS.BSLN_MAINTAIN_STATS_JOB Oracle Scheduler job.

```sql
BEGIN
    DBMS_SCHEDULER.CREATE_SCHEDULE (  
        schedule_name => 'rds_master_user.new_schedule',
        start_date => SYSTIMESTAMP,
```
Turning off autocommit for Oracle Scheduler job creation

When `DBMS_SCHEDULER.CREATE_JOB` creates Oracle Scheduler jobs, it creates the jobs immediately and commits the changes. You might need to incorporate the creation of Oracle Scheduler jobs in the user transaction to do the following:

- Roll back the Oracle Schedule job when the user transaction is rolled back.
- Create the Oracle Scheduler job when the main user transaction is committed.

You can use the procedure `rdsadmin.rdsadmin_dbms_scheduler.set_no_commit_flag` to turn on this behavior. This procedure takes no parameters. You can use this procedure in the following RDS for Oracle releases:

- 21.0.0.0.ru-2022-07.rur-2022-07.r1 and higher
- 19.0.0.0.ru-2022-07.rur-2022-07.r1 and higher

The following example turns off autocommit for Oracle Scheduler, creates an Oracle Scheduler job, and then rolls back the transaction. Because autocommit is turned off, the database also rolls back the creation of the Oracle Scheduler job.

```sql
BEGIN
    rdsadmin.rdsadmin_dbms_scheduler.set_no_commit_flag;
    DBMS_SCHEDULER.CREATE_JOB(job_name => 'EMPTY_JOB',
                                job_type => 'PLSQL_BLOCK',
                                ...)
END;
```
Performing common diagnostic tasks for Oracle DB instances

Oracle Database includes a fault diagnosability infrastructure that you can use to investigate database problems. In Oracle terminology, a *problem* is a critical error such as a code bug or data corruption. An *incident* is the occurrence of a problem. If the same error occurs three times, then the infrastructure shows three incidents of this problem. For more information, see [Diagnosing and resolving problems](#) in the Oracle Database documentation.

The Automatic Diagnostic Repository Command Interpreter (ADRCI) utility is an Oracle command-line tool that you use to manage diagnostic data. For example, you can use this tool to investigate problems and package diagnostic data. An *incident package* includes diagnostic data for an incident or all incidents that reference a specific problem. You can upload an incident package, which is implemented as a .zip file, to Oracle Support.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to ADRCI. To perform diagnostic tasks for your Oracle instance, instead use the Amazon RDS package `rdsadmin.rdsadmin_adrci_util`.

By using the functions in `rdsadmin_adrci_util`, you can list and package problems and incidents, and also show trace files. All functions return a task ID. This ID forms part of the name of log file that contains the ADRCI output, as in `dbtask-task_id.log`. The log file resides in the BDUMP directory. You can download the log file by following the procedure described in [Downloading a database log file](#).

**Common parameters for diagnostic procedures**

To perform diagnostic tasks, use functions in the Amazon RDS package `rdsadmin.rdsadmin_adrci_util`. The package has the following common parameters.
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>incident_id</td>
<td>number</td>
<td>A valid incident ID or null</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, the function shows all incidents. If the value isn't null and represents a valid incident ID, the function shows the specified incident.</td>
</tr>
<tr>
<td>problem_id</td>
<td>number</td>
<td>A valid problem ID or null</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, the function shows all problems. If the value isn't null and represents a valid problem ID, the function shows the specified problem.</td>
</tr>
<tr>
<td>last</td>
<td>number</td>
<td>A valid integer greater than 0 or null</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, then the function displays at most 50 items. If the value isn't null, the function displays the specified number.</td>
</tr>
</tbody>
</table>

**Listing incidents**

To list diagnostic incidents for Oracle, use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents`. You can list incidents in either basic or detailed mode. By default, the function lists the 50 most recent incidents.

This function uses the following common parameters:
- incident_id
- problem_id
- last

If you specify incident_id and problem_id, then incident_id overrides problem_id. For more information, see Common parameters for diagnostic procedures.

This function uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>detail</td>
<td>boolean</td>
<td>TRUE or FALSE</td>
<td>FALSE</td>
<td>No</td>
<td>If TRUE, the function lists incidents in detail mode. If FALSE, the function lists incidents in basic mode.</td>
</tr>
</tbody>
</table>

To list all incidents, query the `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents` function without any arguments. The query returns the task ID.

```
SQL> SELECT rdsadmin.rdsadmin_adrci_util.list_adrci_incidents AS task_id FROM DUAL;

TASK_ID
------------------
1590786706158-3126
```

Or call the `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents` function without any arguments and store the output in a SQL client variable. You can use the variable in other statements.

```
SQL> VAR task_id VARCHAR2(80);
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_incidents;

PL/SQL procedure successfully completed.
```
To read the log file, call the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. Supply the task ID as part of the file name. The following output shows three incidents: 53523, 53522, and 53521.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-||:task_id||'.log'));

2020-05-29 21:11:46.256 UTC [INFO ]

53521       ORA 700 [EVENT_CREATED_INCIDENT] [942] [SIMULATED_ERROR_001 2020-05-29
20:15:06.047000 +00:00
3 rows fetched

2020-05-29 21:11:46.256 UTC [INFO ] The ADRCI incidents were successfully listed.

14 rows selected.
```

To list a particular incident, specify its ID using the `incident_id` parameter. In the following example, you query the log file for incident 53523 only.

```
SQL> EXEC :task_id :=
     rdsadmin.rdsadmin_adrci_util.list_adrci_incidents(incident_id=>53523);

PL/SQL procedure successfully completed.

SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-||:task_id||'.log'));

TEXT
Listing problems

To list diagnostic problems for Oracle, use the Amazon RDS function
rdsadmin.rdsadmin_adrci_util.list_adrci_problems.

By default, the function lists the 50 most recent problems.

This function uses the common parameters problem_id and last. For more information, see
Common parameters for diagnostic procedures.

To get the task ID for all problems, call the
rdsadmin.rdsadmin_adrci_util.list_adrci_problems function without any arguments,
and store the output in a SQL client variable.

```sql
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_problems;
PL/SQL procedure successfully completed.
```

To read the log file, call the rdsadmin.rds_file_util.read_text_file function, supplying
the task ID as part of the file name. In the following output, the log file shows three problems: 1, 2, and 3.
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-'||:task_id||'.log'));

2020-05-29 21:18:50.829 UTC [INFO ]
ADR Home = /rdsdbdata/log/diag/rdbms/orcl_a/ORCL:
*************************************************************************

3 rows fetched

2020-05-29 21:18:50.829 UTC [INFO ] The ADRCI problems were successfully listed.

14 rows selected.

In the following example, you list problem 3 only.

SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_problems(problem_id=>3);
PL/SQL procedure successfully completed.

To read the log file for problem 3, call rdsadmin.rds_file_util.read_text_file. Supply the task ID as part of the file name.

SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-'||:task_id||'.log'));

Diagnostic tasks
Creating incident packages

You can create incident packages using the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.create_adrci_package`. The output is a .zip file that you can supply to Oracle Support.

This function uses the following common parameters:

- `problem_id`
- `incident_id`

Make sure to specify one of the preceding parameters. If you specify both parameters, `incident_id` overrides `problem_id`. For more information, see Common parameters for diagnostic procedures.

To create a package for a specific incident, call the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.create_adrci_package` with the `incident_id` parameter. The following example creates a package for incident 53523.

```
SQL> EXEC :task_id :=
    rdsadmin.rdsadmin_adrci_util.create_adrci_package(incident_id=>53523);

PL/SQL procedure successfully completed.
```
To read the log file, call the `rdsadmin.rds_file_util.read_text_file`. You can supply the task ID as part of the file name. The output shows that you generated incident package `ORA700EVE_20200529212043_COM_1.zip`.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
   'dbtask-''||:task_id||''.log'));

TEXT
--------------------------------------------------------------------------------------------------------------------------------------
2020-05-29 21:20:43.031 UTC [INFO ] The ADRCI package is being created.
   ORA700EVE_20200529212043_COM_1.zip, mode complete
2020-05-29 21:20:47.642 UTC [INFO ] The ADRCI package was successfully created.
```

To package diagnostic data for a particular problem, specify its ID using the `problem_id` parameter. In the following example, you package data for problem 3 only.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.create_adrci_package(problem_id=>3);
PL/SQL procedure successfully completed.
```

To read the task output, call `rdsadmin.rds_file_util.read_text_file`, supplying the task ID as part of the file name. The output shows that you generated incident package `ORA700EVE_20200529212111_COM_1.zip`.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
   'dbtask-''||:task_id||''.log'));

TEXT
------------------------------------------------------------------------------------------------------------------------------------------------------------
   ORA700EVE_20200529212111_COM_1.zip, mode complete
2020-05-29 21:21:15.646 UTC [INFO ] The ADRCI package was successfully created.
```

You can also download the log file. For more information, see [Downloading a database log file](#).
Showing trace files

You can use the Amazon RDS function rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile to list trace files under the trace directory and all incident directories under the current ADR home. You can also show the contents of trace files and incident trace files.

This function uses the following parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename</td>
<td>varchar2</td>
<td>A valid trace file name</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, the function shows all trace files. If it isn't null, the function shows the specified file.</td>
</tr>
</tbody>
</table>

To show the trace file, call the Amazon RDS function rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile.

```sql
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile;
PL/SQL procedure successfully completed.
```

To list the trace file names, call the Amazon RDS procedure rdsadmin.rds_file_util.read_text_file, supplying the task ID as part of the file name.

```sql
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-'||:task_id||'.log')) WHERE TEXT LIKE '%/alert_%';
```

```
TEXT
---------------------------------------------------------------
diag/rdbms/orcl_a/ORCL/trace/alert.ORCL.log.2020-05-28
diag/rdbms/orcl_a/ORCL/trace/alert.ORCL.log.2020-05-27
diag/rdbms/orcl_a/ORCL/trace/alert.ORCL.log.2020-05-26
diag/rdbms/orcl_a/ORCL/trace/alert.ORCL.log.2020-05-25
diag/rdbms/orcl_a/ORCL/trace/alert.ORCL.log.2020-05-24
```
In the following example, you generate output for alert_ORCL.log.

```sql
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile('diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log');
PL/SQL procedure successfully completed.
```

To read the log file, call `rdsadmin.rds_file_util.read_text_file`. Supply the task ID as part of the file name. The output shows the first 10 lines of alert_ORCL.log.

```sql
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-'||:task_id||'.log')) WHERE ROWNUM <= 10;
```

You can also download the log file. For more information, see [Downloading a database log file](#).

### Performing miscellaneous tasks for Oracle DB instances

Following, you can find how to perform miscellaneous DBA tasks on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide
shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

Topics

• Creating and dropping directories in the main data storage space
• Listing files in a DB instance directory
• Reading files in a DB instance directory
• Accessing Opatch files
• Managing advisor tasks
• Transporting tablespaces

Creating and dropping directories in the main data storage space

To create directories, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.create_directory`. You can create up to 10,000 directories, all located in your main data storage space. To drop directories, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_directory`.

The `create_directory` and `drop_directory` procedures have the following required parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory.</td>
</tr>
</tbody>
</table>

The following example creates a new directory named PRODUCT_DESCRIPTIONS.

```sql
EXEC rdsadmin.rdsadmin_util.create_directory(p_directory_name => 'product_descriptions');
```

The data dictionary stores the directory name in uppercase. You can list the directories by querying `DBA_DIRECTORIES`. The system chooses the actual host pathname automatically. The following example gets the directory path for the directory named PRODUCT_DESCRIPTIONS:

```sql
SELECT DIRECTORY_PATH
```
The master user name for the DB instance has read and write privileges in the new directory, and can grant access to other users. EXECUTE privileges are not available for directories on a DB instance. Directories are created in your main data storage space and will consume space and I/O bandwidth.

The following example drops the directory named PRODUCT_DESCRIPTIONS.

```
EXEC rdsadmin.rdsadmin_util.drop_directory(p_directory_name => 'product_descriptions');
```

**Note**

You can also drop a directory by using the Oracle SQL command DROP DIRECTORY.

Dropping a directory doesn't remove its contents. Because the `rdsadmin.rdsadmin_util.create_directory` procedure can reuse pathnames, files in dropped directories can appear in a newly created directory. Before you drop a directory, we recommend that you use `UTL_FILE.FREMOVE` to remove files from the directory. For more information, see [FREMOVE procedure](#) in the Oracle documentation.

### Listing files in a DB instance directory

To list the files in a directory, use the Amazon RDS procedure `rdsadmin.rds_file_util.listdir`. The `listdir` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory to list.</td>
</tr>
</tbody>
</table>
The following example grants read/write privileges on the directory `PRODUCT_DESCRIPTIONS` to user `rdsadmin`, and then lists the files in this directory.

```
GRANT READ,WRITE ON DIRECTORY PRODUCT_DESCRIPTIONS TO rdsadmin;
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'PRODUCT_DESCRIPTIONS'));
```

### Reading files in a DB instance directory

To read a text file, use the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. The `read_text_file` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory that contains the file.</td>
</tr>
<tr>
<td>p_filename</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the file to read.</td>
</tr>
</tbody>
</table>

The following example creates the file `rice.txt` in the directory `PRODUCT_DESCRIPTIONS`.

```
declare
    fh sys.utl_file.file_type;
begin
    fh := utl_file.fopen(location=>'PRODUCT_DESCRIPTIONS', filename=>'rice.txt',
                  open_mode=>'w');
    utl_file.put(file=>fh, buffer=>'AnyCompany brown rice, 15 lbs');
    utl_file.fclose(file=>fh);
end;
/
```

The following example reads the file `rice.txt` from the directory `PRODUCT_DESCRIPTIONS`.

```
SELECT * FROM TABLE
    (rdsadmin.rds_file_util.read_text_file(
        p_directory => 'PRODUCT_DESCRIPTIONS',
    ));
```
Accessing Opatch files

Opatch is an Oracle utility that enables the application and rollback of patches to Oracle software. The Oracle mechanism for determining which patches have been applied to a database is the opatch lsinventory command. To open service requests for Bring Your Own Licence (BYOL) customers, Oracle Support requests the lsinventory file and sometimes the lsinventory_detail file generated by Opatch.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to Opatch. Instead, the lsinventory-\(dbv\).txt in the BDUMP directory contains the patch information related to your current engine version. When you perform a minor or major upgrade, Amazon RDS updates lsinventory-\(dbv\).txt within an hour of applying the patch. To verify the applied patches, read lsinventory-\(dbv\).txt. This action is similar to running the opatch lsinventory command.

**Note**

The examples in this section assume that the BDUMP directory is named BDUMP. On a read replica, the BDUMP directory name is different. To learn how to get the BDUMP name by querying V$DATABASE.DB_UNIQUE_NAME on a read replica, see [Listing files](#).

The inventory files use the Amazon RDS naming convention lsinventory-\(dbv\).txt and lsinventory_detail-\(dbv\).txt, where \(dbv\) is the full name of your DB version. The lsinventory-\(dbv\).txt file is available on all DB versions. The corresponding lsinventory_detail-\(dbv\).txt is available on the following DB versions:

- 19.0.0.0, ru-2020-01.rur-2020-01.r1 or later
- 12.2.0.1, ru-2020-01.rur-2020-01.r1 or later
- 12.1.0.2, v19 or later

For example, if your DB version is 19.0.0.0.ru-2021-07.rur-2021-07.r1, then your inventory files have the following names.

```bash
lsinventory-19.0.0.0.ru-2021-07.rur-2021-07.r1.txt
```
Ensure that you download the files that match the current version of your DB engine.

**Console**

**To download an inventory file using the console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. In the **Logs** section, search for `lsinventory`.
7. Select the file that you want to access, and then choose **Download**.

**SQL**

To read the `lsinventory-dbversion.txt` in a SQL client, you can use a `SELECT` statement. For this technique, use either of the following `rdsadmin` functions: `rdsadmin.rds_file_util.read_text_file` or `rdsadmin.tracefile_listing`.

In the following sample query, replace `dbversion` with your Oracle DB version. For example, your DB version might be 19.0.0.0.ru-2020-04.rur-2020-04.r1.

```
SELECT text
FROM   TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'lsinventory-dbversion.txt'));
```

**PL/SQL**

To read the `lsinventory-dbversion.txt` in a SQL client, you can write a PL/SQL program. This program uses `utl_file` to read the file, and `dbms_output` to print it. These are Oracle-supplied packages.

In the following sample program, replace `dbversion` with your Oracle DB version. For example, your DB version might be 19.0.0.0.ru-2020-04.rur-2020-04.r1.

```
SET SERVEROUTPUT ON
```
Or query rdsadmin.tracefile_listing, and spool the output to a file. The following example spools the output to /tmp/tracefile.txt.

```
SPOOL /tmp/tracefile.txt
SELECT *
FROM rdsadmin.tracefile_listing
WHERE FILENAME LIKE 'lsinventory%';
SPOOL OFF;
```

Managing advisor tasks

Oracle Database includes a number of advisors. Each advisor supports automated and manual tasks. You can use procedures in the rdsadmin.rdsadmin_util package to manage some advisor tasks.

The advisor task procedures are available in the following engine versions:

- Oracle Database 21c (21.0.0)
- Version 19.0.0.0.ru-2021-01.rur-2021-01.r1 and higher Oracle Database 19c versions

For more information, see Version 19.0.0.0.ru-2021-01.rur-2021-01.r1 in the Amazon RDS for Oracle Release Notes.
• Version 12.2.0.1.ru-2021-01.rur-2021-01.r1 and higher Oracle Database 12c (Release 2) 12.2.0.1 versions

For more information, see Version 12.2.0.1.ru-2021-01.rur-2021-01.r1 in the Amazon RDS for Oracle Release Notes.

Topics

• Setting parameters for advisor tasks
• Disabling AUTO_STATS_ADVISOR_TASK
• Re-enabling AUTO_STATS_ADVISOR_TASK

Setting parameters for advisor tasks

To set parameters for some advisor tasks, use the Amazon RDS procedure rdsadmin.rdsadmin_util.advisor_task_set_parameter. The advisor_task_set_parameter procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_task_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the advisor task whose parameters you want to change. The following values are valid:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• AUTO_STATS_ADVISOR_TASK</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• INDIVIDUAL_STATS_ADVISOR_TASK</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• SYS_AUTO_SPM_EVOLVE_TASK</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• SYS_AUTO_SQL_TUNING_TASK</td>
</tr>
<tr>
<td>p_parameter</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the task parameter. To find valid parameters for an advisor task, run the following query. Substitute p_task_name with a valid value for p_task_name:</td>
</tr>
</tbody>
</table>

COL PARAMETER_NAME FORMAT a30
COL PARAMETER_VALUE FORMAT a30

Other tasks
### Parameter Name  | Data Type  | Default | Required | Description
--- | --- | --- | --- | ---
p_value | varchar2 | — | Yes | The value for a task parameter. To find valid values for task parameters, run the following query. Substitute `p_task_name` with a valid value for `p_task_name`:

```sql
COL PARAMETER_NAME FORMAT a30
COL PARAMETER_VALUE FORMAT a30
SELECT PARAMETER_NAME, PARAMETER_VALUE
FROM DBA_ADVISOR_PARAMETERS
WHERE TASK_NAME='p_task_name'
AND PARAMETER_VALUE != 'UNUSED'
ORDER BY PARAMETER_NAME;
```

The following PL/SQL program sets ACCEPT_PLANS to FALSE for SYS_AUTO_SPM_EVOLVE_TASK. The SQL Plan Management automated task verifies the plans and generates a report of its findings, but does not evolve the plans automatically. You can use a report to identify new SQL plan baselines and accept them manually.

```sql
BEGIN
    rdsadmin.rdsadmin_util.advisor_task_set_parameter(
        p_task_name => 'SYS_AUTO_SPM_EVOLVE_TASK',
        p_parameter => 'ACCEPT_PLANS',
        p_value => 'FALSE');
END;
```

The following PL/SQL program sets EXECUTION_DAYS_TO_EXPIRE to 10 for AUTO_STATS_ADVISOR_TASK. The predefined task AUTO_STATS_ADVISOR_TASK runs...
automatically in the maintenance window once per day. The example sets the retention period for the task execution to 10 days.

```sql
BEGIN
    rdsadmin.rdsadmin_util.advisor_task_set_parameter(
        p_task_name => 'AUTO_STATS_ADVISOR_TASK',
        p_parameter => 'EXECUTION_DAYS_TO_EXPIRE',
        p_value     => '10');
END;
```

### Disabling AUTO_STATS_ADVISOR_TASK

To disable AUTO_STATS_ADVISOR_TASK, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.advisor_task_drop`. The `advisor_task_drop` procedure accepts the following parameter.

#### Note

This procedure is available in Oracle Database 12c Release 2 (12.2.0.1) and later.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_task_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the advisor task to be disabled. The only valid value is AUTO_STAT S_ADVISOR_TASK.</td>
</tr>
</tbody>
</table>

The following command drops AUTO_STATS_ADVISOR_TASK.

```sql
EXEC rdsadmin.rdsadmin_util.advisor_task_drop('AUTO_STATS_ADVISOR_TASK')
```

You can re-enable AUTO_STATS_ADVISOR_TASK using `rdsadmin.rdsadmin_util.dbms_stats_init`.
Re-enabling AUTO_STATS_ADVISOR_TASK

To re-enable AUTO_STATS_ADVISOR_TASK, use the Amazon RDS procedure rdsadmin.rdsadmin_util.dbms_stats_init. The dbms_stats_init procedure takes no parameters.

The following command re-enables AUTO_STATS_ADVISOR_TASK.

EXEC rdsadmin.rdsadmin_util.dbms_stats_init()

Transporting tablespaces

Use the Amazon RDS package rdsadmin.rdsadmin_transport_util to copy a set of tablespaces from an on-premises Oracle database to an RDS for Oracle DB instance. At the physical level, the transportable tablespace feature incrementally copies source data files and metadata files to your target instance. You can transfer the files using either Amazon EFS or Amazon S3. For more information, see Migrating using Oracle transportable tablespaces.

Topics

- Importing transported tablespaces to your DB instance
- Importing transportable tablespace metadata into your DB instance
- Listing orphaned files after a tablespace import
- Deleting orphaned data files after a tablespace import

Importing transported tablespaces to your DB instance

Use the procedure rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces to restore tablespaces that you have previously exported from a source DB instance. In the transport phase, you back up your read-only tablespaces, export Data Pump metadata, transfer these files to your target DB instance, and then import the tablespaces. For more information, see Phase 4: Transport the tablespaces.

Syntax

FUNCTION import_xtts_tablespaces(
    p_tablespace_list IN CLOB,
    p_directory_name  IN VARCHAR2,
    p_platform_id     IN NUMBER DEFAULT 13,
p_parallel        IN INTEGER DEFAULT 0) RETURN VARCHAR2;

Parameters

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tablespace_list</td>
<td>CLOB</td>
<td>—</td>
<td>Yes</td>
<td>The list of tablespaces to import.</td>
</tr>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>—</td>
<td>Yes</td>
<td>The directory that contains the tablespace backups.</td>
</tr>
<tr>
<td>p_platform_id</td>
<td>NUMBER</td>
<td>13</td>
<td>No</td>
<td>Provide a platform ID that matches the one specified during the backup phase. To find a list of platforms, query V$TRANSPORTABLE_PLATFORM. The default platform is Linux x86 64-bit, which is little endian.</td>
</tr>
<tr>
<td>p_parallel</td>
<td>INTEGER</td>
<td>0</td>
<td>No</td>
<td>The degree of parallelism. By default, parallelism is disabled.</td>
</tr>
</tbody>
</table>

Examples

The following example imports the tablespaces TBS1, TBS2, and TBS3 from the directory DATA_PUMP_DIR. The source platform is AIX-Based Systems (64-bit), which has the platform ID of 6. You can find the platform IDs by querying V$TRANSPORTABLE_PLATFORM.

VAR task_id CLOB
BEGIN
:task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces(
    'TBS1,TBS2,TBS3',
    'DATA_PUMP_DIR',
);
Importing transportable tablespace metadata into your DB instance

Use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_metadata` to import transportable tablespace metadata into your RDS for Oracle DB instance. During the operation, the status of the metadata import is shown in the table `rdsadmin.rds_xtts_operation_info`. For more information, see Step 5: Import tablespace metadata on your target DB instance.

Syntax

```sql
PROCEDURE import_xtts_metadata(
    p_datapump_metadata_file IN SYS.DBA_DATA_FILES.FILE_NAME%TYPE,
    p_directory_name         IN VARCHAR2,
    p_exclude_stats          IN BOOLEAN DEFAULT FALSE,
    p_remap_tablespace_list  IN CLOB DEFAULT NULL,
    p_remap_user_list        IN CLOB DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_datapump_metadata_file</td>
<td>SYS.DBA_DATA/files.FILE_NAME%TYPE</td>
<td>—</td>
<td>Yes</td>
<td>The name of the Oracle Data Pump file that contains the metadata for your transportable tablespaces.</td>
</tr>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>—</td>
<td>Yes</td>
<td>The directory that contains the Data Pump file.</td>
</tr>
<tr>
<td>p_exclude_stats</td>
<td>BOOLEAN</td>
<td>FALSE</td>
<td>No</td>
<td>Flag that indicates whether to exclude statistics.</td>
</tr>
<tr>
<td>p_remap_tablespace_list</td>
<td>CLOB</td>
<td>DEFAULT NULL</td>
<td></td>
<td></td>
</tr>
<tr>
<td>p_remap_user_list</td>
<td>CLOB</td>
<td>DEFAULT NULL</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------</td>
<td>---------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>p_remap_tablespace_list</code></td>
<td>CLOB</td>
<td>NULL</td>
<td>No</td>
<td>A list of tablespaces to be remapped during the metadata import. Use the format <code>from_tbs:to_tbs</code>. For example, specify <code>users:use_r_data</code>.</td>
</tr>
<tr>
<td><code>p_remap_user_list</code></td>
<td>CLOB</td>
<td>NULL</td>
<td>No</td>
<td>A list of user schemas to be remapped during the metadata import. Use the format <code>from_schema_name:to_schema_name</code>. For example, specify <code>hr:human_resources</code>.</td>
</tr>
</tbody>
</table>

**Examples**

The example imports the tablespace metadata from the file `xttdump.dmp`, which is located in directory `DATA_PUMP_DIR`.

```
BEGIN
  rdsadmin.rdsadmin_transport_util.import_xtts_metadata('xttdump.dmp','DATA_PUMP_DIR');
END;
/
```

**Listing orphaned files after a tablespace import**

Use the `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to list data files that were orphaned after a tablespace import.
import. After you identify the data files, you can delete them by calling
\texttt{rdsadmin.rdsadmin\_transport\_util.cleanup\_incomplete\_xtts\_import}.

### Syntax

\begin{verbatim}
FUNCTION list_xtts_orphan_files RETURN xtts_orphan_files_list_t PIPELINED;
\end{verbatim}

### Examples

The following example runs the procedure
\texttt{rdsadmin.rdsadmin\_transport\_util.list_xtts_orphan\_files}. The output shows two
data files that are orphaned.

\begin{verbatim}
SQL> SELECT * FROM TABLE(rdsadmin.rdsadmin\_transport\_util.list_xtts_orphan\_files);
FILENAME       FILESIZE
-------------- ---------
datafile\_7.dbf 104865792
datafile\_8.dbf 104865792
\end{verbatim}

### Deleting orphaned data files after a tablespace import

Use the \texttt{rdsadmin.rdsadmin\_transport\_util.list_xtts_orphan\_files} procedure to
delete data files that were orphaned after a tablespace import. Running this command generates
a log file that uses the name format \texttt{rds-xtts-delete_xtts_orphaned\_files-YYYY-MM-DD.HH24-MI-SS.FF}.log in the BDUMP directory. Use the procedure
\texttt{rdsadmin.rdsadmin\_transport\_util.cleanup\_incomplete\_xtts\_import}
to find the orphaned files. You can read the log file by calling the procedure
\texttt{rdsadmin.rds\_file\_util.read\_text\_file}. For more information, see \texttt{Phase 6: Clean up leftover files}.

### Syntax

\begin{verbatim}
PROCEDURE cleanup_incomplete_xtts_import(
p\_directory\_name IN VARCHAR2);
\end{verbatim}
**Parameters**

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>—</td>
<td>Yes</td>
<td>The directory that contains the orphaned data files.</td>
</tr>
</tbody>
</table>

**Examples**

The following example deletes the orphaned data files in *DATA_PUMP_DIR*.

```
BEGIN
  rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import('DATA_PUMP_DIR');
END;
/
```

The following example reads the log file generated by the previous command.

```
SELECT *
FROM TABLE(rdsadmin.rds_file_util.read_text_file(
  p_directory => 'BDUMP',
  p_filename  => 'rds-xtts-delete_xtts_orphaned_files-2023-06-01.09-33-11.868894000.log'));

TEXT
--------------------------------------------------------------------------------
orphan transported datafile datafile_7.dbf deleted.
orphan transported datafile datafile_8.dbf deleted.
```
Configuring advanced RDS for Oracle features

RDS for Oracle supports various advanced features, including HugePages, an instance store, and extended data types.

Topics

• Storing temporary data in an RDS for Oracle instance store
• Turning on HugePages for an RDS for Oracle instance
• Turning on extended data types in RDS for Oracle

Storing temporary data in an RDS for Oracle instance store

Use an instance store for the temporary tablespaces and the Database Smart Flash Cache (the flash cache) on supported RDS for Oracle DB instance classes.

Topics

• Overview of the RDS for Oracle instance store
• Turning on an RDS for Oracle instance store
• Configuring an RDS for Oracle instance store
• Considerations when changing the DB instance type
• Working with an instance store on an Oracle read replica
• Configuring a temporary tablespace group on an instance store and Amazon EBS
• Removing an RDS for Oracle instance store

Overview of the RDS for Oracle instance store

An instance store provides temporary block-level storage for an RDS for Oracle DB instance. You can use an instance store for temporary storage of information that changes frequently.

An instance store is based on Non-Volatile Memory Express (NVMe) devices that are physically attached to the host computer. The storage is optimized for low latency, random I/O performance, and sequential read throughput.

The size of the instance store varies by DB instance type. For more information about the instance store, see Amazon EC2 instance store in the Amazon Elastic Compute Cloud User Guide for Linux Instances.
Types of data in the RDS for Oracle instance store

You can place the following types of RDS for Oracle temporary data in an instance store:

A temporary tablespace

Oracle Database uses temporary tablespaces to store intermediate query results that don't fit in memory. Larger queries can generate large amounts of intermediate data that needs to be cached temporarily, but doesn't need to persist. In particular, a temporary tablespace is useful for sorts, hash aggregations, and joins. If your RDS for Oracle DB instance uses the Enterprise Edition or Standard Edition 2, you can place a temporary tablespace in an instance store.

The flash cache

The flash cache improves the performance of single-block random reads in the conventional path. A best practice is to size the cache to accommodate most of your active data set. If your RDS for Oracle DB instance uses the Enterprise Edition, you can place the flash cache in an instance store.

By default, an instance store is configured for a temporary tablespace but not for the flash cache. You can't place Oracle data files and database log files in an instance store.

Benefits of the RDS for Oracle instance store

You might consider using an instance store to store temporary files and caches that you can afford to lose. If you want to improve DB performance, or if an increasing workload is causing performance problems for your Amazon EBS storage, consider scaling to an instance class that supports an instance store.

By placing your temporary tablespace and flash cache on an instance store, you get the following benefits:
- Lower read latencies
- Higher throughput
- Reduced load on your Amazon EBS volumes
- Lower storage and snapshot costs because of reduced Amazon EBS load
- Less need to provision high IOPS, possibly lowering your overall cost

By placing your temporary tablespace on the instance store, you deliver an immediate performance boost to queries that use temporary space. When you place the flash cache on the instance store, cached block reads typically have much lower latency than Amazon EBS reads. The flash cache needs to be "warmed up" before it delivers performance benefits. The cache warms up by itself because the database writes blocks to the flash cache as they age out of the database buffer cache.

**Note**

In some cases, the flash cache causes performance overhead because of cache management. Before you turn on the flash cache in a production environment, we recommend that you analyze your workload and test the cache in a test environment.

**Supported instance classes for the RDS for Oracle instance store**

Amazon RDS supports the instance store for the following DB instance classes:

- db.m5d
- db.r5d
- db.x2idn
- db.x2iedn

RDS for Oracle supports the preceding DB instance classes for the BYOL licensing model only. For more information, see [Supported RDS for Oracle instance classes](#) and [Bring Your Own License (BYOL)](#).

To see the total instance storage for the supported DB instance types, run the following command in the AWS CLI.
Example

```bash
aws ec2 describe-instance-types \
   --filters "Name=instance-type,Values=*5d.*large*" \
   --query "InstanceTypes[?contains(InstanceType,'m5d')]|contains(InstanceType,'r5d')][InstanceType, InstanceStorageInfo.TotalSizeInGB]" \
   --output table
```

The preceding command returns the raw device size for the instance store. RDS for Oracle uses a small portion of this space for configuration. The space in the instance store that is available for temporary tablespaces or the flash cache is slightly smaller.

Supported engine versions for the RDS for Oracle instance store

The instance store is supported for the following RDS for Oracle engine versions:

- 21.0.0.0.ru-2022-01.rur-2022-01.r1 or higher Oracle Database 21c versions
- 19.0.0.0.ru-2021-10.rur-2021-10.r1 or higher Oracle Database 19c versions

Supported AWS Regions for the RDS for Oracle instance store

The instance store is available in all AWS Regions where one or more of these instance types are supported. For more information on the `db.m5d` and `db.r5d` instance classes, see DB instance classes. For more information on the instance classes supported by Amazon RDS for Oracle, see RDS for Oracle instance classes.

Cost of the RDS for Oracle instance store

The cost of the instance store is built into the cost of the instance-store turned on instances. You don't incur additional costs by enabling an instance store on an RDS for Oracle DB instance. For more information about instance-store turned on instances, see Supported instance classes for the RDS for Oracle instance store.

Turning on an RDS for Oracle instance store

To turn on the instance store for RDS for Oracle temporary data, do one of the following:

- Create an RDS for Oracle DB instance using a supported instance class. For more information, see Creating an Amazon RDS DB instance.
• Modify an existing RDS for Oracle DB instance to use a supported instance class. For more information, see Modifying an Amazon RDS DB instance.

Configuring an RDS for Oracle instance store

By default, 100% of instance store space is allocated to the temporary tablespace. To configure the instance store to allocate space to the flash cache and temporary tablespace, set the following parameters in the parameter group for your instance:

**db_flash_cache_size={DBInstanceStore*{0,2,4,6,8,10}/10}**

This parameter specifies the amount of storage space allocated for the flash cache. This parameter is valid only for Oracle Database Enterprise Edition. The default value is {DBInstanceStore*0/10}. If you set a nonzero value for db_flash_cache_size, your RDS for Oracle instance enables the flash cache after you restart the instance.

**rds.instance_store_temp_size={DBInstanceStore*{0,2,4,6,8,10}/10}**

This parameter specifies the amount of storage space allocated for the temporary tablespace. The default value is {DBInstanceStore*10/10}. This parameter is modifiable for Oracle Database Enterprise Edition and read-only for Standard Edition 2. If you set a nonzero value for rds.instance_store_temp_size, Amazon RDS allocates space in the instance store for the temporary tablespace.

You can set the db_flash_cache_size and rds.instance_store_temp_size parameters for DB instances that don't use an instance store. In this case, both settings evaluate to 0, which turns off the feature. In this case, you can use the same parameter group for different instance sizes and for instances that don't use an instance store. If you modify these parameters, make sure to reboot the associated instances so that the changes can take effect.

**Important**

If you allocate space for a temporary tablespace, Amazon RDS doesn't create the temporary tablespace automatically. To learn how to create the temporary tablespace on the instance store, see Creating a temporary tablespace on the instance store.

The combined value of the preceding parameters must not exceed 10/10, or 100%. The following table illustrates valid and invalid parameter settings.
<table>
<thead>
<tr>
<th>db_flash_cache_size setting</th>
<th>rds.instance_store_temp_size setting</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>db flash_cache_size={DBInstanceStore*0/10}</td>
<td>rds.instance_store_temp_size={DBInstanceStore*10/10}</td>
<td>This is a valid configuration for all editions of Oracle Database. Amazon RDS allocates 100% of instance store space to the temporary tablespace. This is the default.</td>
</tr>
<tr>
<td>db_flash_cache_size={DBInstanceStore*10/10}</td>
<td>rds.instance_store_temp_size={DBInstanceStore*0/10}</td>
<td>This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 100% of instance store space to the flash cache.</td>
</tr>
<tr>
<td>db_flash_cache_size={DBInstanceStore*2/10}</td>
<td>rds.instance_store_temp_size={DBInstanceStore*8/10}</td>
<td>This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 20% of instance store space to</td>
</tr>
</tbody>
</table>

Configuring the instance store
<table>
<thead>
<tr>
<th>db_flash_cache_size setting</th>
<th>rds.instance_store_temp_size setting</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db_flash_cache_size={DBInstanceStore*6/10}</code></td>
<td><code>rds.instance_store_temp_size={DBInstanceStore*4/10}</code></td>
<td>the flash cache, and 80% of instance store space to the temporary tablespace. This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 60% of instance store space to the flash cache, and 40% of instance store space to the temporary tablespace.</td>
</tr>
<tr>

<td>db_flash_cache_size={DBInstanceStore*2/10}</td>
<td>rds.instance_store_temp_size={DBInstanceStore*4/10}</td>
<td>This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 20% of instance store space to the flash cache, and 40% of instance store space to the temporary tablespace.</td>
</tr>
<tr>
<td>db_flash_cache_size={DBInstanceStore*8/10}</td>
<td>rds.instance_store_temp_size={DBInstanceStore*8/10}</td>
<td>This is an invalid configuration because the combined percentage of instance store space exceeds 100%. In such cases, Amazon RDS fails the attempt.</td>
</tr>
</tbody>
</table>

**Considerations when changing the DB instance type**

If you change your DB instance type, it can affect the configuration of the flash cache or the temporary tablespace on the instance store. Consider the following modifications and their effects:
You scale up or scale down the DB instance that supports the instance store.

The following values increase or decrease proportionally to the new size of the instance store:

- The new size of the flash cache.
- The space allocated to the temporary tablespaces that reside in the instance store.

For example, the setting `db_flash_cache_size={DBInstanceStore*6/10}` on a `db.m5d.4xlarge` instance provides around 340 GB of flash cache space. If you scale up the instance type to `db.m5d.8xlarge`, the flash cache space increases to around 680 GB.

You modify a DB instance that doesn't use an instance store to an instance that does use an instance store.

If `db_flash_cache_size` is set to a value larger than 0, the flash cache is configured. If `rds.instance_store_temp_size` is set to a value larger than 0, the instance store space is allocated for use by a temporary tablespace. RDS for Oracle doesn't move tempfiles to the instance store automatically. For information about using the allocated space, see Creating a temporary tablespace on the instance store or Adding a tempfile to the instance store on a read replica.

You modify a DB instance that uses an instance store to an instance that doesn't use an instance store.

In this case, RDS for Oracle removes the flash cache. RDS re-creates the tempfile that is currently located on the instance store on an Amazon EBS volume. The maximum size of the new tempfile is the former size of the `rds.instance_store_temp_size` parameter.

Working with an instance store on an Oracle read replica

Read replicas support the flash cache and temporary tablespaces on an instance store. While the flash cache works the same way as on the primary DB instance, note the following differences for temporary tablespaces:

- You can't create a temporary tablespace on a read replica. If you create a new temporary tablespace on the primary instance, RDS for Oracle replicates the tablespace information without tempfiles. To add a new tempfile, use either of the following techniques:
  - Use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_inst_store_tempfile`. RDS for Oracle creates a tempfile in the instance store on your read replica, and adds it to the specified temporary tablespace.
• Run the ALTER TABLESPACE ... ADD TEMPFILE command. RDS for Oracle places the tempfile on Amazon EBS storage.

**Note**

The tempfile sizes and storage types can be different on the primary DB instance and the read replica.

• You can manage the default temporary tablespace setting only on the primary DB instance. RDS for Oracle replicates the setting to all read replicas.

• You can configure the temporary tablespace groups only on the primary DB instance. RDS for Oracle replicates the setting to all read replicas.

### Configuring a temporary tablespace group on an instance store and Amazon EBS

You can configure a temporary tablespace group to include temporary tablespaces on both an instance store and Amazon EBS. This technique is useful when you want more temporary storage than is allowed by the maximum setting of `rds.instance_store_temp_size`.

When you configure a temporary tablespace group on both an instance store and Amazon EBS, the two tablespaces have significantly different performance characteristics. Oracle Database chooses the tablespace to serve queries based on an internal algorithm. Therefore, similar queries can vary in performance.

Typically, you create a temporary tablespace in the instance store as follows:

1. Create a temporary tablespace in the instance store.
2. Set the new tablespace as the database default temporary tablespace.

If the tablespace size in the instance store is insufficient, you can create additional temporary storage as follows:

1. Assign the temporary tablespace in the instance store to a temporary tablespace group.
2. Create a new temporary tablespace in Amazon EBS if one doesn't exist.
3. Assign the temporary tablespace in Amazon EBS to the same tablespace group that includes the instance store tablespace.
4. Set the tablespace group as the default temporary tablespace.
The following example assumes that the size of the temporary tablespace in the instance store doesn't meet your application requirements. The example creates the temporary tablespace `temp_in_inst_store` in the instance store, assigns it to tablespace group `temp_group`, adds the existing Amazon EBS tablespace named `temp_in_ebs` to this group, and sets this group as the default temporary tablespace.

```sql
SQL> EXEC rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace('temp_in_inst_store');
PL/SQL procedure successfully completed.

SQL> ALTER TABLESPACE temp_in_inst_store TABLESPACE GROUP temp_group;
Tablespace altered.

SQL> ALTER TABLESPACE temp_in_ebs TABLESPACE GROUP temp_group;
Tablespace altered.

SQL> EXEC rdsadmin.rdsadmin_util.alter_default_temp_tablespace('temp_group');
PL/SQL procedure successfully completed.

SQL> SELECT * FROM DBA_TABLESPACE_GROUPS;
GROUP_NAME                     TABLESPACE_NAME
------------------------------ ------------------------------
TEMP_GROUP                     TEMP_IN_EBS
TEMP_GROUP                     TEMP_IN_INST_STORE

SQL> SELECT PROPERTY_VALUE FROM DATABASE_PROPERTIES WHERE
   PROPERTY_NAME='DEFAULT_TEMP_TABLESPACE';
PROPERTY_VALUE
--------------
TEMP_GROUP
```

**Removing an RDS for Oracle instance store**

To remove the instance store, modify your RDS for Oracle DB instance to use an instance type that doesn't support instance store, such as db.m5 or db.r5.
Turning on HugePages for an RDS for Oracle instance

Amazon RDS for Oracle supports Linux kernel HugePages for increased database scalability. HugePages results in smaller page tables and less CPU time spent on memory management, increasing the performance of large database instances. For more information, see Overview of HugePages in the Oracle documentation.

You can use HugePages with all supported versions and editions of RDS for Oracle.

The use_large_pages parameter controls whether HugePages are turned on for a DB instance. The possible settings for this parameter are ONLY, FALSE, and {DBInstanceClassHugePagesDefault}. The use_large_pages parameter is set to {DBInstanceClassHugePagesDefault} in the default DB parameter group for Oracle.

To control whether HugePages are turned on for a DB instance automatically, you can use the DBInstanceClassHugePagesDefault formula variable in parameter groups. The value is determined as follows:

- For the DB instance classes mentioned in the table following, DBInstanceClassHugePagesDefault always evaluates to FALSE by default, and use_large_pages evaluates to FALSE. You can turn on HugePages manually for these DB instance classes if the DB instance class has at least 14 GiB of memory.

- For DB instance classes not mentioned in the table following, if the DB instance class has less than 14 GiB of memory, DBInstanceClassHugePagesDefault always evaluates to FALSE. Also, use_large_pages evaluates to FALSE.

- For DB instance classes not mentioned in the table following, if the instance class has at least 14 GiB of memory and less than 100 GiB of memory, DBInstanceClassHugePagesDefault evaluates to TRUE by default. Also, use_large_pages evaluates to ONLY. You can turn off HugePages manually by setting use_large_pages to FALSE.

- For DB instance classes not mentioned in the table following, if the instance class has at least 100 GiB of memory, DBInstanceClassHugePagesDefault always evaluates to TRUE. Also, use_large_pages evaluates to ONLY and HugePages can't be disabled.

HugePages are not turned on by default for the following DB instance classes.
To turn on HugePages for new or existing DB instances manually, set the `use_large_pages` parameter to `ONLY`. You can't use HugePages with Oracle Automatic Memory Management (AMM). If you set the parameter `use_large_pages` to `ONLY`, then you must also set both `memory_target` and `memory_max_target` to 0. For more information about setting DB parameters for your DB instance, see Working with parameter groups.

You can also set the `sga_target`, `sga_max_size`, and `pga_aggregate_target` parameters. When you set system global area (SGA) and program global area (PGA) memory parameters, add the values together. Subtract this total from your available instance memory (`DBInstanceClassMemory`) to determine the free memory beyond the HugePages allocation. You must leave free memory of at least 2 GiB, or 10 percent of the total available instance memory, whichever is smaller.

After you configure your parameters, you must reboot your DB instance for the changes to take effect. For more information, see Rebooting a DB instance.

**Note**

The Oracle DB instance defers changes to SGA-related initialization parameters until you reboot the instance without failover. In the Amazon RDS console, choose Reboot but do not choose Reboot with failover. In the AWS CLI, call the `reboot-db-instance` command with the `--no-force-failover` parameter. The DB instance does not process the SGA-related parameters during failover or during other maintenance operations that cause the instance to restart.

<table>
<thead>
<tr>
<th>DB instance class family</th>
<th>DB instance classes with HugePages not turned on by default</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.m5</td>
<td>db.m5.large</td>
</tr>
<tr>
<td>db.m4</td>
<td>db.m4.large, db.m4.xlarge, db.m4.2xlarge, db.m4.4xlarge, db.m4.10xlarge</td>
</tr>
<tr>
<td>db.t3</td>
<td>db.t3.micro, db.t3.small, db.t3.medium, db.t3.large</td>
</tr>
</tbody>
</table>

For more information about DB instance classes, see Hardware specifications for DB instance classes.
The following is a sample parameter configuration for HugePages that enables HugePages manually. You should set the values to meet your needs.

```
memory_target            = 0
memory_max_target        = 0
pga_aggregate_target     = {DBInstanceClassMemory*1/8}
sga_target               = {DBInstanceClassMemory*3/4}
sga_max_size             = {DBInstanceClassMemory*3/4}
use_large_pages          = ONLY
```

Assume the following parameters values are set in a parameter group.

```
memory_target            = IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})
memory_max_target        = IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})
pga_aggregate_target     = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*1/8}, 0)
sga_target               = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*3/4}, 0)
sga_max_size             = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*3/4}, 0)
use_large_pages          = {DBInstanceClassHugePagesDefault}
```

The parameter group is used by a db.r4 DB instance class with less than 100 GiB of memory. With these parameter settings and `use_large_pages` set to `{DBInstanceClassHugePagesDefault}`, HugePages are turned on for the db.r4 instance.

Consider another example with following parameters values set in a parameter group.

```
memory_target            = IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})
memory_max_target        = IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})
pga_aggregate_target     = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*1/8}, 0)
sga_target               = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*3/4}, 0)
sga_max_size             = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*3/4}, 0)
use_large_pages          = FALSE
```
The parameter group is used by a db.r4 DB instance class and a db.r5 DB instance class, both with less than 100 GiB of memory. With these parameter settings, HugePages are turned off on the db.r4 and db.r5 instance.

**Note**

If this parameter group is used by a db.r4 DB instance class or db.r5 DB instance class with at least 100 GiB of memory, the FALSE setting for use_large_pages is overridden and set to ONLY. In this case, a customer notification regarding the override is sent.

After HugePages are active on your DB instance, you can view HugePages information by enabling enhanced monitoring. For more information, see [Monitoring OS metrics with Enhanced Monitoring](#).

**Turning on extended data types in RDS for Oracle**

Amazon RDS for Oracle supports extended data types. With extended data types, the maximum size is 32,767 bytes for the VARCHAR2, NVARCHAR2, and RAW data types. To use extended data types, set the MAX_STRING_SIZE parameter to EXTENDED. For more information, see [Extended data types](#) in the Oracle documentation.

If you don't want to use extended data types, keep the MAX_STRING_SIZE parameter set to STANDARD (the default). In this case, the size limits are 4,000 bytes for the VARCHAR2 and NVARCHAR2 data types, and 2,000 bytes for the RAW data type.

You can turn on extended data types on a new or existing DB instance. For new DB instances, DB instance creation time is typically longer when you turn on extended data types. For existing DB instances, the DB instance is unavailable during the conversion process.

**Considerations for extended data types**

Consider the following when you enable extended data types for your DB instance:

- When you turn on extended data types, you can't change the DB instance back to use the standard size for data types. After a DB instance is converted to use extended data types, if you set the MAX_STRING_SIZE parameter back to STANDARD it results in the incompatible-parameters status.
• When you restore a DB instance that uses extended data types, you must specify a parameter group with the MAX_STRING_SIZE parameter set to EXTENDED. During restore, if you specify the default parameter group or any other parameter group with MAX_STRING_SIZE set to STANDARD it results in the incompatible-parameters status.

• When the DB instance status is incompatible-parameters because of the MAX_STRING_SIZE setting, the DB instance remains unavailable until you set the MAX_STRING_SIZE parameter to EXTENDED and reboot the DB instance.

• We recommend that you don't turn on extended data types for Oracle DB instances running on the t2.micro DB instance class.

### Turning on extended data types for a new DB instance

#### To turn on extended data types for a new DB instance

1. Set the MAX_STRING_SIZE parameter to EXTENDED in a parameter group.

   To set the parameter, you can either create a new parameter group or modify an existing parameter group.

   For more information, see [Working with parameter groups](#).

2. Create a new RDS for Oracle DB instance.

   For more information, see [Creating an Amazon RDS DB instance](#).

3. Associate the parameter group with MAX_STRING_SIZE set to EXTENDED with the DB instance.

   For more information, see [Creating an Amazon RDS DB instance](#).

### Turning on extended data types for an existing DB instance

When you modify a DB instance to turn on extended data types, RDS converts the data in the database to use the extended sizes. The conversion and downtime occur when you next reboot the database after the parameter change. The DB instance is unavailable during the conversion.

The amount of time it takes to convert the data depends on the DB instance class, the database size, and the time of the last DB snapshot. To reduce downtime, consider taking a snapshot immediately before rebooting. This shortens the time of the backup that occurs during the conversion workflow.
After you turn on extended data types, you can't perform a point-in-time restore to a time during the conversion. You can restore to the time immediately before the conversion or after the conversion.

**To turn on extended data types for an existing DB instance**

1. Take a snapshot of the database.

   If there are invalid objects in the database, Amazon RDS tries to recompile them. The conversion to extended data types can fail if Amazon RDS can't recompile an invalid object. The snapshot enables you to restore the database if there is a problem with the conversion. Always check for invalid objects before conversion and fix or drop those invalid objects. For production databases, we recommend testing the conversion process on a copy of your DB instance first.

   For more information, see [Creating a DB snapshot for a Single-AZ DB instance](#).

2. Set the `MAX_STRING_SIZE` parameter to `EXTENDED` in a parameter group.

   To set the parameter, you can either create a new parameter group or modify an existing parameter group.

   For more information, see [Working with parameter groups](#).

3. Modify the DB instance to associate it with the parameter group with `MAX_STRING_SIZE` set to `EXTENDED`.

   For more information, see [Modifying an Amazon RDS DB instance](#).

4. Reboot the DB instance for the parameter change to take effect.

   For more information, see [Rebooting a DB instance](#).
Importing data into Oracle on Amazon RDS

How you import data into an Amazon RDS for Oracle DB instance depends on the following:

- The amount of data you have
- The number of database objects in your database
- The variety of database objects in your database

For example, you can use the following tools, depending on your requirements:

- **Oracle SQL Developer** – Import a simple, 20 MB database.
- **Oracle Data Pump** – Import complex databases, or databases that are several hundred megabytes or several terabytes in size. For example, you can transport tablespaces from an on-premises database to your RDS for Oracle DB instance. You can use Amazon S3 or Amazon EFS to transfer the data files and metadata. For more information, see [Migrating using Oracle transportable tablespaces](https://aws.amazon.com/documentation/rds/), [Amazon EFS integration](https://aws.amazon.com/documentation/efs/), and [Amazon S3 integration](https://aws.amazon.com/documentation/s3/).

**Important**

Before you use the preceding migration techniques, we recommend that you back up your database. After you import the data, you can back up your RDS for Oracle DB instances by creating snapshots. Later, you can restore the snapshots. For more information, see [Backing up, restoring, and exporting data](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_Migrate.html).

For many database engines, ongoing replication can continue until you are ready to switch over to the target database. You can use AWS DMS to migrate to RDS for Oracle from either the same database engine or a different engine. If you migrate from a different database engine, you can use the AWS Schema Conversion Tool to migrate schema objects that AWS DMS doesn't migrate.

**Topics**

- **Importing using Oracle SQL Developer**
- **Migrating using Oracle transportable tablespaces**
Importing using Oracle SQL Developer

Oracle SQL Developer is a graphical Java tool distributed without cost by Oracle. SQL Developer provides options for migrating data between two Oracle databases, or for migrating data from other databases, such as MySQL, to an Oracle database. This tool is best for migrating small databases.

You can install this tool on your desktop computer (Windows, Linux, or Mac) or on one of your servers. After you install SQL Developer, you can use it to connect to your source and target databases. Use the Database Copy command on the Tools menu to copy your data to your RDS for Oracle DB instance.

We recommend that you read the Oracle SQL Developer product documentation before you begin migrating your data. Oracle also has documentation on how to migrate from other databases, including MySQL and SQL Server. For more information, see http://www.oracle.com/technetwork/database/migration in the Oracle documentation.

Migrating using Oracle transportable tablespaces

You can use the Oracle transportable tablespaces feature to copy a set of tablespaces from an on-premises Oracle database to an RDS for Oracle DB instance. At the physical level, you transfer source data files and metadata files to your target DB instance using either Amazon EFS or Amazon S3. The transportable tablespaces feature uses the rdsadmin.rdsadmin_transport_util package. For syntax and semantics of this package, see Transporting tablespaces.

For blog posts that explain how to transport tablespaces, see Migrate Oracle Databases to AWS using transportable tablespace and Amazon RDS for Oracle Transportable Tablespaces using RMAN.

Topics
Overview of Oracle transportable tablespaces

A transportable tablespace set consists of data files for the set of tablespaces being transported and an export dump file containing tablespace metadata. In a physical migration solution such as transportable tablespaces, you transfer physical files: data files, configuration files, and Data Pump dump files.

Topics

- Advantages and disadvantages of transportable tablespaces
- Limitations for transportable tablespaces
- Prerequisites for transportable tablespaces

Advantages and disadvantages of transportable tablespaces

We recommend that you use transportable tablespaces when you need to migrate one or more large tablespaces to RDS with minimum downtime. Transportable tablespaces offer the following advantages over logical migration:

- Downtime is lower than most other Oracle migration solutions.
- Because the transportable tablespace feature copies only physical files, it avoids the data integrity errors and logical corruption that can occur in logical migration.
- No additional license is required.
- You can migrate a set of tablespaces across different platforms and endianness types, for example, from an Oracle Solaris platform to Linux. However, transporting tablespaces to and from Windows servers isn't supported.
If you use transportable tablespaces, you can transport data using either Amazon S3 or Amazon EFS:

- When you use EFS, your backups remain in the EFS file system for the duration of the import. You can remove the files afterward. In this technique, you don't need to provision EBS storage for your DB instance. For this reason, we recommend using Amazon EFS instead of S3. For more information, see Amazon EFS integration.

- When you use S3, you download RMAN backups to EBS storage attached to your DB instance. The files remain in your EBS storage during the import. After the import, you can free up this space, which remains allocated to your DB instance.

The primary disadvantage of transportable tablespaces is that you need relatively advanced knowledge of Oracle Database. For more information, see Transporting Tablespaces Between Databases in the Oracle Database Administrator’s Guide.

**Limitations for transportable tablespace**

Oracle Database limitations for transportable tablespaces apply when you use this feature in RDS for Oracle. For more information, see Limitations on Transportable Tablespaces and General Limitations on Transporting Data in the Oracle Database Administrator’s Guide. Note the following additional limitations for transportable tablespaces in RDS for Oracle:

- Neither the source or target database can use Standard Edition 2 (SE2). Only Enterprise Edition is supported.

- You can't use an Oracle Database 11g database as a source. The RMAN cross-platform transportable tablespaces feature relies on the RMAN transport mechanism, which Oracle Database 11g doesn't support.

- You can't migrate data from an RDS for Oracle DB instance using transportable table spaces. You can only use transportable tablespaces to migrate data to an RDS for Oracle DB instance.

- The Windows operating system isn't supported.
• You can't transport tablespaces into a database at a lower release level. The target database must be at the same or later release level as the source database. For example, you can't transport tablespaces from Oracle Database 21c into Oracle Database 19c.

• You can't transport administrative tablespaces such as SYSTEM and SYSAUX.

• You can't transport non-data objects such as PL/SQL packages, Java classes, views, triggers, sequences, users, roles, and temporary tables. To transport non-data objects, create them manually or use Data Pump metadata export and import. For more information, see My Oracle Support Note 1454872.1.

• You can't transport tablespaces that are encrypted or use encrypted columns.

• If you transfer files using Amazon S3, the maximum supported file size is 5 TiB.

• If the source database uses Oracle options such as Spatial, you can't transport tablespaces unless the same options are configured on the target database.

• You can't transport tablespaces into an RDS for Oracle DB instance in an Oracle replica configuration. As a workaround, you can delete all replicas, transport the tablespaces, and then recreate the replicas.

Prerequisites for transportable tablespaces

Before you begin, complete the following tasks:

• Review the requirements for transportable tablespaces described in the following documents in My Oracle Support:

  • Reduce Transportable Tablespace Downtime using Cross Platform Incremental Backup (Doc ID 2471245.1)
  • Transportable Tablespace (TTS) Restrictions and Limitations: Details, Reference, and Version Where Applicable (Doc ID 1454872.1)
  • Primary Note for Transportable Tablespaces (TTS) -- Common Questions and Issues (Doc ID 1166564.1)

• Plan for endianness conversion. If you specify the source platform ID, RDS for Oracle converts the endianness automatically. To learn how to find platform IDs, see Data Guard Support for Heterogeneous Primary and Physical Standbys in Same Data Guard Configuration (Doc ID 413484.1).

• Make sure that the transportable tablespace feature is enabled on your target DB instance. The feature is enabled only if you don't get an ORA-20304 error when you run the following query:
If the transportable tablespace feature isn't enabled, reboot your DB instance. For more information, see Rebooting a DB instance.

- If you plan to transfer files using Amazon S3, do the following:
  - Make sure that an Amazon S3 bucket is available for file transfers, and that the Amazon S3 bucket is in the same AWS Region as your DB instance. For instructions, see Create a bucket in the Amazon Simple Storage Service Getting Started Guide.
  - Prepare the Amazon S3 bucket for Amazon RDS integration by following the instructions in Configuring IAM permissions for RDS for Oracle integration with Amazon S3.
- If you plan to transfer files using Amazon EFS, make sure that you have configured EFS according to the instructions in Amazon EFS integration.
- We strongly recommend that you turn on automatic backups in your target DB instance. Because the metadata import step can potentially fail, it's important to be able to restore your DB instance to its state before the import, thereby avoiding the necessity to back up, transfer, and import your tablespaces again.

**Phase 1: Set up your source host**

In this step, you copy the transport tablespaces scripts provided by My Oracle Support and set up necessary configuration files. In the following steps, the source host is running the database that contains the tablespaces to be transported to your target instance.

**To set up your source host**

1. Log in to your source host as the owner of your Oracle home.
2. Make sure that your ORACLE_HOME and ORACLE_SID environment variables point to your source database.
3. Log in to your database as an administrator, and verify that the time zone version, DB character set, and national character set are the same as in your target database.
4. Set up the transportable tablespace utility as described in Oracle Support note 2471245.1.
The setup includes editing the `xtt.properties` file on your source host. The following sample `xtt.properties` file specifies backups of three tablespaces in the `/dsk1/backups` directory. These are the tablespaces that you intend to transport to your target DB instance. It also specifies the source platform ID to convert the endianness automatically.

```properties
#linux system
platformid=13
#list of tablespaces to transport
tablesps=TBS1,TBS2,TBS3
#location where backup will be generated
src_scratch_location=/dsk1/backups
#RMAN command for performing backup
rmantransport=1
```

### Phase 2: Prepare the full tablespace backup

In this phase, you back up your tablespaces for the first time, transfer the backups to your target host, and then restore them using the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`. When this phase is complete, the initial tablespace backups reside on your target DB instance and can be updated with incremental backups.

**Topics**

- **Step 1:** Back up the tablespaces on your source host
- **Step 2:** Transfer the backup files to your target DB instance
- **Step 3:** Import the tablespaces on your target DB instance
Step 1: Back up the tablespaces on your source host

In this step, you use the `xttdriver.pl` script to make a full backup of your tablespaces. The output of `xttdriver.pl` is stored in the TMPDIR environment variable.

To back up your tablespaces

1. If your tablespaces are in read-only mode, log in to your source database as a user with the ALTER TABLESPACE privilege, and place your tablespaces in read/write mode. Otherwise, skip to the next step.

   The following example places `tbs1`, `tbs2`, and `tbs3` in read/write mode.

   ```sql
   ALTER TABLESPACE tbs1 READ WRITE;
   ALTER TABLESPACE tbs2 READ WRITE;
   ALTER TABLESPACE tbs3 READ WRITE;
   ```

2. Back up your tablespaces using the `xttdriver.pl` script. Optionally, you can specify `--debug` to run the script in debug mode.

   ```sh
   export TMPDIR=location_of_log_files
   cd location_of_xttdriver.pl
   $ORACLE_HOME/perl/bin/perl xttdriver.pl --backup
   ```

Step 2: Transfer the backup files to your target DB instance

In this step, copy the backup and configuration files from your scratch location to your target DB instance. Choose one of the following options:

- If the source and target hosts share an Amazon EFS file system, use an operating system utility such as `cp` to copy your backup files and the `res.txt` file from your scratch location to a shared directory. Then skip to Step 3: Import the tablespaces on your target DB instance.

- If you need to stage your backups to an Amazon S3 bucket, complete the following steps.
Step 2.2: Upload the backups to your Amazon S3 bucket

Upload your backups and the res.txt file from your scratch directory to your Amazon S3 bucket. For more information, see Uploading objects in the Amazon Simple Storage Service User Guide.

Step 2.3: Download the backups from your Amazon S3 bucket to your target DB instance

In this step, you use the procedure rdsadmin.rdsadmin_s3_tasks.download_from_s3 to download your backups to your RDS for Oracle DB instance.

**To download your backups from your Amazon S3 bucket**

1. Start SQL*Plus or Oracle SQL Developer and log in to your RDS for Oracle DB instance.
2. Download the backups from the Amazon S3 bucket to your target DB instance by using the Amazon RDS procedure rdsadmin.rdsadmin_s3_tasks.download_from_s3 to d. The following example downloads all of the files from an Amazon S3 bucket named mys3bucket to the DATA_PUMP_DIR directory.

```
EXEC UTL_FILE.FREMOVE ('DATA_PUMP_DIR', 'res.txt');
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name    =>  'mys3bucket',
    p_directory_name =>  'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see Downloading files from an Amazon S3 bucket to an Oracle DB instance.
Step 3: Import the tablespaces on your target DB instance

To restore your tablespaces to your target DB instance, use the procedure rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces. This procedure automatically converts the data files to the correct endian format.

If you import from a platform other than Linux, specify the source platform using the parameter p_platform_id when you call import_xtts_tablespaces. Make sure that the platform ID that you specify matches the one specified in the xtt.properties file in Step 2: Export tablespace metadata on your source host.

Import the tablespaces on your target DB instance

1. Start an Oracle SQL client and log in to your target RDS for Oracle DB instance as the master user.
2. Run the procedure rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces, specifying the tablespaces to import and the directory containing the backups.

The following example imports the tablespaces TBS1, TBS2, and TBS3 from the directory DATA_PUMP_DIR. The source platform is AIX-Based Systems (64-bit), which has the platform ID of 6. You can find the platform IDs by querying V$TRANSPORTABLE_PLATFORM.

```sql
VAR task_id CLOB
BEGIN
 :task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces( 'TBS1,TBS2,TBS3', 'DATA_PUMP_DIR', p_platform_id => 6);
END;
/
PRINT task_id
```

3. (Optional) Monitor progress by querying the table rdsadmin.rds_xtts_operation_info. The xtt_operation_state column shows the value EXECUTING, COMPLETED, or FAILED.

```sql
SELECT * FROM rdsadmin.rds_xtts_operation_info;
```
Note
For long-running operations, you can also query V$SESSION_LONGOPS, V$RMAN_STATUS, and V$RMAN_OUTPUT.

4. View the log of the completed import by using the task ID from the previous step.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
'dbtask-''||&task_id'''||'.log'));
```

Make sure that the import succeeded before continuing to the next step.

Phase 3: Make and transfer incremental backups

In this phase, you make and transfer incremental backups periodically while the source database is active. This technique reduces the size of your final tablespace backup. If you take multiple incremental backups, you must copy the res.txt file after the last incremental backup before you can apply it on the target instance.

The steps are the same as in Phase 2: Prepare the full tablespace backup, except that the import step is optional.

Phase 4: Transport the tablespaces

In this phase, you back up your read-only tablespaces and export Data Pump metadata, transfer these files to your target host, and import both the tablespaces and the metadata.

Topics

- **Step 1: Back up your read-only tablespaces**
- **Step 2: Export tablespace metadata on your source host**
- **Step 3: (Amazon S3 only) Transfer the backup and export files to your target DB instance**
- **Step 4: Import the tablespaces on your target DB instance**
- **Step 5: Import tablespace metadata on your target DB instance**
Step 1: Back up your read-only tablespaces

This step is identical to Step 1: Back up the tablespaces on your source host, with one key difference: you place your tablespaces in read-only mode before backing up your tablespaces for the last time.

The following example places tbs1, tbs2, and tbs3 in read-only mode.

```
ALTER TABLESPACE tbs1 READ ONLY;
ALTER TABLESPACE tbs2 READ ONLY;
ALTER TABLESPACE tbs3 READ ONLY;
```

Step 2: Export tablespace metadata on your source host

Export your tablespace metadata by running the expdb utility on your source host. The following example exports tablespaces TBS1, TBS2, and TBS3 to dump file xttdump.dmp in directory DATA_PUMP_DIR.

```
expdp username/pwd \
dumpfile=xttdump.dmp \
directory=DATA_PUMP_DIR \
statistics=NONE \
transport_tablespaces=TBS1,TBS2,TBS3 \
transport_full_check=y \
logfile=tts_export.log
```

If DATA_PUMP_DIR is a shared directory in Amazon EFS, skip to Step 4: Import the tablespaces on your target DB instance.

Step 3: (Amazon S3 only) Transfer the backup and export files to your target DB instance

If you are using Amazon S3 to stage your tablespace backups and Data Pump export file, complete the following steps.

Step 3.1: Upload the backups and dump file from your source host to your Amazon S3 bucket

Upload your backup and dump files from your source host to your Amazon S3 bucket. For more information, see Uploading objects in the Amazon Simple Storage Service User Guide.
Step 3.2: Download the backups and dump file from your Amazon S3 bucket to your target DB instance

In this step, you use the procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3` to download your backups and dump file to your RDS for Oracle DB instance. Follow the steps in Step 2.3: Download the backups from your Amazon S3 bucket to your target DB instance.

Step 4: Import the tablespaces on your target DB instance

Use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces` to restore the tablespaces. For syntax and semantics of this procedure, see Importing transported tablespaces to your DB instance

⚠️ Important

After you complete your final tablespace import, the next step is importing the Oracle Data Pump metadata. If the import fails, it's important to return your DB instance to its state before the failure. Thus, we recommend that you create a DB snapshot of your DB instance by following the instructions in Creating a DB snapshot for a Single-AZ DB instance. The snapshot will contain all imported tablespaces, so if the import fails, you don't need to repeat the backup and import process.

If your target DB instance has automatic backups turned on, and Amazon RDS doesn't detect that a valid snapshot was initiated before you import the metadata, RDS attempts to create a snapshot. Depending on your instance activity, this snapshot might or might not succeed. If a valid snapshot isn't detected or a snapshot can't be initiated, the metadata import exits with errors.

Import the tablespaces on your target DB instance

1. Start an Oracle SQL client and log in to your target RDS for Oracle DB instance as the master user.
2. Run the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`, specifying the tablespaces to import and the directory containing the backups.

The following example imports the tablespaces `TBS1`, `TBS2`, and `TBS3` from the directory `DATA_PUMP_DIR`.

BEGIN
3. (Optional) Monitor progress by querying the table `rdsadmin.rds_xtts_operation_info`. The `xtts_operation_state` column shows the value EXECUTING, COMPLETED, or FAILED.

```sql
SELECT * FROM rdsadmin.rds_xtts_operation_info;
```

**Note**

For long-running operations, you can also query `V$SESSION_LONGOPS`, `V$RMAN_STATUS`, and `V$RMAN_OUTPUT`.

4. View the log of the completed import by using the task ID from the previous step.

```sql
SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-''&task_id'''.log'));
```

Make sure that the import succeeded before continuing to the next step.

5. Take a manual DB snapshot by following the instructions in [Creating a DB snapshot for a Single-AZ DB instance](#).

**Step 5: Import tablespace metadata on your target DB instance**

In this step, you import the transportable tablespace metadata into your RDS for Oracle DB instance using the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_metadata`. For syntax and semantics of this procedure, see [Importing transportable tablespace metadata into your DB instance](#). During the operation, the status of the import is shown in the table `rdsadmin.rds_xtts_operation_info`. 

```sql
:task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces('TBS1,TBS2,TBS3','DATA_PUMP_DIR')
END;
/
PRINT task_id
```

```sql
3.
```

```sql
SELECT * FROM rdsadmin.rds_xtts_operation_info;
```

```sql
Note
For long-running operations, you can also query V$SESSION_LONGOPS, V$RMAN_STATUS, and V$RMAN_OUTPUT.
```

```sql
4.
```

```sql
SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-''&task_id'''.log'));
```

Make sure that the import succeeded before continuing to the next step.

```sql
5.
```

```sql
SELECT * FROM rdsadmin.rds_xtts_operation_info;
```
Important

Before you import metadata, we strongly recommend that you confirm that a DB snapshot was successfully created after you imported your tablespaces. If the import step fails, restore your DB instance, address the import errors, and then attempt the import again.

Import the Data Pump metadata into your RDS for Oracle DB instance

1. Start your Oracle SQL client and log in to your target DB instance as the master user.

2. Create the users that own schemas in your transported tablespaces, if these users don't already exist.

   CREATE USER tbs_owner IDENTIFIED BY password;

3. Import the metadata, specifying the name of the dump file and its directory location.

   BEGIN
   rdsadmin.rdsadmin_transport_util.import_xtts_metadata('xttdump.dmp','DATA_PUMP_DIR');
   END;
   /

4. (Optional) Query the transportable tablespace history table to see the status of the metadata import.

   SELECT * FROM rdsadmin.rds_xtts_operation_info;

   When the operation completes, your tablespaces are in read-only mode.

5. (Optional) View the log file.

   The following example lists the contents of the BDUMP directory and then queries the import log.

   SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'BDUMP'));
   SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file(p_directory => 'BDUMP'),
Phase 5: Validate the transported tablespaces

In this optional step, you validate your transported tablespaces using the procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`, and then place your tablespaces in read/write mode.

To validate the transported data

1. Start SQL*Plus or SQL Developer and log in to your target DB instance as the master user.
2. Validate the tablespaces using the procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`

   ```sql
   SET SERVEROUTPUT ON
   BEGIN
       rdsadmin.rdsadmin_rman_util.validate_tablespace(
           p_tablespace_name => 'TBS1',
           p_validation_type => 'PHYSICAL+LOGICAL',
           p_rman_to_dbms_output => TRUE);
   rdsadmin.rdsadmin_rman_util.validate_tablespace(
       p_tablespace_name => 'TBS2',
       p_validation_type => 'PHYSICAL+LOGICAL',
       p_rman_to_dbms_output => TRUE);
   rdsadmin.rdsadmin_rman_util.validate_tablespace(
       p_tablespace_name => 'TBS3',
       p_validation_type => 'PHYSICAL+LOGICAL',
       p_rman_to_dbms_output => TRUE);
   END;
   /
   ``
3. Place your tablespaces in read/write mode.

   ```sql
   ALTER TABLESPACE TBS1 READ WRITE;
   ALTER TABLESPACE TBS2 READ WRITE;
   ALTER TABLESPACE TBS3 READ WRITE;
   ```
Phase 6: Clean up leftover files

In this optional step, you remove any unneeded files. Use the `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to list data files that were orphaned after a tablespace import, and then use `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to delete them. For syntax and semantics of these procedures, see [Listing orphaned files after a tablespace import](#) and [Deleting orphaned data files after a tablespace import](#).

To clean up leftover files

1. Remove old backups in `DATA_PUMP_DIR` as follows:
   a. List the backup files by running `rdsadmin.rdsadmin_file_util.listdir`.
      
      ```sql
      SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'DATA_PUMP_DIR'));
      ```
   b. Remove the backups one by one by calling `UTL_FILE.FREMOVE`.
      
      ```sql
      EXEC UTL_FILE.FREMOVE ('DATA_PUMP_DIR', 'backup_filename');
      ```

2. If you imported tablespaces but didn't import metadata for these tablespaces, you can delete the orphaned data files as follows:
   a. List the orphaned data files that you need to delete. The following example runs the procedure `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files`.
      
      ```sql
      SQL> SELECT * FROM
      TABLE(rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files);
      
      | FILENAME  | FILESIZE   |
      |-----------|-----------|
      | datafile_7.dbf | 104865792 |
      | datafile_8.dbf | 104865792 |
      ```
   b. Delete the orphaned files by running the procedure `rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import`.
      
      ```sql
      BEGIN
      ```
The cleanup operation generates a log file that uses the name format `rds-xtts-delete_xtts_orphaned_files-YYYY-MM-DD.HH24-MI-SS.FF.log` in the BDUMP directory.

c. Read the log file generated in the previous step. The following example reads log `rds-xtts-delete_xtts_orphaned_files-2023-06-01.09-33-11.868894000.log`.

```sql
SELECT *
FROM TABLE(rdsadmin.rds_file_util.read_text_file(
    p_directory => 'BDUMP',
    p_filename  => 'rds-xtts-delete_xtts_orphaned_files-2023-06-01.09-33-11.868894000.log'));
```

```
TEXT
--------------------------------------------------------------------------------
orphan transported datafile datafile_7.dbf deleted.
orphan transported datafile datafile_8.dbf deleted.
```

3. If you imported tablespaces and imported metadata for these tablespaces, but you encountered compatibility errors or other Oracle Data Pump issues, clean up the partially transported data files as follows:

a. List the tablespaces that contain partially transported data files by querying `DBA_TABLESPACES`.

```sql
SQL> SELECT TABLESPACE_NAME FROM DBA_TABLESPACES WHERE PLUGGED_IN='YES';
```

```
TABLESPACE_NAME
--------------------------------------------------------------------------------
TBS_3
```

b. Drop the tablespaces and the partially transported data files.

```sql
DROP TABLESPACE TBS_3 INCLUDING CONTENTS AND DATAFILES;
```
Importing using Oracle Data Pump

Oracle Data Pump is a utility that allows you to export Oracle data to a dump file and import it into another Oracle database. It is a long-term replacement for the Oracle Export/Import utilities. Oracle Data Pump is the recommended way to move large amounts of data from an Oracle database to an Amazon RDS DB instance.

The examples in this section show one way to import data into an Oracle database, but Oracle Data Pump supports other techniques. For more information, see the Oracle Database documentation.

The examples in this section use the DBMS_DATAPUMP package. You can accomplish the same tasks using the Oracle Data Pump command line utilities impdp and expdp. You can install these utilities on a remote host as part of an Oracle Client installation, including Oracle Instant Client. For more information, see How do I use Oracle Instant Client to run Data Pump Import or Export for my Amazon RDS for Oracle DB instance?

Topics
- Overview of Oracle Data Pump
- Importing data with Oracle Data Pump and an Amazon S3 bucket
- Importing data with Oracle Data Pump and a database link

Overview of Oracle Data Pump

Oracle Data Pump is made up of the following components:

- Command-line clients expdp and impdp
- The DBMS_DATAPUMP PL/SQL package
- The DBMS_METADATA PL/SQL package

You can use Oracle Data Pump for the following scenarios:

- Import data from an Oracle database, either on-premises or on an Amazon EC2 instance, to an RDS for Oracle DB instance.
- Import data from an RDS for Oracle DB instance to an Oracle database, either on-premises or on an Amazon EC2 instance.
- Import data between RDS for Oracle DB instances, for example, to migrate data from EC2-Classic to VPC.
To download Oracle Data Pump utilities, see Oracle database software downloads on the Oracle Technology Network website. For compatibility considerations when migrating between versions of Oracle Database, see the Oracle Database documentation.

**Oracle Data Pump workflow**

Typically, you use Oracle Data Pump in the following stages:

1. Export your data into a dump file on the source database.
2. Upload your dump file to your destination RDS for Oracle DB instance. You can transfer using an Amazon S3 bucket or by using a database link between the two databases.
3. Import the data from your dump file into your RDS for Oracle DB instance.

**Oracle Data Pump best practices**

When you use Oracle Data Pump to import data into an RDS for Oracle instance, we recommend the following best practices:

- Perform imports in schema or table mode to import specific schemas and objects.
- Limit the schemas you import to those required by your application.
- Don't import in full mode or import schemas for system-maintained components.

Because RDS for Oracle doesn't allow access to SYS or SYSDBA administrative users, these actions might damage the Oracle data dictionary and affect the stability of your database.

- When loading large amounts of data, do the following:
  1. Transfer the dump file to the target RDS for Oracle DB instance.
  2. Take a DB snapshot of your instance.
  3. Test the import to verify that it succeeds.

  If database components are invalidated, you can delete the DB instance and re-create it from the DB snapshot. The restored DB instance includes any dump files staged on the DB instance when you took the DB snapshot.

- Don't import dump files that were created using the Oracle Data Pump export parameters TRANSPORT_TABLESPACES, TRANSPORTABLE, or TRANSPORT_FULL_CHECK. RDS for Oracle DB instances don't support importing these dump files.

- Don't import dump files that contain Oracle Scheduler objects in SYS, SYSTEM, RDSADMIN, RDSSEC, and RDS_DATAGUARD, and belong to the following categories:
• Jobs
• Programs
• Schedules
• Chains
• Rules
• Evaluation contexts
• Rule sets

RDS for Oracle DB instances don't support importing these dump files.

• To exclude unsupported Oracle Scheduler objects, use additional directives during the Data Pump export. If you use DBMS_DATAPUMP, you can add an additional METADATA_FILTER before the DBMS_METADATA.START_JOB:

```sql
DBMS_DATAPUMP.METADATA_FILTER(
  v_hdn1,
  'EXCLUDE_NAME_EXPR',
  q'[IN (SELECT NAME FROM SYS.OBJ$
     WHERE TYPE# IN (66,67,74,79,59,62,46)
     AND OWNER# IN
       (SELECT USER# FROM SYS.USER$
        WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
      )
    ]',
  'PROCOBJ'
);
```

If you use expdp, create a parameter file that contains the exclude directive shown in the following example. Then use PARFILE=parameter_file with your expdp command.

```sql
exclude=procobj:"IN
 (SELECT NAME FROM sys.OBJ$
  WHERE TYPE# IN (66,67,74,79,59,62,46)
  AND OWNER# IN
    (SELECT USER# FROM SYS.USER$
     WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
    )
 )"
```
Importing data with Oracle Data Pump and an Amazon S3 bucket

The following import process uses Oracle Data Pump and an Amazon S3 bucket. The steps are as follows:

1. Export data on the source database using the Oracle DBMS_DATAPUMP package.
2. Place the dump file in an Amazon S3 bucket.
3. Download the dump file from the Amazon S3 bucket to the DATA_PUMP_DIR directory on the target RDS for Oracle DB instance.
4. Import the data from the copied dump file into the RDS for Oracle DB instance using the package DBMS_DATAPUMP.

Topics

- Requirements for Importing data with Oracle Data Pump and an Amazon S3 bucket
- Step 1: Grant privileges to the database user on the RDS for Oracle target DB instance
- Step 2: Export data into a dump file using DBMS_DATAPUMP
- Step 3: Upload the dump file to your Amazon S3 bucket
- Step 4: Download the dump file from your Amazon S3 bucket to your target DB instance
- Step 5: Import your dump file into your target DB instance using DBMS_DATAPUMP
- Step 6: Clean up

Requirements for Importing data with Oracle Data Pump and an Amazon S3 bucket

The process has the following requirements:

- Make sure that an Amazon S3 bucket is available for file transfers, and that the Amazon S3 bucket is in the same AWS Region as the DB instance. For instructions, see Create a bucket in the Amazon Simple Storage Service Getting Started Guide.
- The object that you upload into the Amazon S3 bucket must be 5 TB or less. For more information about working with objects in Amazon S3, see Amazon Simple Storage Service User Guide.
Note
If you dump file exceeds 5 TB, you can run the Oracle Data Pump export with the parallel option. This operation spreads the data into multiple dump files so that you do not exceed the 5 TB limit for individual files.

- You must prepare the Amazon S3 bucket for Amazon RDS integration by following the instructions in Configuring IAM permissions for RDS for Oracle integration with Amazon S3.
- You must ensure that you have enough storage space to store the dump file on the source instance and the target DB instance.

Note
This process imports a dump file into the DATA_PUMP_DIR directory, a preconfigured directory on all Oracle DB instances. This directory is located on the same storage volume as your data files. When you import the dump file, the existing Oracle data files use more space. Thus, you should make sure that your DB instance can accommodate that additional use of space. The imported dump file is not automatically deleted or purged from the DATA_PUMP_DIR directory. To remove the imported dump file, use UTL_FILE.FREMOVE, found on the Oracle website.

Step 1: Grant privileges to the database user on the RDS for Oracle target DB instance

In this step, you create the schemas into which you plan to import data and grant the users necessary privileges.

To create users and grant necessary privileges on the RDS for Oracle target instance

1. Use SQL*Plus or Oracle SQL Developer to log in as the master user to the RDS for Oracle DB instance into which the data will be imported. For information about connecting to a DB instance, see Connecting to your RDS for Oracle DB instance.
2. Create the required tablespaces before you import the data. For more information, see Creating and sizing tablespaces.
3. Create the user account and grant the necessary permissions and roles if the user account into which the data is imported doesn't exist. If you plan to import data into multiple user schemas, create each user account and grant the necessary privileges and roles to it.

For example, the following SQL statements create a new user and grant the necessary permissions and roles to import the data into the schema owned by this user. Replace `schema_1` with the name of your schema in this step and in the following steps.

```
CREATE USER schema_1 IDENTIFIED BY my_password;
GRANT CREATE SESSION, RESOURCE TO schema_1;
ALTER USER schema_1 QUOTA 100M ON users;
```

### Note

Specify a password other than the prompt shown here as a security best practice.

The preceding statements grant the new user the `CREATE SESSION` privilege and the `RESOURCE` role. You might need additional privileges and roles depending on the database objects that you import.

**Step 2: Export data into a dump file using DBMS_DATAPUMP**

To create a dump file, use the DBMS_DATAPUMP package.

**To export Oracle data into a dump file**

1. Use SQL Plus or Oracle SQL Developer to connect to the source RDS for Oracle DB instance with an administrative user. If the source database is an RDS for Oracle DB instance, connect with the Amazon RDS master user.

2. Export the data by calling DBMS_DATAPUMP procedures.

The following script exports the `SCHEMA_1` schema into a dump file named `sample.dmp` in the `DATA_PUMP_DIR` directory. Replace `SCHEMA_1` with the name of the schema that you want to export.

```
DECLARE
    v_hdl NUMBER;
```
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'EXPORT',
    job_mode  => 'SCHEMA',
    job_name  => null
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdnl,
    filename => 'sample.dmp',
    directory => 'DATA_PUMP_DIR',
    filetype => dbms_datapump.ku$_file_type_dump_file
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdnl,
    filename => 'sample_exp.log',
    directory => 'DATA_PUMP_DIR',
    filetype => dbms_datapump.ku$_file_type_log_file
  );
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN ('"SCHEMA_1"')');
  DBMS_DATAPUMP.METADATA_FILTER(
    v_hdnl,
    'EXCLUDE_NAME_EXPR',
    q'[IN (SELECT NAME FROM SYS.OBJ$
        WHERE TYPE# IN (66,67,74,79,59,62,46)
        AND OWNER# IN
        (SELECT USER# FROM SYS.USER$
            WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
        )
    )',
    'PROCOBJ'
  );
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/

Note
Data Pump starts jobs asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation.
3. (Optional) View the contents of the export log by calling the `rdsadmin.rds_file_util.read_text_file` procedure. For more information, see Reading files in a DB instance directory.

**Step 3: Upload the dump file to your Amazon S3 bucket**

Use the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` to copy the dump file to the Amazon S3 bucket. The following example uploads all of the files from the DATA_PUMP_DIR directory to an Amazon S3 bucket named `myS3bucket`.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name    =>  'myS3bucket',
    p_directory_name =>  'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket.

**Step 4: Download the dump file from your Amazon S3 bucket to your target DB instance**

Perform this step using the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`. When you download a file to a directory, the procedure `download_from_s3` skips the download if an identically named file already exists in the directory. To remove a file from the download directory, use `UTL_FILE.FREMOVE`, found on the Oracle website.

**To download your dump file**

1. Start SQL*Plus or Oracle SQL Developer and log in as the master on your Amazon RDS target Oracle DB instance
2. Download the dump file using the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`.

The following example downloads all files from an Amazon S3 bucket named `myS3bucket` to the directory DATA_PUMP_DIR.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name    =>  'myS3bucket',
    p_directory_name =>  'DATA_PUMP_DIR')
```
The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see Downloading files from an Amazon S3 bucket to an Oracle DB instance.

Step 5: Import your dump file into your target DB instance using DBMS_DATAPUMP

Use DBMS_DATAPUMP to import the schema into your RDS for Oracle DB instance. Additional options such as METADATA_REMAP might be required.

To import data into your target DB instance

1. Start SQL*Plus or SQL Developer and log in as the master user to your RDS for Oracle DB instance.
2. Export the data by calling DBMS_DATAPUMP procedures.

The following example imports the $SCHEMA_1$ data from sample_copied.dmp into your target DB instance.

```sql
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode  => 'SCHEMA',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample_copied.dmp',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_dump_file);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample_imp.log',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN ('$SCHEMA_1$')');
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/```
Note

Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the import log by using the rdsadmin.rds_file_util.read_text_file procedure. For more information, see Reading files in a DB instance directory.

3. Verify the data import by listing the schema tables on your target DB instance.

For example, the following query returns the number of tables for SCHEMA_1.

```
SELECT COUNT(*) FROM DBA_TABLES WHERE OWNER='SCHEMA_1';
```

Step 6: Clean up

After the data has been imported, you can delete the files that you don't want to keep.

To remove unneeded files

1. Start SQL*Plus or SQL Developer and log in as the master user to your RDS for Oracle DB instance.

2. List the files in DATA_PUMP_DIR using the following command.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('DATA_PUMP_DIR')) ORDER BY MTIME;
```

3. Delete files in DATA_PUMP_DIR that you no longer require, use the following command.

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','filename');
```

For example, the following command deletes the file named sample_copied.dmp.

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','sample_copied.dmp');
```
Importing data with Oracle Data Pump and a database link

The following import process uses Oracle Data Pump and the Oracle `DBMS_FILE_TRANSFER` package. The steps are as follows:

1. Connect to a source Oracle database, which can be an on-premises database, Amazon EC2 instance, or an RDS for Oracle DB instance.
2. Export data using the `DBMS_DATAPUMP` package.
3. Use `DBMS_FILE_TRANSFER.PUT_FILE` to copy the dump file from the Oracle database to the `DATA_PUMP_DIR` directory on the target RDS for Oracle DB instance that is connected using a database link.
4. Import the data from the copied dump file into the RDS for Oracle DB instance using the `DBMS_DATAPUMP` package.

The import process using Oracle Data Pump and the `DBMS_FILE_TRANSFER` package has the following steps.

Topics

- Requirements for importing data with Oracle Data Pump and a database link
- Step 1: Grant privileges to the user on the RDS for Oracle target DB instance
- Step 2: Grant privileges to the user on the source database
- Step 3: Create a dump file using `DBMS_DATAPUMP`
- Step 4: Create a database link to the target DB instance
- Step 5: Copy the exported dump file to the target DB instance using `DBMS_FILE_TRANSFER`
- Step 6: Import the data file to the target DB instance using `DBMS_DATAPUMP`
- Step 7: Clean up

Requirements for importing data with Oracle Data Pump and a database link

The process has the following requirements:

- You must have execute privileges on the `DBMS_FILE_TRANSFER` and `DBMS_DATAPUMP` packages.
- You must have write privileges to the `DATA_PUMP_DIR` directory on the source DB instance.
- You must ensure that you have enough storage space to store the dump file on the source instance and the target DB instance.
Note

This process imports a dump file into the DATA_PUMP_DIR directory, a preconfigured directory on all Oracle DB instances. This directory is located on the same storage volume as your data files. When you import the dump file, the existing Oracle data files use more space. Thus, you should make sure that your DB instance can accommodate that additional use of space. The imported dump file is not automatically deleted or purged from the DATA_PUMP_DIR directory. To remove the imported dump file, use UTL_FILE.FREMOVE, found on the Oracle website.

Step 1: Grant privileges to the user on the RDS for Oracle target DB instance

To grant privileges to the user on the RDS for Oracle target DB instance, take the following steps:

1. Use SQL Plus or Oracle SQL Developer to connect to the RDS for Oracle DB instance into which you intend to import the data. Connect as the Amazon RDS master user. For information about connecting to the DB instance, see Connecting to your RDS for Oracle DB instance.

2. Create the required tablespaces before you import the data. For more information, see Creating and sizing tablespaces.

3. If the user account into which the data is imported doesn't exist, create the user account and grant the necessary permissions and roles. If you plan to import data into multiple user schemas, create each user account and grant the necessary privileges and roles to it.

For example, the following commands create a new user named schema_1 and grant the necessary permissions and roles to import the data into the schema for this user.

```
CREATE USER schema_1 IDENTIFIED BY my-password;
GRANT CREATE SESSION, RESOURCE TO schema_1;
ALTER USER schema_1 QUOTA 100M ON users;
```

Note

Specify a password other than the prompt shown here as a security best practice.
The preceding example grants the new user the CREATE SESSION privilege and the RESOURCE role. Additional privileges and roles might be required depending on the database objects that you import.

Note
Replace schema_1 with the name of your schema in this step and in the following steps.

Step 2: Grant privileges to the user on the source database

Use SQL*Plus or Oracle SQL Developer to connect to the RDS for Oracle DB instance that contains the data to be imported. If necessary, create a user account and grant the necessary permissions.

Note
If the source database is an Amazon RDS instance, you can skip this step. You use your Amazon RDS master user account to perform the export.

The following commands create a new user and grant the necessary permissions.

```sql
CREATE USER export_user IDENTIFIED BY my-password;
GRANT CREATE SESSION, CREATE TABLE, CREATE DATABASE LINK TO export_user;
ALTER USER export_user QUOTA 100M ON users;
GRANT READ, WRITE ON DIRECTORY data_pump_dir TO export_user;
GRANT SELECT_CATALOG_ROLE TO export_user;
GRANT EXECUTE ON DBMS_DATAPUMP TO export_user;
GRANT EXECUTE ON DBMS_FILE_TRANSFER TO export_user;
```

Note
Specify a password other than the prompt shown here as a security best practice.

Step 3: Create a dump file using DBMS_DATAPUMP

To create a dump file, do the following:
1. Use SQL*Plus or Oracle SQL Developer to connect to the source Oracle instance with an administrative user or with the user you created in step 2. If the source database is an Amazon RDS for Oracle DB instance, connect with the Amazon RDS master user.

2. Create a dump file using the Oracle Data Pump utility.

The following script creates a dump file named `sample.dmp` in the `DATA_PUMP_DIR` directory.

```sql
DECLARE
    v_hdnl NUMBER;
BEGIN
    v_hdnl := DBMS_DATAPUMP.OPEN(
        operation => 'EXPORT',
        job_mode  => 'SCHEMA',
        job_name  => null
    );
    DBMS_DATAPUMP.ADD_FILE(
        handle    => v_hdnl,
        filename  => 'sample.dmp' ,
        directory => 'DATA_PUMP_DIR' ,
        filetype  => dbms_datapump.ku$_file_type_dump_file
    );
    DBMS_DATAPUMP.ADD_FILE(
        handle    => v_hdnl ,
        filename  => 'sample_exp.log' ,
        directory => 'DATA_PUMP_DIR' ,
        filetype  => dbms_datapump.ku$_file_type_log_file
    );
    DBMS_DATAPUMP.METADATA_FILTER(
        v_hdnl              ,
        'SCHEMA_EXPR'       ,
        'IN (''SCHEMA_1'')'
    );
    DBMS_DATAPUMP.METADATA_FILTER(
        v_hdnl,
        'EXCLUDE_NAME_EXPR',
        q'[IN (SELECT name FROM sys.OBJ$
            WHERE type# IN (66,67,74,79,59,62,46)
            AND owner# IN
                (SELECT user# FROM sys.user$
                    WHERE name IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
                )
            ]',
    );
END;
```
Note

Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the export log by using the rdsadmin.rds_file_util.read_text_file procedure. For more information, see Reading files in a DB instance directory.

Step 4: Create a database link to the target DB instance

Create a database link between your source DB instance and your target DB instance. Your local Oracle instance must have network connectivity to the DB instance in order to create a database link and to transfer your export dump file.

Perform this step connected with the same user account as the previous step.

If you are creating a database link between two DB instances inside the same VPC or peered VPCs, the two DB instances should have a valid route between them. The security group of each DB instance must allow ingress to and egress from the other DB instance. The security group inbound and outbound rules can refer to security groups from the same VPC or a peered VPC. For more information, see Adjusting database links for use with DB instances in a VPC.

The following command creates a database link named to_rds that connects to the Amazon RDS master user at the target DB instance.

```
CREATE DATABASE LINK to_rds
    CONNECT TO <master_user_account> IDENTIFIED BY <password>
    USING '(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=<dns or ip address of remote db>)
        (PORT=<listener port>))(CONNECT_DATA=(SID=<remote SID>)))';
```
Step 5: Copy the exported dump file to the target DB instance using DBMS_FILE_TRANSFER

Use DBMS_FILE_TRANSFER to copy the dump file from the source database instance to the target DB instance. The following script copies a dump file named sample.dmp from the source instance to a target database link named to_rds (created in the previous step).

```sql
BEGIN
   DBMS_FILE_TRANSFER.PUT_FILE(
      source_directory_object       => 'DATA_PUMP_DIR',
      source_file_name              => 'sample.dmp',
      destination_directory_object  => 'DATA_PUMP_DIR',
      destination_file_name         => 'sample_copied.dmp',
      destination_database          => 'to_rds' );
END;
/
```

Step 6: Import the data file to the target DB instance using DBMS_DATAPUMP

Use Oracle Data Pump to import the schema in the DB instance. Additional options such as METADATA_REMAP might be required.

Connect to the DB instance with the Amazon RDS master user account to perform the import.

```sql
DECLARE
   v_hdnl NUMBER;
BEGIN
   v_hdnl := DBMS_DATAPUMP.OPEN(
      operation  => 'IMPORT',
      job_mode   => 'SCHEMA',
      job_name   => null);
   DBMS_DATAPUMP.ADD_FILE(
      handle     => v_hdnl,
      filename   => 'sample_copied.dmp',
      directory  => 'DATA_PUMP_DIR',
      filetype   => dbms_datapump.ku$_file_type_dump_file );
   DBMS_DATAPUMP.ADD_FILE(
      handle     => v_hdnl,
      filename   => 'sample_imp.log',
      directory  => 'DATA_PUMP_DIR',
      filetype   => dbms_datapump.ku$_file_type_log_file);
   DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN ('"SCHEMA_1"')');
   DBMS_DATAPUMP.START_JOB(v_hdnl);
```
Note

Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the import log by using the rdsadmin.rds_file_util.read_text_file procedure. For more information, see Reading files in a DB instance directory.

You can verify the data import by viewing the user's tables on the DB instance. For example, the following query returns the number of tables for schema_1.

```
SELECT COUNT(*) FROM DBA_TABLES WHERE OWNER='SCHEMA_1';
```

Step 7: Clean up

After the data has been imported, you can delete the files that you don't want to keep. You can list the files in DATA_PUMP_DIR using the following command.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('DATA_PUMP_DIR')) ORDER BY MTIME;
```

To delete files in DATA_PUMP_DIR that you no longer require, use the following command.

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','<file name>');
```

For example, the following command deletes the file named "sample_copied.dmp".

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','sample_copied.dmp');
```

Importing using Oracle Export/Import

You might consider Oracle Export/Import utilities for migrations in the following conditions:

- Your data size is small.
- Data types such as binary float and double aren't required.
The import process creates the necessary schema objects. Thus, you don't need to run a script to create the objects beforehand.

The easiest way to install the Oracle the export and import utilities is to install the Oracle Instant Client. To download the software, go to https://www.oracle.com/database/technologies/instant-client.html. For documentation, see Instant Client for SQL*Loader, Export, and Import in the Oracle Database Utilities manual.

**To export tables and then import them**

1. Export the tables from the source database using the `exp` command.

   The following command exports the tables named `tab1`, `tab2`, and `tab3`. The dump file is `exp_file.dmp`.

   ```
   exp cust_dba@ORCL FILE=exp_file.dmp TABLES=(tab1,tab2,tab3) LOG=exp_file.log
   ```

   The export creates a binary dump file that contains both the schema and data for the specified tables.

2. Import the schema and data into a target database using the `imp` command.

   The following command imports the tables `tab1`, `tab2`, and `tab3` from dump file `exp_file.dmp`.

   ```
   imp cust_dba@targetdb FROMUSER=cust_schema TOUSER=cust_schema \
   TABLES=(tab1,tab2,tab3) FILE=exp_file.dmp LOG=imp_file.log
   ```

Export and Import have other variations that might be better suited to your requirements. See the Oracle Database documentation for full details.

**Importing using Oracle SQL*Loader**

You might consider Oracle SQL*Loader for large databases that contain a limited number of objects. Because the process of exporting from a source database and loading to a target database is specific to the schema, the following example creates the sample schema objects, exports from a source, and then loads the data into a target database.

The easiest way to install Oracle SQL*Loader is to install the Oracle Instant Client. To download the software, go to https://www.oracle.com/database/technologies/instant-client.html. For
To import data using Oracle SQL*Loader

1. Create a sample source table using the following SQL statement.

   ```sql
   CREATE TABLE customer_0 TABLESPACE users
   AS (SELECT ROWNUM id, o.*
       FROM   ALL_OBJECTS o, ALL_OBJECTS x
       WHERE  ROWNUM <= 1000000);
   ```

2. On the target RDS for Oracle DB instance, create a destination table for loading the data. The clause `WHERE 1=2` ensures that you copy the structure of `ALL_OBJECTS`, but don't copy any rows.

   ```sql
   CREATE TABLE customer_1 TABLESPACE users
   AS (SELECT 0 AS ID, OWNER, OBJECT_NAME, CREATED
       FROM   ALL_OBJECTS
       WHERE  1=2);
   ```

3. Export the data from the source database to a text file. The following example uses SQL*Plus. For your data, you will likely need to generate a script that does the export for all the objects in the database.

   ```sql
   ALTER SESSION SET NLS_DATE_FORMAT = 'YYYY/MM/DD HH24:MI:SS'
   
   SET LINESIZE 800 HEADING OFF FEEDBACK OFF ARRAY 5000 PAGESIZE 0
   SPOOL customer_0.out
   SET MARKUP HTML PREFORMAT ON
   SET COLSEP ','
   
   SELECT id, owner, object_name, created
   FROM   customer_0;
   
   SPOOL OFF
   ```

4. Create a control file to describe the data. You might need to write a script to perform this step.

   ```bash
   cat << EOF > sqlldr_1.ctl
   load data
   infile customer_0.out
   EOF
   ```
If needed, copy the files generated by the preceding code to a staging area, such as an Amazon EC2 instance.

5. Import the data using SQL*Loader with the appropriate user name and password for the target database.

```
sqlldr cust_dba@targetdb CONTROL=sqlldr_1.ctl BINDSIZE=10485760 READSIZE=10485760 ROWS=1000
```

**Migrating with Oracle materialized views**

To migrate large datasets efficiently, you can use Oracle materialized view replication. With replication, you can keep the target tables synchronized with the source tables. Thus, you can switch over to Amazon RDS later, if needed.

Before you can migrate using materialized views, make sure that you meet the following requirements:

- Configure access from the target database to the source database. In the following example, access rules were enabled on the source database to allow the RDS for Oracle target database to connect to the source over SQL*Net.
- Create a database link from the RDS for Oracle DB instance to the source database.

**To migrate data using materialized views**

1. Create a user account on both source and RDS for Oracle target instances that can authenticate with the same password. The following example creates a user named dblink_user.
CREATE USER dblink_user IDENTIFIED BY my-password
    DEFAULT TABLESPACE users
    TEMPORARY TABLESPACE temp;

GRANT CREATE SESSION TO dblink_user;

GRANT SELECT ANY TABLE TO dblink_user;

GRANT SELECT ANY DICTIONARY TO dblink_user;

Note
Specify a password other than the prompt shown here as a security best practice.

2. Create a database link from the RDS for Oracle target instance to the source instance using your newly created user.

CREATE DATABASE LINK remote_site
    CONNECT TO dblink_user IDENTIFIED BY my-password
    USING '(description=(address=(protocol=tcp) (host=my-host)
        (port=my-listener-port)) (connect_data=(sid=my-source-db-sid)))';

Note
Specify a password other than the prompt shown here as a security best practice.

3. Test the link:

   SELECT * FROM V$INSTANCE@remote_site;

4. Create a sample table with primary key and materialized view log on the source instance.

   CREATE TABLE customer_0 TABLESPACE users
      AS (SELECT ROWNUM id, o.*
           FROM   ALL_OBJECTS o, ALL_OBJECTS x
           WHERE  ROWNUM <= 1000000);

   ALTER TABLE customer_0 ADD CONSTRAINT pk_customer_0 PRIMARY KEY (id) USING INDEX;
5. On the target RDS for Oracle DB instance, create a materialized view.

```sql
CREATE MATERIALIZED VIEW customer_0
    BUILD IMMEDIATE REFRESH FAST
AS (SELECT *
      FROM cust_dba.customer_0@remote_site);
```

6. On the target RDS for Oracle DB instance, refresh the materialized view.

```sql
EXEC DBMS_MV.REFRESH('CUSTOMER_0', 'f');
```

7. Drop the materialized view and include the `PRESERVE TABLE` clause to retain the materialized view container table and its contents.

```sql
DROP MATERIALIZED VIEW customer_0 PRESERVE TABLE;
```

The retained table has the same name as the dropped materialized view.
Working with read replicas for Amazon RDS for Oracle

To configure replication between Oracle DB instances, you can create replica databases. For an overview of Amazon RDS read replicas, see Overview of Amazon RDS read replicas. For a summary of the differences between Oracle replicas and other DB engines, see Differences among read replicas for DB engines.

Topics
- Overview of RDS for Oracle replicas
- Requirements and considerations for RDS for Oracle replicas
- Preparing to create an Oracle replica
- Creating an RDS for Oracle replica in mounted mode
- Modifying the RDS for Oracle replica mode
- Working with RDS for Oracle replica backups
- Performing an Oracle Data Guard switchover
- Troubleshooting RDS for Oracle replicas

Overview of RDS for Oracle replicas

An Oracle replica database is a physical copy of your primary database. An Oracle replica in read-only mode is called a read replica. An Oracle replica in mounted mode is called a mounted replica. Oracle Database doesn't permit writes in a replica, but you can promote a replica to make it writable. The promoted read replica has the replicated data to the point when the request was made to promote it.

The following video provides a helpful overview of RDS for Oracle disaster recovery.

For more information, see the blog post Managed disaster recovery with Amazon RDS for Oracle cross-Region automated backups - Part 1 and Managed disaster recovery with Amazon RDS for Oracle cross-Region automated backups - Part 2.

Topics
- Read-only and mounted replicas
- Read replicas of CDBs
Read-only and mounted replicas

When creating or modifying an Oracle replica, you can place it in either of the following modes:

Read-only

This is the default. Active Data Guard transmits and applies changes from the source database to all read replica databases.

You can create up to five read replicas from one source DB instance. For general information about read replicas that applies to all DB engines, see Working with DB instance read replicas. For information about Oracle Data Guard, see Oracle Data Guard concepts and administration in the Oracle documentation.

Mounted

In this case, replication uses Oracle Data Guard, but the replica database doesn't accept user connections. The primary use for mounted replicas is cross-Region disaster recovery.

A mounted replica can't serve a read-only workload. The mounted replica deletes archived redo log files after it applies them, regardless of the archived log retention policy.

You can create a combination of mounted and read-only DB replicas for the same source DB instance. You can change a read-only replica to mounted mode, or change a mounted replica to read-only mode. In either case, the Oracle database preserves the archived log retention setting.

Read replicas of CDBs

RDS for Oracle supports Data Guard read replicas for Oracle Database 19c and 21c CDBs in the single-tenant configuration only. You can create, manage, and promote read replicas in a CDB just as you can in a non-CDB. Mounted replicas are also supported. You get the following benefits:

- Managed disaster recovery, high availability, and read-only access to your replicas
- The ability to create read replicas in a different AWS Region.
- Integration with the existing RDS read replica APIs: CreateDBInstanceReadReplica, PromoteReadReplica, and SwitchoverReadReplica
To use this feature, you need an Active Data Guard license and an Oracle Database Enterprise Edition license for both the replica and primary DB instances. There are no additional costs related to using CDB architecture. You pay only for your DB instances.

For more information about the single-tenant and multi-tenant configurations of the CDB architecture, see Overview of RDS for Oracle CDBs.

** Archived redo log retention **

If a primary DB instance has no cross-Region read replicas, Amazon RDS for Oracle keeps a minimum of two hours of archived redo logs on the source DB instance. This is true regardless of the setting for `archivelog retention` hours in `rdsadmin.rdsadmin_util.set_configuration`.

RDS purges logs from the source DB instance after two hours or after the archive log retention hours setting has passed, whichever is longer. RDS purges logs from the read replica after the archive log retention hours setting has passed only if they have been successfully applied to the database.

In some cases, a primary DB instance might have one or more cross-Region read replicas. If so, Amazon RDS for Oracle keeps the transaction logs on the source DB instance until they have been transmitted and applied to all cross-Region read replicas. For information about `rdsadmin.rdsadmin_util.set_configuration`, see Retaining archived redo logs.

** Outages during replication **

When you create an Oracle replica, no outage occurs for the source DB instance. Amazon RDS takes a snapshot of the source DB instance. This snapshot becomes the replica. Amazon RDS sets the necessary parameters and permissions for the source DB and replica without service interruption. Similarly, if you delete a replica, no outage occurs.

** Requirements and considerations for RDS for Oracle replicas **

Before creating an Oracle replica, familiarize yourself with the following requirements and considerations.

**Topics**

- Version and licensing requirements for RDS for Oracle replicas
- Option group considerations for RDS for Oracle replicas
- Backup and restore considerations for RDS for Oracle replicas
Version and licensing requirements for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- If the replica is in read-only mode, make sure that you have an Active Data Guard license. If you place the replica in mounted mode, you don't need an Active Data Guard license. Only the Oracle DB engine supports mounted replicas.

- Oracle replicas are supported for the Oracle Enterprise Edition (EE) engine only.

- Oracle replicas of non-CDBs are supported only for DB instances created using version Oracle Database 12c Release 1 (12.1.0.2.v10) and higher 12c releases, and for non-CDB instances of Oracle Database 19c.

- Oracle replicas of CDBs are supported only for CDB instances created using version Oracle Database 19c and higher.

- Oracle replicas are available for DB instances running only on DB instance classes with two or more vCPUs. A source DB instance can't use the db.t3.micro or db.t3.small instance classes.

- The Oracle DB engine version of the source DB instance and all of its replicas must be the same. Amazon RDS upgrades the replicas immediately after upgrading the source DB instance, regardless of a replica's maintenance window. For major version upgrades of cross-Region replicas, Amazon RDS automatically does the following:
  - Generates an option group for the target version.
  - Copies all options and option settings from the original option group to the new option group.
  - Associates the upgraded cross-Region replica with the new option group.

For more information about upgrading the DB engine version, see Upgrading the RDS for Oracle DB engine.

Option group considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- If your Oracle replica is in the same AWS Region as its source DB instance, make sure that it belongs to the same option group as the source DB instance. Modifications to the source option
group or source option group membership propagate to replicas. These changes are applied to the replicas immediately after they are applied to the source DB instance, regardless of the replica's maintenance window.

For more information about option groups, see Working with option groups.

- When you create an RDS for Oracle cross-Region replica, Amazon RDS creates a dedicated option group for it.

You can't remove an RDS for Oracle cross-Region replica from its dedicated option group. No other DB instances can use the dedicated option group for an RDS for Oracle cross-Region replica.

You can only add or remove the following nonreplicated options from a dedicated option group:

- NATIVE_NETWORK_ENCRYPTION
- OEM
- OEM_AGENT
- SSL

To add other options to an RDS for Oracle cross-Region replica, add them to the source DB instance's option group. The option is also installed on all of the source DB instance's replicas. For licensed options, make sure that there are sufficient licenses for the replicas.

When you promote an RDS for Oracle cross-Region replica, the promoted replica behaves the same as other Oracle DB instances, including the management of its options. You can promote a replica explicitly or implicitly by deleting its source DB instance.

For more information about option groups, see Working with option groups.

**Backup and restore considerations for RDS for Oracle replicas**

Before you create an RDS for Oracle replica, consider the following:

- To create snapshots of RDS for Oracle replicas or turn on automatic backups, make sure to set the backup retention period manually. Automatic backups aren't turned on by default.

- When you restore a replica backup, you restore to the database time, not the time that the backup was taken. The *database time* refers to the latest applied transaction time of the data in the backup. The difference is significant because a replica can lag behind the primary for minutes or hours.
To find the difference, use the describe-db-snapshots command. Compare the snapshotDatabaseTime, which is the database time of the replica backup, and the OriginalSnapshotCreateTime field, which is the latest applied transaction on the primary database.

Oracle Data Guard requirements and limitations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, note the following requirements and limitations:

- If your primary DB instance uses the single-tenant configuration of the multitenant architecture, consider the following:
  - You must use Oracle Database 19c or higher with the Enterprise Edition.
  - Your primary CDB instance must be in an ACTIVE lifecycle.
  - You can't convert a non-CDB primary instance to a CDB instance and convert its replicas in the same operation. Instead, delete the non-CDB replicas, convert the primary DB instance to a CDB, and then create new replicas.

- Make sure that a logon trigger on a primary DB instance permits access to the RDS_DATAGUARD user and to any user whose AUTHENTICATED_IDENTITY value is RDS_DATAGUARD or rdsdb. Also, the trigger must not set the current schema for the RDS_DATAGUARD user.

- To avoid blocking connections from the Data Guard broker process, don't enable restricted sessions. For more information about restricted sessions, see Enabling and disabling restricted sessions.

Miscellaneous considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- If your DB instance is a source for one or more cross-Region replicas, the source DB retains its archived redo logs until they are applied on all cross-Region replicas. The archived redo logs might result in increased storage consumption.

- To avoid disrupting RDS automation, system triggers must permit specific users to log on to the primary and replica database. System triggers include DDL, logon, and database role triggers. We recommend that you add code to your triggers to exclude the users listed in the following sample code:
-- Determine who the user is
SELECT SYS_CONTEXT('USERENV', 'AUTHENTICATED_IDENTITY') INTO CURRENT_USER FROM DUAL;

-- The following users should always be able to login to either the Primary or Replica
IF CURRENT_USER IN ('master_user', 'SYS', 'SYSTEM', 'RDS_DATAGUARD', 'rdsdb') THEN
  RETURN;
END IF;

• Block change tracking is supported for read-only replicas, but not for mounted replicas. You can change a mounted replica to a read-only replica, and then enable block change tracking. For more information, see Enabling and disabling block change tracking.

Preparing to create an Oracle replica

Before you can begin using your replica, perform the following tasks.

Topics

• Enabling automatic backups
• Enabling force logging mode
• Changing your logging configuration
• Setting the MAX_STRING_SIZE parameter
• Planning compute and storage resources

Enabling automatic backups

Before a DB instance can serve as a source DB instance, make sure to enable automatic backups on the source DB instance. To learn how to perform this procedure, see Enabling automated backups.

Enabling force logging mode

We recommend that you enable force logging mode. In force logging mode, the Oracle database writes redo records even when NOLOGGING is used with data definition language (DDL) statements.

To enable force logging mode

1. Log in to your Oracle database using a client tool such as SQL Developer.
2. Enable force logging mode by running the following procedure.
exec rdsadmin.rdsadmin_util.force_logging(p_enable => true);

For more information about this procedure, see Setting force logging.

**Changing your logging configuration**

For \(n\) online redo logs of size \(m\), RDS automatically creates \(n+1\) standby logs of size \(m\) on the primary DB instance and all replicas. Whenever you change the logging configuration on the primary, the changes propagate automatically to the replicas.

If you change your logging configuration, consider the following guidelines:

- We recommend that you complete the changes before making a DB instance the source for replicas. RDS for Oracle also supports updating the instance after it becomes a source.
- Before you change the logging configuration on the primary DB instance, check that each replica has enough storage to accommodate the new configuration.

You can modify the logging configuration for a DB instance by using the Amazon RDS procedures `rdsadmin.rdsadmin_util.add_logfile` and `rdsadmin.rdsadmin_util.drop_logfile`. For more information, see Adding online redo logs and Dropping online redo logs.

**Setting the MAX_STRING_SIZE parameter**

Before you create an Oracle replica, ensure that the setting of the MAX_STRING_SIZE parameter is the same on the source DB instance and the replica. You can do this by associating them with the same parameter group. If you have different parameter groups for the source and the replica, you can set MAX_STRING_SIZE to the same value. For more information about setting this parameter, see Turning on extended data types for a new DB instance.

**Planning compute and storage resources**

Ensure that the source DB instance and its replicas are sized properly, in terms of compute and storage, to suit their operational load. If a replica reaches compute, network, or storage resource capacity, the replica stops receiving or applying changes from its source. Amazon RDS for Oracle doesn’t intervene to mitigate high replica lag between a source DB instance and its replicas. You can modify the storage and CPU resources of a replica independently from its source and other replicas.
Creating an RDS for Oracle replica in mounted mode

By default, Oracle replicas are read-only. To create a replica in mounted mode, use the console, the AWS CLI, or the RDS API.

Console

To create a mounted replica from a source Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Oracle DB instance that you want to use as the source for a mounted replica.
4. For Actions, choose Create replica.
5. For Replica mode, choose Mounted.
6. Choose the settings that you want to use. For DB instance identifier, enter a name for the read replica. Adjust other settings as needed.
7. For Regions, choose the Region where the mounted replica will be launched.
8. Choose your instance size and storage type. We recommend that you use the same DB instance class and storage type as the source DB instance for the read replica.
9. For Multi-AZ deployment, choose Create a standby instance to create a standby of your replica in another Availability Zone for failover support for the mounted replica. Creating your mounted replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.
10. Choose the other settings that you want to use.
11. Choose Create replica.

In the Databases page, the mounted replica has the role Replica.

AWS CLI

To create an Oracle replica in mounted mode, set --replica-mode to mounted in the AWS CLI command create-db-instance-read-replica.

Example

For Linux, macOS, or Unix:
aws rds create-db-instance-read-replica \
   --db-instance-identifier myreadreplica \
   --source-db-instance-identifier mydbinstance \
   --replica-mode mounted

For Windows:

aws rds create-db-instance-read-replica ^
   --db-instance-identifier myreadreplica ^
   --source-db-instance-identifier mydbinstance ^
   --replica-mode mounted

To change a read-only replica to a mounted state, set --replica-mode to mounted in the AWS CLI command modify-db-instance. To place a mounted replica in read-only mode, set --replica-mode to open-read-only.

RDS API

To create an Oracle replica in mounted mode, specify ReplicaMode=mounted in the RDS API operation CreateDBInstanceReadReplica.

Modifying the RDS for Oracle replica mode

To change the replica mode of an existing replica, use the console, AWS CLI, or RDS API. When you change to mounted mode, the replica disconnects all active connections. When you change to read-only mode, Amazon RDS initializes Active Data Guard.

The change operation can take a few minutes. During the operation, the DB instance status changes to modifying. For more information about status changes, see Viewing Amazon RDS DB instance status.

Console

To change the replica mode of an Oracle replica from mounted to read-only

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the mounted replica database.
4. Choose **Modify**.

5. For **Replica mode**, choose **Read-only**.

6. Choose the other settings that you want to change.

7. Choose **Continue**.

8. For **Scheduling of modifications**, choose **Apply immediately**.

9. Choose **Modify DB instance**.

### AWS CLI

To change a read replica to mounted mode, set `--replica-mode` to `mounted` in the AWS CLI command `modify-db-instance`. To change a mounted replica to read-only mode, set `--replica-mode` to `open-read-only`.

#### Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
   --db-instance-identifier myreadreplica \
   --replica-mode mode
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier myreadreplica ^
   --replica-mode mode
```

### RDS API

To change a read-only replica to mounted mode, set `ReplicaMode=mounted` in `ModifyDBInstance`. To change a mounted replica to read-only mode, set `ReplicaMode=read-only`.

### Working with RDS for Oracle replica backups

You can create and restore backups of an RDS for Oracle replica. Both automatic backups and manual snapshots are supported. For more information, see [Backing up, restoring, and exporting](#).
The following sections describe the key differences between managing backups of a primary and an RDS for Oracle replica.

### Turning on RDS for Oracle replica backups

An Oracle replica doesn't have automated backups turned on by default. You turn on automated backups by setting the backup retention period to a positive nonzero value.

#### Console

**To enable automated backups immediately**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases, and then choose the DB instance or Multi-AZ DB cluster that you want to modify.
3. Choose Modify.
4. For Backup retention period, choose a positive nonzero value, for example 3 days.
5. Choose Continue.
6. Choose Apply immediately.
7. Choose Modify DB instance or Modify cluster to save your changes and enable automated backups.

#### AWS CLI

To enable automated backups, use the AWS CLI `modify-db-instance` or `modify-db-cluster` command.

Include the following parameters:

- `--db-instance-identifier` (or `--db-cluster-identifier` for a Multi-AZ DB cluster)
- `--backup-retention-period`
- `--apply-immediately` or `--no-apply-immediately`

In the following example, we enable automated backups by setting the backup retention period to three days. The changes are applied immediately.
Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --backup-retention-period 3 \
    --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --backup-retention-period 3 ^
    --apply-immediately
```

RDS API

To enable automated backups, use the RDS API `ModifyDBInstance` or `ModifyDBCluster` operation with the following required parameters:

- `DBInstanceIdentifier` or `DBClusterIdentifier`
- `BackupRetentionPeriod`

Restoring an RDS for Oracle replica backup

You can restore an Oracle replica backup just as you can restore a backup of the primary instance. For more information, see the following:

- Restoring from a DB snapshot
- Restoring a DB instance to a specified time

The main consideration when you restore a replica backup is determining the point in time to which you are restoring. The *database time* refers to the latest applied transaction time of the data in the backup. When you restore a replica backup, you restore to the database time, not the time when the backup completed. The difference is significant because an RDS for Oracle replica can lag behind the primary by minutes or hours. Thus, the database time of a replica backup, and thus the point in time to which you restore it, might be much earlier than the backup creation time.
To find the difference between database time and creation time, use the `describe-db-snapshots` command. Compare the `SnapshotDatabaseTime`, which is the database time of the replica backup, and the `OriginalSnapshotCreateTime` field, which is the latest applied transaction on the primary database. The following example shows the difference between the two times:

```bash
aws rds describe-db-snapshots \
   --db-instance-identifier my-oracle-replica \
   --db-snapshot-identifier my-replica-snapshot \
{
   "DBSnapshots": [
       {
           "DBSnapshotIdentifier": "my-replica-snapshot",
           "DBInstanceIdentifier": "my-oracle-replica",
           "SnapshotDatabaseTime": "2022-07-26T17:49:44Z",
           "OriginalSnapshotCreateTime": "2021-07-26T19:49:44Z"
       }
   ]
}
```

Performing an Oracle Data Guard switchover

A *switchover* is a role reversal between a primary database and a standby database. During a switchover, the original primary database transitions to a standby role, while the original standby database transitions to the primary role.

In an Oracle Data Guard environment, a primary database supports one or more standby databases. You can perform a managed, switchover-based role transition from a primary database to a standby database. A *switchover* is a role reversal between a primary database and a standby database. During a switchover, the original primary database transitions to a standby role, while the original standby database transitions to the primary role.

Topics

- [Overview of Oracle Data Guard switchover](#)

Overview of Oracle Data Guard switchover

Amazon RDS supports a fully managed, switchover-based role transition for Oracle Database replicas. The replicas can reside in separate AWS Regions or in different Availability Zones (AZs) of a single Region. You can only initiate a switchover to a standby database that is mounted or open read-only.

A switchover is different from read replica promotion. In a switchover, the source and replica DB instances change roles. In a promotion, a read replica becomes a source DB instance, but the source DB instance doesn't become a replica. For more information, see Promoting a read replica to be a standalone DB instance.

Topics
• Benefits of Oracle Data Guard switchover
• Supported Oracle Database versions
• AWS Region support
• Cost of Oracle Data Guard switchover
• How Oracle Data Guard switchover works

Benefits of Oracle Data Guard switchover

Just as for RDS for Oracle read replicas, a managed switchover relies on Oracle Data Guard. The operation is designed to have zero data loss. Amazon RDS automates the following aspects of the switchover:

• Reverses the roles of your primary database and specified standby database, putting the new standby database in the same state (mounted or read-only) as the original standby
• Ensures data consistency
• Maintains your replication configuration after the transition
• Supports repeated reversals, allowing your new standby database to return to its original primary role

Supported Oracle Database versions

Oracle Data Guard switchover is supported for the following releases:
• Oracle Database 19c
• Oracle Database 12c Release 2 (12.2)
• Oracle Database 12c Release 1 (12.1) using PSU 12.1.0.2.v10 or higher

**AWS Region support**

Oracle Data Guard switchover is available in the following AWS Regions:

• Asia Pacific (Mumbai)
• Asia Pacific (Osaka)
• Asia Pacific (Seoul)
• Asia Pacific (Singapore)
• Asia Pacific (Sydney)
• Asia Pacific (Tokyo)
• Canada (Central)
• Europe (Frankfurt)
• Europe (Ireland)
• Europe (London)
• Europe (Paris)
• Europe (Stockholm)
• South America (São Paulo)
• US East (N. Virginia)
• US East (Ohio)
• US West (N. California)
• US West (Oregon)
• AWS GovCloud (US-East)
• AWS GovCloud (US-West)

**Cost of Oracle Data Guard switchover**

The Oracle Data Guard switchover feature doesn't incur additional costs. Oracle Database Enterprise Edition includes support for standby databases in mounted mode. To open standby databases in read-only mode, you need the Oracle Active Data Guard option.
How Oracle Data Guard switchover works

Oracle Data Guard switchover is a fully managed operation. You initiate the switchover for a standby database by issuing the CLI command `switchover-read-replica`. Then Amazon RDS modifies the primary and standby roles in your replication configuration.

The original standby and original primary are the roles that exist before the switchover. The new standby and new primary are the roles that exist after the switchover. A bystander replica is a replica database that serves as a standby database in the Oracle Data Guard environment but is not switching roles.

Topics

- Stages of the Oracle Data Guard switchover
- After the Oracle Data Guard switchover

Stages of the Oracle Data Guard switchover

To perform the switchover, Amazon RDS must take the following steps:

1. Block new transactions on the original primary database. During the switchover, Amazon RDS interrupts replication for all databases in your Oracle Data Guard configuration. During the switchover, the original primary database can't process write requests.
2. Ship unapplied transactions to the original standby database, and apply them.
3. Restart the new standby database in read-only or mounted mode. The mode depends on the open state of the original standby database before the switchover.
4. Open the new primary database in read/write mode.

After the Oracle Data Guard switchover

Amazon RDS switches the roles of the primary and standby database. You are responsible for reconnecting your application and performing any other desired configuration.

Topics

- Success criteria
- Connection to the new primary database
- Configuration of the new primary database
Success criteria

The Oracle Data Guard switchover is successful when the original standby database does the following:

- Transitions to its role as new primary database
- Completes its reconfiguration

To limit downtime, your new primary database becomes active as soon as possible. Because Amazon RDS configures bystander replicas asynchronously, these replicas might become active after the original primary database.

Connection to the new primary database

Amazon RDS won't propagate your current database connections to the new primary database after the switchover. After the Oracle Data Guard switchover completes, reconnect your application to the new primary database.

Configuration of the new primary database

To perform a switchover to the new primary database, Amazon RDS changes the mode of the original standby database to open. The change in role is the only change to the database. Amazon RDS doesn't set up features such as Multi-AZ replication.

If you perform a switchover to a cross-Region replica with different options, the new primary database keeps its own options. Amazon RDS won't migrate the options on the original primary database. If the original primary database had options such as SSL, NNE, OEM, and OEM_AGENT, Amazon RDS doesn't propagate them to the new primary database.

Preparing for the Oracle Data Guard switchover

Before initiating the Oracle Data Guard switchover, make sure that your replication environment meets the following requirements:

- The original standby database is mounted or open read-only.
- Automatic backups are enabled on the original standby database.
- The original primary database and the original standby database are in an available state.
- The original primary database and the original standby database have no pending maintenance actions.
• The original standby database is in the replicating state.

• You aren’t attempting to initiate a switchover when either the primary database or standby database is currently in a switchover lifecycle. If a replica database is reconfiguring after a switchover, Amazon RDS prevents you from initiating another switchover.

**Note**

A *bystander replica* is a replica in the Oracle Data Guard configuration that isn't the target of the switchover. Bystander replicas can be in any state during the switchover.

• The original standby database has a configuration that is as close as desired to the original primary database. Assume a scenario where the original primary and original standby databases have different options. After the switchover completes, Amazon RDS doesn't automatically reconfigure the new primary database to have the same options as the original primary database.

• You configure your desired Multi-AZ deployment before initiating a switchover. Amazon RDS doesn't manage Multi-AZ as part of the switchover. The Multi-AZ deployment remains as it is.

Assume that `db_maz` is the primary database in a Multi-AZ deployment, and `db_saz` is a Single-AZ replica. You initiate a switchover from `db_maz` to `db_saz`. Afterward, `db_maz` is a Multi-AZ replica database, and `db_saz` is a Single-AZ primary database. The new primary database is now unprotected by a Multi-AZ deployment.

• In preparation for a cross-Region switchover, the primary database doesn't use the same option group as a DB instance outside of the replication configuration. For a cross-Region switchover to succeed, the current primary database and its read replicas must be the only DB instances to use the option group of the current primary database. Otherwise, Amazon RDS prevents the switchover.

**Initiating the Oracle Data Guard switchover**

You can switch over an RDS for Oracle read replica to the primary role, and the former primary DB instance to a replica role.
To switch over an Oracle read replica to the primary DB role

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the Amazon RDS console, choose Databases.

   The Databases pane appears. Each read replica shows Replica in the Role column.

3. Choose the read replica that you want to switch over to the primary role.

4. For Actions, choose Switch over replica.

5. Choose I acknowledge. Then choose Switch over replica.

6. On the Databases page, monitor the progress of the switchover.

   When the switchover completes, the role of the switchover target changes from Replica to Source.
AWS CLI

To switch over an Oracle replica to the primary DB role, use the AWS CLI `switchover-read-replica` command. The following examples make the Oracle replica named `replica-to-be-made-primary` into the new primary database.

**Example**

For Linux, macOS, or Unix:

```
aws rds switchover-read-replica \
   --db-instance-identifier replica-to-be-made-primary
```

For Windows:

```
aws rds switchover-read-replica ^
   --db-instance-identifier replica-to-be-made-primary
```

RDS API

To switch over an Oracle replica to the primary DB role, call the Amazon RDS API `SwitchoverReadReplica` operation with the required parameter `DBInstanceIdentifier`. This parameter specifies the name of the Oracle replica that you want to assume the primary DB role.

Monitoring the Oracle Data Guard switchover

To check the status of your instances, use the AWS CLI command `describe-db-instances`. The following command checks the status of the DB instance `orcl2`. This database was a standby database before the switchover, but is the new primary database after the switchover.

```
aws rds describe-db-instances \
   --db-instance-identifier orcl2
```

To confirm that the switchover completed successfully, query `V$DATABASE.OPEN_MODE`. Check that the value for the new primary database is `READ WRITE`.

```
SELECT OPEN_MODE FROM V$DATABASE;
```

To look for switchover-related events, use the AWS CLI command `describe-events`. The following example looks for events on the `orcl2` instance.
Troubleshooting RDS for Oracle replicas

This section describes possible replication problems and solutions.

Topics

- Monitoring Oracle replication lag
- Troubleshooting Oracle replication failure after adding or modifying triggers

Monitoring Oracle replication lag

To monitor replication lag in Amazon CloudWatch, view the Amazon RDS ReplicaLag metric. For more information about replication lag time, see Monitoring read replication and Amazon CloudWatch metrics for Amazon RDS.

For a read replica, if the lag time is too long, query the following views:

- V$ARCHIVED_LOG – Shows which commits have been applied to the read replica.
- V$DATAGUARD_STATS – Shows a detailed breakdown of the components that make up the ReplicaLag metric.
- V$DATAGUARD_STATUS – Shows the log output from Oracle's internal replication processes.

For a mounted replica, if the lag time is too long, you can't query the V$ views. Instead, do the following:

- Check the ReplicaLag metric in CloudWatch.
- Check the alert log file for the replica in the console. Look for errors in the recovery messages. The messages include the log sequence number, which you can compare to the primary sequence number. For more information, see Oracle database log files.
Troubleshooting Oracle replication failure after adding or modifying triggers

If you add or modify any triggers, and if replication fails afterward, the problem may be the triggers. Ensure that the trigger excludes the following user accounts, which are required by RDS for replication:

- User accounts with administrator privileges
- SYS
- SYSTEM
- RDS_DATAGUARD
- rdsdb

For more information, see *Miscellaneous considerations for RDS for Oracle replicas.*
Adding options to Oracle DB instances

In Amazon RDS, an option is an additional feature. Following, you can find a description of options that you can add to Amazon RDS instances running the Oracle DB engine.

Topics

• **Overview of Oracle DB options**
• Amazon S3 integration
• Oracle Application Express (APEX)
• Amazon EFS integration
• Oracle Java virtual machine
• Oracle Enterprise Manager
• Oracle Label Security
• Oracle Locator
• Oracle Multimedia
• Oracle native network encryption
• Oracle OLAP
• Oracle Secure Sockets Layer
• Oracle Spatial
• Oracle SQLT
• Oracle Statspack
• Oracle time zone
• Oracle time zone file autoupgrade
• Oracle Transparent Data Encryption
• Oracle UTL_MAIL
• Oracle XML DB

Overview of Oracle DB options

To enable options for your Oracle database, add them to an option group, and then associate the option group with your DB instance. For more information, see [Working with option groups](#).

Topics
Summary of Oracle Database options

You can add the following options for Oracle DB instances.

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>

</tr>
</tbody>
</table>

**Options supported for different editions**

RDS for Oracle prevents you from adding options to an edition if they aren't supported. To find out which RDS options are supported in different Oracle Database editions, use the command `aws rds describe-option-group-options`. The following example lists supported options for Oracle Database 19c Enterprise Edition.

```
aws rds describe-option-group-options \
    --engine-name oracle-ee \
    --major-engine-version 19
```

For more information, see [describe-option-group-options](https://docs.aws.amazon.com/cli/latest/reference/rds/describe-option-group-options.html) in the *AWS CLI Command Reference*.

**Memory requirements for specific options**

Some options require additional memory to run on your DB instance. For example, Oracle Enterprise Manager Database Control uses about 300 MB of RAM. If you enable this option for a small DB instance, you might encounter performance problems due to memory constraints. You can adjust the Oracle parameters so that the database requires less RAM. Alternatively, you can scale up to a larger DB instance.
Amazon S3 integration

You can transfer files between your RDS for Oracle DB instance and an Amazon S3 bucket. You can use Amazon S3 integration with Oracle Database features such as Oracle Data Pump. For example, you can download Data Pump files from Amazon S3 to your RDS for Oracle DB instance. For more information, see [Importing data into Oracle on Amazon RDS](https://docs.aws.amazon.com/rds.amazonaws.com/userguide/rds-importing.html).

**Note**

Your DB instance and your Amazon S3 bucket must be in the same AWS Region.

Topics

- **Configuring IAM permissions for RDS for Oracle integration with Amazon S3**
- **Adding the Amazon S3 integration option**
- **Transferring files between Amazon RDS for Oracle and an Amazon S3 bucket**
- **Troubleshooting Amazon S3 integration**
- **Removing the Amazon S3 integration option**

Configuring IAM permissions for RDS for Oracle integration with Amazon S3

For RDS for Oracle to integrate with Amazon S3, your DB instance must have access to an Amazon S3 bucket. The Amazon VPC used by your DB instance doesn't need to provide access to the Amazon S3 endpoints.

RDS for Oracle supports uploading files from a DB instance in one account to an Amazon S3 bucket in a different account. Where additional steps are required, they are noted in the following sections.

Topics

- **Step 1: Create an IAM policy for your Amazon RDS role**
- **Step 2: (Optional) Create an IAM policy for your Amazon S3 bucket**
- **Step 3: Create an IAM role for your DB instance and attach your policy**
- **Step 4: Associate your IAM role with your RDS for Oracle DB instance**
**Step 1: Create an IAM policy for your Amazon RDS role**

In this step, you create an AWS Identity and Access Management (IAM) policy with the permissions required to transfer files from your Amazon S3 bucket to your RDS DB instance. This step assumes that you have already created an S3 bucket.

Before you create the policy, note the following pieces of information:

- The Amazon Resource Name (ARN) for your bucket
- The ARN for your AWS KMS key, if your bucket uses SSE-KMS or SSE-S3 encryption

**Note**

An RDS for Oracle DB instance can't access Amazon S3 buckets encrypted with SSE-C.

**Console**

**To create an IAM policy to allow Amazon RDS to access your Amazon S3 bucket**

1. Open the [IAM Management Console](https://aws.amazon.com/iam/).
2. Under **Access management**, choose **Policies**.
3. Choose **Create Policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **S3**.
5. For **Actions**, choose **Expand all**, and then choose the bucket permissions and object permissions required to transfer files from an Amazon S3 bucket to Amazon RDS. For example, do the following:

   - Expand **List**, and then select **ListBucket**.
   - Expand **Read**, and then select **GetObject**.
   - Expand **Write**, and then select **PutObject** and **DeleteObject**.
   - Expand **Permissions management**, and then select **PutObjectAcl**. This permission is necessary if you plan to upload files to a bucket owned by a different account, and this account needs full control of the bucket contents.
Object permissions are permissions for object operations in Amazon S3. You must grant them for objects in a bucket, not the bucket itself. For more information, see Permissions for object operations.

6. Choose Resources, and then do the following:
   a. Choose Specific.
   b. For bucket, choose Add ARN. Enter your bucket ARN. The bucket name is filled in automatically. Then choose Add.
   c. If the object resource is shown, either choose Add ARN to add resources manually or choose Any.

   Note
   You can set Amazon Resource Name (ARN) to a more specific ARN value to allow Amazon RDS to access only specific files or folders in an Amazon S3 bucket. For more information about how to define an access policy for Amazon S3, see Managing access permissions to your Amazon S3 resources.

7. (Optional) Choose Add additional permissions to add resources to the policy. For example, do the following:
   a. If your bucket is encrypted with a custom KMS key, select KMS for the service.
   b. For Manual actions, select the following:
      - Encrypt
      - ReEncrypt from and ReEncrypt to
      - Decrypt
      - DescribeKey
      - GenerateDataKey
   c. For Resources, choose Specific.
   d. For key, choose Add ARN. Enter the ARN of your custom key as the resource, and then choose Add.

e. If you want Amazon RDS to access to access other buckets, add the ARNs for these buckets. Optionally, you can also grant access to all buckets and objects in Amazon S3.

8. Choose **Next: Tags** and then **Next: Review**.

9. For **Name**, enter a name for your IAM policy, for example `rds-s3-integration-policy`. You use this name when you create an IAM role to associate with your DB instance. You can also add an optional **Description** value.

10. Choose **Create policy**.

**AWS CLI**

Create an AWS Identity and Access Management (IAM) policy that grants Amazon RDS access to an Amazon S3 bucket. After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step.

Include the appropriate actions in the policy based on the type of access required:

- **GetObject** – Required to transfer files from an Amazon S3 bucket to Amazon RDS.
- **ListBucket** – Required to transfer files from an Amazon S3 bucket to Amazon RDS.
- **PutObject** – Required to transfer files from Amazon RDS to an Amazon S3 bucket.

The following AWS CLI command creates an IAM policy named `rds-s3-integration-policy` with these options. It grants access to a bucket named `your-s3-bucket-arn`.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam create-policy \
  --policy-name rds-s3-integration-policy \
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
```
The following example includes permissions for custom KMS keys.

```bash
aws iam create-policy \
   --policy-name rds-s3-integration-policy \n   --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   {"Sid": "s3integration",
    "Action": ["s3:GetObject",
               "s3:ListBucket",
               "s3:PutObject",
               "kms:Decrypt",
               "kms:Encrypt",
               "kms:ReEncrypt",
               "kms:GenerateDataKey",
               "kms:DescribeKey",
               "kms:DescribeKey",
               "kms:Decrypt"
    ],
    "Effect": "Allow",
    "Resource": ["arn:aws:s3:::/your-s3-bucket-arn",
                 "arn:aws:s3:::/your-s3-bucket-arn/*",
                 "arn:aws:kms:::/your-kms-arn"
    ]
   }
   ]
}'
```
For Windows:

```bash
aws iam create-policy
    --policy-name rds-s3-integration-policy
    --policy-document '{
        "Version": "2012-10-17",
        "Statement": [
            {
                "Sid": "s3integration",
                "Action": [
                    "s3:GetObject",
                    "s3:ListBucket",
                    "s3:PutObject"
                ],
                "Effect": "Allow",
                "Resource": [
                    "arn:aws:s3:::your-s3-bucket-arn",
                    "arn:aws:s3:::your-s3-bucket-arn/*"
                ]
            }
        ]
    }
'}
```

The following example includes permissions for custom KMS keys.

```bash
aws iam create-policy
    --policy-name rds-s3-integration-policy
    --policy-document '{
        "Version": "2012-10-17",
        "Statement": [
            {
                "Sid": "s3integration",
                "Action": [
                    "s3:GetObject",
                    "s3:ListBucket",
                    "s3:PutObject",
                    "kms:Decrypt",
                    "kms:Encrypt",
                    "kms:ReEncrypt",
                    "kms:GenerateDataKey",
                    "kms:DescribeKey",
                    "kms:DescribeKey",
                ],
                "Effect": "Allow",
            }
        ]
    }
'}
```
"Resource": [
    "arn:aws:s3:::your-s3-bucket-arn",
    "arn:aws:s3:::your-s3-bucket-arn/*",
    "arn:aws:kms:::your-kms-arn"
  ]
}

\*

Step 2: (Optional) Create an IAM policy for your Amazon S3 bucket

This step is necessary only in the following conditions:

- You plan to upload files to an Amazon S3 bucket from one account (account A) and access them from a different account (account B).
- Account B owns the bucket.
- Account B needs full control of objects loaded into the bucket.

If the preceding conditions don't apply to you, skip to Step 3: Create an IAM role for your DB instance and attach your policy.

To create your bucket policy, make sure you have the following:

- The account ID for account A
- The user name for account A
- The ARN value for the Amazon S3 bucket in account B

Console

To create or edit a bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the Buckets list, choose the name of the bucket that you want to create a bucket policy for or whose bucket policy you want to edit.
3. Choose Permissions.
4. Under Bucket policy, choose Edit. This opens the Edit bucket policy page.
5. On the Edit bucket policy page, explore Policy examples in the Amazon S3 User Guide, choose Policy generator to generate a policy automatically, or edit the JSON in the Policy section.

If you choose Policy generator, the AWS Policy Generator opens in a new window:

a. On the AWS Policy Generator page, in Select Type of Policy, choose S3 Bucket Policy.

b. Add a statement by entering the information in the provided fields, and then choose Add Statement. Repeat for as many statements as you would like to add. For more information about these fields, see the IAM JSON policy elements reference in the IAM User Guide.

c. After you finish adding statements, choose Generate Policy.

d. Copy the generated policy text, choose Close, and return to the Edit bucket policy page in the Amazon S3 console.

6. In the Policy box, edit the existing policy or paste the bucket policy from the Policy generator. Make sure to resolve security warnings, errors, general warnings, and suggestions before you save your policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Example permissions",
            "Effect": "Allow",
            "Principal": {
            },
            "Action": [
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
            "Resource": [
                "arn:aws:s3:::account-B-bucket-arn",
                "arn:aws:s3:::account-B-bucket-arn/*"
            ]
        }
    ]
}
```
Choose **Save changes**, which returns you to the Bucket Permissions page.

**Step 3: Create an IAM role for your DB instance and attach your policy**

This step assumes that you have created the IAM policy in [Step 1: Create an IAM policy for your Amazon RDS role](#). In this step, you create a role for your RDS for Oracle DB instance and then attach your policy to the role.

**Console**

**To create an IAM role to allow Amazon RDS to access an Amazon S3 bucket**

1. Open the [IAM Management Console](#).
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Choose **AWS service**.
5. For **Use cases for other AWS services**: choose RDS and then **RDS – Add Role to Database**. Then choose **Next**.
6. For **Search** under **Permissions policies**, enter the name of the IAM policy you created in [Step 1: Create an IAM policy for your Amazon RDS role](#), and select the policy when it appears in the list. Then choose **Next**.
7. For **Role name**, enter a name for your IAM role, for example, `rds-s3-integration-role`. You can also add an optional **Description** value.
8. Choose **Create role**.

**AWS CLI**

**To create a role and attach your policy to it**

1. Create an IAM role that Amazon RDS can assume on your behalf to access your Amazon S3 buckets.
We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the [confused deputy problem](#).

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role.

The following AWS CLI command creates the role named `rds-s3-integration-role` for this purpose.

**Example**

For Linux, macOS, or Unix:

```
aws iam create-role \
  --role-name rds-s3-integration-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": my_account_ID,
            "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
          }
        }
      }
    ]
  }
```

For Windows:

```bash
aws iam create-role ^
   --role-name rds-s3-integration-role ^
   --assume-role-policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   {
      "Effect": "Allow",
      "Principal": {
         "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
         "StringEquals": {
            "aws:SourceAccount": my_account_ID,
            "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
         }
      }
   ]
   }
}'
```

For more information, see [Creating a role to delegate permissions to an IAM user](#) in the IAM User Guide.

2. After the role is created, note the ARN of the role. You need the ARN for a subsequent step.
3. Attach the policy you created to the role you created.

The following AWS CLI command attaches the policy to the role named `rds-s3-integration-role`.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam attach-role-policy \
   --policy-arn your-policy-arn \
```

Amazon S3 integration
For Windows:

```bash
aws iam attach-role-policy
  --policy-arn your-policy-arn
  --role-name rds-s3-integration-role
```

Replace `your-policy-arn` with the policy ARN that you noted in a previous step.

### Step 4: Associate your IAM role with your RDS for Oracle DB instance

The last step in configuring permissions for Amazon S3 integration is associating your IAM role with your DB instance. Note the following requirements:

- You must have access to an IAM role with the required Amazon S3 permissions policy attached to it.
- You can only associate one IAM role with your RDS for Oracle DB instance at a time.
- Your DB instance must be in the **Available** state.

#### Console

**To associate your IAM role with your RDS for Oracle DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose **Databases** from the navigation pane.
3. Choose the RDS for Oracle DB instance name to display its details.
4. On the **Connectivity & security** tab, scroll down to the **Manage IAM roles** section at the bottom of the page.
5. For **Add IAM roles to this instance**, choose the role that you created in Step 3: Create an IAM role for your DB instance and attach your policy.
6. For **Feature**, choose **S3_INTEGRATION**.
7. Choose Add role.

**AWS CLI**

The following AWS CLI command adds the role to an Oracle DB instance named *mydbinstance*.

**Example**

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
  --db-instance-identifier mydbinstance \
  --feature-name S3_INTEGRATION \
  --role-arn your-role-arn
```

For Windows:

```
aws rds add-role-to-db-instance ^
  --db-instance-identifier mydbinstance ^
  --feature-name S3_INTEGRATION ^
  --role-arn your-role-arn
```

Replace *your-role-arn* with the role ARN that you noted in a previous step. *S3_INTEGRATION* must be specified for the --feature-name option.

**Adding the Amazon S3 integration option**

To integrate Amazon RDS for Oracle with Amazon S3, your DB instance must be associated with an option group that includes the S3_INTEGRATION option.
Console

To configure an option group for Amazon S3 integration

1. Create a new option group or identify an existing option group to which you can add the S3_INTEGRATION option.

   For information about creating an option group, see Creating an option group.

2. Add the S3_INTEGRATION option to the option group.

   For information about adding an option to an option group, see Adding an option to an option group.

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

   For information about creating a DB instance, see Creating an Amazon RDS DB instance.

   For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

AWS CLI

To configure an option group for Amazon S3 integration

1. Create a new option group or identify an existing option group to which you can add the S3_INTEGRATION option.

   For information about creating an option group, see Creating an option group.

2. Add the S3_INTEGRATION option to the option group.

   For example, the following AWS CLI command adds the S3_INTEGRATION option to an option group named myoptiongroup.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
  --option-group-name myoptiongroup \
  --options OptionName=S3_INTEGRATION,OptionVersion=1.0
```
For Windows:

```
aws rds add-option-to-option-group
   --option-group-name myoptiongroup
   --options OptionName=S3_INTEGRATION,OptionVersion=1.0
```

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an
   RDS for Oracle DB instance to associate the option group with it.

   For information about creating a DB instance, see Creating an Amazon RDS DB instance.

   For information about modifying an RDS for Oracle DB instance, see Modifying an Amazon
   RDS DB instance.

Transferring files between Amazon RDS for Oracle and an Amazon S3 bucket

To transfer files between an RDS for Oracle DB instance and an Amazon S3 bucket, you can use the
Amazon RDS package `rdsadmin_s3_tasks`. You can compress files with GZIP when uploading
them, and decompress them when downloading.

Topics

- Requirements and limitations for file transfers
- Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket
- Downloading files from an Amazon S3 bucket to an Oracle DB instance
- Monitoring the status of a file transfer

Requirements and limitations for file transfers

Before transferring files between your DB instance and an Amazon S3 bucket, note the following:

- The `rdsadmin_s3_tasks` package transfers files located in a single directory. You can't include
  subdirectories in a transfer.
- The maximum object size in an Amazon S3 bucket is 5 TB.
- Tasks created by `rdsadmin_s3_tasks` run asynchronously.
- You can upload files from the Data Pump directory, such as `DATA_PUMP_DIR`, or any user-
  created directory. You can't upload files from a directory used by Oracle background processes,
  such as the adump, bdump, or trace directories.
The download limit is 2000 files per procedure call for download_from_s3. If you need to download more than 2000 files from Amazon S3, split your download into separate actions, with no more than 2000 files per procedure call.

If a file exists in your download folder, and you attempt to download a file with the same name, download_from_s3 skips the download. To remove a file from the download directory, use the PL/SQL procedure UTL_FILE.FREMOVE.

### Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket

To upload files from your DB instance to an Amazon S3 bucket, use the procedure rdsadmin.rdsadmin_s3_tasks.upload_to_s3. For example, you can upload Oracle Recovery Manager (RMAN) backup files or Oracle Data Pump files. For more information about working with objects, see Amazon Simple Storage Service User Guide. For more information about performing RMAN backups, see Performing common RMAN tasks for Oracle DB instances.

The rdsadmin.rdsadmin_s3_tasks.upload_to_s3 procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_bucket_name</td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>The name of the Amazon S3 bucket to upload files to.</td>
</tr>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>The name of the Oracle directory object to upload files from. The directory can be any user-created directory object or the Data Pump directory, such as DATA_PUMP_DIR. You can't upload files from a directory used by background processes, such as adump, bdump, and trace.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
<td>---------</td>
<td>----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>p_s3_prefix</td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>An Amazon S3 file name prefix that files are uploaded to. An empty prefix uploads all files to the top level in the specified Amazon S3 bucket and doesn't add a prefix to the file names. For example, if the prefix is <code>folder_1/oradb</code>, files are uploaded to <code>folder_1</code>. In this case, the <code>oradb</code> prefix is added to each file.</td>
</tr>
<tr>
<td>p_prefix</td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>A file name prefix that file names must match to be uploaded. An empty prefix uploads all files in the specified directory.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-------------</td>
<td>---------</td>
<td>------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>p_compression_level</td>
<td>NUMBER</td>
<td>0</td>
<td>optional</td>
<td>The level of GZIP compression. Valid values range from 0 to 9:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• 0 – No compression</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• 1 – Fastest compression</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• 9 – Highest compression</td>
</tr>
<tr>
<td>p_bucket_owner_full_control</td>
<td>VARCHAR2</td>
<td>–</td>
<td>optional</td>
<td>The access control setting for the bucket. The only valid values are null or FULL_CONTROL. This setting is required only if you upload files from one account (account A) into a bucket owned by a different account (account B), and account B needs full control of the files.</td>
</tr>
</tbody>
</table>

The return value for the `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` procedure is a task ID.

The following example uploads all of the files in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`. The files aren't compressed.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name    =>  'mys3bucket',
    p_prefix         =>  '',
    p_s3_prefix      =>  '',
    p_directory_name =>  'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```
The following example uploads all of the files with the prefix `db` in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`. Amazon RDS applies the highest level of GZIP compression to the files.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name       =>  'mys3bucket',
    p_prefix            =>  'db',
    p_s3_prefix         =>  '',
    p_directory_name    =>  'DATA_PUMP_DIR',
    p_compression_level =>  9
) AS TASK_ID FROM DUAL;
```

The following example uploads all of the files in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`. The files are uploaded to a `dbfiles` folder. In this example, the GZIP compression level is `1`, which is the fastest level of compression.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name       =>  'mys3bucket',
    p_prefix            =>  '',
    p_s3_prefix         =>  'dbfiles/',
    p_directory_name    =>  'DATA_PUMP_DIR',
    p_compression_level =>  1
) AS TASK_ID FROM DUAL;
```

The following example uploads all of the files in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`. The files are uploaded to a `dbfiles` folder and `ora` is added to the beginning of each file name. No compression is applied.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name    =>  'mys3bucket',
    p_prefix         =>  '',
    p_s3_prefix      =>  'dbfiles/ora',
    p_directory_name =>  'DATA_PUMP_DIR'
) AS TASK_ID FROM DUAL;
```

The following example assumes that the command is run in account A, but account B requires full control of the bucket contents. The command `rdsadmin_s3_tasks.upload_to_s3` transfers all files in the `DATA_PUMP_DIR` directory to the bucket named `s3bucketOwnedByAccountB`. Access control is set to `FULL_CONTROL` so that account B can access the files in the bucket. The GZIP compression level is `6`, which balances speed and file size.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name    =>  'mys3bucket',
    p_prefix         =>  '',
    p_s3_prefix      =>  'dbfiles/ora',
    p_directory_name =>  'DATA_PUMP_DIR'
) AS TASK_ID FROM DUAL;
```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name => 's3bucketOwnedByAccountB',
    p_prefix => '',
    p_s3_prefix => '',
    p_directory_name => 'DATA_PUMP_DIR',
    p_bucket_owner_full_control => 'FULL_CONTROL',
    p_compression_level => 6
) AS TASK_ID FROM DUAL;

In each example, the SELECT statement returns the ID of the task in a VARCHAR2 data type.

You can view the result by displaying the task's output file.

SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-task-id.log'));

Replace task-id with the task ID returned by the procedure.

Note
Tasks are executed asynchronously.

Downloading files from an Amazon S3 bucket to an Oracle DB instance

To download files from an Amazon S3 bucket to an RDS for Oracle instance, use the Amazon RDS procedure rdsadmin.rdsadmin_s3_tasks.download_from_s3.

The download_from_s3 procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_bucket_name</td>
<td>VARCHAR</td>
<td>–</td>
<td>Required</td>
<td>The name of the Amazon S3 bucket to download files from.</td>
</tr>
<tr>
<td>p_directory_name</td>
<td>VARCHAR</td>
<td>–</td>
<td>Required</td>
<td>The name of the Oracle directory object to download files to. The directory can be any user-created</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>-----------</td>
<td>---------</td>
<td>----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>directory object or the Data Pump</td>
<td></td>
<td></td>
<td></td>
<td>directory object or the Data Pump directory, such as DATA_PUMP_DIR.</td>
</tr>
<tr>
<td>p_error_on_zero_downloads</td>
<td>VARCHAR</td>
<td>FALSE</td>
<td>Optional</td>
<td>A flag that determines whether the task raises an error when no objects in the Amazon S3 bucket match the prefix.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>If this parameter is not set or set to FALSE (default), the task prints a message that no objects were found, but doesn't raise an exception or fail.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>If this parameter is TRUE, the task raises an exception and fails.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Examples of prefix specifications that can fail match tests are spaces in prefixes, as in ' import/test9.log' , and case mismatches, as in test9.log and test9.LOG.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------</td>
<td>---------</td>
<td>----------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>p_s3_prefix</td>
<td>VARCHAR</td>
<td>–</td>
<td>Required</td>
<td>A file name prefix that file names must match to be downloaded. An empty prefix downloads all of the top level files in the specified Amazon S3 bucket, but not the files in folders in the bucket. The procedure downloads Amazon S3 objects only from the first level folder that matches the prefix. Nested directory structures matching the specified prefix are not downloaded. For example, suppose that an Amazon S3 bucket has the folder structure <code>folder_1/folder_2/folder_3</code>. You specify the <code>'folder_1/folder_2/'</code> prefix. In this case, only the files in <code>folder_2</code> are downloaded, not the files in <code>folder_1</code> or <code>folder_3</code>. If, instead, you specify the <code>'folder_1/folder_2'</code> prefix, all files in <code>folder_1</code> that match the <code>'folder_2'</code> prefix are downloaded, and no files in <code>folder_2</code> are downloaded.</td>
</tr>
<tr>
<td>p_decompression_format</td>
<td>VARCHAR</td>
<td>–</td>
<td>Optional</td>
<td>The decompression format. Valid values are NONE for no decompression and GZIP for decompression.</td>
</tr>
</tbody>
</table>

The return value for the `rdsadmin.rdsadmin_s3_tasks.download_from_s3` procedure is a task ID.
The following example downloads all files in the Amazon S3 bucket named `mys3bucket` to the `DATA_PUMP_DIR` directory. The files aren't compressed, so no decompression is applied.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name    =>  'mys3bucket',
    p_directory_name =>  'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The following example downloads all of the files with the prefix `db` in the Amazon S3 bucket named `mys3bucket` to the `DATA_PUMP_DIR` directory. The files are compressed with GZIP, so decompression is applied. The parameter `p_error_on_zero_downloads` turns on prefix error checking, so if the prefix doesn't match any files in the bucket, the task raises an exception and fails.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name               =>  'mys3bucket',
    p_s3_prefix                 =>  'db',
    p_directory_name            =>  'DATA_PUMP_DIR',
    p_decompression_format      =>  'GZIP',
    p_error_on_zero_downloads   =>  'TRUE')
AS TASK_ID FROM DUAL;
```

The following example downloads all of the files in the folder `myfolder/` in the Amazon S3 bucket named `mys3bucket` to the `DATA_PUMP_DIR` directory. Use the `p_s3_prefix` parameter to specify the Amazon S3 folder. The uploaded files are compressed with GZIP, but aren't decompressed during the download.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name          =>  'mys3bucket',
    p_s3_prefix            =>  'myfolder/',
    p_directory_name       =>  'DATA_PUMP_DIR',
    p_decompression_format =>  'NONE')
AS TASK_ID FROM DUAL;
```

The following example downloads the file `mydumpfile.dmp` in the Amazon S3 bucket named `mys3bucket` to the `DATA_PUMP_DIR` directory. No decompression is applied.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name    =>  'mys3bucket',
    p_s3_prefix      =>  'mydumpfile.dmp',
```
In each example, the SELECT statement returns the ID of the task in a VARCHAR2 data type.

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure.

**Note**

Tasks are executed asynchronously.

You can use the UTL_FILE.FREMOVE Oracle procedure to remove files from a directory. For more information, see [FREMOVE procedure](#) in the Oracle documentation.

**Monitoring the status of a file transfer**

File transfer tasks publish Amazon RDS events when they start and when they complete. The event message contains the task ID for the file transfer. For information about viewing events, see [Viewing Amazon RDS events](#).

You can view the status of an ongoing task in a bdump file. The bdump files are located in the `/rdsdbdata/log/trace` directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

Replace `task-id` with the ID of the task that you want to monitor.

**Note**

Tasks are executed asynchronously.

You can use the `rdsadmin.rds_file_util.read_text_file` stored procedure to view the contents of bdump files. For example, the following query returns the contents of the `dbtask-1234567890123-1234.log` bdump file.
The following sample shows the log file for a failed transfer.

<table>
<thead>
<tr>
<th>TASK_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234567890123-1234</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>TEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td>2023-04-17 18:21:33.993 UTC [INFO] File #1: Uploading the file /rdsdbdata/datapump/A123B4CDEF567890G1234567890H1234/sample.dmp to Amazon S3 with bucket name mys3bucket and key sample.dmp.</td>
</tr>
<tr>
<td>2023-04-17 18:21:34.188 UTC [ERROR] RDS doesn't have permission to write to Amazon S3 bucket name mys3bucket and key sample.dmp.</td>
</tr>
</tbody>
</table>

**Troubleshooting Amazon S3 integration**

For troubleshooting tips, see the AWS re:Post article [How do troubleshoot issues when I integrate Amazon RDS for Oracle with Amazon S3?](https://aws.amazon.com/repost/post).
Removing the Amazon S3 integration option

You can remove Amazon S3 integration option from a DB instance.

To remove the Amazon S3 integration option from a DB instance, do one of the following:

- To remove the Amazon S3 integration option from multiple DB instances, remove the S3_INTEGRATION option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.

- To remove the Amazon S3 integration option from a single DB instance, modify the instance and specify a different option group that doesn't include the S3_INTEGRATION option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.
Oracle Application Express (APEX)

Amazon RDS supports Oracle Application Express (APEX) through the use of the APEX and APEX-DEV options. You can deploy Oracle APEX as a run-time environment or as a full development environment for web-based applications. Using Oracle APEX, you can build applications entirely within the web browser. For more information, see Oracle application Express in the Oracle documentation.

Topics

• APEX components
• APEX version requirements
• Oracle APEX and ORDS requirements and limitations
• Adding the APEX and APEX-DEV options
• Unlocking the public user account
• Configuring RESTful services for Oracle APEX
• Setting up ORDS for Oracle APEX
• Setting up Oracle APEX listener
• Upgrading the APEX version
• Removing the APEX option

APEX components

Oracle APEX consists of the following main components:

• A repository that stores the metadata for APEX applications and components. The repository consists of tables, indexes, and other objects that are installed in your Amazon RDS DB instance.

• A listener that manages HTTP communications with Oracle APEX clients. The listener resides on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. The listener accepts incoming connections from web browsers, forwards them to the Amazon RDS DB instance for processing, and then sends results from the repository back to the browsers. RDS for Oracle supports the following types of listeners:

  • For APEX version 5.0 and later, use Oracle Rest Data Services (ORDS) version 19.1 and higher. We recommend that you use the latest supported version of Oracle APEX and ORDS. This documentation describes older versions for backwards compatibility only.
For APEX version 4.1.1, you can use Oracle APEX Listener version 1.1.4.

You can use Oracle HTTP Server and mod_plsql listeners.

### Note

Amazon RDS doesn't support the Oracle XML DB HTTP server with the embedded PL/SQL gateway; you can't use this as a listener for APEX. In general, Oracle recommends against using the embedded PL/SQL gateway for applications that run on the internet.

For more information about these listener types, see [About choosing a web listener](#) in the Oracle documentation.

When you add the Amazon RDS APEX options to your RDS for Oracle DB instance, Amazon RDS installs the Oracle APEX repository only. Install your listener on a separate host.

### APEX version requirements

The APEX option uses storage on the DB instance class for your DB instance. Following are the supported versions and approximate storage requirements for Oracle APEX.

<table>
<thead>
<tr>
<th>APEX version</th>
<th>Storage requirements</th>
<th>Supported Oracle Database versions</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle APEX version 23.1.v1</td>
<td>106 MiB</td>
<td>19c and higher non-CDBs</td>
<td>This version includes patch 35283657: PSE BUNDLE FOR APEX 23.1 (PSES ON TOP OF 23.1.0), PATCH_VERSION 2.</td>
</tr>
<tr>
<td>Oracle APEX version 22.2.v1</td>
<td>106 MiB</td>
<td>All non-CDBs</td>
<td>This version includes patch 34628174: PSE BUNDLE FOR APEX 22.2 (PSES ON TOP OF 22.2.0), PATCH_VERSION 4.</td>
</tr>
<tr>
<td>Oracle APEX version 22.1.v1</td>
<td>124 MiB</td>
<td>All non-CDBs</td>
<td>This version includes patch 34020981: PSE BUNDLE FOR APEX 22.1 (PSES ON TOP OF 22.1.0), PATCH_VERSION 6.</td>
</tr>
<tr>
<td>APEX version</td>
<td>Storage requirements</td>
<td>Supported Oracle Database versions</td>
<td>Notes</td>
</tr>
<tr>
<td>---------------------</td>
<td>----------------------</td>
<td>-----------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Oracle APEX version 21.2.v1</td>
<td>125 MiB</td>
<td>All</td>
<td>This version includes patch 33420059: PSE BUNDLE FOR APEX 21.2 (PSES ON TOP OF 21.2.0), PATCH_VERSION 8.</td>
</tr>
<tr>
<td>Oracle APEX version 21.1.v1</td>
<td>125 MiB</td>
<td>All</td>
<td>This version includes patch 32598392: PSE BUNDLE FOR APEX 21.1, PATCH_VERSION 3.</td>
</tr>
<tr>
<td>Oracle APEX version 20.2.v1</td>
<td>148 MiB</td>
<td>All except 21c</td>
<td>This version includes patch 32006852: PSE BUNDLE FOR APEX 20.2, PATCH_VERSION 2020.11.12. You can see the patch number and date by running the following query:</td>
</tr>
<tr>
<td>Oracle APEX version 20.1.v1</td>
<td>173 MiB</td>
<td>All except 21c</td>
<td>This version includes patch 30990551: PSE BUNDLE FOR APEX 20.1, PATCH_VERSION 2020.07.15.</td>
</tr>
<tr>
<td>Oracle APEX version 19.2.v1</td>
<td>149 MiB</td>
<td>All except 21c</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 19.1.v1</td>
<td>148 MiB</td>
<td>All except 21c</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 18.2.v1</td>
<td>146 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 18.1.v1</td>
<td>145 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
</tbody>
</table>
### Oracle APEX and ORDS requirements and limitations

Note the following requirements for APEX and ORDS:

- You must use the Java Runtime Environment (JRE).
- Your Oracle client installation must include the following:
  - SQL*Plus or SQL Developer for administration tasks
  - Oracle Net Services for configuring connections to your RDS for Oracle DB instance

Note the following limitations for APEX and ORDS:

- You can't use an RDS for Oracle CDB with ORDS v22 and higher. As a workaround, you can either use a lower version of ORDS or use an Oracle Database 19c non-CDB.

### Adding the APEX and APEX-DEV options

To add the APEX and APEX-DEV options to a DB instance, do the following:

---

<table>
<thead>
<tr>
<th>APEX version</th>
<th>Storage requirements</th>
<th>Supported Oracle Database versions</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle APEX version 5.1.4.v1</td>
<td>220 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 5.1.2.v1</td>
<td>150 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 5.0.4.v1</td>
<td>140 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 4.2.6.v1</td>
<td>160 MiB</td>
<td>12.1 only</td>
<td></td>
</tr>
</tbody>
</table>

For downloadable APEX .zip files, see [Oracle APEX Prior Release Archives](https://oracle.com) on the Oracle website.
1. Create a new option group, or copy or modify an existing option group.

2. Add the APEX and APEX-DEV options to the option group.

3. Associate the option group with the DB instance.

When you add the Amazon RDS APEX options, a brief outage occurs while your DB instance is automatically restarted.

Note
APEX_MAIL is available when the APEX option is installed. The execute privilege for the APEX_MAIL package is granted to PUBLIC so you don't need the APEX administrative account to use it.

To add the APEX options to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the Oracle edition that you want to use. The APEX options are supported on all editions.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see [Creating an option group](#).

2. Add the options to the option group. If you want to deploy only the Oracle APEX run-time environment, add only the APEX option. If you want to deploy the full development environment, add both the APEX and APEX-DEV options. For Oracle Database 12c, add the **APEX** and **APEX-DEV** options.

   For **Version**, choose the version of APEX that you want to use. If you don't choose a version, version 4.2.6.v1 is the default for Oracle Database 12c.
Important

If you add the APEX options to an existing option group that is already attached to one or more DB instances, a brief outage occurs. During this outage, all the DB instances are automatically restarted.

For more information about adding options, see Adding an option to an option group.

3. Apply the option group to a new or existing DB instance:

- For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the APEX options to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance.

Unlocking the public user account

After the Amazon RDS APEX options are installed, make sure to do the following:

1. Change the password for the APEX public user account.
2. Unlock the account.

You can do this by using the Oracle SQL*Plus command line utility. Connect to your DB instance as the master user, and issue the following commands. Replace new_password with a password of your choice.

```
ALTER USER APEX_PUBLIC_USER IDENTIFIED BY new_password;
ALTER USER APEX_PUBLIC_USER ACCOUNT UNLOCK;
```

Configuring RESTful services for Oracle APEX

To configure RESTful services in APEX (not needed for APEX 4.1.1.V1), use SQL*Plus to connect to your DB instance as the master user. After you do this, run the
rdsadmin.rdsadmin_run_apex_rest_config stored procedure. When you run the stored procedure, you provide passwords for the following users:

- APEX_LISTENER
- APEX_REST_PUBLIC_USER

The stored procedure runs the apex_rest_config.sql script, which creates new database accounts for these users.

**Note**

Configuration isn't required for Oracle APEX version 4.1.1.v1. For this Oracle APEX version only, you don't need to run the stored procedure.

The following command runs the stored procedure.

```
EXEC rdsadmin.rdsadmin_run_apex_rest_config('apex_listener_password', 'apex_rest_public_user_password');
```

**Setting up ORDS for Oracle APEX**

You are now ready to install and configure Oracle Rest Data Services (ORDS) for use with Oracle APEX. For APEX version 5.0 and later, use Oracle Rest Data Services (ORDS) version 19.1 and higher.

Install the listener on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. For the examples in this section, we assume that the name of your host is `myapexhost.example.com`, and that your host is running Linux.

**Preparing to install ORDS**

Before you can install ORDS, you need to create a nonprivileged OS user, and then download and unzip the APEX installation file.

**To prepare for ORDS installation**

1. Log in to `myapexhost.example.com` as `root`.
2. Create a nonprivileged OS user to own the listener installation. The following command creates a new user named `apexuser`. 
The following command assigns a password to the new user.

```bash
passwd apexuser;
```

3. Log in to myapexhost.example.com as apexuser, and download the APEX installation file from Oracle to your /home/apexuser directory:

   - Oracle application Express prior release archives

4. Unzip the file in the /home/apexuser directory.

   ```bash
   unzip apex_<version>.zip
   ```

   After you unzip the file, there is an apex directory in the /home/apexuser directory.

### Installing and configuring ORDS

Before you can use APEX, you need to download the ords.war file, use Java to install ORDS, and then start the listener.

**To install and configure ORDS for use with Oracle APEX**

1. Create a new directory based on ORDS, and then unzip the listener file.

   ```bash
   mkdir /home/apexuser/ORDS
   cd /home/apexuser/ORDS
   ```

2. Download the file ords.<version>.number.zip from Oracle REST data services.

3. Unzip the file into the /home/apexuser/ORDS directory.

4. If you're installing ORDS in a multitenant database, add the following line to the file /home/apexuser/ORDS/params/ords_params.properties:
5. Grant the master user the required privileges to install ORDS.

After the Amazon RDS APEX option is installed, give the master user the required privileges to install the ORDS schema. You can do this by connecting to the database and running the following commands. Replace `MASTER_USER` with the uppercase name of your master user.

```
Important
When you enter the user name, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run CREATE USER myuser or CREATE USER MYUSER, the data dictionary stores MYUSER. However, if you use double quotes in CREATE USER "MyUser", the data dictionary stores MyUser. For more information, see Granting SELECT or EXECUTE privileges to SYS objects.
```

```
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_OBJECTS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_ROLE_PRIVS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_TAB_COLUMNS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONS_COLUMNS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONSTRAINTS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_OBJECTS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_PROCEDURES', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TAB_COLUMNS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TABLES', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_VIEWS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('WPIUTL', 'MASTER_USER', 'EXECUTE', true);
```
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SESSION', 'MASTER_USER', 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_UTILITY', 'MASTER_USER', 'EXECUTE', true);

**Note**

These commands apply to ORDS version 19.1 and later.

6. Install the ORDS schema using the downloaded ords.war file.

```java
java -jar ords.war install advanced
```

The program prompts you for the following information. The default values are in brackets. For more information, see [Introduction to Oracle REST data services](https://docs.oracle.com/en/database/oracle/oracle-rest-data-services.html) in the Oracle documentation.

- Enter the location to store configuration data:

  Enter `/home/apexuser/ORDS`. This is the location of the ORDS configuration files.

  Choose the desired connection type.

- Enter the name of the database server [localhost]: `DB_instance_endpoint`

  Choose the default or enter the correct value.

- Enter the database listener port [1521]: `DB_instance_port`

  Choose the default or enter the correct value.

- Enter 1 to specify the database service name, or 2 to specify the database SID [1]:

  Choose 2 to specify the database SID.

- Database SID [xe]

  Choose the default or enter the correct value.

- Enter 1 if you want to verify/install Oracle REST Data Services schema or 2 to skip this step [1]:

Application Express (APEX)
Choose 1. This step creates the Oracle REST Data Services proxy user named ORDS_PUBLIC_USER.

- Enter the database password for ORDS_PUBLIC_USER:
  
Enter the password, and then confirm it.

- Requires to login with administrator privileges to verify Oracle REST Data Services schema.

  Enter the administrator user name: *master_user*

  Enter the database password for *master_user*: *master_user_password*

  Confirm the password: *master_user_password*

  **Note**
  
  Specify a password other than the prompt shown here as a security best practice.

- Enter the default tablespace for ORDS_METADATA [SYSAUX].

- Enter the temporary tablespace for ORDS_METADATA [TEMP].

- Enter the default tablespace for ORDS_PUBLIC_USER [USERS].

- Enter the temporary tablespace for ORDS_PUBLIC_USER [TEMP].

- Enter 1 if you want to use PL/SQL Gateway or 2 to skip this step. If you're using Oracle Application Express or migrating from mod_plsql, you must enter 1 [1].

  Choose the default.

- Enter the PL/SQL Gateway database user name [APEX_PUBLIC_USER]

  Choose the default.

- Enter the database password for APEX_PUBLIC_USER:

  Enter the password, and then confirm it.

- Enter 1 to specify passwords for Application Express RESTful Services database users (APEX_LISTENER, APEX_REST_PUBLIC_USER) or 2 to skip this step [1]:

  Choose 2 for APEX 4.1.1.V1; choose 1 for all other APEX versions.
• [Not needed for APEX 4.1.1.v1] Database password for APEX_LISTENER

Enter the password (if required), and then confirm it.

• [Not needed for APEX 4.1.1.v1] Database password for APEX_REST_PUBLIC_USER

Enter the password (if required), and then confirm it.

• Enter a number to select a feature to enable:

Enter 1 to enable all features: SQL Developer Web, REST Enabled SQL, and Database API.

• Enter 1 if you wish to start in standalone mode or 2 to exit [1]:

Enter 1.

• Enter the APEX static resources location:

If you unzipped APEX installation files into /home/apexuser, enter /home/apexuser/apex/images. Otherwise, enter unzip_path/apex/images, where unzip_path is the directory where you unzipped the file.

• Enter 1 if using HTTP or 2 if using HTTPS [1]:

If you enter 1, specify the HTTP port. If you enter 2, specify the HTTPS port and the SSL host name. The HTTPS option prompts you to specify how you will provide the certificate:

• Enter 1 to use the self-signed certificate.

• Enter 2 to provide your own certificate. If you enter 2, specify the path for the SSL certificate and the path for the SSL certificate private key.

7. Set a password for the APEX admin user. To do this, use SQL*Plus to connect to your DB instance as the master user, and then run the following commands.

```sql
EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
grant APEX_ADMINISTRATOR_ROLE to master;
@/home/apexuser/apex/apxchpwd.sql
```

Replace `master` with your master user name. When the apxchpwd.sql script prompts you, enter a new admin password.

8. Start the ORDS listener. Run the following code.

```bash
java -jar ords.war
```
The first time you start ORDS, you are prompted to provide the location of the APEX Static resources. This images folder is located in the /apex/images directory in the installation directory for APEX.

9. Return to the APEX administration window in your browser and choose Administration. Next, choose Application Express Internal Administration. When you are prompted for credentials, enter the following information:

- **User name** – admin
- **Password** – the password you set using the apxchpwd.sql script

Choose Login, and then set a new password for the admin user.

Your listener is now ready for use.

**Setting up Oracle APEX listener**

ℹ️ **Note**

Oracle APEX Listener is deprecated.

Amazon RDS for Oracle continues to support APEX version 4.1.1 and Oracle APEX Listener version 1.1.4. We recommend that you use the latest supported versions of Oracle APEX and ORDS.

Install Oracle APEX Listener on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. We assume that the name of your host is myapexhost.example.com, and that your host is running Linux.

**Preparing to install Oracle APEX listener**

Before you can install Oracle APEX Listener, you need to create a nonprivileged OS user, and then download and unzip the APEX installation file.

**To prepare for Oracle APEX listener installation**

1. Log in to myapexhost.example.com as root.
2. Create a nonprivileged OS user to own the listener installation. The following command creates a new user named apexuser.
useradd -d /home/apexuser apexuser

The following command assigns a password to the new user.

passwd apexuser;

3. Log in to myapexhost.example.com as apexuser, and download the APEX installation file from Oracle to your /home/apexuser directory:

   - [Oracle application Express prior release archives](#)

4. Unzip the file in the /home/apexuser directory.

   unzip apex_<version>.zip

   After you unzip the file, there is an apex directory in the /home/apexuser directory.

5. While you are still logged into myapexhost.example.com as apexuser, download the Oracle APEX Listener file from Oracle to your /home/apexuser directory.

### Installing and configuring Oracle APEX listener

Before you can use APEX, you need to download the apex.war file, use Java to install Oracle APEX Listener, and then start the listener.

**To install and configure Oracle APEX listener**

1. Create a new directory based on Oracle APEX Listener and open the listener file.

   Run the following code:

   ```
   mkdir /home/apexuser/apexlistener
   cd /home/apexuser/apexlistener
   unzip ../apex_listener.<version>.zip
   ```

2. Run the following code.

   ```
   java -Dapex.home=./apex -Dapex.images=/home/apexuser/apex/images -Dapex.erase -jar ./apex.war
   ```
3. Enter information for the program prompts following:

   • The APEX Listener Administrator user name. The default is adminlistener.
   • A password for the APEX Listener Administrator.
   • The APEX Listener Manager user name. The default is managerlistener.
   • A password for the APEX Listener Administrator.

   The program prints a URL that you need to complete the configuration, as follows.

   INFO: Please complete configuration at: http://localhost:8080/apex/listenerConfigure
   Database is not yet configured

4. Leave Oracle APEX Listener running so that you can use Oracle Application Express. When you have finished this configuration procedure, you can run the listener in the background.

5. From your web browser, go to the URL provided by the APEX Listener program. The Oracle Application Express Listener administration window appears. Enter the following information:

   • Username – APEX_PUBLIC_USER
   • Password – the password for APEX_PUBLIC_USER. This password is the one that you specified earlier when you configured the APEX repository. For more information, see Unlocking the public user account.
   • Connection type – Basic
   • Hostname – the endpoint of your Amazon RDS DB instance, such as mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com.
   • Port – 1521
   • SID – the name of the database on your Amazon RDS DB instance, such as mydb.

6. Choose Apply. The APEX administration window appears.

7. Set a password for the APEX admin user. To do this, use SQL*Plus to connect to your DB instance as the master user, and then run the following commands.

   EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
   grant APEX_ADMINISTRATOR_ROLE to master;
   @/home/apexuser/apex/apxchpwd.sql
Replace `master` with your master user name. When the `apxchpwd.sql` script prompts you, enter a new admin password.

8. Return to the APEX administration window in your browser and choose **Administration**. Next, choose **Application Express Internal Administration**. When you are prompted for credentials, enter the following information:

- **User name** – `admin`
- **Password** – the password you set using the `apxchpwd.sql` script

Choose **Login**, and then set a new password for the admin user.

Your listener is now ready for use.

### Upgrading the APEX version

⚠️ **Important**

Back up your DB instance before you upgrade APEX. For more information, see [Creating a DB snapshot for a Single-AZ DB instance](#) and [Testing an Oracle DB upgrade](#).

To upgrade APEX with your DB instance, do the following:

- Create a new option group for the upgraded version of your DB instance.
- Add the upgraded versions of APEX and APEX-DEV to the new option group. Be sure to include any other options that your DB instance uses. For more information, see [Option group considerations](#).
- When you upgrade your DB instance, specify the new option group for your upgraded DB instance.

After you upgrade your version of APEX, the APEX schema for the previous version might still exist in your database. If you don't need it anymore, you can drop the old APEX schema from your database after you upgrade.
If you upgrade the APEX version and RESTful services were not configured in the previous APEX version, we recommend that you configure RESTful services. For more information, see Configuring RESTful services for Oracle APEX.

In some cases when you plan to do a major version upgrade of your DB instance, you might find that you're using an APEX version that isn't compatible with your target database version. In these cases, you can upgrade your version of APEX before you upgrade your DB instance. Upgrading APEX first can reduce the amount of time that it takes to upgrade your DB instance.

ℹ️ Note
After upgrading APEX, install and configure a listener for use with the upgraded version. For instructions, see Setting up Oracle APEX listener.

Removing the APEX option

You can remove the Amazon RDS APEX options from a DB instance. To remove the APEX options from a DB instance, do one of the following:

- To remove the APEX options from multiple DB instances, remove the APEX options from the option group they belong to. This change affects all DB instances that use the option group. When you remove the APEX options from an option group that is attached to multiple DB instances, a brief outage occurs while all the DB instances are restarted.
  
  For more information, see Removing an option from an option group.

- To remove the APEX options from a single DB instance, modify the DB instance and specify a different option group that doesn't include the APEX options. You can specify the default (empty) option group, or a different custom option group. When you remove the APEX options, a brief outage occurs while your DB instance is automatically restarted.

  For more information, see Modifying an Amazon RDS DB instance.

When you remove the APEX options from a DB instance, the APEX schema is removed from your database.
Amazon Elastic File System (Amazon EFS) provides serverless, fully elastic file storage so that you can share file data without provisioning or managing storage capacity and performance. With Amazon EFS, you can create a file system and then mount it in your VPC through the NFS versions 4.0 and 4.1 (NFSv4) protocol. Then you can use the EFS file system like any other POSIX-compliant file system. For general information, see What is Amazon Elastic File System? and the AWS blog Integrate Amazon RDS for Oracle with Amazon EFS.

**Topics**

- **Overview of Amazon EFS integration**
- **Configuring network permissions for RDS for Oracle integration with Amazon EFS**
- **Configuring IAM permissions for RDS for Oracle integration with Amazon EFS**
- **Adding the EFS_INTEGRATION option**
- **Configuring Amazon EFS file system permissions**
- **Transferring files between RDS for Oracle and an Amazon EFS file system**
- **Removing the EFS_INTEGRATION option**
- **Troubleshooting Amazon EFS integration**

**Overview of Amazon EFS integration**

With Amazon EFS, you can transfer files between your RDS for Oracle DB instance and an EFS file system. For example, you can use EFS to support the following use cases:

- Share a file system between applications and multiple database servers.
- Create a shared directory for migration-related files, including transportable tablespace data files. For more information, see Migrating using Oracle transportable tablespaces.
- Store and share archived redo log files without allocating additional storage space on the server.
- Use Oracle Database utilities such as UTL_FILE to read and write files.

**Advantages to Amazon EFS integration**

When you choose an EFS file system over alternative data transfer solutions, you get the following benefits:
• You can transfer Oracle Data Pump files between Amazon EFS and your RDS for Oracle DB instance. You don’t need to copy these files locally because Data Pump imports directly from the EFS file system. For more information, see Importing data into Oracle on Amazon RDS.

• Data migration is faster than using a database link.

• You avoid allocating storage space on your RDS for Oracle DB instance to hold the files.

• An EFS file systems can automatically scale storage without requiring you to provision it.

• Amazon EFS integration has no minimum fees or setup costs. You pay only for what you use.

**Requirements for Amazon EFS integration**

Make sure that you meet the following requirements:

• Your database runs database version 19.0.0.0.ru-2022-07.rur-2022-07.r1 or later.

• Your DB instance and your EFS file system are in the same AWS Region and the same VPC.

• Your VPC has the **enableDnsSupport** attribute enabled. For more information, see DNS attributes in your VPC in the Amazon Virtual Private Cloud User Guide.

• Your EFS file system uses the Standard or Standard-IA storage class.

• To be able to use a DNS name in the *mount* command, the following must be true:
  • The connecting DB instance is inside a VPC and is configured to use the DNS server provided by Amazon. Custom DNS servers aren't supported.
  • The VPC of the connecting instance must have both DNS Resolution and DNS Hostnames enabled.
  • The connecting instance must be inside the same VPC as the EFS file system.

• You use non-RDS solutions to back up your EFS file system. RDS for Oracle doesn't support automated backups or manual DB snapshots of an EFS file system. For more information, see Backing up your Amazon EFS file systems.

**Configuring network permissions for RDS for Oracle integration with Amazon EFS**

For RDS for Oracle to integrate with Amazon EFS, make sure that your DB instance has network access to an EFS file system. For more information, see Controlling network access to Amazon EFS file systems for NFS clients in the Amazon Elastic File System User Guide.

**Topics**
Controlling network access with security groups

You can control your DB instance access to EFS file systems using network layer security mechanisms such as VPC security groups. To allow access to an EFS file system for your DB instance, make sure that your EFS file system meets the following requirements:

- An EFS mount target exists in every Availability Zone used by an RDS for Oracle DB instance.

  An EFS mount target provides an IP address for an NFSv4 endpoint at which you can mount an EFS file system. You mount your file system using its DNS name, which resolves to the IP address of the EFS mount target in the used by the Availability Zone of your DB instance.

  You can configure DB instances in different AZs to use the same EFS file system. For Multi-AZ, you need a mount point for each AZ in your deployment. You might need to move a DB instance to a different AZ. For these reasons, we recommend that you create an EFS mount point in each AZ in your VPC. By default, when you create a new EFS file system using the console, RDS creates mount targets for all AZs.

- A security group is attached to the mount target.

- The security group has an inbound rule to allow the network subnet or security group of the RDS for Oracle DB instance on TCP/2049 (Type NFS).

For more information, see Creating Amazon EFS file systems and Creating and managing EFS mount targets and security groups in the Amazon Elastic File System User Guide.

Controlling network access with file system policies

Amazon EFS integration with RDS for Oracle works with the default (empty) EFS file system policy. The default policy doesn’t use IAM to authenticate. Instead, it grants full access to any anonymous client that can connect to the file system using a mount target. The default policy is in effect whenever a user-configured file system policy isn’t in effect, including at file system creation. For more information, see Default EFS file system policy in the Amazon Elastic File System User Guide.

To strengthen access to your EFS file system for all clients, including RDS for Oracle, you can configure IAM permissions. In this approach, you create a file system policy. For more information, see Creating file system policies in the Amazon Elastic File System User Guide.
Configuring IAM permissions for RDS for Oracle integration with Amazon EFS

By default, Amazon EFS integration feature doesn't use an IAM role: the USE_IAM_ROLE option setting is FALSE. To integrate RDS for Oracle with Amazon EFS and an IAM role, your DB instance must have IAM permissions to access an Amazon EFS file system.

Topics

- Step 1: Create an IAM role for your DB instance and attach your policy
- Step 2: Create a file system policy for your Amazon EFS file system
- Step 3: Associate your IAM role with your RDS for Oracle DB instance

Step 1: Create an IAM role for your DB instance and attach your policy

In this step, you create a role for your RDS for Oracle DB instance to allow Amazon RDS to access your EFS file system.

Console

To create an IAM role to allow Amazon RDS access to an EFS file system

1. Open the IAM Management Console.
2. In the navigation pane, choose Roles.
3. Choose Create role.
4. For AWS service, choose RDS.
5. For Select your use case, choose RDS – Add Role to Database.
6. Choose Next.
7. Don't add any permissions policies. Choose Next.
8. Set Role name to a name for your IAM role, for example rds-efs-integration-role. You can also add an optional Description value.
9. Choose Create role.

AWS CLI

To limit the service's permissions to a specific resource, we recommend using the aws:SourceArn and aws:SourceAccount global condition context keys in resource-based trust relationships. This is the most effective way to protect against the confused deputy problem.
You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role.

The following AWS CLI command creates the role named `rds-efs-integration-role` for this purpose.

**Example**

For Linux, macOS, or Unix:

```
aws iam create-role \
  --role-name rds-efs-integration-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": "my_account_ID",
            "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
          }
        }
      }
    ]
  }

For Windows:
aws iam create-role
--role-name rds-efs-integration-role
--assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": my_account_ID,
                    "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
                }
            }
        }
    ]
}'

For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

Step 2: Create a file system policy for your Amazon EFS file system

In this step, you create a file system policy for your EFS file system.

To create or edit an EFS file system policy

1. Open the EFS Management Console.
3. On the File systems page, choose the file system that you want to edit or create a file system policy for. The details page for that file system is displayed.
4. Choose the File system policy tab.

   If the policy is empty, then the default EFS file system policy is in use. For more information, see Default EFS file system policy in the Amazon Elastic File System User Guide.
5. Choose Edit. The File system policy page appears.
6. In Policy editor, enter a policy such as the following, and then choose Save.
Step 3: Associate your IAM role with your RDS for Oracle DB instance

In this step, you associate your IAM role with your DB instance. Be aware of the following requirements:

- You must have access to an IAM role with the required Amazon EFS permissions policy attached to it.
- You can associate only one IAM role with your RDS for Oracle DB instance at a time.
- The status of your instance must be Available.

For more information, see Identity and access management for Amazon EFS in the Amazon Elastic File System User Guide.
Console

To associate your IAM role with your RDS for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases.
3. If your database instance is unavailable, choose Actions and then Start. When the instance status shows Started, go to the next step.
4. Choose the Oracle DB instance name to display its details.
5. On the Connectivity & security tab, scroll down to the Manage IAM roles section at the bottom of the page.
6. Choose the role to add in the Add IAM roles to this instance section.
7. For Feature, choose EFS_INTEGRATION.
8. Choose Add role.

AWS CLI

The following AWS CLI command adds the role to an Oracle DB instance named mydbinstance.

Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
    --db-instance-identifier mydbinstance \
    --feature-name EFS_INTEGRATION \
    --role-arn your-role-arn
```

For Windows:

```
aws rds add-role-to-db-instance ^
    --db-instance-identifier mydbinstance ^
    --feature-name EFS_INTEGRATION ^
    --role-arn your-role-arn
```

Replace your-role-arn with the role ARN that you noted in a previous step. EFS_INTEGRATION must be specified for the --feature-name option.
Adding the EFS_INTEGRATION option

To integrate Amazon RDS for Oracle with Amazon EFS, your DB instance must be associated with an option group that includes the EFS_INTEGRATION option.

Multiple Oracle DB instances that belong to the same option group share the same EFS file system. Different DB instances can access the same data, but access can be divided by using different Oracle directories. For more information see Transferring files between RDS for Oracle and an Amazon EFS file system.

Console

To configure an option group for Amazon EFS integration

1. Create a new option group or identify an existing option group to which you can add the EFS_INTEGRATION option.

   For information about creating an option group, see Creating an option group.

2. Add the EFS_INTEGRATION option to the option group. You need to specify the EFS_ID file system ID and set the USE_IAM_ROLE flag.

   For more information, see Adding an option to an option group.

3. Associate the option group with your DB instance in either of the following ways:

   • Create a new Oracle DB instance and associate the option group with it. For information about creating a DB instance, see Creating an Amazon RDS DB instance.

   • Modify an Oracle DB instance to associate the option group with it. For information about modifying an Oracle DB instance, see Modifying an Amazon RDS DB instance.

AWS CLI

To configure an option group for EFS integration

1. Create a new option group or identify an existing option group to which you can add the EFS_INTEGRATION option.

   For information about creating an option group, see Creating an option group.

2. Add the EFS_INTEGRATION option to the option group.
For example, the following AWS CLI command adds the EFS_INTEGRATION option to an option group named myoptiongroup.

Example

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
  --option-group-name myoptiongroup \
  --options "OptionName=EFS_INTEGRATION,OptionSettings="\n  [{Name=EFS_ID,Value=fs-1234567890abcdef0},{Name=USE_IAM_ROLE,Value=TRUE}]"
```

For Windows:

```bash
aws rds add-option-to-option-group ^
  --option-group-name myoptiongroup ^
  --options "OptionName=EFS_INTEGRATION,OptionSettings="^\n  [{Name=EFS_ID,Value=fs-1234567890abcdef0},{Name=USE_IAM_ROLE,Value=TRUE}]"
```

3. Associate the option group with your DB instance in either of the following ways:

   - Create a new Oracle DB instance and associate the option group with it. For information about creating a DB instance, see Creating an Amazon RDS DB instance.
   - Modify an Oracle DB instance to associate the option group with it. For information about modifying an Oracle DB instance, see Modifying an Amazon RDS DB instance.

Configuring Amazon EFS file system permissions

By default, only the root user (UID 0) has read, write, and execute permissions for a newly created EFS file system. For other users to modify the file system, the root user must explicitly grant them access. The user for the RDS for Oracle DB instance is in the others category. For more information, see Working with users, groups, and permissions at the Network File System (NFS) Level in the Amazon Elastic File System User Guide.

To allow your RDS for Oracle DB instance to read and write files on an EFS file system, do the following:

   - Mount an EFS file system locally on your Amazon EC2 or on-premises instance.
   - Configure fine grain permissions.
For example, to grant other users permissions to write to the EFS file system root, run chmod 777 on this directory. For more information, see Example Amazon EFS file system use cases and permissions in the Amazon Elastic File System User Guide.

Transferring files between RDS for Oracle and an Amazon EFS file system

To transfer files between an RDS for Oracle instance and an Amazon EFS file system, create at least one Oracle directory and configure EFS file system permissions to control DB instance access.

Topics

- Creating an Oracle directory
- Transferring data to and from an EFS file system: examples

Creating an Oracle directory

To create an Oracle directory, use the procedure rdsadmin.rdsadmin_util.create_directory_efs. The procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>–</td>
<td>Yes</td>
<td>The name of the Oracle directory.</td>
</tr>
<tr>
<td>p_path_on_efs</td>
<td>VARCHAR2</td>
<td>–</td>
<td>Yes</td>
<td>The path on the EFS file system. The prefix of the path name uses the pattern <code>/rdsefs-&lt;fsid&gt;/</code>, where <code>&lt;fsid&gt;</code> is a placeholder for your EFS file system ID. For example, if your EFS file system is named <code>fs-1234567890abcdef0</code>, and you create a subdirectory on this file system named <code>mydir</code>, you could specify the following value: /rdsefs-fs-1234567890abcdef0/mydir</td>
</tr>
</tbody>
</table>
Assume that you create a subdirectory named /datapump1 on the EFS file system
fs-1234567890abcdef0. The following example creates an Oracle directory
DATA_PUMP_DIR_EFS that points to the /datapump1 directory on the EFS file system. The file
system path value for the p_path_on_efs parameter is prefixed with the string /rdsefs-.

BEGIN
    rdsadmin.rdsadmin_util.create_directory_efs(
        p_directory_name => 'DATA_PUMP_DIR_EFS',
        p_path_on_efs    => '/rdsefs-fs-1234567890abcdef0/datapump1');
END;
/

Transferring data to and from an EFS file system: examples

The following example uses Oracle Data Pump to export the table named MY_TABLE to file
datapump.dmp. This file resides on an EFS file system.

DECLARE
    v_hdnl NUMBER;
BEGIN
    v_hdnl := DBMS_DATAPUMP.OPEN(operation => 'EXPORT', job_mode => 'TABLE',
                                   job_name=>null);
    DBMS_DATAPUMP.ADD_FILE(
        handle    => v_hdnl,
        filename  => 'datapump.dmp',
        directory => 'DATA_PUMP_DIR_EFS',
        filetype  => dbms_datapump.ku$_file_type_dump_file);
    DBMS_DATAPUMP.ADD_FILE(
        handle    => v_hdnl,
        filename  => 'datapump-exp.log',
        directory => 'DATA_PUMP_DIR_EFS',
        filetype  => dbms_datapump.ku$_file_type_log_file);
    DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'NAME_EXPR','IN (''MY_TABLE'')');
    DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/

The following example uses Oracle Data Pump to import the table named MY_TABLE from file
datapump.dmp. This file resides on an EFS file system.

DECLARE
v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode => 'TABLE',
    job_name => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdnl,
    filename => 'datapump.dmp',
    directory => 'DATA_PUMP_DIR_EFS',
    filetype => dbms_datapump.ku$_file_type_dump_file);
  DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdnl,
    filename => 'datapump-imp.log',
    directory => 'DATA_PUMP_DIR_EFS',
    filetype => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'NAME_EXPR','IN (''MY_TABLE'')');
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/

For more information, see Importing data into Oracle on Amazon RDS.

Removing the EFS_INTEGRATION option

To remove the EFS_INTEGRATION option from an RDS for Oracle DB instance, do one of the following:

- To remove the EFS_INTEGRATION option from multiple DB instances, remove the EFS_INTEGRATION option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.

- To remove the EFS_INTEGRATION option from a single DB instance, modify the instance and specify a different option group that doesn't include the EFS_INTEGRATION option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.
Troubleshooting Amazon EFS integration

Your RDS for Oracle DB instance monitors the connectivity to an Amazon EFS file system. When monitoring detects an issue, it might try to correct the issue and publish an event in the RDS console. For more information, see Viewing Amazon RDS events.

Use the information in this section to help you diagnose and fix common issues when you work with Amazon EFS integration.

<table>
<thead>
<tr>
<th>Notification</th>
<th>Description</th>

</tr>
<tr>
<td></td>
<td></td>
<td>• The connecting instance must be inside the same VPC as the EFS file system.</td>
</tr>
</tbody>
</table>
Oracle Java virtual machine

Amazon RDS supports Oracle Java Virtual Machine (JVM) through the use of the JVM option. Oracle Java provides a SQL schema and functions that facilitate Oracle Java features in an Oracle database. For more information, see Introduction to Java in Oracle database in the Oracle documentation.

You can use Oracle JVM with the following Oracle Database versions:

- Oracle Database 21c (21.0.0), all versions
- Oracle Database 19c (19.0.0), all versions
- Oracle Database 12c Release 2 (12.2), all versions
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v13 and higher

Java implementation in Amazon RDS has a limited set of permissions. The master user is granted the RDS_JAVA_ADMIN role, which grants a subset of the privileges granted by the JAVA_ADMIN role. To list the privileges granted to the RDS_JAVA_ADMIN role, run the following query on your DB instance:

```sql
SELECT * FROM dba_java_policy
WHERE grantee IN ('RDS_JAVA_ADMIN', 'PUBLIC')
AND enabled = 'ENABLED'
ORDER BY type_name, name, grantee;
```

Prerequisites for Oracle JVM

The following are prerequisites for using Oracle Java:

- Your DB instance must be of a large enough class. Oracle Java isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see DB instance classes.

- Your DB instance must have **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available. Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance.
Best practices for Oracle JVM

The following are best practices for using Oracle Java:

- For maximum security, use the JVM option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer.
- Configure your DB instance to restrict network access. For more information, see Scenarios for accessing a DB instance in a VPC and Working with a DB instance in a VPC.
- Update the configuration of your HTTPS endpoints to support TLSv1.2 if you meet the following conditions:
  - You use Oracle Java Virtual Machine (JVM) to connect an HTTPS endpoint over TLSv1 or TLSv1.1 protocols.
  - Your endpoint doesn't support the TLSv1.2 protocol.
  - You haven't applied the April 2021 release update to your Oracle DB.

By updating your endpoint configuration, you ensure that the connectivity of the JVM to the HTTPS endpoint will continue to work. For more information about TLS changes in the Oracle JRE and JDK, see Oracle JRE and JDK Cryptographic Roadmap.

Adding the Oracle JVM option

The following is the general process for adding the JVM option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

There is a brief outage while the JVM option is added. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Java is available.

Note

During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.
To add the JVM option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   - For **Engine**, choose the DB engine used by the DB instance (**oracle-ee**, **oracle-se**, **oracle-se1**, or **oracle-se2**).
   - For **Major engine version**, choose the version of your DB instance.

   For more information, see [Creating an option group](#).

2. Add the **JVM** option to the option group. For more information about adding options, see [Adding an option to an option group](#).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).

4. Grant the required permissions to users.

   The Amazon RDS master user has the permissions to use the JVM option by default. If other users require these permissions, connect to the DB instance as the master user in a SQL client and grant the permissions to the users.

   The following example grants the permissions to use the JVM option to the test_proc user.

   ```sql
   create user test_proc identified by password;
   CALL dbms_java.grant_permission('TEST_PROC', 'oracle.aurora.security.JServerPermission', 'LoadClassInPackage.*', '');
   ```

   **Note**
   Specify a password other than the prompt shown here as a security best practice.
After the user is granted the permissions, the following query should return output.

```sql
select * from dba_java_policy where grantee='TEST_PROC';
```

**Note**

The Oracle user name is case-sensitive, and it usually has all uppercase characters.

**Removing the Oracle JVM option**

You can remove the JVM option from a DB instance. There is a brief outage while the option is removed. After you remove the JVM option, you don't need to restart your DB instance.

**Warning**

Removing the JVM option can result in data loss if the DB instance is using data types that were enabled as part of the option. Back up your data before proceeding. For more information, see [Backing up, restoring, and exporting data](#).

To remove the JVM option from a DB instance, do one of the following:

- Remove the JVM option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#).

- Modify the DB instance and specify a different option group that doesn't include the JVM option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](#).
Amazon RDS supports Oracle Enterprise Manager (OEM). OEM is the Oracle product line for integrated management of enterprise information technology.

Amazon RDS supports OEM through the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>
<th>Supported OEM releases</th>
<th>Supported Oracle Database releases</th>
</tr>
</thead>
<tbody>
<tr>
<td>OEM Database Express</td>
<td>OEM</td>
<td>OEM Database Express 12c</td>
<td>Oracle Database 19c (non-CDB only)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Oracle Database 12c</td>
</tr>
<tr>
<td>OEM Management Agent</td>
<td>OEM_AGENT</td>
<td>OEM Cloud Control for 13c</td>
<td>Oracle Database 19c (non-CDB only)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>OEM Cloud Control for 12c</td>
<td>Oracle Database 12c</td>
</tr>
</tbody>
</table>

**Note**

You can use OEM Database or OEM Management Agent, but not both.

**Note**

These options aren't supported for the Oracle multitenant architecture.
Oracle Enterprise Manager Database Express

Amazon RDS supports Oracle Enterprise Manager (OEM) Database Express through the use of the OEM option. Amazon RDS supports Oracle Enterprise Manager Database Express for the following releases:

- Oracle Database 19c (non-CDB only)
- Oracle Database 12c

OEM Database Express and Database Control are similar tools that have a web-based interface for Oracle database administration. For more information about these tools, see Accessing Enterprise Manager database Express 18c and Accessing Enterprise Manager Database Express 12c in the Oracle documentation.

The following is a limitation for OEM Database Express:

- OEM Database Express isn't supported on the db.t3.micro or db.t3.small DB instance classes.

For more information about DB instance classes, see RDS for Oracle instance classes.

OEM Database option settings

Amazon RDS supports the following settings for the OEM option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>An integer value</td>
<td>The port on the DB instance that listens for OEM Database. The default for OEM Database Express is 5500.</td>
</tr>
<tr>
<td>Security Groups</td>
<td>—</td>
<td>A security group that has access to Port.</td>
</tr>
</tbody>
</table>

Adding the OEM Database option

The general process for adding the OEM option to a DB instance is the following:
1. Create a new option group, or copy or modify an existing option group.

2. Add the option to the option group.

3. Associate the option group with the DB instance.

When you add the OEM option for an Oracle Database 12c or later DB instance, a brief outage occurs while your DB instance is automatically restarted.

To add the OEM option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine** choose the oracle edition for your DB instance.
   b. For **Major engine version** choose the version of your DB instance.

   For more information, see [Creating an option group](#).

2. Add the OEM option to the option group, and configure the option settings. For more information about adding options, see [Adding an option to an option group](#). For more information about each setting, see [OEM Database option settings](#).

   **Note**
   
   If you add the OEM option to an existing option group that is already attached to one or more Oracle Database 19c (non-CDB only) or Oracle Database 12c DB instances, a brief outage occurs while all the DB instances are automatically restarted.

3. Apply the option group to a new or existing DB instance:
   
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the OEM option for an Oracle Database 19c (non-CDB only) or Oracle Database 12c DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see [Modifying an Amazon RDS DB instance](#).
Note

You can also use the AWS CLI to add the OEM option. For examples, see Adding an option to an option group.

Accessing OEM through your browser

After you enable the OEM option, you can begin using the OEM Database tool from your web browser.

You can access either OEM Database Control or OEM Database Express from your web browser. For example, if the endpoint for your Amazon RDS DB instance is `mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com`, and your OEM port is 1158, then the URL to access the OEM Database Control the following.

```
https://mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com:1158/em
```

When you access either tool from your web browser, a login window appears that prompts you for a user name and password. Type the master user name and master password for your DB instance. You are now ready to manage your Oracle databases.

Modifying OEM Database settings

After you enable OEM Database, you can modify the Security Groups setting for the option.

You can't modify the OEM port number after you have associated the option group with a DB instance. To change the OEM port number for a DB instance, do the following:

1. Create a new option group.
2. Add the OEM option with the new port number to the new option group.
3. Remove the existing option group from the DB instance.
4. Add the new option group to the DB instance.

For more information about how to modify option settings, see Modifying an option setting. For more information about each setting, see OEM Database option settings.
Running OEM Database Express tasks

You can use Amazon RDS procedures to run certain OEM Database Express tasks. By running these procedures, you can do the tasks listed following.

**Note**

OEM Database Express tasks run asynchronously.

**Tasks**

- **Switching the website front end for OEM Database Express to Adobe Flash**
- **Switching the website front end for OEM Database Express to Oracle JET**

**Switching the website front end for OEM Database Express to Adobe Flash**

**Note**

This task is available only for Oracle Database 19c non-CDBs.

Starting with Oracle Database 19c, Oracle has deprecated the former OEM Database Express user interface, which was based on Adobe Flash. Instead, OEM Database Express now uses an interface built with Oracle JET. If you experience difficulties with the new interface, you can switch back to the deprecated Flash-based interface. Difficulties you might experience with the new interface include being stuck on a Loading screen after logging in to OEM Database Express. You might also miss certain features that were present in the Flash-based version of OEM Database Express.

To switch the OEM Database Express website front end to Adobe Flash, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash`. This procedure is equivalent to the `execemx emx` SQL command.

Security best practices discourage the use of Adobe Flash. Although you can revert to the Flash-based OEM Database Express, we recommend the use of the JET-based OEM Database Express websites if possible. If you revert to using Adobe Flash and want to switch back to using Oracle JET, use the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet` procedure. After an Oracle database upgrade, a newer version of Oracle JET might resolve JET-related issues in OEM Enterprise Manager.
Database Express. For more information about switching to Oracle JET, see Switching the website front end for OEM Database Express to Oracle JET.

Note
Running this task from the source DB instance for a read replica also causes the read replica to switch its OEM Database Express website front ends to Adobe Flash.

The following procedure invocation creates a task to switch the OEM Database Express website to Adobe Flash and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash() as TASK_ID from DUAL;
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure. For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory.

You can also view the contents of the task's output file in the AWS Management Console by searching the log entries in the Logs & events section for the `task-id`.

Switching the website front end for OEM Database Express to Oracle JET

Note
This task is available only for Oracle Database 19c non-CDBs.

To switch the OEM Database Express website front end to Oracle JET, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet`. This procedure is equivalent to the `execemx omx SQL` command.

By default, the OEM Database Express websites for Oracle DB instances running 19c or later use Oracle JET. If you used the
The rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash procedure to switch the OEM Database Express website front end to Adobe Flash, you can switch back to Oracle JET. To do this, use the rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet procedure. For more information about switching to Adobe Flash, see Switching the website front end for OEM Database Express to Adobe Flash.

Note
Running this task from the source DB instance for a read replica also causes the read replica to switch its OEM Database Express website front ends to Oracle JET.

The following procedure invocation creates a task to switch the OEM Database Express website to Oracle JET and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet() as TASK_ID from DUAL;
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure. For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory.

You can also view the contents of the task's output file in the AWS Management Console by searching the log entries in the Logs & events section for the `task-id`.

Removing the OEM Database option

You can remove the OEM option from a DB instance. When you remove the OEM option for an Oracle Database 12c or later DB instance, a brief outage occurs while your instance is automatically restarted. Therefore, after you remove the OEM option, you don't need to restart your DB instance.

To remove the OEM option from a DB instance, do one of the following:

- Remove the OEM option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
• Modify the DB instance and specify a different option group that doesn't include the OEM option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.
Oracle Management Agent for Enterprise Manager Cloud Control

Oracle Enterprise Manager (OEM) Management Agent is a software component that monitors targets running on hosts and communicates that information to the middle-tier Oracle Management Service (OMS). For more information, see Overview of Oracle Enterprise Manager cloud control 12c and Overview of Oracle Enterprise Manager cloud control 13c in the Oracle documentation.

Amazon RDS supports Management Agent through the use of the OEM_AGENT option. Management Agent requires an Amazon RDS DB instance running any of the following releases:

- Oracle Database 19c (19.0.0.0) using the non-CDB architecture
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1.0.2)

Amazon RDS supports Management Agent for the following versions of OEM:

- Oracle Enterprise Manager Cloud Control for 13c
- Oracle Enterprise Manager Cloud Control for 12c

Topics
- Prerequisites for Management Agent
- Limitations for Management Agent
- Option settings for Management Agent
- Adding the Management Agent option
- Using the Management Agent
- Modifying Management Agent settings
- Performing database tasks with the Management Agent
- Removing the Management Agent option

Prerequisites for Management Agent

To use Management Agent, ensure that you meet the following prerequisites.
General prerequisites

Following are general prerequisites for using Management Agent:

- You need an Oracle Management Service (OMS) that is configured to connect to your Amazon RDS DB instance.
- In most cases, you must configure your VPC to allow connections from OMS to your DB instance. If you aren't familiar with Amazon Virtual Private Cloud (Amazon VPC), we recommend that you complete the steps in [Tutorial: Create a VPC for use with a DB instance (IPv4 only)](link) before continuing.
- Management Agent version 13.5.0.0.v1 requires OMS version 13.5.0.0 or later.
- Management Agent version 13.4.0.9.v1 requires OMS version 13.4.0.9 or later and patch 32198287.
- Ensure that you have sufficient storage space for your OEM release:
  - At least 8.5 GiB for OEM 13c Release 5
  - At least 8.5 GiB for OEM 13c Release 4
  - At least 8.5 GiB for OEM 13c Release 3
  - At least 5.5 GiB for OEM 13c Release 2
  - At least 4.5 GiB OEM 13c Release 1
  - At least 2.5 GiB for OEM 12c
- If you are using Management Agent versions OEM_AGENT 13.2.0.0.v3 and 13.3.0.0.v2, and if you want to use TCPS connectivity, follow the instructions in [Configuring third party CA certificates for communication with target databases](link) in the Oracle documentation. Also, update the JDK on your OMS by following the instructions in the Oracle document with the Oracle Doc ID 2241358.1. This step ensures that OMS supports all the cipher suites that the database supports.

### Note

TCPS connectivity between the Management Agent and the DB instance is supported for Management Agent OEM_AGENT 13.2.0.0.v3, 13.3.0.0.v2, 13.4.0.9.v1, and higher versions.
Oracle Database release prerequisites

Following are the supported Oracle Database versions for each Management Agent version.

<table>
<thead>
<tr>
<th>Management Agent version</th>
<th>Oracle Database 19c using the non-CDB architecture</th>
<th>Oracle Database 12c Release 2 (12.2)</th>
<th>Oracle Database 12c Release 1 (12.1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>13.5.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.4.0.9.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.3.0.0.v2</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.3.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.2.0.0.v3</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.2.0.0.v2</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.2.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.1.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>12.1.0.5.v1</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>12.1.0.4.v1</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>

Following are prerequisites for different database versions:

- For an Amazon RDS DB instance running Oracle Database 19c (19.0.0.0), the minimum `AGENT_VERSION` is 13.1.0.0.v1.

- For an Amazon RDS DB instance running Oracle Database Release 2 (12.2.0.1) or lower, meet the following requirements:
  - For OMS 13c Release 2 with Oracle patch 25163555 applied, use OEM Agent 13.2.0.0.v2 or later.
    
    Use OMSPatcher to apply the patch.
  
  - For unpatched OMS 13c Release 2, use OEM Agent 13.2.0.0.v1.
Use OMS Patcher to apply patches.

**OMS host communication prerequisites**

Make sure that your OMS host and your Amazon RDS DB instance can communicate. Do the following:

- To connect from the Management Agent to your OMS, if your OMS is behind a firewall, add the IP addresses of your DB instances to your OMS.

  Make sure the firewall for the OMS allows traffic from both the DB listener port (default 1521) and the OEM Agent port (default 3872), originating from the IP address of the DB instance.

- To connect from your OMS to the Management Agent, if your OMS has a publicly resolvable host name, add the OMS address to a security group. Your security group must have inbound rules that allow access to the DB listener port and the Management Agent port. For an example of creating a security and adding inbound rules, see Tutorial: Create a VPC for use with a DB instance (IPv4 only).

  - To connect from your OMS to the Management Agent, if your OMS doesn't have a publicly resolvable host name, use one of the following:

    - If your OMS is hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance in a private VPC, you can set up VPC peering to connect from OMS to Management Agent. For more information, see A DB instance in a VPC accessed by an EC2 instance in a different VPC.

    - If your OMS is hosted on-premises, you can set up a VPN connection to allow access from OMS to Management Agent. For more information, see A DB instance in a VPC accessed by a client application through the internet or VPN connections.

**Limitations for Management Agent**

Following are some limitations to using Management Agent:

- You can't provide custom Oracle Management Agent images.

- Administrative tasks such as job execution and database patching, that require host credentials, aren't supported.

- Host metrics and the process list aren't guaranteed to reflect the actual system state. Thus, you shouldn't use OEM to monitor the root file system or mount point file system. For more
information about monitoring the operating system, see Monitoring OS metrics with Enhanced Monitoring.

- Autodiscovery isn't supported. You must manually add database targets.
- OMS module availability depends on your database edition. For example, the database performance diagnosis and tuning module is only available for Oracle Database Enterprise Edition.
- Management Agent consumes additional memory and computing resources. If you experience performance problems after enabling the OEM_AGENT option, we recommend that you scale up to a larger DB instance class. For more information, see DB instance classes and Modifying an Amazon RDS DB instance.
- The user running the OEM_AGENT on the Amazon RDS host doesn't have operating system access to the alert log. Thus, you can't collect metrics for DB Alert Log and DB Alert Log Error Status in OEM.

**Option settings for Management Agent**

Amazon RDS supports the following settings for the Management Agent option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Require</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version</strong> (AGENT_VERSION )</td>
<td>Yes</td>
<td>13.5.0.0. v1</td>
<td>The version of the Management Agent software.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.4.0.9. v1</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.3.0.0. v2</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.3.0.0. v1</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.2.0.0. v3</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.2.0.0. v2</td>
<td></td>
</tr>
</tbody>
</table>

**Note**

In the AWS GovCloud (US) Regions, 12.1 and 13.1 versions aren't available.
<table>
<thead>
<tr>
<th>Option setting</th>
<th>Required</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port (AGENT_PORT)</td>
<td>Yes</td>
<td>13.2.0.0. v1 13.1.0.0. v1 12.1.0.5. v1 12.1.0.4. v1</td>
<td>The port on the DB instance that listens for the OMS host. The default is 3872. Your OMS host must belong to a security group that has access to this port. The AWS CLI option name is Port.</td>
</tr>
<tr>
<td>Security Groups</td>
<td>Yes</td>
<td>Existing security groups</td>
<td>A security group that has access to Port. Your OMS host must belong to this security group. The AWS CLI option name is VpcSecurityGroupMemberships or DBSecurityGroupMemberships.</td>
</tr>
<tr>
<td>OMS_HOST</td>
<td>Yes</td>
<td>A string value, for example my.example.oms</td>
<td>The publicly accessible host name or IP address of the OMS. The AWS CLI option name is OMS_HOST.</td>
</tr>
<tr>
<td>Option setting</td>
<td>Require</td>
<td>Valid values</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>---------</td>
<td>--------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **OMS_PORT**                 | Yes     | An integer value | The HTTPS upload port on the OMS Host that listens for the Management Agent.  
To determine the HTTPS upload port, connect to the OMS host, and run the following command (which requires the SYSMAN password):  
emctl status oms -details  
The AWS CLI option name is OMS_PORT. |
| **AGENT_REGISTRATION_PASSWORD** | Yes     | A string value | The password that the Management Agent uses to authenticate itself with the OMS. We recommend that you create a persistent password in your OMS before enabling the OEM_AGENT option. With a persistent password you can share a single Management Agent option group among multiple Amazon RDS databases.  
The AWS CLI option name is AGENT_REGISTRATION_PASSWORD. |
| **ALLOW_TLS_ONLY**           | No      | true, false (default) | A value that configures the OEM Agent to support only the TLSv1 protocol while the agent listens as a server.  
This setting is only supported for 12.1 agent versions. Later agent versions only support Transport Layer Security (TLS) by default. |
<table>
<thead>
<tr>
<th>Option setting</th>
<th>Required</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MINIMUM_TLS_VERSION</td>
<td>No</td>
<td>TLSv1 (default),</td>
<td>A value that specifies the minimum TLS version supported by the OEM Agent while the agent listens as a server. This setting is only supported for agent versions 13.1.0.0.v1 and higher. Earlier agent versions only support the TLSv1 setting.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>TLSv1.2</td>
<td></td>
</tr>
<tr>
<td>TLS_CIPHER_SUITE</td>
<td>No</td>
<td>See <a href="#">TLS settings for the Management Agent option</a></td>
<td>A value that specifies the TLS cipher suite used by the OEM Agent while the agent listens as a server.</td>
</tr>
</tbody>
</table>

The following table lists the TLS cipher suites that the Management Agent option supports.

### TLS settings for the Management Agent option

<table>
<thead>
<tr>
<th>Cipher suite</th>
<th>Agent version supported</th>
<th>FedRAMP compliant</th>
</tr>
</thead>
<tbody>
<tr>
<td>TLS_RSA_WITH_AES_128_CBC_SHA</td>
<td>All</td>
<td>No</td>
</tr>
<tr>
<td>TLS_RSA_WITH_AES_128_CBC_SHA256</td>
<td>13.1.0.0.v1 or higher</td>
<td>No</td>
</tr>
<tr>
<td>TLS_RSA_WITH_AES_256_CBC_SHA</td>
<td>13.2.0.0.v3 or higher</td>
<td>No</td>
</tr>
<tr>
<td>TLS_RSA_WITH_AES_256_CBC_SHA256</td>
<td>13.2.0.0.v3 or higher</td>
<td>No</td>
</tr>
<tr>
<td>TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA</td>
<td>13.2.0.0.v3 or higher</td>
<td>Yes</td>
</tr>
<tr>
<td>TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA</td>
<td>13.2.0.0.v3 or higher</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Adding the Management Agent option

The general process for adding the Management Agent option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If you encounter errors, check [My Oracle Support](https://www.oracle.com) documents for information about resolving specific problems.

After you add the Management Agent option, you don’t need to restart your DB instance. As soon as the option group is active, the OEM Agent is active.

If your OMS host is using an untrusted third-party certificate, Amazon RDS returns the following error.

You successfully installed the OEM_AGENT option. Your OMS host is using an untrusted third party certificate. Configure your OMS host with the trusted certificates from your third party.

If this error is returned, the Management Agent option isn't enabled until the problem is corrected. For information about correcting the problem, see the My Oracle Support document 2202569.1.

Console

To add the Management Agent option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
a. For **Engine** choose the oracle edition for your DB instance.

b. For **Major engine version** choose the version of your DB instance.

For more information, see [Creating an option group](#).

2. Add the **OEM_AGENT** option to the option group, and configure the option settings. For more information about adding options, see [Adding an option to an option group](#). For more information about each setting, see [Option settings for Management Agent](#).

3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).

   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).

### AWS CLI

The following example uses the AWS CLI `add-option-to-option-group` command to add the **OEM_AGENT** option to an option group called **myoptiongroup**.

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
  --option-group-name "myoptiongroup" \
  --options
  OptionName=OEM_AGENT,OptionVersion=13.1.0.0.v1,Port=3872,VpcSecurityGroupMemberships=sg-1234567890
  {Name=OMS_HOST,Value=my.example.oms}
  {Name=OMS_PORT,Value=4903}
  {Name=AGENT_REGISTRATION_PASSWORD,Value=password} \
  --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^
  --option-group-name "myoptiongroup" ^
  --options
  OptionName=OEM_AGENT,OptionVersion=13.1.0.0.v1,Port=3872,VpcSecurityGroupMemberships=sg-1234567890
  {Name=OMS_HOST,Value=my.example.oms}
  {Name=OMS_PORT,Value=4903}
  {Name=AGENT_REGISTRATION_PASSWORD,Value=password} ^
  --apply-immediately
```
Using the Management Agent

After you enable the Management Agent option, take the following steps to begin using it.

To use the Management Agent

1. Unlock and reset the DBSNMP account credential. Do this by running the following code on your target database on your DB instance and using your master user account.

   ```sql
   ALTER USER dbsnmp IDENTIFIED BY new_password ACCOUNT UNLOCK;
   ```

2. Add your targets to the OMS console manually:
   a. In your OMS console, choose Setup, Add Target, Add Targets Manually.
   b. Choose Add Targets Declaratively by Specifying Target Monitoring Properties.
   c. For Target Type, choose Database Instance.
   d. For Monitoring Agent, choose the agent with the identifier that is the same as your RDS DB instance identifier.
   e. Choose Add Manually.
   f. Enter the endpoint for the Amazon RDS DB instance, or choose it from the host name list. Make sure that the specified host name matches the endpoint of the Amazon RDS DB instance.

   For information about finding the endpoint for your Amazon RDS DB instance, see Finding the endpoint of your RDS for Oracle DB instance.

   g. Specify the following database properties:

      • For Target name, enter a name.
      • For Database system name, enter a name.
      • For Monitor username, enter dbsnmp.
      • For Monitor password, enter the password from step 1.
      • For Role, enter normal.
      • For Oracle home path, enter /oracle.
      • For Listener Machine name, the agent identifier already appears.
      • For Port, enter the database port. The RDS default port is 1521.
      • For Database name, enter the name of your database.
h. Choose **Test Connection**.

i. Choose **Next**. The target database appears in your list of monitored resources.

**Modifying Management Agent settings**

After you enable the Management Agent, you can modify settings for the option. For more information about how to modify option settings, see [Modifying an option setting](#). For more information about each setting, see [Option settings for Management Agent](#).

**Performing database tasks with the Management Agent**

You can use Amazon RDS procedures to run certain EMCTL commands on the Management Agent. By running these procedures, you can do the tasks listed following.

![Note]

Tasks are executed asynchronously.

**Tasks**

- [Getting the status of the Management Agent](#)
- [Restarting the Management Agent](#)
- [Listing the targets monitored by the Management Agent](#)
- [Listing the collection threads monitored by the Management Agent](#)
- [Clearing the Management Agent state](#)
- [Making the Management Agent upload its OMS](#)
- [Pinging the OMS](#)
- [Viewing the status of an ongoing task](#)

**Getting the status of the Management Agent**

To get the status of the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.get_status_oem_agent`. This procedure is equivalent to the `emctl status agent` command.

The following procedure creates a task to get the Management Agent's status and returns the ID of the task.
To view the result by displaying the task's output file, see Viewing the status of an ongoing task.

**Restarting the Management Agent**

To restart the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.restart_oem_agent`. This procedure is equivalent to running the `emctl stop agent` and `emctl start agent` commands.

The following procedure creates a task to restart the Management Agent and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.restart_oem_agent as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task.

**Listing the targets monitored by the Management Agent**

To list the targets monitored by the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.list_targets_oem_agent`. This procedure is equivalent to running the `emctl config agent listtargets` command.

The following procedure creates a task to list the targets monitored by the Management Agent and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.list_targets_oem_agent as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task.

**Listing the collection threads monitored by the Management Agent**

To list all the running, ready, and scheduled collection threads monitored by the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.list_clxn_threads_oem_agent`. This procedure is equivalent to the `emctl status agent scheduler` command.

The following procedure creates a task to list the collection threads and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.list_clxn_threads_oem_agent as TASK_ID from DUAL;
```
To clear the Management Agent's state, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.clearstate_oem_agent`. This procedure is equivalent to running the `emctl clearstate agent` command.

The following procedure creates a task that clears the Management Agent's state and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_agent_tasks.clearstate_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see **Viewing the status of an ongoing task**.

### Making the Management Agent upload its OMS

To make the Management Agent upload the Oracle Management Server (OMS) associated with it, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.upload_oem_agent`. This procedure is equivalent to running the `emctl upload agent` command.

The following procedure creates a task that makes the Management Agent upload its associated OMS and return the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_agent_tasks.upload_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see **Viewing the status of an ongoing task**.

### Pinging the OMS

To ping the Management Agent's OMS, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent`. This procedure is equivalent to running the `emctl pingOMS` command.

The following procedure creates a task that pings the Management Agent's OMS and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent() as TASK_ID from DUAL;
```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent() as TASK_ID from DUAL;

To view the result by displaying the task's output file, see Viewing the status of an ongoing task.

Viewing the status of an ongoing task

You can view the status of an ongoing task in a bdump file. The bdump files are located in the /rdsdbdata/log/trace directory. Each bdump file name is in the following format.

dbtask-task-id.log

When you want to monitor a task, replace task-id with the ID of the task that you want to monitor.

To view the contents of bdump files, run the Amazon RDS procedure rdsadmin.rds_file_util.read_text_file. The following query returns the contents of the dbtask-1546988886389-2444.log bdump file.

SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-1546988886389-2444.log'));

For more information about the Amazon RDS procedure rdsadmin.rds_file_util.read_text_file, see Reading files in a DB instance directory.

Removing the Management Agent option

You can remove the OEM Agent from a DB instance. After you remove the OEM Agent, you don't need to restart your DB instance.

To remove the OEM Agent from a DB instance, do one of the following:

- Remove the OEM Agent option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- Modify the DB instance and specify a different option group that doesn't include the OEM Agent option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.
Oracle Label Security

Amazon RDS supports Oracle Label Security for the Enterprise Edition of Oracle Database through the use of the OLS option.

Most database security controls access at the object level. Oracle Label Security provides fine-grained control of access to individual table rows. For example, you can use Label Security to enforce regulatory compliance with a policy-based administration model. You can use Label Security policies to control access to sensitive data, and restrict access to only users with the appropriate clearance level. For more information, see Introduction to Oracle Label Security in the Oracle documentation.

Topics

- Prerequisites for Oracle Label Security
- Adding the Oracle Label Security option
- Using Oracle Label Security
- Removing the Oracle Label Security option (not supported)
- Troubleshooting

Prerequisites for Oracle Label Security

Familiarize yourself with the following prerequisites for Oracle Label Security:

- Your DB instance must use the Bring Your Own License model. For more information, see RDS for Oracle licensing options.
- You must have a valid license for Oracle Enterprise Edition with Software Update License and Support.
- Your Oracle license must include the Label Security option.
- You must be using the non-multitenant (non-CDB) database architecture. For more information, see Single-tenant configuration of the CDB architecture.

Adding the Oracle Label Security option

The general process for adding the Oracle Label Security option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.

Important
Oracle Label Security is a permanent and persistent option.

3. Associate the option group with the DB instance.

After you add the Label Security option, as soon as the option group is active, Label Security is active.

To add the label security option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For Engine, choose oracle-ee.
   b. For Major engine version, choose the version of your DB instance.

For more information, see Creating an option group.

2. Add the OLS option to the option group. For more information about adding options, see Adding an option to an option group.

Important
If you add Label Security to an existing option group that is already attached to one or more DB instances, all the DB instances are restarted.

3. Apply the option group to a new or existing DB instance:
   a. For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   
   b. For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the Label Security option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance.
Using Oracle Label Security

To use Oracle Label Security, you create policies that control access to specific rows in your tables. For more information, see Creating an Oracle Label Security policy in the Oracle documentation.

When you work with Label Security, you perform all actions as the LBAC_DBA role. The master user for your DB instance is granted the LBAC_DBA role. You can grant the LBAC_DBA role to other users so that they can administer Label Security policies.

For the following releases, make sure to grant access to the OLS_ENFORCEMENT package to any new users who require access to Oracle Label Security:

- Oracle Database 19c using the non-CDB architecture
- Oracle Database 12c Release 2 (12.2)

To grant access to the OLS_ENFORCEMENT package, connect to the DB instance as the master user and run the following SQL statement:

```
GRANT ALL ON LBACSYS.OLS_ENFORCEMENT TO username;
```

You can configure Label Security through the Oracle Enterprise Manager (OEM) Cloud Control. Amazon RDS supports the OEM Cloud Control through the Management Agent option. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.

Removing the Oracle Label Security option (not supported)

Starting with Oracle Database 12c Release 2 (12.2), Oracle Label Security is a permanent and persistent option. Because the option is permanent, you can't remove it from an option group. If you add Oracle Label Security to an option group and associate it with your DB instance, you can later associate a different option group with your DB instance, but this group must also contain the Oracle Label Security option.

Troubleshooting

The following are issues you might encounter when you use Oracle Label Security.
<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you try to create a policy, you see an error message similar to the following: <strong>insufficient authorization</strong> for the SYSDBA package.</td>
<td>A known issue with Oracle's Label Security feature prevents users with usernames of 16 or 24 characters from running Label Security commands. You can create a new user with a different number of characters, grant LBAC_DBA to the new user, log in as the new user, and run the OLS commands as the new user. For additional information, please contact Oracle support.</td>
</tr>
</tbody>
</table>
Oracle Locator

Amazon RDS supports Oracle Locator through the use of the LOCATOR option. Oracle Locator provides capabilities that are typically required to support internet and wireless service-based applications and partner-based GIS solutions. Oracle Locator is a limited subset of Oracle Spatial. For more information, see Oracle Locator in the Oracle documentation.

⚠️ **Important**

If you use Oracle Locator, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle Locator for the following releases of Oracle Database:

- Oracle Database 19c (19.0.0.0)
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v13 or later

Oracle Locator isn't supported for Oracle Database 21c, but its functionality is available in the Oracle Spatial option. Formerly, the Spatial option required additional licenses. Oracle Locator represented a subset of Oracle Spatial features and didn't require additional licenses. In 2019, Oracle announced that all Oracle Spatial features were included in the Enterprise Edition and Standard Edition 2 licenses without additional cost. Consequently, the Oracle Spatial option no longer required additional licensing.

Starting with Oracle Database 21c, the Oracle Locator option is no longer supported. To use the Oracle Locator features in Oracle Database 21c, install the Oracle Spatial option instead. For more information, see Machine Learning, Spatial and Graph - No License Required! in the Oracle Database Insider blog.

**Prerequisites for Oracle Locator**

The following are prerequisites for using Oracle Locator:

- Your DB instance must be of sufficient class. Oracle Locator is not supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes.
• Your DB instance must have **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see [Modifying an Amazon RDS DB instance](#).

---

**Best practices for Oracle Locator**

The following are best practices for using Oracle Locator:

• For maximum security, use the LOCATOR option with Secure Sockets Layer (SSL). For more information, see [Oracle Secure Sockets Layer](#).

• Configure your DB instance to restrict access to your DB instance. For more information, see [Scenarios for accessing a DB instance in a VPC](#) and [Working with a DB instance in a VPC](#).

---

**Adding the Oracle Locator option**

The following is the general process for adding the LOCATOR option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the LOCATOR option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Locator is available.

---

### Note

During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.
To add the LOCATOR option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   
   a. For **Engine**, choose the oracle edition for your DB instance.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see [Creating an option group](#).

2. Add the **LOCATOR** option to the option group. For more information about adding options, see [Adding an option to an option group](#).

3. Apply the option group to a new or existing DB instance:

   a. For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
   b. For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).

**Using Oracle Locator**

After you enable the Oracle Locator option, you can begin using it. You should only use Oracle Locator features. Don't use any Oracle Spatial features unless you have a license for Oracle Spatial.

For a list of features that are supported for Oracle Locator, see [Features Included with Locator](#) in the Oracle documentation.

For a list of features that are not supported for Oracle Locator, see [Features Not Included with Locator](#) in the Oracle documentation.

**Removing the Oracle Locator option**

After you drop all objects that use data types provided by the LOCATOR option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the LOCATOR option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the LOCATOR option, you don't need to restart your DB instance.
To drop the LOCATOR option

1. Back up your data.

   **Warning**
   If the instance uses data types that were enabled as part of the option, and if you remove the LOCATOR option, you can lose data. For more information, see [Backing up, restoring, and exporting data](#).

2. Check whether any existing objects reference data types or features of the LOCATOR option.

   If LOCATOR options exist, the instance can get stuck when applying the new option group that doesn't have the LOCATOR option. You can identify the objects by using the following queries:

   ```sql
   SELECT OWNER, SEGMENT_NAME, TABLESPACE_NAME, BYTES/1024/1024 mbytes
   FROM   DBA_SEGMENTS
   WHERE  SEGMENT_TYPE LIKE '%TABLE%'
   AND    (OWNER, SEGMENT_NAME) IN
   (SELECT DISTINCT OWNER, TABLE_NAME
    FROM   DBA_TAB_COLUMNS
    WHERE  DATA_TYPE='SDO_GEOMETRY'
    AND    OWNER <> 'MDSYS')
   ORDER BY 1,2,3,4;

   SELECT OWNER, TABLE_NAME, COLUMN_NAME
   FROM   DBA_TAB_COLUMNS
   WHERE  DATA_TYPE = 'SDO_GEOMETRY'
   AND    OWNER <> 'MDSYS'
   ORDER BY 1,2,3;
   ```

3. Drop any objects that reference data types or features of the LOCATOR option.

4. Do one of the following:

   - Remove the LOCATOR option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#).
   - Modify the DB instance and specify a different option group that doesn't include the LOCATOR option. This change affects a single DB instance. You can specify the default
(empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.
Oracle Multimedia

Amazon RDS supports Oracle Multimedia through the use of the MULTIMEDIA option. You can use Oracle Multimedia to store, manage, and retrieve images, audio, video, and other heterogeneous media data. For more information, see Oracle Multimedia in the Oracle documentation.

⚠️ Important

If you use Oracle Multimedia, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle Multimedia for all editions of the following versions:

- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v13 or higher

>Note

Oracle desupported Oracle Multimedia in Oracle Database 19c. So, Oracle Multimedia isn't supported for Oracle Database 19c DB instances. For more information, see Desupport of Oracle Multimedia in the Oracle documentation.

Prerequisites for Oracle Multimedia

The following are prerequisites for using Oracle Multimedia:

- Your DB instance must be of sufficient class. Oracle Multimedia is not supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes.
- Your DB instance must have Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance.
Best practices for Oracle Multimedia

The following are best practices for using Oracle Multimedia:

- For maximum security, use the MULTIMEDIA option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer.
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC and Working with a DB instance in a VPC.

Adding the Oracle Multimedia option

The following is the general process for adding the MULTIMEDIA option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the MULTIMEDIA option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Multimedia is available.

Note

During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

To add the MULTIMEDIA option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For Engine, choose the edition for your Oracle DB instance.
   b. For Major engine version, choose the version of your DB instance.
For more information, see Creating an option group.

2. Add the MULTIMEDIA option to the option group. For more information about adding options, see Adding an option to an option group.

3. Apply the option group to a new or existing DB instance:

   • For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   
   • For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Removing the Oracle Multimedia option

After you drop all objects that use data types provided by the MULTIMEDIA option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the MULTIMEDIA option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the MULTIMEDIA option, you don't need to restart your DB instance.

To drop the MULTIMEDIA option

1. Back up your data.

   Warning
   
   If the instance uses data types that were enabled as part of the option, and if you remove the MULTIMEDIA option, you can lose data. For more information, see Backing up, restoring, and exporting data.

2. Check whether any existing objects reference data types or features of the MULTIMEDIA option.

3. Drop any objects that reference data types or features of the MULTIMEDIA option.

4. Do one of the following:
- Remove the MULTIMEDIA option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.

- Modify the DB instance and specify a different option group that doesn't include the MULTIMEDIA option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.
Oracle native network encryption

Amazon RDS supports Oracle native network encryption (NNE). With native network encryption, you can encrypt data as it moves to and from a DB instance. Amazon RDS supports NNE for all editions of Oracle Database.

A detailed discussion of Oracle native network encryption is beyond the scope of this guide, but you should understand the strengths and weaknesses of each algorithm and key before you decide on a solution for your deployment. For information about the algorithms and keys that are available through Oracle native network encryption, see Configuring network data encryption in the Oracle documentation. For more information about AWS security, see the AWS security center.

Note
You can use Native Network Encryption or Secure Sockets Layer, but not both. For more information, see Oracle Secure Sockets Layer.

NNE option settings

You can specify encryption requirements on both the server and the client. The DB instance can act as a client when, for example, it uses a database link to connect to another database. You might want to avoid forcing encryption on the server side. For example, you might not want to force all client communications to use encryption because the server requires it. In this case, you can force encryption on the client side using the SQLNET.*CLIENT options.

Amazon RDS supports the following settings for the NNE option.

Note
When you use commas to separate values for an option setting, don't put a space after the comma.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS</td>
<td>TRUE, FALSE</td>
<td>TRUE</td>
<td>The behavior of the server when a client using a non-secure cipher</td>

<tr>
<td>Option setting</td>
<td>Valid values</td>
<td>Default values</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------</td>
<td>--------------</td>
<td>----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS           | TRUE         | FALSE          | attempts to connect to the database. If TRUE, clients can connect even if they aren't patched with the July 2021 PSU. If the setting is FALSE, clients can connect to the database only when they are patched with the July 2021 PSU. Before you set SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS to FALSE, make sure that the following conditions are met:  
  • SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT have one matching encryption method that is not DES, 3DES, or RC4 (all key lengths).  
  • SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method that is not MD5.  
  • The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error. |

### Adding the NNE option

The general process for adding the NNE option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When the option group is active, NNE is active.

### To add the NNE option to a DB instance using the AWS Management Console

1. For **Engine**, choose the Oracle edition that you want to use. NNE is supported on all editions.
2. For **Major engine version**, choose the version of your DB instance.

   For more information, see [Creating an option group](#).
3. Add the **NNE** option to the option group. For more information about adding options, see [Adding an option to an option group](#).

   ![Note](https://via.placeholder.com/15)

   **Note**

   After you add the NNE option, you don't need to restart your DB instances. As soon as the option group is active, NNE is active.

4. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
• For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. After you add the NNE option, you don't need to restart your DB instance. As soon as the option group is active, NNE is active. For more information, see Modifying an Amazon RDS DB instance.

Setting NNE values in the sqlnet.ora

With Oracle native network encryption, you can set network encryption on the server side and client side. The client is the computer used to connect to the DB instance. You can specify the following client settings in the sqlnet.ora:

• SQLNET.ALLOW_WEAK_CRYPTO
• SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS
• SQLNET.CRYPTO_CHECKSUM_CLIENT
• SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT
• SQLNET.ENCRYPTION_CLIENT
• SQLNET.ENCRYPTION_TYPES_CLIENT

For information, see Configuring network data encryption and integrity for Oracle servers and clients in the Oracle documentation.

Sometimes, the DB instance rejects a connection request from an application. For example, a rejection can occur when the encryption algorithms on the client and on the server don't match. To test Oracle native network encryption, add the following lines to the sqlnet.ora file on the client:

```
DIAG_ADR_ENABLED=off
TRACE_DIRECTORY_CLIENT=/tmp
TRACE_FILE_CLIENT=nettrace
TRACE_LEVEL_CLIENT=16
```

When a connection is attempted, the preceding lines generate a trace file on the client called /tmp/nettrace*. The trace file contains information about the connection. For more information about connection-related issues when you are using Oracle Native Network Encryption, see About negotiating encryption and integrity in the Oracle Database documentation.
Modifying NNE option settings

After you enable NNE, you can modify its settings. Currently, you can modify NNE option settings only with the AWS CLI or RDS API. You can't use the console. To learn how to modify option settings using the CLI, see AWS CLI. For more information about each setting, see NNE option settings.

Topics
- Modifying CRYPTO_CHECKSUM_* values
- Modifying ALLOW_WEAK_CRYPTO* settings

Modifying CRYPTO_CHECKSUM_* values

If you modify NNE option settings, make sure that the following option settings have at least one common cipher:

- SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER
- SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT

The following example shows a scenario in which you modify SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER. The configuration is valid because the CRYPTO_CHECKSUM_TYPES_CLIENT and CRYPTO_CHECKSUM_TYPES_SERVER both use SHA256.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Values before modification</th>
<th>Values after modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT</td>
<td>SHA256, SHA384, SHA512</td>
<td>No change</td>
</tr>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER</td>
<td>SHA256, SHA384, SHA512, SHA1, MD5</td>
<td>SHA1, MD5, SHA256</td>
</tr>
</tbody>
</table>

For another example, assume that you want to modify SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER from its default setting to SHA1, MD5. In this case, make sure you set SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT to SHA1 or MD5. These algorithms aren't included in the default values for SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT.
Modifying ALLOW_WEAK_CRYPTO* settings

To set the SQLNET.ALLOW_WEAK_CRYPTO* options from the default value to FALSE, make sure that the following conditions are met:

- SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT have one matching secure encryption method. A method is considered secure if it's not DES, 3DES, or RC4 (all key lengths).
- SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method. A method is considered secure if it's not MD5.
- The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error.

The following example shows sample NNE settings. Assume that you want to set SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT to FALSE, thereby blocking non-secure connections. The checksum option settings meet the prerequisites because they both have SHA256. However, SQLNET.ENCRYPTION_TYPES_CLIENT and SQLNET.ENCRYPTION_TYPES_SERVER use the DES, 3DES, and RC4 encryption methods, which are non-secure. Therefore, to set the SQLNET.ALLOW_WEAK_CRYPTO* options to FALSE, first set SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT to a secure encryption method such as AES256.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT</td>
<td>SHA256, SHA384, SHA512</td>
</tr>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER</td>
<td>SHA1, MD5, SHA256</td>
</tr>
<tr>
<td>SQLNET.ENCRYPTION_TYPES_CLIENT</td>
<td>RC4_256, 3DES168, DES40</td>
</tr>
<tr>
<td>SQLNET.ENCRYPTION_TYPES_SERVER</td>
<td>RC4_256, 3DES168, DES40</td>
</tr>
</tbody>
</table>
Removing the NNE option

You can remove NNE from a DB instance.

To remove NNE from a DB instance, do one of the following:

- To remove NNE from multiple DB instances, remove the NNE option from the option group they belong to. This change affects all DB instances that use the option group. After you remove the NNE option, you don't need to restart your DB instances. For more information, see Removing an option from an option group.

- To remove NNE from a single DB instance, modify the DB instance and specify a different option group that doesn't include the NNE option. You can specify the default (empty) option group, or a different custom option group. After you remove the NNE option, you don't need to restart your DB instance. For more information, see Modifying an Amazon RDS DB instance.
Oracle OLAP

Amazon RDS supports Oracle OLAP through the use of the OLAP option. This option provides Online Analytical Processing (OLAP) for Oracle DB instances. You can use Oracle OLAP to analyze large amounts of data by creating dimensional objects and cubes in accordance with the OLAP standard. For more information, see the Oracle documentation.

⚠️ Important

If you use Oracle OLAP, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle OLAP for the following editions and versions of Oracle:

- Oracle Database 21c Enterprise Edition, all versions
- Oracle Database 19c Enterprise Edition, all versions
- Oracle Database 12c Release 2 (12.2.0.1) Enterprise Edition, all versions
- Oracle Database 12c Release 1 (12.1.0.2) Enterprise Edition, version 12.1.0.2.v13 or later

Prerequisites for Oracle OLAP

The following are prerequisites for using Oracle OLAP:

- You must have an Oracle OLAP license from Oracle. For more information, see Licensing Information in the Oracle documentation.
- Your DB instance must be of a sufficient instance class. Oracle OLAP isn’t supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes.
- Your DB instance must have Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance.
- Your DB instance must not have a user named OLAPSYS. If it does, the OLAP option installation fails.
Best practices for Oracle OLAP

The following are best practices for using Oracle OLAP:

- For maximum security, use the OLAP option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer.
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC and Working with a DB instance in a VPC.

Adding the Oracle OLAP option

The following is the general process for adding the OLAP option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the OLAP option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle OLAP is available.

To add the OLAP option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   - For **Engine**, choose the Oracle edition for your DB instance.
   - For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group.

2. Add the **OLAP** option to the option group. For more information about adding options, see Adding an option to an option group.

3. Apply the option group to a new or existing DB instance:
For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.

For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Using Oracle OLAP

After you enable the Oracle OLAP option, you can begin using it. For a list of features that are supported for Oracle OLAP, see the Oracle documentation.

Removing the Oracle OLAP option

After you drop all objects that use data types provided by the OLAP option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the OLAP option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the OLAP option, you don't need to restart your DB instance.

To drop the OLAP option

1. Back up your data.

   Warning
   If the instance uses data types that were enabled as part of the option, and if you remove the OLAP option, you can lose data. For more information, see Backing up, restoring, and exporting data.

2. Check whether any existing objects reference data types or features of the OLAP option.
3. Drop any objects that reference data types or features of the OLAP option.
4. Do one of the following:

   • Remove the OLAP option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
   • Modify the DB instance and specify a different option group that doesn't include the OLAP option. This change affects a single DB instance. You can specify the default (empty) option
group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.
Oracle Secure Sockets Layer

You enable SSL encryption for an RDS for Oracle DB instance by adding the Oracle SSL option to the option group associated with the DB instance. Amazon RDS uses a second port, as required by Oracle, for SSL connections. This approach allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and SQL*Plus. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

Note

You can use either SSL or Native Network Encryption (NNE) on the same RDS for Oracle DB instance, but not both. If you use SSL encryption, make sure to turn off any other connection encryption. For more information, see Oracle native network encryption.

SSL/TLS and NNE are no longer part of Oracle Advanced Security. In RDS for Oracle, you can use SSL encryption with all licensed editions of the following database versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2) – this release is no longer supported
- Oracle Database 12c Release 1 (12.1) – this release is no longer supported

TLS versions for the Oracle SSL option

Amazon RDS for Oracle supports Transport Layer Security (TLS) versions 1.0 and 1.2. When you add a new Oracle SSL option, set SQLNET.SSL_VERSION explicitly to a valid value. The following values are allowed for this option setting:

- "1.0" – Clients can connect to the DB instance using TLS version 1.0 only. For existing Oracle SSL options, SQLNET.SSL_VERSION is set to "1.0" automatically. You can change the setting if necessary.
- "1.2" – Clients can connect to the DB instance using TLS 1.2 only.
- "1.2 or 1.0" – Clients can connect to the DB instance using either TLS 1.2 or 1.0.
Cipher suites for the Oracle SSL option

Amazon RDS for Oracle supports multiple SSL cipher suites. By default, the Oracle SSL option is configured to use the SSL_RSA_WITH_AES_256_CBC_SHA cipher suite. To specify a different cipher suite to use over SSL connections, use the SQLNET.CIPHER_SUITE option setting.

The following table summarizes SSL support for RDS for Oracle. The specified Oracle Database releases support all editions.

<table>
<thead>
<tr>
<th>Cipher suite (SQLNET.CIPHER_SUITE)</th>
<th>TLS version support (SQLNET.SSL_VERSION)</th>
<th>Supported Oracle Database releases</th>
<th>FIPS support</th>
<th>FedRAMP compliant</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSL_RSA_WITH_AES_256_CBC_SHA (default)</td>
<td>1.0 and 1.2</td>
<td>12c, 19c, 21c</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>SSL_RSA_WITH_AES_256_CBC_SHA256</td>
<td>1.2</td>
<td>12c, 19c, 21c</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>SSL_RSA_WITH_AES_256_GCM_SHA384</td>
<td>1.2</td>
<td>12c, 19c, 21c</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384</td>
<td>1.2</td>
<td>19c, 21c</td>
<td>Yes</td>
<td>Yes</td>

<tr>
<td>TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA</td>
<td>1.2</td>
<td>19c, 21c</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>
FIPS support

RDS for Oracle allows you to use the Federal Information Processing Standard (FIPS) standard for 140-2. FIPS 140-2 is a United States government standard that defines cryptographic module security requirements. You turn on the FIPS standard by setting FIPS.SSLFIPS_140 to TRUE for the Oracle SSL option. When FIPS 140-2 is configured for SSL, the cryptographic libraries encrypt data between the client and the RDS for Oracle DB instance.

Clients must use the cipher suite that is FIPS-compliant. When establishing a connection, the client and RDS for Oracle DB instance negotiate which cipher suite to use when transmitting messages back and forth. The table in Cipher suites for the Oracle SSL option shows the FIPS-compliant SSL cipher suites for each TLS version. For more information, see Oracle database FIPS 140-2 settings in the Oracle Database documentation.

Adding the SSL option

To use SSL, your RDS for Oracle DB instance must be associated with an option group that includes the SSL option.

Console

To add the SSL option to an option group

1. Create a new option group or identify an existing option group to which you can add the SSL option.
   
   For information about creating an option group, see Creating an option group.

2. Add the SSL option to the option group.

   If you want to use only FIPS-verified cipher suites for SSL connections, set the option FIPS.SSLFIPS_140 to TRUE. For information about the FIPS standard, see FIPS support.
For information about adding an option to an option group, see [Adding an option to an option group](#).

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

For information about creating an DB instance, see [Creating an Amazon RDS DB instance](#).

For information about modifying an DB instance, see [Modifying an Amazon RDS DB instance](#).

**AWS CLI**

**To add the SSL option to an option group**

1. Create a new option group or identify an existing option group to which you can add the SSL option.

   For information about creating an option group, see [Creating an option group](#).

2. Add the SSL option to the option group.

   Specify the following option settings:

   - **Port** – The SSL port number
   - **VpcSecurityGroupMemberships** – The VPC security group for which the option is enabled
   - **SQLNET.SSL_VERSION** – The TLS version that client can use to connect to the DB instance

   For example, the following AWS CLI command adds the SSL option to an option group named `ora-option-group`.

   **Example**

   For Linux, macOS, or Unix:

   ```bash
   aws rds add-option-to-option-group --option-group-name ora-option-group \
   --options
   'OptionName=SSL,Port=2484,VpcSecurityGroupMemberships="sg-68184619",OptionSettings=[{Name=SQLNET.SSL_VERSION,Value=1.0}]
   ```
For Windows:

```bash
aws rds add-option-to-option-group --option-group-name ora-option-group
    --options
    'OptionName=SSL,Port=2484,VpcSecurityGroupMemberships="sg-68184619",OptionSettings=[{Name=SQLNET.SSL_Version,Value=1.0}]
```

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

   For information about creating an DB instance, see [Creating an Amazon RDS DB instance](#).

   For information about modifying an DB instance, see [Modifying an Amazon RDS DB instance](#).

### Configuring SQL*Plus to use SSL with an RDS for Oracle DB instance

Before you can connect to an RDS for Oracle DB instance that uses the Oracle SSL option, you must configure SQL*Plus before connecting.

**Note**

To allow access to the DB instance from the appropriate clients, ensure that your security groups are configured correctly. For more information, see [Controlling access with security groups](#). Also, these instructions are for SQL*Plus and other clients that directly use an Oracle home. For JDBC connections, see [Setting up an SSL connection over JDBC](#).

**To configure SQL*Plus to use SSL to connect to an RDS for Oracle DB instance**

1. Set the `ORACLE_HOME` environment variable to the location of your Oracle home directory.

   The path to your Oracle home directory depends on your installation. The following example sets the `ORACLE_HOME` environment variable.

   ```bash
   export ORACLE_HOME=/home/user/app/user/product/12.1.0/dbhome_1
   ```

   For information about setting Oracle environment variables, see [SQL*Plus environment variables](#) in the Oracle documentation, and also see the Oracle installation guide for your operating system.
2. Append $ORACLE_HOME/lib to the LD_LIBRARY_PATH environment variable.

   The following is an example that sets the LD_LIBRARY_PATH environment variable.

   ```
   prompt>export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:$ORACLE_HOME/lib
   ```

3. Create a directory for the Oracle wallet at $ORACLE_HOME/ssl_wallet.

   The following is an example that creates the Oracle wallet directory.

   ```
   prompt>mkdir $ORACLE_HOME/ssl_wallet
   ```

4. Download the certificate bundle .pem file that works for all AWS Regions and put the file in the ssl_wallet directory. For information, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

5. In the $ORACLE_HOME/network/admin directory, modify or create the tnsnames.ora file and include the following entry.

   ```
   net_service_name =
   (DESCRIPTION =
   (ADDRESS_LIST =
   (ADDRESS =
   (PROTOCOL = TCPS)
   (HOST = endpoint)
   (PORT = ssl_port_number)
   )
   )
   (CONNECT_DATA =
   (SID = database_name)
   )
   (SECURITY =
   (SSL_SERVER_CERT_DN =
   "C=US,ST=Washington,L=Seattle,O=Amazon.com,OU=RDS,CN=endpoint")
   )
   )
   )
   ```

6. In the same directory, modify or create the sqlnet.ora file and include the following parameters.
Note

To communicate with entities over a TLS secured connection, Oracle requires a wallet with the necessary certificates for authentication. You can use Oracle's ORAPKI utility to create and maintain Oracle wallets, as shown in step 7. For more information, see Setting up Oracle wallet using ORAPKI in the Oracle documentation.

WALLET_LOCATION = (SOURCE = (METHOD = FILE) (METHOD_DATA = (DIRECTORY = $ORACLE_HOME/ssl_wallet)))
SSL_CLIENT_AUTHENTICATION = FALSE
SSL_VERSION = 1.0
SSL_CIPHER_SUITES = (SSL_RSA_WITH_AES_256_CBC_SHA)
SSL_SERVER_DN_MATCH = ON

Note

You can set SSL_VERSION to a higher value if your DB instance supports it.

7. Run the following command to create the Oracle wallet.

```
prompt>orapki wallet create -wallet $ORACLE_HOME/ssl_wallet -auto_login_only
```

8. Extract each certificate in the .pem bundle file into a separate .pem file using an OS utility.

9. Add each certificate to your wallet using separate orapki commands, replacing certificate-pem-file with the absolute file name of the .pem file.

```
prompt>orapki wallet add -wallet $ORACLE_HOME/ssl_wallet -trusted_cert -cert certificate-pem-file -auto_login_only
```

For more information, see Rotating your SSL/TLS certificate.

Connecting to an RDS for Oracle DB instance using SSL

After you configure SQL*Plus to use SSL as described previously, you can connect to the RDS for Oracle DB instance with the SSL option. Optionally, you can first export the TNS_ADMIN value that
points to the directory that contains the tnsnames.ora and sqlnet.ora files. Doing so ensures that SQL*Plus can find these files consistently. The following example exports the TNS_ADMIN value.

```sh
export TNS_ADMIN = ${ORACLE_HOME}/network/admin
```

Connect to the DB instance. For example, you can connect using SQL*Plus and a `<net_service_name>` in a tnsnames.ora file.

```sql
sqlplus mydbuser@net_service_name
```

You can also connect to the DB instance using SQL*Plus without using a tnsnames.ora file by using the following command.

```sql
sqlplus 'mydbuser@(DESCRIPTION = (ADDRESS = (PROTOCOL = TCPS)(HOST = endpoint) (PORT = ssl_port_number))(CONNECT_DATA = (SID = database_name)))'
```

You can also connect to the RDS for Oracle DB instance without using SSL. For example, the following command connects to the DB instance through the clear text port without SSL encryption.

```sql
sqlplus 'mydbuser@(DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(HOST = endpoint) (PORT = port_number))(CONNECT_DATA = (SID = database_name)))'
```

If you want to close Transmission Control Protocol (TCP) port access, create a security group with no IP address ingresses and add it to the instance. This addition closes connections over the TCP port, while still allowing connections over the SSL port that are specified from IP addresses within the range permitted by the SSL option security group.

**Setting up an SSL connection over JDBC**

To use an SSL connection over JDBC, you must create a keystore, trust the Amazon RDS root CA certificate, and use the code snippet specified following.

To create the keystore in JKS format, you can use the following command. For more information about creating the keystore, see the [Creating a keystore](https://docs.oracle.com/en/database/oracle/oracle-database/19/dsql/jdbc-ssl-keystore.html) in the Oracle documentation. For reference information, see `keytool` in the [Java Platform, Standard Edition Tools Reference](https://docs.oracle.com/en/java/javase/11/docs/tooldocs/jdk11/keytool.html).

```bash
keytool -genkey -alias client -validity 365 -keyalg RSA -keystore clientkeystore
```
Take the following steps to trust the Amazon RDS root CA certificate.

**To trust the Amazon RDS root CA certificate**

1. Download the certificate bundle .pem file that works for all AWS Regions and put the file in the ssl_wallet directory.
   
   For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

2. Extract each certificate in the .pem file into a separate file using an OS utility.

3. Convert each certificate to .der format using a separate openssl command, replacing `certificate-pem-file` with the name of the certificate .pem file (without the .pem extension).

   ```bash
   openssl x509 -outform der -in certificate-pem-file.pem -out certificate-pem-file.der
   ```

4. Import each certificate into the keystore using the following command.

   ```bash
   keytool -import -alias rds-root -keystore clientkeystore.jks -file certificate-pem-file.der
   ```

   For more information, see [Rotating your SSL/TLS certificate](#).

5. Confirm that the key store was created successfully.

   ```bash
   keytool -list -v -keystore clientkeystore.jks
   ```

   Enter the keystore password when you are prompted for it.

The following code example shows how to set up the SSL connection using JDBC.

```java
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.util.Properties;
import java.util.Properties;

public class OracleSslConnectionTest {
    private static final String DB_SERVER_NAME = "dns-name-provided-by-amazon-rds";
```
private static final Integer SSL_PORT = "ssl-option-port-configured-in-option-group";
private static final String DB_SID = "oracle-sid";
private static final String DB_USER = "user-name";
private static final String DB_PASSWORD = "password";
// This key store has only the prod root ca.
private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
private static final String KEY_STORE_PASS = "keystore-password";

public static void main(String[] args) throws SQLException {
    final Properties properties = new Properties();
    final String connectionString = String.format("jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))(CONNECT_DATA=(SID=%s)))",
            DB_SERVER_NAME, SSL_PORT, DB_SID);
    properties.put("user", DB_USER);
    properties.put("password", DB_PASSWORD);
    properties.put("oracle.jdbc.J2EE13Compliant", "true");
    properties.put("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
    properties.put("javax.net.ssl.trustStoreType", "JKS");
    properties.put("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
    final Connection connection = DriverManager.getConnection(connectionString, properties);
    // If no exception, that means handshake has passed, and an SSL connection can be opened
}

Note
Specify a password other than the prompt shown here as a security best practice.

Enforcing a DN match with an SSL connection

You can use the Oracle parameter SSL_SERVER_DN_MATCH to enforce that the distinguished name (DN) for the database server matches its service name. If you enforce the match verifications, then SSL ensures that the certificate is from the server. If you don’t enforce the match verification, then SSL performs the check but allows the connection, regardless if there is a match. If you do not enforce the match, you allow the server to potentially fake its identify.
To enforce DN matching, add the DN match property and use the connection string specified below.

Add the property to the client connection to enforce DN matching.

```java
properties.put("oracle.net.ssl_server_dn_match", "TRUE");
```

Use the following connection string to enforce DN matching when using SSL.

```java
final String connectionString = String.format(
        "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))" +
        "(CONNECT_DATA=(SID=%s))" +
        "(SECURITY = (SSL_SERVER_CERT_DN = \"C=US,ST=Washington,L=Seattle,O=Amazon.com,OU=RDS,CN=%s\")))",
        DB_SERVER_NAME, SSL_PORT, DB_SID, DB_SERVER_NAME);
```

**Troubleshooting SSL connections**

You might query your database and receive the ORA-28860 error.

ORA-28860: Fatal SSL error
28860. 00000 - "Fatal SSL error"
*Cause: An error occurred during the SSL connection to the peer. It is likely that this side sent data which the peer rejected.
*Action: Enable tracing to determine the exact cause of this error.

This error occurs when the client attempts to connect using a version of TLS that the server doesn't support. To avoid this error, edit the sqlnet.ora and set SSL_VERSION to the correct TLS version. For more information, see [Oracle Support Document 2748438.1](https://support.oracle.com/knowledge/database/secure-sockets-layer-ssl/2748438.1) in My Oracle Support.
Amazon RDS supports Oracle Spatial through the use of the SPATIAL option. Oracle Spatial provides a SQL schema and functions that facilitate the storage, retrieval, update, and query of collections of spatial data in an Oracle database. For more information, see Spatial Concepts in the Oracle documentation.

⚠️ **Important**

If you use Oracle Spatial, Amazon RDS automatically updates your DB instance to the latest Oracle PSU when any of the following exist:

- Security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+
- Other announced security vulnerabilities

Amazon RDS supports Oracle Spatial only in Oracle Enterprise Edition (EE) and Oracle Standard Edition 2 (SE2). The following table shows the versions of the DB engine that support EE and SE2.

<table>
<thead>
<tr>
<th>Oracle DB Version</th>
<th>EE</th>
<th>SE2</th>
</tr>
</thead>
<tbody>
<tr>
<td>21.0.0.0, all versions</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>19.0.0.0, all versions</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>12.2.0.1, all versions</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>12.1.0.2.v13 or later</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

⚠️ **Note**

In Oracle Database 19c, Spatial patch bundles are separate from the database Patch Set Updates (PSUs) and Release Updates (RUs). RDS for Oracle doesn't support applying Spatial batch bundles.
Prerequisites for Oracle Spatial

The following are prerequisites for using Oracle Spatial:

- Make sure that your DB instance is of a sufficient instance class. Oracle Spatial isn’t supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes.

- Make sure that your DB instance has Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance.

Best practices for Oracle Spatial

The following are best practices for using Oracle Spatial:

- For maximum security, use the SPATIAL option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer.

- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC and Working with a DB instance in a VPC.

Adding the Oracle Spatial option

The following is the general process for adding the SPATIAL option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the SPATIAL option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don’t need to restart your DB instance. As soon as the option group is active, Oracle Spatial is available.
Note

During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

To add the SPATIAL option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For Engine, choose the Oracle edition for your DB instance.
   b. For Major engine version, choose the version of your DB instance.

   For more information, see Creating an option group.

2. Add the SPATIAL option to the option group. For more information about adding options, see Adding an option to an option group.

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Removing the Oracle Spatial option

After you drop all objects that use data types provided by the SPATIAL option, you can drop the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the SPATIAL option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the SPATIAL option, you don’t need to restart your DB instance.
To drop the SPATIAL option

1. Back up your data.

   **Warning**
   
   If the instance uses data types that were enabled as part of the option, and if you remove the SPATIAL option, you can lose data. For more information, see [Backing up, restoring, and exporting data](#).

2. Check whether any existing objects reference data types or features of the SPATIAL option.

   If SPATIAL options exist, the instance can get stuck when applying the new option group that doesn't have the SPATIAL option. You can identify the objects by using the following queries:

   ```sql
   SELECT OWNER, SEGMENT_NAME, TABLESPACE_NAME, BYTES/1024/1024 mbytes
   FROM   DBA_SEGMENTS
   WHERE  SEGMENT_TYPE LIKE '%TABLE%'
   AND    (OWNER, SEGMENT_NAME) IN
           (SELECT DISTINCT OWNER, TABLE_NAME
            FROM   DBA_TAB_COLUMNS
            WHERE  DATA_TYPE='SDO_GEOMETRY'
            AND    OWNER <> 'MDSYS')
   ORDER BY 1,2,3,4;
   
   SELECT OWNER, TABLE_NAME, COLUMN_NAME
   FROM   DBA_TAB_COLUMNS
   WHERE  DATA_TYPE = 'SDO_GEOMETRY'
   AND    OWNER <> 'MDSYS'
   ORDER BY 1,2,3;
   ```

3. Drop any objects that reference data types or features of the SPATIAL option.

4. Do one of the following:

   - Remove the SPATIAL option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#).
   - Modify the DB instance and specify a different option group that doesn't include the SPATIAL option. This change affects a single DB instance. You can specify the default
(empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.
Oracle SQLT

Amazon RDS supports Oracle SQLT (SQLXPLAIN) through the use of the SQLT option.

The Oracle EXPLAIN PLAN statement can determine the execution plan of a SQL statement. It can verify whether the Oracle optimizer chooses a certain execution plan, such as a nested loops join. It also helps you understand the optimizer's decisions, such as why it chose a nested loops join over a hash join. So EXPLAIN PLAN helps you understand the statement's performance.

SQLT is an Oracle utility that produces a report. The report includes object statistics, object metadata, optimizer-related initialization parameters, and other information that a database administrator can use to tune a SQL statement for optimal performance. SQLT produces an HTML report with hyperlinks to all of the sections in the report.

Unlike Automatic Workload Repository or Statspack reports, SQLT works on individual SQL statements. SQLT is a collection of SQL, PL/SQL, and SQL*Plus files that collect, store, and display performance data.

Following are the supported Oracle versions for each SQLT version.

<table>
<thead>
<tr>
<th>SQLT version</th>
<th>Oracle Database 21c</th>
<th>Oracle Database 19c</th>
<th>Oracle Database 12c Release 2 (12.2)</th>
<th>Oracle Database 12c Release 1 (12.1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2018-07-25.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>2018-03-31.v1</td>
<td>Not supported</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>2016-04-29.v1</td>
<td>Not supported</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>

To download SQLT and access instructions for using it:

- Log in to your My Oracle Support account, and open the following documents:
- To download SQLT: Document 215187.1
- For SQLT usage instructions: Document 1614107.1
- For frequently asked questions about SQLT: Document 1454160.1
- For information about reading SQLT output: Document 1456176.1
- For interpreting the Main report: Document 1922234.1
You can use SQLT with any edition of the following Oracle Database versions:

- Oracle Database 21c (21.0.0.0)
- Oracle Database 19c (19.0.0.0)
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1.0.2)

Amazon RDS does not support the following SQLT methods:

- XPLORE
- XHUME

Prerequisites for SQLT

The following are prerequisites for using SQLT:

- You must remove users and roles that are required by SQLT, if they exist.

  The SQLT option creates the following users and roles on a DB instance:

  - SQLTXPLAIN user
  - SQLTXADMIN user
  - SQLT_USER_ROLE role

If your DB instance has any of these users or roles, log in to the DB instance using a SQL client, and drop them using the following statements:

```
DROP USER SQLTXPLAIN CASCADE;
DROP USER SQLTXADMIN CASCADE;
DROP ROLE SQLT_USER_ROLE CASCADE;
```

- You must remove tablespaces that are required by SQLT, if they exist.

  The SQLT option creates the following tablespaces on a DB instance:

  - RDS_SQLT_TS
  - RDS_TEMP_SQLT_TS
If your DB instance has these tablespaces, log in to the DB instance using a SQL client, and drop them.

**SQLT option settings**

SQLT can work with licensed features that are provided by the Oracle Tuning Pack and the Oracle Diagnostics Pack. The Oracle Tuning Pack includes the SQL Tuning Advisor, and the Oracle Diagnostics Pack includes the Automatic Workload Repository. The SQLT settings enable or disable access to these features from SQLT.

Amazon RDS supports the following settings for the SQLT option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LICENSE_PACK</td>
<td>T, D, N</td>
<td>N</td>
<td>The Oracle Management Packs that you want to access with SQLT. Enter one of the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• T indicates that you have a license for the Oracle Tuning Pack and the Oracle Diagnostics Pack, and you want to access the SQL Tuning Advisor and Automatic Workload Repository from SQLT.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• D indicates that you have a license for the Oracle Diagnostics Pack, and you want to access the Automatic Workload Repository from SQLT.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• N indicates that you don't have a license for the Oracle Tuning Pack and the Oracle Diagnostics Pack, or that you have a license for one or both of them, but you don't want SQLT to access them.</td>
</tr>
</tbody>
</table>
Amazon RDS does not provide licenses for these Oracle Management Packs. If you indicate that you want to use a pack that is not included in your DB instance, you can use SQLT with the DB instance. However, SQLT can't access the pack, and the SQLT report doesn't include the data for the pack. For example, if you specify T, but the DB instance doesn't include the Oracle Tuning Pack, SQLT works on the DB instance, but the report it generates doesn't contain data related to the Oracle Tuning Pack.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VERSION</td>
<td>2016-04-29.v1</td>
<td>2016-04-29.v1</td>
<td>The version of SQLT that you want to install.</td>
</tr>
<tr>
<td></td>
<td>2018-03-31.v1</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>2018-07-25.v1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note**

For Oracle Database 19c and 21c, the only supported version is 2018-07-25.v1. This version is the default for these releases.
Adding the SQLT option

The following is the general process for adding the SQLT option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the SQLT option to the option group.
3. Associate the option group with the DB instance.

After you add the SQLT option, as soon as the option group is active, SQLT is active.

To add the SQLT option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the Oracle edition that you want to use. The SQLT option is supported on all editions.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see [Creating an option group](#).

2. Add the **SQLT** option to the option group. For more information about adding options, see [Adding an option to an option group](#).

3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).

4. (Optional) Verify the SQLT installation on each DB instance with the SQLT option.
   a. Use a SQL client to connect to the DB instance as the master user.

   For information about connecting to an Oracle DB instance using a SQL client, see [Connecting to your RDS for Oracle DB instance](#).
b. Run the following query:

```
SELECT sqltxplain.sqlt$a.get_param('tool_version') sqlt_version FROM DUAL;
```

The query returns the current version of the SQLT option on Amazon RDS. 12.1.160429 is an example of a version of SQLT that is available on Amazon RDS.

5. Change the passwords of the users that are created by the SQLT option.

   a. Use a SQL client to connect to the DB instance as the master user.

   b. Run the following SQL statement to change the password for the SQLTXADMIN user:

```
ALTER USER SQLTXADMIN IDENTIFIED BY new_password ACCOUNT UNLOCK;
```

   Note

Specify a password other than the prompt shown here as a security best practice.

   c. Run the following SQL statement to change the password for the SQLTXPLAIN user:

```
ALTER USER SQLTXPLAIN IDENTIFIED BY new_password ACCOUNT UNLOCK;
```

   Note

Specify a password other than the prompt shown here as a security best practice.
Note

Upgrading SQLT requires uninstalling an older version of SQLT and then installing the new version. So, all SQLT metadata can be lost when you upgrade SQLT. A major version upgrade of a database also uninstalls and re-installs SQLT. An example of a major version upgrade is an upgrade from Oracle Database 12c Release 2 (12.2) to Oracle Database 19c.

Using SQLT

SQLT works with the Oracle SQL*Plus utility.

To use SQLT

1. Download the SQLT .zip file from Document 215187.1 on the My Oracle Support site.

   Note
   
   You can't download SQLT 12.1.160429 from the My Oracle Support site. Oracle has deprecated this older version.

2. Unzip the SQLT .zip file.

3. From a command prompt, change to the sqlt/run directory on your file system.

4. From the command prompt, open SQL*Plus, and connect to the DB instance as the master user.

   For information about connecting to a DB instance using SQL*Plus, see Connecting to your RDS for Oracle DB instance.

5. Get the SQL ID of a SQL statement:

   ```sql
   SELECT SQL_ID FROM V$SQL WHERE SQL_TEXT = 'sql_statement';
   ```

   Your output is similar to the following:
6. Analyze a SQL statement with SQLT:

   START sqltxtract.sql sql_id sqltxplain_user_password

   For example, for the SQL ID chvsmttqjzjkn, enter the following:

   START sqltxtract.sql chvsmttqjzjkn sqltxplain_user_password

   SQLT generates the HTML report and related resources as a .zip file in the directory from which the SQLT command was run.

7. (Optional) To enable application users to diagnose SQL statements with SQLT, grant SQLT_USER_ROLE to each application user with the following statement:

   GRANT SQLT_USER_ROLE TO application_user_name;

   Note
   Oracle does not recommend running SQLT with the SYS user or with users that have the DBA role. It is a best practice to run SQLT diagnostics using the application user's account, by granting SQLT_USER_ROLE to the application user.

Upgrading the SQLT option

With Amazon RDS for Oracle, you can upgrade the SQLT option from your existing version to a higher version. To upgrade the SQLT option, complete steps 1–3 in Using SQLT for the new version of SQLT. Also, if you granted privileges for the previous version of SQLT in step 7 of that section, grant the privileges again for the new SQLT version.
Upgrading the SQLT option results in the loss of the older SQLT version's metadata. The older SQLT version's schema and related objects are dropped, and the newer version of SQLT is installed. For more information about the changes in the latest SQLT version, see Document 1614201.1 on the My Oracle Support site.

Note
Version downgrades are not supported.

Modifying SQLT settings

After you enable SQLT, you can modify the LICENSE_PACK and VERSION settings for the option.

For more information about how to modify option settings, see Modifying an option setting. For more information about each setting, see SQLT option settings.

Removing the SQLT option

You can remove SQLT from a DB instance.

To remove SQLT from a DB instance, do one of the following:

- To remove SQLT from multiple DB instances, remove the SQLT option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.

- To remove SQLT from a single DB instance, modify the DB instance and specify a different option group that doesn't include the SQLT option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.
Oracle Statspack

The Oracle Statspack option installs and enables the Oracle Statspack performance statistics feature. Oracle Statspack is a collection of SQL, PL/SQL, and SQL*Plus scripts that collect, store, and display performance data. For information about using Oracle Statspack, see Oracle Statspack in the Oracle documentation.

 Quaternion Note

Oracle Statspack is no longer supported by Oracle and has been replaced by the more advanced Automatic Workload Repository (AWR). AWR is available only for Oracle Enterprise Edition customers who have purchased the Diagnostics Pack. You can use Oracle Statspack with any Oracle DB engine on Amazon RDS. You can't run Oracle Statspack on Amazon RDS read replicas.

Setting up Oracle Statspack

To run Statspack scripts, you must add the Statspack option.

To set up Oracle Statspack

1. In a SQL client, log in to the Oracle DB with an administrative account.
2. Do either of the following actions, depending on whether Statspack is installed:
   - If Statspack is installed, and the\PERFSTAT\ account is associated with Statspack, skip to Step 4.
   - If Statspack is not installed, and the\PERFSTAT\ account exists, drop the account as follows:
     ```
     DROP USER PERFSTAT CASCADE;
     ```
     Otherwise, attempting to add the Statspack option generates an error and RDS-Event\0058.
3. Add the Statspack option to an option group. See Adding an option to an option group.

   Amazon RDS automatically installs the Statspack scripts on the DB instance and then sets up the\PERFSTAT\ account.
4. Reset the password using the following SQL statement, replacing *pwd* with your new password:

```sql
ALTER USER PERFSTAT IDENTIFIED BY *pwd* ACCOUNT UNLOCK;
```

You can log in using the PERFSTAT user account and run the Statspack scripts.

5. Do either of the following actions, depending on your DB engine version:

- If you are using Oracle Database 12c Release 2 (12.2) or lower, skip this step.
- If you are using Oracle Database 19c or higher, grant the CREATE JOB privilege to the PERFSTAT account using the following statement:

```sql
GRANT CREATE JOB TO PERFSTAT;
```

6. Ensure that idle wait events in the PERFSTAT.STATS$IDLE_EVENT table are populated.

Because of Oracle Bug 28523746, the idle wait events in PERFSTAT.STATS$IDLE_EVENT may not be populated. To ensure all idle events are available, run the following statement:

```sql
INSERT INTO PERFSTAT.STATS$IDLE_EVENT (EVENT)
SELECT NAME FROM V$EVENT_NAME WHERE WAIT_CLASS='Idle'
MINUS
SELECT EVENT FROM PERFSTAT.STATS$IDLE_EVENT;
COMMIT;
```

### Generating Statspack reports

A Statspack report compares two snapshots.

**To generate Statspack reports**

1. In a SQL client, log in to the Oracle DB with the PERFSTAT account.
2. Create a snapshot using either of the following techniques:
   - Create a Statspack snapshot manually.
   - Create a job that takes a Statspack snapshot after a given time interval. For example, the following job creates a Statspack snapshot every hour:
3. View the snapshots using the following query:

```sql
SELECT SNAP_ID, SNAP_TIME FROM STATS$SNAPSHOT ORDER BY 1;
```

4. Run the Amazon RDS procedure `rdsadmin.rds_run_spreport`, replacing `begin_snap` and `end_snap` with the snapshot IDs:

```sql
exec rdsadmin.rds_run_spreport(begin_snap,end_snap);
```

For example, the following command creates a report based on the interval between Statspack snapshots 1 and 2:

```sql
exec rdsadmin.rds_run_spreport(1,2);
```

The file name of the Statspack report includes the number of the two snapshots. For example, a report file created using Statspack snapshots 1 and 2 would be named `ORCL_spreport_1_2.lst`.

5. Monitor the output for errors.

Oracle Statspack performs checks before running the report. Therefore, you could also see error messages in the command output. For example, you might try to generate a report based on an invalid range, where the beginning Statspack snapshot value is larger than the ending value. In this case, the output shows the error message, but the DB engine does not generate an error file.

```sql
exec rdsadmin.rds_run_spreport(2,1);
* 
ERROR at line 1:
ORA-20000: Invalid snapshot IDs. Find valid ones in perfstat.stats$snapshot.
```

If you use an invalid number a Statspack snapshot, the output shows an error. For example, if you try to generate a report for snapshots 1 and 50, but snapshot 50 doesn’t exist, the output shows an error.
exec rdsadmin.rds_run_spreport(1,50);
*
ERROR at line 1:
ORA-20000: Could not find both snapshot IDs

6. (Optional)

To retrieve the report, call the trace file procedures, as explained in Working with Oracle trace files.

Alternatively, download the Statspack report from the RDS console. Go to the Log section of the DB instance details and choose Download:

![Log section of DB instance details]

If an error occurs while generating a report, the DB engine uses the same naming conventions as for a report but with an extension of .err. For example, if an error occurred while creating a report using Statspack snapshots 1 and 7, the report file would be named ORCL_spreport_1_7.err. You can download the error report using the same techniques as for a standard Snapshot report.

Removing Statspack snapshots

To remove a range of Oracle Statspack snapshots, use the following command:

exec statspack.purge(begin snap, end snap);
Oracle time zone

To change the system time zone used by your Oracle DB instance, use the time zone option. For example, you might change the time zone of a DB instance to be compatible with an on-premises environment, or a legacy application. The time zone option changes the time zone at the host level. Changing the time zone impacts all date columns and values, including SYSDATE and SYSTIMESTAMP.

The time zone option differs from the rdsadmin_util.alter_db_time_zone command. The alter_db_time_zone command changes the time zone only for certain data types. The time zone option changes the time zone for all date columns and values. For more information about alter_db_time_zone, see Setting the database time zone. For more information about upgrade considerations, see Time zone considerations.

Considerations for setting the time zone

The time zone option is a permanent and persistent option. Therefore, you can't do the following:

- Remove the option from an option group after you add the option.
- Remove the option group from a DB instance after you add the group.
- Modify the time zone setting of the option to a different time zone.

Before you add the time zone option to your production database, we strongly recommend that you do the following:

- Take a snapshot of your DB instance. If you accidentally set the time zone incorrectly, you must recover your DB instance to its previous time zone setting. For more information, see Creating a DB snapshot for a Single-AZ DB instance.
- Add the time zone option to a test DB instance. Adding the time zone option can cause problems with tables that use the system date to add dates or times. We recommend that you analyze your data and applications on the test instance to assess the impact of changing the time zone on your production instance.

Time zone option settings

Amazon RDS supports the following settings for the time zone option.
<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIME_ZONE</td>
<td>One of the available time zones. For the full list, see <a href="#">Available time zones</a>.</td>
<td>The new time zone for your DB instance.</td>
</tr>
</tbody>
</table>

**Adding the time zone option**

The general process for adding the time zone option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When you add the time zone option, a brief outage occurs while your DB instance is automatically restarted.

**Console**

**To add the time zone option to a DB instance**

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine** choose the oracle edition for your DB instance.
   b. For **Major engine version** choose the version of your DB instance.

   For more information, see [Creating an option group](#).

2. Add the **Timezone** option to the option group, and configure the option settings.

⚠️ **Important**

If you add the time zone option to an existing option group that is already attached to one or more DB instances, a brief outage occurs while all the DB instances are automatically restarted.
For more information about adding options, see Adding an option to an option group. For more information about each setting, see Time zone option settings.

3. Apply the option group to a new or existing DB instance:

   • For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   
   • For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the time zone option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance.

AWS CLI

The following example uses the AWS CLI add-option-to-option-group command to add the Timezone option and the TIME_ZONE option setting to an option group called myoptiongroup. The time zone is set to Africa/Cairo.

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
   --option-group-name "myoptiongroup" \
   --options "OptionName=Timezone,OptionSettings=[[Name=TIME_ZONE,Value=Africa/Cairo]]" \
   --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^
   --option-group-name "myoptiongroup" ^
   --options "OptionName=Timezone,OptionSettings=[[Name=TIME_ZONE,Value=Africa/Cairo]]" ^
   --apply-immediately
```

Modifying time zone settings

The time zone option is a permanent and persistent option. You can't remove the option from an option group after you add it. You can't remove the option group from a DB instance after you
add it. You can't modify the time zone setting of the option to a different time zone. If you set the time zone incorrectly, restore a snapshot of your DB instance from before you added the time zone option.

**Removing the time zone option**

The time zone option is a permanent and persistent option. You can't remove the option from an option group after you add it. You can't remove the option group from a DB instance after you add it. To remove the time zone option, restore a snapshot of your DB instance from before you added the time zone option.

**Available time zones**

You can use the following values for the time zone option.

<table>
<thead>
<tr>
<th>Zone</th>
<th>Time zone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Africa</td>
<td>Africa/Cairo, Africa/Casablanca, Africa/Harare, Africa/Lagos, Africa/Luanda, Africa/Monrovia, Africa/Nairobi, Africa/Tripoli, Africa/Windhoek</td>
</tr>
<tr>
<td>America</td>
<td>America/Ariguaina, America/Argentina/Buenos Aires, America/Asuncion, America/Bogota, America/Caracas, America/Chicago, America/Chihuahua, America/Cuiaba, America/Denver, America/Detroit, America/Fortaleza, America/Godthab, America/Guatemala, America/Halifax, America/Lima, America/Los Angeles, America/Manaus, America/Matamoros, America/Mexico_City, America/Monterrey, America/Montervideo, America/New York, America/Phoenix, America/Santiago, America/Sao Paulo, America/Tijuana, America/Toronto</td>
</tr>
<tr>
<td>Asia</td>

</tbody>
</table>
Oracle time zone file autoupgrade

With the TIMEZONE_FILE_AUTOUPGRADE option, you can upgrade the current time zone file to the latest version on your RDS for Oracle DB instance.

Topics

- Overview of Oracle time zone files
- Strategies for updating your time zone file
- Downtime during the time zone file update
- Preparing to update the time zone file
- Adding the time zone file autoupgrade option
- Checking your data after the update of the time zone file

Overview of Oracle time zone files

An Oracle Database time zone file stores the following information:

- Offset from Coordinated Universal Time (UTC)
- Transition times for Daylight Saving Time (DST)
- Abbreviations for standard time and DST

Oracle Database supplies multiple versions of time zone files. When you create an Oracle database in an on-premises environment, you choose the time zone file version. For more information, see Choosing a Time Zone File in the Oracle Database Globalization Support Guide.

If the rules change for DST, Oracle publishes new time zone files. Oracle releases these new time zone files independently of the schedule for quarterly Release Updates (RUs) and Release Update Revisions (RURs). The time zone files reside on the database host in the directory $ORACLE_HOME/oracore/zoneinfo/. The time zone file names use the format DSTvversion, as in DSTv35.

How the time zone file affects data transfer

In Oracle Database, the TIMESTAMP WITH TIME ZONE data type stores time stamp and time zone data. Data with the TIMESTAMP WITH TIME ZONE data type uses the rules in the associated time zone file version. Thus, existing TIMESTAMP WITH TIME ZONE data is affected when you update the time zone file.
Problems can occur when you transfer data between databases that use different versions of the time zone file. For example, if you import data from a source database with a higher time zone file version than the target database, the database issues the ORA-39405 error. Previously, you had to work around this error by using either of the following techniques:

- Create an RDS for Oracle DB instance with the desired time zone file, export data from your source database, and then import it into the new database.
- Use AWS DMS or logical replication to migrate your data.

**Automatic updates using the TIMEZONE_FILE_AUTOUPGRADE option**

When the option group attached to your RDS for Oracle DB instance includes the TIMEZONE_FILE_AUTOUPGRADE option, RDS updates your time zone files automatically. By ensuring that your Oracle databases use the same time zone file version, you avoid time-consuming manual techniques when you move data between different environments. The TIMEZONE_FILE_AUTOUPGRADE option is supported for both container databases (CDBs) and non-CDBs.

When you add the TIMEZONE_FILE_AUTOUPGRADE option to your option group, you can choose whether to add the option immediately or during the maintenance window. After your DB instance applies the new option, RDS checks whether it can install a newer DSTvversion file. The target DSTvversion depends on the following:

- The minor engine version that your DB instance is currently running
- The minor engine version to which you want to upgrade your DB instance

For example, your current time zone file version might be DSTv33. When RDS applies the update to your option group, it might determine that DSTv34 is currently available on your DB instance file system. RDS will then update your time zone file to DSTv34 automatically.

To find the available DST versions in the supported RDS release updates, look at the patches in [Release notes for Amazon Relational Database Service (Amazon RDS) for Oracle](https://aws.amazon.com/rds/oracle-release-notes/). For example, `version 19.0.0.0.ru-2022-10.rur-2022-10.r1` lists patch 34533061: RDBMS - DSTV39 UPDATE - TZDATA2022C.
Strategies for updating your time zone file

Upgrading your DB engine and adding the TIMEZONE_FILE_AUTOPGRADE option to an option group are separate operations. Adding the TIMEZONE_FILE_AUTOPGRADE option initiates the update of your time zone file if a more current one is available. You run the following commands (only relevant options are shown) either immediately or at the next maintenance window:

- Upgrade your DB engine only using the following RDS CLI command:

  ```
  modify-db-instance --engine-version name ...
  ```

- Add the TIMEZONE_FILE_AUTOPGRADE option only using the following CLI command:

  ```
  add-option-to-option-group --option-group-name name --options
  OptionName=TIMEZONE_FILE_AUTOPGRADE ...
  ```

- Upgrade your DB engine and add a new option group to your instance using the following CLI command:

  ```
  modify-db-instance --engine-version name --option-group-name name ...
  ```

Your update strategy depends on whether you want to upgrade your database and time zone file together or perform just one of these operations. Keep in mind that if you update your option group and then upgrade your DB engine in separate API operations, it's possible for a time zone file update to be currently in progress when you upgrade your DB engine.

The examples in this section assume the following:

- You have not yet added TIMEZONE_FILE_AUTOPGRADE to the option group currently associated with your DB instance.
- Your DB instance file system includes file DSTv34.

To update your time zone file, you can use the following strategies.

Topics

Time zone file autoupgrade
- **Update the time zone file without upgrading the engine**
- **Upgrade the time zone file and DB engine version**
- **Upgrade your DB engine version without updating the time zone file**

**Update the time zone file without upgrading the engine**

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to update the time zone file used by your DB instance from DSTv33 to DSTv34, but you don’t want to upgrade your engine to a new minor version, which includes DSTv35.

In an add-option-to-option-group command, add TIMEZONE_FILE_AUTOUPGRADE to the option group used by your DB instance. Specify whether to add the option immediately or defer it to the maintenance window. After applying the TIMEZONE_FILE_AUTOUPGRADE option, RDS does the following:

1. Checks for a new DST version.
2. Determines that DSTv34 is available on the file system.
3. Updates the time zone file immediately.

**Upgrade the time zone file and DB engine version**

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to upgrade your DB engine to minor version 19.0.0.0.ru-2022-10.rur-2022-10.r1, which includes DSTv35, and update your time zone file to DSTv35 during the engine upgrade. Thus, your goal is to skip DSTv34 and update your time zone files directly to DSTv35.

To upgrade the engine and time zone file together, run modify-db-instance with the --option-group-name and --engine-version options. You can run the command immediately or defer it to maintenance window. In --option-group-name, specify an option group that includes the TIMEZONE_FILE_AUTOUPGRADE option. For example:

```
aws rds modify-db-instance
   --db-instance-identifier my-instance \
   --engine-version new-version \
   ----option-group-name og-with-timezone-file-autoupgrade \
   --apply-immediately
```
RDS begins upgrading your engine to 19.0.0.0.ru-2022-10.rur-2022-10.r1. After applying the TIMEZONE_FILE_AUTOUPGRADE option, RDS checks for a new DST version, sees that DSTv35 is available in 19.0.0.0.ru-2022-10.rur-2022-10.r1, and immediately starts the update to DSTv35.

To upgrade your engine immediately and then upgrade your a timezone file, perform the operations in sequence:

1. Upgrade your DB engine only using the following CLI command:

   ```bash
   aws rds modify-db-instance
   --db-instance-identifier my-instance
   --engine-version new-version
   --apply-immediately
   ```

2. Add the TIMEZONE_FILE_AUTOUPGRADE option to the option group attached to your instance using the following CLI command:

   ```bash
   aws rds add-option-to-option-group
   --option-group-name og-in-use-by-your-instance
   --options OptionName=TIMEZONE_FILE_AUTOUPGRADE
   --apply-immediately
   ```

**Upgrade your DB engine version without updating the time zone file**

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to upgrade your DB engine to version 19.0.0.0.ru-2022-10.rur-2022-10.r1, which includes DSTv35, but retain time zone file DSTv33. You might choose this strategy for the following reasons:

- Your data doesn’t use the `TIMESTAMP WITH TIME ZONE` data type.
- Your data uses the `TIMESTAMP WITH TIME ZONE` data type, but your data is not affected by the time zone changes.
- You want to postpone updating the time zone file because you can’t tolerate the extra downtime.

Your strategy depends on which of the following possibilities are true:
• Your DB instance isn't associated with an option group that includes `TIMEZONE_FILE_AUTOUPGRADE`. In your `modify-db-instance` command, don't specify a new option group so that RDS doesn't update your time zone file.

• Your DB instance is currently associated with an option group that includes `TIMEZONE_FILE_AUTOUPGRADE`. Within a single `modify-db-instance` command, associate your DB instance with an option group that doesn't include `TIMEZONE_FILE_AUTOUPGRADE` and upgrade your DB engine to 19.0.0.0.ru-2022-10.rur-2022-10.r1.

**Downtime during the time zone file update**

When RDS updates your time zone file, existing data that uses `TIMESTAMP WITH TIME ZONE` might change. In this case, your primary consideration is downtime.

⚠️ **Warning**

If you add the `TIMEZONE_FILE_AUTOUPGRADE` option, your engine upgrade might have prolonged downtime. Updating time zone data for a large database might take hours or even days.

The length of the time zone file update depends on factors such as the following:

- The amount of `TIMESTAMP WITH TIME ZONE` data in your database
- The DB instance configuration
- The DB instance class
- The storage configuration
- The database configuration
- The database parameter settings

Additional downtime can occur when you do the following:

- Add the option to the option group when the DB instance uses an outdated time zone file
- Upgrade the Oracle database engine when the new engine version contains a new version of the time zone file
Preparing to update the time zone file

A time zone file upgrade has two separate phases: prepare and upgrade. While not required, we strongly recommend that you perform the prepare step. In this step, you find out which data will be affected by running the PL/SQL procedure DBMS_DST.FIND_AFFECTED_TABLES. For more information about the prepare window, see Upgrading the Time Zone File and Timestamp with Time Zone Data in the Oracle Database documentation.

To prepare to update the time zone file

1. Connect to your Oracle database using a SQL client.
2. Determine the current timezone file version used.

```sql
SELECT * FROM V$TIMEZONE_FILE;
```

3. Determine the latest timezone file version available on your DB instance. This step is only applicable if you use Oracle Database 12c Release 2 (12.2) or higher.

```sql
SELECT DBMS_DST.GET_LATEST_TIMEZONE_VERSION FROM DUAL;
```

4. Determine the total size of tables that have columns of type TIMESTAMP WITH LOCAL TIME ZONE or TIMESTAMP WITH TIME ZONE.

```sql
SELECT SUM(BYTES)/1024/1024/1024 "Total_size_w_TSTZ_columns_GB"
FROM   DBA_SEGMENTS
WHERE  SEGMENT_TYPE LIKE 'TABLE'
AND    (OWNER, SEGMENT_NAME) IN
   (SELECT OWNER, TABLE_NAME
    FROM   DBA_TAB_COLUMNS
    WHERE  DATA_TYPE LIKE 'TIMESTAMP%TIME ZONE');
```

5. Determine the names and sizes of segments that have columns of type TIMESTAMP WITH LOCAL TIME ZONE or TIMESTAMP WITH TIME ZONE.
SELECT OWNER, SEGMENT_NAME, SUM(BYTES)/1024/1024/1024
"SEGMENT_SIZE_W_TSTZ_COLUMNS_GB"
FROM   DBA_SEGMENTS
WHERE  SEGMENT_TYPE LIKE 'TABLE%'
AND    (OWNER, SEGMENT_NAME) IN
       (SELECT OWNER, TABLE_NAME
        FROM   DBA_TAB_COLUMNS
        WHERE  DATA_TYPE LIKE 'TIMESTAMP%TIME ZONE')
GROUP BY OWNER, SEGMENT_NAME;

6. Run the prepare step.

   - The procedure DBMS_DST.CREATE_AFFECTED_TABLE creates a table to store any affected data. You pass the name of this table to the DBMS_DST.FIND_AFFECTED_TABLES procedure. For more information, see CREATE_AFFECTED_TABLE Procedure in the Oracle Database documentation.

   - This procedure CREATE_ERROR_TABLE creates a table to log errors. For more information, see CREATE_ERROR_TABLE Procedure in the Oracle Database documentation.

The following example creates the affected data and error tables, and finds all affected tables.

EXEC DBMS_DST.CREATE_ERROR_TABLE('my_error_table')
EXEC DBMS_DST.CREATE_AFFECTED_TABLE('my_affected_table')
EXEC DBMS_DST.BEGIN_PREPARE(new_version);
EXEC DBMS_DST.FIND_AFFECTED_TABLES('my_affected_table', TRUE, 'my_error_table');
EXEC DBMS_DST.END_PREPARE;
SELECT * FROM my_affected_table;
SELECT * FROM my_error_table;

7. Query the affected and error tables.

SELECT * FROM my_affected_table;
SELECT * FROM my_error_table;

Adding the time zone file autoupgrade option

When you add the option to an option group, the option group is in one of the following states:
• An existing option group is currently attached to at least one DB instance. When you add the option, all DB instances that use this option group automatically restart. This causes a brief outage.

• An existing option group is not attached to any DB instance. You plan to add the option and then associate the existing option group with existing DB instances or with a new DB instance.

• You create a new option group and add the option. You plan to associate the new option group with existing DB instances or with a new DB instance.

Console

To add the time zone file autoupgrade option to a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose Option groups.

3. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For Engine choose the Oracle Database edition for your DB instance.
   b. For Major engine version choose the version of your DB instance.

   For more information, see Creating an option group.

4. Choose the option group that you want to modify, and then choose Add option.

5. In the Add option window, do the following:
   a. Choose TIMEZONE_FILE_AUTOPURGE.
   b. To enable the option on all associated DB instances as soon as you add it, for Apply Immediately, choose Yes. If you choose No (the default), the option is enabled for each associated DB instance during its next maintenance window.

6. When the settings are as you want them, choose Add option.
AWS CLI

The following example uses the AWS CLI add-option-to-option-group command to add the TIMEZONE_FILE_AUTOPURGE option to an option group called myoptiongroup.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
   --option-group-name "myoptiongroup" \
   --options "OptionName=TIMEZONE_FILE_AUTOPURGE" \
   --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
   --option-group-name "myoptiongroup" ^
   --options "OptionName=TIMEZONE_FILE_AUTOPURGE" ^
   --apply-immediately
```

Checking your data after the update of the time zone file

We recommend that you check your data after you update the time zone file. During the prepare step, RDS for Oracle automatically creates the following tables:

- **rdsadmin.rds_dst_affected_tables** – Lists the tables that contain data affected by the update
- **rdsadmin.rds_dst_error_table** – Lists the errors generated during the update

These tables are independent of any tables that you create in the prepare window. To see the results of the update, query the tables as follows.

```
SELECT * FROM rdsadmin.rds_dst_affected_tables;
SELECT * FROM rdsadmin.rds_dst_error_table;
```

For more information about the schema for the affected data and error tables, see [FIND_AFFECTED_TABLES Procedure](#) in the Oracle documentation.
Oracle Transparent Data Encryption

Amazon RDS supports Oracle Transparent Data Encryption (TDE), a feature of the Oracle Advanced Security option available in Oracle Enterprise Edition. This feature automatically encrypts data before it is written to storage and automatically decrypts data when the data is read from storage.

TDE is useful in scenarios where you need to encrypt sensitive data in case data files and backups are obtained by a third party. TDE is also useful when you need to comply with security-related regulations.

The TDE option is persistent and permanent. If you associate your RDS for Oracle DB instance with an option group that has the TDE option enabled, you can't disable it. You can change the option group, but the new option group must include the TDE option. For more information about persistent and permanent options, see Persistent and permanent options.

⚠️ Note

You can't share a DB snapshot that uses the TDE option. For more information about sharing DB snapshots, see Sharing a DB snapshot.

A detailed explanation about TDE in Oracle Database is beyond the scope of this guide. For information, see the following Oracle Database resources:

- Securing stored data using Transparent Data Encryption in the Oracle Database documentation
- Oracle advanced security in the Oracle Database documentation
- Oracle advanced security Transparent Data Encryption best practices, which is an Oracle whitepaper

For more information about using TDE with RDS for Oracle, see the following blogs:

- Oracle Database Encryption Options on Amazon RDS
- Migrate a cross-account TDE-enabled Amazon RDS for Oracle DB instance with reduced downtime using AWS DMS
TDE encryption modes

Oracle Transparent Data Encryption supports two encryption modes: TDE tablespace encryption and TDE column encryption. TDE tablespace encryption is used to encrypt entire application tables. TDE column encryption is used to encrypt individual data elements that contain sensitive data. You can also apply a hybrid encryption solution that uses both TDE tablespace and column encryption.

Note
Amazon RDS manages the Oracle Wallet and TDE master key for the DB instance. You do not need to set the encryption key using the command ALTER SYSTEM set encryption key.

After you enable the TDE option, you can check the status of the Oracle Wallet by using the following command:

```
SELECT * FROM v$encryption_wallet;
```

To create an encrypted tablespace, use the following command:

```
CREATE TABLESPACE encrypt_ts ENCRYPTION DEFAULT STORAGE (ENCRYPT);
```

To specify the encryption algorithm, use the following command:

```
CREATE TABLESPACE encrypt_ts ENCRYPTION USING 'AES256' DEFAULT STORAGE (ENCRYPT);
```

The previous statements for encrypting a tablespace are the same as you would use on an on-premises Oracle database.

Determining whether your DB instance is using TDE

You might want to determine whether your DB instance is associated with an option group that has the TDE option enabled. To view the option group that a DB instance is associated with, use the RDS console, the describe-db-instance AWS CLI command, or the API operation DescribeDBInstances.

Adding the TDE option

The process for using Oracle Transparent Data Encryption (TDE) with Amazon RDS is as follows:
1. If the DB instance is not associated with an option group that has the TDE option enabled, you must either create an option group and add the TDE option or modify the associated option group to add the TDE option. For information about creating or modifying an option group, see Working with option groups. For information about adding an option to an option group, see Adding an option to an option group.

2. Associate the DB instance with the option group with the TDE option. For information about associating a DB instance with an option group, see Modifying an Amazon RDS DB instance.

**Copying your data to a DB instance that doesn't include the TDE option**

You can't remove the TDE option from DB instance or associate it with an option group that doesn't include the TDE option. To migrate your data to an instance that doesn't include the TDE option, do the following:

1. Decrypt the data on your DB instance.
2. Copy the data to a new DB instance that is not associated with an option group that has TDE enabled.
3. Delete your original DB instance.

You can name the new instance the same name as the previous DB instance.

**Using TDE with Oracle Data Pump**

You can use Oracle Data Pump to import or export encrypted dump files. Amazon RDS supports the password encryption mode (ENCRYPTION_MODE=PASSWORD) for Oracle Data Pump. Amazon RDS does not support transparent encryption mode (ENCRYPTION_MODE=TRANSPARENT) for Oracle Data Pump. For more information, see Importing using Oracle Data Pump.
Oracle UTL_MAIL

Amazon RDS supports Oracle UTL_MAIL through the use of the UTL_MAIL option and SMTP
servers. You can send email directly from your database by using the UTL_MAIL package. Amazon
RDS supports UTL_MAIL for the following versions of Oracle:

- Oracle Database 21c (21.0.0.0), all versions
- Oracle Database 19c (19.0.0.0), all versions
- Oracle Database 12c Release 2 (12.2), all versions
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v5 and later

The following are some limitations to using UTL_MAIL:

- UTL_MAIL does not support Transport Layer Security (TLS) and therefore emails are not
  encrypted.

To connect securely to remote SSL/TLS resources by creating and uploading custom Oracle
wallets, follow the instructions in Configuring UTL_HTTP access using certificates and an Oracle
wallet.

The specific certificates that are required for your wallet vary by service. For AWS services, these
can typically be found in the Amazon trust services repository.

- UTL_MAIL does not support authentication with SMTP servers.
- You can only send a single attachment in an email.
- You can't send attachments larger than 32 K.
- You can only use ASCII and Extended Binary Coded Decimal Interchange Code (EBCDIC) character
  encodings.
- SMTP port (25) is throttled based on the elastic network interface owner's policies.

When you enable UTL_MAIL, only the master user for your DB instance is granted the execute
privilege. If necessary, the master user can grant the execute privilege to other users so that they
can use UTL_MAIL.
Important

We recommend that you enable Oracle's built-in auditing feature to track the use of UTL_MAIL procedures.

Prerequisites for Oracle UTL_MAIL

The following are prerequisites for using Oracle UTL_MAIL:

- One or more SMTP servers, and the corresponding IP addresses or public or private Domain Name Server (DNS) names. For more information about private DNS names resolved through a custom DNS server, see Setting up a custom DNS server.
- For Oracle versions prior to 12c, your DB instance must also use the XML DB option. For more information, see Oracle XML DB.

Adding the Oracle UTL_MAIL option

The general process for adding the Oracle UTL_MAIL option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

After you add the UTL_MAIL option, as soon as the option group is active, UTL_MAIL is active.

To add the UTL_MAIL option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For Engine, choose the edition of Oracle you want to use.
   b. For Major engine version, choose the version of your DB instance.

For more information, see Creating an option group.
2. Add the UTL_MAIL option to the option group. For more information about adding options, see Adding an option to an option group.

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Using Oracle UTL_MAIL

After you enable the UTL_MAIL option, you must configure the SMTP server before you can begin using it.

You configure the SMTP server by setting the SMTP_OUT_SERVER parameter to a valid IP address or public DNS name. For the SMTP_OUT_SERVER parameter, you can specify a comma-separated list of the addresses of multiple servers. If the first server is unavailable, UTL_MAIL tries the next server, and so on.

You can set the default SMTP_OUT_SERVER for a DB instance by using a DB parameter group. You can set the SMTP_OUT_SERVER parameter for a session by running the following code on your database on your DB instance.

```
ALTER SESSION SET smtp_out_server = mailserver.domain.com:25;
```

After the UTL_MAIL option is enabled, and your SMTP_OUT_SERVER is configured, you can send mail by using the SEND procedure. For more information, see UTL_MAIL in the Oracle documentation.

Removing the Oracle UTL_MAIL option

You can remove Oracle UTL_MAIL from a DB instance.

To remove UTL_MAIL from a DB instance, do one of the following:
• To remove UTL_MAIL from multiple DB instances, remove the UTL_MAIL option from the option group they belong to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.

• To remove UTL_MAIL from a single DB instance, modify the DB instance and specify a different option group that doesn't include the UTL_MAIL option. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Troubleshooting

The following are issues you might encounter when you use UTL_MAIL with Amazon RDS.

• Throttling. SMTP port (25) is throttled based on the elastic network interface owner’s policies. If you can successfully send email by using UTL_MAIL, and you see the error ORA-29278: SMTP transient error: 421 Service not available, you are possibly being throttled. If you experience throttling with email delivery, we recommend that you implement a backoff algorithm. For more information about backoff algorithms, see Error retries and exponential backoff in AWS and How to handle a "throttling – Maximum sending rate exceeded" error.

You can request that this throttle be removed. For more information, see How do I remove the throttle on port 25 from my EC2 instance?
Oracle XML DB

Oracle XML DB adds native XML support to your DB instance. With XML DB, you can store and retrieve structured or unstructured XML, in addition to relational data. XML DB is preinstalled on Oracle version 12c and later.
Upgrading the RDS for Oracle DB engine

When Amazon RDS supports a new version of Oracle Database, you can upgrade your DB instances to the new version. For information about which Oracle versions are available on Amazon RDS, see Amazon RDS for Oracle Release Notes.

⚠ Important
RDS for Oracle Databases 11g, 12c, and 18c are no longer supported. If you maintain Oracle Database 11g, 12c, or 18c snapshots, you can upgrade them to a later release. For more information, see Upgrading an Oracle DB snapshot.

Topics
• Overview of RDS for Oracle engine upgrades
• Oracle major version upgrades
• Oracle minor version upgrades
• Considerations for Oracle DB upgrades
• Testing an Oracle DB upgrade
• Upgrading an Oracle DB instance
• Upgrading an Oracle DB snapshot

Overview of RDS for Oracle engine upgrades

Before upgrading your RDS for Oracle DB instance, familiarize yourself with the following concepts.

Topics
• Major and minor version upgrades
• Expected support dates for RDS for Oracle major releases
• Oracle engine version management
• Automatic snapshots during engine upgrades
• Oracle upgrades in a Multi-AZ deployment
• Oracle upgrades of read replicas
• Oracle upgrades of micro DB instances
Major and minor version upgrades

Major versions are major releases of Oracle Database that occur every 1-2 years. Examples of major releases are Oracle Database 19c and Oracle Database 21c.

Minor versions, which are also called Release Updates (RUs), are typically released by Oracle every quarter. Minor versions contain small feature enhancements and bug fixes. Examples of minor versions are 21.0.0.0.ru-2023-10.rur-2023-10.r1 and 19.0.0.0.ru-2023-10.rur-2023-10.r1. For more information, see Release notes for Amazon Relational Database Service (Amazon RDS) for Oracle.

RDS for Oracle supports the following upgrades to a DB instance.

<table>
<thead>
<tr>
<th>Upgrade type</th>
<th>Application compatibility</th>
<th>Upgrade methods</th>
<th>Sample upgrade path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Major version</td>
<td>A major version upgrade can introduce changes that aren't compatible with existing applications.</td>
<td>Manual only</td>
<td>From Oracle Database 19c to Oracle Database 21c</td>
</tr>
<tr>
<td>Minor version</td>
<td>A minor version upgrade includes only changes that are backward-compatible with existing applications.</td>
<td>Automatic or manual</td>
<td>From 21.0.0.0.ru-2023-07.rur-2022-07.r1 to 21.0.0.0.ru-2023-10.rur-2022-10.r1</td>
</tr>
</tbody>
</table>

⚠️ Important

When you upgrade your DB engine, an outage occurs. The duration of the outage depends on your engine version and DB instance size. Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see Testing an Oracle DB upgrade.
Expected support dates for RDS for Oracle major releases

RDS for Oracle major versions remain available at least until the end of support date for the corresponding Oracle Database release version. You can use the following dates to plan your testing and upgrade cycles. These dates represent the earliest date that an upgrade to a newer version might be required. If Amazon extends support for an RDS for Oracle version for longer than originally stated, we plan to update this table to reflect the later date.

<table>
<thead>
<tr>
<th>Oracle Database major release version</th>
<th>Expected date for upgrading to a newer version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Database 19c</td>
<td>April 30, 2026 with BYOL Premier Support (fees waived for Extended Support)</td>
</tr>
<tr>
<td></td>
<td>April 30, 2027 with BYOL Extended Support (extra cost) or an Unlimited License Agreement</td>
</tr>
<tr>
<td></td>
<td>April 30, 2027 with License Included (LI)</td>
</tr>
<tr>
<td>Oracle Database 21c</td>
<td>April 30, 2024 (not available for Extended Support)</td>
</tr>
</tbody>
</table>

Before we ask you to upgrade to a newer major version, we remind you at least 12 months in advance. We detail the upgrade process, including the timing of important milestones, the impact on your DB instances, and recommended actions. You should thoroughly test your applications with new RDS for Oracle versions before you upgrade to a major version.

After this advance notification period, an automatic upgrade to the subsequent major version might be applied to any RDS for Oracle DB instance still running the older version. If so, the upgrade is started during scheduled maintenance windows.

For more information, see Release Schedule of Current Database Releases in My Oracle Support.

Oracle engine version management

With DB engine version management, you control when and how the database engine is patched and upgraded. You get the flexibility to maintain compatibility with database engine patch versions. You can also test new patch versions of RDS for Oracle to ensure they work with your application before deploying them in production. In addition, you upgrade the versions on your own terms and timelines.
Note
Amazon RDS periodically aggregates official Oracle database patches using an Amazon RDS-specific DB engine version. To see a list of which Oracle patches are contained in an Amazon RDS Oracle-specific engine version, go to Amazon RDS for Oracle Release Notes.

Automatic snapshots during engine upgrades

During upgrades of an Oracle DB instance, snapshots offer protection against upgrade issues. If the backup retention period for your DB instance is greater than 0, Amazon RDS takes the following DB snapshots during the upgrade:

1. A snapshot of the DB instance before any upgrade changes have been made. If the upgrade fails, you can restore this snapshot to create a DB instance running the old version.
2. A snapshot of the DB instance after the upgrade completes.

Note
To change your backup retention period, see Modifying an Amazon RDS DB instance.

After an upgrade, you can't revert to the previous engine version. However, you can create a new Oracle DB instance by restoring the pre-upgrade snapshot.

Oracle upgrades in a Multi-AZ deployment

If your DB instance is in a Multi-AZ deployment, Amazon RDS upgrades both the primary and standby replicas. If no operating system updates are required, the primary and standby upgrades occur simultaneously. The instances are not available until the upgrade completes.

If operating system updates are required in a Multi-AZ deployment, Amazon RDS applies the updates when you request the database upgrade. Amazon RDS performs the following steps:

1. Updates the operating system on the current standby DB instance.
2. Fails over the primary DB instance to the standby DB instance.
3. Upgrades the database version on the new primary DB instance, which was formerly the standby instance. The primary database is unavailable during the upgrade.
4. Updates the operating system on the new standby DB instance, which was formerly the primary DB instance.

5. Upgrades the database version on the new standby DB instance.

6. Fails over the new primary DB instance back to the original primary DB instance, and the new standby DB instance back to the original standby DB instance. Thus, Amazon RDS returns the replication configuration to its original state.

**Oracle upgrades of read replicas**

The Oracle DB engine version of the source DB instance and all of its read replicas must be the same. Amazon RDS performs the upgrade in the following stages:

1. Upgrades the source DB instance. The read replicas are available during this stage.

2. Upgrades the read replicas in parallel, regardless of the replica maintenance windows. The source DB is available during this stage.

For major version upgrades of cross-Region read replicas, Amazon RDS performs additional actions:

- Generates an option group for the target version automatically
- Copies all options and option settings from the original option group to the new option group
- Associates the upgraded cross-Region read replica with the new option group

**Oracle upgrades of micro DB instances**

We don't recommend upgrading databases running on micro DB instances. Because these instances have limited CPU, the upgrade can take hours to complete.

You can upgrade micro DB instances with small amounts of storage (10–20 GiB) by copying your data using Data Pump. Before you migrate your production DB instances, we recommend that you test by copying data using Data Pump.

**Oracle major version upgrades**

To perform a major version upgrade, modify the DB instance manually. Major version upgrades don't occur automatically.
Important
Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see Testing an Oracle DB upgrade.

Topics
• Supported versions for major upgrades
• Supported instance classes for major upgrades
• Gathering statistics before major upgrades
• Allowing major upgrades

Supported versions for major upgrades

Amazon RDS supports the following major version upgrades.

<table>
<thead>
<tr>
<th>Current version</th>
<th>Upgrade supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>19.0.0.0 using the CDB architecture</td>
<td>21.0.0.0</td>
</tr>
</tbody>
</table>

A major version upgrade of Oracle Database must upgrade to a Release Update (RU) that was released in the same month or later. Major version downgrades aren't supported for any Oracle Database versions.

Supported instance classes for major upgrades

Your current Oracle DB instance might run on a DB instance class that isn't supported for the version to which you are upgrading. In this case, before you upgrade, migrate the DB instance to a supported DB instance class. For more information about the supported DB instance classes for each version and edition of Amazon RDS for Oracle, see DB instance classes.

Gathering statistics before major upgrades

Before you perform a major version upgrade, Oracle recommends that you gather optimizer statistics on the DB instance that you are upgrading. This action can reduce DB instance downtime during the upgrade.
To gather optimizer statistics, connect to the DB instance as the master user, and run the DBMS_STATS.GATHER_DICTIONARY STATS procedure, as in the following example.

```sql
EXEC DBMS_STATS.GATHER_DICTIONARY_STATS;
```

For more information, see _Gathering optimizer statistics to decrease Oracle database downtime_ in the Oracle documentation.

### Allowing major upgrades

A major engine version upgrade might be incompatible with your application. The upgrade is irreversible. If you specify a major version for the EngineVersion parameter that is different from the current major version, you must allow major version upgrades.

If you upgrade a major version using the CLI command `modify-db-instance`, specify `--allow-major-version-upgrade`. This setting isn't persistent, so you must specify `--allow-major-version-upgrade` whenever you perform a major upgrade. This parameter has no impact on upgrades of minor engine versions. For more information, see _Upgrading a DB instance engine version_.

If you upgrade a major version using the console, you don't need to choose an option to allow the upgrade. Instead, the console displays a warning that major upgrades are irreversible.

### Oracle minor version upgrades

A minor version upgrade applies an Oracle Database Patch Set Update (PSU) or Release Update (RU) to a major engine version. For example, if your DB instance runs major version Oracle Database 21c and minor version 21.0.0.0.ru-2022-07.rur-2022-07.r1, you can upgrade your upgrade to minor version 21.0.0.0.ru-2022-10.rur-2022-10.r1. Typically, a new minor version is available every quarter.

---

**Note**

RDS for Oracle doesn't support minor version downgrades.

You can upgrade your DB engine to a minor version manually or automatically. To learn how to upgrade manually, see _Manually upgrading the engine version_. To learn how to configure
automatic upgrades, see Automatically upgrading the minor engine version. Whether you upgrade manually or automatically, a minor version upgrade entails downtime. Keep this in mind when planning your upgrades.

⚠️ Important

Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see Testing an Oracle DB upgrade.

**Topics**

- Turning on automatic minor version upgrades for Oracle
- Before an automatic minor version upgrade for Oracle is scheduled
- When RDS schedules automatic minor version upgrades for Oracle
- Managing an automatic minor version upgrade for Oracle

**Turning on automatic minor version upgrades for Oracle**

In an automatic minor version upgrade, RDS applies the latest available minor version to your Oracle database without manual intervention. An Amazon RDS for Oracle DB instance schedules your upgrade during the next maintenance window in the following circumstances:

- Your DB instance has the Auto minor version upgrade option turned on.
- Your DB instance isn't already running the latest minor DB engine version.
- Your DB instance doesn't already have a pending upgrade scheduled.

To learn how to turn on automatic upgrades, see Automatically upgrading the minor engine version.

**Before an automatic minor version upgrade for Oracle is scheduled**

RDS publishes an advance notice before it begins scheduling automatic upgrades. You can find the notification in the Maintenance & backups tab of the database details page. The message has the following format:
An automatic minor version upgrade to *engine version* will become available on *availability-date* and will be applied during a subsequent maintenance window.

The *availability-date* in the preceding message is the date when RDS starts scheduling upgrades for DB instances in your AWS Region. It is not the date on which the upgrade of your DB instance is scheduled to occur.

You can also get the upgrade availability date by using the `describe-pending-maintenance-actions` command in the AWS CLI, as shown in the following example:

```
aws rds describe-pending-maintenance-actions
{
    "PendingMaintenanceActions": [ 
        {
            "PendingMaintenanceActionDetails": [ 
                {
                    "Action": "db-upgrade",
                    "Description": "Automatic minor version upgrade to 21.0.0.0.ru-2022-10.rur-2022-10.r1",
                    "CurrentApplyDate": "2022-12-02T08:10:00Z",
                    "OptInStatus": "next-maintenance"
                }
            ]
        }, ...
    }
}
```

The following table describes your options for each type of pending maintenance action message.

<table>
<thead>
<tr>
<th>Pending maintenance action message</th>
<th>When message appears</th>
<th>Eligible to be applied at the next maintenance window?</th>
<th>Eligible to be applied immediately?</th>
<th>Eligible to have the opt-in undone?</th>
</tr>
</thead>
<tbody>
<tr>
<td>An automatic minor version upgrade to <em>engine-version</em> will become available on</td>
<td>4-6 weeks before automatic upgrades are scheduled.</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Pending maintenance action message</td>
<td>When message appears</td>
<td>Eligible to be applied at the next maintenance window?</td>
<td>Eligible to be applied immediately?</td>
<td>Eligible to have the opt-in undone?</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>---------------------</td>
<td>-------------------------------------------------------</td>
<td>-----------------------------------</td>
<td>-----------------------------------</td>
</tr>
<tr>
<td>availability-date and should be applied during a subsequent maintenance window.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Automatic minor version upgrade to engine-version</td>
<td>On or after availability-date. RDS automatically applies this upgrade in the next maintenance window of the DB instance.</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

For more information about `describe-pending-maintenance-actions`, see the AWS CLI Command Reference.

**When RDS schedules automatic minor version upgrades for Oracle**

When the availability date for automatic upgrades arrives, RDS begins scheduling upgrades. For most AWS Regions, RDS schedules your upgrade to the latest quarterly RU approximately four to six weeks after the availability date. The scheduled date varies depending on the AWS Region and other factors. For more information about RUs and RURs, see Amazon RDS for Oracle Release Notes.

When RDS schedules the upgrade, the following notification appears in the Maintenance & backups tab of the database details page:

```
Automatic minor version upgrade to engine-version
```

The preceding message indicates that RDS has scheduled your DB engine to be upgraded in the next maintenance window.
Managing an automatic minor version upgrade for Oracle

When a new minor version becomes available, you can upgrade your DB instance to this version manually. The following example upgrades the DB instance named orclinst1 immediately:

```
aws rds apply-pending-maintenance-action \
    --resource-identifier arn:aws:rds:us-east-1:123456789012:db:orclinst1 \
    --apply-action db-upgrade \ 
    --opt-in-type immediate
```

To opt out of an automatic minor version upgrade that hasn't been scheduled yet, set opt-in-type to undo-opt-in, as in the following example:

```
aws rds apply-pending-maintenance-action \
    --resource-identifier arn:aws:rds:us-east-1:123456789012:db:orclinst1 \
    --apply-action db-upgrade \ 
    --opt-in-type undo-opt-in
```

If RDS has already scheduled an upgrade for your DB instance, you can't use apply-pending-maintenance-action to cancel it. But you can modify your DB instance and turn off the automatic minor upgrade feature, which then unschedules the upgrade.

To learn how to turn off automatic minor version upgrades, see [Automatically upgrading the minor engine version](#). For more information about apply-pending-maintenance-action, see the [AWS CLI Command Reference](#).

Considerations for Oracle DB upgrades

Before you upgrade your Oracle instance, review the following information.

Topics
- [Oracle Multitenant considerations](#)
- [Option group considerations](#)
- [Parameter group considerations](#)
- [Time zone considerations](#)

Oracle Multitenant considerations

The following table describes the architectures supported in different releases.
<table>
<thead>
<tr>
<th>Oracle Database release</th>
<th>RDS support status</th>
<th>Architecture</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Database 21c</td>
<td>Supported</td>
<td>CDB only</td>
</tr>
<tr>
<td>Oracle Database 19c</td>
<td>Supported</td>
<td>CDB or non-CDB</td>
</tr>
<tr>
<td>Oracle Database 12c Release 2 (12.2)</td>
<td>Desupported</td>
<td>Non-CDB only</td>
</tr>
<tr>
<td>Oracle Database 12c Release 1 (12.1)</td>
<td>Desupported</td>
<td>Non-CDB only</td>
</tr>
</tbody>
</table>

The following table describes supported and unsupported upgrade paths.

<table>
<thead>
<tr>
<th>Upgrade path</th>
<th>Supported?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-CDB to non-CDB</td>
<td>Yes</td>
</tr>
<tr>
<td>CDB to CDB</td>
<td>Yes</td>
</tr>
<tr>
<td>Non-CDB to CDB</td>
<td>No</td>
</tr>
<tr>
<td>CDB to non-CDB</td>
<td>No</td>
</tr>
</tbody>
</table>

For more information about Oracle Multitenant in RDS for Oracle, see [Single-tenant configuration of the CDB architecture](#).

**Option group considerations**

If your DB instance uses a custom option group, sometimes Amazon RDS can't automatically assign a new option group. For example, this situation occurs when you upgrade to a new major version. In such cases, specify a new option group when you upgrade. We recommend that you create a new option group, and add the same options to it as in your existing custom option group.

For more information, see [Creating an option group](#) or [Copying an option group](#).
If your DB instance uses a custom option group that contains the APEX option, you can sometimes reduce the upgrade time. To do this, upgrade your version of APEX at the same time as your DB instance. For more information, see Upgrading the APEX version.

Parameter group considerations

If your DB instance uses a custom parameter group, sometimes Amazon RDS can't automatically assign your DB instance a new parameter group. For example, this situation occurs when you upgrade to a new major version. In such cases, make sure to specify a new parameter group when you upgrade. We recommend that you create a new parameter group, and configure the parameters as in your existing custom parameter group.

For more information, see Creating a DB parameter group or Copying a DB parameter group.

Time zone considerations

You can use the time zone option to change the system time zone used by your Oracle DB instance. For example, you might change the time zone of a DB instance to be compatible with an on-premises environment, or a legacy application. The time zone option changes the time zone at the host level. Amazon RDS for Oracle updates the system time zone automatically throughout the year. For more information about the system time zone, see Oracle time zone.

When you create an Oracle DB instance, the database automatically sets the database time zone. The database time zone is also known as the Daylight Saving Time (DST) time zone. The database time zone is distinct from the system time zone.

Between Oracle Database releases, patch sets or individual patches may include new DST versions. These patches reflect the changes in transition rules for various time zone regions. For example, a government might change when DST takes effect. Changes to DST rules may affect existing data of the TIMESTAMP WITH TIME ZONE data type.

If you upgrade an RDS for Oracle DB instance, Amazon RDS doesn't upgrade the database time zone file automatically. To upgrade the time zone file automatically, you can include the TIMEZONE_FILE_AUTOUPGRADE option in the option group associated with your DB instance during or after the engine version upgrade. For more information, see Oracle time zone file autoupgrade.

Alternatively, to upgrade the database time zone file manually, create a new Oracle DB instance that has the desired DST patch. However, we recommend that you upgrade the database time zone file using the TIMEZONE_FILE_AUTOUPGRADE option.
After upgrading the time zone file, migrate the data from your current instance to the new instance. You can migrate data using several techniques, including the following:

- AWS Database Migration Service
- Oracle GoldenGate
- Oracle Data Pump
- Original Export/Import (desupported for general use)

**Note**

When you migrate data using Oracle Data Pump, the utility raises the error ORA-39405 when the target time zone version is lower than the source time zone version.

For more information, see [TIMESTAMP WITH TIMEZONE restrictions](#) in the Oracle documentation.

### Testing an Oracle DB upgrade

Before you upgrade your DB instance to a major version, thoroughly test your database and all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.

**To test a major version upgrade**

1. Review the Oracle upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications. For more information, see [Database Upgrade Guide](#) in the Oracle documentation.

2. If your DB instance uses a custom option group, create a new option group compatible with the new version you are upgrading to. For more information, see [Option group considerations](#).

3. If your DB instance uses a custom parameter group, create a new parameter group compatible with the new version you are upgrading to. For more information, see [Parameter group considerations](#).

4. Create a DB snapshot of the DB instance to be upgraded. For more information, see [Creating a DB snapshot for a Single-AZ DB instance](#).

5. Restore the DB snapshot to create a new test DB instance. For more information, see [Restoring from a DB snapshot](#).
6. Modify this new test DB instance to upgrade it to the new version, by using one of the following methods:

   - Console
   - AWS CLI
   - RDS API

7. Perform testing:

   - Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version.
   - Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1.
   - Test all stored procedures, functions, and triggers.
   - Direct test versions of your applications to the upgraded DB instance. Verify that the applications work correctly with the new version.
   - Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage. You might need to choose a larger instance class to support the new version in production. For more information, see DB instance classes.

8. If all tests pass, upgrade your production DB instance. We recommend that you confirm that the DB instance working correctly before allowing write operations to the DB instance.

### Upgrading an Oracle DB instance

To learn how to upgrade an Oracle DB instance, see Upgrading a DB instance engine version.

### Upgrading an Oracle DB snapshot

If you have existing manual DB snapshots, you can upgrade them to a later version of the Oracle database engine.

When Oracle stops providing patches for a version, and Amazon RDS deprecates the version, you can upgrade your snapshots that correspond to the deprecated version. For more information, see Oracle engine version management.

Amazon RDS supports upgrading snapshots in all AWS Regions.
Console

To upgrade an Oracle DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots, and then select the DB snapshot that you want to upgrade.
3. For Actions, choose Upgrade snapshot. The Upgrade snapshot page appears.
4. Choose the New engine version to upgrade the snapshot to.
5. (Optional) For Option group, choose the option group for the upgraded DB snapshot. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations.
6. Choose Save changes to save your changes.

During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from available to upgrading, and then changes to active upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to unavailable. You can't recover the snapshot from this state.

Note

If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade an Oracle DB snapshot by using the AWS CLI, call the modify-db-snapshot command with the following parameters:

- --db-snapshot-identifier – The name of the DB snapshot.
- --engine-version – The version to upgrade the snapshot to.

You might also need to include the following parameter. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations.
• `--option-group-name` – The option group for the upgraded DB snapshot.

**Example**

The following example upgrades a DB snapshot.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-snapshot \
    --db-snapshot-identifier mydbsnapshot \
    --engine-version 19.0.0.0.ru-2020-10.rur-2020-10.r1 \
    --option-group-name default:oracle-se2-19
```

For Windows:

```bash
aws rds modify-db-snapshot ^
    --db-snapshot-identifier mydbsnapshot ^
    --engine-version 19.0.0.0.ru-2020-10.rur-2020-10.r1 ^
    --option-group-name default:oracle-se2-19
```

**RDS API**

To upgrade an Oracle DB snapshot by using the Amazon RDS API, call the [ModifyDBSnapshot](https://docs.aws.amazon.com/AmazonRDS/latest/APIReference/API_ModifyDBSnapshot.html) operation with the following parameters:

- `DBSnapshotIdentifier` – The name of the DB snapshot.
- `EngineVersion` – The version to upgrade the snapshot to.

You might also need to include the `OptionGroupName` parameter. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see [Option group considerations](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Concepts.DBUpgrade.html).
Using third-party software with your RDS for Oracle DB instance

To use tools and third-party software with RDS for Oracle DB instances, review the information in the following sections.

Topics

- Setting up Amazon RDS to host tools and third-party software for Oracle
- Using Oracle GoldenGate with Amazon RDS for Oracle
- Using the Oracle Repository Creation Utility on RDS for Oracle
- Configuring Oracle Connection Manager on an Amazon EC2 instance
- Installing a Siebel database on Oracle on Amazon RDS
Setting up Amazon RDS to host tools and third-party software for Oracle

You can use Amazon RDS to host an Oracle DB instance that supports software and components such as the following:

- Siebel Customer Relationship Management (CRM)
- Oracle Fusion Middleware Metadata — installed by the Repository Creation Utility (RCU)

The following procedures help you create an Oracle DB instance on Amazon RDS that you can use to host additional software and components for Oracle.

Topics

- Creating a VPC for use with an Oracle database
- Creating an Oracle DB instance
- Additional Amazon RDS interfaces

Creating a VPC for use with an Oracle database

In the following procedure, you create a virtual private cloud (VPC) based on the Amazon VPC service, a private subnet, and a security group. Your Amazon RDS DB instance needs to be available only to your middle-tier components, and not to the public internet. Thus, your Amazon RDS DB instance is hosted in a private subnet, providing greater security.

To create a VPC based on Amazon VPC

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region for your VPC. This example uses the US West (Oregon) region.
3. In the upper-left corner, choose VPC Dashboard, and then choose Start VPC Wizard.
4. On the page Step 1: Select a VPC Configuration, choose VPC with Public and Private Subnets, and then choose Select.
5. On the page Step 2: VPC with Public and Private Subnets, shown following, set the following values.
<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv4 CIDR block</td>
<td>10.0.0.0/16</td>
</tr>
<tr>
<td></td>
<td>For more information about selecting CIDR blocks for your VPC, see VPC sizing.</td>
</tr>
<tr>
<td>IPv6 CIDR block</td>
<td>No IPv6 CIDR Block</td>
</tr>
<tr>
<td>VPC name</td>
<td>The name for your VPC, for example vpc-1.</td>
</tr>
<tr>
<td>Public subnet's IPv4 CIDR</td>
<td>10.0.0.0/24</td>
</tr>
<tr>
<td></td>
<td>For more information about subnet sizing, see Subnet sizing.</td>
</tr>
<tr>
<td>Availability Zone</td>
<td>An Availability Zone for your AWS Region.</td>
</tr>
<tr>
<td>Public subnet name</td>
<td>The name for your public subnet, for example subnet-public-1.</td>
</tr>
<tr>
<td>Private subnet's IPv4 CIDR</td>
<td>10.0.1.0/24</td>
</tr>
<tr>
<td></td>
<td>For more information about subnet sizing, see Subnet sizing.</td>
</tr>
<tr>
<td>Availability Zone</td>
<td>An Availability Zone for your AWS Region.</td>
</tr>
<tr>
<td>Private subnet name</td>
<td>The name for your private subnet, for example subnet-private-1.</td>
</tr>
<tr>
<td>Instance type</td>
<td>An instance type for your NAT instance, for example t2.small.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td>If you don't see Instance type in the console, choose Use a NAT instance instead.</td>
</tr>
<tr>
<td>Key pair name</td>
<td>No key pair</td>
</tr>
<tr>
<td>Service endpoints</td>
<td>None</td>
</tr>
</tbody>
</table>
### Option | Value
--- | ---
Enable DNS hostnames | Yes
Hardware tenancy | Default

6. Choose **Create VPC**.

An Amazon RDS DB instance in a VPC requires at least two private subnets or at least two public subnets, to support Multi-AZ deployment. For more information about working with multiple
Availability Zones, see Regions, Availability Zones, and Local Zones. Because your database is private, add a second private subnet to your VPC.

To create an additional subnet

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose VPC Dashboard, choose Subnets, and then choose Create Subnet.
4. On the Create Subnet page, set the following values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name tag</td>
<td>The name for your second private subnet, for example subnet-private-2.</td>
</tr>
<tr>
<td>VPC</td>
<td>Your VPC, for example vpc-1.</td>
</tr>
<tr>
<td>Availability Zone</td>
<td>An Availability Zone for your AWS Region.</td>
</tr>
<tr>
<td>Note</td>
<td>Choose an Availability Zone different from the one that you chose for the first private subnet.</td>
</tr>
<tr>
<td>CIDR block</td>
<td>10.0.2.0/24</td>
</tr>
</tbody>
</table>

5. Choose Yes, Create.

Both private subnets must use the same route table. In the following procedure, you check to make sure the route tables match, and if not you edit one of them.

To ensure the subnets use the same route table.

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.

3. In the upper-left corner, choose VPC Dashboard, choose Subnets, and then choose your first private subnet, for example subnet-private-1.

4. At the bottom of the console, choose the Route Table tab, shown following.

![Route Table Tab](image)

5. Make a note of the route table, for example rtb-0d9fc668.

6. In the list of subnets, choose the second private subnet, for example subnet-private-2.

7. At the bottom of the console, choose the Route Table tab.

8. If the route table for the second subnet is not the same as the route table for the first subnet, edit it to match:

   a. Choose Edit.
   
   b. For Change to, choose the route table that matches your first subnet.
   
   c. Choose Save.

A security group acts as a virtual firewall for your DB instance to control inbound and outbound traffic. In the following procedure, you create a security group for your DB instance. For more information about security groups, see Security groups for your VPC.

**To create a VPC security group for a private Amazon RDS DB instance**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose VPC Dashboard, choose Security Groups, and then choose Create Security Group.

4. On the page Create Security Group, set the following values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name tag</td>
<td>The name for your security group, for example sgdb-1.</td>
</tr>
<tr>
<td>Group name</td>
<td>The name for your security group, for example sgdb-1.</td>
</tr>
<tr>
<td>Description</td>
<td>A description for your security group.</td>
</tr>
<tr>
<td>VPC</td>
<td>Your VPC, for example vpc-1.</td>
</tr>
</tbody>
</table>

5. Choose Yes, Create.

In the following procedure, you add rules to your security group to control inbound traffic to your DB instance. For more information about inbound rules, see Security group rules.

To add inbound rules to the security group

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose VPC Dashboard, choose Security Groups, and then choose your security group, for example sgdb-1.
4. At the bottom of the console, choose the Inbound Rules tab, and then choose Edit.
5. Set these values, as shown following.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Oracle (1521)</td>
</tr>
<tr>
<td>Protocol</td>
<td>TCP (6)</td>
</tr>
<tr>
<td>Port Range</td>
<td>1521</td>
</tr>
<tr>
<td>Option</td>
<td>Value</td>
</tr>
<tr>
<td>--------</td>
<td>-------</td>
</tr>
<tr>
<td>Source</td>
<td>The identifier of your security group. When you choose the box, you see the name of your security group, for example <strong>sgdb-1</strong>.</td>
</tr>
</tbody>
</table>

6. Choose **Save**.

**Creating an Oracle DB instance**

You can use Amazon RDS to host an Oracle DB instance. When you create the new DB instance, specify the VPC and security group you created previously using the instructions in [Creating a VPC for use with an Oracle database](Creating%20a%20VPC%20for%20use%20with%20an%20Oracle%20database). Also, choose **No** for **Publicly accessible**.

For information about creating a DB instance, see [Creating an Amazon RDS DB instance](Creating%20an%20Amazon%20RDS%20DB%20instance).

**Additional Amazon RDS interfaces**

In the preceding tasks, you use the AWS Management Console to perform tasks. Amazon Web Services also provides the AWS Command Line Interface (AWS CLI), and an application programming interface (API). You can use the AWS CLI or the API to automate many of the tasks for managing Amazon RDS, including tasks to manage an Oracle DB instance with Amazon RDS.

For more information, see [AWS Command Line Interface reference for Amazon RDS](AWS%20Command%20Line%20Interface%20reference%20for%20Amazon%20RDS) and [Amazon RDS API Reference](Amazon%20RDS%20API%20Reference).
Oracle GoldenGate collects, replicates, and manages transactional data between databases. It is a log-based change data capture (CDC) and replication software package used with databases for online transaction processing (OLTP) systems. Oracle GoldenGate creates trail files that contain the most recent changed data from the source database. It then pushes these files to the server, where a process converts the trail file into standard SQL to be applied to the target database.

Oracle GoldenGate with RDS for Oracle supports the following features:

- Active-Active database replication
- Disaster recovery
- Data protection
- In-Region and cross-Region replication
- Zero-downtime migration and upgrades
- Data replication between an RDS for Oracle DB instance and a non-Oracle database

**Note**

For a list of supported databases, see [Oracle Fusion Middleware Supported System Configurations](https://docs.oracle.com/en/middleware/) in the Oracle documentation.

You can use Oracle GoldenGate with RDS for Oracle to upgrade to major versions of Oracle Database. For example, you can use Oracle GoldenGate to upgrade from an Oracle Database 11g on-premises database to Oracle Database 19c on an Amazon RDS DB instance.

**Topics**

- [Supported versions and licensing options for Oracle GoldenGate](#)
- [Requirements and limitations for Oracle GoldenGate](#)
- [Oracle GoldenGate architecture](#)
- [Setting up Oracle GoldenGate](#)
- [Working with the EXTRACT and REPLICAT utilities of Oracle GoldenGate](#)
- [Monitoring Oracle GoldenGate](#)
- [Troubleshooting Oracle GoldenGate](#)
Supported versions and licensing options for Oracle GoldenGate

You can use Standard Edition 2 (SE2) or Enterprise Edition (EE) of RDS for Oracle with Oracle GoldenGate version 12c and higher. You can use the following Oracle GoldenGate features:

- **Oracle GoldenGate Remote Capture (extract) is supported.**
- **Capture (extract) is supported on RDS for Oracle DB instances that use the traditional non-CDB database architecture. Oracle GoldenGate Remote PDB capture is supported on Oracle Database 21c container databases (CDBs).**
- **Oracle GoldenGate Remote Delivery (replicat) is supported on RDS for Oracle DB instances that use either the non-CDB or CDB architectures. Remote Delivery supports Integrated Replicat, Parallel Replicat, Coordinated Replicat, and classic Replicat.**
- **RDS for Oracle supports the Classic and Microservices architectures of Oracle GoldenGate.**
- **Oracle GoldenGate DDL and Sequence value replication is supported when using Integrated capture mode.**

You are responsible for managing Oracle GoldenGate licensing (BYOL) for use with Amazon RDS in all AWS Regions. For more information, see [RDS for Oracle licensing options](#).

Requirements and limitations for Oracle GoldenGate

When you’re working with Oracle GoldenGate and RDS for Oracle, consider the following requirements and limitations:

- You're responsible for setting up and managing Oracle GoldenGate for use with RDS for Oracle.
- You're responsible for setting up an Oracle GoldenGate version that is certified with the source and the target databases. For more information, see [Oracle Fusion Middleware Supported System Configurations](#) in the Oracle documentation.
- You can use Oracle GoldenGate on many different AWS environments for many different use cases. If you have a support-related issue relating to Oracle GoldenGate, contact Oracle Support Services.
- You can use Oracle GoldenGate on RDS for Oracle DB instances that use Oracle Transparent Data Encryption (TDE). To maintain the integrity of replicated data, configure encryption on the Oracle GoldenGate hub using Amazon EBS encrypted volumes or trail file encryption. Also configure encryption for data sent between the Oracle GoldenGate hub and the source and
target database instances. RDS for Oracle DB instances support encryption with Oracle Secure Sockets Layer or Oracle native network encryption.

**Oracle GoldenGate architecture**

The Oracle GoldenGate architecture for use with Amazon RDS consists of the following decoupled modules:

Source database

    Your source database can be either an on-premises Oracle database, an Oracle database on an Amazon EC2 instance, or an Oracle database on an Amazon RDS DB instance.

Oracle GoldenGate hub

    An Oracle GoldenGate hub moves transaction information from the source database to the target database. Your hub can be either of the following:

    • An Amazon EC2 instance with Oracle Database and Oracle GoldenGate installed
    • An on-premises Oracle installation

    You can have more than one Amazon EC2 hub. We recommend that you use two hubs if you use Oracle GoldenGate for cross-Region replication.

Target database

    Your target database can be on either an Amazon RDS DB instance, an Amazon EC2 instance, or an on-premises location.

The following sections describe common scenarios for Oracle GoldenGate on Amazon RDS.

**Topics**

- [On-premises source database and Oracle GoldenGate hub](#)
- [On-premises source database and Amazon EC2 hub](#)
- [Amazon RDS source database and Amazon EC2 hub](#)
- [Amazon EC2 source database and Amazon EC2 hub](#)
- [Amazon EC2 hubs in different AWS Regions](#)
On-premises source database and Oracle GoldenGate hub

In this scenario, an on-premises Oracle source database and on-premises Oracle GoldenGate hub provides data to a target Amazon RDS DB instance.

On-premises source database and Amazon EC2 hub

In this scenario, an on-premises Oracle database acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.

Amazon RDS source database and Amazon EC2 hub

In this scenario, an RDS for Oracle DB instance acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.
Amazon EC2 source database and Amazon EC2 hub

In this scenario, an Oracle database on an Amazon EC2 instance acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.

Amazon EC2 hubs in different AWS Regions

In this scenario, an Oracle database on an Amazon RDS DB instance is connected to an Amazon EC2 instance hub in the same AWS Region. The hub is connected to an Amazon EC2 instance hub in a
different AWS Region. This second hub provides data to the target RDS for Oracle DB instance in the same AWS Region as the second Amazon EC2 instance hub.

Note

Any issues that affect running Oracle GoldenGate on an on-premises environment also affect running Oracle GoldenGate on AWS. We strongly recommend that you monitor the Oracle GoldenGate hub to ensure that EXTRACT and REPLICATE are resumed if a failover occurs. Because the Oracle GoldenGate hub is run on an Amazon EC2 instance, Amazon RDS does not manage the Oracle GoldenGate hub and cannot ensure that it is running.

Setting up Oracle GoldenGate

To set up Oracle GoldenGate using Amazon RDS, configure the hub on an Amazon EC2 instance, and then configure the source and target databases. The following sections give an example of how to set up Oracle GoldenGate for use with Amazon RDS for Oracle.

Topics

- Setting up an Oracle GoldenGate hub on Amazon EC2
- Setting up a source database for use with Oracle GoldenGate on Amazon RDS
- Setting up a target database for use with Oracle GoldenGate on Amazon RDS
**Setting up an Oracle GoldenGate hub on Amazon EC2**

To create an Oracle GoldenGate hub on an Amazon EC2 instance, you first create an Amazon EC2 instance with a full client installation of Oracle RDBMS. The Amazon EC2 instance must also have Oracle GoldenGate software installed. The Oracle GoldenGate software versions depend on the source and target database versions. For more information about installing Oracle GoldenGate, see the [Oracle GoldenGate documentation](#).

The Amazon EC2 instance that serves as the Oracle GoldenGate hub stores and processes the transaction information from the source database into trail files. To support this process, make sure that you meet the following requirements:

- You have allocated enough storage for the trail files.
- The Amazon EC2 instance has enough processing power to manage the amount of data.
- The EC2 instance has enough memory to store the transaction information before it's written to the trail file.

**To set up an Oracle GoldenGate classic architecture hub on an Amazon EC2 instance**

1. Create subdirectories in the Oracle GoldenGate directory.

   In the Amazon EC2 command line shell, start `ggsci`, the Oracle GoldenGate command interpreter. The `CREATE SUBDIRS` command creates subdirectories under the `/gg` directory for parameter, report, and checkpoint files.

   ```shell
   prompt$ cd /gg
   prompt$ ./ggsci
   GGSCI> CREATE SUBDIRS
   ```

2. Configure the `mgr.prm` file.

   The following example adds lines to the `$GGHOME/dirprm/mgr.prm` file.

   ```shell
   PORT 8199
   PurgeOldExtracts ./dirdat/*, UseCheckpoints, MINKEEPDAYS 5
   ```

3. Start the manager.

   The following example starts `ggsci` and runs the `start mgr` command.
The Oracle GoldenGate hub is now ready for use.

**Setting up a source database for use with Oracle GoldenGate on Amazon RDS**

When your source database is running Oracle Database 12c or later, complete the following tasks to set up a source database for use with Oracle GoldenGate.

**Setup steps**

- **Step 1: Turn on supplemental logging on the source database**
- **Step 2: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true**
- **Step 3: Set the log retention period on the source database**
- **Step 4: Create an Oracle GoldenGate user account on the source database**
- **Step 5: Grant user account privileges on the source database**
- **Step 6: Add a TNS alias for the source database**

**Step 1: Turn on supplemental logging on the source database**

To turn on the minimum database-level supplemental logging, run the following PL/SQL procedure:

```
EXEC rdsadmin.rdsadmin_util.alter_supplemental_logging(p_action => 'ADD')
```

**Step 2: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true**

When you set the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter to `true`, it allows database services to support logical replication. If your source database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter set to `true`. For more information about the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter, see the [Oracle Database documentation](https://docs.oracle.com/en/database/oracle/oracle-database/18/database行政-information.html).

**Step 3: Set the log retention period on the source database**

Make sure that you configure the source database to retain archived redo logs. Consider the following guidelines:
• Specify the duration for log retention in hours. The minimum value is one hour.
• Set the duration to exceed any potential downtime of the source DB instance, any potential period of communication, and any potential period of networking issues for the source instance. Such a duration lets Oracle GoldenGate recover logs from the source instance as needed.
• Ensure that you have sufficient storage on your instance for the files.

For example, set the retention period for archived redo logs to 24 hours.

```
EXEC rdsadmin.rdsadmin_util.set_configuration('archivelog retention hours',24)
```

If you don't have log retention enabled, or if the retention value is too small, you receive an error message similar to the following.

```
2022-03-06 06:17:27   ERROR   OGG-00446  error 2 (No such file or directory)
opening redo log /rdsdbdata/db/GGTEST3_A/onlinelog/o1_mf_2_9k4bp1n6_.log for sequence 1306
Not able to establish initial position for begin time 2022-03-06 06:16:55.
```

Because your DB instance retains your archived redo logs, make sure that you have sufficient space for the files. To see how much space you have used in the last `num_hours` hours, run the following query, replacing `num_hours` with the number of hours.

```
SELECT SUM(BLOCKS * BLOCK_SIZE) BYTES FROM V$ARCHIVED_LOG
WHERE NEXT_TIME>=SYSDATE-`num_hours`/24 AND DEST_ID=1;
```

**Step 4: Create an Oracle GoldenGate user account on the source database**

Oracle GoldenGate runs as a database user and requires the appropriate database privileges to access the redo and archived redo logs for the source database. To provide these, create a user account on the source database. For more information about the permissions for an Oracle GoldenGate user account, see the [Oracle documentation](https://docs.oracle.com/en/database/oracle/database/19/dbadmin/index.html).

The following statements create a user account named oggadm1.

```
CREATE TABLESPACE administrator;
CREATE USER oggadm1 IDENTIFIED BY "password"
    DEFAULT TABLESPACE ADMINISTRATOR TEMPORARY TABLESPACE TEMP;
```
ALTER USER oggadm1 QUOTA UNLIMITED ON administrator;

**Note**
Specify a password other than the prompt shown here as a security best practice.

### Step 5: Grant user account privileges on the source database

In this task, you grant necessary account privileges for database users on your source database.

#### To grant account privileges on the source database

1. Grant the necessary privileges to the Oracle GoldenGate user account using the SQL command `grant` and the `rdsadmin.rdsadmin_util` procedure `grant_sys_object`. The following statements grant privileges to a user named oggadm1.

   ```sql
   GRANT CREATE SESSION, ALTER SESSION TO oggadm1;
   GRANT RESOURCE TO oggadm1;
   GRANT SELECT ANY DICTIONARY TO oggadm1;
   GRANT FLASHBACK ANY TABLE TO oggadm1;
   GRANT SELECT ANY TABLE TO oggadm1;
   GRANT SELECT_CATALOG_ROLE TO rds_master_user_name WITH ADMIN OPTION;
   EXEC rdsadmin.rdsadmin_util.grant_sys_object ('DBA_CLUSTERS', 'OGGADM1');
   GRANT EXECUTE ON DBMS_FLASHBACK TO oggadm1;
   GRANT SELECT ON SYS.V_$DATABASE TO oggadm1;
   GRANT ALTER ANY TABLE TO oggadm1;
   ```

2. Grant the privileges needed by a user account to be an Oracle GoldenGate administrator. The package that you use to perform the grant, `dbms_goldengate_auth` or `rdsadmin_dbms_goldengate_auth`, depends on the Oracle DB engine version.

   - For Oracle DB versions that are later than or equal to Oracle Database 12c Release 2 (12.2), which requires patch level 12.2.0.1.ru-2019-04.rur-2019-04.r1 or later, run the following PL/SQL program.

   ```sql
   EXEC rdsadmin.rdsadmin_dbms_goldengate_auth.grant_admin_privilege (grantee => 'OGGADM1', privilege_type => 'capture', grant_select_privileges => true, do_grants => TRUE);
   ```
• For Oracle database versions that are earlier than Oracle Database 12c Release 2 (12.2), run the following PL/SQL program.

```plsql
EXEC dbms_goldengate_auth.grant_admin_privilege (  
grantee => 'OGGADM1',  
privilege_type => 'capture',  
grant_select_privileges => true,  
do_grants => TRUE);
```

To revoke privileges, use the procedure `revoke_admin_privilege` in the same package.

**Step 6: Add a TNS alias for the source database**

Add the following entry to `$ORACLE_HOME/network/admin/tnsnames.ora` in the Oracle home to be used by the EXTRACT process. For more information on the `tnsnames.ora` file, see the Oracle documentation.

```
OGGSOURCE=  
(DESCRIPTION=  
    (ENABLE=BROKEN)  
    (ADDRESS_LIST=  
        (ADDRESS=(PROTOCOL=TCP)(HOST=goldengate-source.abcdef12345.us-west-2.rds.amazonaws.com)(PORT=8200))  
       (CONNECT_DATA=(SERVICE_NAME=ORCL))
    )
)
```

**Setting up a target database for use with Oracle GoldenGate on Amazon RDS**

In this task, you set up a target DB instance for use with Oracle GoldenGate.

**Setup steps**

• **Step 1: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true**

• **Step 2: Create an Oracle GoldenGate user account on the target database**

• **Step 3: Grant account privileges on the target database**

• **Step 4: Add a TNS alias for the target database**
Step 1: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true

When you set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true, it allows database services to support logical replication. If your source database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with the ENABLE_GOLDENGATE_REPLICATION initialization parameter set to true. For more information about the ENABLE_GOLDENGATE_REPLICATION initialization parameter, see the Oracle Database documentation.

Step 2: Create an Oracle GoldenGate user account on the target database

Oracle GoldenGate runs as a database user and requires the appropriate database privileges. To make sure it has these privileges, create a user account on the target database.

The following statement creates a user named oggadm1.

```
CREATE TABLESPACE administrator;
CREATE USER oggadm1 IDENTIFIED BY "password"
    DEFAULT TABLESPACE administrator
    TEMPORARY TABLESPACE temp;
ALTER USER oggadm1 QUOTA UNLIMITED ON administrator;
```

**Note**

Specify a password other than the prompt shown here as a security best practice.

Step 3: Grant account privileges on the target database

In this task, you grant necessary account privileges for database users on your target database.

**To grant account privileges on the target database**

1. Grant necessary privileges to the Oracle GoldenGate user account on the target database. In the following example, you grant privileges to oggadm1.

```
GRANT CREATE SESSION TO oggadm1;
GRANT ALTER SESSION TO oggadm1;
GRANT CREATE CLUSTER TO oggadm1;
GRANT CREATE INDEXTYPE TO oggadm1;
```
GRANT CREATE OPERATOR TO oggadm1;
GRANT CREATE PROCEDURE TO oggadm1;
GRANT CREATE SEQUENCE TO oggadm1;
GRANT CREATE TABLE TO oggadm1;
GRANT CREATE TRIGGER TO oggadm1;
GRANT CREATE TYPE TO oggadm1;
GRANT SELECT ANY DICTIONARY TO oggadm1;
GRANT CREATE ANY TABLE TO oggadm1;
GRANT ALTER ANY TABLE TO oggadm1;
GRANT LOCK ANY TABLE TO oggadm1;
GRANT SELECT ANY TABLE TO oggadm1;
GRANT INSERT ANY TABLE TO oggadm1;
GRANT UPDATE ANY TABLE TO oggadm1;
GRANT DELETE ANY TABLE TO oggadm1;

2. Grant the privileges needed by a user account to be an Oracle GoldenGate administrator. The package that you use to perform the grant, dbms_goldengate_auth or rdsadmin_dbms_goldengate_auth, depends on the Oracle DB engine version.

- For Oracle database versions that are later than or equal to Oracle Database 12c Release 2 (12.2), which requires patch level 12.2.0.1.ru-2019-04.rur-2019-04.r1 or later, run the following PL/SQL program.

```sql
EXEC rdsadmin.rdsadmin_dbms_goldengate_auth.grant_admin_privilege (
    grantee => 'OGGADM1',
    privilege_type => 'apply',
    grant_select_privileges => true,
    do_grants => TRUE);
```

- For Oracle database versions that are lower than Oracle Database 12c Release 2 (12.2), run the following PL/SQL program.

```sql
EXEC dbms_goldengate_auth.grant_admin_privilege (
    grantee => 'OGGADM1',
    privilege_type => 'apply',
    grant_select_privileges => true,
    do_grants => TRUE);
```

To revoke privileges, use the procedure revoke_admin_privilege in the same package.
Step 4: Add a TNS alias for the target database

Add the following entry to `$ORACLE_HOME/network/admin/tnsnames.ora` in the Oracle home to be used by the REPLICAT process. For Oracle Multitenant databases, make sure that the TNS alias points to the service name of the PDB. For more information on the `tnsnames.ora` file, see the [Oracle documentation](https://docs.oracle.com/en/database/oracle/database/12.2.0/c14453/tnsnamesora.html).

```sql
OGGTARGET=
  (DESCRIPTION=
    (ENABLE=BROKEN)
    (ADDRESS_LIST=
      (ADDRESS=(PROTOCOL=TCP)(HOST=goldengate-target.abcdef12345.us-west-2.rds.amazonaws.com)(PORT=8200))
      (CONNECT_DATA=(SERVICE_NAME=ORCL))
    )
  )
```

Working with the EXTRACT and REPLICAT utilities of Oracle GoldenGate

The Oracle GoldenGate utilities EXTRACT and REPLICAT work together to keep the source and target databases in sync via incremental transaction replication using trail files. All changes that occur on the source database are automatically detected by EXTRACT, then formatted and transferred to trail files on the Oracle GoldenGate on-premises or Amazon EC2 instance hub. After initial load is completed, the data is read from these files and replicated to the target database by the REPLICAT utility.

Running the Oracle GoldenGate EXTRACT utility

The EXTRACT utility retrieves, converts, and outputs data from the source database to trail files. The basic process is as follows:

1. EXTRACT queues transaction details to memory or to temporary disk storage.
2. The source database commits the transaction.
3. EXTRACT writes the transaction details to a trail file.
4. The trail file routes these details to the Oracle GoldenGate on-premises or the Amazon EC2 instance hub and then to the target database.

The following steps start the EXTRACT utility, capture the data from `EXAMPLE TABLE` in source database `OGGSOURCE`, and create the trail files.
To run the EXTRACT utility

1. Configure the EXTRACT parameter file on the Oracle GoldenGate hub (on-premises or Amazon EC2 instance). The following listing shows an example EXTRACT parameter file named $GGHOME/dirprm/eabc.prm.

```
EXTRACT EABC

USERID oggadm1@OGGSOURCE, PASSWORD "my-password"
EXTRAIL /path/to/goldengate/dirdat/ab

IGNOREREPLICATES
GETAPPLOPS
TRANLOGOPTIONS EXCLUDEUSER OGGADM1

TABLE EXAMPLE.TABLE;
```

2. On the Oracle GoldenGate hub, log in to the source database and launch the Oracle GoldenGate command line interface ggsci. The following example shows the format for logging in.

```
dblogin oggadm1@OGGSOURCE
```

3. Add transaction data to turn on supplemental logging for the database table.

```
add trandata EXAMPLE.TABLE
```

4. Using the ggsci command line, enable the EXTRACT utility using the following commands.

```
add extract EABC tranlog, INTEGRATED tranlog, begin now
add exttrail /path/to/goldengate/dirdat/ab
    extract EABC,
    MEGABYTES 100
```

5. Register the EXTRACT utility with the database so that the archive logs are not deleted. This task allows you to recover old, uncommitted transactions if necessary. To register the EXTRACT utility with the database, use the following command.

```
register EXTRACT EABC, DATABASE
```

6. Start the EXTRACT utility with the following command.
Running the Oracle GoldenGate REPLICAT utility

The REPLICAT utility "pushes" transaction information in the trail files to the target database.

The following steps enable and start the REPLICAT utility so that it can replicate the captured data to the table EXAMPLE.TABLE in target database OGGTARGET.

To run the REPLICATE utility

1. Configure the REPLICAT parameter file on the Oracle GoldenGate hub (on-premises or EC2 instance). The following listing shows an example REPLICAT parameter file named $GGHOME/dirprm/rabc.prm.

   ```
   REPLICA RABC
   USERID oggadm1@OGGTARGET, password "my-password"
   ASSUMETARGETDEFS
   MAP EXAMPLE.TABLE, TARGET EXAMPLE.TABLE;
   ```

   **Note**
   Specify a password other than the prompt shown here as a security best practice.

2. Log in to the target database and launch the Oracle GoldenGate command line interface (ggsci). The following example shows the format for logging in.

   ```
   dblogin userid oggadm1@OGGTARGET
   ```

3. Using the ggsci command line, add a checkpoint table. The user indicated should be the Oracle GoldenGate user account, not the target table schema owner. The following example creates a checkpoint table named gg_checkpoint.

   ```
   add checkpointtable oggadm1oggchkpt
   ```

4. To enable the REPLICAT utility, use the following command.

   ```
   start EABC
   ```
add replicat RABC EXTRAIL /path/to/goldengate/dirdat/ab CHECKPOINTTABLE oggadm1.oggchkpt

5. Start the REPLICAT utility by using the following command.

```
start RABC
```

**Monitoring Oracle GoldenGate**

When you use Oracle GoldenGate for replication, make sure that the Oracle GoldenGate process is up and running and the source and target databases are synchronized. You can use the following monitoring tools:

- **Amazon CloudWatch** is a monitoring service that is used in this pattern to monitor GoldenGate error logs.
- **Amazon SNS** is a message notification service that is used in this pattern to send email notifications.

For detailed instructions, see [Monitor Oracle GoldenGate logs by using Amazon CloudWatch](#).

**Troubleshooting Oracle GoldenGate**

This section explains the most common issues when using Oracle GoldenGate with Amazon RDS for Oracle.

**Topics**

- [Error opening an online redo log](#)
- [Oracle GoldenGate appears to be properly configured but replication is not working](#)
- [Integrated REPLICAT slow due to query on SYS."_DBA_APPLY_CDR_INFO"](#)

**Error opening an online redo log**

Make sure that you configure your databases to retain archived redo logs. Consider the following guidelines:

- Specify the duration for log retention in hours. The minimum value is one hour.
• Set the duration to exceed any potential downtime of the source DB instance, any potential period of communication, and any potential period of networking issues for the source DB instance. Such a duration lets Oracle GoldenGate recover logs from the source DB instance as needed.

• Ensure that you have sufficient storage on your instance for the files.

If you don't have log retention enabled, or if the retention value is too small, you receive an error message similar to the following.

```
2022-03-06 06:17:27   ERROR   OGG-00446   error 2 (No such file or directory) opening redo log /rdsdbdata/db/GGTEST3_A/onlinelog/o1-mf_2_9k4bp1n6_.log for sequence 1306
Not able to establish initial position for begin time 2022-03-06 06:16:55.
```

**Oracle GoldenGate appears to be properly configured but replication is not working**

For pre-existing tables, you must specify the SCN that Oracle GoldenGate works from.

**To fix this issue**

1. Log in to the source database and launch the Oracle GoldenGate command line interface (`ggsci`). The following example shows the format for logging in.

   ```
   dblogin userid oggadm1@OGGSOURCE
   ```

2. Using the `ggsci` command line, set up the start SCN for the `EXTRACT` process. The following example sets the SCN to 223274 for the `EXTRACT`.

   ```
   ALTER EXTRACT EABC SCN 223274
   start EABC
   ```

3. Log in to the target database. The following example shows the format for logging in.

   ```
   dblogin userid oggadm1@OGGTARGET
   ```

4. Using the `ggsci` command line, set up the start SCN for the `REPLICAT` process. The following example sets the SCN to 223274 for the `REPLICAT`.

   ```
   start RABC atcsn 223274
   ```
Integrated REPLICAT slow due to query on SYS."_DBA_APPLY_CDR_INFO"

Oracle GoldenGate Conflict Detection and Resolution (CDR) provides basic conflict resolution routines. For example, CDR can resolve a unique conflict for an INSERT statement.

When CDR resolves a collision, it can insert records into the exception table _DBA_APPLY_CDR_INFO temporarily. Integrated REPLICAT deletes these records later. In a rare scenario, the integrated REPLICAT can process a large number of collisions, but a new integrated REPLICAT does not replace it. Instead of being removed, the existing rows in _DBA_APPLY_CDR_INFO are orphaned. Any new integrated REPLICAT processes slow down because they are querying orphaned rows in _DBA_APPLY_CDR_INFO.

To remove all rows from _DBA_APPLY_CDR_INFO, use the Amazon RDS procedure rdsadmin.rdsadmin_util.truncate_apply$_cdr_info. This procedure is released as part of the October 2020 release and patch update. The procedure is available in the following database versions:

- **Version 21.0.0.0.ru-2022-01.rur-2022-01.r1** and higher
- **Version 19.0.0.0.ru-2020-10.rur-2020-10.r1** and higher

The following example truncates the table _DBA_APPLY_CDR_INFO.

```sql
SET SERVEROUTPUT ON SIZE 2000
EXEC rdsadmin.rdsadmin_util.truncate_apply$_cdr_info;
```
Using the Oracle Repository Creation Utility on RDS for Oracle

You can use Amazon RDS to host an RDS for Oracle DB instance that holds the schemas to support your Oracle Fusion Middleware components. Before you can use Fusion Middleware components, create and populate schemas for them in your database. You create and populate the schemas by using the Oracle Repository Creation Utility (RCU).

Supported versions and licensing options for RCU

Amazon RDS supports Oracle Repository Creation Utility (RCU) version 12c only. You can use the RCU in the following configurations:

- RCU 12c with Oracle Database 21c
- RCU 12c with Oracle Database 19c
- RCU 12c with Oracle Database 12c Release 2 (12.2)
- RCU 12c with Oracle Database 12c Release 1 (12.1) using 12.1.0.2.v4 or higher

Before you can use RCU, make sure that you do the following:

- Obtain a license for Oracle Fusion Middleware.
- Follow the Oracle licensing guidelines for the Oracle database that hosts the repository. For more information, see Oracle Fusion Middleware Licensing Information User Manual in the Oracle documentation.

Fusion Middleware supports repositories on Oracle Database Enterprise Edition and Standard Edition 2. Oracle recommends Enterprise Edition for production installations that require partitioning and installations that require online index rebuild.

Before you create your RDS for Oracle instance, confirm the Oracle database version that you need to support the components that you want to deploy. To find the requirements for the Fusion Middleware components and versions you want to deploy, use the Certification Matrix. For more information, see Oracle Fusion Middleware Supported System Configurations in the Oracle documentation.

Amazon RDS supports Oracle database version upgrades as needed. For more information, see Upgrading a DB instance engine version.
Requirements and limitations for RCU

To use RCU, you need an Amazon VPC. Your Amazon RDS DB instance must be available only to your Fusion Middleware components, and not to the public Internet. Thus, host your Amazon RDS DB instance in a private subnet, which provides greater security. For information about how to create an Amazon VPC for use with an RDS for Oracle instance, see Creating a VPC for use with an Oracle database.

You also need an RDS for Oracle DB instance. For information about how to create an RDS for Oracle DB instance for use with Fusion Middleware metadata, see Creating an Oracle DB instance.

You can store the schemas for any Fusion Middleware components in your Amazon RDS DB instance. The following schemas have been verified to install correctly:

- Analytics (ACTIVITIES)
- Audit Services (IAU)
- Audit Services Append (IAU_APPEND)
- Audit Services Viewer (IAU_VIEWER)
- Discussions (DISCUSSIONS)
- Metadata Services (MDS)
- Oracle Business Intelligence (BIPLATFORM)
- Oracle Platform Security Services (OPSS)
- Portal and Services (WEBCENTER)
- Portlet Producers (PORTLET)
- Service Table (STB)
- SOA Infrastructure (SOAINFRA)
- User Messaging Service (UCSUMS)
- WebLogic Services (WLS)

Guidelines for using RCU

The following are some recommendations for working with your DB instance in this scenario:

- We recommend that you use Multi-AZ for production workloads. For more information about working with multiple Availability Zones, see Regions, Availability Zones, and Local Zones.
For additional security, Oracle recommends that you use Transparent Data Encryption (TDE) to encrypt your data at rest. If you have an Enterprise Edition license that includes the Advanced Security Option, you can enable encryption at rest by using the TDE option. For more information, see Oracle Transparent Data Encryption.

Amazon RDS also provides an encryption at rest option for all database editions. For more information, see Encrypting Amazon RDS resources.

Configure your VPC Security Groups to allow communication between your application servers and your Amazon RDS DB instance. The application servers that host the Fusion Middleware components can be on Amazon EC2 or on-premises.

Running RCU

To create and populate the schemas to support your Fusion Middleware components, use the Oracle Repository Creation Utility (RCU). You can run RCU in different ways.

Topics

• Running RCU using the command line in one step
• Running RCU using the command line in multiple steps
• Running RCU in interactive mode

Running RCU using the command line in one step

If you don't need to edit any of your schemas before populating them, you can run RCU in a single step. Otherwise, see the following section for running RCU in multiple steps.

You can run the RCU in silent mode by using the command-line parameter -silent. When you run RCU in silent mode, you can avoid typing passwords on the command line by creating a text file containing the passwords. Create a text file with the password for dbUser on the first line, and the password for each component on subsequent lines. You specify the name of the password file as the last parameter to the RCU command.

Example

The following example creates and populates schemas for the SOA Infrastructure component (and its dependencies) in a single step.

For Linux, macOS, or Unix:
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
  -silent \
  -createRepository \
  -connectString ${dbhost}:${dbport}:${dbname} \
  -dbUser ${dbuser} \
  -dbRole Normal \
  -honorOMF \
  -schemaPrefix ${SCHEMA_PREFIX} \
  -component MDS \
  -component STB \
  -component OPSS \
  -component IAU \
  -component IAU_APPEND \
  -component IAU_VIEWER \
  -component UCSUMS \
  -component WLS \
  -component SOAINFRA \
  -f < /tmp/passwordfile.txt

For more information, see Running Repository Creation Utility from the command line in the Oracle documentation.

Running RCU using the command line in multiple steps

To manually edit your schema scripts, run RCU in multiple steps:

1. Run RCU in Prepare Scripts for System Load mode by using the -generateScript command-line parameter to create the scripts for your schemas.

2. Manually edit and run the generated script script_systemLoad.sql.

3. Run RCU again in Perform Product Load mode by using the -dataLoad command-line parameter to populate the schemas.

4. Run the generated cleanup script script_postDataLoad.sql.

To run RCU in silent mode, specify the command-line parameter -silent. When you run RCU in silent mode, you can avoid typing passwords on the command line by creating a text file containing the passwords. Create a text file with the password for dbUser on the first line, and the password for each component on subsequent lines. Specify the name of the password file as the last parameter to the RCU command.
Example

The following example creates schema scripts for the SOA Infrastructure component and its dependencies.

For Linux, macOS, or Unix:

```bash
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
-silent \n-generateScript \n-connectString ${dbhost}:${dbport}:${dbname} \n-dbUser ${dbuser} \n-dbRole Normal \n-honorOMF \n[-encryptTablespace true] \n-schemaPrefix ${SCHEMA_PREFIX} \n-component MDS \n-component STB \n-component OPSS \n-component IAU \n-component IAU_APPEND \n-component IAU_VIEWER \n-component UCSUMS \n-component WLS \n-component SOAINFRA \n-scriptLocation /tmp/rcuscripts \n-f < /tmp/passwordfile.txt
```

Now you can edit the generated script, connect to your Oracle DB instance, and run the script. The generated script is named `script_systemLoad.sql`. For information about connecting to your Oracle DB instance, see [Step 3: Connect your SQL client to an Oracle DB instance](#).

The following example populates the schemas for the SOA Infrastructure component (and its dependencies).

For Linux, macOS, or Unix:

```bash
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
-silent \n`
To finish, you connect to your Oracle DB instance, and run the clean-up script. The script is named `script_postDataLoad.sql`.

For more information, see [Running Repository Creation Utility from the command line](#) in the Oracle documentation.

**Running RCU in interactive mode**

To use the RCU graphical user interface, run RCU in interactive mode. Include the `--interactive` parameter and omit the `--silent` parameter. For more information, see [Understanding Repository Creation Utility screens](#) in the Oracle documentation.

**Example**

The following example starts RCU in interactive mode and pre-populates the connection information.

For Linux, macOS, or Unix:

```bash
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
$ORACLE_HOME/oracle_common/bin/rcu \
--interactive \
--createRepository \
--connectString ${dbhost}:${dbport}:${dbname} \ 
--dbUser ${dbuser} \
```

```bash
-dataload \ 
-connectString ${dbhost}:${dbport}:${dbname} \ 
-dbUser ${dbuser} \ 
-dbRole Normal \ 
-honorOMF \ 
-schemaPrefix ${SCHEMA_PREFIX} \ 
-component MDS \ 
-component STB \ 
-component OPSS \ 
-component IAU \ 
-component IAU_APPEND \ 
-component IAU_VIEWER \ 
-component UCSUMS \ 
-component WLS \ 
-component SOAINFRA \ 
-f < /tmp/passwordfile.txt
```

To finish, you connect to your Oracle DB instance, and run the clean-up script. The script is named `script_postDataLoad.sql`.

For more information, see [Running Repository Creation Utility from the command line](#) in the Oracle documentation.

**Running RCU in interactive mode**

To use the RCU graphical user interface, run RCU in interactive mode. Include the `--interactive` parameter and omit the `--silent` parameter. For more information, see [Understanding Repository Creation Utility screens](#) in the Oracle documentation.

**Example**

The following example starts RCU in interactive mode and pre-populates the connection information.

For Linux, macOS, or Unix:

```bash
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
$ORACLE_HOME/oracle_common/bin/rcu \
--interactive \
--createRepository \
--connectString ${dbhost}:${dbport}:${dbname} \ 
--dbUser ${dbuser} \
```
Troubleshooting RCU

Be mindful of the following issues.

Topics

• Oracle Managed Files (OMF)
• Object privileges
• Enterprise Scheduler Service

Oracle Managed Files (OMF)

Amazon RDS uses OMF data files to simplify storage management. You can customize tablespace attributes, such as size and extent management. However, if you specify a data file name when you run RCU, the tablespace code fails with **ORA-20900**. You can use RCU with OMF in the following ways:

• In RCU 12.2.1.0 and later, use the `-honorOMF` command-line parameter.
• In RCU 12.1.0.3 and later, use multiple steps and edit the generated script. For more information, see [Running RCU using the command line in multiple steps](#).

Object privileges

Because Amazon RDS is a managed service, you don't have full SYSDBA access to your RDS for Oracle DB instance. However, RCU 12c supports users with lower privileges. In most cases, the master user privilege is sufficient to create repositories.

The master account can directly grant privileges that it has already been granted `WITH GRANT OPTION`. In some cases, when you attempt to grant SYS object privileges, the RCU might fail with **ORA-01031**. You can retry and run the `rdsadmin_util.grant_sys_object` stored procedure, as shown in the following example:

```sql
BEGIN
  rdsadmin.rdsadmin_util.grant_sys_object('GV_$SESSION','MY_DBA','SELECT');
END;
/
```
If you attempt to grant SYS privileges on the object SCHEMA_VERSION_REGISTRY, the operation might fail with ORA-20199: Error in rdsadmin_util.grant_sys_object. You can qualify the table SCHEMA_VERSION_REGISTRY$ and the view SCHEMA_VERSION_REGISTRY with the schema owner name, which is SYSTEM, and retry the operation. Or, you can create a synonym. Log in as the master user and run the following statements:

```sql
CREATE OR REPLACE VIEW SYSTEM.SCHEMA_VERSION_REGISTRY
    AS SELECT * FROM SYSTEM.SCHEMA_VERSION_REGISTRY$;
CREATE OR REPLACE PUBLIC SYNONYM SCHEMA_VERSION_REGISTRY FOR
    SYSTEM.SCHEMA_VERSION_REGISTRY;
CREATE OR REPLACE PUBLIC SYNONYM SCHEMA_VERSION_REGISTRY$ FOR SCHEMA_VERSION_REGISTRY;
```

**Enterprise Scheduler Service**

When you use the RCU to drop an Enterprise Scheduler Service repository, the RCU might fail with Error: Component drop check failed.
Configuring Oracle Connection Manager on an Amazon EC2 instance

Oracle Connection Manager (CMAN) is a proxy server that forwards connection requests to database servers or other proxy servers. You can use CMAN to configure the following:

Access control

You can create rules that filter out user-specified client requests and accept others.

Session multiplexing

You can funnel multiple client sessions through a network connection to a shared server destination.

Typically, CMAN resides on a host separate from the database server and client hosts. For more information, see Configuring Oracle Connection Manager in the Oracle Database documentation.

Topics

- Supported versions and licensing options for CMAN
- Requirements and limitations for CMAN
- Configuring CMAN

Supported versions and licensing options for CMAN

CMAN supports the Enterprise Edition of all versions of Oracle Database that Amazon RDS supports. For more information, see RDS for Oracle releases.

You can install Oracle Connection Manager on a separate host from the host where Oracle Database is installed. You don't need a separate license for the host that runs CMAN.

Requirements and limitations for CMAN

To provide a fully managed experience, Amazon RDS restricts access to the operating system. You can't modify database parameters that require operating system access. Thus, Amazon RDS doesn't support features of CMAN that require you to log in to the operating system.

Configuring CMAN

When you configure CMAN, you perform most of the work outside of your RDS for Oracle database.
Topics

- **Step 1**: Configure CMAN on an Amazon EC2 instance in the same VPC as the RDS for Oracle instance
- **Step 2**: Configure database parameters for CMAN
- **Step 3**: Associate your DB instance with the parameter group

**Step 1: Configure CMAN on an Amazon EC2 instance in the same VPC as the RDS for Oracle instance**

To learn how to set up CMAN, follow the detailed instructions in the blog post [Configuring and using Oracle Connection Manager on Amazon EC2 for Amazon RDS for Oracle](#).

**Step 2: Configure database parameters for CMAN**

For CMAN features such as Traffic Director Mode and session multiplexing, set `REMOTE_LISTENER` parameter to the address of CMAN instance in a DB parameter group. Consider the following scenario:

- The CMAN instance resides on a host with IP address `10.0.159.100` and uses port `1521`.
- The databases `orcla`, `orclb`, and `orclc` reside on separate RDS for Oracle DB instances.

The following table shows how to set the `REMOTE_LISTENER` value. The `LOCAL_LISTENER` value is set automatically by Amazon RDS.

<table>
<thead>
<tr>
<th>DB instance name</th>
<th>DB instance IP</th>
<th>Local listener value (set automatically)</th>
<th>Remote listener value (set by user)</th>
</tr>
</thead>
<tbody>
<tr>
<td>orcla</td>
<td>10.0.159.200</td>
<td>(address= (protocol=tcp) (host=10.0.159.200) (port=1521) )</td>
<td>10.0.159.100:1521</td>
</tr>
<tr>
<td>orclb</td>
<td>10.0.159.300</td>
<td>(address= (protocol=tcp) (host=10.0.159.300) )</td>
<td>10.0.159.100:1521</td>
</tr>
<tr>
<td>DB instance name</td>
<td>DB instance IP</td>
<td>Local listener value (set automatically)</td>
<td>Remote listener value (set by user)</td>
</tr>
<tr>
<td>------------------</td>
<td>----------------</td>
<td>-----------------------------------------</td>
<td>-----------------------------------</td>
</tr>
<tr>
<td>orclc</td>
<td>10.0.159.400</td>
<td>(protocol=tcp)</td>
<td>10.0.159.100:1521</td>
</tr>
<tr>
<td></td>
<td></td>
<td>(host=10.0.159.400)</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>(port=1521)</td>
<td></td>
</tr>
</tbody>
</table>

**Step 3: Associate your DB instance with the parameter group**

Create or modify your DB instance to use the parameter group that you configured in Step 2: Configure database parameters for CMAN. For more information, see Associating a DB parameter group with a DB instance.
Installing a Siebel database on Oracle on Amazon RDS

You can use Amazon RDS to host a Siebel Database on an Oracle DB instance. The Siebel Database is part of the Siebel Customer Relationship Management (CRM) application architecture. For an illustration, see Generic architecture of Siebel business application.

Use the following topic to help set up a Siebel Database on an Oracle DB instance on Amazon RDS. You can also find out how to use Amazon Web Services to support the other components required by the Siebel CRM application architecture.

Note

To install a Siebel Database on Oracle on Amazon RDS, you need to use the master user account. You don't need SYSDBA privilege; master user privilege is sufficient. For more information, see Master user account privileges.

Licensing and versions

To install a Siebel Database on Amazon RDS, you must use your own Oracle Database license, and your own Siebel license. You must have the appropriate Oracle Database license (with Software Update License and Support) for the DB instance class and Oracle Database edition. For more information, see RDS for Oracle licensing options.

Oracle Database Enterprise Edition is the only edition certified by Siebel for this scenario. Amazon RDS supports Siebel CRM version 15.0 or 16.0. Use Oracle Database 12c Release 1 (12.1.0.2.0). For the procedures following, we use Siebel CRM version 15.0 and Oracle Database Release 1 (12.1.0.2) or Oracle Database Release 2 (12.2.0.1). For more information, see Oracle Database 12c with Amazon RDS.

Amazon RDS supports database version upgrades. For more information, see Upgrading a DB instance engine version.

Before you begin

Before you begin, you need an Amazon VPC. Because your Amazon RDS DB instance needs to be available only to your Siebel Enterprise Server, and not to the public Internet, your Amazon RDS DB instance is hosted in a private subnet, providing greater security. For information about
how to create an Amazon VPC for use with Siebel CRM, see Creating a VPC for use with an Oracle database.

Before you begin, you also need an Oracle DB instance. For information about how to create an Oracle DB instance for use with Siebel CRM, see Creating an Oracle DB instance.

Installing and configuring a Siebel database

After you create your Oracle DB instance, you can install your Siebel Database. You install the database by creating table owner and administrator accounts, installing stored procedures and functions, and then running the Siebel Database Configuration Wizard. For more information, see Installing the Siebel database on the RDBMS.

To run the Siebel Database Configuration Wizard, you need to use the master user account. You don't need SYSDBA privilege; master user privilege is sufficient. For more information, see Master user account privileges.

Using other Amazon RDS features with a Siebel database

After you create your Oracle DB instance, you can use additional Amazon RDS features to help you customize your Siebel Database.

Collecting statistics with the Oracle Statspack option

You can add features to your DB instance through the use of options in DB option groups. When you created your Oracle DB instance, you used the default DB option group. If you want to add features to your database, you can create a new option group for your DB instance.

If you want to collect performance statistics on your Siebel Database, you can add the Oracle Statspack feature. For more information, see Oracle Statspack.

Some option changes are applied immediately, and some option changes are applied during the next maintenance window for the DB instance. For more information, see Working with option groups. After you create a customized option group, modify your DB instance to attach it. For more information, see Modifying an Amazon RDS DB instance.

Performance tuning with parameters

You manage your DB engine configuration through the use of parameters in a DB parameter group. When you created your Oracle DB instance, you used the default DB parameter group. If you want
to customize your database configuration, you can create a new parameter group for your DB instance.

When you change a parameter, depending on the type of the parameter, the changes are applied either immediately or after you manually reboot the DB instance. For more information, see Working with parameter groups. After you create a customized parameter group, modify your DB instance to attach it. For more information, see Modifying an Amazon RDS DB instance.

To optimize your Oracle DB instance for Siebel CRM, you can customize certain parameters. The following table shows some recommended parameter settings. For more information about performance tuning Siebel CRM, see Siebel CRM Performance Tuning Guide.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Default value</th>
<th>Guidance for optimal Siebel CRM performance</th>
</tr>
</thead>
<tbody>
<tr>
<td>_always_semi_join</td>
<td>CHOOSE</td>
<td>OFF</td>
</tr>
<tr>
<td>_b_tree_bitmap_plans</td>
<td>TRUE</td>
<td>FALSE</td>
</tr>
<tr>
<td>_like_with_bind_as_equality</td>
<td>FALSE</td>
<td>TRUE</td>
</tr>
<tr>
<td>_no_or_expansion</td>
<td>FALSE</td>
<td>FALSE</td>
</tr>
<tr>
<td>_optimize_r_join_serial_sanity_check</td>
<td>TRUE</td>
<td>TRUE</td>
</tr>
<tr>
<td>_optimize_r_max_permutations</td>
<td>2000</td>
<td>100</td>
</tr>
<tr>

<td>---------------------------------------------</td>
</tr>
<tr>
<td>_optimize_r_sortmerge_join_enabled</td>
<td>TRUE</td>
<td>FALSE</td>
</tr>
<tr>
<td>_partition_view_enabled</td>
<td>TRUE</td>
<td>FALSE</td>
</tr>
<tr>
<td>open_cursors</td>
<td>300</td>
<td>At least 2000</td>
</tr>
</tbody>
</table>

**Creating snapshots**

After you create your Siebel Database, you can copy the database by using the snapshot features of Amazon RDS. For more information, see [Creating a DB snapshot for a Single-AZ DB instance](#) and [Restoring from a DB snapshot](#).

**Support for other Siebel CRM components**

In addition to your Siebel Database, you can also use Amazon Web Services to support the other components of your Siebel CRM application architecture. You can find more information about the support provided by Amazon AWS for additional Siebel CRM components in the following table.

<table>
<thead>
<tr>
<th>Siebel CRM component</th>
<th>Amazon AWS Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Siebel Enterprise (with one or more Siebel Servers)</td>
<td>You can host your Siebel Servers on Amazon Elastic Compute Cloud (Amazon EC2) instances. You can use Amazon EC2 to launch as many or as few virtual servers as you need. Using Amazon EC2, you can scale up or down easily to handle changes in requirements. For more information, see <a href="#">What is Amazon EC2?</a> You can put your servers in the same VPC with your DB instance and use the VPC security group to access the</td>
</tr>
<tr>
<td>Siebel CRM component</td>
<td>Amazon AWS Support</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>---------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>database. For more information, see Working with a DB instance in a VPC.</td>
</tr>
<tr>
<td>Web Servers (with Siebel Web Server Extensions)</td>
<td>You can install multiple Web Servers on multiple EC2 instances. You can then use Elastic Load Balancing to distribute incoming traffic among the instances. For more information, see What is Elastic Load Balancing?</td>
</tr>
<tr>
<td>Siebel Gateway Name Server</td>
<td>You can host your Siebel Gateway Name Server on an EC2 instance. You can then put your server in the same VPC with the DB instance and use the VPC security group to access the database. For more information, see Working with a DB instance in a VPC.</td>
</tr>
</tbody>
</table>
Oracle Database engine release notes

Updates to your Amazon RDS for Oracle DB instances keep them current. If you apply updates, you can be confident that your DB instance is running a version of the database software that has been tested by both Oracle and Amazon. We don't support applying one-off patches to individual RDS for Oracle DB instances.

You can specify any currently supported Oracle Database version when you create a new DB instance. You can specify the major version, such as Oracle Database 19c, and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version that you have specified. To see a list of supported versions and defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

For details about the Oracle Database versions that Amazon RDS supports, see the Amazon RDS for Oracle Release Notes.
Amazon RDS for PostgreSQL

Amazon RDS supports DB instances running several versions of PostgreSQL. For a list of available versions, see Available PostgreSQL database versions.

**Note**

Deprecation of PostgreSQL 9.6 is scheduled for April 26, 2022. For more information, see Deprecation of PostgreSQL version 9.6.

You can create DB instances and DB snapshots, point-in-time restores and backups. DB instances running PostgreSQL support Multi-AZ deployments, read replicas, Provisioned IOPS, and can be created inside a virtual private cloud (VPC). You can also use Secure Socket Layer (SSL) to connect to a DB instance running PostgreSQL.

Before creating a DB instance, make sure to complete the steps in Setting up for Amazon RDS.

You can use any standard SQL client application to run commands for the instance from your client computer. Such applications include pgAdmin, a popular Open Source administration and development tool for PostgreSQL, or psql, a command line utility that is part of a PostgreSQL installation. To deliver a managed service experience, Amazon RDS doesn't provide host access to DB instances. Also, it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet or Secure Shell (SSH).

Amazon RDS for PostgreSQL is compliant with many industry standards. For example, you can use Amazon RDS for PostgreSQL databases to build HIPAA-compliant applications and to store healthcare-related information. This includes storage for protected health information (PHI) under a completed Business Associate Agreement (BAA) with AWS. Amazon RDS for PostgreSQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements. Amazon RDS for PostgreSQL has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see AWS cloud compliance.

To import PostgreSQL data into a DB instance, follow the information in the Importing data into PostgreSQL on Amazon RDS section.
Common management tasks for Amazon RDS for PostgreSQL

The following are the common management tasks you perform with an Amazon RDS for PostgreSQL DB instance, with links to relevant documentation for each task.

Following is a list of other sections in this guide that can help you understand and use important features of RDS for PostgreSQL:

- [Understanding PostgreSQL roles and permissions](#)
- [Controlling user access to the PostgreSQL database](#)
- [Working with parameters on your RDS for PostgreSQL DB instance](#)
- [Understanding logging mechanisms supported by RDS for PostgreSQL](#)
- [Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL](#)
- [Using a custom DNS server for outbound network access](#)
Working with the Database Preview environment

The PostgreSQL community continuously releases new PostgreSQL version and extensions, including beta versions. This gives PostgreSQL users the opportunity to try out a new PostgreSQL version early. To learn more about the PostgreSQL community beta release process, see Beta Information in the PostgreSQL documentation. Similarly, Amazon RDS makes certain PostgreSQL beta versions available as Preview releases. This allows you to create DB instances using the Preview version and test out its features in the Database Preview Environment.

RDS for PostgreSQL DB instances in the Database Preview Environment are functionally similar to other RDS for PostgreSQL instances. However, you can't use a Preview version for production.

Keep in mind the following important limitations:

- All DB instances are deleted 60 days after you create them, along with any backups and snapshots.
- You can only create a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service.
- You can only use General Purpose SSD and Provisioned IOPS SSD storage.
- You can't get help from AWS Support with DB instances. Instead, you can post your questions to the AWS-managed Q&A community, AWS re:Post.
- You can't copy a snapshot of a DB instance to a production environment.

The following options are supported by the Preview.

- You can create DB instances using M6i, R6i, M6g, M5, T3, R6g, and R5 instance types only. For more information about RDS instance classes, see DB instance classes.
- You can use both single-AZ and multi-AZ deployments.
- You can use standard PostgreSQL dump and load functions to export databases from or import databases to the Database Preview Environment.

Features not supported in the Database Preview environment

The following features aren't available in the Database Preview environment:

- Cross-Region snapshot copy
• Cross-Region read replicas

Creating a new DB instance in the Database Preview environment

Use the following procedure to create a DB instance in the preview environment.

To create a DB instance in the Database Preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Dashboard from the navigation pane.
3. In the Dashboard page, locate the Database Preview Environment section on the Dashboard page, as shown in the following image.

You can navigate directly to the Database Preview environment. Before you can proceed, you must acknowledge and accept the limitations.
4. To create the RDS for PostgreSQL DB instance, follow the same process as that for creating any Amazon RDS DB instance. For more information, see the Console procedure in Creating a DB instance.

To create an instance in the Database Preview Environment using the RDS API or the AWS CLI, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

**PostgreSQL version 16 in the Database Preview environment**

⚠️ *This is preview documentation for Amazon RDS PostgreSQL version 16. It is subject to change.*
Note

RDS for PostgreSQL versions 16 RC1, 16 Beta 3, 16 Beta 2, and 16 Beta 1 will not be supported after RDS for PostgreSQL version 16.0 is released in the Database Preview environment.

PostgreSQL version 16.0 is now available in the Amazon RDS Database Preview environment. PostgreSQL version 16 contains several improvements that are described in the following PostgreSQL documentation:

- PostgreSQL 16 Released
- PostgreSQL 16 RC1 Released
- PostgreSQL 16 Beta 1 Released!
- PostgreSQL 16 Beta 2 Released!
- PostgreSQL 16 Beta 3 Released!

For information on the Database Preview Environment, see the section called “The Database Preview environment”. To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.
Available PostgreSQL database versions

Amazon RDS supports DB instances running several editions of PostgreSQL. You can specify any currently available PostgreSQL version when creating a new DB instance. You can specify the major version (such as PostgreSQL 14), and any available minor version for the specified major version. If no version is specified, Amazon RDS defaults to an available version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified.

To see a list of available versions, as well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command. For example, to display the default PostgreSQL engine version, use the following command:

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

For details about the PostgreSQL versions that are supported on Amazon RDS, see the Amazon RDS for PostgreSQL Release Notes.

If you aren't ready to manually upgrade to a new major engine version before the RDS end of standard support date, Amazon RDS will automatically enroll your databases in Amazon RDS Extended Support after the RDS end of standard support date. And then you can continue to run RDS for PostgreSQL version 11 and higher. For more information, see Using Amazon RDS Extended Support and Amazon RDS pricing.

Deprecation of PostgreSQL version 10

On April 17, 2023, Amazon RDS plans to deprecate PostgreSQL 10 using the following schedule. We recommend that you take action and upgrade your PostgreSQL databases running on major version 10 to a later version, such as PostgreSQL version 14. To upgrade your RDS for PostgreSQL major version 10 DB instance from a PostgreSQL version older than 10.19, we recommend that you first upgrade to version 10.19 and then upgrade to version 14. For more information, see Upgrading the PostgreSQL DB engine for Amazon RDS.

</tr>
</tbody>
</table>

For more information about RDS for PostgreSQL version 10 deprecation, see [Announcement]: RDS for PostgreSQL 10 deprecation in AWS re:Post.

**Deprecation of PostgreSQL version 9.6**

On March 31, 2022, Amazon RDS plans to deprecate PostgreSQL 9.6 using the following schedule. This extends the previously announced date of January 18, 2022 to April 26, 2022. You should upgrade all your PostgreSQL 9.6 DB instances to PostgreSQL 12 or higher as soon as possible. We recommend that you first upgrade to minor version 9.6.20 or higher and then upgrade directly to PostgreSQL 12 rather than upgrading to an intermediate major version. For more information, see Upgrading the PostgreSQL DB engine for Amazon RDS.

**Deprecated versions for Amazon RDS for PostgreSQL**

RDS for PostgreSQL 9.5 is deprecated as of March, 2021. For more information about RDS for PostgreSQL 9.5 deprecation, see [Upgrading from Amazon RDS for PostgreSQL version 9.5](#).

To learn more about deprecation policy for RDS for PostgreSQL, see [Amazon RDS FAQs](#). For more information about PostgreSQL versions, see [Versioning Policy](#) in the PostgreSQL documentation.
Supported PostgreSQL extension versions

RDS for PostgreSQL supports many PostgreSQL extensions. The PostgreSQL community sometimes refers to these as modules. Extensions expand on the functionality provided by the PostgreSQL engine. You can find a list of extensions supported by Amazon RDS in the default DB parameter group for that PostgreSQL version. You can also see the current extensions list using psql by showing the `rds.extensions` parameter as in the following example.

```
SHOW rds.extensions;
```

**Note**

Parameters added in a minor version release might display inaccurately when using the `rds.extensions` parameter in psql.

As of RDS for PostgreSQL 13, certain extensions can be installed by database users other than the `rds_superuser`. These are known as trusted extensions. To learn more, see PostgreSQL trusted extensions.

Certain versions of RDS for PostgreSQL support the `rds.allowed_extensions` parameter. This parameter lets an `rds_superuser` limit the extensions that can be installed in the RDS for PostgreSQL DB instance. For more information, see Restricting installation of PostgreSQL extensions.

For lists of PostgreSQL extensions and versions that are supported by each available RDS for PostgreSQL version, see PostgreSQL extensions supported on Amazon RDS in Amazon RDS for PostgreSQL Release Notes.

Restricting installation of PostgreSQL extensions

You can restrict which extensions can be installed on a PostgreSQL DB instance. By default, this parameter isn't set, so any supported extension can be added if the user has permissions to do so. To do so, set the `rds.allowed_extensions` parameter to a string of comma-separated extension names. By adding a list of extensions to this parameter, you explicitly identify the extensions that your RDS for PostgreSQL DB instance can use. Only these extensions can then be installed in the PostgreSQL DB instance.
The default string for the `rds.allowed_extensions` parameter is `*`, which means that any extension available for the engine version can be installed. Changing the `rds.allowed_extensions` parameter does not require a database restart because it's a dynamic parameter.

The PostgreSQL DB instance engine must be one of the following versions for you to use the `rds.allowed_extensions` parameter:

- All PostgreSQL 16 versions
- PostgreSQL 15 and all higher versions
- PostgreSQL 14 and all higher versions
- PostgreSQL 13.3 and higher minor versions
- PostgreSQL 12.7 and higher minor versions

To see which extension installations are allowed, use the following psql command.

```
postgres=> SHOW rds.allowed_extensions;
  rds.allowed_extensions
------------------------
        *
```

If an extension was installed prior to it being left out of the list in the `rds.allowed_extensions` parameter, the extension can still be used normally, and commands such as `ALTER EXTENSION` and `DROP EXTENSION` will continue to work. However, after an extension is restricted, `CREATE EXTENSION` commands for the restricted extension will fail.

Installation of extension dependencies with `CREATE EXTENSION CASCADE` are also restricted. The extension and its dependencies must be specified in `rds.allowed_extensions`. If an extension dependency installation fails, the entire `CREATE EXTENSION CASCADE` statement will fail.

If an extension is not included with the `rds.allowed_extensions` parameter, you will see an error such as the following if you try to install it.

```
ERROR: permission denied to create extension "extension-name"
HINT: This extension is not specified in "rds.allowed_extensions".
```
PostgreSQL trusted extensions

To install most PostgreSQL extensions requires `rds_superuser` privileges. PostgreSQL 13 introduced trusted extensions, which reduce the need to grant `rds_superuser` privileges to regular users. With this feature, users can install many extensions if they have the CREATE privilege on the current database instead of requiring the `rds_superuser` role. For more information, see the SQL CREATE EXTENSION command in the PostgreSQL documentation.

The following lists the extensions that can be installed by a user who has the CREATE privilege on the current database and do not require the `rds_superuser` role:

- `bool_plperl`
- `btree_gin`
- `btree_gist`
- `citext`
- `cube`
- `dict_int`
- `fuzzystrmatch`
- `hstore`
- `intarray`
- `isn`
- `jsonb_plperl`
- `ltree`
- `pg_trgm`
- `pgcrypto`
- `plperl`
- `plpgsql`
- `pltcl`
- `tablefunc`
- `tsm_system_rows`
- `tsm_system_time`
- `unaccent`
- `uuid-ossp`
For lists of PostgreSQL extensions and versions that are supported by each available RDS for PostgreSQL version, see PostgreSQL extensions supported on Amazon RDS in Amazon RDS for PostgreSQL Release Notes.
Working with PostgreSQL features supported by Amazon RDS for PostgreSQL

Amazon RDS for PostgreSQL supports many of the most common PostgreSQL features. For example, PostgreSQL has an autovacuum feature that performs routine maintenance on the database. The autovacuum feature is active by default. Although you can turn off this feature, we highly recommend that you keep it on. Understanding this feature and what you can do to make sure it works as it should is a basic task of any DBA. For more information about the autovacuum, see Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL. To learn more about other common DBA tasks, Common DBA tasks for Amazon RDS for PostgreSQL.

RDS for PostgreSQL also supports extensions that add important functionality to the DB instance. For example, you can use the PostGIS extension to work with spatial data, or use the pg_cron extension to schedule maintenance from within the instance. For more information about PostgreSQL extensions, see Using PostgreSQL extensions with Amazon RDS for PostgreSQL.

Foreign data wrappers are a specific type of extension designed to let your RDS for PostgreSQL DB instance work with other commercial databases or data types. For more information about foreign data wrappers supported by RDS for PostgreSQL, see Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL.

Following, you can find information about some other features supported by RDS for PostgreSQL.

Topics

- Custom data types and enumerations with RDS for PostgreSQL
- Event triggers for RDS for PostgreSQL
- Huge pages for RDS for PostgreSQL
- Performing logical replication for Amazon RDS for PostgreSQL
- RAM disk for the stats_temp_directory
- Tablespaces for RDS for PostgreSQL
- RDS for PostgreSQL collations for EBCDIC and other mainframe migrations
Custom data types and enumerations with RDS for PostgreSQL

PostgreSQL supports creating custom data types and working with enumerations. For more information about creating and working with enumerations and other data types, see [Enumerated types](#) in the PostgreSQL documentation.

The following is an example of creating a type as an enumeration and then inserting values into a table.

```sql
CREATE TYPE rainbow AS ENUM ('red', 'orange', 'yellow', 'green', 'blue', 'purple');
CREATE TABLE t1 (colors rainbow);
INSERT INTO t1 VALUES ('red'), ('orange');
SELECT * from t1;
```

```
colors
--------
red
orange
(2 rows)
```

```sql
ALTER TYPE rainbow RENAME VALUE 'red' TO 'crimson';
SELECT * from t1;
```

```
colors
-------
crimson
orange
(2 rows)
```

Event triggers for RDS for PostgreSQL

All current PostgreSQL versions support event triggers, and so do all available versions of RDS for PostgreSQL. You can use the main user account (default, `postgres`) to create, modify, rename, and delete event triggers. Event triggers are at the DB instance level, so they can apply to all databases on an instance.

For example, the following code creates an event trigger that prints the current user at the end of every data definition language (DDL) command.

```sql
CREATE OR REPLACE FUNCTION raise_notice_func()
RETURNS event_trigger
LANGUAGE plpgsql AS
$$
BEGIN
    RAISE NOTICE 'In trigger function: %', current_user;
END;
$$;

CREATE EVENT TRIGGER event_trigger_1
    ON ddl_command_end
    EXECUTE PROCEDURE raise_notice_func();

For more information about PostgreSQL event triggers, see [Event triggers](#) in the PostgreSQL documentation.

There are several limitations to using PostgreSQL event triggers on Amazon RDS. These include the following:

- You can't create event triggers on read replicas. You can, however, create event triggers on a read replica source. The event triggers are then copied to the read replica. The event triggers on the read replica don't fire on the read replica when changes are pushed from the source. However, if the read replica is promoted, the existing event triggers fire when database operations occur.
- To perform a major version upgrade to a PostgreSQL DB instance that uses event triggers, make sure to delete the event triggers before you upgrade the instance.

### Huge pages for RDS for PostgreSQL

Huge pages are a memory management feature that reduces overhead when a DB instance is working with large contiguous chunks of memory, such as that used by shared buffers. This PostgreSQL feature is supported by all currently available RDS for PostgreSQL versions. You allocate huge pages for your application by using calls to `mmap` or `SYSV` shared memory. RDS for PostgreSQL supports both 4-KB and 2-MB page sizes.

You can turn huge pages on or off by changing the value of the `huge_pages` parameter. The feature is turned on by default for all the DB instance classes other than micro, small, and medium DB instance classes.

RDS for PostgreSQL uses huge pages based on the available shared memory. If the DB instance can't use huge pages due to shared memory constraints, Amazon RDS prevents the DB instance...
from starting. In this case, Amazon RDS sets the status of the DB instance to an incompatible parameters state. If this occurs, you can set the `huge_pages` parameter to `off` to allow Amazon RDS to start the DB instance.

The `shared_buffers` parameter is key to setting the shared memory pool that is required for using huge pages. The default value for the `shared_buffers` parameter uses a database parameters macro. This macro sets a percentage of the total 8 KB pages available for the DB instance's memory. When you use huge pages, those pages are located with the huge pages. Amazon RDS puts a DB instance into an incompatible parameters state if the shared memory parameters are set to require more than 90 percent of the DB instance memory.

To learn more about PostgreSQL memory management, see [Resource Consumption](#) in the PostgreSQL documentation.

**Performing logical replication for Amazon RDS for PostgreSQL**

Starting with version 10.4, RDS for PostgreSQL supports the publication and subscription SQL syntax that was introduced in PostgreSQL 10. To learn more, see [Logical replication](#) in the PostgreSQL documentation.

**Note**

In addition to the native PostgreSQL logical replication feature introduced in PostgreSQL 10, RDS for PostgreSQL also supports the pglogical extension. For more information, see [Using pglogical to synchronize data across instances](#).

Following, you can find information about setting up logical replication for an RDS for PostgreSQL DB instance.

**Topics**

- Understanding logical replication and logical decoding
- Working with logical replication slots

**Understanding logical replication and logical decoding**

RDS for PostgreSQL supports the streaming of write-ahead log (WAL) changes using PostgreSQL's logical replication slots. It also supports using logical decoding. You can set up logical replication
slots on your instance and stream database changes through these slots to a client such as `pg_recvlogical`. You create logical replication slots at the database level, and they support replication connections to a single database.

The most common clients for PostgreSQL logical replication are AWS Database Migration Service or a custom-managed host on an Amazon EC2 instance. The logical replication slot has no information about the receiver of the stream. Also, there's no requirement that the target be a replica database. If you set up a logical replication slot and don't read from the slot, data can be written and quickly fill up your DB instance's storage.

You turn on PostgreSQL logical replication and logical decoding for Amazon RDS with a parameter, a replication connection type, and a security role. The client for logical decoding can be any client that can establish a replication connection to a database on a PostgreSQL DB instance.

**To turn on logical decoding for an RDS for PostgreSQL DB instance**

1. Make sure that the user account that you're using has these roles:
   - The `rds_superuser` role so you can turn on logical replication
   - The `rds_replication` role to grant permissions to manage logical slots and to stream data using logical slots

2. Set the `rds.logical_replication` static parameter to 1. As part of applying this parameter, also set the parameters `wal_level`, `max_wal_senders`, `max_replication_slots`, and `max_connections`. These parameter changes can increase WAL generation, so set the `rds.logical_replication` parameter only when you are using logical slots.

3. Reboot the DB instance for the static `rds.logical_replication` parameter to take effect.

4. Create a logical replication slot as explained in the next section. This process requires that you specify a decoding plugin. Currently, RDS for PostgreSQL supports the `test_decoding` and `wal2json` output plugins that ship with PostgreSQL.

For more information on PostgreSQL logical decoding, see the [PostgreSQL documentation](#).

**Working with logical replication slots**

You can use SQL commands to work with logical slots. For example, the following command creates a logical slot named `test_slot` using the default PostgreSQL output plugin `test_decoding`.
SELECT * FROM `test_slot`, 'test_decoding');

<table>
<thead>
<tr>
<th>slot_name</th>
<th>xlog_position</th>
</tr>
</thead>
<tbody>
<tr>
<td>regression_slot</td>
<td>0/16B1970</td>
</tr>
</tbody>
</table>

(1 row)

To list logical slots, use the following command.

```
SELECT * FROM pg_replication_slots;
```

To drop a logical slot, use the following command.

```
SELECT pg_drop_replication_slot('test_slot');
```

(1 row)

For more examples on working with logical replication slots, see [Logical decoding examples](#) in the PostgreSQL documentation.

After you create the logical replication slot, you can start streaming. The following example shows how logical decoding is controlled over the streaming replication protocol. This example uses the program `pg_recvlogical`, which is included in the PostgreSQL distribution. Doing this requires that client authentication is set up to allow replication connections.

```
pg_recvlogical -d postgres --slot test_slot -U postgres  
--host -instance-name.111122223333.aws-region.rds.amazonaws.com 
-f - --start
```

To see the contents of the `pg_replication_origin_status` view, query the `pg_show_replication_origin_status` function.

```
SELECT * FROM pg_show_replication_origin_status();
```

(0 rows)
RAM disk for the stats_temp_directory

You can use the RDS for PostgreSQL parameter rds.pg_stat_ramdisk_size to specify the system memory allocated to a RAM disk for storing the PostgreSQL stats_temp_directory. The RAM disk parameter is available for all PostgreSQL versions on Amazon RDS.

Under certain workloads, setting this parameter can improve performance and decrease I/O requirements. For more information about the stats_temp_directory, see [the PostgreSQL documentation](https://www.postgresql.org/docs/current/static/runtime-parameters-server-wide.html).

To set up a RAM disk for your stats_temp_directory, set the rds.pg_stat_ramdisk_size parameter to an integer literal value in the parameter group used by your DB instance. This parameter denotes MB, so you must use an integer value. Expressions, formulas, and functions aren't valid for the rds.pg_stat_ramdisk_size parameter. Be sure to reboot the DB instance so that the change takes effect. For information about setting parameters, see [Working with parameter groups](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_UsingParameters.html).

For example, the following AWS CLI command sets the RAM disk parameter to 256 MB.

```bash
aws rds modify-db-parameter-group \
   --db-parameter-group-name pg-95-ramdisk-testing \
   --parameters "ParameterName=rds.pg_stat_ramdisk_size, ParameterValue=256, ApplyMethod=pending-reboot"
```

After you reboot, run the following command to see the status of the stats_temp_directory.

```sql
postgres=> SHOW stats_temp_directory;
```

The command should return the following.

```
stats_temp_directory
---------------------------
/rdsdbramdisk/pg_stat_tmp
(1 row)
```

Tablespaces for RDS for PostgreSQL

RDS for PostgreSQL supports tablespaces for compatibility. Because all storage is on a single logical volume, you can't use tablespaces for I/O splitting or isolation. Our benchmarks and experience indicate that a single logical volume is the best setup for most use cases.
To create and use tablespaces with your RDS for PostgreSQL DB instance requires the `rds_superuser` role. Your RDS for PostgreSQL DB instance's main user account (default name, `postgres`) is a member of this role. For more information, see Understanding PostgreSQL roles and permissions.

If you specify a file name when you create a tablespace, the path prefix is `/rdsdbdata/db/base/tablespace`. The following example places tablespace files in `/rdsdbdata/db/base/tablespace/data`. This example assumes that a `dbadmin` user (role) exists and that it's been granted the `rds_superuser` role needed to work with tablespaces.

```sql
postgres=> CREATE TABLESPACE act_data
   OWNER dbadmin
   LOCATION '/data';
CREATE TABLESPACE
```

To learn more about PostgreSQL tablespaces, see Tablespace in the PostgreSQL documentation.

**RDS for PostgreSQL collations for EBCDIC and other mainframe migrations**

RDS for PostgreSQL versions 10 and higher include ICU version 60.2, which is based on Unicode 10.0 and includes collations from the Unicode Common Locale Data Repository, CLDR 32. These software internationalization libraries ensure that character encodings are presented in a consistent way, regardless of operating system or platform. For more information about Unicode CLDR-32, see the [CLDR 32 Release Note](https://unicode.org/reports/tr32/) on the Unicode CLDR website. You can learn more about the internationalization components for Unicode (ICU) at the [ICU Technical Committee (ICU-TC)](https://icu-project.org/) website. For information about ICU-60, see [Download ICU 60](https://icu-project.org/download/).

Starting with version 14.3, RDS for PostgreSQL also includes collations that help with data integration and conversion from EBCDIC-based systems. The extended binary coded decimal interchange code or EBCDIC encoding is commonly used by mainframe operating systems. These Amazon RDS-provided collations are narrowly defined to sort only those Unicode characters that directly map to EBCDIC code pages. The characters are sorted in EBCDIC code-point order to allow for data validation after conversion. These collations don't include denormalized forms, nor do they include Unicode characters that don't directly map to a character on the source EBCDIC code page.

The character mappings between EBCDIC code pages and Unicode code points are based on tables published by IBM. The complete set is available from IBM as a [compressed file](https://www.ibm.com/support/pages/node/369400) for download. RDS
Amazon Relational Database Service

User Guide

for PostgreSQL used these mappings with tools provided by the ICU to create the collations listed in the tables in this section. The collation names include a language and country as required by the ICU. However, EBCDIC code pages don't specify languages, and some EBCDIC code pages cover multiple countries. That means that the language and country portion of the collation names in the table are arbitrary, and they don't need to match the current locale. In other words, the code page number is the most important part of the collation name in this table. You can use any of the collations listed in the following tables in any RDS for PostgreSQL database.

- **Unicode to EBCDIC collations table** – Some mainframe data migration tools internally use LATIN1 or LATIN9 to encode and process data. Such tools use round-trip schemes to preserve data integrity and support reverse conversion. The collations in this table can be used by tools that process data using LATIN1 encoding, which doesn't require special handling.

- **Unicode to LATIN9 collations table** – You can use these collations in any RDS for PostgreSQL database.

In the following table, you find collations available in RDS for PostgreSQL that map EBCDIC code pages to Unicode code points. We recommend that you use the collations in this table for application development that requires sorting based on the ordering of IBM code pages.

<table>
<thead>
<tr>
<th>PostgreSQL collation name</th>
<th>Description of code-page mapping and sort order</th>
</tr>
</thead>
<tbody>
<tr>
<td>da-DK-cp277-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 277 (per conversion tables) are sorted in IBM CP 277 code point order</td>
</tr>
<tr>
<td>de-DE-cp273-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 273 (per conversion tables) are sorted in IBM CP 273 code point order</td>
</tr>
<tr>
<td>en-GB-cp285-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 285 (per conversion tables) are sorted in IBM CP 285 code point order</td>
</tr>
<tr>
<td>PostgreSQL collation name</td>
<td>Description of code-page mapping and sort order</td>
</tr>
<tr>
<td>--------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>en-US-cp037-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 037 (per conversion tables) are sorted in IBM CP 37 code point order</td>
</tr>
<tr>
<td>es-ES-cp284-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 284 (per conversion tables) are sorted in IBM CP 284 code point order</td>
</tr>
<tr>

<td>Unicode characters that directly map to IBM EBCDIC Code Page 278 (per conversion tables) are sorted in IBM CP 278 code point order</td>
</tr>
<tr>
<td>fr-FR-cp297-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 297 (per conversion tables) are sorted in IBM CP 297 code point order</td>
</tr>
<tr>
<td>it-IT-cp280-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 280 (per conversion tables) are sorted in IBM CP 280 code point order</td>
</tr>
<tr>
<td>nl-BE-cp500-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 500 (per conversion tables) are sorted in IBM CP 500 code point order</td>
</tr>
</tbody>
</table>

Amazon RDS provides a set of additional collations that sort Unicode code points that map to LATIN9 characters using the tables published by IBM, in the order of the original code points according to the EBCDIC code page of the source data.

<table>
<thead>
<tr>
<th>PostgreSQL collation name</th>
<th>Description of code-page mapping and sort order</th>
</tr>
</thead>
<tbody>
<tr>
<td>da-DK-cp1142m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1142 (per conversion</td>
</tr>
<tr>
<td>PostgreSQL collation name</td>
<td>Description of code-page mapping and sort order</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>de-DE-cp1141m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1141 (per conversion tables) are sorted in IBM CP 1141 code point order</td>
</tr>
<tr>
<td>en-GB-cp1146m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1146 (per conversion tables) are sorted in IBM CP 1146 code point order</td>
</tr>
<tr>
<td>en-US-cp1140m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1140 (per conversion tables) are sorted in IBM CP 1140 code point order</td>
</tr>
<tr>
<td>es-ES-cp1145m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1145 (per conversion tables) are sorted in IBM CP 1145 code point order</td>
</tr>
<tr>
<td>fi-FI-cp1143m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1143 (per conversion tables) are sorted in IBM CP 1143 code point order</td>
</tr>
</tbody>
</table>
In the following, you can find an example of using an RDS for PostgreSQL collation.

```
db1=> SELECT pg_import_system_collations('pg_catalog');
 pg_import_system_collations
-----------------------------
      36
```

```
db1=> SELECT '¶' < 'a' col1;
   col1
------
   t
```

```
db1=> SELECT '¶' < 'a' COLLATE "da-DK-cp277-x-icu" col1;
   col1
------
   f
```

We recommend that you use the collations in the Unicode to EBCDIC collations table and in the Unicode to LATIN9 collations table for application development that requires sorting based on the

---

<table>
<thead>
<tr>
<th>PostgreSQL collation name</th>

- fr-FR-cp297b-x-icu
- it-IT-cp1144b-x-icu
- it-IT-cp280b-x-icu
- nl-BE-cp1148b-x-icu
- nl-BE-cp500b-x-icu

To learn more about migrating applications from mainframe environments to AWS, see What is AWS Mainframe Modernization?

For more information about managing collations in PostgreSQL, see Collation Support in the PostgreSQL documentation.
Connecting to a DB instance running the PostgreSQL database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the instance. Before you can connect, the DB instance must be available and accessible. Whether you can connect to the instance from outside the VPC depends on how you created the Amazon RDS DB instance:

- If you created your DB instance as `public`, devices and Amazon EC2 instances outside the VPC can connect to your database.
- If you created your DB instance as `private`, only Amazon EC2 instances and devices inside the Amazon VPC can connect to your database.

To connect to your DB instance from an EC2 instance, you can install a PostgreSQL client on the EC2 instance. To install the `psql` client on Amazon Linux 2023, run the following command:

```
sudo dnf install postgresql15
```

To install the `psql` client on Amazon Linux 2, run the following command:

```
sudo amazon-linux-extras install postgresql14
```

To install the `psql` client on Ubuntu, run the following command:

```
sudo apt-get install -y postgresql14
```

To check whether your DB instance is public or private, use the AWS Management Console to view the **Connectivity & security** tab for your instance. Under **Security**, you can find the "Publicly accessible" value, with No for private, Yes for public.

To learn more about different Amazon RDS and Amazon VPC configurations and how they affect accessibility, see [Scenarios for accessing a DB instance in a VPC](#).

If the DB instance is available and accessible, you can connect by providing the following information to the SQL client application:

- The DB instance endpoint, which serves as the host name (DNS name) for the instance.
• The port on which the DB instance is listening. For PostgreSQL, the default port is 5432.
• The user name and password for the DB instance. The default 'master username' for PostgreSQL is postgres.
• The name and password of the database (DB name).

You can obtain these details by using the AWS Management Console, the AWS CLI `describe-db-instances` command, or the Amazon RDS API `DescribeDBInstances` operation.

To find the endpoint, port number, and DB name using the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Open the RDS console and then choose Databases to display a list of your DB instances.
3. Choose the PostgreSQL DB instance name to display its details.
4. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
5. On the **Configuration** tab, note the DB name. If you created a database when you created the RDS for PostgreSQL instance, you see the name listed under DB name. If you didn't create a database, the DB name displays a dash (-).
Following are two ways to connect to a PostgreSQL DB instance. The first example uses pgAdmin, a popular open-source administration and development tool for PostgreSQL. The second example uses psql, a command line utility that is part of a PostgreSQL installation.

**Topics**
- [Using pgAdmin to connect to a RDS for PostgreSQL DB instance](#)
- [Using psql to connect to your RDS for PostgreSQL DB instance](#)
- [Connecting with the AWS JDBC Driver for PostgreSQL](#)
- [Troubleshooting connections to your RDS for PostgreSQL instance](#)

**Using pgAdmin to connect to a RDS for PostgreSQL DB instance**

You can use the open-source tool pgAdmin to connect to your RDS for PostgreSQL DB instance. You can download and install pgAdmin from [http://www.pgadmin.org/](http://www.pgadmin.org/) without having a local instance of PostgreSQL on your client computer.

**To connect to your RDS for PostgreSQL DB instance using pgAdmin**

1. Launch the pgAdmin application on your client computer.
2. On the **Dashboard** tab, choose **Add New Server**.

3. In the **Create - Server** dialog box, type a name on the **General** tab to identify the server in pgAdmin.

4. On the **Connection** tab, type the following information from your DB instance:
   
   - For **Host**, type the endpoint, for example `mypostgresql.c6c8dntfzzhgv0.us-east-2.rds.amazonaws.com`.
   - For **Port**, type the assigned port.
   - For **Username**, type the user name that you entered when you created the DB instance (if you changed the 'master username' from the default, `postgres`).
   - For **Password**, type the password that you entered when you created the DB instance.

5. Choose **Save**.

   If you have any problems connecting, see [Troubleshooting connections to your RDS for PostgreSQL instance](#).
6. To access a database in the pgAdmin browser, expand **Servers**, the DB instance, and **Databases**. Choose the DB instance's database name.

7. To open a panel where you can enter SQL commands, choose **Tools**, **Query Tool**.

**Using psql to connect to your RDS for PostgreSQL DB instance**

You can use a local instance of the psql command line utility to connect to a RDS for PostgreSQL DB instance. You need either PostgreSQL or the psql client installed on your client computer.

You can download the PostgreSQL client from the [PostgreSQL](https://www.postgresql.org) website. Follow the instructions specific to your operating system version to install psql.

To connect to your RDS for PostgreSQL DB instance using psql, you need to provide host (DNS) information, access credentials, and the name of the database.

Use one of the following formats to connect to your RDS for PostgreSQL DB instance. When you connect, you're prompted for a password. For batch jobs or scripts, use the `--no-password` option. This option is set for the entire session.
**Note**

A connection attempt with `--no-password` fails when the server requires password authentication and a password is not available from other sources. For more information, see the `psql documentation`.

If this is the first time you are connecting to this DB instance, or if you didn't yet create a database for this RDS for PostgreSQL instance, you can connect to the `postgres` database using the 'master username' and password.

For Unix, use the following format.

```
psql \
--host=<DB instance endpoint> \
--port=<port> \
--username=<master username> \
--password \
--dbname=<database name>
```

For Windows, use the following format.

```
psql ^
--host=<DB instance endpoint> ^
--port=<port> ^
--username=<master username> ^
--password ^
--dbname=<database name>
```

For example, the following command connects to a database called `mypgdb` on a PostgreSQL DB instance called `mypostgresql` using fictitious credentials.

```
psql --host=mypostgresql.c6c8mwvfdgv0.us-west-2.rds.amazonaws.com --port=5432 --username=awsuser --password --dbname=mypgdb
```

**Connecting with the AWS JDBC Driver for PostgreSQL**

The AWS JDBC Driver for PostgreSQL is a client wrapper designed for use with RDS for PostgreSQL. The AWS JDBC Driver for PostgreSQL extends the functionality of the community pgJDBC driver by enabling AWS features such as authentication. For more information about the AWS JDBC Driver
for PostgreSQL and complete instructions for using it, see the AWS JDBC Driver for PostgreSQL GitHub repository.

The AWS JDBC Driver for PostgreSQL supports AWS Identity and Access Management (IAM) database authentication and AWS Secrets Manager. For more information on using these authentication mechanisms with the driver, see AWS IAM Authentication Plugin and AWS Secrets Manager Plugin in the AWS JDBC Driver for PostgreSQL GitHub repository.

For more information about IAM database authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL. For more information about Secrets Manager, see the AWS Secrets Manager User Guide.

Troubleshooting connections to your RDS for PostgreSQL instance

Topics

• Error – FATAL: database name does not exist
• Error – Could not connect to server: Connection timed out
• Errors with security group access rules

Error – FATAL: database name does not exist

If when trying to connect you receive an error like FATAL: database name does not exist, try using the default database name postgres for the --dbname option.

Error – Could not connect to server: Connection timed out

If you can't connect to the DB instance, the most common error is Could not connect to server: Connection timed out. If you receive this error, check the following:

• Check that the host name used is the DB instance endpoint and that the port number used is correct.
• Make sure that the DB instance's public accessibility is set to Yes to allow external connections. To modify the Public access setting, see Modifying an Amazon RDS DB instance.
• Make sure that the user connecting to the database has CONNECT access to it. You can use the following query to provide connect access to the database.

```sql
GRANT CONNECT ON DATABASE database name TO username;
```
• Check that the security group assigned to the DB instance has rules to allow access through any firewall your connection might go through. For example, if the DB instance was created using the default port of 5432, your company might have firewall rules blocking connections to that port from external company devices.

To fix this, modify the DB instance to use a different port. Also, make sure that the security group applied to the DB instance allows connections to the new port. To modify the Database port setting, see Modifying an Amazon RDS DB instance.

• See also Errors with security group access rules.

Errors with security group access rules

By far the most common connection problem is with the security group's access rules assigned to the DB instance. If you used the default security group when you created the DB instance, the security group likely didn't have access rules that allow you to access the instance.

For the connection to work, the security group you assigned to the DB instance at its creation must allow access to the DB instance. For example, if the DB instance was created in a VPC, it must have a VPC security group that authorizes connections. Check if the DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the application is running.

You can add or edit an inbound rule in the security group. For Source, choosing My IP allows access to the DB instance from the IP address detected in your browser. For more information, see Provide access to your DB instance in your VPC by creating a security group.

Alternatively, if the DB instance was created outside of a VPC, it must have a database security group that authorizes those connections.

For more information about Amazon RDS security groups, see Controlling access with security groups.
Securing connections to RDS for PostgreSQL with SSL/TLS

RDS for PostgreSQL supports Secure Socket Layer (SSL) encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your PostgreSQL DB instances. You can also force all connections to your PostgreSQL DB instance to use SSL. RDS for PostgreSQL also supports Transport Layer Security (TLS), the successor protocol to SSL.

To learn more about Amazon RDS and data protection, including encrypting connections using SSL/TLS, see Data protection in Amazon RDS.

Topics
- Using SSL with a PostgreSQL DB instance
- Updating applications to connect to PostgreSQL DB instances using new SSL/TLS certificates

Using SSL with a PostgreSQL DB instance

Amazon RDS supports Secure Socket Layer (SSL) encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your PostgreSQL DB instances. By default, RDS for PostgreSQL uses and expects all clients to connect using SSL/TLS, but you can also require it. RDS for PostgreSQL supports Transport Layer Security (TLS) versions 1.1, 1.2, and 1.3.

For general information about SSL support and PostgreSQL databases, see SSL support in the PostgreSQL documentation. For information about using an SSL connection over JDBC, see Configuring the client in the PostgreSQL documentation.

SSL support is available in all AWS Regions for PostgreSQL. Amazon RDS creates an SSL certificate for your PostgreSQL DB instance when the instance is created. If you enable SSL certificate verification, then the SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

Topics
- Connecting to a PostgreSQL DB instance over SSL
- Requiring an SSL connection to a PostgreSQL DB instance
- Determining the SSL connection status
- SSL cipher suites in RDS for PostgreSQL
Connecting to a PostgreSQL DB instance over SSL

To connect to a PostgreSQL DB instance over SSL

1. Download the certificate.

   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

2. Connect to your PostgreSQL DB instance over SSL.

   When you connect using SSL, your client can choose whether to verify the certificate chain. If your connection parameters specify `sslmode=verify-ca` or `sslmode=verify-full`, then your client requires the RDS CA certificates to be in their trust store or referenced in the connection URL. This requirement is to verify the certificate chain that signs your database certificate.

   When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used is different between libpq-based clients (such as psql) and JDBC. The libpq-based clients default to `prefer`, and JDBC clients default to `verify-full`.

   Use the `sslrootcert` parameter to reference the certificate, for example `sslrootcert=rds-ssl-ca-cert.pem`.

The following is an example of using psql to connect to a PostgreSQL DB instance using SSL with certificate verification.

```
$ psql "host=db-name.555555555555.ap-southeast-1.rds.amazonaws.com -p 5432 dbname=testDB user=testuser sslrootcert=rds-ca-rsa2048-g1.pem sslmode=verify-full"
```

Requiring an SSL connection to a PostgreSQL DB instance

You can require that connections to your PostgreSQL DB instance use SSL by using the `rds.force_ssl` parameter. The default `rds.force_ssl` parameter is set to 1 (on) for RDS for PostgreSQL version 15. All other RDS for PostgreSQL major version 14 and older have the default value for `rds.force_ssl` parameter set to 0 (off). You can set the `rds.force_ssl` parameter to 1 (on) to require SSL for connections to your DB instance.
To change the value of this parameter, you need to create a custom DB parameter group. You then change the value for `rds.force_ssl` in your custom DB parameter group to 1 to turn on this feature. If you prepare the custom DB parameter group before creating your RDS for PostgreSQL DB instance you can choose it (instead of a default parameter group) during the creation process. If you do this after your RDS for PostgreSQL DB instance is already running, you need to reboot the instance so that your instance uses the custom parameter group. For more information, see Working with parameter groups.

When the `rds.force_ssl` feature is active on your DB instance, connection attempts that aren't using SSL are rejected with the following message:

```
$ psql -h db-name.555555555555.ap-southeast-1.rds.amazonaws.com -p 5432 dbname=testDB user=testuser
psql: error: FATAL: no pg_hba.conf entry for host "w.x.y.z", user "testuser", database "testDB", SSL off
```

Determining the SSL connection status

The encrypted status of your connection is shown in the logon banner when you connect to the DB instance:

```
Password for user master:
psql (10.3)
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.
postgres=>
```

You can also load the `sslinfo` extension and then call the `ssl_is_used()` function to determine if SSL is being used. The function returns `t` if the connection is using SSL, otherwise it returns `f`.

```
postgres=> CREATE EXTENSION sslinfo;
CREATE EXTENSION
postgres=> SELECT ssl_is_used();
ssl_is_used
-------
t
(1 row)
```

For more detailed information, you can use the following query to get information from `pg_settings`:
SELECT name as "Parameter name", setting as value, short_desc FROM pg_settings WHERE name LIKE '%ssl%';

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>value</th>
<th>short_desc</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssl</td>
<td>on</td>
<td>Enables SSL connections.</td>
</tr>
<tr>
<td>ssl_ca_file</td>
<td>/rdsdbdata/rds-metadata/ca-cert.pem</td>
<td>Location of the SSL certificate authority file.</td>
</tr>
<tr>
<td>ssl_cert_file</td>
<td>/rdsdbdata/rds-metadata/server-cert.pem</td>
<td>Location of the SSL server certificate file.</td>
</tr>
<tr>
<td>ssl_ciphers</td>
<td>HIGH:!aNULL:!3DES</td>
<td>Sets the list of allowed SSL ciphers.</td>
</tr>
<tr>
<td>ssl_crl_file</td>
<td></td>
<td>Location of the SSL certificate revocation list file.</td>
</tr>
<tr>
<td>ssl_dh_params_file</td>
<td></td>
<td>Location of the SSL DH parameters file.</td>
</tr>
<tr>
<td>ssl_ecdh_curve</td>
<td>prime256v1</td>
<td>Sets the curve to use for ECDH.</td>
</tr>

<td>Also use ssl_passphrase_command during server reload.</td>
</tr>
<tr>
<td>ssl_prefer_server_ciphers</td>
<td>on</td>
<td>Give priority to server ciphersuite order.</td>
</tr>
</tbody>
</table>

(14 rows)

You can also collect all the information about your RDS for PostgreSQL DB instance's SSL usage by process, client, and application by using the following query:

```
SELECT datname as "Database name", usename as "User name", ssl, client_addr, application_name, backend_type
FROM pg_stat_ssl
JOIN pg_stat_activity
```

Using SSL with a PostgreSQL DB instance
ON pg_stat_ssl.pid = pg_stat_activity.pid
ORDER BY ssl;

Database name | User name | ssl | client_addr | application_name | backend_type
-----------------+-----------+-----+-------------+-------------------+---------------------
+-------------------+-----------+-----+-------------+-------------------+---------------------
|                  | rdsadmin  | t   | 127.0.0.1   |                    | client backend      |
|                  | postgres  | t   | 204.246.162.36 | psql              | client backend      |

(8 rows)

To identify the cipher used for your SSL connection, you can query as follows:

postgres=> SELECT ssl_cipher();
ssl_cipher
-------------------
DHE-RSA-AES256-SHA
(1 row)

To learn more about the sslmode option, see [Database connection control functions](https://www.postgresql.org/docs/current/ssl-reference.html) in the [PostgreSQL documentation](https://www.postgresql.org/).

**SSL cipher suites in RDS for PostgreSQL**

The PostgreSQL configuration parameter `ssl_ciphers` specifies the categories of cipher suites that are allowed for SSL connections. The following table lists the default cipher suites used in RDS for PostgreSQL.
### Cipher suites

<table>
<thead>
<tr>
<th>PostgreSQL engine version</th>
<th>Cipher suites</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>HIGH:!aNULL!:3DES</td>
</tr>
<tr>
<td>15</td>
<td>HIGH:!aNULL!:3DES</td>
</tr>
<tr>
<td>14</td>
<td>HIGH:!aNULL!:3DES</td>
</tr>
<tr>
<td>13</td>
<td>HIGH:!aNULL!:3DES</td>
</tr>
<tr>
<td>12</td>
<td>HIGH:!aNULL!:3DES</td>
</tr>
<tr>
<td>11.4 and higher minor versions</td>
<td>HIGH:MEDIUM:+3DES:!aNULL:!RC4</td>
</tr>
<tr>
<td>11.1, 11.2</td>
<td>HIGH:MEDIUM:+3DES:!aNULL</td>
</tr>
<tr>
<td>10.9 and higher minor versions</td>
<td>HIGH:MEDIUM:+3DES:!aNULL:!RC4</td>
</tr>
<tr>
<td>10.7 and lower minor versions</td>
<td>HIGH:MEDIUM:+3DES:!aNULL</td>
</tr>
</tbody>
</table>

### Updating applications to connect to PostgreSQL DB instances using new SSL/TLS certificates

Certificates used for Secure Socket Layer or Transport Layer Security (SSL/TLS) typically have a set lifetime. When service providers update their Certificate Authority (CA) certificates, clients must update their applications to use the new certificates. Following, you can find information about how to determine if your client applications use SSL/TLS to connect to your Amazon RDS for PostgreSQL DB instance. You also find information about how to check if those applications verify the server certificate when they connect.

**Note**

A client application that's configured to verify the server certificate before SSL/TLS connection must have a valid CA certificate in the client's trust store. Update the client trust store when necessary for new certificates.
After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a nonproduction environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster. For information about using SSL/TLS with PostgreSQL DB instances, see Using SSL with a PostgreSQL DB instance.

Topics

- Determining whether applications are connecting to PostgreSQL DB instances using SSL
- Determining whether a client requires certificate verification in order to connect
- Updating your application trust store
- Using SSL/TLS connections for different types of applications

Determining whether applications are connecting to PostgreSQL DB instances using SSL

Check the DB instance configuration for the value of the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off) for DB instances using PostgreSQL versions before version 15. By default, `rds.force_ssl` is set to 1 (on) for DB instances using PostgreSQL version 15 and later major versions. If the `rds.force_ssl` parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see Working with parameter groups.

If you are using RDS PostgreSQL version 9.5 or later major version and `rds.force_ssl` is not set to 1 (on), query the `pg_stat_ssl` view to check connections using SSL. For example, the following query returns only SSL connections and information about the clients using SSL.

```sql
SELECT datname, usename, ssl, client_addr
FROM pg_stat_ssl INNER JOIN pg_stat_activity ON pg_stat_ssl.pid = pg_stat_activity.pid
WHERE ssl is true and usename<>'rdsadmin';
```

Only rows using SSL/TLS connections are displayed with information about the connection. The following is sample output.

```
datname | usename | ssl | client_addr
------- | ------- | ---- | ------------
```
This query displays only the current connections at the time of the query. The absence of results doesn’t indicate that no applications are using SSL connections. Other SSL connections might be established at a different time.

**Determining whether a client requires certificate verification in order to connect**

When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used is different between libpq-based clients (such as psql) and JDBC. The libpq-based clients default to `prefer`, where JDBC clients default to `verify-full`. The certificate on the server is verified only when `sslrootcert` is provided with `sslmode` set to `verify-ca` or `verify-full`. An error is thrown if the certificate is invalid.

Use `PGSSLROOTCERT` to verify the certificate with the `PGSSLMODE` environment variable, with `PGSSLMODE` set to `verify-ca` or `verify-full`.

```
PGSSLMODE=verify-full PGSSLROOTCERT=/fullpath/ssl-cert.pem psql -h pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com -U masteruser -d postgres
```

Use the `sslrootcert` argument to verify the certificate with `sslmode` in connection string format, with `sslmode` set to `verify-ca` or `verify-full` to verify the certificate.

```
psql "host=pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com sslmode=verify-full
sslrootcert=/full/path/ssl-cert.pem user=masteruser dbname=postgres"
```

For example, in the preceding case, if you are using an invalid root certificate, then you see an error similar to the following on your client.

```
psql: SSL error: certificate verify failed
```

**Updating your application trust store**

For information about updating the trust store for PostgreSQL applications, see [Secure TCP/IP connections with SSL](#) in the PostgreSQL documentation.
For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

For sample scripts that import certificates, see Sample script for importing certificates into your trust store.

### Note

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

### Using SSL/TLS connections for different types of applications

The following provides information about using SSL/TLS connections for different types of applications:

- **psql**

  The client is invoked from the command line by specifying options either as a connection string or as environment variables. For SSL/TLS connections, the relevant options are `sslmode` (environment variable `PGSSLMODE`), `sslrootcert` (environment variable `PGSSLROOTCERT`).

  For the complete list of options, see Parameter key words in the PostgreSQL documentation. For the complete list of environment variables, see Environment variables in the PostgreSQL documentation.

- **pgAdmin**

  This browser-based client is a more user-friendly interface for connecting to a PostgreSQL database.

  For information about configuring connections, see the pgAdmin documentation.

- **JDBC**

  JDBC enables database connections with Java applications.

  For general information about connecting to a PostgreSQL database with JDBC, see Connecting to the database in the PostgreSQL JDBC driver documentation. For information about connecting with SSL/TLS, see Configuring the client in the PostgreSQL JDBC driver documentation.
• Python

A popular Python library for connecting to PostgreSQL databases is **psycopg2**.

For information about using psycopg2, see the [psycopg2 documentation](#). For a short tutorial on how to connect to a PostgreSQL database, see [Psycopg2 tutorial](#). You can find information about the options the connect command accepts in [The psycopg2 module content](#).

⚠️ **Important**

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance or cluster](#).
Using Kerberos authentication with Amazon RDS for PostgreSQL

You can use Kerberos to authenticate users when they connect to your DB instance running PostgreSQL. To do so, configure your DB instance to use AWS Directory Service for Microsoft Active Directory for Kerberos authentication. AWS Directory Service for Microsoft Active Directory is also called AWS Managed Microsoft AD. It's a feature available with AWS Directory Service. To learn more, see What is AWS Directory Service? in the AWS Directory Service Administration Guide.

To start, create an AWS Managed Microsoft AD directory to store user credentials. Then, provide to your PostgreSQL DB instance the Active Directory's domain and other information. When users authenticate with the PostgreSQL DB instance, authentication requests are forwarded to the AWS Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized location for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

In addition, you can access credentials from your own on-premises Microsoft Active Directory. To do so, create a trusting domain relationship so that the AWS Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your PostgreSQL instances with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

A database can use password authentication or password authentication with either Kerberos or AWS Identity and Access Management (IAM) authentication. For more information about IAM authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

Topics

- Region and version availability
- Overview of Kerberos authentication for PostgreSQL DB instances
- Setting up Kerberos authentication for PostgreSQL DB instances
- Managing a DB instance in a Domain
- Connecting to PostgreSQL with Kerberos authentication
Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS for PostgreSQL with Kerberos authentication, see Kerberos authentication.

Overview of Kerberos authentication for PostgreSQL DB instances

To set up Kerberos authentication for a PostgreSQL DB instance, take the following steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service API to create the directory. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the instance.

2. Create a role that provides Amazon RDS access to make calls to your AWS Managed Microsoft AD directory. To do so, create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

   For the IAM role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

4. If you plan to locate the directory and the DB instance in different AWS accounts or virtual private clouds (VPCs), configure VPC peering. For more information, see What is VPC peering? in the Amazon VPC Peering Guide.

5. Create or modify a PostgreSQL DB instance either from the console, CLI, or RDS API using one of the following methods:
   - Creating an Amazon RDS DB instance
   - Modifying an Amazon RDS DB instance
   - Restoring from a DB snapshot
   - Restoring a DB instance to a specified time
You can locate the instance in the same Amazon Virtual Private Cloud (VPC) as the directory or in a different AWS account or VPC. When you create or modify the PostgreSQL DB instance, do the following:

- Provide the domain identifier (d-* identifier) that was generated when you created your directory.
- Provide the name of the IAM role that you created.
- Ensure that the DB instance security group can receive inbound traffic from the directory security group.

6. Use the RDS master user credentials to connect to the PostgreSQL DB instance. Create the user in PostgreSQL to be identified externally. Externally identified users can log in to the PostgreSQL DB instance using Kerberos authentication.

**Setting up Kerberos authentication for PostgreSQL DB instances**

You use AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to set up Kerberos authentication for a PostgreSQL DB instance. To set up Kerberos authentication, take the following steps.

**Topics**

- **Step 1: Create a directory using AWS Managed Microsoft AD**
- **Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and AWS Directory Service**
- **Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service**
- **Step 4: Create and configure users**
- **Step 5: Enable cross-VPC traffic between the directory and the DB instance**
- **Step 6: Create or modify a PostgreSQL DB instance**
- **Step 7: Create PostgreSQL users for your Kerberos principals**
- **Step 8: Configure a PostgreSQL client**

**Step 1: Create a directory using AWS Managed Microsoft AD**

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers
and DNS servers for you. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within your VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

⚠️ **Important**

Make sure to save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

- Creates a security group for the directory controllers. The security group must permit communication with the PostgreSQL DB instance.

When you launch AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU, which has the NetBIOS name that you entered when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run Active Directory and Domain Name Service (DNS) modules for Windows PowerShell on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:
• Manage DNS configurations (add, remove, or update records, zones, and forwarders)
• View DNS event logs
• View security event logs

**To create a directory with AWS Managed Microsoft AD**

1. In the [AWS Directory Service console](https://aws.amazon.com/directoryservice) navigation pane, choose **Directories**, and then choose **Set up directory**.
2. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option currently supported for use with Amazon RDS.
3. Choose **Next**.
4. On the **Enter directory information** page, provide the following information:

   **Edition**

   Choose the edition that meets your requirements.

   **Directory DNS name**

   The fully qualified name for the directory, such as `corp.example.com`.

   **Directory NetBIOS name**

   An optional short name for the directory, such as `CORP`.

   **Directory description**

   An optional description for the directory.

   **Admin password**

   The password for the directory administrator. The directory creation process creates an administrator account with the user name `Admin` and this password.

   The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:
   
   • Lowercase letters (a–z)
   • Uppercase letters (A–Z)
   • Numbers (0–9)
- Nonalphanumeric characters (~!@#$%^&*_-+=`|(){}[]:;"'<>,.?/)

**Confirm password**

Retype the administrator password.

⚠️ **Important**

Make sure that you save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

5. Choose **Next**.

6. On the **Choose VPC and subnets** page, provide the following information:

   **VPC**

   Choose the VPC for the directory. You can create the PostgreSQL DB instance in this same VPC or in a different VPC.

   **Subnets**

   Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose **Next**.

8. Review the directory information. If changes are needed, choose **Previous** and make the changes. When the information is correct, choose **Create directory**.
It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID** value. You need this value when you create or modify your PostgreSQL DB instance.
Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and AWS Directory Service

If you don't plan to use your own on-premises Microsoft Active Directory, skip to Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service.

To get Kerberos authentication using your on-premises Active Directory, you need to create a trusting domain relationship using a forest trust between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD directory (created in Step 1: Create a directory using AWS Managed Microsoft AD). The trust can be one-way, where the AWS Managed Microsoft
AD directory trusts the on-premises Microsoft Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.

Note

If you use an on-premises Microsoft Active Directory, Windows clients connect using the domain name of the AWS Directory Service in the endpoint rather than rds.amazonaws.com. To learn more, see Connecting to PostgreSQL with Kerberos authentication.

Make sure that your on-premises Microsoft Active Directory domain name includes a DNS suffix routing that corresponds to the newly created trust relationship. The following screenshot shows an example.

Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service

For Amazon RDS to call AWS Directory Service for you, your AWS account needs an IAM role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess. This role allows Amazon RDS to make calls to AWS Directory Service.

When you create a DB instance using the AWS Management Console and your console user account has the iam:CreateRole permission, the console creates the needed IAM role automatically. In this case, the role name is rds-directoryservice-kerberos-access-role. Otherwise, you must create the IAM role manually. When you create this IAM role, choose Directory Service, and attach the AWS managed policy AmazonRDSDirectoryServiceAccess to it.
For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

**Note**

The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for Amazon RDS for PostgreSQL.

As an alternative to using the AmazonRDSDirectoryServiceAccess managed policy, you can create policies with the required permissions. In this case, the IAM role must have the following IAM trust policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "",
         "Effect": "Allow",
         "Principal": {
            "Service": [
               "directoryservice.rds.amazonaws.com",
               "rds.amazonaws.com"
            ]
         },
         "Action": "sts:AssumeRole"
      }
   ]
}
```

The role must also have the following IAM role policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Action": [
            "ds:DescribeDirectories",
            "ds:AuthorizeApplication",
            "ds:UnauthorizeApplication",
            "ds:GetAuthorizedApplicationDetails"
         ]
      }
   ]
}
```
Step 4: Create and configure users

You can create users by using the Active Directory Users and Computers tool. This is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. For more information, see Add Users and Computers to the Active Directory domain in the Microsoft documentation. In this case, users are individuals or other entities, such as their computers that are part of the domain and whose identities are being maintained in the directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that's a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information, see Create a user in the AWS Directory Service Administration Guide.

Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 6: Create or modify a PostgreSQL DB instance.

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway.

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the Amazon Virtual Private Cloud Peering Guide.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance security group can receive inbound traffic from the directory security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.
To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join in the AWS Directory Service Administration Guide.

2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.

3. While signed into the AWS Directory Service console using the account for the DB instance, note the Directory ID value. You use this directory ID to join the DB instance to the domain.

Step 6: Create or modify a PostgreSQL DB instance

Create or modify a PostgreSQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new PostgreSQL DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation. For instructions, see Creating an Amazon RDS DB instance.

- Modify an existing PostgreSQL DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation. For instructions, see Modifying an Amazon RDS DB instance.

- Restore a PostgreSQL DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation. For instructions, see Restoring from a DB snapshot.

- Restore a PostgreSQL DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation. For instructions, see Restoring a DB instance to a specified time.

Kerberos authentication is only supported for PostgreSQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows ingress and egress within the directory's VPC so the DB instance can communicate with the directory.
Console

When you use the console to create, modify, or restore a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Then choose **Browse Directory**. Select the directory or choose **Create a new directory** to use the Directory Service.

AWS CLI

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the **--domain** parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the **--domain-iam-role-name** parameter, use the role you created that uses the managed IAM policy **AmazonRDSDirectoryServiceAccess**.

For example, the following CLI command modifies a DB instance to use a directory.

```
aws rds modify-db-instance --db-instance-identifier mydbinstance --domain d-Directory-ID --domain-iam-role-name role-name
```

⚠️ **Important**

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.
Step 7: Create PostgreSQL users for your Kerberos principals

At this point, your RDS for PostgreSQL DB instance is joined to the AWS Managed Microsoft AD domain. The users that you created in the directory in Step 4: Create and configure users need to be set up as PostgreSQL database users and granted privileges to login to the database. You do that by signing in as the database user with rds_superuser privileges. For example, if you accepted the defaults when you created your RDS for PostgreSQL DB instance, you use postgres, as shown in the following steps.

To create PostgreSQL database users for Kerberos principals

1. Use psql to connect to your RDS for PostgreSQL DB instance endpoint using psql. The following example uses the default postgres account for the rds_superuser role.

   ```
   psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Create a database user name for each Kerberos principal (Active Directory username) that you want to have access to the database. Use the canonical username (identity) as defined in the Active Directory instance, that is, a lower-case alias (username in Active Directory) and the upper-case name of the Active Directory domain for that user name. The Active Directory user name is an externally authenticated user, so use quotes around the name as shown following.

   ```
   psql=> CREATE USER "username@CORP.EXAMPLE.COM" WITH LOGIN;
   CREATE ROLE
   ```

3. Grant the rds_ad role to the database user.

   ```
   psql=> GRANT rds_ad TO "username@CORP.EXAMPLE.COM";
   GRANT ROLE
   ```

After you finish creating all the PostgreSQL users for your Active Directory user identities, users can access the RDS for PostgreSQL DB instance by using their Kerberos credentials.

It's assumed that the database users who authenticate using Kerberos are doing so from client machines that are members of the Active Directory domain.
Database users that have been granted the `rds_ad` role can't also have the `rds_iam` role. This also applies to nested memberships. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

**Step 8: Configure a PostgreSQL client**

To configure a PostgreSQL client, take the following steps:

- Create a krb5.conf file (or equivalent) to point to the domain.
- Verify that traffic can flow between the client host and AWS Directory Service. Use a network utility such as Netcat for the following:
  - Verify traffic over DNS for port 53.
  - Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for AWS Directory Service.
- Verify that traffic can flow between the client host and the DB instance over the database port. For example, use psql to connect and access the database.

The following is sample krb5.conf content for AWS Managed Microsoft AD.

```plaintext
[libdefaults]
    default_realm = EXAMPLE.COM

[realms]
    EXAMPLE.COM = {
        kdc = example.com
        admin_server = example.com
    }

[domain_realm]
    .example.com = EXAMPLE.COM
    example.com = EXAMPLE.COM
```

The following is sample krb5.conf content for an on-premises Microsoft Active Directory.

```plaintext
[libdefaults]
    default_realm = EXAMPLE.COM

[realms]
    EXAMPLE.COM = {
        kdc = example.com
        admin_server = example.com
    }
```
Managing a DB instance in a Domain

You can use the console, the CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate an Active Directory to enable Kerberos authentication. You can also remove the association for an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the `modify-db-instance` CLI command. Specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the `modify-db-instance` CLI command. Specify none for the `--domain` option.
- To move a DB instance from one domain to another, use the `modify-db-instance` CLI command. Specify the domain identifier of the new domain for the `--domain` option.

Understanding Domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership in the console or by running the `describe-db-instances` CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
• pending-enable-kerberos – Enabling Kerberos authentication is pending on this DB instance.

• pending-maintenance-enable-kerberos – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.

• pending-disable-kerberos – Disabling Kerberos authentication is pending on this DB instance.

• pending-maintenance-disable-kerberos – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.

• enable-kerberos-failed – A configuration problem prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.

• disabling-kerberos – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. In some cases, the attempt to enable Kerberos authentication might fail when you create or modify a DB instance. If so, make sure that you are using the correct IAM role, then modify the DB instance to join the domain.

Note

Only Kerberos authentication with RDS for PostgreSQL sends traffic to the domain’s DNS servers. All other DNS requests are treated as outbound network access on your DB instances running PostgreSQL. For more information about outbound network access with RDS for PostgreSQL, see Using a custom DNS server for outbound network access.

Connecting to PostgreSQL with Kerberos authentication

You can connect to PostgreSQL with Kerberos authentication with the pgAdmin interface or with a command-line interface such as psql. For more information about connecting, see Connecting to a DB instance running the PostgreSQL database engine. For information about obtaining the endpoint, port number, and other details needed for connection, see Step 3: Connect to a PostgreSQL DB instance.
pgAdmin

To use pgAdmin to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. Launch the pgAdmin application on your client computer.
3. In the Create - Server dialog box, enter a name on the General tab to identify the server in pgAdmin.
4. On the Connection tab, enter the following information from your RDS for PostgreSQL database.
   - For Host, enter the endpoint for the RDS for PostgreSQL DB instance. An endpoint looks similar to the following:

   ```
   RDS-DB-instance.111122223333.aws-region.rds.amazonaws.com
   ```
   
   To connect to an on-premises Microsoft Active Directory from a Windows client, you use the domain name of the AWS Managed Active Directory instead of rds.amazonaws.com in the host endpoint. For example, suppose that the domain name for the AWS Managed Active Directory is corp.example.com. Then for Host, the endpoint would be specified as follows:

   ```
   RDS-DB-instance.111122223333.aws-region.corp.example.com
   ```
   
   - For Port, enter the assigned port.
   - For Maintenance database, enter the name of the initial database to which the client will connect.
   - For Username, enter the user name that you entered for Kerberos authentication in Step 7: Create PostgreSQL users for your Kerberos principals.
5. Choose Save.

Psq1

To use psql to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. At a command prompt, run the following command.

   ```
   kinit username
   ```
Replace `username` with the user name. At the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. If the PostgreSQL DB instance is using a publicly accessible VPC, put IP address for your DB instance endpoint in your `/etc/hosts` file on the EC2 client. For example, the following commands obtain the IP address and then put it in the `/etc/hosts` file.

```bash
% dig +short PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com
;; Truncated, retrying in TCP mode.
e2-34-210-197-118.AWS-Region.compute.amazonaws.com.
34.210.197.118

% echo "34.210.197.118 PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com" >> /etc/hosts
```

If you're using an on-premises Microsoft Active Directory from a Windows client, then you need to connect using a specialized endpoint. Instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint, use the domain name of the AWS Managed Active Directory.

For example, suppose that the domain name for your AWS Managed Active Directory is `corp.example.com`. Then use the format `PostgreSQL-endpoint.AWS-Region.corp.example.com` for the endpoint and put it in the `/etc/hosts` file.

```bash
% echo "34.210.197.118 PostgreSQL-endpoint.AWS-Region.corp.example.com" >> /etc/hosts
```

3. Use the following `psql` command to log in to a PostgreSQL DB instance that is integrated with Active Directory.

```bash
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com postgres
```

To log in to the PostgreSQL DB cluster from a Windows client using an on-premises Active Directory, use the following `psql` command with the domain name from the previous step (`corp.example.com`):

```bash
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.corp.example.com.com postgres
```
Using a custom DNS server for outbound network access

RDS for PostgreSQL supports outbound network access on your DB instances and allows Domain Name Service (DNS) resolution from a custom DNS server owned by the customer. You can resolve only fully qualified domain names from your RDS for PostgreSQL DB instance through your custom DNS server.

Topics

• Turning on custom DNS resolution
• Turning off custom DNS resolution
• Setting up a custom DNS server

Turning on custom DNS resolution

To turn on DNS resolution in your customer VPC, first associate a custom DB parameter group to your RDS for PostgreSQL instance. Then turn on the `rds.custom_dns_resolution` parameter by setting it to 1, and then restart the DB instance for the changes to take place.

Turning off custom DNS resolution

To turn off DNS resolution in your customer VPC, first turn off the `rds.custom_dns_resolution` parameter of your custom DB parameter group by setting it to 0. Then restart the DB instance for the changes to take place.

Setting up a custom DNS server

After you set up your custom DNS name server, it takes up to 30 minutes to propagate the changes to your DB instance. After the changes are propagated to your DB instance, all outbound network traffic requiring a DNS lookup queries your DNS server over port 53.

Note

If you don't set up a custom DNS server and `rds.custom_dns_resolution` is set to 1, hosts are resolved using an Amazon Route 53 private zone. For more information, see Working with private hosted zones.
To set up a custom DNS server for your RDS for PostgreSQL DB instance

1. From the Dynamic Host Configuration Protocol (DHCP) options set attached to your VPC, set the domain-name-servers option to the IP address of your DNS name server. For more information, see DHCP options sets.

   **Note**
   The domain-name-servers option accepts up to four values, but your Amazon RDS DB instance uses only the first value.

2. Ensure that your DNS server can resolve all lookup queries, including public DNS names, Amazon EC2 private DNS names, and customer-specific DNS names. If the outbound network traffic contains any DNS lookups that your DNS server can't handle, your DNS server must have appropriate upstream DNS providers configured.

3. Configure your DNS server to produce User Datagram Protocol (UDP) responses of 512 bytes or less.

4. Configure your DNS server to produce Transmission Control Protocol (TCP) responses of 1,024 bytes or less.

5. Configure your DNS server to allow inbound traffic from your Amazon RDS DB instances over port 53. If your DNS server is in an Amazon VPC, the VPC must have a security group that contains inbound rules that allow UDP and TCP traffic on port 53. If your DNS server is not in an Amazon VPC, it must have appropriate firewall settings to allow UDP and TCP inbound traffic on port 53.

   For more information, see Security groups for your VPC and Adding and removing rules.

6. Configure the VPC of your Amazon RDS DB instance to allow outbound traffic over port 53. Your VPC must have a security group that contains outbound rules that allow UDP and TCP traffic on port 53.

   For more information, see Security groups for your VPC and Adding and removing rules in the Amazon VPC User Guide.

7. Make sure that the routing path between the Amazon RDS DB instance and the DNS server is configured correctly to allow DNS traffic.
Also, if the Amazon RDS DB instance and the DNS server are not in the same VPC, make sure that a peering connection is set up between them. For more information, see [What is VPC peering?](#) in *Amazon VPC Peering Guide*. 
Upgrading the PostgreSQL DB engine for Amazon RDS

There are two types of upgrades that you can manage for your PostgreSQL database:

- Operating system updates – Occasionally, Amazon RDS might need to update the underlying operating system of your database to apply security fixes or OS changes. You can decide when Amazon RDS applies OS updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API. For more information about OS updates, see Applying updates for a DB instance.

- Database engine upgrades – When Amazon RDS supports a new version of a database engine, you can upgrade your databases to the new version.

A database in this context is an RDS for PostgreSQL DB instance or Multi-AZ DB cluster.

There are two kinds of engine upgrades for PostgreSQL databases: major version upgrades and minor version upgrades.

**Major version upgrades**

*Major version upgrades* can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your databases. You can initiate a major version upgrade by modifying your DB instance or Multi-AZ DB cluster. Before you perform a major version upgrade, we recommend that you follow the steps described in Choosing a major version upgrade for PostgreSQL.

If you're upgrading a DB instance that has in-Region read replicas, Amazon RDS upgrades the replicas along with the primary DB instance.

Amazon RDS doesn't upgrade Multi-AZ DB cluster read replicas. If you perform a major version upgrade of a Multi-AZ DB cluster, then the replication state of its read replicas changes to terminated. You must manually delete and recreate the read replicas after the upgrade completes.

**Tip**

You can minimize the downtime required for a major version upgrade by using a blue/green deployment. For more information, see Using Blue/Green Deployments for database updates.
Minor version upgrades

In contrast, *minor version upgrades* include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your database. Or, you can enable the **Auto minor version upgrade** option when creating or modifying a database. Doing so means that Amazon RDS automatically upgrades your database after testing and approving the new version. If your PostgreSQL database uses read replicas, you must first upgrade all of the read replicas before upgrading the source instance or cluster.

If your database is a Multi-AZ DB instance deployment, Amazon RDS simultaneously upgrades the primary and any standby instances. Therefore, your database might not be available until the upgrade completes. If your database is a Multi-AZ DB cluster deployment, Amazon RDS upgrades the reader DB instances one at a time. Then, one of the reader DB instances switches to be the new writer DB instance. Amazon RDS then upgrades the old writer instance (which is now a reader instance).

**Note**
The downtime for a minor version upgrade of a Multi-AZ DB instance deployment can last for several minutes. Multi-AZ DB clusters typically reduce the downtime of minor version upgrades to approximately 35 seconds. When used with RDS Proxy, you can further reduce downtime to one second or less. For more information, see *Using RDS Proxy*. Alternately, you can use an open source database proxy such as ProxySQL, PgBouncer, or the AWS JDBC Driver for MySQL.

For more information, see [Automatic minor version upgrades for PostgreSQL](#). For information about manually performing a minor version upgrade, see [Manually upgrading the engine version](#).

For more information about database engine versions and the policy for deprecating database engine versions, see [Database Engine Versions](#) in the Amazon RDS FAQs.

**Topics**
- [Overview of upgrading PostgreSQL](#)
- [PostgreSQL version numbers](#)
- [RDS version number](#)
Overview of upgrading PostgreSQL

To safely upgrade your databases, Amazon RDS uses the pg_upgrade utility described in the PostgreSQL documentation.

When you use the AWS Management Console to upgrade a database, it shows the valid upgrade targets for the database. You can also use the following AWS CLI command to identify the valid upgrade targets for a database:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
   --engine postgres \
   --engine-version version-number \
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
   --engine postgres ^
   --engine-version version-number ^
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For example, to identify the valid upgrade targets for a PostgreSQL version 12.13 database, run the following AWS CLI command:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
   --engine postgres \
   --engine-version 12.13 \
```
For Windows:

```
aws rds describe-db-engine-versions ^
   --engine postgres ^
   --engine-version 12.13 ^
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

If your backup retention period is greater than 0, Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the database before any upgrade changes have been made. If the upgrade fails for your databases, you can restore this snapshot to create a database running the old version. The second DB snapshot is taken after the upgrade completes.

Note

Amazon RDS takes DB snapshots during the upgrade process only if you have set the backup retention period for your database to a number greater than 0. To change the backup retention period for a DB instance, see the section called “Modifying a DB instance”. You can't configure a custom backup retention period for a Multi-AZ DB cluster.

When you perform a major version upgrade of a DB instance, any in-Region read replicas are also automatically upgraded. After the upgrade workflow starts, the read replicas wait for the `pg_upgrade` to complete successfully on the primary DB instance. Then the primary DB instance upgrade waits for the read replica upgrades to complete. You experience an outage until the upgrade is complete. When you perform a major version upgrade of a Multi-AZ DB cluster, the replication state of its read replicas changes to **terminated**.

After an upgrade is complete, you can't revert to the previous version of the DB engine. If you want to return to the previous version, restore the DB snapshot that was taken before the upgrade to create a new database.

**PostgreSQL version numbers**

The version numbering sequence for the PostgreSQL database engine is as follows:
• For PostgreSQL versions 10 and later, the engine version number is in the form `major.minor`. The major version number is the integer part of the version number. The minor version number is the fractional part of the version number.

A major version upgrade increases the integer part of the version number, such as upgrading from `10.minor` to `11.minor`.

• For PostgreSQL versions earlier than 10, the engine version number is in the form `major.major.minor`. The major engine version number is both the integer and the first fractional part of the version number. For example, 9.6 is a major version. The minor version number is the third part of the version number. For example, for version 9.6.12, the 12 is the minor version number.

A major version upgrade increases the major part of the version number. For example, an upgrade from `9.6.12` to `11.14` is a major version upgrade, where 9.6 and 11 are the major version numbers.

For information about RDS Extended Support version numbering, see [Amazon RDS Extended Support version naming](#).

**RDS version number**

RDS version numbers use the `major.minor.patch` naming scheme. An RDS patch version includes important bug fixes added to a minor version after its release. For information about RDS Extended Support version numbering, see [Amazon RDS Extended Support version naming](#).

To identify the Amazon RDS version number of your database, you must first create the `rds_tools` extension by using the following command:

```sql
CREATE EXTENSION rds_tools;
```

Starting with the release of PostgreSQL version 15.2-R2, you can find out the RDS version number of your RDS for PostgreSQL database with the following SQL query:

```sql
postgres=> SELECT rds_tools.rds_version();
```

For example, querying an RDS for PostgreSQL 15.2 database returns the following:

```sql
rds_version
```
Choosing a major version upgrade for PostgreSQL

Major version upgrades can contain changes that are not backward-compatible with previous versions of the database. New functionality can cause your existing applications to stop working correctly. For this reason, Amazon RDS doesn't apply major version upgrades automatically. To perform a major version upgrade, you modify your database manually. Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. When you do a PostgreSQL major version upgrade, we recommend that you follow the steps described in How to perform a major version upgrade.

When you upgrade a PostgreSQL Single-AZ DB instance or Multi-AZ DB instance deployment to its next major version, any read replicas associated with the database are also upgraded to that next major version. In some cases, you can skip to a higher major version when upgrading. If your upgrade skips a major version, the read replicas are also upgraded to that target major version. Upgrades to version 11 that skip other major versions have certain limitations. You can find the details in the steps described in How to perform a major version upgrade.

Most PostgreSQL extensions aren't upgraded during a PostgreSQL engine upgrade. These must be upgraded separately. For more information, see Upgrading PostgreSQL extensions.

You can find out which major versions are available for your RDS for PostgreSQL database by running the following AWS CLI query:

```
aws rds describe-db-engine-versions --engine postgres --engine-version your-version
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

The following table summarizes the results of this query for all available versions. An asterisk (*) on the version number means that version is deprecated. If your current version is deprecated, we recommend that you upgrade to the newest minor version upgrade target or to one of the other available upgrade targets for that version. For more information about the RDS for PostgreSQL version 9.6 deprecation, see Deprecation of PostgreSQL version 9.6. For more information about the RDS for PostgreSQL version 10 deprecation, see Deprecation of PostgreSQL version 10.

Choosing a major version upgrade
### How to perform a major version upgrade

We recommend the following process when performing a major version upgrade on an Amazon RDS for PostgreSQL database:

1. **Have a version-compatible parameter group ready** – If you are using a custom parameter group, you have two options. You can specify a default parameter group for the new DB engine version. Or you can create your own custom parameter group for the new DB engine version. For more information, see the section called “Working with parameter groups” and the section called “Working with DB cluster parameter groups”.

<table>
<thead>
<tr>
<th>Current major version (UTC)</th>
<th>New major version</th>
<th>Other available upgrade targets</th>
</tr>
</thead>
<tbody>
<tr>
<td>9.6.1</td>
<td>9.6</td>

</table>

How to perform a major version upgrade
2. **Check for unsupported database classes** – Check that your database's instance class is compatible with the PostgreSQL version you are upgrading to. For more information, see [Supported DB engines for DB instance classes](#).

3. **Check for unsupported usage:**

   • **Prepared transactions** – Commit or roll back all open prepared transactions before attempting an upgrade.

     You can use the following query to verify that there are no open prepared transactions on your database.

     ```sql
     SELECT count(*) FROM pg_catalog.pg_prepared_xacts;
     ```

   • **Reg* data types** – Remove all uses of the `reg*` data types before attempting an upgrade. Except for `regtype` and `regclass`, you can't upgrade the `reg*` data types. The `pg_upgrade` utility can't persist this data type, which is used by Amazon RDS to do the upgrade.

     To verify that there are no uses of unsupported `reg*` data types, use the following query for each database.

     ```sql
     SELECT count(*) FROM pg_catalog.pg_class c, pg_catalog.pg_namespace n, pg_catalog.pg_attribute a
     WHERE c.oid = a.attrelid
     AND NOT a.attisdropped
     AND c.relnamespace = n.oid
     AND n.nspname NOT IN ('pg_catalog', 'information_schema');
     ```

4. **Handle logical replication slots** – An upgrade can't occur if the database has any logical replication slots. Logical replication slots are typically used for AWS DMS migration and for replicating tables from the database to data lakes, BI tools, and other targets. Before upgrading, make sure that you know the purpose of any logical replication slots that are in use, and confirm that it's okay to delete them. If the logical replication slots are still being used, you shouldn't delete them, and you can't proceed with the upgrade.
If the logical replication slots aren't needed, you can delete them using the following SQL:

```sql
SELECT * FROM pg_replication_slots;
SELECT pg_drop_replication_slot(slot_name);
```

Logical replication setups that use the `pglogical` extension also need to have slots dropped for a successful major version upgrade. For information about how to identify and drop slots created using the `pglogical` extension, see Managing logical replication slots for RDS for PostgreSQL.

5. **Handle read replicas** – An upgrade of a Single-AZ DB instance or Multi-AZ DB instance deployment also upgrades the in-Region read replicas along with the primary DB instance. Amazon RDS doesn’t upgrade Multi-AZ DB cluster read replicas.

You can’t upgrade read replicas separately. If you could, it could lead to situations where the primary and replica databases have different PostgreSQL major versions. However, read replica upgrades might increase downtime on the primary DB instance. To prevent a read replica upgrade, promote the replica to a standalone instance or delete it before starting the upgrade process.

The upgrade process recreates the read replica's parameter group based on the read replica's current parameter group. You can apply a custom parameter group to a read replica only after the upgrade completes by modifying the read replica. For more information about read replicas, see Working with read replicas for Amazon RDS for PostgreSQL.

6. **Perform a backup** – We recommend that you perform a backup before performing the major version upgrade so that you have a known restore point for your database. If your backup retention period is greater than 0, the upgrade process creates DB snapshots of your database before and after upgrading. To change your backup retention period, see Modifying an Amazon RDS DB instance and the section called “Modifying a Multi-AZ DB cluster”.

   To perform a backup manually, see the section called “Creating a DB snapshot for a Single-AZ DB instance” and the section called “Creating a Multi-AZ DB cluster snapshot”.

7. **Upgrade certain extensions before a major version upgrade** – If you plan to skip a major version with the upgrade, you need to update certain extensions before performing the major version upgrade. For example, upgrading from versions 9.5.x or 9.6.x to version 11.x skips a major version. The extensions to update include PostGIS and related extensions for processing spatial data.
• address_standardizer
• address_standardizer_data_us
• postgis_raster
• postgis_tiger_geocoder
• postgis_topology

Run the following command for each extension that you're using:

```
ALTER EXTENSION PostgreSQL-extension UPDATE TO 'new-version';
```

For more information, see Upgrading PostgreSQL extensions. To learn more about upgrading PostGIS, see Step 6: Upgrade the PostGIS extension.

8. **Drop certain extensions before the major version upgrade** – An upgrade that skips a major version to version 11.x doesn't support updating the pgRouting extension. Upgrading from versions 9.4.x, 9.5.x, or 9.6.x to versions 11.x skips a major version. It's safe to drop the pgRouting extension and then reinstall it to a compatible version after the upgrade. For the extension versions you can update to, see Supported PostgreSQL extension versions.

The tsearch2 and chkpass extensions are no longer supported for PostgreSQL versions 11 or later. If you are upgrading to version 11.x, drop the tsearch2, and chkpass extensions before the upgrade.

9. **Drop unknown data types** – Drop unknown data types depending on the target version.

PostgreSQL version 10 stopped supporting the unknown data type. If a version 9.6 database uses the unknown data type, an upgrade to a version 10 shows an error message such as the following:

```
Database instance is in a state that cannot be upgraded: PreUpgrade checks failed:
The instance could not be upgraded because the 'unknown' data type is used in user tables.
Please remove all usages of the 'unknown' data type and try again."
```

To find the unknown data type in your database so you can remove the offending column or change it to a supported data type, use the following SQL:
10 **Perform an upgrade dry run** – We highly recommend testing a major version upgrade on a duplicate of your production database before attempting the upgrade on your production database. You can monitor the execution plans on the duplicate test database for any possible execution plan regressions and to evaluate its performance. To create a duplicate test instance, you can either restore your database from a recent snapshot or do a point-in-time restore of your database to its latest restorable time.

For more information, see the section called “Restoring from a snapshot” or the section called “Restoring a DB instance to a specified time”. For Multi-AZ DB clusters, see the section called “Restoring from a snapshot to a Multi-AZ DB cluster” or the section called “Restoring a Multi-AZ DB cluster to a specified time”.

For details on performing the upgrade, see the section called “Manually upgrading the engine version”.

In upgrading a version 9.6 database to version 10, be aware that PostgreSQL 10 enables parallel queries by default. You can test the impact of parallelism before the upgrade by changing the `max_parallel_workers_per_gather` parameter on your test database to 2.

### Note
The default value for `max_parallel_workers_per_gather` parameter in the default.postgresql10 DB parameter group is 2.

For more information, see Parallel Query in the PostgreSQL documentation. To disable parallelism on version 10, set the `max_parallel_workers_per_gather` parameter to 0.

During the major version upgrade, the public and template1 databases and the public schema in every database are temporarily renamed. These objects appear in the logs with their original name and a random string appended. The string is appended so that custom settings such as locale and owner are preserved during the major version upgrade. After the upgrade completes, the objects are renamed back to their original names.
**Note**

During the major version upgrade process, you can’t do a point-in-time restore of your DB instance or Multi-AZ DB cluster. After Amazon RDS performs the upgrade, it takes an automatic backup of the database. You can perform a point-in-time restore to times before the upgrade began and after the automatic backup of your database has completed.

---

11. If an upgrade fails with precheck procedure errors, resolve the issues – During the major version upgrade process, Amazon RDS for PostgreSQL first runs a precheck procedure to identify any issues that might cause the upgrade to fail. The precheck procedure checks all potential incompatible conditions across all databases in the instance.

If the precheck encounters an issue, it creates a log event indicating the upgrade precheck failed. The precheck process details are in an upgrade log named `pg_upgrade_precheck.log` for all the databases of a database. Amazon RDS appends a timestamp to the file name. For more information about viewing logs, see [Monitoring Amazon RDS log files](#).

If a read replica upgrade fails at precheck, replication on the failed read replica is broken and the read replica is put in the terminated state. Delete the read replica and recreate a new read replica based on the upgraded primary DB instance.

Resolve all of the issues identified in the precheck log and then retry the major version upgrade. The following is an example of a precheck log.

```
Upgrade could not be run on Wed Apr 4 18:30:52 2018

The instance could not be upgraded from 9.6.11 to 10.6 for the following reasons.
Please take appropriate action on databases that have usage incompatible with the requested major engine version upgrade and try the upgrade again.

* There are uncommitted prepared transactions. Please commit or rollback all prepared transactions.* One or more role names start with 'pg_'. Rename all role names that start with 'pg_'.

* The following issues in the database 'my"million$"db' need to be corrected before upgrading:** The ["line","reg"] data types are used in user tables. Remove all usage of these data types.
```
** The database name contains characters that are not supported by RDS for PostgreSQL. Rename the database.
** The database has extensions installed that are not supported on the target database version. Drop the following extensions from your database: ["tsearch2"].

* The following issues in the database 'mydb' need to be corrected before upgrading:** The database has views or materialized views that depend on 'pg_stat_activity'. Drop the views.

12 If a read replica upgrade fails while upgrading the database, resolve the issue – A failed read replica is placed in the incompatible-restore state and replication is terminated on the database. Delete the read replica and recreate a new read replica based on the upgraded primary DB instance.

** Note
Amazon RDS doesn't upgrade read replicas for Multi-AZ DB clusters. If you perform a major version upgrade on a Multi-AZ DB cluster, then the replication state of its read replicas changes to terminated.

A read replica upgrade might fail for the following reasons:

- It was unable to catch up with the primary DB instance even after a wait time.
- It was in a terminal or incompatible lifecycle state such as storage-full, incompatible-restore, and so on.
- When the primary DB instance upgrade started, there was a separate minor version upgrade running on the read replica.
- The read replica used incompatible parameters.
- The read replica was unable to communicate with the primary DB instance to synchronize the data folder.

13 Upgrade your production database – When the dry-run major version upgrade is successful, you should be able to upgrade your production database with confidence. For more information, see Manually upgrading the engine version.

14 Run the ANALYZE operation to refresh the pg_statistic table. You should do this for every database on all your PostgreSQL databases. Optimizer statistics aren't transferred during a major version upgrade, so you need to regenerate all statistics to avoid performance issues. Run
the command without any parameters to generate statistics for all regular tables in the current database, as follows:

```
ANALYZE VERBOSE;
```

The VERBOSE flag is optional, but using it shows you the progress. For more information, see ANALYZE in the PostgreSQL documentation.

**Note**

Run ANALYZE on your system after the upgrade to avoid performance issues.

After the major version upgrade is complete, we recommend the following:

- A PostgreSQL upgrade doesn't upgrade any PostgreSQL extensions. To upgrade extensions, see Upgrading PostgreSQL extensions.

- Optionally, use Amazon RDS to view two logs that the `pg_upgrade` utility produces. These are `pg_upgrade_internal.log` and `pg_upgrade_server.log`. Amazon RDS appends a timestamp to the file name for these logs. You can view these logs as you can any other log. For more information, see Monitoring Amazon RDS log files.

  You can also upload the upgrade logs to Amazon CloudWatch Logs. For more information, see Publishing PostgreSQL logs to Amazon CloudWatch Logs.

- To verify that everything works as expected, test your application on the upgraded database with a similar workload. After the upgrade is verified, you can delete this test instance.

**Automatic minor version upgrades for PostgreSQL**

If you enable the Auto minor version upgrade option when creating or modifying a DB instance or Multi-AZ DB cluster, you can have your database automatically upgraded.

For each RDS for PostgreSQL major version, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before
RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the PostgreSQL community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified PostgreSQL minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
   --engine postgres \
   --engine-version minor-version \
   --region region \
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].
   {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
   --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
   --engine postgres ^
   --engine-version minor-version ^
   --region region ^
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].
   {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
   --output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for PostgreSQL minor version 12.13 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
   --engine postgres \
   --engine-version 12.13 \
   --region us-east-2 \
```
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output table

For Windows:

aws rds describe-db-engine-versions ^
--engine postgres ^
--engine-version 12.13 ^
--region us-east-2 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output table

Your output is similar to the following.

<table>
<thead>
<tr>
<th>DescribeDBEngineVersions</th>
</tr>
</thead>
<tbody>
<tr>
<td>-----------------------------------</td>
</tr>
<tr>
<td>AutoUpgrade</td>
</tr>
<tr>
<td>-------------------</td>
</tr>
<tr>
<td>True</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>-------------------</td>
</tr>
</tbody>
</table>

In this example, the AutoUpgrade value is True for PostgreSQL version 12.14. So, the automatic minor upgrade target is PostgreSQL version 12.14, which is highlighted in the output.

A PostgreSQL database is automatically upgraded during your maintenance window if the following criteria are met:

- The database has the **Auto minor version upgrade** option enabled.
- The database is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see [Automatically upgrading the minor engine version](#).
A PostgreSQL upgrade doesn’t upgrade PostgreSQL extensions. To upgrade extensions, see [Upgrading PostgreSQL extensions](#).

### Upgrading PostgreSQL extensions

A PostgreSQL engine upgrade doesn’t upgrade most PostgreSQL extensions. To update an extension after a version upgrade, use the `ALTER EXTENSION UPDATE` command.

**Note**

For information about updating the PostGIS extension, see [Managing spatial data with the PostGIS extension](#) (Step 6: Upgrade the PostGIS extension).

To update the `pg_repack` extension, drop the extension and then create the new version in the upgraded database. For more information, see [pg_repack installation](#) in the pg_repack documentation.

To upgrade an extension, use the following command.

```
ALTER EXTENSION extension_name UPDATE TO 'new_version';
```

For the list of supported versions of PostgreSQL extensions, see [Supported PostgreSQL extension versions](#).

To list your currently installed extensions, use the PostgreSQL `pg_extension` catalog in the following command.

```
SELECT * FROM pg_extension;
```

To view a list of the specific extension versions that are available for your installation, use the PostgreSQL `pg_available_extension_versions` view in the following command.

```
SELECT * FROM pg_available_extension_versions;
```
Upgrading a PostgreSQL DB snapshot engine version

With Amazon RDS, you can create a storage volume DB snapshot of your PostgreSQL DB instance. When you create a DB snapshot, the snapshot is based on the engine version used by your Amazon RDS instance. In addition to upgrading the DB engine version of your DB instance, you can also upgrade the engine version for your DB snapshots.

After restoring a DB snapshot upgraded to a new engine version, make sure to test that the upgrade was successful. For more information about a major version upgrade, see Upgrading the PostgreSQL DB engine for Amazon RDS. To learn how to restore a DB snapshot, see Restoring from a DB snapshot.

You can upgrade manual DB snapshots that are either encrypted or not encrypted.

For the list of engine versions that are available for upgrading a DB snapshot, see Upgrading the PostgreSQL DB engine for Amazon RDS.

⚠️ **Note**

You can't upgrade automated DB snapshots that are created during the automated backup process.

**Console**

**To upgrade a DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the snapshot that you want to upgrade.
4. For Actions, choose Upgrade snapshot. The Upgrade snapshot page appears.
5. Choose the New engine version to upgrade to.
6. Choose Save changes to upgrade the snapshot.

During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from available to upgrading, and then changes to active upon
completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to **unavailable**. You can't recover the snapshot from this state.

**Note**

If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

**AWS CLI**

To upgrade a DB snapshot to a new database engine version, use the AWS CLI `modify-db-snapshot` command.

**Parameters**

- `--db-snapshot-identifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see [Working with Amazon Resource Names (ARNs) in Amazon RDS](#).
- `--engine-version` – The engine version to upgrade the DB snapshot to.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \
    --db-snapshot-identifier my_db_snapshot \
    --engine-version new_version
```

For Windows:

```
aws rds modify-db-snapshot ^
    --db-snapshot-identifier my_db_snapshot ^
    --engine-version new_version
```

**RDS API**

To upgrade a DB snapshot to a new database engine version, call the Amazon RDS API `ModifyDBSnapshot` operation.
- **DBSnapshotIdentifier** – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see [Working with Amazon Resource Names (ARNs) in Amazon RDS](#).

- **EngineVersion** – The engine version to upgrade the DB snapshot to.
Working with read replicas for Amazon RDS for PostgreSQL

You can scale reads for your Amazon RDS for PostgreSQL DB instances by adding read replicas to the instances. As with other Amazon RDS database engines, RDS for PostgreSQL uses native replication mechanisms of PostgreSQL to keep read replicas up to date with changes on the source DB. For general information about read replicas and Amazon RDS, see Working with DB instance read replicas.

Following, you can find information specific to working with read replicas with RDS for PostgreSQL.

Logical decoding on a read replica

RDS for PostgreSQL supports logical replication from standbys with PostgreSQL 16.1. This allows you to create logical decoding from a read-only standby that reduces the load on the primary DB instance. You can achieve higher-availability for your applications that need to synchronize data across multiple systems. This feature boosts the performance of your data warehouse and data analytics.

Also, replication slots on a given standby persist the promotion of that standby to a primary. This means that in the event of a primary DB instance failover or the promotion of a standby to be the new primary, the replication slots will persist and the former standby subscribers will not be affected.

To create logical decoding on a read replica

1. **Turn on logical replication** – To create logical decoding on a standby, you must turn on logical replication on your source DB instance and its physical replica. For more information, see Read replica configuration with PostgreSQL.

   - **To turn on logical replication for a newly created RDS for PostgreSQL DB instance** – Create a new DB custom parameter group and set the static parameter rds.logical_replication to 1. Then, associate this DB parameter group with the Source DB instance and its physical read replica. For more information, see Associating a DB parameter group with a DB instance.

   - **To turn on logical replication for an existing RDS for PostgreSQL DB instance** – Modify the DB custom parameter group of the source DB instance and its physical read replica to set the static parameter rds.logical_replication to 1. For more information, see Modifying parameters in a DB parameter group.
You must reboot the DB instance to apply these parameter changes.

You can use the following query to verify the values for `wal_level` and `rds.logical_replication` on the source DB instance and its physical read replica.

```
Postgres=> SELECT name,setting FROM pg_settings WHERE name IN ('wal_level','rds.logical_replication');
```

<table>
<thead>
<tr>
<th>name</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>rds.logical_replication</td>
<td>on</td>
</tr>
<tr>
<td>wal_level</td>
<td>logical</td>
</tr>
</tbody>
</table>

(2 rows)

2. **Create a table in the source database** – Connect to the database in your source DB instance. For more information, see [Connecting to a DB instance running the PostgreSQL database engine](#).

Use the following queries to create table in your source database and to insert values:

```
Postgres=>CREATE TABLE LR_test (a int PRIMARY KEY);
CREATE TABLE

Postgres=>INSERT INTO LR_test VALUES (generate_series(1,10000));
INSERT 0 10000
```

3. **Create a publication for the source table** – Use the following query to create a publication for the table on the source DB instance.

```
Postgres=>CREATE PUBLICATION testpub FOR TABLE LR_test;
CREATE PUBLICATION
```

Use a SELECT query to verify the details of the publication that was created on both the source DB instance and the physical read replica instance.
4. **Create a subscription from logical replica instance** – Create another RDS for PostgreSQL DB instance as the logical replica instance. Make sure that VPC is setup correctly to ensure that this logical replica instance can access the physical read replica instance. For more information, see [Amazon VPC VPCs and Amazon RDS](https://aws.amazon.com/rds/postgresql/). If your source DB instance is idle, connectivity issues might occur and the primary doesn’t send the data to standby.

```sql
CREATE SUBSCRIPTION testsub CONNECTION 'host=Physical replica host name port=port dbname=source_db_name user=user password=password PUBLICATION testpub;
```

Notice: created replication slot "testsub" on publisher

CREATE SUBSCRIPTION

```sql
CREATE TABLE LR_test (a int PRIMARY KEY);
CREATE TABLE
```

Use a SELECT query to verify the details of the subscription on the logical replica instance.

```sql
SELECT oid, subname, subenabled, subslotname, subpublications FROM pg_subscription;
```

<table>
<thead>
<tr>
<th>oid</th>
<th>subname</th>
<th>subenabled</th>
<th>subslotname</th>
<th>subpublications</th>
</tr>
</thead>
<tbody>
<tr>
<td>16429</td>
<td>testsub</td>
<td>t</td>
<td>testsub</td>
<td>{testpub}</td>
</tr>
</tbody>
</table>

(1 row)

```sql
postgres=> select count(*) from LR_test;
count
-------
10000
(1 row)
```
5. **Inspect logical replication slot state** – You can only see the physical replication slot on your source DB instance.

```
Postgres=> select slot_name, slot_type, confirmed_flush_lsn from pg_replication_slots;

slot_name                                    | slot_type | confirmed_flush_lsn
---------------------------------------------+-----------+---------------------
rds_us_west_2_db_dhqfsmo5wbjqrn3m6b6ivdhu4 | physical  |
(1 row)
```

However, on your read replica instance, you can see the logical replication slot and the confirmed_flush_lsn value changes as the application actively consumes logical changes.

```
Postgres=> select slot_name, slot_type, confirmed_flush_lsn from pg_replication_slots;

slot_name | slot_type | confirmed_flush_lsn
-----------+-----------+---------------------
testsub    | logical   | 0/500002F0
(1 row)
```

```
Postgres=> select slot_name, slot_type, confirmed_flush_lsn from pg_replication_slots;

slot_name | slot_type | confirmed_flush_lsn
-----------+-----------+---------------------
testsub    | logical   | 0/5413F5C0
(1 row)
```

**Read replica limitations with PostgreSQL**

The following are limitations for PostgreSQL read replicas:
Note

A read replica for RDS for PostgreSQL Multi-AZ and Single-AZ DB instance running PostgreSQL version 12 and earlier, reboots automatically to apply the password rotation during the 60 to 90 days maintenance window.

- PostgreSQL read replicas are read-only. Although a read replica isn't a writeable DB instance, you can promote it to become a standalone RDS for PostgreSQL DB instance. However, the process isn't reversible.

- You can't create a read replica from another read replica if your RDS for PostgreSQL DB instance is running a PostgreSQL version earlier than 14.1. RDS for PostgreSQL supports cascading read replicas on RDS for PostgreSQL version 14.1 and higher releases only. For more information, see Using cascading read replicas with RDS for PostgreSQL.

- If you promote a PostgreSQL read replica, it becomes a writable DB instance. It stops receiving write-ahead log (WAL) files from a source DB instance, and it's no longer a read-only instance. You can create new read replicas from the promoted DB instance as you do for any RDS for PostgreSQL DB instance. For more information, see Promoting a read replica to be a standalone DB instance.

- If you promote a PostgreSQL read replica from within a replication chain (a series of cascading read replicas), any existing downstream read replicas continue receiving WAL files from the promoted instance automatically. For more information, see Using cascading read replicas with RDS for PostgreSQL.

- If no user transactions are running on the source DB instance, the associated PostgreSQL read replica reports a replication lag of up to five minutes. The replica lag is calculated as current_time - last_committed_transaction_timestamp, which means that when no transactions are being processed, the value of replica lag increases for a period of time until the write-ahead log (WAL) segment switches. By default RDS for PostgreSQL switches the WAL segment every 5 minutes, which results in a transaction record and a decrease in the reported lag.

- You can't turn on automated backups for PostgreSQL read replicas for RDS for PostgreSQL versions earlier than 14.1. Automated backups for read replicas are supported for RDS for PostgreSQL 14.1 and higher versions only. For RDS for PostgreSQL 13 and earlier versions, create a snapshot from a read replica if you want a backup of it.
Point-in-time recovery (PITR) isn't supported for read replicas. You can use PITR with a primary (writer) instance only, not a read replica. To learn more, see Restoring a DB instance to a specified time.

Read replica configuration with PostgreSQL

RDS for PostgreSQL uses PostgreSQL native streaming replication to create a read-only copy of a source DB instance. This read replica DB instance is an asynchronously created physical replica of the source DB instance. It's created by a special connection that transmits write ahead log (WAL) data from the source DB instance to the read replica. For more information, see Streaming Replication in the PostgreSQL documentation.

PostgreSQL asynchronously streams database changes to this secure connection as they're made on the source DB instance. You can encrypt communications from your client applications to the source DB instance or any read replicas by setting the ssl parameter to 1. For more information, see Using SSL with a PostgreSQL DB instance.

PostgreSQL uses a replication role to perform streaming replication. The role is privileged, but you can't use it to modify any data. PostgreSQL uses a single process for handling replication.

You can create a PostgreSQL read replica without affecting operations or users of the source DB instance. Amazon RDS sets the necessary parameters and permissions for you, on the source DB instance and the read replica, without affecting the service. A snapshot is taken of the source DB instance, and this snapshot is used to create the read replica. If you delete the read replica at some point in the future, no outage occurs.

You can create up to 15 read replicas from one source DB instance within the same Region. As of RDS for PostgreSQL 14.1, you can also create up to three levels of read replica in a chain (cascade) from a source DB instance. For more information, see Using cascading read replicas with RDS for PostgreSQL. In all cases, the source DB instance needs to have automated backups configured. You do this by setting the backup retention period on your DB instance to any value other than 0. For more information, see Creating a read replica.

You can create read replicas for your RDS for PostgreSQL DB instance in the same AWS Region as your source DB instance. This is known as in-Region replication. You can also create read replicas in different AWS Regions than the source DB instance. This is known as cross-Region replication. For more information about setting up cross-Region read replicas, see Creating a read replica in a different AWS Region. The various mechanisms supporting the replication process for in-Region
and cross-Region differ slightly depending on the RDS for PostgreSQL version as explained in How streaming replication works for different RDS for PostgreSQL versions.

For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, be sure to also scale the read replicas.

Amazon RDS overrides any incompatible parameters on a read replica if they prevent the read replica from starting. For example, suppose that the `max_connections` parameter value is higher on the source DB instance than on the read replica. In that case, Amazon RDS updates the parameter on the read replica to be the same value as that on the source DB instance.

RDS for PostgreSQL read replicas have access to external databases that are available through foreign data wrappers (FDWs) on the source DB instance. For example, suppose that your RDS for PostgreSQL DB instance is using the `mysql_fdw` wrapper to access data from RDS for MySQL. If so, your read replicas can also access that data. Other supported FDWs include `oracle_fdw`, `postgres_fdw`, and `tds_fdw`. For more information, see Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL.

**Using RDS for PostgreSQL read replicas with Multi-AZ configurations**

You can create a read replica from a single-AZ or Multi-AZ DB instance. You can use Multi-AZ deployments to improve the durability and availability of critical data, with a standby replica. A *standby replica* is a dedicated read replica that can assume the workload if the source DB fails over. You can't use your standby replica to serve read traffic. However, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. To learn more about Multi-AZ deployments, see Multi-AZ DB instance deployments.

If the source DB instance of a Multi-AZ deployment fails over to a standby, the associated read replicas switch to using the standby (now primary) as their replication source. The read replicas might need to restart, depending on the RDS for PostgreSQL version, as follows:

- **PostgreSQL 13 and higher versions** – Restarting isn't required. The read replicas are automatically synchronized with the new primary. However, in some cases your client application might cache Domain Name Service (DNS) details for your read replicas. If so, set the time-to-live (TTL) value to less than 30 seconds. Doing this prevents the read replica from holding on to a stale IP address (and thus, prevents it from synchronizing with the new primary). To learn more about this and other best practices, see Amazon RDS basic operational guidelines.
• **PostgreSQL 12 and all earlier versions** – The read replicas restart automatically after a failover to the standby replica because the standby (now primary) has a different IP address and a different instance name. Restarting synchronizes the read replica with the new primary.

To learn more about failover, see [Failover process for Amazon RDS](#). To learn more about how read replicas work in a Multi-AZ deployment, see [Working with DB instance read replicas](#).

To provide failover support for a read replica, you can create the read replica as a Multi-AZ DB instance so that Amazon RDS creates a standby of your replica in another Availability Zone (AZ). Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

### Using cascading read replicas with RDS for PostgreSQL

As of version 14.1, RDS for PostgreSQL supports cascading read replicas. With **cascading read replicas**, you can scale reads without adding overhead to your source RDS for PostgreSQL DB instance. Updates to the WAL log aren't sent by the source DB instance to each read replica. Instead, each read replica in a cascading series sends WAL log updates to the next read replica in the series. This reduces the burden on the source DB instance.

With cascading read replicas, your RDS for PostgreSQL DB instance sends WAL data to the first read replica in the chain. That read replica then sends WAL data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for PostgreSQL DB instance, but without the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for PostgreSQL DB instance. For example, suppose that you have an RDS for PostgreSQL 14.1 DB instance, `rpg-db-main`. You can do the following:

- Starting with `rpg-db-main`, create the first read replica in the chain, `read-replica-1`.
- Next, from `read-replica-1`, create the next read replica in the chain, `read-replica-2`.
- Finally, from `read-replica-2`, create the third read replica in the chain, `read-replica-3`.

You can't create another read replica beyond this third cascading read replica in the series for `rpg-db-main`. A complete series of instances from an RDS for PostgreSQL source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.
For cascading read replicas to work, turn on automatic backups on your RDS for PostgreSQL. Create the read replica first and then turn on automatic backups on the RDS for PostgreSQL DB instance. The process is the same as for other Amazon RDS DB engines. For more information, see [Creating a read replica](#).

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload off of your `rpg-db-main` DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote `read-replica-2`. The chain is affected as follows:

- Promoting `read-replica-2` removes it from the replication chain.
  - It is now a full read/write DB instance.
  - It continues replicating to `read-replica-3`, just as it was doing before promotion.
- Your `rpg-db-main` continues replicating to `read-replica-1`.

For more information about promoting read replicas, see [Promoting a read replica to be a standalone DB instance](#).

### Note

For cascading read replicas, RDS for PostgreSQL supports 15 read replicas for each source DB instance at first level of replication, and 5 read replicas for each source DB instance at the second and third level of replication.

---

## How streaming replication works for different RDS for PostgreSQL versions

As discussed in [Read replica configuration with PostgreSQL](#), RDS for PostgreSQL uses PostgreSQL's native streaming replication protocol to send WAL data from the source DB instance. It sends source WAL data to read replicas for both in-Region and cross-Region read replicas. With version 9.4, PostgreSQL introduced physical replication slots as a supporting mechanism for the replication process.

A *physical replication slot* prevents a source DB instance from removing WAL data before it's consumed by all read replicas. Each read replica has its own physical slot on the source DB instance.
The slot keeps track of the oldest WAL (by logical sequence number, LSN) that might be needed by the replica. After all slots and DB connections have progressed beyond a given WAL (LSN), that LSN becomes a candidate for removal at the next checkpoint.

Amazon RDS uses Amazon S3 to archive WAL data. For in-Region read replicas, you can use this archived data to recover the read replica when necessary. An example of when you might do so is if the connection between source DB and read replica is interrupted for any reason.

In the following table, you can find a summary of differences between PostgreSQL versions and the supporting mechanisms for in-Region and cross-Region used by RDS for PostgreSQL.

<table>
<thead>
<tr>
<th>In-Region</th>
<th>Cross-Region</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PostgreSQL 14.1 and higher versions</strong></td>
<td><strong>PostgreSQL 14.1 and higher versions</strong></td>
</tr>
<tr>
<td>• Replication slots</td>
<td>• Replication slots</td>
</tr>
<tr>
<td>• Amazon S3 archive</td>
<td></td>
</tr>
<tr>
<td><strong>PostgreSQL 13 and lower versions</strong></td>
<td><strong>PostgreSQL 13 and lower versions</strong></td>
</tr>
<tr>
<td>• Amazon S3 archive</td>
<td>• Replication slots</td>
</tr>
</tbody>
</table>

For more information, see [Monitoring and tuning the replication process](#).  

**Understanding the parameters that control PostgreSQL replication**

The following parameters affect the replication process and determine how well read replicas stay up to date with the source DB instance:

**max_wal_senders**

The `max_wal_senders` parameter specifies the maximum number of connections that the source DB instance can support at the same time over the streaming replication protocol. The default for RDS for PostgreSQL 13 and higher releases is 20. This parameter should be set to slightly higher than the actual number of read replicas. If this parameter is set too low for the number of read replicas, replication stops.

For more information, see [max_wal_senders](#) in the PostgreSQL documentation.
wal_keep_segments

The `wal_keep_segments` parameter specifies the number of write-ahead log (WAL) files that the source DB instance keeps in the `pg_wal` directory. The default setting is 32.

If `wal_keep_segments` isn't set to a large enough value for your deployment, a read replica can fall so far behind that streaming replication stops. If that happens, Amazon RDS generates a replication error and begins recovery on the read replica. It does so by replaying the source DB instance's archived WAL data from Amazon S3. This recovery process continues until the read replica has caught up enough to continue streaming replication. You can see this process in action as captured by the PostgreSQL log in Example: How a read replica recovers from replication interruptions.

Note

In PostgreSQL version 13, the `wal_keep_segments` parameter is named `wal_keep_size`. It serves the same purpose as `wal_keep_segments`, but its default value is in megabytes (MB) (2048 MB) rather than the number of files. For more information, see `wal_keep_segments` and `wal_keep_size` in the PostgreSQL documentation.

max_slot_wal_keep_size

The `max_slot_wal_keep_size` parameter controls the quantity of WAL data that the RDS for PostgreSQL DB instance retains in the `pg_wal` directory to serve slots. This parameter is used for configurations that use replication slots. The default value for this parameter is -1, meaning that there's no limit to how much WAL data is kept on the source DB instance. For information about monitoring your replication slots, see Monitoring replication slots for your RDS for PostgreSQL DB instance.

For more information about this parameter, see `max_slot_wal_keep_size` in the PostgreSQL documentation.

Whenever the stream that provides WAL data to a read replica is interrupted, PostgreSQL switches into recovery mode. It restores the read replica by using archived WAL data from Amazon S3 or by using the WAL data associated with the replication slot. When this process is complete, PostgreSQL re-establishes streaming replication.
Example: How a read replica recovers from replication interruptions

In the following example, you find the log details that demonstrate the recovery process for a read replica. The example is from an RDS for PostgreSQL DB instance running PostgreSQL version 12.9 in the same AWS Region as the source DB, so replication slots aren't used. The recovery process is the same for other RDS for PostgreSQL DB instances running PostgreSQL earlier than version 14.1 with in-Region read replicas.

When the read replica lost contact with the source DB instance, Amazon RDS records the issue in the log as FATAL: could not receive data from WAL stream message, along with the ERROR: requested WAL segment ... has already been removed. As shown in the bold line, Amazon RDS recovers the replica by replaying an archived WAL file.

```
2014-11-07 19:01:10 UTC::@:[23180]:DEBUG: switched WAL source from archive to stream after failure
2014-11-07 19:01:10 UTC::@:[11575]:LOG: started streaming WAL from primary at 1A/D3000000 on timeline 1
2014-11-07 19:01:10 UTC::@:[11575]:FATAL: could not receive data from WAL stream:
ERROR: requested WAL segment 00000010000001A0000000D3 has already been removed
2014-11-07 19:01:10 UTC::@:[23180]:DEBUG: could not restore file "00000002.history" from archive: return code 0
2014-11-07 19:01:15 UTC::@:[23180]:DEBUG: switched WAL source from stream to archive after failure recovering 000000010000001A000000D3
2014-11-07 19:01:16 UTC::@:[23180]:LOG: restored log file "00000010000001A000000D3" from archive
```

When Amazon RDS replays enough archived WAL data on the replica to catch up, streaming to the read replica begins again. When streaming resumes, Amazon RDS writes an entry to the log file similar to the following.

```
2014-11-07 19:41:36 UTC::@:[24714]:LOG:started streaming WAL from primary at 1B/B6000000 on timeline 1
```

Setting the parameters that control shared memory

The parameters you set determine the size of shared memory for tracking transaction IDs, locks, and prepared transactions. The shared memory structure of a standby instance must be equal or greater than that of a primary instance. This ensures that the former doesn't run out of shared memory during recovery. If the parameter values on the replica are less than the parameter values
on the primary, Amazon RDS will automatically adjust the replica parameters and restart the engine.

The parameters affected are:

- `max_connections`
- `max_worker_processes`
- `max_wal_senders`
- `max_prepared_transactions`
- `max_locks_per_transaction`

To avoid RDS reboots of replicas due to insufficient memory, we recommend applying the parameter changes as a rolling reboot to each replica. You must apply the following rules, when you set the parameters:

- **Increasing the parameter values:**
  - You should always increase the parameter values of all the read replicas first, and perform a rolling reboot of all replicas. Then, apply the parameter changes on the primary instance and reboot.

- **Decreasing the parameter values:**
  - You should first decrease the parameter values of the primary instance and perform a reboot. Then, apply the parameter changes to all the associated read replicas and perform a rolling reboot.

**Monitoring and tuning the replication process**

We strongly recommend that you routinely monitor your RDS for PostgreSQL DB instance and read replicas. You need to ensure that your read replicas are keeping up with changes on the source DB instance. Amazon RDS transparently recovers your read replicas when interruptions to the replication process occur. However, it’s best to avoid needing to recover at all. Recovering using replication slots is faster than using the Amazon S3 archive, but any recovery process can affect read performance.

To determine how well your read replicas are keeping up with the source DB instance, you can do the following:
• **Check the amount of ReplicaLag between source DB instance and replicas.** *Replica lag* is the amount of time, in seconds, that a read replica lags behind its source DB instance. This metric reports the result of the following query.

```
SELECT extract(epoch from now() - pg_last_xact_replay_timestamp()) AS "ReplicaLag";
```

Replica lag is an indication of how well a read replica is keeping up with the source DB instance. It's the amount of latency between the source DB instance and a specific read instance. A high value for replica lag can indicate a mismatch between the DB instance classes or storage types (or both) used by the source DB instance and its read replicas. The DB instance class and storage types for DB source instance and all read replicas should be the same.

Replica lag can also be the result of intermittent connection issues. You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric. To learn more about ReplicaLag and other metrics for Amazon RDS, see [Amazon CloudWatch metrics for Amazon RDS](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/RDS-metrics.html).

• **Check the PostgreSQL log for information you can use to adjust your settings.** At every checkpoint, the PostgreSQL log captures the number of recycled transaction log files, as shown in the following example.

```
2014-11-07 19:59:35 UTC::@:[26820]:LOG: checkpoint complete: wrote 376 buffers (0.2%);
0 transaction log file(s) added, 0 removed, 1 recycled; write=35.681 s, sync=0.013 s, total=35.703 s;
sync files=10, longest=0.013 s, average=0.001 s
```

You can use this information to figure out how many transaction files are being recycled in a given time period. You can then change the setting for `wal_keep_segments` if necessary. For example, suppose that the PostgreSQL log at checkpoint complete shows 35 recycled for a 5-minute interval. In this case, the `wal_keep_segments` default value of 32 isn't sufficient to keep pace with the streaming activity, so you should increase the value of this parameter.

• **Use Amazon CloudWatch to monitor metrics that can predict replication issues.** Rather than analyzing the PostgreSQL log directly, you can use Amazon CloudWatch to check metrics that have been collected. For example, you can check the value of the `TransactionLogsGeneration` metric to see how much WAL data is being generated by the source DB instance. In some cases, the workload on your DB instance might generate a large amount of WAL data. If so, you might need to change the DB instance class for your source DB...
instance and read replicas. Using an instance class with high (10 Gbps) network performance can reduce replica lag.

### Monitoring replication slots for your RDS for PostgreSQL DB instance

All versions of RDS for PostgreSQL use replication slots for cross-Region read replicas. RDS for PostgreSQL 14.1 and higher versions use replication slots for in-Region read replicas. In-region read replicas also use Amazon S3 to archive WAL data. In other words, if your DB instance and read replicas are running PostgreSQL 14.1 or higher, replication slots and Amazon S3 archives are both available for recovering the read replica. Recovering a read replica using its replication slot is faster than recovering from Amazon S3 archive. So, we recommend that you monitor the replication slots and related metrics.

You can view the replication slots on your RDS for PostgreSQL DB instances by querying the `pg_replication_slots` view, as follows.

```
postgres=> SELECT * FROM pg_replication_slots;
```

| slot_name                | plugin | slot_type | datoid | database | temporary | active | active_pid | xmin | catalog_xmin | restart_lsn | confirmed_flush_lsn | wal_status | safe_wal_size | two_phase | res
|--------------------------|--------|-----------|--------|----------|-----------|--------|------------|------|--------------|-------------|---------------------|------------|---------------|-----------|-----
| rds_us_west_1_db_555555555 |        | physical  |        |          | f         | t      | 13194 |      |              | 23/D80000060 |                     | reserved   |               |           | 1   |

(1 row)

The `wal_status` of `reserved` value means that the amount of WAL data held by the slot is within the bounds of the `max_wal_size` parameter. In other words, the replication slot is properly sized. Other possible status values are as follows:

- **extended** – The slot exceeds the `max_wal_size` setting, but the WAL data is retained.
- **unreserved** – The slot no longer has the all required WAL data. Some of it will be removed at the next checkpoint.
- **lost** – Some required WAL data has been removed. The slot is no longer usable.
The unreserved and lost states of the wal_status are seen only when max_slot_wal_keep_size is non-negative.

The pg_replication_slots view shows you the current state of your replication slots. To assess the performance of your replication slots, you can use Amazon CloudWatch and monitor the following metrics:

- **OldestReplicationSlotLag** – Lists the slot that has the most lag, that is the one that's furthest behind the primary. This lag can be associated with the read replica but also the connection.

- **TransactionLogsDiskUsage** – Shows how much storage is being used for WAL data. When a read replica lags significantly, the value of this metric can increase substantially.

To learn more about using Amazon CloudWatch and its metrics for RDS for PostgreSQL, see [Monitoring Amazon RDS metrics with Amazon CloudWatch](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_MonitoringCloudWatch.html). For more information about monitoring streaming replication on your RDS for PostgreSQL DB instances, see [Best practices for Amazon RDS PostgreSQL replication](https://aws.amazon.com/blogs/database/best-practices-for-amazon-rds-postgresql-replication/) on the AWS Database Blog.
Improving query performance for RDS for PostgreSQL with Amazon RDS Optimized Reads

You can achieve faster query processing for RDS for PostgreSQL with Amazon RDS Optimized Reads. An RDS for PostgreSQL DB instance or Multi-AZ DB cluster that uses RDS Optimized Reads can achieve up to 50% faster query processing compared to one that doesn't use it.

Topics

- Overview of RDS Optimized Reads in PostgreSQL
- Use cases for RDS Optimized Reads
- Best practices for RDS Optimized Reads
- Using RDS Optimized Reads
- Monitoring DB instances that use RDS Optimized Reads
- Limitations for RDS Optimized Reads in PostgreSQL

Overview of RDS Optimized Reads in PostgreSQL

Optimized Reads is available by default on RDS for PostgreSQL versions 15.2 and higher, 14.7 and higher, and 13.10 and higher.

When you use an RDS for PostgreSQL DB instance or Multi-AZ DB cluster that has RDS Optimized Reads turned on, it achieves up to 50% faster query performance using the local Non-Volatile Memory Express (NVMe) based solid state drive (SSD) block-level storage. You can achieve faster query processing by placing the temporary tables that are generated by PostgreSQL on the local storage, which reduces the traffic to Elastic Block Storage (EBS) over the network.

In PostgreSQL, temporary objects are assigned to a temporary namespace that drops automatically at the end of the session. The temporary namespace while dropping removes any objects that are session-dependent, including schema-qualified objects, such as tables, functions, operators, or even extensions.

In RDS for PostgreSQL, the temp_tablespaces parameter is configured for this temporary work area where the temporary objects are stored.

The following queries return the name of the tablespace and its location.
postgres=> show temp_tablespaces;
  temp_tablespaces         
---------------------------
   rds_temp_tablespace      
(1 row)

The rds_temp_tablespace is a tablespace configured by RDS that points to the NVMe local storage. You can always switch back to Amazon EBS storage by modifying this parameter in the Parameter group using the AWS Management Console to point to any tablespace other than rds_temp_tablespace. For more information, see Modifying parameters in a DB parameter group. You can also use the SET command to modify the value of the temp_tablespaces parameter to pg_default at the session level using SET command. Modifying the parameter redirects the temporary work area to Amazon EBS. Switching back to Amazon EBS helps when the local storage for your RDS instance or cluster isn't sufficient to perform a specific SQL operation.

postgres=> SET temp_tablespaces TO 'pg_default';
   SET

postgres=> show temp_tablespaces;
  temp_tablespaces         
---------------------------
   pg_default              

Use cases for RDS Optimized Reads

The following are some use cases that can benefit from Optimized Reads:

- Analytical queries that include Common Table Expressions (CTEs), derived tables, and grouping operations.
- Read replicas that handle the unoptimized queries for an application.
- On-demand or dynamic reporting queries with complex operations such as GROUP BY and ORDER BY that can't always use appropriate indexes.
- Other workloads that use internal temporary tables.
- CREATE INDEX or REINDEX operations for sorting.
Best practices for RDS Optimized Reads

Use the following best practices for RDS Optimized Reads:

- Add retry logic for read-only queries in case they fail because the instance store is full during the execution.

- Monitor the storage space available on the instance store with the CloudWatch metric `FreeLocalStorage`. If the instance store is reaching its limit because of the workload on the DB instance or Multi-AZ DB cluster, modify it to use a larger DB instance class.

Using RDS Optimized Reads

When you provision an RDS for PostgreSQL DB instance with one of the NVMe based DB instance classes in a Single-AZ DB instance deployment, Multi-AZ DB instance deployment, or Multi-AZ DB cluster deployment, the DB instance automatically uses RDS Optimized Reads.

For more information about Multi-AZ deployment, see Configuring and managing a Multi-AZ deployment.

To turn on RDS Optimized Reads, do one of the following:

- Create an RDS for PostgreSQL DB instance or Multi-AZ DB cluster using one of the NVMe based DB instance classes. For more information, see Creating an Amazon RDS DB instance.

- Modify an existing RDS for PostgreSQL DB instance or Multi-AZ DB cluster to use one of the NVMe based DB instance classes. For more information, see Modifying an Amazon RDS DB instance.

RDS Optimized Reads is available in all AWS Regions where one or more of the DB instance classes with local NVMe SSD storage are supported. For more information, see DB instance classes.

To switch back to a non-optimized reads RDS instance, modify the DB instance class of your RDS instance or cluster to the similar instance class that only supports EBS storage for your database workloads. For example, if the current DB instance class is db.r6gd.4xlarge, choose db.r6g.4xlarge to switch back. For more information, see Modifying an Amazon RDS DB instance.
Monitoring DB instances that use RDS Optimized Reads

You can monitor DB instances that use RDS Optimized Reads using the following CloudWatch metrics:

- FreeLocalStorage
- ReadIOPSLocalStorage
- ReadLatencyLocalStorage
- ReadThroughputLocalStorage
- WriteIOPSLocalStorage
- WriteLatencyLocalStorage
- WriteThroughputLocalStorage

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS.

To monitor current usage of your local storage, log in to your database using the following query:

```
SELECT spcname AS "Name",
    pg_catalog.pg_size_pretty(pg_catalog.pg_tablespace_size(oid)) AS "size"
FROM pg_catalog.pg_tablespace
WHERE spcname IN ('rds_temp_tablespace');
```

For more information about the temporary files and their usage, see Managing temporary files with PostgreSQL.

Limitations for RDS Optimized Reads in PostgreSQL

The following limitation apply to RDS Optimized Reads in PostgreSQL:

- Transactions can fail when the instance store is full.
Suppose that you have an existing PostgreSQL deployment that you want to move to Amazon RDS. The complexity of your task depends on the size of your database and the types of database objects that you're transferring. For example, consider a database that contains datasets on the order of gigabytes, along with stored procedures and triggers. Such a database is going to be more complicated than a simple database with only a few megabytes of test data and no triggers or stored procedures.

We recommend that you use native PostgreSQL database migration tools under the following conditions:

- You have a homogeneous migration, where you are migrating from a database with the same database engine as the target database.
- You are migrating an entire database.
- The native tools allow you to migrate your system with minimal downtime.

In most other cases, performing a database migration using AWS Database Migration Service (AWS DMS) is the best approach. AWS DMS can migrate databases without downtime and, for many database engines, continue ongoing replication until you are ready to switch over to the target database. You can migrate to either the same database engine or a different database engine using AWS DMS. If you are migrating to a different database engine than your source database, you can use the AWS Schema Conversion Tool (AWS SCT). You use AWS SCT to migrate schema objects that are not migrated by AWS DMS. For more information about AWS DMS, see What is AWS Database Migration Service?

Modify your DB parameter group to include the following settings for your import only. You should test the parameter settings to find the most efficient settings for your DB instance size. You also need to revert back to production values for these parameters after your import completes.

Modify your DB instance settings to the following:

- Disable DB instance backups (set backup_retention to 0).
- Disable Multi-AZ.

Modify your DB parameter group to include the following settings. You should only use these settings when importing data. You should test the parameter settings to find the most efficient
settings for your DB instance size. You also need to revert back to production values for these parameters after your import completes.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Recommended value when importing</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maintenance_work_mem</td>
<td>524288, 1048576, 2097152, or 4194304 (in KB). These settings are comparable to 512 MB, 1 GB, 2 GB, and 4 GB.</td>
<td>The value for this setting depends on the size of your host. This parameter is used during CREATE INDEX statements and each parallel command can use this much memory. Calculate the best value so that you don't set this value so high that you run out of memory.</td>
</tr>
<tr>
<td>max_wal_size</td>
<td>256 (for version 9.6), 4096 (for versions 10 and higher)</td>
<td>Maximum size to let the WAL grow during automatic checkpoints. Increasing this parameter can increase the amount of time needed for crash recovery. This parameter replaces checkpoint_segments for PostgreSQL 9.6 and later. For PostgreSQL version 9.6, this value is in 16 MB units. For later versions, the value is in 1 MB units. For example, in version 9.6, 128 means 128 chunks that are each 16 MB in size. In version 12.4, 2048 means 2048 chunks that are each 1 MB in size.</td>
</tr>
<tr>
<td>checkpoint_timeout</td>
<td>1800</td>
<td>The value for this setting allows for less frequent WAL rotation.</td>
</tr>
<tr>
<td>synchronous_commit</td>
<td>Off</td>
<td>Disable this setting to speed up writes. Turning this parameter off can increase the risk of data loss in the event of a server crash (do not turn off FSYNC).</td>
</tr>
<tr>
<td>wal_buffers</td>
<td>8192</td>
<td>This is value is in 8 KB units. This again helps your WAL generation speed</td>
</tr>

<td>Recommended value when importing</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>autovacuum</td>
<td>0</td>
<td>Disable the PostgreSQL auto vacuum parameter while you are loading data so that it doesn't use resources</td>
</tr>
</tbody>
</table>

Use the `pg_dump -Fc` (compressed) or `pg_restore -j` (parallel) commands with these settings.

**Note**
The PostgreSQL command `pg_dumpall` requires super_user permissions that are not granted when you create a DB instance, so it cannot be used for importing data.

**Topics**

- Importing a PostgreSQL database from an Amazon EC2 instance
- Using the `\copy` command to import data to a table on a PostgreSQL DB instance
- Importing data from Amazon S3 into an RDS for PostgreSQL DB instance
- Transporting PostgreSQL databases between DB instances

**Importing a PostgreSQL database from an Amazon EC2 instance**

If you have data in a PostgreSQL server on an Amazon EC2 instance and want to move it to a PostgreSQL DB instance, you can use the following process. The following list shows the steps to take. Each step is discussed in more detail in the following sections.

1. Create a file using `pg_dump` that contains the data to be loaded
2. Create the target DB instance
3. Use `psql` to create the database on the DB instance and load the data
4. Create a DB snapshot of the DB instance
Step 1: Create a file using `pg_dump` that contains the data to load

The `pg_dump` utility uses the COPY command to create a schema and data dump of a PostgreSQL database. The dump script generated by `pg_dump` loads data into a database with the same name and recreates the tables, indexes, and foreign keys. You can use the `pg_restore` command and the `-d` parameter to restore the data to a database with a different name.

Before you create the data dump, you should query the tables to be dumped to get a row count so you can confirm the count on the target DB instance.

The following command creates a dump file called `mydb2dump.sql` for a database called `mydb2`.

```plaintext
prompt>pg_dump dbname=mydb2 -f mydb2dump.sql
```

Step 2: Create the target DB instance

Create the target PostgreSQL DB instance using either the Amazon RDS console, AWS CLI, or API. Create the instance with the backup retention setting set to 0 and disable Multi-AZ. Doing so allows faster data import. You must create a database on the instance before you can dump the data. The database can have the same name as the database that is contained the dumped data. Alternatively, you can create a database with a different name. In this case, you use the `pg_restore` command and the `-d` parameter to restore the data into the newly named database.

For example, the following commands can be used to dump, restore, and rename a database.

```plaintext
pg_dump -Fc -v -h [endpoint of instance] -U [master username] [database]
> [database].dump
createdb [new database name]
pg_restore -v -h [endpoint of instance] -U [master username] -d [new database name] [database].dump
```

Step 3: Use `psql` to create the database on the DB instance and load data

You can use the same connection you used to run the `pg_dump` command to connect to the target DB instance and recreate the database. Using `psql`, you can use the master user name and master password to create the database on the DB instance.

The following example uses `psql` and a dump file named `mydb2dump.sql` to create a database called `mydb2` on a PostgreSQL DB instance called `mypginstance`.

```
```

```plaintext
```

---

Importing a PostgreSQL database from an Amazon EC2 instance
For Linux, macOS, or Unix:

```bash
psql \
  -f mydb2dump.sql \n  --host mypginstance.555555555555.aws-region.rds.amazonaws.com \n  --port 8199 \n  --username myawsuser \n  --password password \n  --dbname mydb2
```

For Windows:

```bash
psql ^
  -f mydb2dump.sql ^
  --host mypginstance.555555555555.aws-region.rds.amazonaws.com ^
  --port 8199 ^
  --username myawsuser ^
  --password password ^
  --dbname mydb2
```

⚠️ **Note**

Specify a password other than the prompt shown here as a security best practice.

### Step 4: Create a DB snapshot of the DB instance

Once you have verified that the data was loaded into your DB instance, we recommend that you create a DB snapshot of the target PostgreSQL DB instance. DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap. You can also use such a snapshot to seed new DB instances. For information about creating a DB snapshot, see [Creating a DB snapshot for a Single-AZ DB instance](#).

### Using the `\copy` command to import data to a table on a PostgreSQL DB instance

The PostgreSQL `\copy` command is a meta-command available from the `psql` interactive client tool. You can use `\copy` to import data into a table on your RDS for PostgreSQL DB instance. To
use the `\copy` command, you need to first create the table structure on the target DB instance so that `\copy` has a destination for the data being copied.

You can use `\copy` to load data from a comma-separated values (CSV) file, such as one that's been exported and saved to your client workstation.

To import the CSV data to the target RDS for PostgreSQL DB instance, first connect to the target DB instance using `psql`.

```bash
psql --host=\textit{db-instance.111122223333.aws-region}.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=target-db
```

You then run `\copy` command with the following parameters to identify the target for the data and its format.

- **target_table** – The name of the table that should receive the data being copied from the CSV file.
- **column_list** – Column specifications for the table.
- **'filename'** – The complete path to the CSV file on your local workstation.

```sql
\copy \textit{target_table} from '/\textit{path/to/local/filename.csv}' WITH DELIMITER ',' CSV;
```

If your CSV file has column heading information, you can use this version of the command and parameters.

```sql
\copy \textit{target_table} (column-1, column-2, column-3, ...) from '/\textit{path/to/local/filename.csv}' WITH DELIMITER ',' CSV HEADER;
```

If the `\copy` command fails, PostgreSQL outputs error messages.

Creating a new DB instance in the Database Preview environment using `psql` command with the `\copy` meta-command as shown in the following examples. This example uses `source-table` as the source table name, `source-table.csv` as the .csv file, and `target-db` as the target database:

For Linux, macOS, or Unix:

```bash
$psql target-db \
    -U <admin user> \
```
You can import data that's been stored using Amazon Simple Storage Service into a table on an RDS for PostgreSQL DB instance. To do this, you first install the RDS for PostgreSQL aws_s3 extension. This extension provides the functions that you use to import data from an Amazon S3 bucket. A bucket is an Amazon S3 container for objects and files. The data can be in a comma-separate value (CSV) file, a text file, or a compressed (gzip) file. Following, you can learn how to install the extension and how to import data from Amazon S3 into a table.

Your database must be running PostgreSQL version 10.7 or higher to import from Amazon S3 into RDS for PostgreSQL.

If you don't have data stored on Amazon S3, you need to first create a bucket and store the data. For more information, see the following topics in the Amazon Simple Storage Service User Guide.

- Create a bucket
- Add an object to a bucket

Cross-account import from Amazon S3 is supported. For more information, see Granting cross-account permissions in the Amazon Simple Storage Service User Guide.

You can use the customer managed key for encryption while importing data from S3. For more information, see KMS keys stored in AWS KMS in the Amazon Simple Storage Service User Guide.
Note

Importing data from Amazon S3 isn't supported for Aurora Serverless v1. It is supported for Aurora Serverless v2.

Topics

- Installing the aws_s3 extension
- Overview of importing data from Amazon S3 data
- Setting up access to an Amazon S3 bucket
- Importing data from Amazon S3 to your RDS for PostgreSQL DB instance
- Function reference

Installing the aws_s3 extension

Before you can use Amazon S3 with your RDS for PostgreSQL DB instance, you need to install the aws_s3 extension. This extension provides functions for importing data from an Amazon S3. It also provides functions for exporting data from an RDS for PostgreSQL DB instance to an Amazon S3 bucket. For more information, see Exporting data from an RDS for PostgreSQL DB instance to Amazon S3. The aws_s3 extension depends on some of the helper functions in the aws_commons extension, which is installed automatically when needed.

To install the aws_s3 extension

1. Use psql (or pgAdmin) to connect to the RDS for PostgreSQL DB instance as a user that has rds_superuser privileges. If you kept the default name during the setup process, you connect as postgres.

   ```bash
   psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. To install the extension, run the following command.

   ```sql
   postgres=> CREATE EXTENSION aws_s3 CASCADE;
   NOTICE: installing required extension "aws_commons"
   CREATE EXTENSION
   ```

3. To verify that the extension is installed, you can use the psql \dx metacommand.
The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

**Overview of importing data from Amazon S3 data**

**To import S3 data into Amazon RDS**

First, gather the details that you need to supply to the function. These include the name of the table on your RDS for PostgreSQL DB instance, and the bucket name, file path, file type, and AWS Region where the Amazon S3 data is stored. For more information, see [View an object](https://console.aws.amazon.com/s3/) in the *Amazon Simple Storage Service User Guide*.

**Note**

Multi part data import from Amazon S3 isn't currently supported.

1. Get the name of the table into which the `aws_s3.table_import_from_s3` function is to import the data. As an example, the following command creates a table `t1` that can be used in later steps.

   ```sql
   postgres=> CREATE TABLE t1
          (col1 varchar(80),
           col2 varchar(80),
           col3 varchar(80));
   ```

2. Get the details about the Amazon S3 bucket and the data to import. To do this, open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/), and choose **Buckets**. Find the bucket containing your data in the list. Choose the bucket, open its Object overview page, and then choose Properties.
Make a note of the bucket name, path, the AWS Region, and file type. You need the Amazon Resource Name (ARN) later, to set up access to Amazon S3 through an IAM role. For more more information, see Setting up access to an Amazon S3 bucket. The image following shows an example.

3. You can verify the path to the data on the Amazon S3 bucket by using the AWS CLI command `aws s3 cp`. If the information is correct, this command downloads a copy of the Amazon S3 file.

```
aws s3 cp s3://sample_s3_bucket/sample_file_path ./
```

4. Set up permissions on your RDS for PostgreSQL DB instance to allow access to the file on the Amazon S3 bucket. To do so, you use either an AWS Identity and Access Management (IAM) role or security credentials. For more information, see Setting up access to an Amazon S3 bucket.

5. Supply the path and other Amazon S3 object details gathered (see step 2) to the `create_s3_uri` function to construct an Amazon S3 URI object. To learn more about this function, see `aws_commons.create_s3_uri`. The following is an example of constructing this object during a psql session.
In the next step, you pass this object (aws_commons._s3_uri_1) to the aws_s3.table_import_from_s3 function to import the data to the table.

6. Invoke the aws_s3.table_import_from_s3 function to import the data from Amazon S3 into your table. For reference information, see aws_s3.table_import_from_s3. For examples, see Importing data from Amazon S3 to your RDS for PostgreSQL DB instance.

Setting up access to an Amazon S3 bucket

To import data from an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket containing the file. You provide access to an Amazon S3 bucket in one of two ways, as described in the following topics.

Topics

- Using an IAM role to access an Amazon S3 bucket
- Using security credentials to access an Amazon S3 bucket
- Troubleshooting access to Amazon S3

Using an IAM role to access an Amazon S3 bucket

Before you load data from an Amazon S3 file, give your RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket the file is in. This way, you don't have to manage additional credential information or provide it in the aws_s3.table_import_from_s3 function call.

To do this, create an IAM policy that provides access to the Amazon S3 bucket. Create an IAM role and attach the policy to the role. Then assign the IAM role to your DB instance.

Note

You can't associate an IAM role with an Aurora Serverless v1 DB cluster, so the following steps don't apply.
To give an RDS for PostgreSQL DB instance access to Amazon S3 through an IAM role

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your RDS for PostgreSQL DB instance to access Amazon S3.

   Include in the policy the following required actions to allow the transfer of files from an Amazon S3 bucket to Amazon RDS:
   
   • s3:GetObject
   • s3:ListBucket

   Include in the policy the following resources to identify the Amazon S3 bucket and objects in the bucket. This shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

   • arn:aws:s3:::your-s3-bucket
   • arn:aws:s3:::your-s3-bucket/*

   For more information on creating an IAM policy for RDS for PostgreSQL, see Creating and using an IAM policy for IAM database access. See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

   The following AWS CLI command creates an IAM policy named rds-s3-import-policy with these options. It grants access to a bucket named your-s3-bucket.

   ```
   Note
   Make a note of the Amazon Resource Name (ARN) of the policy returned by this command. You need the ARN in a subsequent step when you attach the policy to an IAM role.
   ```

   Example

   For Linux, macOS, or Unix:

   ```
   aws iam create-policy
   ```
--policy-name rds-s3-import-policy \
--policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "s3import",
            "Action": ["s3:GetObject", "s3:ListBucket"],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:s3:::your-s3-bucket",
                "arn:aws:s3:::your-s3-bucket/*"
            ]
        }
    ]
}
}'

For Windows:

aws iam create-policy ^
--policy-name rds-s3-import-policy ^
--policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "s3import",
            "Action": ["s3:GetObject", "s3:ListBucket"],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:s3:::your-s3-bucket",
                "arn:aws:s3:::your-s3-bucket/*"
            ]
        }
    ]
}
}'

2. Create an IAM role.
You do this so Amazon RDS can assume this IAM role to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-import-role`.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam create-role \
  --role-name rds-s3-import-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": "111122223333",
          }
```
For Windows:

```bash
aws iam create-role ^
   --role-name rds-s3-import-role ^
   --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "Service": "rds.amazonaws.com"
         },
         "Action": "sts:AssumeRole",
         "Condition": {
           "StringEquals": {
             "aws:SourceAccount": "111122223333",
           }
         }
       }
     ]
   }'
```

3. Attach the IAM policy that you created to the IAM role that you created.

   The following AWS CLI command attaches the policy created in the previous step to the role named rds-s3-import-role Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

   **Example**

   For Linux, macOS, or Unix:

   ```bash
   aws iam attach-role-policy \
       --policy-arn your-policy-arn \
       --role-name rds-s3-import-role
   ```
For Windows:

```
aws iam attach-role-policy ^
   --policy-arn your-policy-arn ^
   --role-name rds-s3-import-role
```

4. Add the IAM role to the DB instance.

   You do so by using the AWS Management Console or AWS CLI, as described following.

**Console**

To add an IAM role for a PostgreSQL DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the PostgreSQL DB instance name to display its details.
3. On the Connectivity & security tab, in the Manage IAM roles section, choose the role to add under Add IAM roles to this instance.
4. Under Feature, choose s3Import.
5. Choose Add role.

**AWS CLI**

To add an IAM role for a PostgreSQL DB instance using the CLI

- Use the following command to add the role to the PostgreSQL DB instance named my-db-instance. Replace your-role-arn with the role ARN that you noted in a previous step. Use s3Import for the value of the --feature-name option.

  Example

  For Linux, macOS, or Unix:

  ```
  aws rds add-role-to-db-instance \
   --db-instance-identifier my-db-instance \
   --feature-name s3Import \
   --role-arn your-role-arn \
  ```
For Windows:

```bash
aws rds add-role-to-db-instance ^
  --db-instance-identifier my-db-instance ^
  --feature-name s3Import ^
  --role-arn your-role-arn ^
  --region your-region
```

**RDS API**

To add an IAM role for a PostgreSQL DB instance using the Amazon RDS API, call the `AddRoleToDBInstance` operation.

**Using security credentials to access an Amazon S3 bucket**

If you prefer, you can use security credentials to provide access to an Amazon S3 bucket instead of providing access with an IAM role. You do so by specifying the `credentials` parameter in the `aws_s3.table_import_from_s3` function call.

The `credentials` parameter is a structure of type `aws_commons._aws_credentials_1`, which contains AWS credentials. Use the `aws_commons.create_aws_credentials` function to set the access key and secret key in an `aws_commons._aws_credentials_1` structure, as shown following.

```sql
postgres=> SELECT aws_commons.create_aws_credentials(
    'sample_access_key', 'sample_secret_key', '')
  AS creds \gset
```

After creating the `aws_commons._aws_credentials_1` structure, use the `aws_s3.table_import_from_s3` function with the `credentials` parameter to import the data, as shown following.

```sql
postgres=> SELECT aws_s3.table_import_from_s3(
    't', '', '(format csv)',
    :'s3_uri',
    :'creds'
);
Or you can include the `aws_commons.create_aws_credentials` function call inline within the `aws_s3.table_import_from_s3` function call.

```sql
postgres=> SELECT aws_s3.table_import_from_s3(
    't', '', '(format csv)',
    's3_uri',
    aws_commons.create_aws_credentials('sample_access_key', 'sample_secret_key', '')
);
```

**Troubleshooting access to Amazon S3**

If you encounter connection problems when attempting to import data from Amazon S3, see the following for recommendations:

- [Troubleshooting Amazon RDS identity and access](#)
- [Troubleshooting Amazon S3](#) in the *Amazon Simple Storage Service User Guide*
- [Troubleshooting Amazon S3 and IAM](#) in the *IAM User Guide*

**Importing data from Amazon S3 to your RDS for PostgreSQL DB instance**

You import data from your Amazon S3 bucket by using the `table_import_from_s3` function of the `aws_s3` extension. For reference information, see `aws_s3.table_import_from_s3`.

**Note**

The following examples use the IAM role method to allow access to the Amazon S3 bucket. Thus, the `aws_s3.table_import_from_s3` function calls don't include credential parameters.

The following shows a typical example.

```sql
postgres=> SELECT aws_s3.table_import_from_s3(
    't1',
    '',
    '(format csv)',
    's3_uri'
);
```
The parameters are the following:

- `t1` – The name for the table in the PostgreSQL DB instance to copy the data into.
- `' '– An optional list of columns in the database table. You can use this parameter to indicate which columns of the S3 data go in which table columns. If no columns are specified, all the columns are copied to the table. For an example of using a column list, see [Importing an Amazon S3 file that uses a custom delimiter](#).
- `(format csv)` – PostgreSQL COPY arguments. The copy process uses the arguments and format of the `PostgreSQL COPY` command to import the data. Choices for format include comma-separated value (CSV) as shown in this example, text, and binary. The default is text.
- `s3_uri` – A structure that contains the information identifying the Amazon S3 file. For an example of using the `aws_commons.create_s3_uri` function to create an `s3_uri` structure, see [Overview of importing data from Amazon S3 data](#).

For more information about this function, see [aws_s3.table_import_from_s3](#).

The `aws_s3.table_import_from_s3` function returns text. To specify other kinds of files for import from an Amazon S3 bucket, see one of the following examples.

> **Note**
> Importing 0 bytes file will cause an error.

**Topics**

- [Importing an Amazon S3 file that uses a custom delimiter](#)
- [Importing an Amazon S3 compressed (gzip) file](#)
- [Importing an encoded Amazon S3 file](#)

**Importing an Amazon S3 file that uses a custom delimiter**

The following example shows how to import a file that uses a custom delimiter. It also shows how to control where to put the data in the database table using the `column_list` parameter of the `aws_s3.table_import_from_s3` function.

For this example, assume that the following information is organized into pipe-delimited columns in the Amazon S3 file.
To import a file that uses a custom delimiter

1. Create a table in the database for the imported data.

   postgres=> CREATE TABLE test (a text, b text, c text, d text, e text);

2. Use the following form of the `aws_s3.table_import_from_s3` function to import data from the Amazon S3 file.

   You can include the `aws_commons.create_s3_uri` function call inline within the `aws_s3.table_import_from_s3` function call to specify the file.

   postgres=> SELECT aws_s3.table_import_from_s3(
        'test',
        'a,b,d,e',
        'DELIMITER ''|''',
        aws_commons.create_s3_uri('sampleBucket', 'pipeDelimitedSampleFile', 'us-east-2'))
   );

The data is now in the table in the following columns.

   postgres=> SELECT * FROM test;
   a | b  | c  | d  | e
   ---+----+----+----+---
   1  | foo1| bar1| elephant1
   2  | foo2| bar2| elephant2
   3  | foo3| bar3| elephant3
   4  | foo4| bar4| elephant4

Importing an Amazon S3 compressed (gzip) file

The following example shows how to import a file from Amazon S3 that is compressed with gzip. The file that you import needs to have the following Amazon S3 metadata:
Key: Content-Encoding
Value: gzip

If you upload the file using the AWS Management Console, the metadata is typically applied by the system. For information about uploading files to Amazon S3 using the AWS Management Console, the AWS CLI, or the API, see Uploading objects in the Amazon Simple Storage Service User Guide.

For more information about Amazon S3 metadata and details about system-provided metadata, see Editing object metadata in the Amazon S3 console in the Amazon Simple Storage Service User Guide.

Import the gzip file into your RDS for PostgreSQL DB instance as shown following.

```sql
postgres=> CREATE TABLE test_gzip(id int, a text, b text, c text, d text);
postgres=> SELECT aws_s3.table_import_from_s3(  
   'test_gzip', '', '(format csv)',  
   'myS3Bucket', 'test-data.gz', 'us-east-2'
);
```

Importing an encoded Amazon S3 file

The following example shows how to import a file from Amazon S3 that has Windows-1252 encoding.

```sql
postgres=> SELECT aws_s3.table_import_from_s3(  
   'test_table', '', 'encoding ''WIN1252''',  
   aws_commons.create_s3_uri('sampleBucket', 'SampleFile', 'us-east-2')
);
```

Function reference

Functions

- `aws_s3.table_import_from_s3`
- `aws_commons.create_s3_uri`
- `aws_commons.create_aws_credentials`
**aws_s3.table_import_from_s3**

Imports Amazon S3 data into an Amazon RDS table. The `aws_s3` extension provides the `aws_s3.table_import_from_s3` function. The return value is text.

**Syntax**

The required parameters are `table_name`, `column_list` and `options`. These identify the database table and specify how the data is copied into the table.

You can also use the following parameters:

- The `s3_info` parameter specifies the Amazon S3 file to import. When you use this parameter, access to Amazon S3 is provided by an IAM role for the PostgreSQL DB instance.

```sql
aws_s3.table_import_from_s3 (    table_name text,    column_list text,    options text,    s3_info aws_commons._s3_uri_1)
```

- The `credentials` parameter specifies the credentials to access Amazon S3. When you use this parameter, you don't use an IAM role.

```sql
aws_s3.table_import_from_s3 (    table_name text,    column_list text,    options text,    s3_info aws_commons._s3_uri_1,    credentials aws_commons._aws_credentials_1)
```

**Parameters**

**table_name**

A required text string containing the name of the PostgreSQL database table to import the data into.
**column_list**

A required text string containing an optional list of the PostgreSQL database table columns in which to copy the data. If the string is empty, all columns of the table are used. For an example, see [Importing an Amazon S3 file that uses a custom delimiter](#).

**options**

A required text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied into the PostgreSQL table. For more details, see the [PostgreSQL COPY documentation](#).

**s3_info**

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- **bucket** – The name of the Amazon S3 bucket containing the file.
- **file_path** – The Amazon S3 file name including the path of the file.
- **region** – The AWS Region that the file is in. For a listing of AWS Region names and associated values, see [Regions, Availability Zones, and Local Zones](#).

**credentials**

An `aws_commons._aws_credentials_1` composite type containing the following credentials to use for the import operation:

- Access key
- Secret key
- Session token

For information about creating an `aws_commons._aws_credentials_1` composite structure, see [aws_commons.create_aws_credentials](#).

**Alternate syntax**

To help with testing, you can use an expanded set of parameters instead of the `s3_info` and `credentials` parameters. Following are additional syntax variations for the `aws_s3.table_import_from_s3` function:
• Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters. With this form of the function, access to Amazon S3 is provided by an IAM role on the PostgreSQL DB instance.

```sql
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    bucket text,  
    file_path text,  
    region text  
)
```

• Instead of using the `credentials` parameter to specify Amazon S3 access, use the combination of the `access_key`, `session_key`, and `session_token` parameters.

```sql
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    bucket text,  
    file_path text,  
    region text,  
    access_key text,  
    secret_key text,  
    session_token text  
)
```

**Alternate parameters**

`bucket`

A text string containing the name of the Amazon S3 bucket that contains the file.

`file_path`

A text string containing the Amazon S3 file name including the path of the file.

`region`

A text string identifying the AWS Region location of the file. For a listing of AWS Region names and associated values, see [Regions, Availability Zones, and Local Zones](#).
access_key

A text string containing the access key to use for the import operation. The default is NULL.

secret_key

A text string containing the secret key to use for the import operation. The default is NULL.

session_token

(Optional) A text string containing the session key to use for the import operation. The default is NULL.

aws_commons.create_s3_uri

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. Use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the `aws_s3.table_import_from_s3` function.

Syntax

```python
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
    region text
)
```

Parameters

bucket

A required text string containing the Amazon S3 bucket name for the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see [Regions, Availability Zones, and Local Zones](https://docs.aws.amazon.com/AmazonS3/latest/userguide/regions.html).
aws_commons.create_aws_credentials

Sets an access key and secret key in an aws_commons._aws_credentials_1 structure. Use the results of the aws_commons.create_aws_credentials function in the credentials parameter of the aws_s3.table_import_from_s3 function.

Syntax

```python
aws_commons.create_aws_credentials(
    access_key text,
    secret_key text,
    session_token text
)
```

Parameters

**access_key**

A required text string containing the access key to use for importing an Amazon S3 file. The default is NULL.

**secret_key**

A required text string containing the secret key to use for importing an Amazon S3 file. The default is NULL.

**session_token**

An optional text string containing the session token to use for importing an Amazon S3 file. The default is NULL. If you provide an optional session_token, you can use temporary credentials.

Transporting PostgreSQL databases between DB instances

By using PostgreSQL transportable databases for Amazon RDS, you can move a PostgreSQL database between two DB instances. This is a very fast way to migrate large databases between different DB instances. To use this approach, your DB instances must both run the same major version of PostgreSQL.

This capability requires that you install the pg_transport extension on both the source and the destination DB instance. The pg_transport extension provides a physical transport mechanism
that moves the database files with minimal processing. This mechanism moves data much faster than traditional dump and load processes, with less downtime.

![Note]

PostgreSQL transportable databases are available in RDS for PostgreSQL 11.5 and higher, and RDS for PostgreSQL version 10.10 and higher.

To transport a PostgreSQL DB instance from one RDS for PostgreSQL DB instance to another, you first set up the source and destination instances as detailed in [Setting up a DB instance for transport](#). You can then transport the database by using the function described in [Transporting a PostgreSQL database](#).

### Topics

- [Limitations for using PostgreSQL transportable databases](#)
- [Setting up to transport a PostgreSQL database](#)
- [Transporting a PostgreSQL database to the destination from the source](#)
- [What happens during database transport](#)
- [Transportable databases function reference](#)
- [Transportable databases parameter reference](#)

### Limitations for using PostgreSQL transportable databases

Transportable databases have the following limitations:

- **Read replicas** – You can’t use transportable databases on read replicas or parent instances of read replicas.

- **Unsupported column types** – You can't use the `reg` data types in any database tables that you plan to transport with this method. These types depend on system catalog object IDs (OIDs), which often change during transport.

- **Tablespaces** – All source database objects must be in the default `pg_default` tablespace.

- **Compatibility** – Both the source and destination DB instances must run the same major version of PostgreSQL.

- **Extensions** – The source DB instance can have only the `pg_transport` installed.
Roles and ACLs – The source database's access privileges and ownership information aren't carried over to the destination database. All database objects are created and owned by the local destination user of the transport.

Concurrent transports – A single DB instance can support up to 32 concurrent transports, including both imports and exports, if worker processes have been configured properly.

RDS for PostgreSQL DB instances only – PostgreSQL transportable databases are supported on RDS for PostgreSQL DB instances only. You can't use it with on-premises databases or databases running on Amazon EC2.

Setting up to transport a PostgreSQL database

Before you begin, make sure that your RDS for PostgreSQL DB instances meet the following requirements:

- The RDS for PostgreSQL DB instances for source and destination must run the same version of PostgreSQL.
- The destination DB can't have a database of the same name as the source DB that you want to transport.
- The account you use to run the transport needs rds_superuser privileges on both the source DB and the destination DB.
- The security group for the source DB instance must allow inbound access from the destination DB instance. This might already be the case if your source and destination DB instances are located in the VPC. For more information about security groups, see Controlling access with security groups.

Transporting databases from a source DB instance to a destination DB instance requires several changes to the DB parameter group associated with each instance. That means that you must create a custom DB parameter group for the source DB instance and create a custom DB parameter group for the destination DB instance.

Note

If your DB instances are already configured using custom DB parameter groups, you can start with step 2 in the following procedure.
To configure the custom DB group parameters for transporting databases

For the following steps, use an account that has `rds_superuser` privileges.

1. If the source and destination DB instances use a default DB parameter group, you need to create a custom DB parameter using the appropriate version for your instances. You do this so you can change values for several parameters. For more information, see [Working with parameter groups](#).

2. In the custom DB parameter group, change values for the following parameters:

   - `shared_preload_libraries` – Add `pg_transport` to the list of libraries.
   - `pg_transport.num_workers` – The default value is 3. Increase or reduce this value as needed for your database. For a 200 GB database, we recommend no larger than 8. Keep in mind that if you increase the default value for this parameter, you should also increase the value of `max_worker_processes`.
   - `pg_transport.work_mem` – The default value is either 128 MB or 256 MB, depending on the PostgreSQL version. The default setting can typically be left unchanged.
   - `max_worker_processes` – The value of this parameter needs to be set using the following calculation:

     \[
     3 \times \text{pg\_transport\_num\_workers} + 9
     \]

     This value is required on the destination to handle various background worker processes involved in the transport. To learn more about `max_worker_processes`, see [Resource Consumption](#) in the PostgreSQL documentation.

     For more information about `pg_transport` parameters, see [Transportable databases parameter reference](#).

3. Reboot the source RDS for PostgreSQL DB instance and the destination instance so that the settings for the parameters take effect.

4. Connect to your RDS for PostgreSQL source DB instance.

   ```
   psql --host=source-instance.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

5. Remove extraneous extensions from the public schema of the DB instance. Only the `pg_transport` extension is allowed during the actual transport operation.
6. Install the `pg_transport` extension as follows:

```
postgres=> CREATE EXTENSION pg_transport;
CREATE EXTENSION
```

7. Connect to your RDS for PostgreSQL destination DB instance. Remove any extraneous extensions, and then install the `pg_transport` extension.

```
postgres=> CREATE EXTENSION pg_transport;
CREATE EXTENSION
```

### Transporting a PostgreSQL database to the destination from the source

After you complete the process described in [Setting up to transport a PostgreSQL database](#), you can start the transport. To do so, run the `transport.import_from_server` function on the destination DB instance. In the syntax following you can find the function parameters.

```
SELECT transport.import_from_server(
    'source-db-instance-endpoint',
    'source-db-instance-port',
    'source-db-instance-user',
    'source-user-password',
    'source-database-name',
    'destination-user-password',
    false);
```

The `false` value shown in the example tells the function that this is not a dry run. To test your transport setup, you can specify `true` for the `dry_run` option when you call the function, as shown following:

```
postgres=> SELECT transport.import_from_server(
    'docs-lab-source-db.666666666666aws-region.rds.amazonaws.com', 5432,
    'postgres', '********', 'labdb', '******', true);
INFO: Starting dry-run of import of database "labdb".
INFO: Created connections to remote database         (took 0.03 seconds).
INFO: Checked remote cluster compatibility          (took 0.05 seconds).
INFO: Dry-run complete                         (took 0.08 seconds total).
import_from_server
---------------------
The INFO lines are output because the `pg_transport.timing` parameter is set to its default value, true. Set the `dry_run` to false when you run the command and the source database is imported to the destination, as shown following:

```
INFO: Starting import of database "labdb".
INFO: Created connections to remote database (took 0.02 seconds).
INFO: Marked remote database as read only (took 0.13 seconds).
INFO: Checked remote cluster compatibility (took 0.03 seconds).
INFO: Signaled creation of PITR blackout window (took 2.01 seconds).

import_from_server
-------------------
(1 row)
```

This function requires that you provide database user passwords. Thus, we recommend that you change the passwords of the user roles you used after transport is complete. Or, you can use SQL bind variables to create temporary user roles. Use these temporary roles for the transport and then discard the roles afterwards.

If your transport isn't successful, you might see an error message similar to the following:

```
pg_transport.num_workers=8 25% of files transported failed to download file data
```

The "failed to download file data" error message indicates that the number of worker processes isn't set correctly for the size of the database. You might need to increase or decrease the value set for `pg_transport.num_workers`. Each failure reports the percentage of completion, so you can see the impact of your changes. For example, changing the setting from 8 to 4 in one case resulted in the following:

```
pg_transport.num_workers=4 75% of files transported failed to download file data
```

Keep in mind that the `max_worker_processes` parameter is also taken into account during the transport process. In other words, you might need to modify both `pg_transport.num_workers`
and `max_worker_processes` to successfully transport the database. The example shown finally worked when the `pg_transport.num_workers` was set to 2:

```
pg_transport.num_workers=2 100% of files transported
```

For more information about the `transport.import_from_server` function and its parameters, see [Transportable databases function reference](#).

### What happens during database transport

The PostgreSQL transportable databases feature uses a pull model to import the database from the source DB instance to the destination. The `transport.import_from_server` function creates the in-transit database on the destination DB instance. The in-transit database is inaccessible on the destination DB instance for the duration of the transport.

When transport begins, all current sessions on the source database are ended. Any databases other than the source database on the source DB instance aren't affected by the transport.

The source database is put into a special read-only mode. While it's in this mode, you can connect to the source database and run read-only queries. However, write-enabled queries and some other types of commands are blocked. Only the specific source database that is being transported is affected by these restrictions.

During transport, you can't restore the destination DB instance to a point in time. This is because the transport isn't transactional and doesn't use the PostgreSQL write-ahead log to record changes. If the destination DB instance has automatic backups enabled, a backup is automatically taken after transport completes. Point-in-time restores are available for times *after* the backup finishes.

If the transport fails, the `pg_transport` extension attempts to undo all changes to the source and destination DB instances. This includes removing the destination’s partially transported database. Depending on the type of failure, the source database might continue to reject write-enabled queries. If this happens, use the following command to allow write-enabled queries.

```
ALTER DATABASE db-name SET default_transaction_read_only = false;
```
Transportable databases function reference

The transport.import_from_server function transports a PostgreSQL database by importing it from a source DB instance to a destination DB instance. It does this by using a physical database connection transport mechanism.

Before starting the transport, this function verifies that the source and the destination DB instances are the same version and are compatible for the migration. It also confirms that the destination DB instance has enough space for the source.

Syntax

```python
transport.import_from_server(
    host text,
    port int,
    username text,
    password text,
    database text,
    local_password text,
    dry_run bool
)
```

Return Value

None.

Parameters

You can find descriptions of the transport.import_from_server function parameters in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>The endpoint of the source DB instance.</td>
</tr>
<tr>
<td>port</td>
<td>An integer representing the port of the source DB instance. PostgreSQL DB instances often use port 5432.</td>
</tr>
<tr>
<td>username</td>
<td>The user of the source DB instance. This user must be a member of the rds_superuser role.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>password</td>
<td>The user password of the source DB instance.</td>
</tr>
<tr>
<td>database</td>
<td>The name of the database in the source DB instance to transport.</td>
</tr>
<tr>
<td>local_password</td>
<td>The local password of the current user for the destination DB instance. This user must be a member of the rds_superuser role.</td>
</tr>
<tr>
<td>dry_run</td>
<td>An optional Boolean value specifying whether to perform a dry run. The default is false, which means the transport proceeds. To confirm compatibility between the source and destination DB instances without performing the actual transport, set dry_run to true.</td>
</tr>
</tbody>
</table>

**Example**

For an example, see [Transporting a PostgreSQL database to the destination from the source](#).

**Transportable databases parameter reference**

Several parameters control the behavior of the `pg_transport` extension. Following, you can find descriptions of these parameters.

**pg_transport.num_workers**

The number of workers to use for the transport process. The default is 3. Valid values are 1–32. Even the largest database transports typically require fewer than 8 workers. The value of this setting on the destination DB instance is used by both destination and source during transport.

**pg_transport.timing**

Specifies whether to report timing information during the transport. The default is `true`, meaning that timing information is reported. We recommend that you leave this parameter set to `true` so you can monitor progress. For example output, see [Transporting a PostgreSQL database to the destination from the source](#).

**pg_transport.work_mem**

The maximum amount of memory to allocate for each worker. The default is 131072 kilobytes (KB) or 262144 KB (256 MB), depending on the PostgreSQL version. The minimum value is 64
megabytes (65536 KB). Valid values are in kilobytes (KBs) as binary base-2 units, where 1 KB = 1024 bytes.

The transport might use less memory than is specified in this parameter. Even large database transports typically require less than 256 MB (262144 KB) of memory per worker.
Exporting data from an RDS for PostgreSQL DB instance to Amazon S3

You can query data from an RDS for PostgreSQL DB instance and export it directly into files stored in an Amazon S3 bucket. To do this, you first install the RDS for PostgreSQL aws_s3 extension. This extension provides you with the functions that you use to export the results of queries to Amazon S3. Following, you can find out how to install the extension and how to export data to Amazon S3.

You can export from a provisioned or an Aurora Serverless v2 DB instance. These steps aren't supported for Aurora Serverless v1.

Note
Cross-account export to Amazon S3 isn't supported.

All currently available versions of RDS for PostgreSQL support exporting data to Amazon Simple Storage Service. For detailed version information, see Amazon RDS for PostgreSQL updates in the Amazon RDS for PostgreSQL Release Notes.

If you don't have a bucket set up for your export, see the following topics the Amazon Simple Storage Service User Guide.

- Setting up Amazon S3
- Create a bucket

The upload to Amazon S3 uses server-side encryption by default. If you are using encryption, the Amazon S3 bucket must be encrypted with an AWS managed key. You can export data to a bucket that's encrypted with a customer managed key.

Note
You can save DB snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see Exporting DB snapshot data to Amazon S3.
Installing the aws_s3 extension

Before you can use Amazon Simple Storage Service with your RDS for PostgreSQL DB instance, you need to install the aws_s3 extension. This extension provides functions for exporting data from an RDS for PostgreSQL DB instance to an Amazon S3 bucket. It also provides functions for importing data from an Amazon S3. For more information, see Importing data from Amazon S3 into an RDS for PostgreSQL DB instance. The aws_s3 extension depends on some of the helper functions in the aws_commons extension, which is installed automatically when needed.

To install the aws_s3 extension

1. Use psql (or pgAdmin) to connect to the RDS for PostgreSQL DB instance as a user that has rds_superuser privileges. If you kept the default name during the setup process, you connect as postgres.

```bash
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

2. To install the extension, run the following command.

```bash
postgres=> CREATE EXTENSION aws_s3 CASCADE;
NOTICE: installing required extension "aws_commons"
CREATE EXTENSION
```

3. To verify that the extension is installed, you can use the psql \dx metacommand.

```bash
postgres=> \dx
  List of installed extensions
```
The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

**Verify that your RDS for PostgreSQL version supports exports to Amazon S3**

You can verify that your RDS for PostgreSQL version supports export to Amazon S3 by using the `describe-db-engine-versions` command. The following example verifies support for version 10.14.

```
aws rds describe-db-engine-versions --region us-east-1
  --engine postgres --engine-version 10.14 | grep s3Export
```

If the output includes the string "s3Export", then the engine supports Amazon S3 exports. Otherwise, the engine doesn't support them.

**Overview of exporting data to Amazon S3**

To export data stored in an RDS for PostgreSQL database to an Amazon S3 bucket, use the following procedure.

**To export RDS for PostgreSQL data to S3**

1. Identify an Amazon S3 file path to use for exporting data. For details about this process, see [Specifying the Amazon S3 file path to export to](#).
2. Provide permission to access the Amazon S3 bucket.

   To export data to an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket that the export will use for storage. Doing this includes the following steps:

   1. Create an IAM policy that provides access to an Amazon S3 bucket that you want to export to.
2. Create an IAM role.

3. Attach the policy you created to the role you created.

4. Add this IAM role to your DB instance.

For details about this process, see Setting up access to an Amazon S3 bucket.

3. Identify a database query to get the data. Export the query data by calling the `aws_s3.query_export_to_s3` function.

After you complete the preceding preparation tasks, use the `aws_s3.query_export_to_s3` function to export query results to Amazon S3. For details about this process, see Exporting query data using the `aws_s3.query_export_to_s3` function.

**Specifying the Amazon S3 file path to export to**

Specify the following information to identify the location in Amazon S3 where you want to export data to:

- **Bucket name** – A *bucket* is a container for Amazon S3 objects or files.

  For more information on storing data with Amazon S3, see Create a bucket and View an object in the Amazon Simple Storage Service User Guide.

- **File path** – The file path identifies where the export is stored in the Amazon S3 bucket. The file path consists of the following:
  - An optional path prefix that identifies a virtual folder path.
  - A file prefix that identifies one or more files to be stored. Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on.

  For example, a file path with an `exports` folder and a `query-1-export` file prefix is `/exports/query-1-export`.

- **AWS Region** (optional) – The AWS Region where the Amazon S3 bucket is located. If you don't specify an AWS Region value, then Amazon RDS saves your files into Amazon S3 in the same AWS Region as the exporting DB instance.
Note
Currently, the AWS Region must be the same as the region of the exporting DB instance.

For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

To hold the Amazon S3 file information about where the export is to be stored, you can use the `aws_commons.create_s3_uri` function to create an `aws_commons._s3_uri_1` composite structure as follows.

```sql
psql=> SELECT aws_commons.create_s3_uri('sample-bucket', 'sample-filepath', 'us-west-2') AS s3_uri_1 \gset
```

You later provide this `s3_uri_1` value as a parameter in the call to the `aws_s3.query_export_to_s3` function. For examples, see Exporting query data using the `aws_s3.query_export_to_s3` function.

**Setting up access to an Amazon S3 bucket**

To export data to Amazon S3, give your PostgreSQL DB instance permission to access the Amazon S3 bucket that the files are to go in.

To do this, use the following procedure.

**To give a PostgreSQL DB instance access to Amazon S3 through an IAM role**

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your PostgreSQL DB instance to access Amazon S3.

   As part of creating this policy, take the following steps:

   a. Include in the policy the following required actions to allow the transfer of files from your PostgreSQL DB instance to an Amazon S3 bucket:
b. Include the Amazon Resource Name (ARN) that identifies the Amazon S3 bucket and objects in the bucket. The ARN format for accessing Amazon S3 is: arn:aws:s3:::your-s3-bucket/*

For more information on creating an IAM policy for Amazon RDS for PostgreSQL, see Creating and using an IAM policy for IAM database access. See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

The following AWS CLI command creates an IAM policy named rds-s3-export-policy with these options. It grants access to a bucket named your-s3-bucket.

```
aws iam create-policy --policy-name rds-s3-export-policy --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Sid": "s3export",
        "Action": [
            "s3:PutObject",
            "s3:AbortMultipartUpload"
        ]
    },
}
```

Warning

We recommend that you set up your database within a private VPC that has endpoint policies configured for accessing specific buckets. For more information, see Using endpoint policies for Amazon S3 in the Amazon VPC User Guide.

We strongly recommend that you do not create a policy with all-resource access. This access can pose a threat for data security. If you create a policy that gives S3:PutObject access to all resources using "Resource":"*", then a user with export privileges can export data to all buckets in your account. In addition, the user can export data to any publicly writable bucket within your AWS Region.

After you create the policy, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.
2. Create an IAM role.

You do this so Amazon RDS can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-export-role`.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam create-role \
  --role-name rds-s3-export-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
```
"Principal": {
    "Service": "rds.amazonaws.com"
},
"Action": "sts:AssumeRole",
"Condition": {
    "StringEquals": {
        "aws:SourceAccount": "111122223333",
    }
}
}]

For Windows:

```bash
aws iam create-role
--role-name rds-s3-export-role
--assume-role-policy-document '{
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
            "StringEquals": {
                "aws:SourceAccount": "111122223333",
            }
        }
    }
]
}'
```

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named rds-s3-export-role. Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.
4. Add the IAM role to the DB instance. You do so by using the AWS Management Console or AWS CLI, as described following.

**Console**

**To add an IAM role for a PostgreSQL DB instance using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose the PostgreSQL DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this instance**.
4. Under **Feature**, choose **s3Export**.
5. Choose **Add role**.

**AWS CLI**

**To add an IAM role for a PostgreSQL DB instance using the CLI**

- Use the following command to add the role to the PostgreSQL DB instance named `my-db-instance`. Replace `your-role-arn` with the role ARN that you noted in a previous step. Use `s3Export` for the value of the `--feature-name` option.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-role-to-db-instance \
    --db-instance-identifier my-db-instance \
    --feature-name s3Export \
    --role-arn your-role-arn \
    --region your-region
```

For Windows:
aws rds add-role-to-db-instance
  --db-instance-identifier my-db-instance
  --feature-name s3Export
  --role-arn your-role-arn
  --region your-region

Exporting query data using the aws_s3.query_export_to_s3 function

Export your PostgreSQL data to Amazon S3 by calling the aws_s3.query_export_to_s3 function.

Topics

• Prerequisites
• Calling aws_s3.query_export_to_s3
• Exporting to a CSV file that uses a custom delimiter
• Exporting to a binary file with encoding

Prerequisites

Before you use the aws_s3.query_export_to_s3 function, be sure to complete the following prerequisites:

• Install the required PostgreSQL extensions as described in Overview of exporting data to Amazon S3.
• Determine where to export your data to Amazon S3 as described in Specifying the Amazon S3 file path to export to.
• Make sure that the DB instance has export access to Amazon S3 as described in Setting up access to an Amazon S3 bucket.

The examples following use a database table called sample_table. These examples export the data into a bucket called sample-bucket. The example table and data are created with the following SQL statements in psql.

```sql
psql=> CREATE TABLE sample_table (bid bigint PRIMARY KEY, name varchar(80));
psql=> INSERT INTO sample_table (bid,name) VALUES (1, 'Monday'), (2,'Tuesday'), (3,'Wednesday');
```
Calling **aws_s3.query_export_to_s3**

The following shows the basic ways of calling the **aws_s3.query_export_to_s3** function.

These examples use the variable `s3_uri_1` to identify a structure that contains the information identifying the Amazon S3 file. Use the **aws_commons.create_s3_uri** function to create the structure.

```
psql=> SELECT aws_commons.create_s3_uri(  
      'sample-bucket',  
      'sample-filepath',  
      'us-west-2'  
    ) AS s3_uri_1 \gset
```

Although the parameters vary for the following two **aws_s3.query_export_to_s3** function calls, the results are the same for these examples. All rows of the `sample_table` table are exported into a bucket called `sample-bucket`.

```
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', :'s3_uri_1');
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', :'s3_uri_1', options :='format text');
```

The parameters are described as follows:

- `'SELECT * FROM sample_table'` – The first parameter is a required text string containing an SQL query. The PostgreSQL engine runs this query. The results of the query are copied to the S3 bucket identified in other parameters.
- `:'s3_uri_1'` – This parameter is a structure that identifies the Amazon S3 file. This example uses a variable to identify the previously created structure. You can instead create the structure by including the **aws_commons.create_s3_uri** function call inline within the **aws_s3.query_export_to_s3** function call as follows.

```
SELECT * from aws_s3.query_export_to_s3('select * from sample_table',  
aws_commons.create_s3_uri('sample-bucket', 'sample-filepath', 'us-west-2'))
```
• **options :='format text'** – The options parameter is an optional text string containing PostgreSQL COPY arguments. The copy process uses the arguments and format of the PostgreSQL COPY command.

If the file specified doesn't exist in the Amazon S3 bucket, it's created. If the file already exists, it's overwritten. The syntax for accessing the exported data in Amazon S3 is the following.

```s3-region://bucket-name[/path-prefix]/file-prefix```

Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with _partXX appended. The XX represents 2, then 3, and so on. For example, suppose that you specify the path where you store data files as the following.

```s3-us-west-2://my-bucket/my-prefix```

If the export has to create three data files, the Amazon S3 bucket contains the following data files.

```s3-us-west-2://my-bucket/my-prefix
s3-us-west-2://my-bucket/my-prefix_part2
s3-us-west-2://my-bucket/my-prefix_part3```

For the full reference for this function and additional ways to call it, see [aws_s3.query_export_to_s3](#). For more about accessing files in Amazon S3, see [View an object](#) in the [Amazon Simple Storage Service User Guide](#).

**Exporting to a CSV file that uses a custom delimiter**

The following example shows how to call the `aws_s3.query_export_to_s3` function to export data to a file that uses a custom delimiter. The example uses arguments of the PostgreSQL COPY command to specify the comma-separated value (CSV) format and a colon (:) delimiter.

```
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :'s3_uri_1',
options :='format csv, delimiter $$:$$');
```

**Exporting to a binary file with encoding**

The following example shows how to call the `aws_s3.query_export_to_s3` function to export data to a binary file that has Windows-1253 encoding.
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :'s3_uri_1', options :='format binary, encoding WIN1253');

Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to export data to Amazon S3, first confirm that the outbound access rules for the VPC security group associated with your DB instance permit network connectivity. Specifically, the security group must have a rule that allows the DB instance to send TCP traffic to port 443 and to any IPv4 addresses (0.0.0.0/0). For more information, see Provide access to your DB instance in your VPC by creating a security group.

See also the following for recommendations:

- Troubleshooting Amazon RDS identity and access
- Troubleshooting Amazon S3 in the Amazon Simple Storage Service User Guide
- Troubleshooting Amazon S3 and IAM in the IAM User Guide

Function reference

Functions

- aws_s3.query_export_to_s3
- aws_commons.create_s3_uri

aws_s3.query_export_to_s3

Exports a PostgreSQL query result to an Amazon S3 bucket. The aws_s3 extension provides the aws_s3.query_export_to_s3 function.

The two required parameters are query and s3_info. These define the query to be exported and identify the Amazon S3 bucket to export to. An optional parameter called options provides for defining various export parameters. For examples of using the aws_s3.query_export_to_s3 function, see Exporting query data using the aws_s3.query_export_to_s3 function.

Syntax

```sql
aws_s3.query_export_to_s3(
    query text,
    s3_info aws_commons._s3_uri_1,
```
Input parameters

query

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the s3_info parameter.

s3_info

An aws_commons._s3_uri_1 composite type containing the following information about the S3 object:

- bucket – The name of the Amazon S3 bucket to contain the file.
- file_path – The Amazon S3 file name and path.
- region – The AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

Currently, this value must be the same AWS Region as that of the exporting DB instance. The default is the AWS Region of the exporting DB instance.

To create an aws_commons._s3_uri_1 composite structure, see the aws_commons.create_s3_uri function.

options

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the PostgreSQL COPY documentation.

kms_key text

An optional text string containing the customer managed KMS key of the S3 bucket to export the data to.

Alternate input parameters

To help with testing, you can use an expanded set of parameters instead of the s3_info parameter. Following are additional syntax variations for the aws_s3.query_export_to_s3 function.
Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters.

```python
aws_s3.query_export_to_s3(
    query text,
    bucket text,
    file_path text,
    region text,
    options text,
    kms_key text
)
```

**query**

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the `s3_info` parameter.

**bucket**

A required text string containing the name of the Amazon S3 bucket that contains the file.

**file_path**

A required text string containing the Amazon S3 file name including the path of the file.

**region**

An optional text string containing the AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

Currently, this value must be the same AWS Region as that of the exporting DB instance. The default is the AWS Region of the exporting DB instance.

**options**

An optional text string containing arguments for the PostgreSQL \texttt{COPY} command. These arguments specify how the data is to be copied when exported. For more details, see the PostgreSQL \texttt{COPY} documentation.

**kms_key text**

An optional text string containing the customer managed KMS key of the S3 bucket to export the data to.
Output parameters

```sql
aws_s3.query_export_to_s3(
    OUT rows_uploaded bigint,
    OUT files_uploaded bigint,
    OUT bytes_uploaded bigint
)
```

**rows_uploaded**

The number of table rows that were successfully uploaded to Amazon S3 for the given query.

**files_uploaded**

The number of files uploaded to Amazon S3. Files are created in sizes of approximately 6 GB. Each additional file created has _partXX appended to the name. The XX represents 2, then 3, and so on as needed.

**bytes_uploaded**

The total number of bytes uploaded to Amazon S3.

Examples

```sql
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath','us-west-2');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath','us-west-2','format text');
```

**aws_commons.create_s3_uri**

Creates an aws_commons._s3_uri_1 structure to hold Amazon S3 file information. You use the results of the aws_commons.create_s3_uri function in the s3_info parameter of the aws_s3.query_export_to_s3 function. For an example of using the aws_commons.create_s3_uri function, see Specifying the Amazon S3 file path to export to.

**Syntax**

```sql
aws_commons.create_s3_uri()
```
Input parameters

bucket

A required text string containing the Amazon S3 bucket name for the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see [Regions, Availability Zones, and Local Zones](#).
Invoking an AWS Lambda function from an RDS for PostgreSQL DB instance

AWS Lambda is an event-driven compute service that lets you run code without provisioning or managing servers. It’s available for use with many AWS services, including RDS for PostgreSQL. For example, you can use Lambda functions to process event notifications from a database, or to load data from files whenever a new file is uploaded to Amazon S3. To learn more about Lambda, see What is AWS Lambda? in the AWS Lambda Developer Guide.

**Note**

Invoking an AWS Lambda function is supported in these RDS for PostgreSQL versions:

- All PostgreSQL 16 versions
- All PostgreSQL 15 versions
- PostgreSQL 14.1 and higher minor versions
- PostgreSQL 13.2 and higher minor versions
- PostgreSQL 12.6 and higher minor versions

Setting up RDS for PostgreSQL to work with Lambda functions is a multi-step process involving AWS Lambda, IAM, your VPC, and your RDS for PostgreSQL DB instance. Following, you can find summaries of the necessary steps.

For more information about Lambda functions, see Getting started with Lambda and AWS Lambda foundations in the AWS Lambda Developer Guide.

**Topics**

- Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda
- Step 2: Configure IAM for your RDS for PostgreSQL DB instance and AWS Lambda
- Step 3: Install the aws_lambda extension for an RDS for PostgreSQL DB instance
- Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional)
- Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance
- Step 6: Grant other users permission to invoke Lambda functions
Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda

Lambda functions always run inside an Amazon VPC that's owned by the AWS Lambda service. Lambda applies network access and security rules to this VPC and it maintains and monitors the VPC automatically. Your RDS for PostgreSQL DB instance sends network traffic to the Lambda service's VPC. How you configure this depends on whether your DB instance is public or private.

- **Public RDS for PostgreSQL DB instance** – A DB instance is public if it's located in a public subnet on your VPC, and if the instance's "PubliclyAccessible" property is true. To find the value of this property, you can use the `describe-db-instances` AWS CLI command. Or, you can use the AWS Management Console to open the Connectivity & security tab and check that Publicly accessible is Yes. To verify that the instance is in the public subnet of your VPC, you can use the AWS Management Console or the AWS CLI.

  To set up access to Lambda, you use the AWS Management Console or the AWS CLI to create an outbound rule on your VPC's security group. The outbound rule specifies that TCP can use port 443 to send packets to any IPv4 addresses (0.0.0.0/0).

- **Private RDS for PostgreSQL DB instance** – In this case, the instance's "PubliclyAccessible" property is false or it's in a private subnet. To allow the instance to work with Lambda, you can use a Network Address Translation) NAT gateway. For more information, see [NAT gateways](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/guides_nat.html). Or, you can configure your VPC with a VPC endpoint for Lambda. For more information, see [VPC endpoints](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/guides_vpc-endpoints.html) in the Amazon VPC User Guide. The endpoint responds to calls made by your RDS for PostgreSQL DB instance to your Lambda functions. The VPC endpoint uses its own private DNS resolution. RDS for PostgreSQL can't use the Lambda VPC endpoint until you change the value of the `rds.custom_dns_resolution` parameter from its default value of 0 (not enabled) to 1. To do so:

  - Create a custom DB parameter group.
  - Change the value of the `rds.custom_dns_resolution` parameter from its default of 0 to 1.
  - Modify your DB instance to use your custom DB parameter group.
  - Reboot the instance to have the modified parameter take effect.
Your VPC can now interact with the AWS Lambda VPC at the network level. Next, you configure the permissions using IAM.

**Step 2: Configure IAM for your RDS for PostgreSQL DB instance and AWS Lambda**

Invoking Lambda functions from your RDS for PostgreSQL DB instance requires certain privileges. To configure the necessary privileges, we recommend that you create an IAM policy that allows invoking Lambda functions, assign that policy to a role, and then attach it to your DB instance. This approach gives the DB instance privileges to invoke the specified Lambda function on your behalf. The following steps show you how to do this using the AWS CLI.

**To configure IAM permissions for using your Amazon RDS instance with Lambda**

1. Use the `create-policy` AWS CLI command to create an IAM policy that allows your RDS for PostgreSQL DB instance to invoke the specified Lambda function. (The statement ID (Sid) is an optional description for your policy statement and has no effect on usage.) This policy gives your DB instance the minimum permissions needed to invoke the specified Lambda function.

   ```bash
   aws iam create-policy --policy-name rds-lambda-policy --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "AllowAccessToExampleFunction",
   "Effect": "Allow",
   "Action": "lambda:InvokeFunction",
   }
   ]
   }
   '
   
   Alternatively, you can use the predefined AWSLambdaRole policy that allows you to invoke any of your Lambda functions. For more information, see Identity-based IAM policies for Lambda.

2. Use the `create-role` AWS CLI command to create an IAM role that the policy can assume at runtime.

   ```bash
   aws iam create-role --role-name rds-lambda-role --assume-role-policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   
   ```
"Effect": "Allow",
"Principal": {
    "Service": "rds.amazonaws.com"
},
"Action": "sts:AssumeRole"
}
]
}

3. Apply the policy to the role by using the `attach-role-policy` AWS CLI command.

```bash
aws iam attach-role-policy \
    --policy-arn arn:aws:iam::444455556666:policy/rds-lambda-policy \
    --role-name rds-lambda-role --region aws-region
```

4. Apply the role to your RDS for PostgreSQL DB instance by using the `add-role-to-db-instance` AWS CLI command. This last step allows your DB instance's database users to invoke Lambda functions.

```bash
aws rds add-role-to-db-instance \
    --db-instance-identifier my-instance-name \
    --feature-name Lambda \
    --role-arn arn:aws:iam::444455556666:role/rds-lambda-role \
    --region aws-region
```

With the VPC and the IAM configurations complete, you can now install the `aws_lambda` extension. (Note that you can install the extension at any time, but until you set up the correct VPC support and IAM privileges, the `aws_lambda` extension adds nothing to your RDS for PostgreSQL DB instance's capabilities.)

**Step 3: Install the `aws_lambda` extension for an RDS for PostgreSQL DB instance**

To use AWS Lambda with your RDS for PostgreSQL DB instance, add the `aws_lambda` PostgreSQL extension to your RDS for PostgreSQL DB instance. This extension provides your RDS for PostgreSQL DB instance with the ability to call Lambda functions from PostgreSQL.
To install the `aws_lambda` extension in your RDS for PostgreSQL DB instance

Use the PostgreSQL `psql` command-line or the pgAdmin tool to connect to your RDS for PostgreSQL DB instance.

1. Connect to your RDS for PostgreSQL DB instance as a user with `rds_superuser` privileges. The default `postgres` user is shown in the example.

   ```
   psql -h instance.444455566666.aws-region.rds.amazonaws.com -U postgres -p 5432
   ```

2. Install the `aws_lambda` extension. The `aws_commons` extension is also required. It provides helper functions to `aws_lambda` and many other Aurora extensions for PostgreSQL. If it's not already on your RDS for PostgreSQL DB instance, it's installed with `aws_lambda` as shown following.

   ```
   CREATE EXTENSION IF NOT EXISTS aws_lambda CASCADE;
   NOTICE:  installing required extension "aws_commons"
   CREATE EXTENSION
   ```

The `aws_lambda` extension is installed in your DB instance. You can now create convenience structures for invoking your Lambda functions.

**Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional)**

You can use the helper functions in the `aws_commons` extension to prepare entities that you can more easily invoke from PostgreSQL. To do this, you need to have the following information about your Lambda functions:

- **Function name** – The name, Amazon Resource Name (ARN), version, or alias of the Lambda function. The IAM policy created in **Step 2: Configure IAM for your instance and Lambda** requires the ARN, so we recommend that you use your function's ARN.

- **AWS Region** – (Optional) The AWS Region where the Lambda function is located if it's not in the same Region as your RDS for PostgreSQL DB instance.

To hold the Lambda function name information, you use the `aws_commons.create_lambda_function_arn` function. This helper function creates an
aws_commons._lambda_function_arn_1 composite structure with the details needed by the
invoke function. Following, you can find three alternative approaches to setting up this composite
structure.

```
SELECT aws_commons.create_lambda_function_arn(
    'my-function',
    'aws-region'
) AS aws_lambda_arn_1 \
```

```
SELECT aws_commons.create_lambda_function_arn(
    '111122223333:function:my-function',
    'aws-region'
) AS lambda_partial_arn_1 \
```

```
SELECT aws_commons.create_lambda_function_arn(
) AS lambda_arn_1 \
```

Any of these values can be used in calls to the `aws_lambda.invoke` function. For examples, see Step
5: Invoke a Lambda function from your RDS for PostgreSQL DB instance.

**Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance**

The `aws_lambda.invoke` function behaves synchronously or asynchronously, depending on the
invocation_type. The two alternatives for this parameter are RequestResponse (the default) and Event, as follows.

- **RequestResponse** – This invocation type is **synchronous**. It's the default behavior when the call
  is made without specifying an invocation type. The response payload includes the results of the
  `aws_lambda.invoke` function. Use this invocation type when your workflow requires receiving
  results from the Lambda function before proceeding.

- **Event** – This invocation type is **asynchronous**. The response doesn't include a payload containing
  results. Use this invocation type when your workflow doesn't need a result from the Lambda
  function to continue processing.
As a simple test of your setup, you can connect to your DB instance using psql and invoke an example function from the command line. Suppose that you have one of the basic functions set up on your Lambda service, such as the simple Python function shown in the following screenshot.

To invoke an example function

1. Connect to your DB instance using psql or pgAdmin.

   ```
   psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
   ```

2. Invoke the function using its ARN.

   ```
   SELECT * from aws_lambda.invoke(aws_commons.create_lambda_function_arn('arn:aws:lambda:aws-region:444455556666:function:simple', 'us-west-1'), '{"body": "Hello from Postgres!"'}::json )
   ```

   The response looks as follows.

<table>
<thead>
<tr>
<th>status_code</th>
<th>payload</th>
</tr>
</thead>
</table>
   | 200         | {"statusCode": 200, "body": "\"Hello from Lambda!\""} | $LATEST

If your invocation attempt doesn't succeed, see [Lambda function error messages](#).
Step 6: Grant other users permission to invoke Lambda functions

At this point in the procedures, only you as rds_superuser can invoke your Lambda functions. To allow other users to invoke any functions that you create, you need to grant them permission.

To grant others permission to invoke Lambda functions

1. Connect to your DB instance using psql or pgAdmin.

   ```
   psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
   ```

2. Run the following SQL commands:

   ```
   postgres=> GRANT USAGE ON SCHEMA aws_lambda TO db_username;
   GRANT EXECUTE ON ALL FUNCTIONS IN SCHEMA aws_lambda TO db_username;
   ```

Examples: Invoking Lambda functions from your RDS for PostgreSQL DB instance

Following, you can find several examples of calling the `aws_lambda.invoke` function. Most all the examples use the composite structure `aws_lambda_arn_1` that you create in Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional) to simplify passing the function details. For an example of asynchronous invocation, see Example: Asynchronous (Event) invocation of Lambda functions. All the other examples listed use synchronous invocation.

To learn more about Lambda invocation types, see Invoking Lambda functions in the AWS Lambda Developer Guide. For more information about `aws_lambda_arn_1`, see `aws_commons.create_lambda_function_arn`.

Examples list

- Example: Synchronous (RequestResponse) invocation of Lambda functions
- Example: Asynchronous (Event) invocation of Lambda functions
- Example: Capturing the Lambda execution log in a function response
- Example: Including client context in a Lambda function
- Example: Invoking a specific version of a Lambda function
Example: Synchronous (RequestResponse) invocation of Lambda functions

Following are two examples of a synchronous Lambda function invocation. The results of these `aws_lambda.invoke` function calls are the same.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':'json');
```

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':'json', 'RequestResponse');
```

The parameters are described as follows:

- `'aws_lambda_arn_1'` – This parameter identifies the composite structure created in Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional), with the `aws_commons.create_lambda_function_arn` helper function. You can also create this structure inline within your `aws_lambda.invoke` call as follows.

```
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function', 'aws-region'), '{"body": "Hello from Postgres!"}':'json');
```

- '{"body": "Hello from PostgreSQL!"}':'json' – The JSON payload to pass to the Lambda function.

- 'RequestResponse' – The Lambda invocation type.

Example: Asynchronous (Event) invocation of Lambda functions

Following is an example of an asynchronous Lambda function invocation. The Event invocation type schedules the Lambda function invocation with the specified input payload and returns immediately. Use the Event invocation type in certain workflows that don't depend on the results of the Lambda function.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':'json', 'Event');
```
Example: Capturing the Lambda execution log in a function response

You can include the last 4 KB of the execution log in the function response by using the log_type parameter in your aws_lambda.invoke function call. By default, this parameter is set to None, but you can specify Tail to capture the results of the Lambda execution log in the response, as shown following.

```sql
SELECT *, select convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json, 'RequestResponse', 'Tail');
```

Set the aws_lambda.invoke function's log_type parameter to Tail to include the execution log in the response. The default value for the log_type parameter is None.

The log_result that's returned is a base64 encoded string. You can decode the contents using a combination of the decode and convert_from PostgreSQL functions.

For more information about log_type, see aws_lambda.invoke.

Example: Including client context in a Lambda function

The aws_lambda.invoke function has a context parameter that you can use to pass information separate from the payload, as shown following.

```sql
SELECT *, convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json, 'RequestResponse', 'Tail');
```

To include client context, use a JSON object for the aws_lambda.invoke function's context parameter.

For more information about the context parameter, see the aws_lambda.invoke reference.

Example: Invoking a specific version of a Lambda function

You can specify a particular version of a Lambda function by including the qualifier parameter with the aws_lambda.invoke call. Following, you can find an example that does this using 'custom_version' as an alias for the version.

```sql
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json, 'RequestResponse', 'None', NULL, 'custom_version');
```
You can also supply a Lambda function qualifier with the function name details instead, as follows.

```sql
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function:custom_version', 'us-west-2'),
'{"body": "Hello from Postgres!"}':::json);
```

For more information about qualifier and other parameters, see the `aws_lambda.invoke` reference.

### Lambda function error messages

In the following list you can find information about error messages, with possible causes and solutions.

- **VPC configuration issues**

  VPC configuration issues can raise the following error messages when trying to connect:

  ```
  ERROR: invoke API failed
  DETAIL: AWS Lambda client returned 'Unable to connect to endpoint'.
  CONTEXT: SQL function "invoke" statement 1
  ```

  A common cause for this error is improperly configured VPC security group. Make sure you have an outbound rule for TCP open on port 443 of your VPC security group so that your VPC can connect to the Lambda VPC.

  If your DB instance is private, check the private DNS setup for your VPC. Make sure that you set the `rds.custom_dns_resolution` parameter to 1 and setup AWS PrivateLink as outlined in Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda. For more information, see Interface VPC endpoints (AWS PrivateLink).

- **Lack of permissions needed to invoke Lambda functions**

  If you see either of the following error messages, the user (role) invoking the function doesn't have proper permissions.

  ```
  ERROR: permission denied for schema aws_lambda
  ```

  ```
  ERROR: permission denied for function invoke
  ```
A user (role) must be given specific grants to invoke Lambda functions. For more information, see Step 6: Grant other users permission to invoke Lambda functions.

• Improper handling of errors in your Lambda functions

If a Lambda function throws an exception during request processing, `aws_lambda.invoke` fails with a PostgreSQL error such as the following.

```sql
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json);
ERROR:  lambda invocation failed
```

Be sure to handle errors in your Lambda functions or in your PostgreSQL application.

AWS Lambda function and parameter reference

Following is the reference for the functions and parameters to use for invoking Lambda with RDS for PostgreSQL.

Functions and parameters

• `aws_lambda.invoke`
• `aws_commons.create_lambda_function_arn`
• `aws_lambda parameters`

`aws_lambda.invoke` runs a Lambda function for an RDS for PostgreSQL DB instance.

For more details about invoking Lambda functions, see also Invoke in the AWS Lambda Developer Guide.

Syntax

JSON

```
aws_lambda.invoke()
```
aws_lambda.invoke(
  IN function_name TEXT,
  IN payload JSON,
  IN region TEXT DEFAULT NULL,
  IN invocation_type TEXT DEFAULT 'RequestResponse',
  IN log_type TEXT DEFAULT 'None',
  IN context JSON DEFAULT NULL,
  IN qualifier VARCHAR(128) DEFAULT NULL,
  OUT status_code INT,
  OUT payload JSON,
  OUT executed_version TEXT,
  OUT log_result TEXT)

aws_lambda.invoke(
  IN function_name aws_commons._lambda_function_arn_1,
  IN payload JSON,
  IN region TEXT DEFAULT NULL,
  IN invocation_type TEXT DEFAULT 'RequestResponse',
  IN log_type TEXT DEFAULT 'None',
  IN context JSON DEFAULT NULL,
  IN qualifier VARCHAR(128) DEFAULT NULL,
  OUT status_code INT,
  OUT payload JSON,
  OUT executed_version TEXT,
  OUT log_result TEXT)

**JSONB**

aws_lambda.invoke(
  IN function_name TEXT,
  IN payload JSONB,
  IN region TEXT DEFAULT NULL,
  IN invocation_type TEXT DEFAULT 'RequestResponse',
  IN log_type TEXT DEFAULT 'None',
  IN context JSONB DEFAULT NULL,
  IN qualifier VARCHAR(128) DEFAULT NULL,
  OUT status_code INT,
  OUT payload JSONB,
  OUT executed_version TEXT,
  OUT log_result TEXT)

aws_lambda.invoke(
  IN function_name aws_commons._lambda_function_arn_1,
  IN payload JSONB,
IN invocation_type TEXT DEFAULT 'RequestResponse',
IN log_type TEXT DEFAULT 'None',
IN context JSONB DEFAULT NULL,
IN qualifier VARCHAR(128) DEFAULT NULL,
OUT status_code INT,
OUT payload JSONB,
OUT executed_version TEXT,
OUT log_result TEXT
)

**Input parameters**

*function_name*

The identifying name of the Lambda function. The value can be the function name, an ARN, or a partial ARN. For a listing of possible formats, see [Lambda function name formats](#) in the AWS Lambda Developer Guide.

*payload*

The input for the Lambda function. The format can be JSON or JSONB. For more information, see [JSON Types](#) in the PostgreSQL documentation.

*region*

(Optional) The Lambda Region for the function. By default, RDS resolves the AWS Region from the full ARN in the function_name or it uses the RDS for PostgreSQL DB instance Region. If this Region value conflicts with the one provided in the function_name ARN, an error is raised.

*invocation_type*

The invocation type of the Lambda function. The value is case-sensitive. Possible values include the following:

- **RequestResponse** – The default. This type of invocation for a Lambda function is synchronous and returns a response payload in the result. Use the RequestResponse invocation type when your workflow depends on receiving the Lambda function result immediately.

- **Event** – This type of invocation for a Lambda function is asynchronous and returns immediately without a returned payload. Use the Event invocation type when you don't need results of the Lambda function before your workflow moves on.

- **DryRun** – This type of invocation tests access without running the Lambda function.
**log_type**

The type of Lambda log to return in the `log_result` output parameter. The value is case-sensitive. Possible values include the following:

- Tail – The returned `log_result` output parameter will include the last 4 KB of the execution log.
- None – No Lambda log information is returned.

**context**

Client context in JSON or JSONB format. Fields to use include than custom and `env`.

**qualifier**

A qualifier that identifies a Lambda function's version to be invoked. If this value conflicts with one provided in the `function_name` ARN, an error is raised.

**Output parameters**

**status_code**

An HTTP status response code. For more information, see [Lambda Invoke response elements](https://docs.aws.amazon.com/lambda/latest/dg/http-request-response.html) in the AWS Lambda Developer Guide.

**payload**

The information returned from the Lambda function that ran. The format is in JSON or JSONB.

**executed_version**

The version of the Lambda function that ran.

**log_result**

The execution log information returned if the `log_type` value is Tail when the Lambda function was invoked. The result contains the last 4 KB of the execution log encoded in Base64.

**aws_commons.create_lambda_function_arn**

Creates an `aws_commons._lambda_function_arn_1` structure to hold Lambda function name information. You can use the results of the `aws_commons.create_lambda_function_arn` function in the `function_name` parameter of the `aws_lambda.invoke` function.
Syntax

```python
aws_commons.create_lambda_function_arn(
    function_name TEXT,
    region TEXT DEFAULT NULL
)
RETURNS aws_commons._lambda_function_arn_1
```

Input parameters

`function_name`

A required text string containing the Lambda function name. The value can be a function name, a partial ARN, or a full ARN.

`region`

An optional text string containing the AWS Region that the Lambda function is in. For a listing of Region names and associated values, see [Regions, Availability Zones, and Local Zones](#).

aws_lambda parameters

In this table, you can find parameters associated with the aws_lambda function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws_lambda.connect_timeout_ms</td>
<td>This is a dynamic parameter and it sets the maximum wait time while connecting to AWS Lambda. The default value is 1000. Allowed values for this parameter are 1 - 900000.</td>
</tr>
<tr>
<td>aws_lambda.request_timeout_ms</td>
<td>This is a dynamic parameter and it sets the maximum wait time while waiting for response from AWS Lambda. The default value is 3000. Allowed values for this parameter are 1 - 900000.</td>
</tr>
<tr>
<td>aws_lambda.endpoint_override</td>
<td>Specifies the endpoint that can be used to connect to AWS Lambda. An empty string selects the default AWS Lambda endpoint for the region. You must restart the database for this static parameter change to take effect.</td>
</tr>
</tbody>
</table>
Common DBA tasks for Amazon RDS for PostgreSQL

Database administrators (DBAs) perform a variety of tasks when administering an Amazon RDS for PostgreSQL DB instance. If you're a DBA already familiar with PostgreSQL, you need to be aware of some of the important differences between running PostgreSQL on your hardware and RDS for PostgreSQL. For example, because it's a managed service, Amazon RDS doesn't allow shell access to your DB instances. That means that you don't have direct access to pg_hba.conf and other configuration files. For RDS for PostgreSQL, changes that are typically made to the PostgreSQL configuration file of an on-premises instance are made to a custom DB parameter group associated with the RDS for PostgreSQL DB instance. For more information, see Working with parameter groups.

You also can’t access log files in the same way that you do with an on-premises PostgreSQL instance. To learn more about logging, see RDS for PostgreSQL database log files.

As another example, you don't have access to the PostgreSQL superuser account. On RDS for PostgreSQL, the rds_superuser role is the most highly privileged role, and it's granted to postgres at set up time. Whether you're familiar with using PostgreSQL on-premises or completely new to RDS for PostgreSQL, we recommend that you understand the rds_superuser role, and how to work with roles, users, groups, and permissions. For more information, see Understanding PostgreSQL roles and permissions.

Following are some common DBA tasks for RDS for PostgreSQL.

Topics

- Collations supported in RDS for PostgreSQL
- Understanding PostgreSQL roles and permissions
- Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL
- Working with logging mechanisms supported by RDS for PostgreSQL
- Managing temporary files with PostgreSQL
- Using pgBadger for log analysis with PostgreSQL
- Using PGSnapper for monitoring PostgreSQL
- Working with parameters on your RDS for PostgreSQL DB instance
Collations supported in RDS for PostgreSQL

Collations are set of rules that determine how character strings stored in the database are sorted and compared. Collations play a fundamental role in the computer system and are included as part of the operating system. Collations change over time when new characters are added to languages or when ordering rules change.

Collation libraries define specific rules and algorithms for a collation. The most popular collation libraries used within PostgreSQL are GNU C (glibc) and Internationalization components for Unicode (ICU). By default, RDS for PostgreSQL uses the glibc collation that includes unicode character sort orders for multi-byte character sequences.

When you create a new DB instance in RDS for PostgreSQL, it checks the operating system for the available collation. The PostgreSQL parameters of the CREATE DATABASE command LC_COLLATE and LC_CTYPE are used to specify a collation, which stands as the default collation in that database. Alternatively, you can also use the LOCALE parameter in CREATE DATABASE to set these parameters. This determines the default collation for character strings in the database and the rules for classifying characters as letters, numbers, or symbols. You can also choose a collation to use on a column, index, or on a query.

RDS for PostgreSQL depends on the glibc library in the operating system for collation support. RDS for PostgreSQL instance is periodically updated with the latest versions of the operating system. These updates sometimes include a newer version of the glibc library. Rarely, newer versions of glibc change the sort order or collation of some characters, which can cause the data to sort differently or produce invalid index entries. If you discover sort order issues for collation during an update, you might need to rebuild the indexes.

To reduce the possible impacts of the glibc updates, RDS for PostgreSQL now includes an independent default collation library. This collation library is available in RDS for PostgreSQL 14.6, 13.9, 12.13, 11.18, 10.23 and newer minor version releases. It is compatible with glibc 2.26-59.amzn2, and provides sort order stability to prevent incorrect query results.

Understanding PostgreSQL roles and permissions

When you create an RDS for PostgreSQL DB instance using the AWS Management Console, an administrator account is created at the same time. By default, its name is postgres, as shown in the following screenshot:
You can choose another name rather than accept the default (postgres). If you do, the name you choose must start with a letter and be between 1 and 16 alphanumeric characters. For simplicity's sake, we refer to this main user account by its default value (postgres) throughout this guide.

If you use the create-db-instance AWS CLI rather than the AWS Management Console, you create the name by passing it with the master-username parameter in the command. For more information, see [Creating an Amazon RDS DB instance](#).

Whether you use the AWS Management Console, the AWS CLI, or the Amazon RDS API, and whether you use the default postgres name or choose a different name, this first database user account is a member of the rds_superuser group and has rds_superuser privileges.

**Topics**

- [Understanding the rds_superuser role](#)
- [Controlling user access to the PostgreSQL database](#)
- [Delegating and controlling user password management](#)
- [Using SCRAM for PostgreSQL password encryption](#)

**Understanding the rds_superuser role**

In PostgreSQL, a role can define a user, a group, or a set of specific permissions granted to a group or user for various objects in the database. PostgreSQL commands to CREATE USER and CREATE GROUP have been replaced by the more general, CREATE ROLE with specific properties to distinguish database users. A database user can be thought of as a role with the LOGIN privilege.
The postgres user is the most highly privileged database user on your RDS for PostgreSQL DB instance. It has the characteristics defined by the following CREATE ROLE statement.

```
CREATE ROLE postgres WITH LOGIN NOSUPERUSER INHERIT CREATEDB CREATEROLE NOREPLICATION VALID UNTIL 'infinity'
```

The properties NOSUPERUSER, NOREPLICATION, INHERIT, and VALID UNTIL 'infinity' are the default options for CREATE ROLE, unless otherwise specified.

By default, postgres has privileges granted to the rds_superuser role, and permissions to create roles and databases. The rds_superuser role allows the postgres user to do the following:

- Add extensions that are available for use with Amazon RDS. For more information, see Working with PostgreSQL features supported by Amazon RDS for PostgreSQL
- Create roles for users and grant privileges to users. For more information, see CREATE ROLE and GRANT in the PostgreSQL documentation.
- Create databases. For more information, see CREATE DATABASE in the PostgreSQL documentation.
- Grant rds_superuser privileges to user roles that don't have these privileges, and revoke privileges as needed. We recommend that you grant this role only to those users who perform superuser tasks. In other words, you can grant this role to database administrators (DBAs) or system administrators.
- Grant (and revoke) the rds_replication role to database users that don't have the rds_superuser role.
- Grant (and revoke) the rds_password role to database users that don't have the rds_superuser role.
- Obtain status information about all database connections by using the pg_stat_activity view. When needed, rds_superuser can stop any connections by using pg_terminate_backend or pg_cancel_backend.
In the CREATE ROLE postgres... statement, you can see that the postgres user role specifically disallows PostgreSQL superuser permissions. RDS for PostgreSQL is a managed service, so you can't access the host OS, and you can't connect using the PostgreSQL superuser account. Many of the tasks that require superuser access on a stand-alone PostgreSQL are managed automatically by Amazon RDS.

For more information about granting privileges, see GRANT in the PostgreSQL documentation.

The rds_superuser role is one of several predefined roles in an RDS for PostgreSQL DB instance.

⚠️ Note

In PostgreSQL 13 and earlier releases, predefined roles are known as default roles.

In the following list, you find some of the other predefined roles that are created automatically for a new RDS for PostgreSQL DB instance. Predefined roles and their privileges can't be changed. You can't drop, rename, or modify privileges for these predefined roles. Attempting to do so results in an error.

- **rds_password** – A role that can change passwords and set up password constraints for database users. The rds_superuser role is granted with this role by default, and can grant the role to database users. For more information, see Controlling user access to the PostgreSQL database.
  
  For RDS for PostgreSQL versions older than 14, rds_password role can change passwords and set up password constraints for database users and users with rds_superuser role. From RDS for PostgreSQL version 14 and later, rds_password role can change passwords and set up password constraints only for database users. Only users with rds_superuser role can perform these actions on other users with rds_superuser role.

- **rdsadmin** – A role that's created to handle many of the management tasks that the administrator with superuser privileges would perform on a standalone PostgreSQL database. This role is used internally by RDS for PostgreSQL for many management tasks.

- **rdstopmgr** – A role that's used internally by Amazon RDS to support Multi-AZ deployments.

To see all predefined roles, you can connect to your RDS for PostgreSQL DB instance and use the psql \du metacommand. The output looks as follows:

<table>
<thead>
<tr>
<th>List of roles</th>
</tr>
</thead>
</table>
In the output, you can see that `rds_superuser` isn't a database user role (it can't login), but it has the privileges of many other roles. You can also see that database user `postgres` is a member of the `rds_superuser` role. As mentioned previously, `postgres` is the default value in the Amazon RDS console's `Create database` page. If you chose another name, that name is shown in the list of roles instead.

**Controlling user access to the PostgreSQL database**

New databases in PostgreSQL are always created with a default set of privileges in the database's public schema that allow all database users and roles to create objects. These privileges allow database users to connect to the database, for example, and create temporary tables while connected.

To better control user access to the databases instances that you create on your RDS for PostgreSQL DB instance, we recommend that you revoke these default public privileges. After doing so, you then grant specific privileges for database users on a more granular basis, as shown in the following procedure.

**To set up roles and privileges for a new database instance**

Suppose you're setting up a database on a newly created RDS for PostgreSQL DB instance for use by several researchers, all of whom need read-write access to the database.

1. Use `psql` (or pgAdmin) to connect to your RDS for PostgreSQL DB instance:

   ```bash
   psql --host=your-db-instance.666666666666.aws-region.rds.amazonaws.com --port=5432
   --username=postgres --password
   
   When prompted, enter your password. The `psql` client connects and displays the default administrative connection database, `postgres=>`, as the prompt.
   ```

2. To prevent database users from creating objects in the public schema, do the following:
3. Next, you create a new database instance:

```
postgres=> CREATE DATABASE lab_db;
```

4. Revoke all privileges from the PUBLIC schema on this new database.

```
postgres=> REVOKE ALL ON DATABASE lab_db FROM public;
```

5. Create a role for database users.

```
postgres=> CREATE ROLE lab_tech;
```

6. Give database users that have this role the ability to connect to the database.

```
postgres=> GRANT CONNECT ON DATABASE lab_db TO lab_tech;
```

7. Grant all users with the lab_tech role all privileges on this database.

```
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_db TO lab_tech;
```

8. Create database users, as follows:

```
postgres=> CREATE ROLE lab_user1 LOGIN PASSWORD 'change_me';
postgres=> CREATE ROLE lab_user2 LOGIN PASSWORD 'change_me';
```

9. Grant these two users the privileges associated with the lab_tech role:

```
postgres=> GRANT lab_tech TO lab_user1;
postgres=> GRANT lab_tech TO lab_user2;
```
At this point, `lab_user1` and `lab_user2` can connect to the `lab_db` database. This example doesn't follow best practices for enterprise usage, which might include creating multiple database instances, different schemas, and granting limited permissions. For more complete information and additional scenarios, see Managing PostgreSQL Users and Roles.

For more information about privileges in PostgreSQL databases, see the GRANT command in the PostgreSQL documentation.

**Delegating and controlling user password management**

As a DBA, you might want to delegate the management of user passwords. Or, you might want to prevent database users from changing their passwords or reconfiguring password constraints, such as password lifetime. To ensure that only the database users that you choose can change password settings, you can turn on the restricted password management feature. When you activate this feature, only those database users that have been granted the `rds_password` role can manage passwords.

### Note

To use restricted password management, your RDS for PostgreSQL DB instance must be running PostgreSQL 10.6 or higher.

By default, this feature is off, as shown in the following:

```sql
postgres=> SHOW rds.restrict_password_commands;
  rds.restrict_password_commands
-----------------------------
     off
(1 row)
```

To turn on this feature, you use a custom parameter group and change the setting for `rds.restrict_password_commands` to 1. Be sure to reboot your RDS for PostgreSQL DB instance so that the setting takes effect.

With this feature active, `rds_password` privileges are needed for the following SQL commands:

```sql
CREATE ROLE myrole WITH PASSWORD 'mypassword';
CREATE ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
ALTER ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
```
ALTER ROLE myrole WITH PASSWORD 'mypassword';
ALTER ROLE myrole VALID UNTIL '2023-01-01';
ALTER ROLE myrole RENAME TO myrole2;

Renaming a role (ALTER ROLE myrole RENAME TO newname) is also restricted if the password uses the MD5 hashing algorithm.

With this feature active, attempting any of these SQL commands without the rds_password role permissions generates the following error:

ERROR: must be a member of rds_password to alter passwords

We recommend that you grant the rds_password to only a few roles that you use solely for password management. If you grant rds_password privileges to database users that don't have rds_superuser privileges, you need to also grant them the CREATEROLE attribute.

Make sure that you verify password requirements such as expiration and needed complexity on the client side. If you use your own client-side utility for password related changes, the utility needs to be a member of rds_password and have CREATE ROLE privileges.

**Using SCRAM for PostgreSQL password encryption**

The *Salted Challenge Response Authentication Mechanism (SCRAM)* is an alternative to PostgreSQL's default message digest (MD5) algorithm for encrypting passwords. The SCRAM authentication mechanism is considered more secure than MD5. To learn more about these two different approaches to securing passwords, see [Password Authentication](https://www.postgresql.org/docs/current/static/auth-pam.html) in the PostgreSQL documentation.

We recommend that you use SCRAM rather than MD5 as the password encryption scheme for your RDS for PostgreSQL DB instance. It's a cryptographic challenge-response mechanism that uses the scram-sha-256 algorithm for password authentication and encryption.

You might need to update libraries for your client applications to support SCRAM. For example, JDBC versions before 42.2.0 don't support SCRAM. For more information, see [PostgreSQL JDBC Driver](https://jdbc.postgresql.org/) in the PostgreSQL JDBC Driver documentation. For a list of other PostgreSQL drivers and SCRAM support, see [List of drivers](https://www.postgresql.org/docs/current/interfaces.html) in the PostgreSQL documentation.

---

**Note**

RDS for PostgreSQL version 13.1 and higher support scram-sha-256. These versions also let you configure your DB instance to require SCRAM, as discussed in the following procedures.
Setting up RDS for PostgreSQL DB instance to require SCRAM

you can require the RDS for PostgreSQL DB instance to accept only passwords that use the scram-sha-256 algorithm.

⚠️ Important

For existing RDS Proxies with PostgreSQL databases, if you modify the database authentication to use SCRAM only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:

- Ensure that the database allows both SCRAM and MD5 authentication.
- To use only SCRAM authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

Before making changes to your system, be sure you understand the complete process, as follows:

- Get information about all roles and password encryption for all database users.
- Double-check the parameter settings for your RDS for PostgreSQL DB instance for the parameters that control password encryption.
- If your RDS for PostgreSQL DB instance uses a default parameter group, you need to create a custom DB parameter group and apply it to your RDS for PostgreSQL DB instance so that you can modify parameters when needed. If your RDS for PostgreSQL DB instance uses a custom parameter group, you can modify the necessary parameters later in the process, as needed.
- Change the password_encryption parameter to scram-sha-256.
- Notify all database users that they need to update their passwords. Do the same for your postgres account. The new passwords are encrypted and stored using the scram-sha-256 algorithm.
- Verify that all passwords are encrypted using as the type of encryption.
- If all passwords use scram-sha-256, you can change the rds.accepted_password_auth_method parameter from md5+scram to scram-sha-256.
Warning

After you change `rds.accepted_password_auth_method` to `scram-sha-256` alone, any users (roles) with md5-encrypted passwords can't connect.

Getting ready to require SCRAM for your RDS for PostgreSQL DB instance

Before making any changes to your RDS for PostgreSQL DB instance, check all existing database user accounts. Also, check the type of encryption used for passwords. You can do these tasks by using the `rds_tools` extension. This extension is supported on RDS for PostgreSQL 13.1 and higher releases.

To get a list of database users (roles) and password encryption methods

1. Use `psql` to connect to your RDS for PostgreSQL DB instance, as shown in the following.

   ```bash
   psql --host=db-name.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Install the `rds_tools` extension.

   ```sql
   postgres=> CREATE EXTENSION rds_tools;
   CREATE EXTENSION
   ```

3. Get a listing of roles and encryption.

   ```sql
   postgres=> SELECT * FROM rds_tools.role_password_encryption_type();
   ```

You see output similar to the following.

```text
rolname             | encryption_type
--------------------+---------------------
pg_monitor          |                     
pg_read_all_settings|                     
pg_read_all_stats   |                     
pg_stat_scan_tables |                     
pg_signal_backend   |                     
lab_tester          | md5                 
user_465            | md5                 
```
Creating a custom DB parameter group

Note

If your RDS for PostgreSQL DB instance already uses a custom parameter group, you don't need to create a new one.

For an overview of parameter groups for Amazon RDS, see Working with parameters on your RDS for PostgreSQL DB instance.

The password encryption type used for passwords is set in one parameter, password_encryption. The encryption that the RDS for PostgreSQL DB instance allows is set in another parameter, rds.accepted_password_auth_method. Changing either of these from the default values requires that you create a custom DB parameter group and apply it to your instance.

You can also use the AWS Management Console or the RDS API to create a custom DB parameter group. For more information, see

You can now associate the custom parameter group with your DB instance.

To create a custom DB parameter group

1. Use the create-db-parameter-group CLI command to create the custom DB parameter group. This example uses postgres13 as the source for this custom parameter group.

For Linux, macOS, or Unix:

```bash
aws rds create-db-parameter-group --db-parameter-group-name 'docs-lab-scram-passwords' \
    --db-parameter-group-family postgres13 --description 'Custom parameter group for SCRAM'
```

For Windows:

```bash
aws rds create-db-parameter-group --db-parameter-group-name "docs-lab-scram-passwords" ^
```
2. Use the `modify-db-instance` CLI command to apply this custom parameter group to your RDS for PostgreSQL DB cluster.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance --db-instance-identifier 'your-instance-name' \
  --db-parameter-group-name "docs-lab-scram-passwords"
```

For Windows:

```
aws rds modify-db-instance --db-instance-identifier "your-instance-name" ^
  --db-parameter-group-name "docs-lab-scram-passwords"
```

To resynchronize your RDS for PostgreSQL DB instance with your custom DB parameter group, you need to reboot the primary and all other instances of the cluster. To minimize impact to your users, schedule this to occur during your regular maintenance window.

**Configuring password encryption to use SCRAM**

The password encryption mechanism used by an RDS for PostgreSQL DB instance is set in the DB parameter group in the `password_encryption` parameter. Allowed values are unset, `md5`, or `scram-sha-256`. The default value depends on the RDS for PostgreSQL version, as follows:

- RDS for PostgreSQL 14 and above – Default is `scram-sha-256`
- RDS for PostgreSQL 13 – Default is `md5`

With a custom DB parameter group attached to your RDS for PostgreSQL DB instance, you can modify values for the password encryption parameter.

<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Allowed values</th>
<th>Modifiable</th>
<th>Source</th>
<th>Apply type</th>
</tr>
</thead>
<tbody>
<tr>
<td>password_encryption</td>
<td>md5</td>
<td>md5, scram-sha-256</td>
<td>true</td>
<td>system</td>
<td>dynamic</td>
</tr>
<tr>
<td>rds.accepted_password_auth_method</td>
<td>md5+scram, scram</td>
<td>md5+scram, scram</td>
<td>true</td>
<td>system</td>
<td>dynamic</td>
</tr>
</tbody>
</table>
To change password encryption setting to scram-sha-256

- Change the value of password encryption to scram-sha-256, as shown following. The change can be applied immediately because the parameter is dynamic, so a restart isn't required for the change to take effect.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group --db-parameter-group-name 'docs-lab-scram-passwords' --parameters 'ParameterName=password_encryption,ParameterValue=scram-sha-256,ApplyMethod=immediate'
```

For Windows:

```bash
aws rds modify-db-parameter-group --db-parameter-group-name ^
"docs-lab-scram-passwords" --parameters
"ParameterName=password_encryption,ParameterValue=scram-sha-256,ApplyMethod=immediate"
```

Migrating passwords for user roles to SCRAM

You can migrate passwords for user roles to SCRAM as described following.

To migrate database user (role) passwords from MD5 to SCRAM

1. Log in as the administrator user (default user name, postgres) as shown following.

   ```bash
   psql --host=\$db-name.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Check the setting of the password_encryption parameter on your RDS for PostgreSQL DB instance by using the following command.

   ```bash
   postgres=> SHOW password_encryption;
   password_encryption
   ------------------------
   md5
   (1 row)
   ```
3. Change the value of this parameter to scram-sha-256. This is a dynamic parameter, so you don't need to reboot the instance after making this change. Check the value again to make sure that it's now set to **scram-sha-256**, as follows.

```sql
postgres=> SHOW password_encryption;
password_encryption
---------------------
scram-sha-256
(1 row)
```

4. Notify all database users to change their passwords. Be sure to also change your own password for account **postgres** (the database user with **rds_superuser** privileges).

```
labdb=> ALTER ROLE postgres WITH LOGIN PASSWORD 'change_me';
ALTER ROLE
```

5. Repeat the process for all databases on your RDS for PostgreSQL DB instance.

**Changing parameter to require SCRAM**

This is the final step in the process. After you make the change in the following procedure, any user accounts (roles) that still use md5 encryption for passwords can't log in to the RDS for PostgreSQL DB instance.

The `rds.accepted_password_auth_method` specifies the encryption method that the RDS for PostgreSQL DB instance accepts for a user password during the login process. The default value is `md5+scram`, meaning that either method is accepted. In the following image, you can find the default setting for this parameter.

![Parameter settings](image)

The allowed values for this parameter are `md5+scram` or `scram` alone. Changing this parameter value to `scram` makes this a requirement.
To change the parameter value to require SCRAM authentication for passwords

1. Verify that all database user passwords for all databases on your RDS for PostgreSQL DB instance use scram-sha-256 for password encryption. To do so, query `rds_tools` for the role (user) and encryption type, as follows.

```sql
postgres=> SELECT * FROM rds_tools.role_password_encryption_type();
```

```
rolname        | encryption_type
----------------+-----------------
pg_monitor      |              
pg_read_all_settings |            
pg_read_all_stats  |              
pg_stat_scan_tables |              
pg_signal_backend  |              
lab_tester      | scram-sha-256 
user_465        | scram-sha-256 
postgres        | scram-sha-256 
(rows)
```

2. Repeat the query across all DB instances in your RDS for PostgreSQL DB instance.

If all passwords use scram-sha-256, you can proceed.

3. Change the value of the accepted password authentication to scram-sha-256, as follows.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group --db-parameter-group-name 'docs-lab-scram-passwords' \
   --parameters
   'ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediate'
```

For Windows:

```bash
aws rds modify-db-parameter-group --db-parameter-group-name "docs-lab-scram-passwords" ^ \
   --parameters
   "ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediate"
```
Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL

We strongly recommend that you use the autovacuum feature to maintain the health of your PostgreSQL DB instance. Autovacuum automates the start of the VACUUM and the ANALYZE commands. It checks for tables with a large number of inserted, updated, or deleted tuples. After this check, it reclaims storage by removing obsolete data or tuples from the PostgreSQL database.

By default, autovacuum is turned on for the Amazon RDS for PostgreSQL DB instances that you create using any of the default PostgreSQL DB parameter groups. These include default.postgres10, default.postgres11, and so on. All default PostgreSQL DB parameter groups have an rds.adaptive_autovacuum parameter that's set to 1, thus activating the feature. Other configuration parameters associated with the autovacuum feature are also set by default. Because these defaults are somewhat generic, you can benefit from tuning some of the parameters associated with the autovacuum feature for your specific workload.

Following, you can find more information about the autovacuum and how to tune some of its parameters on your RDS for PostgreSQL DB instance. For high-level information, see Best practices for working with PostgreSQL.

Topics

- Allocating memory for autovacuum
- Reducing the likelihood of transaction ID wraparound
- Determining if the tables in your database need vacuuming
- Determining which tables are currently eligible for autovacuum
- Determining if autovacuum is currently running and for how long
- Performing a manual vacuum freeze
- Reindexing a table when autovacuum is running
- Managing autovacuum with large indexes
- Other parameters that affect autovacuum
- Setting table-level autovacuum parameters
- Logging autovacuum and vacuum activities
Allocating memory for autovacuum

One of the most important parameters influencing autovacuum performance is the `maintenance_work_mem` parameter. This parameter determines how much memory that you allocate for autovacuum to use to scan a database table and to hold all the row IDs that are going to be vacuumed. If you set the value of the `maintenance_work_mem` parameter too low, the vacuum process might have to scan the table multiple times to complete its work. Such multiple scans can have a negative impact on performance.

When doing calculations to determine the `maintenance_work_mem` parameter value, keep in mind two things:

- The default unit is kilobytes (KB) for this parameter.
- The `maintenance_work_mem` parameter works in conjunction with the `autovacuum_max_workers` parameter. If you have many small tables, allocate more `autovacuum_max_workers` and less `maintenance_work_mem`. If you have large tables (say, larger than 100 GB), allocate more memory and fewer worker processes. You need to have enough memory allocated to succeed on your biggest table. Each `autovacuum_max_workers` can use the memory that you allocate. Thus, make sure that the combination of worker processes and memory equal the total memory that you want to allocate.

In general terms, for large hosts set the `maintenance_work_mem` parameter to a value between one and two gigabytes (between 1,048,576 and 2,097,152 KB). For extremely large hosts, set the parameter to a value between two and four gigabytes (between 2,097,152 and 4,194,304 KB). The value that you set for this parameter depends on the workload. Amazon RDS has updated its default for this parameter to be kilobytes calculated as follows.

\[
\text{GREATEST}\left(\frac{\text{DBInstanceClassMemory}}{63963136*1024},65536\right).
\]

Reducing the likelihood of transaction ID wraparound

In some cases, parameter group settings related to autovacuum might not be aggressive enough to prevent transaction ID wraparound. To address this, RDS for PostgreSQL provides a mechanism that adapts the autovacuum parameter values automatically. Adaptive autovacuum parameter tuning is a feature for RDS for PostgreSQL. A detailed explanation of TransactionID wraparound is found in the PostgreSQL documentation.

Adaptive autovacuum parameter tuning is turned on by default for RDS for PostgreSQL instances with the dynamic parameter `rds.adaptive_autovacuum` set to ON. We strongly recommend...
that you keep this turned on. However, to turn off adaptive autovacuum parameter tuning, set the `rds.adaptive_autovacuum` parameter to 0 or OFF.

Transaction ID wraparound is still possible even when Amazon RDS tunes the autovacuum parameters. We encourage you to implement an Amazon CloudWatch alarm for transaction ID wraparound. For more information, see the post [Implement an early warning system for transaction ID wraparound in RDS for PostgreSQL](https://aws.amazon.com/blogs/database/implement-an-early-warning-system-for-transaction-id-wraparound-in-rds-for-postgresql/) on the AWS Database Blog.

With adaptive autovacuum parameter tuning turned on, Amazon RDS begins adjusting autovacuum parameters when the CloudWatch metric `MaximumUsedTransactionIDs` reaches the value of the `autovacuum_freeze_max_age` parameter or 500,000,000, whichever is greater.

Amazon RDS continues to adjust parameters for autovacuum if a table continues to trend toward transaction ID wraparound. Each of these adjustments dedicates more resources to autovacuum to avoid wraparound. Amazon RDS updates the following autovacuum-related parameters:

- `autovacuum_vacuum_cost_delay`
- `autovacuum_vacuum_cost_limit`
- `autovacuum_work_mem`
- `autovacuum_naptime`

RDS modifies these parameters only if the new value makes autovacuum more aggressive. The parameters are modified in memory on the DB instance. The values in the parameter group aren't changed. To view the current in-memory settings, use the PostgreSQL `SHOW` SQL command.

When Amazon RDS modifies any of these autovacuum parameters, it generates an event for the affected DB instance. This event is visible on the AWS Management Console and through the Amazon RDS API. After the `MaximumUsedTransactionIDs` CloudWatch metric returns below the threshold, Amazon RDS resets the autovacuum-related parameters in memory back to the values specified in the parameter group. It then generates another event corresponding to this change.

**Determining if the tables in your database need vacuuming**

You can use the following query to show the number of unvacuumed transactions in a database. The `datfrozenxid` column of a database's `pg_database` row is a lower bound on the normal transaction IDs appearing in that database. This column is the minimum of the per-table `relfrozenxid` values within the database.
For example, the results of running the preceding query might be the following.

<table>
<thead>
<tr>
<th>datname</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydb</td>
<td>1771757888</td>
</tr>
<tr>
<td>template0</td>
<td>1721757888</td>
</tr>
<tr>
<td>template1</td>
<td>1721757888</td>
</tr>
<tr>
<td>rdsadmin</td>
<td>1694008527</td>
</tr>
<tr>
<td>postgres</td>
<td>1693881061</td>
</tr>
</tbody>
</table>

(5 rows)

When the age of a database reaches 2 billion transaction IDs, transaction ID (XID) wraparound occurs and the database becomes read-only. You can use this query to produce a metric and run a few times a day. By default, autovacuum is set to keep the age of transactions to no more than 200,000,000 (`autovacuum_freeze_max_age`).

A sample monitoring strategy might look like this:

- Set the `autovacuum_freeze_max_age` value to 200 million transactions.
- If a table reaches 500 million unvacuumed transactions, that triggers a low-severity alarm. This isn't an unreasonable value, but it can indicate that autovacuum isn't keeping up.
- If a table ages to 1 billion, this should be treated as an alarm to take action on. In general, you want to keep ages closer to `autovacuum_freeze_max_age` for performance reasons. We recommend that you investigate using the recommendations that follow.
- If a table reaches 1.5 billion unvacuumed transactions, that triggers a high-severity alarm. Depending on how quickly your database uses transaction IDs, this alarm can indicate that the system is running out of time to run autovacuum. In this case, we recommend that you resolve this immediately.

If a table is constantly breaching these thresholds, modify your autovacuum parameters further. By default, using VACUUM manually (which has cost-based delays disabled) is more aggressive than using the default autovacuum, but it is also more intrusive to the system as a whole.

We recommend the following:
• Be aware and turn on a monitoring mechanism so that you are aware of the age of your oldest transactions.

For information on creating a process that warns you about transaction ID wraparound, see the AWS Database Blog post implement an early warning system for transaction ID wraparound in Amazon RDS for PostgreSQL.

• For busier tables, perform a manual vacuum freeze regularly during a maintenance window, in addition to relying on autovacuum. For information on performing a manual vacuum freeze, see Performing a manual vacuum freeze.

Determining which tables are currently eligible for autovacuum

Often, it is one or two tables in need of vacuuming. Tables whose relfrozenxid value is greater than the number of transactions in autovacuum_freeze_max_age are always targeted by autovacuum. Otherwise, if the number of tuples made obsolete since the last VACUUM exceeds the vacuum threshold, the table is vacuumed.

The autovacuum threshold is defined as:

\[
\text{Vacuum-threshold} = \text{vacuum-base-threshold} + \text{vacuum-scale-factor} \times \text{number-of-tuples}
\]

where the vacuum base threshold is autovacuum_vacuum_threshold, the vacuum scale factor is autovacuum_vacuum_scale_factor, and the number of tuples is pg_class.reltuples.

While you are connected to your database, run the following query to see a list of tables that autovacuum sees as eligible for vacuuming.

```
WITH vbt AS (SELECT setting AS autovacuum_vacuum_threshold FROM pg_settings WHERE name = 'autovacuum_vacuum_threshold'),
vsf AS (SELECT setting AS autovacuum_vacuum_scale_factor FROM pg_settings WHERE name = 'autovacuum_vacuum_scale_factor'),
fma AS (SELECT setting AS autovacuum_freeze_max_age FROM pg_settings WHERE name = 'autovacuum_freeze_max_age'),
sto AS (select opt_oid, split_part(setting, '=', 1) as param, split_part(setting, '=', 2) as value from (select oid opt_oid, unnest(reloptions) setting from pg_class) opt)
SELECT '"'||ns.nspname||'". '"'||c.relname||'"' as relation, pg_size_pretty(pg_table_size(c.oid)) as table_size,
```
Determining if autovacuum is currently running and for how long

If you need to manually vacuum a table, make sure to determine if autovacuum is currently running. If it is, you might need to adjust parameters to make it run more efficiently, or turn off autovacuum temporarily so that you can manually run VACUUM.

Use the following query to determine if autovacuum is running, how long it has been running, and if it is waiting on another session.

```
SELECT datname, usename, pid, state, wait_event, current_timestamp - xact_start AS xact_runtime, query
FROM pg_stat_activity
WHERE upper(query) LIKE '%%VACUUM%%'
ORDER BY xact_start;
```

After running the query, you should see output similar to the following.

```
<table>
<thead>
<tr>
<th>datname</th>
<th>usename</th>
<th>pid</th>
<th>state</th>
<th>wait_event</th>
<th>xact_runtime</th>
<th>query</th>
</tr>
</thead>
<tbody>
<tr>
<td>--------+---------+-----+-------+------------+--------------+-------</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>+-----------------------------------------------+---------------</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
Several issues can cause a long-running autovacuum session (that is, multiple days long). The most common issue is that your `maintenance_work_mem` parameter value is set too low for the size of the table or rate of updates.

We recommend that you use the following formula to set the `maintenance_work_mem` parameter value:

\[
\text{GREATEST}\left(\frac{\text{DBInstanceClassMemory}}{63963136} \times 1024, 65536\right)
\]

Short running autovacuum sessions can also indicate problems:

- It can indicate that there aren't enough `autovacuum_max_workers` for your workload. In this case, you need to indicate the number of workers.

- It can indicate that there is an index corruption (autovacuum crashes and restarts on the same relation but makes no progress). In this case, run a manual `vacuum freeze verbose table` to see the exact cause.
Performing a manual vacuum freeze

You might want to perform a manual vacuum on a table that has a vacuum process already running. This is useful if you have identified a table with an age approaching 2 billion transactions (or above any threshold you are monitoring).

The following steps are guidelines, with several variations to the process. For example, during testing, suppose that you find that the `maintenance_work_mem` parameter value is set too small and that you need to take immediate action on a table. However, perhaps you don't want to bounce the instance at the moment. Using the queries in previous sections, you determine which table is the problem and notice a long running autovacuum session. You know that you need to change the `maintenance_work_mem` parameter setting, but you also need to take immediate action and vacuum the table in question. The following procedure shows what to do in this situation.

To manually perform a vacuum freeze

1. Open two sessions to the database containing the table you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.

2. In session one, get the process ID (PID) of the autovacuum session running on the table. Run the following query to get the PID of the autovacuum session.

   ```sql
   SELECT datname, usename, pid, current_timestamp - xact_start AS xact_runtime, query
   FROM pg_stat_activity WHERE upper(query) LIKE '%VACUUM%' ORDER BY xact_start;
   ```

3. In session two, calculate the amount of memory that you need for this operation. In this example, we determine that we can afford to use up to 2 GB of memory for this operation, so we set `maintenance_work_mem` for the current session to 2 GB.

   ```sql
   SET maintenance_work_mem='2 GB';
   SET
   ```

4. In session two, issue a `vacuum freeze` verbose command for the table. The verbose setting is useful because, although there is no progress report for this in PostgreSQL currently, you can see activity.
5. In session one, if autovacuum was blocking the vacuum session, you see in `pg_stat_activity` that waiting is "T" for your vacuum session. In this case, you need to end the autovacuum process as follows.

```sql
SELECT pg_terminate_backend('the_pid');
```

At this point, your session begins. It's important to note that autovacuum restarts immediately because this table is probably the highest on its list of work.

6. Initiate your `vacuum freeze verbose` command in session two, and then end the autovacuum process in session one.

**Reindexing a table when autovacuum is running**

If an index has become corrupt, autovacuum continues to process the table and fails. If you attempt a manual vacuum in this situation, you receive an error message like the following.

```sql
postgres=> vacuum freeze pgbench_branches;
```
ERROR: index "pgbench_branches_test_index" contains unexpected zero page at block 30521
HINT: Please REINDEX it.

When the index is corrupted and autovacuum is attempting to run on the table, you contend with an already running autovacuum session. When you issue a REINDEX command, you take out an exclusive lock on the table. Write operations are blocked, and also read operations that use that specific index.

To reindex a table when autovacuum is running on the table

1. Open two sessions to the database containing the table that you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.
2. In session one, get the PID of the autovacuum session running on the table.

Run the following query to get the PID of the autovacuum session.

```
SELECT datname, usename, pid, current_timestamp - xact_start
AS xact_runtime, query
FROM pg_stat_activity WHERE upper(query) like '%VACUUM%' ORDER BY xact_start;
```

3. In session two, issue the reindex command.

```
\timing on
Timing is on.
reindex index pgbench_branches_test_index;
REINDEX
  Time: 9.966 ms
```

4. In session one, if autovacuum was blocking the process, you see in pg_stat_activity that waiting is "T" for your vacuum session. In this case, you end the autovacuum process.

```
SELECT pg_terminate_backend('the_pid');
```

At this point, your session begins. It's important to note that autovacuum restarts immediately because this table is probably the highest on its list of work.

5. Initiate your command in session two, and then end the autovacuum process in session 1.
Managing autovacuum with large indexes

As part of its operation, autovacuum performs several vacuum phases while running on a table. Before the table is cleaned up, all of its indexes are first vacuumed. When removing multiple large indexes, this phase consumes a significant amount of time and resources. Therefore, as a best practice, be sure to control the number of indexes on a table and eliminate unused indexes.

For this process, first check the overall index size. Then, determine if there are potentially unused indexes that can be removed as shown in the following examples.

To check the size of the table and its indexes

```sql
postgres=> select pg_size_pretty(pg_relation_size('pgbench_accounts'));
pg_size_pretty
6404 MB
(1 row)
```

```sql
postgres=> select pg_size_pretty(pg_indexes_size('pgbench_accounts'));
pg_size_pretty
11 GB
(1 row)
```

In this example, the size of indexes is larger than the table. This difference can cause performance issues as the indexes are bloated or unused, which impacts the autovacuum as well as insert operations.

To check for unused indexes

Using the pg_stat_user_indexes view, you can check how frequently an index is used with the idx_scan column. In the following example, the unused indexes have the idx_scan value of 0.

```sql
postgres=> select * from pg_stat_user_indexes where relname = 'pgbench_accounts' order by idx_scan desc;
relid  | indexrelid | schemaname | relname          | indexrelname          | idx_scan
-------+------------+------------+------------------+-----------------------+----------
| 16433  | 16454      | public     | pgbench_accounts | index_f               | 6
```

Working with the PostgreSQL autovacuum
These statistics are incremental from the time that the statistics are reset. Suppose you have an index that is only used at the end of a business quarter or just for a specific report. It's possible that this index hasn't been used since the statistics were reset. For more information, see Statistics Functions. Indexes that are used to enforce uniqueness won't have scans performed and shouldn't be identified as unused indexes. To identify the unused indexes, you should have in-depth knowledge of the application and its queries.

To check when the stats were last reset for a database, use pg_stat_database
Vacuuming a table as quickly as possible

RDS for PostgreSQL 12 and higher

If you have too many indexes in a large table, your DB instance could be nearing transaction ID wraparound (XID), which is when the XID counter wraps around to zero. Left unchecked, this situation could result in data loss. However, you can quickly vacuum the table without cleaning up the indexes. In RDS for PostgreSQL 12 and higher, you can use VACUUM with the `INDEX_CLEANUP` clause.

```
postgres=> VACUUM (INDEX_CLEANUP FALSE, VERBOSE TRUE) pgbench_accounts;
```

```
INFO: vacuuming "public.pgbench_accounts"
INFO: table "pgbench_accounts": found 0 removable, 8 nonremovable row versions in 1 out of 819673 pages
DETAIL: 0 dead row versions cannot be removed yet, oldest xmin: 7517
Skipped 0 pages due to buffer pins, 0 frozen pages.
CPU: user: 0.01 s, system: 0.00 s, elapsed: 0.01 s.
```

If an autovacuum session is already running, you must terminate it to begin the manual VACUUM. For information on performing a manual vacuum freeze, see [Performing a manual vacuum freeze](#).

**Note**

Skipping index cleanup regularly might cause index bloat, which impacts the overall scan performance. As a best practice, use the preceding procedure only to prevent transaction ID wraparound.

RDS for PostgreSQL 11 and older
However, in RDS for PostgreSQL 11 and lower versions, the only way to allow vacuum to complete faster is to reduce the number of indexes on a table. Dropping an index can affect query plans. We recommend that you drop unused indexes first, then drop the indexes when XID wraparound is very near. After the vacuum process completes, you can recreate these indexes.

**Other parameters that affect autovacuum**

The following query shows the values of some of the parameters that directly affect autovacuum and its behavior. The [autovacuum parameters](https://www.postgresql.org/docs/current/autovacuum.html) are described fully in the PostgreSQL documentation.

```sql
SELECT name, setting, unit, short_desc
FROM pg_settings
WHERE name IN ('autovacuum_max_workers',
'autovacuum_analyze_scale_factor',
'autovacuum_naptime',
'autovacuum_analyze_threshold',
'autovacuum_analyze_scale_factor',
'autovacuum_vacuum_threshold',
'autovacuum_vacuum_scale_factor',
'autovacuum_vacuum_threshold',
'autovacuum_vacuum_cost_delay',
'autovacuum_vacuum_cost_limit',
'veacuum_cost_limit',
'autovacuum_freeze_max_age',
'maintenance_work_mem',
'vacuum_freeze_min_age');
```

While these all affect autovacuum, some of the most important ones are:

- [maintenance_work_mem](https://www.postgresql.org/docs/current/autovacuum.html#AQP-Maintenance-Work-Memory)
- [autovacuum_freeze_max_age](https://www.postgresql.org/docs/current/autovacuum.html#AQP-Freeze-Thresholds)
- [autovacuum_max_workers](https://www.postgresql.org/docs/current/autovacuum.html#AQP-Max-Workers)
- [autovacuum_vacuum_cost_delay](https://www.postgresql.org/docs/current/autovacuum.html#AQP-Vacuum-Cost-Delay)
- [autovacuum_vacuum_cost_limit](https://www.postgresql.org/docs/current/autovacuum.html#AQP-Vacuum-Cost-Limit)
Setting table-level autovacuum parameters

You can set autovacuum-related storage parameters at a table level, which can be better than altering the behavior of the entire database. For large tables, you might need to set aggressive settings and you might not want to make autovacuum behave that way for all tables.

The following query shows which tables currently have table-level options in place.

```
SELECT relname, reloptions
FROM pg_class
WHERE reloptions IS NOT null;
```

An example where this might be useful is on tables that are much larger than the rest of your tables. Suppose that you have one 300-GB table and 30 other tables less than 1 GB. In this case, you might set some specific parameters for your large table so you don't alter the behavior of your entire system.

```
ALTER TABLE mytable set (autovacuum_vacuum_cost_delay=0);
```

Doing this turns off the cost-based autovacuum delay for this table at the expense of more resource usage on your system. Normally, autovacuum pauses for `autovacuum_vacuum_cost_delay` each time `autovacuum_cost_limit` is reached. For more details, see the PostgreSQL documentation about cost-based vacuuming.

Logging autovacuum and vacuum activities

Information about autovacuum activities is sent to the `postgresql.log` based on the level specified in the `rds.force_autovacuum_logging_level` parameter. Following are the values allowed for this parameter and the PostgreSQL versions for which that value is the default setting:

- disabled (PostgreSQL 10, PostgreSQL 9.6)
- debug5, debug4, debug3, debug2, debug1
- info (PostgreSQL 12, PostgreSQL 11)
- notice
- warning (PostgreSQL 13 and above)
- error, log, fatal, panic
The `rds.force_autovacuum_logging_level` works with the `log_autovacuum_min_duration` parameter. The `log_autovacuum_min_duration` parameter's value is the threshold (in milliseconds) above which autovacuum actions get logged. A setting of -1 logs nothing, while a setting of 0 logs all actions. As with `rds.force_autovacuum_logging_level`, default values for `log_autovacuum_min_duration` are version dependent, as follows:

- 10000 ms – PostgreSQL 14, PostgreSQL 13, PostgreSQL 12, and PostgreSQL 11
- (empty) – No default value for PostgreSQL 10 and PostgreSQL 9.6

We recommend that you set `rds.force_autovacuum_logging_level` to WARNING. We also recommend that you set `log_autovacuum_min_duration` to a value from 1000 to 5000. A setting of 5000 logs activity that takes longer than 5,000 milliseconds. Any setting other than -1 also logs messages if the autovacuum action is skipped because of a conflicting lock or concurrently dropped relations. For more information, see [Automatic Vacuuming](#) in the PostgreSQL documentation.

To troubleshoot issues, you can change the `rds.force_autovacuum_logging_level` parameter to one of the debug levels, from `debug1` up to `debug5` for the most verbose information. We recommend that you use debug settings for short periods of time and for troubleshooting purposes only. To learn more, see [When to log](#) in the PostgreSQL documentation.

---

**Note**

PostgreSQL allows the `rds_superuser` account to view autovacuum sessions in `pg_stat_activity`. For example, you can identify and end an autovacuum session that is blocking a command from running, or running slower than a manually issued vacuum command.

---

**Working with logging mechanisms supported by RDS for PostgreSQL**

There are several parameters, extensions, and other configurable items that you can set to log activities that occur on your PostgreSQL DB instance. These include the following:

- The `log_statement` parameter can be used to log user activity in your PostgreSQL database. To learn more about RDS for PostgreSQL logging and how to monitor the logs, see [RDS for PostgreSQL database log files](#).
• The rds.force_admin_logging_level parameter logs actions by the Amazon RDS internal user (rdsadmin) in the databases on the DB instance. It writes the output to the PostgreSQL error log. Allowed values are disabled, debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, and panic. The default value is disabled.

• The rds.force_autovacuumLogging_level parameter can be set to capture various autovacuum operations in the PostgreSQL error log. For more information, see Logging autovacuum and vacuum activities.

• The PostgreSQL Audit (pgAudit) extension can be installed and configured to capture activities at the session level or at the object level. For more information, see Using pgAudit to log database activity.

• The log_fdw extension makes it possible for you to access the database engine log using SQL. For more information, see Using the log_fdw extension to access the DB log using SQL.

• The pg_stat_statements library is specified as the default for the shared_preload_libraries parameter in RDS for PostgreSQL version 10 and higher. It's this library that you can use to analyze running queries. Be sure that pg_stat_statements is set in your DB parameter group. For more information about monitoring your RDS for PostgreSQL DB instance using the information that this library provides, see SQL statistics for RDS PostgreSQL.

• The log_hostname parameter captures to the log the hostname of each client connection. For RDS for PostgreSQL version 12 and higher versions, this parameter is set to off by default. If you turn it on, be sure to monitor session connection times. When turned on, the service uses the domain name system (DNS) reverse lookup request to get the hostname of the client that's making the connection and add it to the PostgreSQL log. This has a noticeable impact during session connection. We recommend that you turn on this parameter for troubleshooting purposes only.

In general terms, the point of logging is so that the DBA can monitor, tune performance, and troubleshoot. Many of the logs are uploaded automatically to Amazon CloudWatch or Performance Insights. Here, they're sorted and grouped to provide complete metrics for your DB instance. To learn more about Amazon RDS monitoring and metrics, see Monitoring metrics in an Amazon RDS instance.

Managing temporary files with PostgreSQL

In PostgreSQL, a query performing sort and hash operations uses the instance memory to store results up to the value specified in the work_mem parameter. When the instance memory is not sufficient, temporary files are created to store the results. These are written to disk to complete
the query execution. Later, these files are automatically removed after the query completes. In RDS for PostgreSQL, these files are stored in Amazon EBS on the data volume. For more information, see Amazon RDS DB instance storage. You can monitor the FreeStorageSpace metric published in CloudWatch to make sure that your DB instance has enough free storage space. For more information, see FreeStorageSpace.

We recommend using Amazon RDS Optimized Read instances for the workloads involving multiple concurrent queries that increase the usage of temporary files. These instances use local Non-Volatile Memory Express (NVMe) based solid state drive (SSD) block-level storage to place the temporary files. For more information, see Amazon RDS Optimized Reads.

You can use the following parameters and functions to manage the temporary files in your instance.

- **temp_file_limit** – This parameter cancels any query exceeding the size of temp_files in KB. This limit prevents any query from running endlessly and consuming disk space with temporary files. You can estimate the value using the results from the log_temp_files parameter. As a best practice, examine the workload behavior and set the limit according to the estimation. The following example shows how a query is canceled when it exceeds the limit.

  ```sql
  postgres=> select * from pgbench_accounts, pg_class, big_table;
  ERROR: temporary file size exceeds temp_file_limit (64kB)
  ```

- **log_temp_files** – This parameter sends messages to the postgresql.log when the temporary files of a session are removed. This parameter produces logs after a query successfully completes. Therefore, it might not help in troubleshooting active, long-running queries.

  The following example shows that when the query successfully completes, the entries are logged in the postgresql.log file while the temporary files are cleaned up.

  ```plaintext
  2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:STATEMENT: select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by a.bid limit 10;
  ```
pg_ls_tmpdir – This function that is available from RDS for PostgreSQL 13 and above provides visibility into the current temporary file usage. The completed query doesn't appear in the results of the function. In the following example, you can view the results of this function.

```
postgres=> select * from pg_ls_tmpdir();
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgsql_tmp8355.1</td>
<td>1072250880</td>
<td>2023-02-06 22:54:56+00</td>
</tr>
<tr>
<td>pgsql_tmp8351.0</td>
<td>1072250880</td>
<td>2023-02-06 22:54:43+00</td>
</tr>
<tr>
<td>pgsql_tmp8327.0</td>
<td>1072250880</td>
<td>2023-02-06 22:54:56+00</td>
</tr>
<tr>
<td>pgsql_tmp8351.1</td>
<td>703168512</td>
<td>2023-02-06 22:54:56+00</td>

<tr>
<td>pgsql_tmp8350.0</td>
<td>1072250880</td>
<td>2023-02-06 22:54:00+00</td>
</tr>
<tr>
<td>pgsql_tmp8328.1</td>
<td>835031040</td>
<td>2023-02-06 22:54:56+00</td>
</tr>
<tr>
<td>pgsql_tmp8328.0</td>
<td>1072250880</td>
<td>2023-02-06 22:54:40+00</td>
</tr>
</tbody>
</table>

(7 rows)

```
postgres=> select query from pg_stat_activity where pid = 8355;
```

```
query
----------------------------------------
select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by a.bid limit 10;
```

The file name includes the processing ID (PID) of the session that generated the temporary file. A more advanced query, such as in the following example, performs a sum of the temporary files for each PID.
postgres=> select replace(left(name, strpos(name, '.')-1), 'pgsql_tmp', '') as pid, count(*), sum(size) from pg_ls_tmpdir() group by pid;

<table>
<thead>
<tr>
<th>pid</th>
<th>count</th>
<th>sum</th>

</tr>
</tbody>
</table>
(4 rows)

• **pg_stat_statements** – If you activate the pg_stat_statements parameter, then you can view the average temporary file usage per call. You can identify the query_id of the query and use it to examine the temporary file usage as shown in the following example.

```sql
postgres=> select queryid from pg_stat_statements where query like 'select a.aid from pgbench%';
```

<table>
<thead>
<tr>
<th>queryid</th>
</tr>
</thead>
<tbody>
<tr>
<td>-7170349228837045701</td>
</tr>
</tbody>
</table>
(1 row)

```sql
postgres=> select queryid, substr(query,1,25), calls, temp_blks_read/calls temp_blks_read_per_call, temp_blks_written/calls temp_blks_written_per_call from pg_stat_statements where queryid = -7170349228837045701;
```

<table>
<thead>
<tr>
<th>queryid</th>
<th>substr</th>
<th>calls</th>
<th>temp_blks_read_per_call</th>
<th>temp_blks_written_per_call</th>
</tr>
</thead>
<tbody>
<tr>
<td>-7170349228837045701</td>
<td>select a.aid from pgbench%</td>
<td>50</td>
<td>239226</td>
<td>388678</td>
</tr>
</tbody>
</table>
• **Performance Insights** – In the Performance Insights dashboard, you can view temporary file usage by turning on the metrics `temp_bytes` and `temp_files`. Then, you can see the average of both of these metrics and see how they correspond to the query workload. The view within Performance Insights doesn't show specifically the queries that are generating the temporary files. However, when you combine Performance Insights with the query shown for `pg_ls_tmdir`, you can troubleshoot, analyze, and determine the changes in your query workload.

For more information about how to analyze metrics and queries with Performance Insights, see [Analyzing metrics with the Performance Insights dashboard](#).

**To view the temporary file usage with Performance Insights**

1. In the Performance Insights dashboard, choose **Manage Metrics**.
2. Choose **Database metrics**, and select the `temp_bytes` and `temp_files` metrics as shown in the following image.
3. In the Top SQL tab, choose the Preferences icon.

4. In the Preferences window, turn on the following statistics to appear in the Top SQL tab and choose Continue.
   - Temp writes/sec
   - Temp reads/sec
   - Tmp blk write/call
   - Tmp blk read/call

5. The temporary file is broken out when combined with the query shown for pg_ls_tmpdir, as shown in the following example.
The **IO:BufFileRead** and **IO:BufFileWrite** events occur when the top queries in your workload often create temporary files. You can use Performance Insights to identify top queries waiting on **IO:BufFileRead** and **IO:BufFileWrite** by reviewing Average Active Session (AAS) in Database Load and Top SQL sections.

For more information on how to analyze top queries and load by wait event with Performance Insights, see [Overview of the Top SQL tab](#). You should identify and tune the queries that cause increase in temporary file usage and related wait events. For more information on these wait events and remediation, see [IO:BufFileRead and IO:BufFileWrite](#).

**Note**

The **work_mem** parameter controls when the sort operation runs out of memory and results are written into temporary files. We recommend that you don't change the setting of this parameter higher than the default value because it would permit every database session to consume more memory. Also, a single session that performs complex joins and sorts can perform parallel operations in which each operation consumes memory.

As a best practice, when you have a large report with multiple joins and sorts, set this parameter at the session level by using the `SET work_mem` command. Then the change is only applied to the current session and doesn't change the value globally.
Using pgBadger for log analysis with PostgreSQL

You can use a log analyzer such as pgBadger to analyze PostgreSQL logs. The pgBadger documentation states that the %l pattern (the log line for the session or process) should be a part of the prefix. However, if you provide the current RDS log_line_prefix as a parameter to pgBadger it should still produce a report.

For example, the following command correctly formats an Amazon RDS for PostgreSQL log file dated 2014-02-04 using pgBadger.

```bash
./pgbadger -f stderr -p '%t:%r:%u@%d:[%p]:' postgresql.log.2014-02-04-00
```

Using PGSnapper for monitoring PostgreSQL

You can use PGSnapper to assist with periodic collection of Amazon RDS for PostgreSQL performance-related statistics and metrics. For more information, see Monitor Amazon RDS for PostgreSQL performance using PGSnapper.

Working with parameters on your RDS for PostgreSQL DB instance

In some cases, you might create an RDS for PostgreSQL DB instance without specifying a custom parameter group. If so, your DB instance is created using the default parameter group for the version of PostgreSQL that you choose. For example, suppose that you create an RDS for PostgreSQL DB instance using PostgreSQL 13.3. In this case, the DB instance is created using the values in the parameter group for PostgreSQL 13 releases, default.postgres13.

You can also create your own custom DB parameter group. You need to do this if you want to modify any settings for the RDS for PostgreSQL DB instance from their default values. To learn how, see Working with parameter groups.

You can track the settings on your RDS for PostgreSQL DB instance in several different ways. You can use the AWS Management Console, the AWS CLI, or the Amazon RDS API. You can also query the values from the PostgreSQL pg_settings table of your instance, as shown following.

```sql
SELECT name, setting, boot_val, reset_val, unit
FROM pg_settings
ORDER BY name;
```

To learn more about the values returned from this query, see pg_settings in the PostgreSQL documentation.
Be especially careful when changing the settings for `max_connections` and `shared_buffers` on your RDS for PostgreSQL DB instance. For example, suppose that you modify settings for `max_connections` or `shared_buffers` and you use values that are too high for your actual workload. In this case, your RDS for PostgreSQL DB instance won't start. If this happens, you see an error such as the following in the `postgres.log`.

```plaintext
2018-09-18 21:13:15 UTC::@:[8097]:FATAL: could not map anonymous shared memory: Cannot allocate memory
2018-09-18 21:13:15 UTC::@:[8097]:HINT: This error usually means that PostgreSQL's request for a shared memory segment exceeded available memory or swap space. To reduce the request size (currently 3514134274048 bytes), reduce PostgreSQL's shared memory usage, perhaps by reducing shared_buffers or max_connections.
```

However, you can't change any values of the settings contained in the default RDS for PostgreSQL DB parameter groups. To change settings for any parameters, first create a custom DB parameter group. Then change the settings in that custom group, and then apply the custom parameter group to your RDS for PostgreSQL DB instance. To learn more, see [Working with parameter groups](#).

There are two types of RDS for PostgreSQL DB parameters.

- **Static parameters** – Static parameters require that the RDS for PostgreSQL DB instance be rebooted after a change so that the new value can take effect.
- **Dynamic parameters** – Dynamic parameters don't require a reboot after changing their settings.

**Note**

If your RDS for PostgreSQL DB instance is using your own custom DB parameter group, you can change the values of dynamic parameters on the running DB instance. You can do this by using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

If you have privileges to do so, you can also change parameter values by using the `ALTER DATABASE`, `ALTER ROLE`, and `SET` commands.
RDS for PostgreSQL DB instance parameter list

The following table lists some (but not all) parameters available in an RDS for PostgreSQL DB instance. To view all available parameters, you use the `describe-db-parameters` AWS CLI command. For example, to get the list of all parameters available in the default parameter group for RDS for PostgreSQL version 13, run the following.

```
aws rds describe-db-parameters --db-parameter-group-name default.postgres13
```

You can also use the Console. Choose **Parameter groups** from the Amazon RDS menu, and then choose the parameter group from those available in your AWS Region.

<td>client_encoding</td>
<td>Dynamic</td>
<td>Sets the client's character set encoding.</td>
</tr>
<tr>
<td>client_min_messages</td>
<td>Dynamic</td>
<td>Sets the message levels that are sent to the client.</td>
</tr>
<tr>
<td>commit_delay</td>
<td>Dynamic</td>
<td>Sets the delay in microseconds between transaction commit and flushing WAL to disk.</td>
</tr>
<tr>
<td>commit_siblings</td>
<td>Dynamic</td>
<td>Sets the minimum concurrent open transactions before performing commit_delay.</td>
</tr>
<tr>
<td>constraint_exclusion</td>
<td>Dynamic</td>
<td>Enables the planner to use constraints to optimize queries.</td>
</tr>
<tr>
<td>cpu_index_tuple_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of processing each index entry during an index scan.</td>
</tr>
<tr>
<td>cpu_operator_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of processing each operator or function call.</td>
</tr>
<tr>
<td>cpu_tuple_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of processing each tuple (row).</td>
</tr>
<tr>
<td>cursor_tuple_fraction</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the fraction of a cursor's rows that will be retrieved.</td>

<tr>
<td>enable_mergejoin</td>
<td>Dynamic</td>
<td>Enables the planner's use of merge join plans.</td>
</tr>
<tr>
<td>enable_nestloop</td>
<td>Dynamic</td>
<td>Enables the planner's use of nested-loop join plans.</td>
</tr>
<tr>
<td>enable_seqscan</td>
<td>Dynamic</td>
<td>Enables the planner's use of sequential-scan plans.</td>
</tr>
<tr>
<td>enable_sort</td>
<td>Dynamic</td>
<td>Enables the planner's use of explicit sort steps.</td>
</tr>
<tr>
<td>enable_tidscan</td>
<td>Dynamic</td>
<td>Enables the planner's use of TID scan plans.</td>
</tr>
<tr>
<td>escape_string_waring</td>
<td>Dynamic</td>
<td>Warns about backslash () escapes in ordinary string literals.</td>
</tr>
<tr>
<td>extra_float_digits</td>
<td>Dynamic</td>
<td>Sets the number of digits displayed for floating-point values.</td>
</tr>
<tr>
<td>from_collapse_limit</td>
<td>Dynamic</td>
<td>Sets the FROM-list size beyond which subqueries are not collapsed.</td>
</tr>
<tr>
<td>fsync</td>
<td>Dynamic</td>
<td>Forces synchronization of updates to disk.</td>
</tr>
<tr>
<td>full_page_writes</td>
<td>Dynamic</td>
<td>Writes full pages to WAL when first modified after a checkpoint.</td>
</tr>
<tr>
<td>geqo</td>
<td>Dynamic</td>
<td>Enables genetic query optimization.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>geqo_effort</td>
<td>Dynamic</td>
<td>GEQO: effort is used to set the default for other GEQO parameters.</td>
</tr>
<tr>
<td>geqo_generations</td>
<td>Dynamic</td>
<td>GEQO: number of iterations of the algorithm.</td>
</tr>
<tr>
<td>geqo_pool_size</td>
<td>Dynamic</td>
<td>GEQO: number of individuals in the population.</td>
</tr>
<tr>
<td>geqo_seed</td>
<td>Dynamic</td>
<td>GEQO: seed for random path selection.</td>
</tr>
<tr>
<td>geqo_selection_bias</td>
<td>Dynamic</td>
<td>GEQO: selective pressure within the population.</td>
</tr>
<tr>
<td>geqo_threshold</td>
<td>Dynamic</td>
<td>Sets the threshold of FROM items beyond which GEQO is used.</td>
</tr>
<tr>
<td>gin_fuzzy_search_limit</td>
<td>Dynamic</td>
<td>Sets the maximum allowed result for exact search by GIN.</td>
</tr>
<tr>
<td>hot_standby_feedback</td>
<td>Dynamic</td>
<td>Determines whether a hot standby sends feedback messages to the primary or upstream standby.</td>
</tr>
<tr>
<td>intervalstyle</td>
<td>Dynamic</td>
<td>Sets the display format for interval values.</td>
</tr>
<tr>
<td>join-collapse-limit</td>
<td>Dynamic</td>
<td>Sets the FROM-list size beyond which JOIN constructs are not flattened.</td>
</tr>
<tr>
<td>lc_messages</td>
<td>Dynamic</td>
<td>Sets the language in which messages are displayed.</td>
</tr>
<tr>
<td>lc_monetary</td>
<td>Dynamic</td>
<td>Sets the locale for formatting monetary amounts.</td>
</tr>
<tr>
<td>lc_numeric</td>
<td>Dynamic</td>
<td>Sets the locale for formatting numbers.</td>
</tr>
<tr>
<td>lc_time</td>
<td>Dynamic</td>
<td>Sets the locale for formatting date and time values.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>log_autovacuum_min_duration</td>
<td>Dynamic</td>
<td>Sets the minimum running time above which autovacuum actions will be logged.</td>
</tr>
<tr>
<td>log_checkpoints</td>
<td>Dynamic</td>
<td>Logs each checkpoint.</td>
</tr>
<tr>
<td>log_connections</td>
<td>Dynamic</td>
<td>Logs each successful connection.</td>
</tr>
<tr>
<td>log_disconnections</td>
<td>Dynamic</td>
<td>Logs end of a session, including duration.</td>
</tr>
<tr>
<td>log_duration</td>
<td>Dynamic</td>
<td>Logs the duration of each completed SQL statement.</td>
</tr>
<tr>
<td>log_error_verbosity</td>
<td>Dynamic</td>
<td>Sets the verbosity of logged messages.</td>
</tr>
<tr>
<td>log_executor_stats</td>
<td>Dynamic</td>
<td>Writes executor performance statistics to the server log.</td>
</tr>
<tr>
<td>log_filename</td>
<td>Dynamic</td>
<td>Sets the file name pattern for log files.</td>
</tr>
<tr>
<td>log_file_mode</td>
<td>Dynamic</td>
<td>Sets file permissions for log files. Default value is 0644.</td>
</tr>
<tr>
<td>log_hostname</td>
<td>Dynamic</td>
<td>Logs the host name in the connection logs. As of PostgreSQL 12 and later versions, this parameter is 'off' by default. When turned on, the connection uses DNS reverse-lookup to get the hostname that gets captured to the connection logs. If you turn on this parameter, you should monitor the impact that it has on the time it takes to establish connections.</td>
</tr>
<tr>
<td>log_line_prefix</td>
<td>Dynamic</td>
<td>Controls information prefixed to each log line.</td>
</tr>
<tr>
<td>log_lock_waits</td>
<td>Dynamic</td>
<td>Logs long lock waits.</td>
</tr>
<tr>
<td>log_min_duration_statement</td>
<td>Dynamic</td>
<td>Sets the minimum running time above which statements will be logged.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>log_min_error_statement</td>
<td>Dynamic</td>
<td>Causes all statements generating an error at or above this level to be logged.</td>
</tr>
<tr>
<td>log_min_messages</td>
<td>Dynamic</td>
<td>Sets the message levels that are logged.</td>
</tr>
<tr>
<td>log_parser_stats</td>
<td>Dynamic</td>
<td>Writes parser performance statistics to the server log.</td>
</tr>
<tr>
<td>log_planner_stats</td>
<td>Dynamic</td>
<td>Writes planner performance statistics to the server log.</td>
</tr>
<tr>
<td>log_rotation_age</td>
<td>Dynamic</td>
<td>Automatic log file rotation will occur after N minutes.</td>
</tr>
<tr>
<td>log_rotation_size</td>
<td>Dynamic</td>
<td>Automatic log file rotation will occur after N kilobytes.</td>
</tr>
<tr>
<td>log_statement</td>
<td>Dynamic</td>
<td>Sets the type of statements logged.</td>
</tr>
<tr>
<td>log_statement_stats</td>
<td>Dynamic</td>
<td>Writes cumulative performance statistics to the server log.</td>
</tr>
<tr>
<td>log_temp_files</td>
<td>Dynamic</td>
<td>Logs the use of temporary files larger than this number of kilobytes.</td>
</tr>
<tr>
<td>log_timezone</td>
<td>Dynamic</td>
<td>Sets the time zone to use in log messages.</td>
</tr>
<tr>
<td>log_truncate_on_rotation</td>
<td>Dynamic</td>
<td>Truncate existing log files of same name during log rotation.</td>
</tr>
<tr>
<td>logging_collector</td>
<td>Static</td>
<td>Start a subprocess to capture stderr output and/or csvlogs into log files.</td>
</tr>
<tr>
<td>maintenance_work_mem</td>
<td>Dynamic</td>
<td>Sets the maximum memory to be used for maintenance operations.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>max_connections</td>
<td>Static</td>
<td>Sets the maximum number of concurrent connections.</td>
</tr>
<tr>
<td>max_files_per_process</td>
<td>Static</td>
<td>Sets the maximum number of simultaneously open files for each server process.</td>
</tr>
<tr>
<td>max_locks_per_transaction</td>
<td>Static</td>
<td>Sets the maximum number of locks per transaction.</td>
</tr>
<tr>
<td>max_pred_locks_per_transaction</td>
<td>Static</td>
<td>Sets the maximum number of predicate locks per transaction.</td>
</tr>
<tr>
<td>max_prepared_transactions</td>
<td>Static</td>
<td>Sets the maximum number of simultaneously prepared transactions.</td>
</tr>
<tr>
<td>max_stack_depth</td>
<td>Dynamic</td>
<td>Sets the maximum stack depth, in kilobytes.</td>
</tr>
<tr>
<td>max_standby_archive_delay</td>
<td>Dynamic</td>
<td>Sets the maximum delay before canceling queries when a hot standby server is processing archived WAL data.</td>
</tr>
<tr>
<td>max_standby_streaming_delay</td>
<td>Dynamic</td>
<td>Sets the maximum delay before canceling queries when a hot standby server is processing streamed WAL data.</td>
</tr>
<tr>
<td>max_wal_size</td>
<td>Dynamic</td>
<td>Sets the WAL size (MB) that triggers a checkpoint. For all versions after RDS for PostgreSQL 10, the default is at least 1 GB (1024 MB). For example, max_wal_size setting for RDS for PostgreSQL 14 is 2 GB (2048 MB). Use the SHOW max_wal_size; command on your RDS for PostgreSQL DB instance to see its current value.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>min_wal_size</td>
<td>Dynamic</td>
<td>Sets the minimum size to shrink the WAL to. For PostgreSQL version 9.6 and earlier, min_wal_size is in units of 16 MB. For PostgreSQL version 10 and later, min_wal_size is in units of 1 MB.</td>
</tr>
<tr>
<td>quote_all_identifiers</td>
<td>Dynamic</td>
<td>Adds quotes (&quot;) to all identifiers when generating SQL fragments.</td>
</tr>
<tr>
<td>random_page_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of a non-sequentially fetched disk page. This parameter has no value unless query plan management (QPM) is turned on. When QPM is on, the default value for this parameter 4.</td>
</tr>
<tr>
<td>rds.adaptive_autovacuum</td>
<td>Dynamic</td>
<td>Automatically tunes the autovacuum parameters whenever the transaction ID thresholds are exceeded.</td>
</tr>
<tr>
<td>rds.force_ssl</td>
<td>Dynamic</td>
<td>Requires the use of SSL connections. The default value is set to 1 (on) for RDS for PostgreSQL version 15. All other RDS for PostgreSQL major version 14 and older have the default value set to 0 (off).</td>
</tr>
<tr>
<td>rds.log_retention_period</td>
<td>Dynamic</td>
<td>Sets log retention such that Amazon RDS deletes PostgreSQL logs that are older than n minutes.</td>
</tr>
<tr>
<td>rds.restrict_password_commands</td>
<td>Static</td>
<td>Restricts who can manage passwords to users with the rds_password role. Set this parameter to 1 to enable password restriction. The default is 0.</td>
</tr>
<tr>
<td>search_path</td>
<td>Dynamic</td>
<td>Sets the schema search order for names that are not schema-qualified.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>seq_page_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of a sequentially fetched disk page.</td>
</tr>
<tr>
<td>session_replication_role</td>
<td>Dynamic</td>
<td>Sets the sessions behavior for triggers and rewrite rules.</td>
</tr>
<tr>
<td>shared_buffers</td>
<td>Static</td>
<td>Sets the number of shared memory buffers used by the server.</td>
</tr>
<tr>
<td>shared_preload_libraries</td>
<td>Static</td>
<td>Lists the shared libraries to preload into the RDS for PostgreSQL DB instance.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Supported values include auto_explain, orafce, pgaudit, pglogical, pg_bigm,</td>
</tr>
<tr>
<td></td>

<td></td>
<td></td>
<td>pg_transport, plprofiler, and plrust.</td>
</tr>
<tr>
<td>ssl</td>
<td>Dynamic</td>
<td>Enables SSL connections.</td>
</tr>
<tr>
<td>sql_inheritance</td>
<td>Dynamic</td>
<td>Causes subtables to be included by default in various commands.</td>
</tr>
<tr>
<td>ssl_renegotiation_limit</td>
<td>Dynamic</td>
<td>Sets the amount of traffic to send and receive before renegotiating the encryption keys.</td>
</tr>
<tr>
<td>standard_conforming_strings</td>
<td>Dynamic</td>
<td>Causes ... strings to treat backslashes literally.</td>
</tr>
<tr>
<td>statement_timeout</td>
<td>Dynamic</td>
<td>Sets the maximum allowed duration of any statement.</td>
</tr>
<tr>
<td>synchronize_seqscans</td>
<td>Dynamic</td>
<td>Enables synchronized sequential scans.</td>
</tr>
<tr>
<td>synchronous_commit</td>
<td>Dynamic</td>
<td>Sets the current transactions synchronization level.</td>
</tr>
<tr>
<td>tcp_keepalives_count</td>
<td>Dynamic</td>
<td>Maximum number of TCP keepalive retransmits.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>tcp_keepalives_idle</td>
<td>Dynamic</td>
<td>Time between issuing TCP keepalives.</td>
</tr>
<tr>
<td>tcp_keepalives_interval</td>
<td>Dynamic</td>
<td>Time between TCP keepalive retransmits.</td>
</tr>
<tr>
<td>temp_buffers</td>
<td>Dynamic</td>
<td>Sets the maximum number of temporary buffers used by each session.</td>
</tr>
<tr>
<td>temp_file_limit</td>
<td>Dynamic</td>
<td>Sets the maximum size in KB to which the temporary files can grow.</td>
</tr>
<tr>
<td>temp_tablespaces</td>
<td>Dynamic</td>
<td>Sets the tablespaces to use for temporary tables and sort files.</td>
</tr>
<tr>
<td>timezone</td>
<td>Dynamic</td>
<td>Sets the time zone for displaying and interpreting time stamps.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The Internet Assigned Numbers Authority (IANA) publishes new time zones at</td>
</tr>
<tr>
<td></td>
<td></td>
<td><a href="https://www.iana.org/time-zones">https://www.iana.org/time-zones</a> several</td>

</tr>
<tr>
<td></td>
<td></td>
<td>time zone data is installed only when you perform a database engine version</td>
</tr>
<tr>
<td></td>
<td></td>
<td>upgrade.</td>
</tr>
<tr>
<td>track_activities</td>
<td>Dynamic</td>
<td>Collects information about running commands.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>track_activity_query_size</td>
<td>Static</td>
<td>Sets the size reserved for pg_stat_activity.current_query, in bytes.</td>
</tr>
<tr>
<td>track_counts</td>
<td>Dynamic</td>
<td>Collects statistics on database activity.</td>
</tr>
<tr>
<td>track_functions</td>
<td>Dynamic</td>
<td>Collects function-level statistics on database activity.</td>
</tr>
<tr>
<td>track_io_timing</td>
<td>Dynamic</td>
<td>Collects timing statistics on database I/O activity.</td>
</tr>
<tr>
<td>transaction_deferrable</td>
<td>Dynamic</td>
<td>Indicates whether to defer a read-only serializable transaction until it can be started with no possible serialization failures.</td>
</tr>
<tr>
<td>transaction_isolation</td>
<td>Dynamic</td>
<td>Sets the current transactions isolation level.</td>
</tr>
<tr>
<td>transaction_read_only</td>
<td>Dynamic</td>
<td>Sets the current transactions read-only status.</td>
</tr>
<tr>
<td>transform_null_equals</td>
<td>Dynamic</td>
<td>Treats expr=NULL as expr IS NULL.</td>
</tr>
<tr>
<td>update_process_title</td>
<td>Dynamic</td>
<td>Updates the process title to show the active SQL command.</td>
</tr>
<tr>
<td>vacuum_cost_delay</td>
<td>Dynamic</td>
<td>Vacuum cost delay in milliseconds.</td>
</tr>
<tr>
<td>vacuum_cost_limit</td>
<td>Dynamic</td>
<td>Vacuum cost amount available before napping.</td>
</tr>
<tr>
<td>vacuum_cost_page_dirty</td>
<td>Dynamic</td>
<td>Vacuum cost for a page dirtied by vacuum.</td>
</tr>
<tr>
<td>vacuum_cost_page_hit</td>
<td>Dynamic</td>
<td>Vacuum cost for a page found in the buffer cache.</td>
</tr>
<tr>
<td>vacuum_cost_page_miss</td>
<td>Dynamic</td>
<td>Vacuum cost for a page not found in the buffer cache.</td>
</tr>
</tbody>
</table>
### Parameter Name

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Apply_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vacuum_defer_cleanup_age</td>
<td>Dynamic</td>
<td>Number of transactions by which vacuum and hot cleanup should be deferred, if any.</td>
</tr>
<tr>
<td>vacuum_freeze_min_age</td>
<td>Dynamic</td>
<td>Minimum age at which vacuum should freeze a table row.</td>
</tr>
<tr>
<td>vacuum_freeze_table_age</td>
<td>Dynamic</td>
<td>Age at which vacuum should scan a whole table to freeze tuples.</td>
</tr>
<tr>
<td>wal_buffers</td>
<td>Static</td>
<td>Sets the number of disk-page buffers in shared memory for WAL.</td>
</tr>
<tr>
<td>wal_writer_delay</td>
<td>Dynamic</td>
<td>WAL writer sleep time between WAL flushes.</td>
</tr>
<tr>
<td>work_mem</td>
<td>Dynamic</td>
<td>Sets the maximum memory to be used for query workspaces.</td>
</tr>
<tr>
<td>xmlbinary</td>
<td>Dynamic</td>
<td>Sets how binary values are to be encoded in XML.</td>
</tr>
<tr>
<td>xmloption</td>
<td>Dynamic</td>
<td>Sets whether XML data in implicit parsing and serialization operations is to be considered as documents or content fragments.</td>
</tr>
</tbody>
</table>

Amazon RDS uses the default PostgreSQL units for all parameters. The following table shows the PostgreSQL default unit for each parameter.

### Parameter Name

Tuning with wait events for RDS for PostgreSQL

Wait events are an important tuning tool for RDS for PostgreSQL. When you can find out why sessions are waiting for resources and what they are doing, you're better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions. This section also discusses basic PostgreSQL tuning concepts.

The wait events in this section are specific to RDS for PostgreSQL.

- Timeout:VacuumDelay
Essential concepts for RDS for PostgreSQL tuning

Before you tune your RDS for PostgreSQL database, make sure to learn what wait events are and why they occur. Also review the basic memory and disk architecture of RDS for PostgreSQL. For a helpful architecture diagram, see the PostgreSQL wikibook.

Topics

- RDS for PostgreSQL wait events
- RDS for PostgreSQL memory
- RDS for PostgreSQL processes

RDS for PostgreSQL wait events

A wait event is an indication that the session is waiting for a resource. For example, the wait event Client:ClientRead occurs when RDS for PostgreSQL is waiting to receive data from the client. Sessions typically wait for resources such as the following.

- Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
- A row that is currently locked by another session
- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

By itself, a single wait event doesn't indicate a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

On the other hand, large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now takes hours to run, you can identify the wait events that
contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.

**RDS for PostgreSQL memory**

RDS for PostgreSQL memory is divided into shared and local.

**Topics**

- [Shared memory in RDS for PostgreSQL](#)
- [Local memory in RDS for PostgreSQL](#)

**Shared memory in RDS for PostgreSQL**

RDS for PostgreSQL allocates shared memory when the instance starts. Shared memory is divided into multiple subareas. Following, you can find a description of the most important ones.

**Topics**

- [Shared buffers](#)
- [Write ahead log (WAL) buffers](#)

**Shared buffers**

The *shared buffer pool* is an RDS for PostgreSQL memory area that holds all pages that are or were being used by application connections. A *page* is the memory version of a disk block. The shared buffer pool caches the data blocks read from disk. The pool reduces the need to reread data from disk, making the database operate more efficiently.

Every table and index is stored as an array of pages of a fixed size. Each block contains multiple tuples, which correspond to rows. A tuple can be stored in any page.

The shared buffer pool has finite memory. If a new request requires a page that isn't in memory, and no more memory exists, RDS for PostgreSQL evicts a less frequently used page to accommodate the request. The eviction policy is implemented by a clock sweep algorithm.

The *shared_buffers* parameter determines how much memory the server dedicates to caching data.
Write ahead log (WAL) buffers

A write-ahead log (WAL) buffer holds transaction data that RDS for PostgreSQL later writes to persistent storage. Using the WAL mechanism, RDS for PostgreSQL can do the following:

- Recover data after a failure
- Reduce disk I/O by avoiding frequent writes to disk

When a client changes data, RDS for PostgreSQL writes the changes to the WAL buffer. When the client issues a COMMIT, the WAL writer process writes transaction data to the WAL file.

The `wal_level` parameter determines how much information is written to the WAL.

Local memory in RDS for PostgreSQL

Every backend process allocates local memory for query processing.

Topics

- Work memory area
- Maintenance work memory area
- Temporary buffer area

Work memory area

The work memory area holds temporary data for queries that performs sorts and hashes. For example, a query with an ORDER BY clause performs a sort. Queries use hash tables in hash joins and aggregations.

The `work_mem` parameter the amount of memory to be used by internal sort operations and hash tables before writing to temporary disk files. The default value is 4 MB. Multiple sessions can run simultaneously, and each session can run maintenance operations in parallel. For this reason, the total work memory used can be multiples of the `work_mem` setting.

Maintenance work memory area

The maintenance work memory area caches data for maintenance operations. These operations include vacuuming, creating an index, and adding foreign keys.
The `maintenance_work_mem` parameter specifies the maximum amount of memory to be used by maintenance operations. The default value is 64 MB. A database session can only run one maintenance operation at a time.

**Temporary buffer area**

The *temporary buffer area* caches temporary tables for each database session.

Each session allocates temporary buffers as needed up to the limit you specify. When the session ends, the server clears the buffers.

The `temp_buffers` parameter sets the maximum number of temporary buffers used by each session. Before the first use of temporary tables within a session, you can change the `temp_buffers` value.

**RDS for PostgreSQL processes**

RDS for PostgreSQL uses multiple processes.

**Topics**

- [Postmaster process](#)
- [Backend processes](#)
- [Background processes](#)

**Postmaster process**

The *postmaster process* is the first process started when you start RDS for PostgreSQL. The postmaster process has the following primary responsibilities:

- Fork and monitor background processes
- Receive authentication requests from client processes, and authenticate them before allowing the database to service requests

**Backend processes**

If the postmaster authenticates a client request, the postmaster forks a new backend process, also called a *postgres process*. One client process connects to exactly one backend process. The client process and the backend process communicate directly without intervention by the postmaster process.
**Background processes**

The postmaster process forks several processes that perform different backend tasks. Some of the more important include the following:

- **WAL writer**

  RDS for PostgreSQL writes data in the WAL (write ahead logging) buffer to the log files. The principle of write ahead logging is that the database can't write changes to the data files until after the database writes log records describing those changes to disk. The WAL mechanism reduces disk I/O, and allows RDS for PostgreSQL to use the logs to recover the database after a failure.

- **Background writer**

  This process periodically write dirty (modified) pages from the memory buffers to the data files. A page becomes dirty when a backend process modifies it in memory.

- **Autovacuum daemon**

  The daemon consists of the following:
  - The autovacuum launcher
  - The autovacuum worker processes

  When autovacuum is turned on, it checks for tables that have had a large number of inserted, updated, or deleted tuples. The daemon has the following responsibilities:
  - Recover or reuse disk space occupied by updated or deleted rows
  - Update statistics used by the planner
  - Protect against loss of old data because of transaction ID wraparound

  The autovacuum feature automates the execution of VACUUM and ANALYZE commands. VACUUM has the following variants: standard and full. Standard vacuum runs in parallel with other database operations. VACUUM FULL requires an exclusive lock on the table it is working on. Thus, it can't run in parallel with operations that access the same table. VACUUM creates a substantial amount of I/O traffic, which can cause poor performance for other active sessions.
RDS for PostgreSQL wait events

The following table lists the wait events for RDS for PostgreSQL that most commonly indicate performance problems, and summarizes the most common causes and corrective actions.

<table>
<thead>
<tr>
<th>Wait event</th>
<th>Definition</th>
</tr>
</thead>

<td><strong>Timeout:VacuumDelay</strong></td>
<td>This event indicates that the vacuum process is sleeping because the estimated cost limit has been reached.</td>
</tr>
</tbody>
</table>

**Client:ClientRead**

The Client:ClientRead event occurs when RDS for PostgreSQL is waiting to receive data from the client.

**Topics**

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

**Supported engine versions**

This wait event information is supported for RDS for PostgreSQL version 10 and higher.

**Context**

An RDS for PostgreSQL DB instance is waiting to receive data from the client. The RDS for PostgreSQL DB instance must receive the data from the client before it can send more data to the client. The time that the instance waits before receiving data from the client is a Client:ClientRead event.

**Likely causes of increased waits**

Common causes for the Client:ClientRead event to appear in top waits include the following:

**Increased network latency**

There might be increased network latency between the RDS for PostgreSQL DB instance and client. Higher network latency increases the time required for DB instance to receive data from the client.

**Increased load on the client**

There might be CPU pressure or network saturation on the client. An increase in load on the client can delay transmission of data from the client to the RDS for PostgreSQL DB instance.

**Excessive network round trips**

A large number of network round trips between the RDS for PostgreSQL DB instance and the client can delay transmission of data from the client to the RDS for PostgreSQL DB instance.
Large copy operation

During a copy operation, the data is transferred from the client's file system to the RDS for PostgreSQL DB instance. Sending a large amount of data to the DB instance can delay transmission of data from the client to the DB instance.

Idle client connection

When a client connects to the RDS for PostgreSQL DB instance in an idle_in_transaction state, the DB instance might wait for the client to send more data or issue a command. A connection in this state can lead to an increase in Client:ClientRead events.

PgBouncer used for connection pooling

PgBouncer has a low-level network configuration setting called pkt_buf, which is set to 4,096 by default. If the workload is sending query packets larger than 4,096 bytes through PgBouncer, we recommend increasing the pkt_buf setting to 8,192. If the new setting doesn't decrease the number of Client:ClientRead events, we recommend increasing the pkt_buf setting to larger values, such as 16,384 or 32,768. If the query text is large, the larger setting can be particularly helpful.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

• Place the clients in the same Availability Zone and VPC subnet as the instance
• Scale your client
• Use current generation instances
• Increase network bandwidth
• Monitor maximums for network performance
• Monitor for transactions in the "idle in transaction" state

Place the clients in the same Availability Zone and VPC subnet as the instance

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the RDS for PostgreSQL DB instance. Make sure that the clients are as geographically close to the DB instance as possible.
Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see Jumbo frames (9001 MTU) in the Amazon EC2 User Guide for Linux Instances.

For information about DB instance classes, see DB instance classes. To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place db. before the Amazon EC2 instance type name. For example, the r5.8xlarge Amazon EC2 instance is equivalent to the db.r5.8xlarge DB instance class.

Increase network bandwidth

Use NetworkReceiveThroughput and NetworkTransmitThroughput Amazon CloudWatch metrics to monitor incoming and outgoing network traffic on the DB instance. These metrics can help you to determine if network bandwidth is sufficient for your workload.

If your network bandwidth isn't enough, increase it. If the AWS client or your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size. For more information, see DB instance class types.

For more information about CloudWatch metrics, see Amazon CloudWatch metrics for Amazon RDS.

Monitor maximums for network performance

If you are using Amazon EC2 clients, Amazon EC2 provides maximums for network performance metrics, including aggregate inbound and outbound network bandwidth. It also provides connection tracking to ensure that packets are returned as expected and link-local services access for services such as the Domain Name System (DNS). To monitor these maximums, use a current enhanced networking driver and monitor network performance for your client.
For more information, see Monitor network performance for your Amazon EC2 instance in the Amazon EC2 User Guide for Linux Instances and Monitor network performance for your Amazon EC2 instance in the Amazon EC2 User Guide for Windows Instances.

Monitor for transactions in the "idle in transaction" state

Check whether you have an increasing number of idle in transaction connections. To do this, monitor the state column in the pg_stat_activity table. You might be able to identify the connection source by running a query similar to the following.

```sql
select client_addr, state, count(1) from pg_stat_activity where state like 'idle in transaction%' group by 1,2 order by 3 desc
```

Client:ClientWrite

The Client:ClientWrite event occurs when RDS for PostgreSQL is waiting to write data to the client.

Topics
- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for RDS for PostgreSQL version 10 and higher.

Context

A client process must read all of the data received from an RDS for PostgreSQL DB cluster before the cluster can send more data. The time that the cluster waits before sending more data to the client is a Client:ClientWrite event.

Reduced network throughput between the RDS for PostgreSQL DB instance and the client can cause this event. CPU pressure and network saturation on the client can also cause this event.
CPU pressure is when the CPU is fully utilized and there are tasks waiting for CPU time. Network saturation is when the network between the database and client is carrying more data than it can handle.

Likely causes of increased waits

Common causes for the Client:ClientWrite event to appear in top waits include the following:

Increased network latency

There might be increased network latency between the RDS for PostgreSQL DB instance and client. Higher network latency increases the time required for the client to receive the data.

Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client delays the reception of data from the RDS for PostgreSQL DB instance.

Large volume of data sent to the client

The RDS for PostgreSQL DB instance might be sending a large amount of data to the client. A client might not be able to receive the data as fast as the cluster is sending it. Activities such as a copy of a large table can result in an increase in Client:ClientWrite events.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Place the clients in the same Availability Zone and VPC subnet as the cluster
- Use current generation instances
- Reduce the amount of data sent to the client
- Scale your client

Place the clients in the same Availability Zone and VPC subnet as the cluster

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the RDS for PostgreSQL DB instance.
Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see Jumbo frames (9001 MTU) in the Amazon EC2 User Guide for Linux Instances.

For information about DB instance classes, see DB instance classes. To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place `db.` before the Amazon EC2 instance type name. For example, the `r5.8xlarge` Amazon EC2 instance is equivalent to the `db.r5.8xlarge` DB instance class.

Reduce the amount of data sent to the client

When possible, adjust your application to reduce the amount of data that the RDS for PostgreSQL DB instance sends to the client. Making such adjustments relieves CPU and network contention on the client.

Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

CPU

This event occurs when a thread is active in CPU or is waiting for CPU.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is relevant for all versions of RDS for PostgreSQL.
Context

The central processing unit (CPU) is the component of a computer that runs instructions. For example, CPU instructions perform arithmetic operations and exchange data in memory. If a query increases the number of instructions that it performs through the database engine, the time spent running the query increases. CPU scheduling is giving CPU time to a process. Scheduling is orchestrated by the kernel of the operating system.

Topics

- How to tell when this wait occurs
- DBLoadCPU metric
- os.cpuUtilization metrics
- Likely cause of CPU scheduling

How to tell when this wait occurs

This CPU wait event indicates that a backend process is active in CPU or is waiting for CPU. You know that it's occurring when a query shows the following information:

- The pg_stat_activity.state column has the value active.
- The wait_event_type and wait_event columns in pg_stat_activity are both null.

To see the backend processes that are using or waiting on CPU, run the following query.

```sql
SELECT * 
FROM   pg_stat_activity 
WHERE  state = 'active' 
AND    wait_event_type IS NULL 
AND    wait_event IS NULL;
```

DBLoadCPU metric

The Performance Insights metric for CPU is DBLoadCPU. The value for DBLoadCPU can differ from the value for the Amazon CloudWatch metric CPUUtilization. The latter metric is collected from the HyperVisor for a database instance.
os.cpuUtilization metrics

Performance Insights operating-system metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- os.cpuUtilization.nice.avg
- os.cpuUtilization.total.avg
- os.cpuUtilization.wait.avg
- os.cpuUtilization.idle.avg

Performance Insights reports the CPU usage by the database engine as os.cpuUtilization.nice.avg.

Likely cause of CPU scheduling

The operating system (OS) kernel handles scheduling for the CPU. When the CPU is active, a process might need to wait to get scheduled. The CPU is active while it's performing computations. It's also active while it has an idle thread that it's not running, that is, an idle thread that's waiting on memory I/O. This type of I/O dominates the typical database workload.

Processes are likely to wait to get scheduled on a CPU when the following conditions are met:

- The CloudWatch CPUUtilization metric is near 100 percent.
- The average load is greater than the number of vCPUs, indicating a heavy load. You can find the loadAverageMinute metric in the OS metrics section in Performance Insights.

Likely causes of increased waits

When the CPU wait event occurs more than normal, possibly indicating a performance problem, typical causes include the following.

Topics

- Likely causes of sudden spikes
- Likely causes of long-term high frequency
- Corner cases
Likely causes of sudden spikes

The most likely causes of sudden spikes are as follows:

- Your application has opened too many simultaneous connections to the database. This scenario is known as a "connection storm."
- Your application workload changed in any of the following ways:
  - New queries
  - An increase in the size of your dataset
  - Index maintenance or creation
  - New functions
  - New operators
  - An increase in parallel query execution
- Your query execution plans have changed. In some cases, a change can cause an increase in buffers. For example, the query is now using a sequential scan when it previously used an index. In this case, the queries need more CPU to accomplish the same goal.

Likely causes of long-term high frequency

The most likely causes of events that recur over a long period:

- Too many backend processes are running concurrently on CPU. These processes can be parallel workers.
- Queries are performing suboptimally because they need a large number of buffers.

Corner cases

If none of the likely causes turn out to be actual causes, the following situations might be occurring:

- The CPU is swapping processes in and out.
- The CPU might be managing page table entries if the huge pages feature has been turned off. This memory management feature is turned on by default for all DB instance classes other than micro, small, and medium DB instance classes. For more information, see [Huge pages for RDS for PostgreSQL](https://aws.amazon.com/rds/user-guides/postgresql-limits/).
Actions

If the CPU wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

Topics

- Investigate whether the database is causing the CPU increase
- Determine whether the number of connections increased
- Respond to workload changes

Investigate whether the database is causing the CPU increase

Examine the os.cpuUtilization.nice.avg metric in Performance Insights. If this value is far less than the CPU usage, nondatabase processes are the main contributor to CPU.

Determine whether the number of connections increased

Examine the DatabaseConnections metric in Amazon CloudWatch. Your action depends on whether the number increased or decreased during the period of increased CPU wait events.

The connections increased

If the number of connections went up, compare the number of backend processes consuming CPU to the number of vCPUs. The following scenarios are possible:

- The number of backend processes consuming CPU is less than the number of vCPUs.
  
  In this case, the number of connections isn't an issue. However, you might still try to reduce CPU utilization.

- The number of backend processes consuming CPU is greater than the number of vCPUs.
  
  In this case, consider the following options:
  
  - Decrease the number of backend processes connected to your database. For example, implement a connection pooling solution such as RDS Proxy. To learn more, see Using Amazon RDS Proxy.
  
  - Upgrade your instance size to get a higher number of vCPUs.
  
  - Redirect some read-only workloads to reader nodes, if applicable.
The connections didn't increase

Examine the blks_hit metrics in Performance Insights. Look for a correlation between an increase in blks_hit and CPU usage. The following scenarios are possible:

- CPU usage and blks_hit are correlated.

  In this case, find the top SQL statements that are linked to the CPU usage, and look for plan changes. You can use either of the following techniques:

  - Explain the plans manually and compare them to the expected execution plan.
  - Look for an increase in block hits per second and local block hits per second. In the Top SQL section of Performance Insights dashboard, choose Preferences.

- CPU usage and blks_hit aren't correlated.

  In this case, determine whether any of the following occurs:

  - The application is rapidly connecting to and disconnecting from the database.

    Diagnose this behavior by turning on log_connections and log_disconnections, then analyzing the PostgreSQL logs. Consider using the pgbadger log analyzer. For more information, see https://github.com/darold/pgbadger.

  - The OS is overloaded.

    In this case, Performance Insights shows that backend processes are consuming CPU for a longer time than usual. Look for evidence in the Performance Insights os.cpuUtilization metrics or the CloudWatch CPUUtilization metric. If the operating system is overloaded, look at Enhanced Monitoring metrics to diagnose further. Specifically, look at the process list and the percentage of CPU consumed by each process.

  - Top SQL statements are consuming too much CPU.

    Examine statements that are linked to the CPU usage to see whether they can use less CPU. Run an EXPLAIN command, and focus on the plan nodes that have the most impact. Consider using a PostgreSQL execution plan visualizer. To try out this tool, see http://explain.dalibo.com/.

Respond to workload changes

If your workload has changed, look for the following types of changes:
New queries

Check whether the new queries are expected. If so, ensure that their execution plans and the number of executions per second are expected.

An increase in the size of the data set

Determine whether partitioning, if it's not already implemented, might help. This strategy might reduce the number of pages that a query needs to retrieve.

Index maintenance or creation

Check whether the schedule for the maintenance is expected. A best practice is to schedule maintenance activities outside of peak activities.

New functions

Check whether these functions perform as expected during testing. Specifically, check whether the number of executions per second is expected.

New operators

Check whether they perform as expected during the testing.

An increase in running parallel queries

Determine whether any of the following situations has occurred:

- The relations or indexes involved have suddenly grown in size so that they differ significantly from `min_parallel_table_scan_size` or `min_parallel_index_scan_size`.
- Recent changes have been made to `parallel_setup_cost` or `parallel_tuple_cost`.
- Recent changes have been made to `max_parallel_workers` or `max_parallel_workers_per_gather`.

**IO:BufFileRead and IO:BufFileWrite**

The `IO:BufFileRead` and `IO:BufFileWrite` events occur when RDS for PostgreSQL creates temporary files. When operations require more memory than the working memory parameters currently define, they write temporary data to persistent storage. This operation is sometimes called "spilling to disk."

**Topics**

- [Supported engine versions](#)
Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

I0:BufFileRead and I0:BufFileWrite relate to the work memory area and maintenance work memory area. For more information about these local memory areas, see Resource Consumption in the PostgreSQL documentation.

The default value for work_mem is 4 MB. If one session performs operations in parallel, each worker handling the parallelism uses 4 MB of memory. For this reason, set work_mem carefully. If you increase the value too much, a database running many sessions might consume too much memory. If you set the value too low, RDS for PostgreSQL creates temporary files in local storage. The disk I/O for these temporary files can reduce performance.

If you observe the following sequence of events, your database might be generating temporary files:

1. Sudden and sharp decreases in availability
2. Fast recovery for the free space

You might also see a "chainsaw" pattern. This pattern can indicate that your database is creating small files constantly.

Likely causes of increased waits

In general, these wait events are caused by operations that consume more memory than the work_mem or maintenance_work_mem parameters allocate. To compensate, the operations write to temporary files. Common causes for the I0:BufFileRead and I0:BufFileWrite events include the following:

Queries that need more memory than exists in the work memory area

Queries with the following characteristics use the work memory area:
- Hash joins
- ORDER BY clause
- GROUP BY clause
- DISTINCT
- Window functions
- CREATE TABLE AS SELECT
- Materialized view refresh

Statements that need more memory than exists in the maintenance work memory area

The following statements use the maintenance work memory area:
- CREATE INDEX
- CLUSTER

Actions

We recommend different actions depending on the causes of your wait event.

Topics
- Identify the problem
- Examine your join queries
- Examine your ORDER BY and GROUP BY queries
- Avoid using the DISTINCT operation
- Consider using window functions instead of GROUP BY functions
- Investigate materialized views and CTAS statements
- Use pg_repack when you rebuild indexes
- Increase maintenance_work_mem when you cluster tables
- Tune memory to prevent IO:BufFileRead and IO:BufFileWrite

Identify the problem

Assume a situation in which Performance Insights isn't turned on and you suspect that IO:BufFileRead and IO:BufFileWrite are occurring more frequently than is normal. To
identify the source of the problem, you can set the `log_temp_files` parameter to log all queries that generate more than your specified threshold KB of temporary files. By default, `log_temp_files` is set to -1, which turns off this logging feature. If you set this parameter to 0, RDS for PostgreSQL logs all temporary files. If you set it to is 1024, RDS for PostgreSQL logs all queries that produce temporary files larger than 1 MB. For more information about `log_temp_files`, see Error Reporting and Logging in the PostgreSQL documentation.

Examine your join queries

It's likely that your query uses joins. For example, the following query joins four tables.

```sql
SELECT *
FROM "order"
INNER JOIN order_item
    ON (order.id = order_item.order_id)
INNER JOIN customer
    ON (customer.id = order.customer_id)
INNER JOIN customer_address
    ON (customer_address.customer_id = customer.id AND
        order.customer_address_id = customer_address.id)
WHERE customer.id = 1234567890;
```

A possible cause of spikes in temporary file usage is a problem in the query itself. For example, a broken clause might not filter the joins properly. Consider the second inner join in the following example.

```sql
SELECT *
FROM "order"
INNER JOIN order_item
    ON (order.id = order_item.order_id)
INNER JOIN customer
    ON (customer.id = order.customer_id)
INNER JOIN customer_address
    ON (customer_address.customer_id = customer.id AND
        order.customer_address_id = customer_address.id)
WHERE customer.id = 1234567890;
```

The preceding query mistakenly joins `customer.id` to `customer.id`, generating a Cartesian product between every customer and every order. This type of accidental join generates large temporary files. Depending on the size of the tables, a Cartesian query can even fill up storage. Your application might have Cartesian joins when the following conditions are met:
• You see large, sharp decreases in storage availability, followed by fast recovery.

• No indexes are being created.

• No CREATE TABLE FROM SELECT statements are being issued.

• No materialized views are being refreshed.

To see whether the tables are being joined using the proper keys, inspect your query and object-relational mapping directives. Bear in mind that certain queries of your application are not called all the time, and some queries are dynamically generated.

Examine your ORDER BY and GROUP BY queries

In some cases, an ORDER BY clause can result in excessive temporary files. Consider the following guidelines:

• Only include columns in an ORDER BY clause when they need to be ordered. This guideline is especially important for queries that return thousands of rows and specify many columns in the ORDER BY clause.

• Considering creating indexes to accelerate ORDER BY clauses when they match columns that have the same ascending or descending order. Partial indexes are preferable because they are smaller. Smaller indexes are read and traversed more quickly.

• If you create indexes for columns that can accept null values, consider whether you want the null values stored at the end or at the beginning of the indexes.

If possible, reduce the number of rows that need to be ordered by filtering the result set. If you use WITH clause statements or subqueries, remember that an inner query generates a result set and passes it to the outside query. The more rows that a query can filter out, the less ordering the query needs to do.

• If you don't need to obtain the full result set, use the LIMIT clause. For example, if you only want the top five rows, a query using the LIMIT clause doesn't keep generating results. In this way, the query requires less memory and temporary files.

A query that uses a GROUP BY clause can also require temporary files. GROUP BY queries summarize values by using functions such as the following:

• COUNT

• AVG
• MIN
• MAX
• SUM
• STDDEV

To tune GROUP BY queries, follow the recommendations for ORDER BY queries.

Avoid using the DISTINCT operation

If possible, avoid using the DISTINCT operation to remove duplicated rows. The more unnecessary and duplicated rows that your query returns, the more expensive the DISTINCT operation becomes. If possible, add filters in the WHERE clause even if you use the same filters for different tables. Filtering the query and joining correctly improves your performance and reduces resource use. It also prevents incorrect reports and results.

If you need to use DISTINCT for multiple rows of a same table, consider creating a composite index. Grouping multiple columns in an index can improve the time to evaluate distinct rows. Also, if you use RDS for PostgreSQL version 10 or higher, you can correlate statistics among multiple columns by using the CREATE STATISTICS command.

Consider using window functions instead of GROUP BY functions

Using GROUP BY, you change the result set, and then retrieve the aggregated result. Using window functions, you aggregate data without changing the result set. A window function uses the OVER clause to perform calculations across the sets defined by the query, correlating one row with another. You can use all the GROUP BY functions in window functions, but also use functions such as the following:

• RANK
• ARRAY_AGG
• ROW_NUMBER
• LAG
• LEAD

To minimize the number of temporary files generated by a window function, remove duplications for the same result set when you need two distinct aggregations. Consider the following query.
SELECT sum(salary) OVER (PARTITION BY dept ORDER BY salary DESC) as sum_salary
    , avg(salary) OVER (PARTITION BY dept ORDER BY salary ASC) as avg_salary
FROM empsalary;

You can rewrite the query with the WINDOW clause as follows.

SELECT sum(salary) OVER w as sum_salary
    , avg(salary) OVER w as_avg_salary
FROM empsalary
WINDOW w AS (PARTITION BY dept ORDER BY salary DESC);

By default, the RDS for PostgreSQL execution planner consolidates similar nodes so that it doesn't duplicate operations. However, by using an explicit declaration for the window block, you can maintain the query more easily. You might also improve performance by preventing duplication.

**Investigate materialized views and CTAS statements**

When a materialized view refreshes, it runs a query. This query can contain an operation such as GROUP BY, ORDER BY, or DISTINCT. During a refresh, you might observe large numbers of temporary files and the wait events IO:BufFileWrite and IO:BufFileRead. Similarly, when you create a table based on a SELECT statement, the CREATE TABLE statement runs a query. To reduce the temporary files needed, optimize the query.

**Use pg_repack when you rebuild indexes**

When you create an index, the engine orders the result set. As tables grow in size, and as values in the indexed column become more diverse, the temporary files require more space. In most cases, you can't prevent the creation of temporary files for large tables without modifying the maintenance work memory area. For more information about maintenance_work_mem, see [https://www.postgresql.org/docs/current/runtime-config-resource.html](https://www.postgresql.org/docs/current/runtime-config-resource.html) in the PostgreSQL documentation.

A possible workaround when recreating a large index is to use the pg_repack extension. For more information, see [Reorganize tables in PostgreSQL databases with minimal locks](https://www.postgresql.org/docs/current/runtime-config-resource.html) in the pg_repack documentation. For information about setting up the extension in your RDS for PostgreSQL DB instance, see [Reducing bloat in tables and indexes with the pg_repack extension](https://www.postgresql.org/docs/current/runtime-config-resource.html).
Increase maintenance_work_mem when you cluster tables

The CLUSTER command clusters the table specified by `table_name` based on an existing index specified by `index_name`. RDS for PostgreSQL physically recreates the table to match the order of a given index.

When magnetic storage was prevalent, clustering was common because storage throughput was limited. Now that SSD-based storage is common, clustering is less popular. However, if you cluster tables, you can still increase performance slightly depending on the table size, index, query, and so on.

If you run the CLUSTER command and observe the wait events `IO:BufFileWrite` and `IO:BufFileRead`, tune `maintenance_work_mem`. Increase the memory size to a fairly large amount. A high value means that the engine can use more memory for the clustering operation.

Tune memory to prevent `IO:BufFileRead` and `IO:BufFileWrite`

In some situations, you need to tune memory. Your goal is to balance memory across the following areas of consumption using the appropriate parameters, as follows.

- The `work_mem` value
- The memory remaining after discounting the `shared_buffers` value
- The maximum connections opened and in use, which is limited by `max_connections`

For more information about tuning memory, see Resource Consumption in the PostgreSQL documentation.

Increase the size of the work memory area

In some situations, your only option is to increase the memory used by your session. If your queries are correctly written and are using the correct keys for joins, consider increasing the `work_mem` value.

To find out how many temporary files a query generates, set `log_temp_files` to 0. If you increase the `work_mem` value to the maximum value identified in the logs, you prevent the query from generating temporary files. However, `work_mem` sets the maximum per plan node for each connection or parallel worker. If the database has 5,000 connections, and if each one uses 256 MiB memory, the engine needs 1.2 TiB of RAM. Thus, your instance might run out of memory.
Reserve sufficient memory for the shared buffer pool

Your database uses memory areas such as the shared buffer pool, not just the work memory area. Consider the requirements of these additional memory areas before you increase work_mem.

For example, assume that your RDS for PostgreSQL instance class is db.r5.2xlarge. This class has 64 GiB of memory. By default, 25 percent of the memory is reserved for the shared buffer pool. After you subtract the amount allocated to the shared memory area, 16,384 MB remains. Don’t allocate the remaining memory exclusively to the work memory area because the operating system and the engine also require memory.

The memory that you can allocate to work_mem depends on the instance class. If you use a larger instance class, more memory is available. However, in the preceding example, you can’t use more than 16 GiB. Otherwise, your instance becomes unavailable when it runs out of memory. To recover the instance from the unavailable state, the RDS for PostgreSQL automation services automatically restart.

Manage the number of connections

Suppose that your database instance has 5,000 simultaneous connections. Each connection uses at least 4 MiB of work_mem. The high memory consumption of the connections is likely to degrade performance. In response, you have the following options:

• Upgrade to a larger instance class.
• Decrease the number of simultaneous database connections by using a connection proxy or pooler.

For proxies, consider Amazon RDS Proxy, pgBouncer, or a connection pooler based on your application. This solution alleviates the CPU load. It also reduces the risk when all connections require the work memory area. When fewer database connections exist, you can increase the value of work_mem. In this way, you reduce the occurrence of the IO:BufFileRead and IO:BufFileWrite wait events. Also, the queries waiting for the work memory area speed up significantly.

IO:DataFileRead

The IO:DataFileRead event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.
Topics

• Supported engine versions
• Context
• Likely causes of increased waits
• Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

All queries and data manipulation (DML) operations access pages in the buffer pool. Statements that can induce reads include SELECT, UPDATE, and DELETE. For example, an UPDATE can read pages from tables or indexes. If the page being requested or updated isn't in the shared buffer pool, this read can lead to the IO:DataFileRead event.

Because the shared buffer pool is finite, it can fill up. In this case, requests for pages that aren't in memory force the database to read blocks from disk. If the IO:DataFileRead event occurs frequently, your shared buffer pool might be too small to accommodate your workload. This problem is acute for SELECT queries that read a large number of rows that don't fit in the buffer pool. For more information about the buffer pool, see Resource Consumption in the PostgreSQL documentation.

Likely causes of increased waits

Common causes for the IO:DataFileRead event include the following:

Connection spikes

You might find multiple connections generating the same number of IO:DataFileRead wait events. In this case, a spike (sudden and large increase) in IO:DataFileRead events can occur.

SELECT and DML statements performing sequential scans

Your application might be performing a new operation. Or an existing operation might change because of a new execution plan. In such cases, look for tables (particularly large tables) that have a greater seq_scan value. Find them by querying pg_stat_user_tables. To track queries that are generating more read operations, use the extension pg_stat_statements.
CTAS and CREATE INDEX for large data sets

A CTAS is a CREATE TABLE AS SELECT statement. If you run a CTAS using a large data set as a source, or create an index on a large table, the IO:DataFileRead event can occur. When you create an index, the database might need to read the entire object using a sequential scan. A CTAS generates IO:DataFile reads when pages aren't in memory.

Multiple vacuum workers running at the same time

Vacuum workers can be triggered manually or automatically. We recommend adopting an aggressive vacuum strategy. However, when a table has many updated or deleted rows, the IO:DataFileRead waits increase. After space is reclaimed, the vacuum time spent on IO:DataFileRead decreases.

Ingesting large amounts of data

When your application ingests large amounts of data, ANALYZE operations might occur more often. The ANALYZE process can be triggered by an autovacuum launcher or invoked manually.

The ANALYZE operation reads a subset of the table. The number of pages that must be scanned is calculated by multiplying 30 by the default_statistics_target value. For more information, see the PostgreSQL documentation. The default_statistics_target parameter accepts values between 1 and 10,000, where the default is 100.

Resource starvation

If instance network bandwidth or CPU are consumed, the IO:DataFileRead event might occur more frequently.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Check predicate filters for queries that generate waits
- Minimize the effect of maintenance operations
- Respond to high numbers of connections
Check predicate filters for queries that generate waits

Assume that you identify specific queries that are generating \texttt{IO:DataFileRead} wait events. You might identify them using the following techniques:

- Performance Insights
- Catalog views such as the one provided by the extension \texttt{pg_stat_statements}
- The catalog view \texttt{pg_stat_all_tables}, if it periodically shows an increased number of physical reads
- The \texttt{pg_statio_all_tables} view, if it shows that \texttt{_read} counters are increasing

We recommend that you determine which filters are used in the predicate (WHERE clause) of these queries. Follow these guidelines:

- Run the \texttt{EXPLAIN} command. In the output, identify which types of scans are used. A sequential scan doesn't necessarily indicate a problem. Queries that use sequential scans naturally produce more \texttt{IO:DataFileRead} events when compared to queries that use filters.

  Find out whether the column listed in the WHERE clause is indexed. If not, consider creating an index for this column. This approach avoids the sequential scans and reduces the \texttt{IO:DataFileRead} events. If a query has restrictive filters and still produces sequential scans, evaluate whether the proper indexes are being used.

- Find out whether the query is accessing a very large table. In some cases, partitioning a table can improve performance, allowing the query to only read necessary partitions.

- Examine the cardinality (total number of rows) from your join operations. Note how restrictive the values are that you're passing in the filters for your WHERE clause. If possible, tune your query to reduce the number of rows that are passed in each step of the plan.

Minimize the effect of maintenance operations

Maintenance operations such as \texttt{VACUUM} and \texttt{ANALYZE} are important. We recommend that you don't turn them off because you find \texttt{IO:DataFileRead} wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours. This technique prevents the database from reaching the threshold for automatic operations.
• For very large tables, consider partitioning the table. This technique reduces the overhead of maintenance operations. The database only accesses the partitions that require maintenance.

• When you ingest large amounts of data, consider disabling the autoanalyze feature.

The autovacuum feature is automatically triggered for a table when the following formula is true.

\[
\text{pg\_stat\_user\_tables.n\_dead\_tup} > (\text{pg\_class.reltuples} \times \text{autovacuum\_vacuum\_scale\_factor}) + \text{autovacuum\_vacuum\_threshold}
\]

The view \text{pg\_stat\_user\_tables} and catalog \text{pg\_class} have multiple rows. One row can correspond to one row in your table. This formula assumes that the \text{reltuples} are for a specific table. The parameters \text{autovacuum\_vacuum\_scale\_factor} (0.20 by default) and \text{autovacuum\_vacuum\_threshold} (50 tuples by default) are usually set globally for the whole instance. However, you can set different values for a specific table.

Topics

• Find tables consuming space unnecessarily
• Find indexes consuming space unnecessarily
• Find tables that are eligible to be autovacuumed

Find tables consuming space unnecessarily

To find tables consuming space unnecessarily, you can use functions from the PostgreSQL pgstattuple extension. This extension (module) is available by default on all RDS for PostgreSQL DB instances and can be instantiated on the instance with the following command.

```sql
CREATE EXTENSION pgstattuple;
```

For more information about this extension, see \text{pgstattuple} in the PostgreSQL documentation.

You can check for table and index bloat in your application. For more information, see Diagnosing table and index bloat.

Find indexes consuming space unnecessarily

To find bloated indexes and estimate the amount of space consumed unnecessarily on the tables for which you have read privileges, you can run the following query.
-- WARNING: rows with is_na = 't' are known to have bad statistics ("name" type is not supported).
-- This query is compatible with PostgreSQL 8.2 and later.

SELECT current_database(), nspname AS schemaname, tblname, idxname,
     bs*(relpages)::bigint AS real_size,
     bs*(relpages-est_pages)::bigint AS extra_size,
     100 * (relpages-est_pages)::float / relpages AS extra_ratio,
     fillfactor, bs*(relpages-est_pages_ff) AS bloat_size,
     100 * (relpages-est_pages_ff)::float / relpages AS bloat_ratio,
     is_na
-- , 100-(sub.pst).avg_leaf_density, est_pages, index_tuple_hdr_bm,

    coalesce(cvsf.value::float,autovacuum_vacuum_scale_factor::float) * c.reltuples
<= n_dead_tup
    -- or 1 = 1
)
ORDER BY age(relfrozenxid) DESC;

Respond to high numbers of connections

When you monitor Amazon CloudWatch, you might find that the DatabaseConnections metric spikes. This increase indicates an increased number of connections to your database. We recommend the following approach:

- Limit the number of connections that the application can open with each instance. If your application has an embedded connection pool feature, set a reasonable number of connections. Base the number on what the vCPUs in your instance can parallelize effectively.

  If your application doesn't use a connection pool feature, considering using Amazon RDS Proxy or an alternative. This approach lets your application open multiple connections with the load balancer. The balancer can then open a restricted number of connections with the database. As fewer connections are running in parallel, your DB instance performs less context switching in the kernel. Queries should progress faster, leading to fewer wait events. For more information, see [Using Amazon RDS Proxy](#).

- Whenever possible, take advantage of read replicas for RDS for PostgreSQL. When your application runs a read-only operation, send these requests to the read replica(s). This technique reduces the I/O pressure on the primary (writer) node.
• Consider scaling up your DB instance. A higher-capacity instance class gives more memory, which gives RDS for PostgreSQL a larger shared buffer pool to hold pages. The larger size also gives the DB instance more vCPUs to handle connections. More vCPUs are particularly helpful when the operations that are generating IO:DataFileRead wait events are writes.

**IO:WALWrite**

**Topics**
- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

**Supported engine versions**

This wait event information is supported for all versions of RDS for PostgreSQL 10 and higher.

**Context**

Activity in the database that's generating write-ahead log data fills up the WAL buffers first and then writes to disk, asynchronously. The wait event IO:WALWrite is generated when the SQL session is waiting for the WAL data to complete writing to disk so that it can release the transaction's COMMIT call.

**Likely causes of increased waits**

If this wait event occurs often, you should review your workload and the type of updates that your workload performs and their frequency. In particular, look for the following types of activity.

**Heavy DML activity**

Changing data in database tables doesn't happen instantaneously. An insert to one table might need to wait for an insert or an update to the same table from another client. The data manipulation language (DML) statements for changing data values (INSERT, UPDATE, DELETE, COMMIT, ROLLBACK TRANSACTION) can result in contention that causes the write-ahead logfile to be waiting for the buffers to be flushed. This situation is captured in the following Amazon RDS Performance Insights metrics that indicate heavy DML activity.
• tup_inserted
• tup_updated
• tup_deleted
• xcat_rollback
• xact_commit

For more information about these metrics, see Performance Insights counters for Amazon RDS for PostgreSQL.

Frequent checkpoint activity

Frequent checkpoints contribute to larger WAL size. In RDS for PostgreSQL, full page writes are always "on." Full page writes help protect against data loss. However, when checkpointing occurs too frequently, the system can suffer overall performance issues. This is especially true on systems with heavy DML activity. In some cases, you might find error messages in your postgresql.log stating that “checkpoints are occurring too frequently.”

We recommend that when tuning checkpoints, you carefully balance performance against expected time need to recover in the event of an abnormal shutdown.

Actions

We recommend the following actions to reduce the numbers of this wait event.

Topics

• Reduce the number of commits
• Monitor your checkpoints
• Scale up IO
• Dedicated log volume (DLV)

Reduce the number of commits

To reduce the number of commits, you can combine statements into transaction blocks. Use Amazon RDS Performance Insights to examine the type of queries being run. You can also move large maintenance operations to off-peak hours. For example, create indexes or use pg_repack operations during non-production hours.
Monitor your checkpoints

There are two parameters that you can monitor to see how frequently your RDS for PostgreSQL DB instance is writing to the WAL file for checkpoints.

- **log_checkpoints** – This parameter is set to "on" by default. It causes a message to get sent to the PostgreSQL log for each checkpoint. These log messages include the number of buffers written, the time spent writing them, and the number of WAL files added, removed, or recycled for the given checkpoint.

  For more information about this parameter, see [Error Reporting and Logging](https://www.postgresql.org/docs/current/error-reporting.html) in the PostgreSQL documentation.

- **checkpoint_warning** – This parameter sets a threshold value (in seconds) for checkpoint frequency above which a warning is generated. By default, this parameter isn't set in RDS for PostgreSQL. You can set the value of this parameter to get a warning when the database changes in your RDS for PostgreSQL DB instance are written at a rate for which the WAL files are not sized to handle. For example, say you set this parameter to 30. If your RDS for PostgreSQL instance needs to write changes more often than every 30 seconds, the warning that "checkpoints are occurring too frequently" is sent to the PostgreSQL log. This can indicate that your `max_wal_size` value should be increased.

  For more information, see [Write Ahead Log](https://www.postgresql.org/docs/current/wal.html) in the PostgreSQL documentation.

Scale up IO

This type of input/output (IO) wait event can remediated by scaling the input/output operations per second (IOPs) to provide faster IO. Scaling IO is preferable to scaling CPU, because scaling CPU can result in even more IO contention because the increased CPU can handle more work and thus make the IO bottleneck even worse. In general, we recommend that you consider tuning your workload before performing scaling operations.

Dedicated log volume (DLV)

You can use a dedicated log volume (DLV) for a DB instance that uses Provisioned IOPS (PIOPS) storage by using the Amazon RDS console, AWS CLI, or Amazon RDS API. A DLV moves PostgreSQL database transaction logs to a storage volume that's separate from the volume containing the database tables. For more information, see [Dedicated log volume (DLV)](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_DevGuide-DLV.html).
Lock:advisory

The Lock:advisory event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.

Topics

- Relevant engine versions
- Context
- Causes
- Actions

Relevant engine versions

This wait event information is relevant for RDS for PostgreSQL versions 9.6 and higher.

Context

PostgreSQL advisory locks are application-level, cooperative locks explicitly locked and unlocked by the user's application code. An application can use PostgreSQL advisory locks to coordinate activity across multiple sessions. Unlike regular, object- or row-level locks, the application has full control over the lifetime of the lock. For more information, see Advisory Locks in the PostgreSQL documentation.

Advisory locks can be released before a transaction ends or be held by a session across transactions. This isn't true for implicit, system-enforced locks, such as an access-exclusive lock on a table acquired by a CREATE INDEX statement.

For a description of the functions used to acquire (lock) and release (unlock) advisory locks, see Advisory Lock Functions in the PostgreSQL documentation.

Advisory locks are implemented on top of the regular PostgreSQL locking system and are visible in the pg_locks system view.

Causes

This lock type is exclusively controlled by an application explicitly using it. Advisory locks that are acquired for each row as part of a query can cause a spike in locks or a long-term buildup.
These effects happen when the query is run in a way that acquires locks on more rows than are returned by the query. The application must eventually release every lock, but if locks are acquired on rows that aren't returned, the application can't find all of the locks.

The following example is from [Advisory Locks](#) in the PostgreSQL documentation.

```
SELECT pg_advisory_lock(id) FROM foo WHERE id > 12345 LIMIT 100;
```

In this example, the `LIMIT` clause can only stop the query's output after the rows have already been internally selected and their ID values locked. This can happen suddenly when a growing data volume causes the planner to choose a different execution plan that wasn't tested during development. The buildup in this case happens because the application explicitly calls `pg_advisory_unlock` for every ID value that was locked. However, in this case it can't find the set of locks acquired on rows that weren't returned. Because the locks are acquired on the session level, they aren't released automatically at the end of the transaction.

Another possible cause for spikes in blocked lock attempts is unintended conflicts. In these conflicts, unrelated parts of the application share the same lock ID space by mistake.

**Actions**

Review application usage of advisory locks and detail where and when in the application flow each type of advisory lock is acquired and released.

Determine whether a session is acquiring too many locks or a long-running session isn't releasing locks early enough, leading to a slow buildup of locks. You can correct a slow buildup of session-level locks by ending the session using `pg_terminate_backend(pid)`.

A client waiting for an advisory lock appears in `pg_stat_activity` with `wait_event_type=Lock` and `wait_event=advisory`. You can obtain specific lock values by querying the `pg_locks` system view for the same `pid`, looking for `locktype=advisory` and `granted=f`.

You can then identify the blocking session by querying `pg_locks` for the same advisory lock having `granted=t`, as shown in the following example.

```
SELECT blocked_locks.pid AS blocked_pid,
    blocking_locks.pid AS blocking_pid,
    blocked_activity.usename AS blocked_user,
    blocking_activity.usename AS blocking_user,
    now() - blocked_activity.xact_start AS blocked_transaction_duration,
```
All of the advisory lock API functions have two sets of arguments, either one bigint argument or two integer arguments:

- For the API functions with one bigint argument, the upper 32 bits are in \texttt{pg\_locks.classid} and the lower 32 bits are in \texttt{pg\_locks.objid}.
- For the API functions with two integer arguments, the first argument is \texttt{pg\_locks.classid} and the second argument is \texttt{pg\_locks.objid}.

The \texttt{pg\_locks.objsubid} value indicates which API form was used: 1 means one bigint argument; 2 means two integer arguments.
Lock:extend

The Lock:extend event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

The event Lock:extend indicates that a backend process is waiting to extend a relation that another backend process holds a lock on while it's extending that relation. Because only one process at a time can extend a relation, the system generates a Lock:extend wait event. INSERT, COPY, and UPDATE operations can generate this event.

Likely causes of increased waits

When the Lock:extend event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Surge in concurrent inserts or updates to the same table

There might be an increase in the number of concurrent sessions with queries that insert into or update the same table.

Insufficient network bandwidth

The network bandwidth on the DB instance might be insufficient for the storage communication needs of the current workload. This can contribute to storage latency that causes an increase in Lock:extend events.
Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Reduce concurrent inserts and updates to the same relation
- Increase network bandwidth

Reduce concurrent inserts and updates to the same relation

First, determine whether there's an increase in \texttt{tup\_inserted} and \texttt{tup\_updated} metrics and an accompanying increase in this wait event. If so, check which relations are in high contention for insert and update operations. To determine this, query the \texttt{pg\_stat\_all\_tables} view for the values in \texttt{n\_tup\_ins} and \texttt{n\_tup\_upd} fields. For information about the \texttt{pg\_stat\_all\_tables} view, see \texttt{pg\_stat\_all\_tables} in the PostgreSQL documentation.

To get more information about blocking and blocked queries, query \texttt{pg\_stat\_activity} as in the following example:

```
SELECT
    blocked.pid,
    blocked.usename,
    blocked.query,
    blocking.pid AS blocking_id,
    blocking.query AS blocking_query,
    blocking.wait_event AS blocking_wait_event,
    blocking.wait_event_type AS blocking_wait_event_type
FROM pg_stat_activity AS blocked
JOIN pg_stat_activity AS blocking ON blocking.pid = ANY(pg_blocking_pids(blocked.pid))
where
    blocked.wait_event = 'extend'
and blocked.wait_event_type = 'Lock';
```

```
+----+-----+--------------------------+-------------------+-------+------------------+
<table>
<thead>
<tr>
<th>pid</th>
<th>usename</th>
<th>query</th>
<th>blocking_id</th>
<th>blocking_wait_event</th>
<th>blocking_wait_event_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>7143</td>
<td>myuser</td>
<td>insert into tab1 values (1);</td>
<td>4600</td>
<td>INSERT INTO tab1 (a)</td>
<td>DataFileExtend</td>
</tr>
</tbody>
</table>
SELECT s FROM generate_series(1,1000000) s; | DataFileExtend |
```

Lock:extend
After you identify relations that contribute to increase Lock:extend events, use the following techniques to reduce the contention:

- Find out whether you can use partitioning to reduce contention for the same table. Separating inserted or updated tuples into different partitions can reduce contention. For information about partitioning, see Managing PostgreSQL partitions with the pg_partman extension.

- If the wait event is mainly due to update activity, consider reducing the relation's fillfactor value. This can reduce requests for new blocks during the update. The fillfactor is a storage parameter for a table that determines the maximum amount of space for packing a table page. It's expressed as a percentage of the total space for a page. For more information about the fillfactor parameter, see CREATE TABLE in the PostgreSQL documentation.

⚠️ Important

We highly recommend that you test your system if you change the fillfactor because changing this value can negatively impact performance, depending on your workload.

Increase network bandwidth

To see whether there's an increase in write latency, check the WriteLatency metric in CloudWatch. If there is, use the WriteThroughput and ReadThroughput Amazon CloudWatch metrics to monitor the storage related traffic on the DB instance. These metrics can help you to determine if network bandwidth is sufficient for the storage activity of your workload.

If your network bandwidth isn't enough, increase it. If your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS. For information about network performance for each DB instance class, see Amazon CloudWatch instance-level metrics for Amazon RDS.

Lock:Relation

The Lock:Relation event occurs when a query is waiting to acquire a lock on a table or view (relation) that's currently locked by another transaction.

Topics

- Supported engine versions
Context

Likely causes of increased waits

Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

Most PostgreSQL commands implicitly use locks to control concurrent access to data in tables. You can also use these locks explicitly in your application code with the LOCK command. Many lock modes aren't compatible with each other, and they can block transactions when they're trying to access the same object. When this happens, RDS for PostgreSQL generates a Lock:Relation event. Some common examples are the following:

- Exclusive locks such as ACCESS EXCLUSIVE can block all concurrent access. Data definition language (DDL) operations such as DROP TABLE, TRUNCATE, VACUUM FULL, and CLUSTER acquire ACCESS EXCLUSIVE locks implicitly. ACCESS EXCLUSIVE is also the default lock mode for LOCK TABLE statements that don't specify a mode explicitly.

- Using CREATE INDEX (without CONCURRENT) on a table conflicts with data manipulation language (DML) statements UPDATE, DELETE, and INSERT, which acquire ROW EXCLUSIVE locks.

For more information about table-level locks and conflicting lock modes, see Explicit Locking in the PostgreSQL documentation.

Blocking queries and transactions typically unblock in one of the following ways:

- Blocking query – The application can cancel the query or the user can end the process. The engine can also force the query to end because of a session's statement-timeout or a deadlock detection mechanism.

- Blocking transaction – A transaction stops blocking when it runs a ROLLBACK or COMMIT statement. Rollbacks also happen automatically when sessions are disconnected by a client or by network issues, or are ended. Sessions can be ended when the database engine is shut down, when the system is out of memory, and so forth.
Likely causes of increased waits

When the Lock:Relation event occurs more frequently than normal, it can indicate a performance issue. Typical causes include the following:

Increased concurrent sessions with conflicting table locks

There might be an increase in the number of concurrent sessions with queries that lock the same table with conflicting locking modes.

Maintenance operations

Health maintenance operations such as VACUUM and ANALYZE can significantly increase the number of conflicting locks. VACUUM FULL acquires an ACCESS EXCLUSIVE lock, and ANALYZE acquires a SHARE UPDATE EXCLUSIVE lock. Both types of locks can cause a Lock:Relation wait event. Application data maintenance operations such as refreshing a materialized view can also increase blocked queries and transactions.

Locks on reader instances

There might be a conflict between the relation locks held by the writer and readers. Currently, only ACCESS EXCLUSIVE relation locks are replicated to reader instances. However, the ACCESS EXCLUSIVE relation lock will conflict with any ACCESS SHARE relation locks held by the reader. This can cause an increase in lock relation wait events on the reader.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Reduce the impact of blocking SQL statements
- Minimize the effect of maintenance operations

Reduce the impact of blocking SQL statements

To reduce the impact of blocking SQL statements, modify your application code where possible. Following are two common techniques for reducing blocks:

- Use the NOWAIT option – Some SQL commands, such as SELECT and LOCK statements, support this option. The NOWAIT directive cancels the lock-requesting query if the lock can't be acquired
immediately. This technique can help prevent a blocking session from causing a pile-up of blocked sessions behind it.

For example: Assume that transaction A is waiting on a lock held by transaction B. Now, if B requests a lock on a table that's locked by transaction C, transaction A might be blocked until transaction C completes. But if transaction B uses a NOWAIT when it requests the lock on C, it can fail fast and ensure that transaction A doesn't have to wait indefinitely.

- Use `SET lock_timeout` – Set a `lock_timeout` value to limit the time a SQL statement waits to acquire a lock on a relation. If the lock isn't acquired within the timeout specified, the transaction requesting the lock is cancelled. Set this value at the session level.

**Minimize the effect of maintenance operations**

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find Lock:Relation wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours.
- To reduce Lock:Relation waits caused by autovacuum tasks, perform any needed autovacuum tuning. For information about tuning autovacuum, see [Working with PostgreSQL autovacuum on Amazon RDS](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_AutoVacuum.html) in the *Amazon RDS User Guide*.

**Lock:transactionid**

The Lock:transactionid event occurs when a transaction is waiting for a row-level lock.

**Topics**

- [Context](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/AWS.RDS.PostgreSQL.IDB.Concepts-db-iowait.html#db-iowait-context)
- [Likely causes of increased waits](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/AWS.RDS.PostgreSQL.IDB.Concepts-db-iowait.html#db-iowait-causes)
- [Actions](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/AWS.RDS.PostgreSQL.IDB.Concepts-db-iowait.html#db-iowait-actions)

**Supported engine versions**

This wait event information is supported for all versions of RDS for PostgreSQL.
Context

The event Lock:transactionid occurs when a transaction is trying to acquire a row-level lock that has already been granted to a transaction that is running at the same time. The session that shows the Lock:transactionid wait event is blocked because of this lock. After the blocking transaction ends in either a COMMIT or ROLLBACK statement, the blocked transaction can proceed.

The multiversion concurrency control semantics of RDS for PostgreSQL guarantee that readers don't block writers and writers don't block readers. For row-level conflicts to occur, blocking and blocked transactions must issue conflicting statements of the following types:

- UPDATE
- SELECT ... FOR UPDATE
- SELECT ... FOR KEY SHARE

The statement SELECT ... FOR KEY SHARE is a special case. The database uses the clause FOR KEY SHARE to optimize the performance of referential integrity. A row-level lock on a row can block INSERT, UPDATE, and DELETE commands on other tables that reference the row.

Likely causes of increased waits

When this event appears more than normal, the cause is typically UPDATE, SELECT ... FOR UPDATE, or SELECT ... FOR KEY SHARE statements combined with the following conditions.

Topics

- High concurrency
- Idle in transaction
- Long-running transactions

High concurrency

RDS for PostgreSQL can use granular row-level locking semantics. The probability of row-level conflicts increases when the following conditions are met:

- A highly concurrent workload contends for the same rows.
- Concurrency increases.
Idle in transaction

Sometimes the pg_stat_activity.state column shows the value idle in transaction. This value appears for sessions that have started a transaction, but haven't yet issued a COMMIT or ROLLBACK. If the pg_stat_activity.state value isn't active, the query shown in pg_stat_activity is the most recent one to finish running. The blocking session isn't actively processing a query because an open transaction is holding a lock.

If an idle transaction acquired a row-level lock, it might be preventing other sessions from acquiring it. This condition leads to frequent occurrence of the wait event Lock:transactionid. To diagnose the issue, examine the output from pg_stat_activity and pg_locks.

Long-running transactions

Transactions that run for a long time get locks for a long time. These long-held locks can block other transactions from running.

Actions

Row-locking is a conflict among UPDATE, SELECT … FOR UPDATE, or SELECT … FOR KEY SHARE statements. Before attempting a solution, find out when these statements are running on the same row. Use this information to choose a strategy described in the following sections.

Topics

• Respond to high concurrency
• Respond to idle transactions
• Respond to long-running transactions

Respond to high concurrency

If concurrency is the issue, try one of the following techniques:

• Lower the concurrency in the application. For example, decrease the number of active sessions.
• Implement a connection pool. To learn how to pool connections with RDS Proxy, see Using Amazon RDS Proxy.
• Design the application or data model to avoid contending UPDATE and SELECT … FOR UPDATE statements. You can also decrease the number of foreign keys accessed by SELECT … FOR KEY SHARE statements.
Respond to idle transactions

If `pg_stat_activity.state` shows `idle in transaction`, use the following strategies:

- Turn on autocommit wherever possible. This approach prevents transactions from blocking other transactions while waiting for a `COMMIT` or `ROLLBACK`.
- Search for code paths that are missing `COMMIT`, `ROLLBACK`, or `END`.
- Make sure that the exception handling logic in your application always has a path to a valid end of transaction.
- Make sure that your application processes query results after ending the transaction with `COMMIT` or `ROLLBACK`.

Respond to long-running transactions

If long-running transactions are causing the frequent occurrence of `Lock:transactionid`, try the following strategies:

- Keep row locks out of long-running transactions.
- Limit the length of queries by implementing autocommit whenever possible.

Lock:tuple

The `Lock:tuple` event occurs when a backend process is waiting to acquire a lock on a tuple.

Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.
Context

The event Lock:tuple indicates that a backend is waiting to acquire a lock on a tuple while another backend holds a conflicting lock on the same tuple. The following table illustrates a scenario in which sessions generate the Lock:tuple event.

<table>
<thead>
<tr>
<th>Time</th>
<th>Session 1</th>
<th>Session 2</th>
<th>Session 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>Starts a transaction.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>t2</td>
<td>Updates row 1.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>t3</td>
<td></td>
<td>Updates row 1. The session acquires an exclusive lock on the tuple and then waits for session 1 to release the lock by committing or rolling back.</td>
<td></td>
</tr>
<tr>
<td>t4</td>
<td></td>
<td></td>
<td>Updates row 1. The session waits for session 2 to release the exclusive lock on the tuple.</td>
</tr>
</tbody>
</table>

Or you can simulate this wait event by using the benchmarking tool pgbench. Configure a high number of concurrent sessions to update the same row in a table with a custom SQL file.

To learn more about conflicting lock modes, see Explicit Locking in the PostgreSQL documentation. To learn more about pgbench, see pgbench in the PostgreSQL documentation.

Likely causes of increased waits

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- A high number of concurrent sessions are trying to acquire a conflicting lock for the same tuple by running UPDATE or DELETE statements.
- Highly concurrent sessions are running a SELECT statement using the FOR UPDATE or FOR NO KEY UPDATE lock modes.
• Various factors drive application or connection pools to open more sessions to execute the same operations. As new sessions are trying to modify the same rows, DB load can spike, and Lock:tuple can appear.

For more information, see Row-Level Locks in the PostgreSQL documentation.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- Investigate your application logic
- Find the blocker session
- Reduce concurrency when it is high
- Troubleshoot bottlenecks

**Investigate your application logic**

Find out whether a blocker session has been in the idle_in_transaction state for long time. If so, consider ending the blocker session as a short-term solution. You can use the `pg_terminate_backend` function. For more information about this function, see Server Signaling Functions in the PostgreSQL documentation.

For a long-term solution, do the following:

- Adjust the application logic.
- Use the idle_in_transaction_session_timeout parameter. This parameter ends any session with an open transaction that has been idle for longer than the specified amount of time. For more information, see Client Connection Defaults in the PostgreSQL documentation.
- Use autocommit as much as possible. For more information, see SET AUTOCOMMIT in the PostgreSQL documentation.

**Find the blocker session**

While the Lock:tuple wait event is occurring, identify the blocker and blocked session by finding out which locks depend on one another. For more information, see Lock dependency information in the PostgreSQL wiki.
The following example queries all sessions, filtering on tuple and ordering by wait_time.

```sql
SELECT blocked_locks.pid AS blocked_pid,
       blocking_locks.pid AS blocking_pid,
       blocked_activity.usename AS blocked_user,
       blocking_activity.usename AS blocking_user,
       now() - blocked_activity.xact_start AS blocked_transaction_duration,
       now() - blocking_activity.xact_start AS blocking_transaction_duration,
       concat(blocked_activity.wait_event_type,'::',blocked_activity.wait_event) AS blocked_wait_event,
       concat(blocking_activity.wait_event_type,'::',blocking_activity.wait_event) AS blocking_wait_event,
       blocked_activity.state AS blocked_state,
       blocking_activity.state AS blocking_state,
       blocked_locks.locktype AS blocked_locktype,
       blocking_locks.locktype AS blocking_locktype,
       blocked_activity.query AS blocked_statement,
       blocking_activity.query AS blocking_statement
FROM pg_catalog.pg_locks blocked_locks
JOIN pg_catalog.pg_stat_activity blocked_activity ON blocked_activity.pid = blocked_locks.pid
JOIN pg_catalog.pg_locks blocking_locks
ON blocking_locks.locktype = blocked_locks.locktype
AND blocking_locks.DATABASE IS NOT DISTINCT FROM blocked_locks.DATABASE
AND blocking_locks.relation IS NOT DISTINCT FROM blocked_locks.relation
AND blocking_locks.page IS NOT DISTINCT FROM blocked_locks.page
AND blocking_locks.tuple IS NOT DISTINCT FROM blocked_locks.tuple
AND blocking_locks.virtualxid IS NOT DISTINCT FROM blocked_locks.virtualxid
AND blocking_locks.transactionid IS NOT DISTINCT FROM blocked_locks.transactionid
AND blocking_locks.classid IS NOT DISTINCT FROM blocked_locks.classid
AND blocking_locks.objid IS NOT DISTINCT FROM blocked_locks.objid
AND blocking_locks.objsubid IS NOT DISTINCT FROM blocked_locks.objsubid
AND blocking_locks.pid != blocked_locks.pid
JOIN pg_catalog.pg_stat_activity blocking_activity ON blocking_activity.pid = blocking_locks.pid
WHERE NOT blocked_locks.GRANTED;
```

**Reduce concurrency when it is high**

The Lock:tuple event might occur constantly, especially in a busy workload time. In this situation, consider reducing the high concurrency for very busy rows. Often, just a few rows control a queue or the Boolean logic, which makes these rows very busy.
You can reduce concurrency by using different approaches based in the business requirement, application logic, and workload type. For example, you can do the following:

- Redesign your table and data logic to reduce high concurrency.
- Change the application logic to reduce high concurrency at the row level.
- Leverage and redesign queries with row-level locks.
- Use the NOWAIT clause with retry operations.
- Consider using optimistic and hybrid-locking logic concurrency control.
- Consider changing the database isolation level.

**Troubleshoot bottlenecks**

The Lock:tuple can occur with bottlenecks such as CPU starvation or maximum usage of Amazon EBS bandwidth. To reduce bottlenecks, consider the following approaches:

- Scale up your instance class type.
- Optimize resource-intensive queries.
- Change the application logic.
- Archive data that is rarely accessed.

**LWLock:BufferMapping (LWLock:buffer_mapping)**

This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.

![Note](https://example.com)

This event is named LWLock:BufferMapping for RDS for PostgreSQL version 13 and higher versions. For RDS for PostgreSQL version 12 and older versions, this event is named LWLock:buffer_mapping.

**Topics**

- Supported engine versions
- Context
Supported engine versions

This wait event information is relevant for RDS for PostgreSQL version 9.6 and higher.

Context

The shared buffer pool is a PostgreSQL memory area that holds all pages that are or were being used by processes. When a process needs a page, it reads the page into the shared buffer pool. The shared_buffers parameter sets the shared buffer size and reserves a memory area to store the table and index pages. If you change this parameter, make sure to restart the database.

The LWLock:buffer_mapping wait event occurs in the following scenarios:

- A process searches the buffer table for a page and acquires a shared buffer mapping lock.
- A process loads a page into the buffer pool and acquires an exclusive buffer mapping lock.
- A process removes a page from the pool and acquires an exclusive buffer mapping lock.

Causes

When this event appears more than normal, possibly indicating a performance problem, the database is paging in and out of the shared buffer pool. Typical causes include the following:

- Large queries
- Bloated indexes and tables
- Full table scans
- A shared pool size that is smaller than the working set

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Monitor buffer-related metrics
- **Assess your indexing strategy**
- **Reduce the number of buffers that must be allocated quickly**

**Monitor buffer-related metrics**

When LWLock:buffer_mapping waits spike, investigate the buffer hit ratio. You can use these metrics to get a better understanding of what is happening in the buffer cache. Examine the following metrics:

**blks_hit**

This Performance Insights counter metric indicates the number of blocks that were retrieved from the shared buffer pool. After the LWLock:buffer_mapping wait event appears, you might observe a spike in blks_hit.

**blks_read**

This Performance Insights counter metric indicates the number of blocks that required I/O to be read into the shared buffer pool. You might observe a spike in blks_read in the lead-up to the LWLock:buffer_mapping wait event.

**Assess your indexing strategy**

To confirm that your indexing strategy is not degrading performance, check the following:

**Index bloat**

Ensure that index and table bloat aren't leading to unnecessary pages being read into the shared buffer. If your tables contain unused rows, consider archiving the data and removing the rows from the tables. You can then rebuild the indexes for the resized tables.

**Indexes for frequently used queries**

To determine whether you have the optimal indexes, monitor DB engine metrics in Performance Insights. The tup_returned metric shows the number of rows read. The tup_fetched metric shows the number of rows returned to the client. If tup_returned is significantly larger than tup_fetched, the data might not be properly indexed. Also, your table statistics might not be current.
Reduce the number of buffers that must be allocated quickly

To reduce the LWLock:buffer_mapping wait events, try to reduce the number of buffers that must be allocated quickly. One strategy is to perform smaller batch operations. You might be able to achieve smaller batches by partitioning your tables.

LWLock:BufferIO (IPC:BufferIO)

The LWLock:BufferIO event occurs when RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page. Its purpose is for the same page to be read into the shared buffer.

Topics

• Relevant engine versions
• Context
• Causes
• Actions

Relevant engine versions

This wait event information is relevant for all RDS for PostgreSQL versions. For RDS for PostgreSQL 12 and earlier versions this wait event is named as lwlock:buffer_io whereas in RDS for PostgreSQL 13 version it is named as lwlock:bufferio. From RDS for PostgreSQL 14 version BufferIO wait event moved from LWLock to IPC wait event type (IPC:BufferIO).

Context

Each shared buffer has an I/O lock that is associated with the LWLock:BufferIO wait event, each time a block (or a page) has to be retrieved outside the shared buffer pool.

This lock is used to handle multiple sessions that all require access to the same block. This block has to be read from outside the shared buffer pool, defined by the sharedBuffers parameter.

As soon as the page is read inside the shared buffer pool, the LWLock:BufferIO lock is released.
Note

The LWLock:BufferIO wait event precedes the IO:DataFileRead wait event. The IO:DataFileRead wait event occurs while data is being read from storage.

For more information on lightweight locks, see Locking Overview.

Causes

Common causes for the LWLock:BufferIO event to appear in top waits include the following:

- Multiple backends or connections trying to access the same page that's also pending an I/O operation
- The ratio between the size of the shared buffer pool (defined by the shared_buffers parameter) and the number of buffers needed by the current workload
- The size of the shared buffer pool not being well balanced with the number of pages being evicted by other operations
- Large or bloated indexes that require the engine to read more pages than necessary into the shared buffer pool
- Lack of indexes that forces the DB engine to read more pages from the tables than necessary
- Checkpoints occurring too frequently or needing to flush too many modified pages
- Sudden spikes for database connections trying to perform operations on the same page

Actions

We recommend different actions depending on the causes of your wait event:

- Observe Amazon CloudWatch metrics for correlation between sharp decreases in the BufferCacheHitRatio and LWLock:BufferIO wait events. This effect can mean that you have a small shared buffers setting. You might need to increase it or scale up your DB instance class. You can split your workload into more reader nodes.
- Tune max_wal_size and checkpoint_timeout based on your workload peak time if you see LWLock:BufferIO coinciding with BufferCacheHitRatio metric dips. Then identify which query might be causing it.
- Verify whether you have unused indexes, then remove them.
• Use partitioned tables (which also have partitioned indexes). Doing this helps to keep index reordering low and reduces its impact.
• Avoid indexing columns unnecessarily.
• Prevent sudden database connection spikes by using a connection pool.
• Restrict the maximum number of connections to the database as a best practice.

**LWLock:buffer_content (BufferContent)**

The LWLock:buffer_content event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing. In RDS for PostgreSQL 13 and higher, this wait event is called BufferContent.

**Topics**

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

**Supported engine versions**

This wait event information is supported for all versions of RDS for PostgreSQL.

**Context**

To read or manipulate data, PostgreSQL accesses it through shared memory buffers. To read from the buffer, a process gets a lightweight lock (LWLock) on the buffer content in shared mode. To write to the buffer, it gets that lock in exclusive mode. Shared locks allow other processes to concurrently acquire shared locks on that content. Exclusive locks prevent other processes from getting any type of lock on it.

The LWLock:buffer_content (BufferContent) event indicates that multiple processes are attempting to get a lock on contents of a specific buffer.

**Likely causes of increased waits**

When the LWLock:buffer_content (BufferContent) event appears more than normal, possibly indicating a performance problem, typical causes include the following:
Increased concurrent updates to the same data

There might be an increase in the number of concurrent sessions with queries that update the same buffer content. This contention can be more pronounced on tables with a lot of indexes.

Workload data is not in memory

When data that the active workload is processing is not in memory, these wait events can increase. This effect is because processes holding locks can keep them longer while they perform disk I/O operations.

Excessive use of foreign key constraints

Foreign key constraints can increase the amount of time a process holds onto a buffer content lock. This effect is because read operations require a shared buffer content lock on the referenced key while that key is being updated.

Actions

We recommend different actions depending on the causes of your wait event. You might identify LWLock:buffer_content (BufferContent) events by using Amazon RDS Performance Insights or by querying the view pg_stat_activity.

Topics

- Improve in-memory efficiency
- Reduce usage of foreign key constraints
- Remove unused indexes
- Increase the cache size when using sequences

Improve in-memory efficiency

To increase the chance that active workload data is in memory, partition tables or scale up your instance class. For information about DB instance classes, see DB instance classes.

Reduce usage of foreign key constraints

Investigate workloads experiencing high numbers of LWLock:buffer_content (BufferContent) wait events for usage of foreign key constraints. Remove unnecessary foreign key constraints.
Remove unused indexes

For workloads experiencing high numbers of LWLock:buffer_content (BufferContent) wait events, identify unused indexes and remove them.

Increase the cache size when using sequences

If your tables uses sequences, increase the cache size to remove contention on sequence pages and index pages. Each sequence is a single page in shared memory. The pre-defined cache is per connection. This might not be enough to handle the workload when many concurrent sessions are getting a sequence value.

LWLock:lock_manager (LWLock:lockmanager)

This event occurs when the RDS for PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is relevant for RDS for PostgreSQL version 9.6 and higher. For RDS for PostgreSQL releases older than version 13, the name of this wait event is LWLock:lock_manager. For RDS for PostgreSQL version 13 and higher, the name of this wait event is LWLock:lockmanager.

Context

When you issue a SQL statement, RDS for PostgreSQL records locks to protect the structure, data, and integrity of your database during concurrent operations. The engine can achieve this goal using a fast path lock or a path lock that isn't fast. A path lock that isn't fast is more expensive and creates more overhead than a fast path lock.
Fast path locking

To reduce the overhead of locks that are taken and released frequently, but that rarely conflict, backend processes can use fast path locking. The database uses this mechanism for locks that meet the following criteria:

- They use the DEFAULT lock method.
- They represent a lock on a database relation rather than a shared relation.
- They are weak locks that are unlikely to conflict.
- The engine can quickly verify that no conflicting locks can possibly exist.

The engine can't use fast path locking when either of the following conditions is true:

- The lock doesn't meet the preceding criteria.
- No more slots are available for the backend process.

To tune your queries for fast-path locking, you can use the following query.

```
SELECT count(*), pid, mode, fastpath
FROM pg_locks
WHERE fastpath IS NOT NULL
GROUP BY 4,3,2
ORDER BY pid, mode;
```

```
count | pid  |      mode       | fastpath
-------+------+-----------------+----------
 16 | 9185 | AccessShareLock | t
 336 | 9185 | AccessShareLock | f
 1  | 9185 | ExclusiveLock   | t
```

The following query shows only the total across the database.

```
SELECT count(*), mode, fastpath
FROM pg_locks
WHERE fastpath IS NOT NULL
GROUP BY 3,2
ORDER BY mode,1;
```

```
count |      mode       | fastpath
-------+-----------------+----------
 16 | AccessShareLock | t
```
For more information about fast path locking, see fast path in the PostgreSQL lock manager README and pg-locks in the PostgreSQL documentation.

**Example of a scaling problem for the lock manager**

In this example, a table named `purchases` stores five years of data, partitioned by day. Each partition has two indexes. The following sequence of events occurs:

1. You query many days worth of data, which requires the database to read many partitions.
2. The database creates a lock entry for each partition. If partition indexes are part of the optimizer access path, the database creates a lock entry for them, too.
3. When the number of requested locks entries for the same backend process is higher than 16, which is the value of `FP_LOCK_SLOTS_PER_BACKEND`, the lock manager uses the non–fast path lock method.

Modern applications might have hundreds of sessions. If concurrent sessions are querying the parent without proper partition pruning, the database might create hundreds or even thousands of non–fast path locks. Typically, when this concurrency is higher than the number of vCPUs, the LWLock:lock_manager wait event appears.

**Note**

The LWLock:lock_manager wait event isn't related to the number of partitions or indexes in a database schema. Instead, it's related to the number of non–fast path locks that the database must control.

**Likely causes of increased waits**

When the LWLock:lock_manager wait event occurs more than normal, possibly indicating a performance problem, the most likely causes of sudden spikes are as follows:

- Concurrent active sessions are running queries that don't use fast path locks. These sessions also exceed the maximum vCPU.
• A large number of concurrent active sessions are accessing a heavily partitioned table. Each partition has multiple indexes.

• The database is experiencing a connection storm. By default, some applications and connection pool software create more connections when the database is slow. This practice makes the problem worse. Tune your connection pool software so that connection storms don’t occur.

• A large number of sessions query a parent table without pruning partitions.

• A data definition language (DDL), data manipulation language (DML), or a maintenance command exclusively locks either a busy relation or tuples that are frequently accessed or modified.

**Actions**

If the CPU wait event occurs, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades and this wait event is dominating DB load.

**Topics**

• **Use partition pruning**

• **Remove unnecessary indexes**

• **Tune your queries for fast path locking**

• **Tune for other wait events**

• **Reduce hardware bottlenecks**

• **Use a connection pooler**

• **Upgrade your RDS for PostgreSQL version**

**Use partition pruning**

*Partition pruning* is a query optimization strategy for declaratively partitioned tables that excludes unneeded partitions from table scans, thereby improving performance. Partition pruning is turned on by default. If it is turned off, turn it on as follows.

```
SET enable_partition_pruning = on;
```

Queries can take advantage of partition pruning when their WHERE clause contains the column used for the partitioning. For more information, see [Partition Pruning](https://www.postgresql.org/docs/current/partition-pruning.html) in the PostgreSQL documentation.
Remove unnecessary indexes

Your database might contain unused or rarely used indexes. If so, consider deleting them. Do either of the following:

- Learn how to find unnecessary indexes by reading [Unused Indexes](https://postgreswiki.com/Unused%20Indexes) in the PostgreSQL wiki.
- Run PG Collector. This SQL script gathers database information and presents it in a consolidated HTML report. Check the "Unused indexes" section. For more information, see [pg-collector](https://github.com/aws/aws-labs) in the AWS Labs GitHub repository.

Tune your queries for fast path locking

To find out whether your queries use fast path locking, query the fastpath column in the `pg_locks` table. If your queries aren't using fast path locking, try to reduce number of relations per query to fewer than 16.

Tune for other wait events

If `LWLock:lock_manager` is first or second in the list of top waits, check whether the following wait events also appear in the list:

- Lock:Relation
- Lock:transactionid
- Lock:tuple

If the preceding events appear high in the list, consider tuning these wait events first. These events can be a driver for `LWLock:lock_manager`.

Reduce hardware bottlenecks

You might have a hardware bottleneck, such as CPU starvation or maximum usage of your Amazon EBS bandwidth. In these cases, consider reducing the hardware bottlenecks. Consider the following actions:

- Scale up your instance class.
- Optimize queries that consume large amounts of CPU and memory.
- Change your application logic.
• Archive your data.

For more information about CPU, memory, and EBS network bandwidth, see Amazon RDS Instance Types.

Use a connection pooler

If your total number of active connections exceeds the maximum vCPU, more OS processes require CPU than your instance type can support. In this case, consider using or tuning a connection pool. For more information about the vCPUs for your instance type, see Amazon RDS Instance Types.

For more information about connection pooling, see the following resources:

• Using Amazon RDS Proxy
• pgbouncer
• Connection Pools and Data Sources in the PostgreSQL Documentation

Upgrade your RDS for PostgreSQL version

If your current version of RDS for PostgreSQL is lower than 12, upgrade to version 12 or higher. PostgreSQL versions 12 and later have an improved partition mechanism. For more information about version 12, see PostgreSQL 12.0 Release Notes. For more information about upgrading RDS for PostgreSQL, see Upgrading the PostgreSQL DB engine for Amazon RDS.

Timeout:PgSleep

The Timeout:PgSleep event occurs when a server process has called the pg_sleep function and is waiting for the sleep timeout to expire.

Topics

• Supported engine versions
• Likely causes of increased waits
• Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.
Likely causes of increased waits

This wait event occurs when an application, stored function, or user issues a SQL statement that calls one of the following functions:

- `pg_sleep`
- `pg_sleep_for`
- `pg_sleep_until`

The preceding functions delay execution until the specified number of seconds have elapsed. For example, `SELECT pg_sleep(1)` pauses for 1 second. For more information, see Delaying Execution in the PostgreSQL documentation.

Actions

Identify the statement that was running the `pg_sleep` function. Determine if the use of the function is appropriate.

Timeout:VacuumDelay

The Timeout:VacuumDelay event indicates that the cost limit for vacuum I/O has been exceeded and that the vacuum process has been put to sleep. Vacuum operations stop for the duration specified in the respective cost delay parameter and then it resumes its work. For the manual vacuum command, the delay is specified in the `vacuum_cost_delay` parameter. For the autovacuum daemon, the delay is specified in the `autovacuum_vacuum_cost_delay` parameter.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.
Context

PostgreSQL has both an autovacuum daemon and a manual vacuum command. The autovacuum process is "on" by default for RDS for PostgreSQL DB instances. The manual vacuum command is used on an as-needed basis, for example, to purge tables of dead tuples or generate new statistics.

When vacuuming is underway, PostgreSQL uses an internal counter to keep track of estimated costs as the system performs various I/O operations. When the counter reaches the value specified by the cost limit parameter, the process performing the operation sleeps for the brief duration specified in the cost delay parameter. It then resets the counter and continues operations.

The vacuum process has parameters that can be used to regulate resource consumption. The autovacuum and the manual vacuum command have their own parameters for setting the cost limit value. They also have their own parameters to specify a cost delay, an amount of time to put the vacuum to sleep when the limit is reached. In this way, the cost delay parameter works as a throttling mechanism for resource consumption. In the following lists, you can find description of these parameters.

Parameters that affect throttling of the autovacuum daemon

- **autovacuum_vacuum_cost_limit** – Specifies the cost limit value to use in automatic vacuum operations. Increasing the setting for this parameter allows the vacuum process to use more resources and decreases the Timeout:VacuumDelay wait event.

- **autovacuum_vacuum_cost_delay** – Specifies the cost delay value to use in automatic vacuum operations. The default value is 2 milliseconds. Setting the delay parameter to 0 turns off the throttling mechanism and thus, the Timeout:VacuumDelay wait event won't appear.

For more information, see [Automatic Vacuuming](https://www.postgresql.org/docs/current/vacuum.html) in the PostgreSQL documentation.

Parameters that affect throttling of the manual vacuum process

- **vacuum_cost_limit** – The threshold at which the vacuuming process is put to sleep. By default, the limit is 200. This number represents the accumulated cost estimates for extra I/O needed by various resources. Increasing this value reduces the number of the Timeout:VacuumDelay wait event.

- **vacuum_cost_delay** – The amount of time that the vacuum process sleeps when the vacuum cost limit has been reached. The default setting is 0, which means that this feature is off. You can
set this to an integer value to specify the number of milliseconds to turn on this feature, but we recommend that you leave it at its default setting.

For more information about the `vacuum_cost_delay` parameter, see [Resource Consumption](https://aws.amazon.com/rds/) in the PostgreSQL documentation.

To learn more about how to configure and use the autovacuum with RDS for PostgreSQL, see [Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL](https://aws.amazon.com/rds/).

**Likely causes of increased waits**

The `Timeout:VacuumDelay` is affected by the balance between the cost limit parameter settings (`vacuum_cost_limit`, `autovacuum_vacuum_cost_limit`) and the cost delay parameters (`vacuum_cost_delay`, `autovacuum_vacuum_cost_delay`) that control the vacuum's sleep duration. Raising a cost limit parameter value allows more resources to be used by the vacuum before being put to sleep. That results in fewer `Timeout:VacuumDelay` wait events. Increasing either of the delay parameters causes the `Timeout:VacuumDelay` wait event to occur more frequently and for longer periods of time.

The `autovacuum_max_workers` parameter setting can also increase numbers of the `Timeout:VacuumDelay`. Each additional autovacuum worker process contributes to the internal counter mechanism, and thus the limit can be reached more quickly than with a single autovacuum worker process. As the cost limit is reached more quickly, the cost delay is put to effect more frequently, resulting in more `Timeout:VacuumDelay` wait events. For more information, see `autovacuum_max_workers` in the PostgreSQL documentation.

Large objects, such as 500GB or larger, also raise this wait event because it can take some time for the vacuum to complete processing large objects.

**Actions**

If the vacuum operations complete as expected, no remediation is needed. In other words, this wait event doesn't necessarily indicate a problem. It indicates that the vacuum is being put to sleep for the period of time specified in the delay parameter so that resources can be applied to other processes that need to complete.

If you want vacuum operations to complete faster, you can lower the delay parameters. This shortens the time that the vacuum sleeps.
Tuning RDS for PostgreSQL with Amazon DevOps Guru proactive insights

DevOps Guru proactive insights detects conditions on your RDS for PostgreSQL DB instances that can cause problems, and lets you know about them before they occur. DevOps Guru can do the following:

- Prevent many common database issues by cross-checking your database configuration against common recommended settings.
- Alert you to critical issues in your fleet that, if left unchecked, can lead to larger problems later.
- Alert you to newly discovered problems.

Every proactive insight contains an analysis of the cause of the problem and recommendations for corrective actions.

Topics

- **Database has long running idle in transaction connection**

Database has long running idle in transaction connection

A connection to the database has been in the idle in transaction state for more than 1800 seconds.

Topics

- **Supported engine versions**
- **Context**
- **Likely causes for this issue**
- **Actions**
- **Relevant metrics**

Supported engine versions

This insight information is supported for all versions of RDS for PostgreSQL.
Context

A transaction in the idle in transaction state can hold locks that block other queries. It can also prevent VACUUM (including autovacuum) from cleaning up dead rows, leading to index or table bloat or transaction ID wraparound.

Likely causes for this issue

A transaction initiated in an interactive session with BEGIN or START TRANSACTION hasn't ended by using a COMMIT, ROLLBACK, or END command. This causes the transaction to move to idle in transaction state.

Actions

You can find idle transactions by querying pg_stat_activity.

In your SQL client, run the following query to list all connections in idle in transaction state and to order them by duration:

```sql
SELECT now() - state_change as idle_in_transaction_duration, now() - xact_start as xact_duration,*
FROM  pg_stat_activity
WHERE state  = 'idle in transaction'
AND xact_start is not null
ORDER BY 1 DESC;
```

We recommend different actions depending on the causes of your insight.

Topics

- [End transaction](#)
- [Terminate the connection](#)
- [Configure the idle_in_transaction_session_timeout parameter](#)
- [Check the AUTOCOMMIT status](#)
- [Check the transaction logic in your application code](#)

End transaction

When you initiate a transaction in an interactive session with BEGIN or START TRANSACTION, it moves to idle in transaction state. It remains in this state until you end the transaction by
issuing a COMMIT, ROLLBACK, END command or disconnect the connection completely to roll back the transaction.

**Terminate the connection**

Terminate the connection with an idle transaction using the following query:

```sql
SELECT pg_terminate_backend(pid);
```

`pid` is the process ID of the connection.

**Configure the idle_in_transaction_session_timeout parameter**

Configure the `idle_in_transaction_session_timeout` parameter in the parameter group. The advantage of configuring this parameter is that it does not require a manual intervention to terminate the long idle in transaction. For more information on this parameter, see the PostgreSQL documentation.

The following message will be reported in the PostgreSQL log file after the connection is terminated, when a transaction is in the idle_in_transaction state for longer than the specified time.

```
FATAL: terminating connection due to idle in transaction timeout
```

**Check the AUTOCOMMIT status**

AUTOCOMMIT is turned on by default. But if it is accidentally turned off in the client ensure that you turn it back on.

- In your psql client, run the following command:

  ```bash
  postgres=> \set AUTOCOMMIT on
  ```

- In pgadmin, turn it on by choosing the AUTOCOMMIT option from the down arrow.
Check the transaction logic in your application code

Investigate your application logic for possible problems. Consider the following actions:

- Check if the JDBC auto commit is set true in your application. Also, consider using explicit COMMIT commands in your code.
- Check your error handling logic to see whether it closes a transaction after errors.
- Check whether your application is taking long to process the rows returned by a query while the transaction is open. If so, consider coding the application to close the transaction before processing the rows.
- Check whether a transaction contains many long-running operations. If so, divide a single transaction into multiple transactions.

Relevant metrics

The following PI metrics are related to this insight:

- idle_in_transaction_count - Number of sessions in idle in transaction state.
- idle_in_transaction_max_time - The duration of the longest running transaction in the idle in transaction state.
You can extend the functionality of PostgreSQL by installing a variety of extensions and modules. For example, to work with spatial data you can install and use the PostGIS extension. For more information, see Managing spatial data with the PostGIS extension. As another example, if you want to improve data entry for very large tables, you can consider partitioning your data by using the pg_partman extension. To learn more, see Managing PostgreSQL partitions with the pg_partman extension.

Note
As of RDS for PostgreSQL 14.5, RDS for PostgreSQL supports Trusted Language Extensions for PostgreSQL. This feature is implemented as the extension pg_tle, which you can add to your RDS for PostgreSQL DB instance. By using this extension, developers can create their own PostgreSQL extensions in a safe environment that simplifies the setup and configuration requirements. For more information, see Working with Trusted Language Extensions for PostgreSQL.

In some cases, rather than installing an extension, you might add a specific module to the list of shared_preload_libraries in your RDS for PostgreSQL DB instance's custom DB parameter group. Typically, the default DB cluster parameter group loads only the pg_stat_statements, but several other modules are available to add to the list. For example, you can add scheduling capability by adding the pg_cron module, as detailed in Scheduling maintenance with the PostgreSQL pg_cron extension. As another example, you can log query execution plans by loading the auto_explain module. To learn more, see Logging execution plans of queries in the AWS knowledge center.

Depending on your version of RDS for PostgreSQL, installing an extension might require rds_superuser permissions, as follows:

- For RDS for PostgreSQL versions 12 and earlier versions, installing extensions requires rds_superuser privileges.
- For RDS for PostgreSQL version 13 and higher versions, users (roles) with create permissions on a given database instance can install and use any trusted extensions. For a list of trusted extensions, see PostgreSQL trusted extensions.
You can also specify precisely which extensions can be installed on your RDS for PostgreSQL DB instance, by listing them in the `rds.allowed_extensions` parameter. For more information, see [Restricting installation of PostgreSQL extensions](#).

To learn more about the `rds_superuser` role, see [Understanding PostgreSQL roles and permissions](#).

**Topics**

- [Using functions from the orafce extension](#)
- [Managing PostgreSQL partitions with the pg_partman extension](#)
- [Using pgAudit to log database activity](#)
- [Scheduling maintenance with the PostgreSQL pg_cron extension](#)
- [Using pglogical to synchronize data across instances](#)
- [Using pgactive to support active-active replication](#)
- [Reducing bloat in tables and indexes with the pg_repack extension](#)
- [Upgrading and using the PLV8 extension](#)
- [Using PL/Rust to write PostgreSQL functions in the Rust language](#)
- [Managing spatial data with the PostGIS extension](#)

**Using functions from the orafce extension**

The orafce extension provides functions and operators that emulate a subset of functions and packages from an Oracle database. The orafce extension makes it easier for you to port an Oracle application to PostgreSQL. RDS for PostgreSQL versions 9.6.6 and higher support this extension. For more information about orafce, see [orafce](https://github.com/orafce) on GitHub.

> **Note**
>
> RDS for PostgreSQL doesn't support the `ut1_file` package that is part of the orafce extension. This is because the `ut1_file` schema functions provide read and write operations on operating-system text files, which requires superuser access to the underlying host. As a managed service, RDS for PostgreSQL doesn't provide host access.
To use the orafce extension

1. Connect to the DB instance with the primary user name that you used to create the DB instance.

   If you want to turn on orafce for a different database in the same DB instance, use the /c dbname psql command. Using this command, you change from the primary database after initiating the connection.

2. Turn on the orafce extension with the CREATE EXTENSION statement.

   CREATE EXTENSION orafce;

3. Transfer ownership of the oracle schema to the rds_superuser role with the ALTER SCHEMA statement.

   ALTER SCHEMA oracle OWNER TO rds_superuser;

   If you want to see the list of owners for the oracle schema, use the \dn psql command.
Managing PostgreSQL partitions with the pg_partman extension

PostgreSQL table partitioning provides a framework for high-performance handling of data input and reporting. Use partitioning for databases that require very fast input of large amounts of data. Partitioning also provides for faster queries of large tables. Partitioning helps maintain data without impacting the database instance because it requires less I/O resources.

By using partitioning, you can split data into custom-sized chunks for processing. For example, you can partition time-series data for ranges such as hourly, daily, weekly, monthly, quarterly, yearly, custom, or any combination of these. For a time-series data example, if you partition the table by hour, each partition contains one hour of data. If you partition the time-series table by day, the partitions hold one day's worth of data, and so on. The partition key controls the size of a partition.

When you use an INSERT or UPDATE SQL command on a partitioned table, the database engine routes the data to the appropriate partition. PostgreSQL table partitions that store the data are child tables of the main table.

During database query reads, the PostgreSQL optimizer examines the WHERE clause of the query and, if possible, directs the database scan to only the relevant partitions.

Starting with version 10, PostgreSQL uses declarative partitioning to implement table partitioning. This is also known as native PostgreSQL partitioning. Before PostgreSQL version 10, you used triggers to implement partitions.

PostgreSQL table partitioning provides the following features:

- Creation of new partitions at any time.
- Variable partition ranges.
- Detachable and reattachable partitions using data definition language (DDL) statements.

  For example, detachable partitions are useful for removing historical data from the main partition but keeping historical data for analysis.

- New partitions inherit the parent database table properties, including the following:
  - Indexes
  - Primary keys, which must include the partition key column
  - Foreign keys
  - Check constraints
• References

• Creating indexes for the full table or each specific partition.

You can’t alter the schema for an individual partition. However, you can alter the parent table (such as adding a new column), which propagates to partitions.

**Topics**

• Overview of the PostgreSQL pg_partman extension

• Enabling the pg_partman extension

• Configuring partitions using the create_parent function

• Configuring partition maintenance using the run_maintenance_proc function

**Overview of the PostgreSQL pg_partman extension**

You can use the PostgreSQL pg_partman extension to automate the creation and maintenance of table partitions. For more general information, see [PG Partition Manager](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/PZe.add.html) in the pg_partman documentation.

**Note**

The pg_partman extension is supported on RDS for PostgreSQL versions 12.5 and higher.

Instead of having to manually create each partition, you configure pg_partman with the following settings:

• Table to be partitioned

• Partition type

• Partition key

• Partition granularity

• Partition precreation and management options

After you create a PostgreSQL partitioned table, you register it with pg_partman by calling the create_parent function. Doing this creates the necessary partitions based on the parameters you pass to the function.
The `pg_partman` extension also provides the `run_maintenance_proc` function, which you can call on a scheduled basis to automatically manage partitions. To ensure that the proper partitions are created as needed, schedule this function to run periodically (such as hourly). You can also ensure that partitions are automatically dropped.

**Enabling the `pg_partman` extension**

If you have multiple databases inside the same PostgreSQL DB instance for which you want to manage partitions, enable the `pg_partman` extension separately for each database. To enable the `pg_partman` extension for a specific database, create the partition maintenance schema and then create the `pg_partman` extension as follows.

```
CREATE SCHEMA partman;
CREATE EXTENSION pg_partman WITH SCHEMA partman;
```

**Note**

To create the `pg_partman` extension, make sure that you have `rds_superuser` privileges.

If you receive an error such as the following, grant the `rds_superuser` privileges to the account or use your superuser account.

```
ERROR: permission denied to create extension "pg_partman"
HINT: Must be superuser to create this extension.
```

To grant `rds_superuser` privileges, connect with your superuser account and run the following command.

```
GRANT rds_superuser TO user-or-role;
```

For the examples that show using the `pg_partman` extension, we use the following sample database table and partition. This database uses a partitioned table based on a timestamp. A schema `data_mart` contains a table named events with a column named `created_at`. The following settings are included in the `events` table:

- Primary keys `event_id` and `created_at`, which must have the column used to guide the partition.
• A check constraint `ck_valid_operation` to enforce values for an operation table column.
• Two foreign keys, where one (`fk_orga_membership`) points to the external table `organization` and the other (`fk_parent_event_id`) is a self-referenced foreign key.
• Two indexes, where one (`idx_org_id`) is for the foreign key and the other (`idx_event_type`) is for the event type.

The following DDL statements create these objects, which are automatically included on each partition.

```sql
CREATE SCHEMA data_mart;
CREATE TABLE data_mart.organization ( org_id BIGSERIAL,
    org_name TEXT,
    CONSTRAINT pk_organization PRIMARY KEY (org_id)
);

CREATE TABLE data_mart.events(
    event_id      BIGSERIAL,
    operation     CHAR(1),
    value         FLOAT(24),
    parent_event_id BIGINT,
    event_type    VARCHAR(25),
    org_id        BIGSERIAL,
    created_at    timestamp,
    CONSTRAINT pk_data_mart_event PRIMARY KEY (event_id, created_at),
    CONSTRAINT ck_valid_operation CHECK (operation = 'C' OR operation = 'D'),
    CONSTRAINT fk_orga_membership
        FOREIGN KEY(org_id)
        REFERENCES data_mart.organization (org_id),
    CONSTRAINT fk_parent_event_id
        FOREIGN KEY(parent_event_id, created_at)
        REFERENCES data_mart.events (event_id,created_at)
) PARTITION BY RANGE (created_at);

CREATE INDEX idx_org_id     ON  data_mart.events(org_id);
CREATE INDEX idx_event_type ON  data_mart.events(event_type);
```

**Configuring partitions using the create_parent function**

After you enable the `pg_partman` extension, use the `create_parent` function to configure partitions inside the partition maintenance schema. The following example uses the events table...
example created in Enabling the pg_partman extension. Call the create_parent function as follows.

```sql
SELECT partman.create_parent( p_parent_table => 'data_mart.events',
    p_control => 'created_at',
    p_type => 'native',
    p_interval=> 'daily',
    p_premake => 30);
```

The parameters are as follows:

- **p_parent_table** – The parent partitioned table. This table must already exist and be fully qualified, including the schema.
- **p_control** – The column on which the partitioning is to be based. The data type must be an integer or time-based.
- **p_type** – The type is either 'native' or 'partman'. You typically use the native type for its performance improvements and flexibility. The partman type relies on inheritance.
- **p_interval** – The time interval or integer range for each partition. Example values include daily, hourly, and so on.
- **p_premake** – The number of partitions to create in advance to support new inserts.

For a complete description of the create_parent function, see Creation Functions in the pg_partman documentation.

### Configuring partition maintenance using the run_maintenance_proc function

You can run partition maintenance operations to automatically create new partitions, detach partitions, or remove old partitions. Partition maintenance relies on the run_maintenance_proc function of the pg_partman extension and the pg_cron extension, which initiates an internal scheduler. The pg_cron scheduler automatically executes SQL statements, functions, and procedures defined in your databases.

The following example uses the events table example created in Enabling the pg_partman extension to set partition maintenance operations to run automatically. As a prerequisite, add pg_cron to the shared_preload_libraries parameter in the DB instance's parameter group.

```sql
CREATE EXTENSION pg_cron;
```
UPDATE partman.part_config
SET infinite_time_partitions = true,
   retention = '3 months',
   retention_keep_table=true
WHERE parent_table = 'data_mart.events';
SELECT cron.schedule('@hourly', $$CALL partman.run_maintenance_proc()$$);

Following, you can find a step-by-step explanation of the preceding example:

1. Modify the parameter group associated with your DB instance and add pg_cron to the shared_preload_libraries parameter value. This change requires a DB instance restart for it to take effect. For more information, see Modifying parameters in a DB parameter group.

2. Run the command CREATE EXTENSION pg_cron; using an account that has the rds_superuser permissions. Doing this enables the pg_cron extension. For more information, see Scheduling maintenance with the PostgreSQL pg_cron extension.

3. Run the command UPDATE partman.part_config to adjust the pg_partman settings for the data_mart.events table.

4. Run the command SET ... to configure the data_mart.events table, with these clauses:
   a. infinite_time_partitions = true, – Configures the table to be able to automatically create new partitions without any limit.
   b. retention = '3 months', – Configures the table to have a maximum retention of three months.
   c. retention_keep_table=true – Configures the table so that when the retention period is due, the table isn't deleted automatically. Instead, partitions that are older than the retention period are only detached from the parent table.

5. Run the command SELECT cron.schedule ... to make a pg_cron function call. This call defines how often the scheduler runs the pg_partman maintenance procedure, partman.run_maintenance_proc. For this example, the procedure runs every hour.

For a complete description of the run_maintenance_proc function, see Maintenance Functions in the pg_partman documentation.
Using pgAudit to log database activity

Financial institutions, government agencies, and many industries need to keep audit logs to meet regulatory requirements. By using the PostgreSQL Audit extension (pgAudit) with your RDS for PostgreSQL DB instance, you can capture the detailed records that are typically needed by auditors or to meet regulatory requirements. For example, you can set up the pgAudit extension to track changes made to specific databases and tables, to record the user who made the change, and many other details.

The pgAudit extension builds on the functionality of the native PostgreSQL logging infrastructure by extending the log messages with more detail. In other words, you use the same approach to view your audit log as you do to view any log messages. For more information about PostgreSQL logging, see RDS for PostgreSQL database log files.

The pgAudit extension redacts sensitive data such as cleartext passwords from the logs. If your RDS for PostgreSQL DB instance is configured to log data manipulation language (DML) statements as detailed in Turning on query logging for your RDS for PostgreSQL DB instance, you can avoid the cleartext password issue by using the PostgreSQL Audit extension.

You can configure auditing on your database instances with a great degree of specificity. You can audit all databases and all users. Or, you can choose to audit only certain databases, users, and other objects. You can also explicitly exclude certain users and databases from being audited. For more information, see Excluding users or databases from audit logging.

Given the amount of detail that can be captured, we recommend that if you do use pgAudit, you monitor your storage consumption.

The pgAudit extension is supported on all available RDS for PostgreSQL versions. For a list of pgAudit versions supported by available RDS for PostgreSQL versions, see Extension versions for Amazon RDS for PostgreSQL in the Amazon RDS for PostgreSQL Release Notes.

Topics

- Setting up the pgAudit extension
- Auditing database objects
- Excluding users or databases from audit logging
- Reference for the pgAudit extension
Setting up the pgAudit extension

To set up the pgAudit extension on your RDS for PostgreSQL DB instance, you first add pgAudit to the shared libraries on the custom DB parameter group for your RDS for PostgreSQL DB instance. For information about creating a custom DB parameter group, see Working with parameter groups. Next, you install the pgAudit extension. Finally, you specify the databases and objects that you want to audit. The procedures in this section show you how. You can use the AWS Management Console or the AWS CLI.

You must have permissions as the rds_superuser role to perform all these tasks.

The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group.

Console

To set up the pgAudit extension

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the Configuration tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the Parameter group link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. In the Parameters search field, type shared_pre to find the shared_preload_libraries parameter.
6. Choose Edit parameters to access the property values.
7. Add pgaudit to the list in the Values field. Use a comma to separate items in the list of values.
8. Reboot the RDS for PostgreSQL DB instance so that your change to the `shared_preload_libraries` parameter takes effect.

9. When the instance is available, verify that pgAudit has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

   ```sql
   SHOW shared_preload_libraries;
   shared_preload_libraries
   --------------------------
   rdsutils,pgaudit          
   (1 row)
   ```

10. With pgAudit initialized, you can now create the extension. You need to create the extension after initializing the library because the `pgaudit` extension installs event triggers for auditing data definition language (DDL) statements.

    ```sql
    CREATE EXTENSION pgaudit;
    ```

11. Close the `psql` session.

   ```
   labdb=> \q
   ```

12. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
13. Find the `pgaudit.log` parameter in the list and set to the appropriate value for your use case. For example, setting the `pgaudit.log` parameter to `write` as shown in the following image captures inserts, updates, deletes, and some other types changes to the log.

You can also choose one of the following values for the `pgaudit.log` parameter.

- **none** – This is the default. No database changes are logged.
- **all** – Logs everything (read, write, function, role, ddl, misc).
- **ddl** – Logs all data definition language (DDL) statements that aren't included in the ROLE class.
- **function** – Logs function calls and DO blocks.
- **misc** – Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.
- **read** – Logs SELECT and COPY when the source is a relation (such as a table) or a query.
- **role** – Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.
- **write** – Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).

14. Choose **Save changes**.

15. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

16. Choose your RDS for PostgreSQL DB instance from the Databases list to select it, and then choose **Reboot** from the Actions menu.
To setup pgAudit using the AWS CLI, you call the `modify-db-parameter-group` operation to modify the audit log parameters in your custom parameter group, as shown in the following procedure.

1. Use the following AWS CLI command to add `pgaudit` to the `shared_preload_libraries` parameter.
   ```bash
   aws rds modify-db-parameter-group \
       --db-parameter-group-name custom-param-group-name \
       --parameters "ParameterName=shared_preload_libraries,ParameterValue=pgaudit,ApplyMethod=pending-reboot" \
       --region aws-region
   ```

2. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the `pgaudit` library is initialized.
   ```bash
   aws rds reboot-db-instance \
       --db-instance-identifier your-instance \
       --region aws-region
   ```

3. When the instance is available, you can verify that `pgaudit` has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.
   ```bash
   SHOW shared_preload_libraries;
   shared_preload_libraries
   --------------------------
   rdsutils,pgaudit
   (1 row)
   ```

   With pgAudit initialized, you can now create the extension.
   ```bash
   CREATE EXTENSION pgaudit;
   ```

4. Close the `psql` session so that you can use the AWS CLI.
   ```bash
   labdb=> \q
   ```
5. Use the following AWS CLI command to specify the classes of statement that want logged by session audit logging. The example sets the pgaudit.log parameter to write, which captures inserts, updates, and deletes to the log.

```bash
aws rds modify-db-parameter-group
   --db-parameter-group-name custom-param-group-name
   --parameters "ParameterName=pgaudit.log,ParameterValue=write,ApplyMethod=pending-reboot"
   --region aws-region
```

You can also choose one of the following values for the `pgaudit.log` parameter.

- **none** – This is the default. No database changes are logged.
- **all** – Logs everything (read, write, function, role, ddl, misc).
- **ddl** – Logs all data definition language (DDL) statements that aren't included in the **ROLE** class.
- **function** – Logs function calls and DO blocks.
- **misc** – Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.
- **read** – Logs SELECT and COPY when the source is a relation (such as a table) or a query.
- **role** – Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.
- **write** – Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).

Reboot the RDS for PostgreSQL DB instance using the following AWS CLI command.

```bash
aws rds reboot-db-instance
   --db-instance-identifier your-instance
   --region aws-region
```

**Auditing database objects**

With pgAudit set up on your RDS for PostgreSQL DB instance and configured for your requirements, more detailed information is captured in the PostgreSQL log. For example, while the default PostgreSQL logging configuration identifies the date and time that a change was made in
a database table, with the pgAudit extension the log entry can include the schema, user who made
the change, and other details depending on how the extension parameters are configured. You can
set up auditing to track changes in the following ways.

- For each session, by user. For the session level, you can capture the fully qualified command text.
- For each object, by user and by database.

The object auditing capability is activated when you create the rds_pgaudit role on your
system and then add this role to the pgaudit.role parameter in your custom parameter
parameter group. By default, the pgaudit.role parameter is unset and the only allowable value
is rds_pgaudit. The following steps assume that pgaudit has been initialized and that you have
created the pgaudit extension by following the procedure in Setting up the pgAudit extension.

As shown in this example, the "LOG: AUDIT: SESSION" line provides information about the table
and its schema, among other details.

To set up object auditing

1. Use psql to connect to the RDS for PostgreSQL DB instance.

   ```
   psql --host=your-instance-name.aws-region.rds.amazonaws.com --port=5432 --username=postgres postgres --password --dbname=labdb
   ```

2. Create a database role named rds_pgaudit using the following command.

   ```
   labdb=> CREATE ROLE rds_pgaudit;
   CREATE ROLE
   labdb=>
   ```

3. Close the psql session.

   ```
   labdb=> \q
   ```
In the next few steps, use the AWS CLI to modify the audit log parameters in your custom parameter group.

4. Use the following AWS CLI command to set the `pgaudit.role` parameter to `rds_pgaudit`. By default, this parameter is empty, and `rds_pgaudit` is the only allowable value.

   ```bash
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=pgaudit.role,ParameterValue=rds_pgaudit,ApplyMethod=pending-reboot" \
   --region aws-region
   ``

5. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that your changes to the parameters take effect.

   ```bash
   aws rds reboot-db-instance \
   --db-instance-identifier your-instance \
   --region aws-region
   ``

6. Run the following command to confirm that the `pgaudit.role` is set to `rds_pgaudit`.

   ```sql
   SHOW pgaudit.role;
   pgaudit.role
   ------------------
   rds_pgaudit
   ``

To test pgAudit logging, you can run several example commands that you want to audit. For example, you might run the following commands.

```sql
CREATE TABLE t1 (id int);
GRANT SELECT ON t1 TO rds_pgaudit;
SELECT * FROM t1;
```

<table>
<thead>
<tr>
<th>id</th>
</tr>
</thead>
<tbody>
<tr>
<td>----</td>
</tr>
<tr>
<td>(0 rows)</td>
</tr>
</tbody>
</table>

The database logs should contain an entry similar to the following.

```
...```
For information on viewing the logs, see Monitoring Amazon RDS log files.

To learn more about the pgAudit extension, see pgAudit on GitHub.

Excluding users or databases from audit logging

As discussed in RDS for PostgreSQL database log files, PostgreSQL logs consume storage space. Using the pgAudit extension adds to the volume of data gathered in your logs to varying degrees, depending on the changes that you track. You might not need to audit every user or database in your RDS for PostgreSQL DB instance.

To minimize impacts to your storage and to avoid needlessly capturing audit records, you can exclude users and databases from being audited. You can also change logging within a given session. The following examples show you how.

Note

Parameter settings at the session level take precedence over the settings in the custom DB parameter group for the RDS for PostgreSQL DB instance. If you don't want database users to bypass your audit logging configuration settings, be sure to change their permissions.

Suppose that your RDS for PostgreSQL DB instance is configured to audit the same level of activity for all users and databases. You then decide that you don't want to audit the user myuser. You can turn off auditing for myuser with the following SQL command.

```
ALTER USER myuser SET pgaudit.log TO 'NONE';
```

Then, you can use the following query to check the user_specific_settings column for pgaudit.log to confirm that the parameter is set to NONE.

```
SELECT
    usename AS user_name,
    useconfig AS user_specific_settings
FROM
    pg_user
WHERE
```
username = 'myuser';

You see output such as the following.

<table>
<thead>
<tr>
<th>user_name</th>
<th>user_specific_settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>myuser</td>
<td>{pgaudit.log=NONE}</td>
</tr>
</tbody>
</table>

(1 row)

You can turn off logging for a given user in the midst of their session with the database with the following command.

ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'none';

Use the following query to check the settings column for pgaudit.log for a specific user and database combination.

```sql
SELECT
    username AS "user_name",
    datname AS "database_name",
    pg_catalog.array_to_string(setconfig, E'\n') AS "settings"
FROM
    pg_catalog.pg_db_role_setting s
LEFT JOIN pg_catalog.pg_database d ON d.oid = setdatabase
LEFT JOIN pg_catalog.pg_user r ON r.usesysid = setrole
WHERE
    username = 'myuser'
    AND datname = 'mydatabase'
ORDER BY
    1,
    2;
```

You see output similar to the following.

<table>
<thead>
<tr>
<th>user_name</th>
<th>database_name</th>
<th>settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>myuser</td>
<td>mydatabase</td>
<td>pgaudit.log=none</td>
</tr>
</tbody>
</table>

(1 row)

After turning off auditing for myuser, you decide that you don't want to track changes to mydatabase. You turn off auditing for that specific database by using the following command.
ALTER DATABASE mydatabase SET pgaudit.log to 'NONE';

Then, use the following query to check the database_specific_settings column to confirm that pgaudit.log is set to NONE.

```
SELECT
  a.datname AS database_name,
  b.setconfig AS database_specific_settings
FROM
  pg_database a
FULL JOIN pg_db_role_setting b ON a.oid = b.setdatabase
WHERE
  a.datname = 'mydatabase';
```

You see output such as the following.

<table>
<thead>
<tr>
<th>database_name</th>
<th>database_specific_settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydatabase</td>
<td>{pgaudit.log=NONE}</td>
</tr>
</tbody>
</table>

(1 row)

To return settings to the default setting for myuser, use the following command:

```
ALTER USER myuser RESET pgaudit.log;
```

To return settings to their default setting for a database, use the following command.

```
ALTER DATABASE mydatabase RESET pgaudit.log;
```

To reset user and database to the default setting, use the following command.

```
ALTER USER myuser IN DATABASE mydatabase RESET pgaudit.log;
```

You can also capture specific events to the log by setting the pgaudit.log to one of the other allowed values for the pgaudit.log parameter. For more information, see List of allowable settings for the pgaudit.log parameter.

```
ALTER USER myuser SET pgaudit.log TO 'read';
ALTER DATABASE mydatabase SET pgaudit.log TO 'function';
```
Reference for the pgAudit extension

You can specify the level of detail that you want for your audit log by changing one or more of the parameters listed in this section.

Controlling pgAudit behavior

You can control the audit logging by changing one or more of the parameters listed in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgaudit.log</td>
<td>Specifies the statement classes that will be logged by session audit logging. Allowable values include ddl, function, misc, read, role, write, none, all. For more information, see List of allowable settings for the <code>pgaudit.log</code> parameter.</td>
</tr>
<tr>
<td>pgaudit.log_catalog</td>
<td>When turned on (set to 1), adds statements to audit trail if all relations in a statement are in pg_catalog.</td>
</tr>
<tr>
<td>pgaudit.log_level</td>
<td>Specifies the log level to use for log entries. Allowed values: debug5, debug4, debug3, debug2, debug1, info, notice, warning, log</td>
</tr>
<tr>
<td>pgaudit.log_parameter</td>
<td>When turned on (set to 1), parameters passed with the statement are captured in the audit log.</td>
</tr>
<tr>
<td>pgaudit.log_relation</td>
<td>When turned on (set to 1), the audit log for the session creates a separate log entry for each relation (TABLE, VIEW, and so on) referenced in a SELECT or DML statement.</td>
</tr>
<tr>
<td>pgaudit.log_statement_once</td>
<td>Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry.</td>
</tr>
<tr>
<td>pgaudit.role</td>
<td>Specifies the master role to use for object audit logging. The only allowable entry is <code>rds_pgaudit</code>.</td>
</tr>
</tbody>
</table>
### List of allowable settings for the `pgaudit.log` parameter

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>This is the default. No database changes are logged.</td>
</tr>
<tr>
<td>all</td>
<td>Logs everything (read, write, function, role, ddl, misc).</td>
</tr>
<tr>
<td>ddl</td>
<td>Logs all data definition language (DDL) statements that aren't included in the ROLE class.</td>
</tr>
<tr>
<td>function</td>
<td>Logs function calls and DO blocks.</td>
</tr>
<tr>
<td>misc</td>
<td>Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.</td>
</tr>
<tr>
<td>read</td>
<td>Logs SELECT and COPY when the source is a relation (such as a table) or a query.</td>
</tr>
<tr>
<td>role</td>
<td>Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.</td>
</tr>
<tr>
<td>write</td>
<td>Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).</td>
</tr>
</tbody>
</table>

To log multiple event types with session auditing, use a comma-separated list. To log all event types, set `pgaudit.log` to ALL. Reboot your DB instance to apply the changes.

With object auditing, you can refine audit logging to work with specific relations. For example, you can specify that you want audit logging for READ operations on one or more tables.
Scheduling maintenance with the PostgreSQL pg_cron extension

You can use the PostgreSQL pg_cron extension to schedule maintenance commands within a PostgreSQL database. For more information about the extension, see What is pg_cron? in the pg_cron documentation.

The pg_cron extension is supported on RDS for PostgreSQL engine versions 12.5 and higher.

To learn more about using pg_cron, see Schedule jobs with pg_cron on your RDS for PostgreSQL or your Aurora PostgreSQL-Compatible Edition databases.

Topics

• Setting up the pg_cron extension
• Granting database users permissions to use pg_cron
• Scheduling pg_cron jobs
• Reference for the pg_cron extension

Setting up the pg_cron extension

Set up the pg_cron extension as follows:

1. Modify the custom parameter group associated with your PostgreSQL DB instance by adding pg_cron to the shared_preload_libraries parameter value.

• If your RDS for PostgreSQL DB instance uses the rds.allowed_extensions parameter to explicitly list extensions that can be installed, you need to add the pg_cron extension to the list. Only certain versions of RDS for PostgreSQL support the rds.allowed_extensions parameter. By default, all available extensions are allowed. For more information, see Restricting installation of PostgreSQL extensions.

   Restart the PostgreSQL DB instance to have changes to the parameter group take effect. To learn more about working with parameter groups, see Modifying parameters in a DB parameter group.

2. After the PostgreSQL DB instance has restarted, run the following command using an account that has rds_superuser permissions. For example, if you used the default settings when you created your RDS for PostgreSQL DB instance, connect as user postgres and create the extension.
The \texttt{pg\_cron} scheduler is set in the default PostgreSQL database named \texttt{postgres}. The \texttt{pg\_cron} objects are created in this \texttt{postgres} database and all scheduling actions run in this database.

3. You can use the default settings, or you can schedule jobs to run in other databases within your PostgreSQL DB instance. To schedule jobs for other databases within your PostgreSQL DB instance, see the example in \texttt{Scheduling a cron job for a database other than the default database}.

\textbf{Granting database users permissions to use \texttt{pg\_cron}}

Installing the \texttt{pg\_cron} extension requires the \texttt{rds\_superuser} privileges. However, permissions to use the \texttt{pg\_cron} can be granted (by a member of the \texttt{rds\_superuser} group/role) to other database users, so that they can schedule their own jobs. We recommend that you grant permissions to the \texttt{cron} schema only as needed if it improves operations in your production environment.

To grant a database user permission in the \texttt{cron} schema, run the following command:

```
postgres=> GRANT USAGE ON SCHEMA cron TO db-user;
```

This gives \texttt{db-user} permission to access the \texttt{cron} schema to schedule cron jobs for the objects that they have permissions to access. If the database user doesn't have permissions, the job fails after posting the error message to the \texttt{postgresql.log} file, as shown in the following:

```
2020-12-08 16:41:00 UTC:@:[30647]:ERROR: permission denied for table table-name
2020-12-08 16:41:00 UTC:@:[27071]:LOG: background worker "pg\_cron" (PID 30647) exited with exit code 1
```

In other words, make sure that database users that are granted permissions on the \texttt{cron} schema also have permissions on the objects (tables, schemas, and so on) that they plan to schedule.

The details of the cron job and its success or failure are also captured in the \texttt{cron.job\_run\_details} table. For more information, see \texttt{Tables for scheduling jobs and capturing status}.
Scheduling pg_cron jobs

The following sections show how you can schedule various management tasks using pg_cron jobs.

### Note

When you create pg_cron jobs, check that the max_worker_processes setting is larger than the number of cron.max_running_jobs. A pg_cron job fails if it runs out of background worker processes. The default number of pg_cron jobs is 5. For more information, see [Parameters for managing the pg_cron extension](#).

### Topics

- [Vacuuming a table](#)
- [Purging the pg_cron history table](#)
- [Logging errors to the postgresql.log file only](#)
- [Scheduling a cron job for a database other than the default database](#)

### Vacuuming a table

Autovacuum handles vacuum maintenance for most cases. However, you might want to schedule a vacuum of a specific table at a time of your choosing.

See also, [Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL](#).

Following is an example of using the cron.schedule function to set up a job to use VACUUM FREEZE on a specific table every day at 22:00 (GMT).

```sql
SELECT cron.schedule('manual vacuum', '0 22 * * *', 'VACUUM FREEZE pgbench_accounts');
```

<table>
<thead>
<tr>
<th>schedule</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

After the preceding example runs, you can check the history in the cron.job_run_details table as follows.

```sql
postgres=> SELECT * FROM cron.job_run_details;
```

Scheduling maintenance with the pg_cron extension | 4106
Job 1:

<table>
<thead>
<tr>
<th>jobid</th>
<th>runid</th>
<th>job_pid</th>
<th>database</th>
<th>username</th>
<th>command</th>
<th>status</th>
<th>return_message</th>
<th>start_time</th>
<th>end_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>3395</td>
<td>postgres</td>
<td>adminuser</td>
<td>vacuum freeze pgbench_accounts</td>
<td>succeeded</td>
<td>VACUUM</td>
<td>2020-12-04 21:10:00.050386+00</td>
<td>2020-12-04 21:10:00.072028+00</td>
</tr>
</tbody>
</table>

Job 2:

<table>
<thead>
<tr>
<th>jobid</th>
<th>runid</th>
<th>job_pid</th>
<th>database</th>
<th>username</th>
<th>command</th>
<th>status</th>
<th>return_message</th>
<th>start_time</th>
<th>end_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>4</td>
<td>30339</td>
<td>postgres</td>
<td>adminuser</td>
<td>vacuum freeze pgbench_account</td>
<td>failed</td>
<td>ERROR: relation &quot;pgbench_account&quot; does not exist</td>
<td>2020-12-04 21:48:00.015145+00</td>
<td>2020-12-04 21:48:00.029567+00</td>
</tr>
</tbody>
</table>

Following is a query of the cron.job_run_details table to see the failed jobs.

```sql
postgres=> SELECT * FROM cron.job_run_details WHERE status = 'failed';
```

For more information, see [Tables for scheduling jobs and capturing status](#).

### Purging the pg_cron history table

The cron.job_run_details table contains a history of cron jobs that can become very large over time. We recommend that you schedule a job that purges this table. For example, keeping a week's worth of entries might be sufficient for troubleshooting purposes.

The following example uses the `cron.schedule` function to schedule a job that runs every day at midnight to purge the cron.job_run_details table. The job keeps only the last seven days. Use your `rds_superuser` account to schedule the job such as the following.

```sql
SELECT cron.schedule('0 0 * * *', $$DELETE FROM cron.job_run_details
WHERE end_time < now() - interval '7 days''$$);
```

For more information, see [Tables for scheduling jobs and capturing status](#).
Logging errors to the postgresql.log file only

To prevent writing to the cron.job_run_details table, modify the parameter group associated with the PostgreSQL DB instance and set the cron.log_run parameter to off. The pg_cron extension no longer writes to the table and captures errors to the postgresql.log file only. For more information, see Modifying parameters in a DB parameter group.

Use the following command to check the value of the cron.log_run parameter.

```
postgres=> SHOW cron.log_run;
```

For more information, see Parameters for managing the pg_cron extension.

Scheduling a cron job for a database other than the default database

The metadata for pg_cron is all held in the PostgreSQL default database named postgres. Because background workers are used for running the maintenance cron jobs, you can schedule a job in any of your databases within the PostgreSQL DB instance:

1. In the cron database, schedule the job as you normally do using the cron.schedule.

```
postgres=> SELECT cron.schedule('database1 manual vacuum', '29 03 * * *', 'vacuum freeze test_table');
```

2. As a user with the rds_superuser role, update the database column for the job that you just created so that it runs in another database within your PostgreSQL DB instance.

```
postgres=> UPDATE cron.job SET database = 'database1' WHERE jobid = 106;
```

3. Verify by querying the cron.job table.

```
postgres=> SELECT * FROM cron.job;
jobid | schedule | command                        | nodename | nodeport | database | username | active | jobname
------+----------+--------------------------------+-----------+----------+----------+----------+--------+-------------------------
 106   | 29 03 * * * | vacuum freeze test_table       | localhost | 8192     | database1| adminuser | t      | database1 manual vacuum
       | 59 23 * * * | vacuum freeze pgbench_accounts | localhost | 8192     | postgres | adminuser | t      | manual vacuum
(2 rows)
```
In some situations, you might add a cron job that you intend to run on a different database. In such cases, the job might try to run in the default database (postgres) before you update the correct database column. If the user name has permissions, the job successfully runs in the default database.

Reference for the pg_cron extension

You can use the following parameters, functions, and tables with the pg_cron extension. For more information, see What is pg_cron? in the pg_cron documentation.

Topics

- Parameters for managing the pg_cron extension
- Function reference: cron.schedule
- Function reference: cron.unschedule
- Tables for scheduling jobs and capturing status

Parameters for managing the pg_cron extension

Following is a list of parameters that control the pg_cron extension behavior.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cron.database_name</td>
<td>The database in which pg_cron metadata is kept.</td>
</tr>
<tr>
<td>cron.host</td>
<td>The hostname to connect to PostgreSQL. You can't modify this value.</td>
</tr>
<tr>
<td>cron.log_run</td>
<td>Log every job that runs in the job_run_details table. Values are on or off. For more information, see Tables for scheduling jobs and capturing status.</td>
</tr>
</tbody>
</table>
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cron.log_statement</code></td>
<td>Log all cron statements before running them. Values are on or off.</td>
</tr>
<tr>
<td><code>cron.max_running_jobs</code></td>
<td>The maximum number of jobs that can run concurrently.</td>
</tr>
<tr>
<td><code>cron.use_background_workers</code></td>
<td>Use background workers instead of client sessions. You can't modify this value.</td>
</tr>
</tbody>
</table>

Use the following SQL command to display these parameters and their values.

```sql
postgres=> SELECT name, setting, short_desc FROM pg_settings WHERE name LIKE 'cron.%'
ORDER BY name;
```

**Function reference: cron.schedule**

This function schedules a cron job. The job is initially scheduled in the default `postgres` database. The function returns a `bigint` value representing the job identifier. To schedule jobs to run in other databases within your PostgreSQL DB instance, see the example in [Scheduling a cron job for a database other than the default database](#).

The function has two syntax formats.

**Syntax**

```sql
cron.schedule (job_name,
    schedule,
    command
);

cron.schedule (schedule,
    command
);
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>The name of the cron job.</td>
</tr>
<tr>
<td>schedule</td>
<td>Text indicating the schedule for the cron job.</td>
</tr>
<tr>
<td></td>
<td>The format is the standard cron format.</td>
</tr>
<tr>
<td>command</td>
<td>Text of the command to run.</td>
</tr>
</tbody>
</table>

Examples

```
postgres=> SELECT cron.schedule ('test','0 10 * * *', 'VACUUM pgbench_history');
schedule  
----------
  145
(1 row)

postgres=> SELECT cron.schedule ('0 15 * * *', 'VACUUM pgbench_accounts');
schedule  
----------
  146
(1 row)
```

Function reference: cron.unschedule

This function deletes a cron job. You can specify either the job_name or the job_id. A policy makes sure that you are the owner to remove the schedule for the job. The function returns a Boolean indicating success or failure.

The function has the following syntax formats.

Syntax

```
cron.unschedule (job_id);
cron.unschedule (job_name);
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_id</td>
<td>A job identifier that was returned from the <code>cron.schedule</code> function when the cron job was scheduled.</td>
</tr>
<tr>
<td>job_name</td>
<td>The name of a cron job that was scheduled with the <code>cron.schedule</code> function.</td>
</tr>
</tbody>
</table>

Examples

```
postgres=> SELECT cron.unschedule(108);
       unschedule
----------
        t
(1 row)

postgres=> SELECT cron.unschedule('test');
       unschedule
----------
        t
(1 row)
```

Tables for scheduling jobs and capturing status

The following tables are used to schedule the cron jobs and record how the jobs completed.

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cron.job</td>
<td>Contains the metadata about each scheduled job. Most interactions with this table should be done by using the <code>cron.schedule</code> and <code>cron.unschedule</code> functions.</td>
</tr>
<tr>
<td>Table</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Important</strong></td>
<td>We recommend that you don't give update or insert privileges directly to this table. Doing so would allow the user to update the <code>username</code> column to run as <code>rds-superuser</code>.</td>
</tr>
<tr>
<td>cron.job_run_details</td>
<td>Contains historic information about past scheduled jobs that ran. This is useful to investigate the status, return messages, and start and end time from the job that ran.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td>To prevent this table from growing indefinitely, purge it on a regular basis. For an example, see <a href="#">Purging the pg_cron history table</a>.</td>
</tr>
</tbody>
</table>
Using pglogical to synchronize data across instances

All currently available RDS for PostgreSQL versions support the pglogical extension. The pglogical extension predates the functionally similar logical replication feature that was introduced by PostgreSQL in version 10. For more information, see Performing logical replication for Amazon RDS for PostgreSQL.

The pglogical extension supports logical replication between two or more RDS for PostgreSQL DB instances. It also supports replication between different PostgreSQL versions, and between databases running on RDS for PostgreSQL DB instances and Aurora PostgreSQL DB clusters. The pglogical extension uses a publish-subscribe model to replicate changes to tables and other objects, such as sequences, from a publisher to a subscriber. It relies on a replication slot to ensure that changes are synchronized from a publisher node to a subscriber node, defined as follows.

- The **publisher node** is the RDS for PostgreSQL DB instance that's the source of data to be replicated to other nodes. The publisher node defines the tables to be replicated in a publication set.

- The **subscriber node** is the RDS for PostgreSQL DB instance that receives WAL updates from the publisher. The subscriber creates a subscription to connect to the publisher and get the decoded WAL data. When the subscriber creates the subscription, the replication slot is created on the publisher node.

Following, you can find information about setting up the pglogical extension.

**Topics**
- Requirements and limitations for the pglogical extension
- Setting up the pglogical extension
- Setting up logical replication for RDS for PostgreSQL DB instance
- Reestablishing logical replication after a major upgrade
- Managing logical replication slots for RDS for PostgreSQL
- Parameter reference for the pglogical extension

**Requirements and limitations for the pglogical extension**

All currently available releases of RDS for PostgreSQL support the pglogical extension.
Both the publisher node and the subscriber node must be set up for logical replication.

The tables that you want to replicate from subscriber to publisher must have the same names and the same schema. These tables must also contain the same columns, and the columns must use the same data types. Both publisher and subscriber tables must have the same primary keys. We recommend that you use only the PRIMARY KEY as the unique constraint.

The tables on the subscriber node can have more permissive constraints than those on the publisher node for CHECK constraints and NOT NULL constraints.

The pglogical extension provides features such as two-way replication that aren't supported by the logical replication feature built into PostgreSQL (version 10 and higher). For more information, see [PostgreSQL bi-directional replication using pglogical](https://aws.amazon.com/rds/user-guide/postgresql-beta/).

### Setting up the pglogical extension

To set up the pglogical extension on your RDS for PostgreSQL DB instance, you add pglogical to the shared libraries on the custom DB parameter group for your RDS for PostgreSQL DB instance. You also need to set the value of the `rds.logical_replication` parameter to 1, to turn on logical decoding. Finally, you create the extension in the database. You can use the AWS Management Console or the AWS CLI for these tasks.

You must have permissions as the `rds_superuser` role to perform these tasks.

The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. For information about creating a custom DB parameter group, see [Working with parameter groups](https://aws.amazon.com/rds/user-guide/postgresql-beta/).

**Console**

### To set up the pglogical extension

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the **Configuration** tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.

---

**Using pglogical to synchronize data**

4115
5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.

6. Choose **Edit parameters** to access the property values.

7. Add `pglogical` to the list in the **Values** field. Use a comma to separate items in the list of values.

8. Find the `rds.logical_replication` parameter and set it to 1, to turn on logical replication.

9. Reboot the RDS for PostgreSQL DB instance so that your changes take effect.

10. When the instance is available, you can use `psql` (or `pgAdmin`) to connect to the RDS for PostgreSQL DB instance.

    ```
    psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
    ```

11. To verify that `pglogical` is initialized, run the following command.

    ```
    SHOW shared_preload_libraries;
    shared_preload_libraries
    --------------------------
    rdsutils,pglogical
    (1 row)
    ```

12. Verify the setting that enables logical decoding, as follows.
SHOW wal_level;

```
wal_level
---------
logical
(1 row)
```

13. Create the extension, as follows.

```
CREATE EXTENSION pglogical;
EXTENSION CREATED
```

14. Choose **Save changes**.

15. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

16. Choose your RDS for PostgreSQL DB instance from the Databases list to select it, and then choose **Reboot** from the Actions menu.

**AWS CLI**

**To setup the pglogical extension**

To setup pglogical using the AWS CLI, you call the `modify-db-parameter-group` operation to modify certain parameters in your custom parameter group as shown in the following procedure.

1. Use the following AWS CLI command to add `pglogical` to the `shared_preload_libraries` parameter.

   ```
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters \
   "ParameterName=shared_preload_libraries,ParameterValue=pglogical,ApplyMethod=pending-reboot" \
   --region aws-region
   ```

2. Use the following AWS CLI command to set `rds.logical_replication` to 1 to turn on the logical decoding capability for the RDS for PostgreSQL DB instance.

   ```
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   ```
3. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the pglogical library is initialized.

```bash
aws rds reboot-db-instance \
  --db-instance-identifier your-instance \
  --region aws-region
```

4. When the instance is available, use `psql` to connect to the RDS for PostgreSQL DB instance.

```bash
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
```

5. Create the extension, as follows.

```bash
CREATE EXTENSION pglogical;
EXTENSION CREATED
```

6. Reboot the RDS for PostgreSQL DB instance using the following AWS CLI command.

```bash
aws rds reboot-db-instance \
  --db-instance-identifier your-instance \
  --region aws-region
```

### Setting up logical replication for RDS for PostgreSQL DB instance

The following procedure shows you how to start logical replication between two RDS for PostgreSQL DB instances. The steps assume that both the source (publisher) and the target (subscriber) have the pglogical extension set up as detailed in Setting up the pglogical extension.

**To create the publisher node and define the tables to replicate**

These steps assume that your RDS for PostgreSQL DB instance has a database that has one or more tables that you want to replicate to another node. You need to recreate the table structure from the publisher on the subscriber, so first, get the table structure if necessary. You can do...
that by using the \texttt{psql} metacommand \texttt{\d \tablename} and then creating the same table on the subscriber instance. The following procedure creates an example table on the publisher (source) for demonstration purposes.

1. Use \texttt{psql} to connect to the instance that has the table you want to use as a source for subscribers.

   \begin{verbatim}
   psql --host=source-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   \end{verbatim}

   If you don't have an existing table that you want to replicate, you can create a sample table as follows.

   a. Create an example table using the following SQL statement.

      \begin{verbatim}
      CREATE TABLE docs_lab_table (a int PRIMARY KEY);
      \end{verbatim}

   b. Populate the table with generated data by using the following SQL statement.

      \begin{verbatim}
      INSERT INTO docs_lab_table VALUES (generate_series(1,5000));
      \end{verbatim}

   c. Verify that data exists in the table by using the following SQL statement.

      \begin{verbatim}
      SELECT count(*) FROM docs_lab_table;
      \end{verbatim}

2. Identify this RDS for PostgreSQL DB instance as the publisher node, as follows.

   \begin{verbatim}
   SELECT pglogical.create_node(
     node_name := 'docs_lab_provider',
     dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432 dbname=labdb';
   create_node
   3410995529
   (1 row)
   \end{verbatim}

3. Add the table that you want to replicate to the default replication set. For more information about replication sets, see \url{Replication sets} in the pglogical documentation.
The publisher node setup is complete. You can now set up the subscriber node to receive the updates from the publisher.

**To set up the subscriber node and create a subscription to receive updates**

These steps assume that the RDS for PostgreSQL DB instance has been set up with the pglogical extension. For more information, see [Setting up the pglogical extension](#).

1. Use `psql` to connect to the instance that you want to receive updates from the publisher.

   ```bash
   psql --host=target-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. On the subscriber RDS for PostgreSQL DB instance, create the same table that exists on the publisher. For this example, the table is `docs_lab_table`. You can create the table as follows.

   ```sql
   CREATE TABLE docs_lab_table (a int PRIMARY KEY);
   ```

3. Verify that this table is empty.

   ```sql
   SELECT count(*) FROM docs_lab_table;
   count
   -------
   0
   (1 row)
   ```

4. Identify this RDS for PostgreSQL DB instance as the subscriber node, as follows.

   ```sql
   SELECT pglogical.create_node(
       node_name := 'docs_lab_target',
       dsn := 'host=target-instance.aws-region.rds.amazonaws.com port=5432
       sslmode=require dbname=labdb user=postgres password=********'));
   ```
5. Create the subscription.

```sql
SELECT pglogical.create_subscription(
    subscription_name := 'docs_lab_subscription',
    provider_dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432 sslmode=require dbname=labdb user=postgres password=******',
    replication_sets := ARRAY['default'],
    synchronize_data := true,
    forward_origins := '{}'),
create_subscription
```

When you complete this step, the data from the table on the publisher is created in the table on the subscriber. You can verify that this has occurred by using the following SQL query.

```sql
SELECT count(*) FROM docs_lab_table;
count
-----
5000
(1 row)
```

From this point forward, changes made to the table on the publisher are replicated to the table on the subscriber.

**Reestablishing logical replication after a major upgrade**

Before you can perform a major version upgrade of an RDS for PostgreSQL DB instance that's set up as a publisher node for logical replication, you must drop all replication slots, even those that aren't active. We recommend that you temporarily divert database transactions from the publisher node, drop the replication slots, upgrade the RDS for PostgreSQL DB instance, and then re-establish and restart replication.

The replication slots are hosted on the publisher node only. The RDS for PostgreSQL subscriber node in a logical replication scenario has no slots to drops, but it can't be upgraded to a major
version while it’s designated as a subscriber node with a subscription to the publisher. Before upgrading the RDS for PostgreSQL subscriber node, drop the subscription and the node. For more information, see Managing logical replication slots for RDS for PostgreSQL.

Determining that logical replication has been disrupted

You can determine that the replication process has been disrupted by querying either the publisher node or the subscriber node, as follows.

To check the publisher node

- Use `psql` to connect to the publisher node, and then query the `pg_replication_slots` function. Note the value in the active column. Normally, this will return `t` (true), showing that replication is active. If the query returns `f` (false), it's an indication that replication to the subscriber has stopped.

```sql
SELECT slot_name, plugin, slot_type, active FROM pg_replication_slots;
```

<table>
<thead>
<tr>
<th>slot_name</th>
<th>plugin</th>
<th>slot_type</th>
<th>active</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgl_labdb_docs_labcb4fa94_docs_lab3de412c</td>
<td>pglogical_output</td>
<td>logical</td>
<td>f</td>
</tr>
</tbody>
</table>

(1 row)

To check the subscriber node

On the subscriber node, you can check the status of replication in three different ways.

- Look through the PostgreSQL logs on the subscriber node to find failure messages. The log identifies failure with messages that include exit code 1, as shown following.

```
2022-07-06 16:17:03 UTC::@:
[7361]:LOG: background worker "pglogical apply 16404:2880255011" (PID 14610) exited with exit code 1
2022-07-06 16:19:44 UTC::@:
[7361]:LOG: background worker "pglogical apply 16404:2880255011" (PID 21783) exited with exit code 1
```

- Query the `pg_replication_origin` function. Connect to the database on the subscriber node using `psql` and query the `pg_replication_origin` function, as follows.

```sql
SELECT * FROM pg_replication_origin;
```

<table>
<thead>
<tr>
<th>roident</th>
<th>roname</th>
</tr>
</thead>
<tbody>
<tr>
<td>-------+--------</td>
<td></td>
</tr>
</tbody>
</table>

(1 row)
The empty result set means that replication has been disrupted. Normally, you see output such as the following.

<table>
<thead>
<tr>
<th>roident</th>
<th>roname</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>pgl_labdb_docs_labcb4fa94_docs_lab3de412c</td>
</tr>
</tbody>
</table>

- Query the `pglogical.show_subscription_status` function as shown in the following example.

```
SELECT subscription_name,status,slot_name FROM pglogical.show_subscription_status();
```

```
subscription_name | status | slot_name
---====----------------+--------+-------------------------------------
docs_lab_subscription | down   | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
```

This output shows that replication has been disrupted. Its status is down. Normally, the output shows the status as replicating.

If your logical replication process has been disrupted, you can re-establish replication by following these steps.

**To reestablish logical replication between publisher and subscriber nodes**

To re-establish replication, you first disconnect the subscriber from the publisher node and then re-establish the subscription, as outlined in these steps.

1. Connect to the subscriber node using `psql` as follows.

   ```
   psql --host=222222222222.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Deactivate the subscription by using the `pglogical.alter_subscription_disable` function.

   ```
   SELECT pglogical.alter_subscription_disable('docs_lab_subscription',true);
   ```

   ```
   alter_subscription_disable
   ```
3. Get the publisher node's identifier by querying the `pg_replication_origin`, as follows.

```sql
SELECT * FROM pg_replication_origin;
roident |               roname
---------+--------------------------------------------------------
1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
```

4. Use the response from the previous step with the `pg_replication_origin_create` command to assign the identifier that can be used by the subscription when re-established.

```sql
SELECT pg_replication_origin_create('pgl_labdb_docs_labcb4fa94_docs_lab3de412c');
```

5. Turn on the subscription by passing its name with a status of `true`, as shown in the following example.

```sql
SELECT pglogical.alter_subscription_enable('docs_lab_subscription',true);
```

Check the status of the node. Its status should be replicating as shown in this example.

```sql
SELECT subscription_name,status,slot_name 
    FROM pglogical.show_subscription_status();
```

```sql
subscription_name | status | slot_name
-------------------+---------+-------------------------------------
docs_lab_subscription | replicating | pgl_labdb_docs_lab98f517b_docs_lab3de412c
```

Using `pglogical` to synchronize data
Check the status of the subscriber's replication slot on the publisher node. The slot's active column should return t (true), indicating that replication has been re-established.

```sql
SELECT slot_name, plugin, slot_type, active
FROM pg_replication_slots;
```

<table>
<thead>
<tr>
<th>slot_name</th>
<th>plugin</th>
<th>slot_type</th>
<th>active</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgl_labdb_docs_lab98f517b_docs_lab3de412c</td>
<td>pglogical_output</td>
<td>logical</td>
<td>t</td>
</tr>
</tbody>
</table>

(1 row)

Managing logical replication slots for RDS for PostgreSQL

Before you can perform a major version upgrade on an RDS for PostgreSQL DB instance that's serving as a publisher node in a logical replication scenario, you must drop the replication slots on the instance. The major version upgrade pre-check process notifies you that the upgrade can't proceed until the slots are dropped.

To drop slots from your RDS for PostgreSQL DB instance, first drop the subscription and then drop the slot.

To identify replication slots that were created using the `pglogical` extension, log in to each database and get the name of the nodes. When you query the subscriber node, you get both the publisher and the subscriber nodes in the output, as shown in this example.

```sql
SELECT * FROM pglogical.node;
```

<table>
<thead>
<tr>
<th>node_id</th>
<th>node_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>2182738256</td>
<td>docs_lab_target</td>
</tr>
<tr>
<td>3410995529</td>
<td>docs_lab_provider</td>
</tr>
</tbody>
</table>

(2 rows)

You can get the details about the subscription with the following query.

```sql
SELECT sub_name, sub_slot_name, sub_target
FROM pglogical.subscription;
```

```
<table>
<thead>
<tr>
<th>sub_name</th>
<th>sub_slot_name</th>
<th>sub_target</th>
</tr>
</thead>
<tbody>
<tr>
<td>docs_lab_subscription</td>
<td>pgl_labdb_docs_labcb4fa94_docs_lab3de412c</td>
<td>2182738256</td>
</tr>
</tbody>
</table>
```

(1 row)

You can now drop the subscription, as follows.
After dropping the subscription, you can delete the node.

You can verify that the node no longer exists, as follows.

Parameter reference for the pglogical extension

In the table you can find parameters associated with the pglogical extension. Parameters such as pglogical.conflict_log_level and pglogical.conflict_resolution are used to handle update conflicts. Conflicts can emerge when changes are made locally to the same tables that are subscribed to changes from the publisher. Conflicts can also occur during various scenarios, such as two-way replication or when multiple subscribers are replicating from the same publisher. For more information, see [PostgreSQL bi-directional replication using pglogical](#).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pglogical.batch_inserts</td>
<td>Batch inserts if possible. Not set by default. Change to '1' to turn on, '0' to turn off.</td>
</tr>
<tr>
<td>pglogical.conflict_log_level</td>
<td>Sets the log level to use for logging resolved conflicts. Supported string values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>pglogical.conflict_resolution</code></td>
<td>Sets method to use to resolve conflicts when conflicts are resolvable. Supported string values are <code>error</code>, <code>apply_remote</code>, <code>keep_local</code>, <code>last_update_wins</code>, <code>first_update_wins</code>.</td>
</tr>
<tr>
<td><code>pglogical.extra_connection_options</code></td>
<td>Connection options to add to all peer node connections.</td>
</tr>
<tr>
<td><code>pglogical.synchronous_commit</code></td>
<td><code>pglogical</code> specific synchronous commit value</td>
</tr>
<tr>
<td><code>pglogical.use_spi</code></td>
<td>Use SPI (server programming interface) instead of low-level API to apply changes. Set to '1' to turn on, '0' to turn off. For more information about SPI, see <a href="#">Server Programming Interface</a> in the PostgreSQL documentation.</td>
</tr>
</tbody>
</table>
Using pgactive to support active-active replication

The pgactive extension uses active-active replication to support and coordinate write operations on multiple RDS for PostgreSQL databases. Amazon RDS for PostgreSQL supports the pgactive extension on the following versions:

- RDS for PostgreSQL 16.1 and higher 16 versions
- RDS for PostgreSQL 15.4-R2 and higher 15 versions
- RDS for PostgreSQL 14.10 and higher 14 versions
- RDS for PostgreSQL 13.13 and higher 13 versions
- RDS for PostgreSQL 12.17 and higher 12 versions
- RDS for PostgreSQL 11.22

Note

When there are write operations on more than one database in a replication configuration, conflicts are possible. For more information, see Handling conflicts in active-active replication

Topics

- Initializing the pgactive extension capability
- Setting up active-active replication for RDS for PostgreSQL DB instances
- Handling conflicts in active-active replication
- Handling sequences in active-active replication
- Parameter reference for the pgactive extension
- Measuring replication lag among pgactive members
- Limitations for the pgactive extension

Initializing the pgactive extension capability

To initialize the pgactive extension capability on your RDS for PostgreSQL DB instance, set the value of the rds.enable_pgactive parameter to 1 and then create the extension in the
database. Doing so automatically turns on the parameters `rds.logical_replication` and `track_commit_timestamp` and sets the value of `wal_level` to `logical`.

You must have permissions as the `rds_superuser` role to perform these tasks.

You can use the AWS Management Console or the AWS CLI to create the required RDS for PostgreSQL DB instances. The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. For information about creating a custom DB parameter group, see Working with parameter groups.

**Console**

**To initialize the pgactive extension capability**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the **Configuration** tab for your RDS for PostgreSQL DB instance. In the instance details, find the **DB instance parameter group** link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. Find the `rds.enable_pgactive` parameter, and set it to `1` to initialize the `pgactive` capability.
6. Choose **Save changes**.
7. In the navigation pane of the Amazon RDS console, choose **Databases**.
8. Select your RDS for PostgreSQL DB instance, and then choose **Reboot** from the **Actions** menu.
9. Confirm the DB instance reboot so that your changes take effect.
10. When the DB instance is available, you can use `psql` or any other PostgreSQL client to connect to the RDS for PostgreSQL DB instance.

The following example assumes that your RDS for PostgreSQL DB instance has a default database named `postgres`.

```
psql --host=mydb.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=master_username --password --dbname=postgres
```

11. To verify that `pgactive` is initialized, run the following command.
postgres=> SELECT setting ~ 'pgactive' 
FROM pg_catalog.pg_settings 
WHERE name = 'shared_preload_libraries';

If `pgactive` is in `shared_preload_libraries`, the preceding command will return the following:

<table>
<thead>
<tr>
<th>column</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
</tr>
</tbody>
</table>

12. Create the extension, as follows.

postgres=> CREATE EXTENSION pgactive;

AWS CLI

To initialize the `pgactive` extension capability

To initialize the `pgactive` using the AWS CLI, call the `modify-db-parameter-group` operation to modify certain parameters in your custom parameter group as shown in the following procedure.

1. Use the following AWS CLI command to set `rds.enable_pgactive` to 1 to initialize the `pgactive` capability for the RDS for PostgreSQL DB instance.

```
postgres=> aws rds modify-db-parameter-group \ 
    --db-parameter-group-name custom-param-group-name \ 
    --parameters "ParameterName=rds.enable_pgactive,ParameterValue=1,ApplyMethod=pending-reboot" \ 
    --region aws-region
```

2. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the `pgactive` library is initialized.

```
aws rds reboot-db-instance \ 
    --db-instance-identifier your-instance \ 
    --region aws-region
```
3. When the instance is available, use psql to connect to the RDS for PostgreSQL DB instance.

```plaintext
psql --host=mydb.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=master user --password --dbname=postgres
```

4. Create the extension, as follows.

```plaintext
postgres=> CREATE EXTENSION pgactive;
```

**Setting up active-active replication for RDS for PostgreSQL DB instances**

The following procedure shows you how to start active-active replication between two RDS for PostgreSQL DB instances running PostgreSQL 15.4 or higher in the same region. To run the multi-region high availability example, you need to deploy Amazon RDS for PostgreSQL instances in two different regions and set up VPC Peering. For more information, see [VPC peering](#).

**Note**

Sending traffic between multiple regions may incur additional costs.

These steps assume that the RDS for PostgreSQL DB instance has been setup with the pgactive extension. For more information, see [Initializing the pgactive extension capability](#).

**To configure the first RDS for PostgreSQL DB instance with the pgactive extension**

The following example illustrates how the pgactive group is created, along with other steps required to create the pgactive extension on the RDS for PostgreSQL DB instance.

1. Use psql or another client tool to connect to your first RDS for PostgreSQL DB instance.

```plaintext
psql --host=firstinstance.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=master username --password --dbname=postgres
```

2. Create a database on the RDS for PostgreSQL instance using the following command:

```plaintext
postgres=> CREATE DATABASE app;
```

3. Switch connection to the new database using the following command:
4. To check if the `shared_preload_libraries` parameter contains `pgactive`, run the following command:

```
app=> SELECT setting ~ 'pgactive' FROM pg_catalog.pg_settings WHERE name = 'shared_preload_libraries';
```

<table>
<thead>
<tr>
<th>column?</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
</tr>
</tbody>
</table>

5. Create and populate a sample table using the following SQL statements:

a. Create an example table using the following SQL statement.

```
app=> CREATE SCHEMA inventory;
CREATE TABLE inventory.products (id int PRIMARY KEY, product_name text NOT NULL, created_at timestamptz NOT NULL DEFAULT CURRENT_TIMESTAMP);
```

b. Populate the table with some sample data by using the following SQL statement.

```
app=> INSERT INTO inventory.products (id, product_name) VALUES (1, 'soap'), (2, 'shampoo'), (3, 'conditioner');
```

c. Verify that data exists in the table by using the following SQL statement.

```
app=> SELECT count(*) FROM inventory.products;
```

```
count
-------
  3
```

6. Create `pgactive` extension on the existing database.

```
app=> CREATE EXTENSION pgactive;
```

7. Create and initialize the `pgactive` group using the following commands:

```
Using pgactive to create active-active replication
```
node1-app is the name that you assign to uniquely identify a node in the pgactive group.

To perform this step successfully on a DB instance that is publicly accessible, you must turn on the rds.custom_dns_resolution parameter by setting it to 1.

8. To check if the DB instance is ready, use the following command:

```
app=> SELECT pgactive.pgactive_wait_for_node_ready();
```

If the command succeeds, you can see the following output:

```
pgactive_wait_for_node_ready
------------------------------
(1 row)
```

To configure the second RDS for PostgreSQL instance and join it to the pgactive group

The following example illustrates how you can join an RDS for PostgreSQL DB instance to the pgactive group, along with other steps that are required to create the pgactive extension on the DB instance.

These steps assume that another RDS for PostgreSQL DB instances has been set up with the pgactive extension. For more information, see Initializing the pgactive extension capability.

1. Use psql to connect to the instance that you want to receive updates from the publisher.

```
psql --host=secondinstance.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=master_username --password --dbname=postgres
```
2. Create a database on the second RDS for PostgreSQL DB instance using the following command:

```
postgres=> CREATE DATABASE app;
```

3. Switch connection to the new database using the following command:

```
\c app
```

4. Create the `pgactive` extension on the existing database.

```
app=> CREATE EXTENSION pgactive;
```

5. Join the RDS for PostgreSQL second DB instance to the `pgactive` group as follows.

```
app=> SELECT pgactive.pgactive_join_group(
    node_name := 'node2-app',
    node_dsn := 'dbname=app host=secondinstance.111122223333.aws-
    region.rds.amazonaws.com user=master username password=PASSWORD',
    join_using_dsn := 'dbname=app host=firstinstance.111122223333.aws-
    region.rds.amazonaws.com user=postgres password=PASSWORD');
```

`node2-app` is the name that you assign to uniquely identify a node in the `pgactive` group.

6. To check if the DB instance is ready, use the following command:

```
app=> SELECT pgactive.pgactive_wait_for_node_ready();
```

If the command succeeds, you can see the following output:

```
pgactive_wait_for_node_ready
-------------------------------
(1 row)
```

If the first RDS for PostgreSQL database is relatively large, you can see `pgactive.pgactive_wait_for_node_ready()` emitting the progress report of the restore operation. The output looks similar to the following:

```
NOTICE:  restoring database 'app', 6% of 7483 MB complete
```
NOTICE: restoring database 'app', 42% of 7483 MB complete
NOTICE: restoring database 'app', 77% of 7483 MB complete
NOTICE: restoring database 'app', 98% of 7483 MB complete
NOTICE: successfully restored database 'app' from node node1-app in 00:04:12.274956
pgactive_wait_for_node_ready
-----------------------------
(1 row)

From this point forward, pgactive synchronizes the data between the two DB instances.

7. You can use the following command to verify if the database of the second DB instance has the data:

    app=> SELECT count(*) FROM inventory.products;

If the data is successfully synchronized, you'll see the following output:

    count
    ------
    3

8. Run the following command to insert new values:

    app=> INSERT INTO inventory.products (id, product_name) VALUES ('lotion');

9. Connect to the database of the first DB instance and run the following query:

    app=> SELECT count(*) FROM inventory.products;

If the active-active replication is initialized, the output is similar to the following:

    count
    ------
    4

**To detach and remove a DB instance from the pgactive group**

You can detach and remove a DB instance from the pgactive group using these steps:
1. You can detach the second DB instance from the first DB instance using the following command:

```
app=> SELECT * FROM pgactive.pgactive_detach_nodes(ARRAY['node2-app']);
```

2. Remove the pgactive extension from the second DB instance using the following command:

```
app=> SELECT * FROM pgactive.pgactive_remove();
```

To forcefully remove the extension:

```
app=> SELECT * FROM pgactive.pgactive_remove(true);
```

3. Drop the extension using the following command:

```
app=> DROP EXTENSION pgactive;
```

**Handling conflicts in active-active replication**

The pgactive extension works per database and not per cluster. Each DB instance that uses pgactive is an independent instance and can accept data changes from any source. When a change is sent to a DB instance, PostgreSQL commits it locally and then uses pgactive to replicate the change asynchronously to other DB instances. When two PostgreSQL DB instances update the same record at nearly the same time, a conflict can occur.

The pgactive extension provides mechanisms for conflict detection and automatic resolution. It tracks the time stamp when the transaction was committed on both the DB instances and automatically applies the change with the latest time stamp. The pgactive extension also logs when a conflict occurs in the pgactive.pgactive_conflict_history table.

The pgactive.pgactive_conflict_history will keep growing. You may want to define a purging policy. This can be done by deleting some records on a regular basis or defining a partitioning scheme for this relation (and later detach, drop, truncate partitions of interest). To implement the purging policy on a regular basis, one option is to use the pg_cron extension. See the following information of an example for the pg_cron history table, [Scheduling maintenance with the PostgreSQL pg_cron extension](#).
Handling sequences in active-active replication

An RDS for PostgreSQL DB instance with the pgactive extension uses two different sequence mechanisms to generate unique values.

Global Sequences

To use a global sequence, create a local sequence with the CREATE SEQUENCE statement. Use `pgactive.pgactive_snowflake_id_nextval(seqname)` instead of `nextval(seqname)` to get the next unique value of the sequence.

The following example creates a global sequence:

```
postgres=> CREATE TABLE gtest (
     id bigint primary key,
     parrot text
 );

postgres=>CREATE SEQUENCE gtest_id_seq OWNED BY gtest.id;

postgres=>ALTER TABLE gtest \
ALTER COLUMN id SET DEFAULT \
    pgactive.pgactive_snowflake_id_nextval('gtest_id_seq');
```

Partitioned sequences

In split-step or partitioned sequences, a normal PostgreSQL sequence is used on each node. Each sequence increments by the same amount and starts at different offsets. For example, with step 100, the node 1 generates sequence as 101, 201, 301, and so on and the node 2 generates sequence as 102, 202, 302, and so on. This scheme works well even if the nodes can't communicate for extended periods, but requires that the designer specify a maximum number of nodes when establishing the schema and requires per-node configuration. Mistakes can easily lead to overlapping sequences.

It is relatively simple to configure this approach with pgactive by creating the desired sequence on a node as follows:

```
CREATE TABLE some_table (generated_value bigint primary key);
```
postgres=> CREATE SEQUENCE some_seq INCREMENT 100 OWNED BY some_table.generated_value;

postgres=> ALTER TABLE some_table ALTER COLUMN generated_value SET DEFAULT nextval('some_seq');

Then call setval on each node to give a different offset starting value as follows.

postgres=>
  -- On node 1
  SELECT setval('some_seq', 1);

  -- On node 2
  SELECT setval('some_seq', 2);

Parameter reference for the pgactive extension

You can use the following query to view all the parameters associated with pgactive extension.

postgres=> SELECT * FROM pg_settings WHERE name LIKE 'pgactive.%';

Measuring replication lag among pgactive members

You can use the following query to view the replication lag among the pgactive members. Run this query on every pgactive node to get the full picture.

```
postgres=# SELECT *, (last_applied_xact_at - last_applied_xact_committs) AS lag
FROM pgactive.pgactive_node_slots;
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>node2-app</th>
</tr>
</thead>
<tbody>
<tr>
<td>slot_name</td>
<td>pgactive_5_7332551165694385385_0_5__</td>
</tr>
<tr>
<td>slot_restart_lsn</td>
<td>0/1A898A8</td>
</tr>
<tr>
<td>slot_confirmed_lsn</td>
<td>0/1A898E0</td>
</tr>
<tr>
<td>walsender_active</td>
<td>t</td>
</tr>
<tr>
<td>walsender_pid</td>
<td>69022</td>
</tr>
<tr>
<td>sent_lsn</td>
<td>0/1A898E0</td>
</tr>
<tr>
<td>write_lsn</td>
<td>0/1A898E0</td>
</tr>
<tr>
<td>flush_lsn</td>
<td>0/1A898E0</td>
</tr>
</tbody>
</table>
Limitations for the pgactive extension

- All tables require a Primary Key, otherwise Update's and Delete's aren't allowed. The values in the Primary Key column shouldn't be updated.
- Sequences may have gaps and sometimes might not follow an order. Sequences are not replicated. For more information, see [Handling sequences in active-active replication](#).
- DDL and large objects are not replicated.
- Secondary unique indexes can cause data divergence.
- Collation needs to be identical on all node in the group.
- Load balancing across nodes is an anti-pattern.
- Large transactions can cause replication lag.
Reducing bloat in tables and indexes with the `pg_repack` extension

You can use the `pg_repack` extension to remove bloat from tables and indexes as an alternative to VACUUM FULL. This extension is supported on RDS for PostgreSQL versions 9.6.3 and higher. For more information on the `pg_repack` extension and the full table repack, see the [GitHub project documentation](https://github.com/postgres/procedures). Unlike VACUUM FULL, the `pg_repack` extension requires an exclusive lock (AccessExclusiveLock) only for a short period of time during the table rebuild operation in the following cases:

- Initial creation of log table – A log table is created to record changes that occur during initial copy of the data, as shown in the following example:

  ```sql
  postgres=> \dt+ repack.log_*
  List of relations
  -[ RECORD 1 ]-+----------
  Schema | repack
  Name   | log_16490
  Type   | table
  Owner  | postgres
  Persistence | permanent
  Access method | heap
  Size    | 65 MB
  Description |
  ```

- Final swap-and-drop phase.

For the rest of the rebuild operation, it only needs an ACCESS SHARE lock on the original table to copy rows from it to the new table. This helps the INSERT, UPDATE, and DELETE operations to proceed as usual.

**Recommendations**

The following recommendations apply when you remove bloat from the tables and indexes using the `pg_repack` extension:

- Perform repack during non-business hours or over a maintenance window to minimize its impact on performance of other database activities.
- Closely monitor blocking sessions during the rebuild activity and ensure that there is no activity on the original table that could potentially block `pg_repack`, specifically during the final swap-
and-drop phase when it needs an exclusive lock on the original table. For more information, see Identifying what is blocking a query.

When you see a blocking session, you can terminate it using the following command after careful consideration. This helps in the continuation of pg_repack to finish the rebuild:

```
SELECT pg_terminate_backend(pid);
```

- While applying the accrued changes from the pg_repack's log table on systems with a very high transaction rate, the apply process might not be able to keep up with the rate of changes. In such cases, pg_repack would not be able to complete the apply process. For more information, see Monitoring the new table during the repack. If indexes are severely bloated, an alternative solution is to perform an index only repack. This also helps VACUUM's index cleanup cycles to finish faster.

You can skip the index cleanup phase using manual VACUUM from PostgreSQL version 12, and it is skipped automatically during emergency autovacuum from PostgreSQL version 14. This helps VACUUM complete faster without removing the index bloat and is only meant for emergency situations such as preventing wraparound VACUUM. For more information, see Avoiding bloat in indexes in the Amazon Aurora User Guide.

### Pre-requisites

- The table must have PRIMARY KEY or not-null UNIQUE constraint.
- The extension version must be the same for both the client and the server.
- Ensure that the RDS instance has more FreeStorageSpace than the total size of the table without the bloat. As an example, consider the total size of the table including TOAST and indexes as 2TB, and total bloat in the table as 1TB. The required FreeStorageSpace must be more than value returned by the following calculation:

\[
2TB \text{ (Table size)} - 1TB \text{ (Table bloat)} = 1TB
\]

You can use the following query to check the total size of the table and use pgstattuple to derive bloat. For more information, see Diagnosing table and index bloat in the Amazon Aurora User Guide.

```
SELECT pg_size_pretty(pg_total_relation_size('table_name')) AS total_table_size;
```
This space is reclaimed after the completion of the activity.

- Ensure that the RDS instance has enough compute and IO capacity to handle the repack operation. You might consider to scale up the instance class for optimal balance of performance.

**To use the pg_repack extension**

1. Install the pg_repack extension on your RDS for PostgreSQL DB instance by running the following command.

   ```sql
   CREATE EXTENSION pg_repack;
   ```

2. Run the following commands to grant write access to temporary log tables created by pg_repack.

   ```sql
   ALTER DEFAULT PRIVILEGES IN SCHEMA repack GRANT INSERT ON TABLES TO PUBLIC;
   ALTER DEFAULT PRIVILEGES IN SCHEMA repack GRANT USAGE, SELECT ON SEQUENCES TO PUBLIC;
   ```

3. Connect to the database using the pg_repack client utility. Use an account that has `rds_superuser` privileges. As an example, assume that `rds_test` role has `rds_superuser` privileges. The following syntax performs pg_repack for full tables including all the table indexes in the `postgres` database.

   ```sh
   pg_repack -h db-instance-name.111122223333.aws-region.rds.amazonaws.com -U rds_test -k postgres
   ```

   **Note**

   You must connect using the `-k` option. The `-a` option is not supported.

The response from the pg_repack client provides information on the tables on the DB instance that are repacked.

- INFO: repacking table "pgbench_tellers"
- INFO: repacking table "pgbench_accounts"
- INFO: repacking table "pgbench_branches"
4. The following syntax repacks a single table `orders` including indexes in `postgres` database.

```
pg_repack -h db-instance-name.111122223333.aws-region.rds.amazonaws.com -U rds_test
--table orders -k postgres
```

The following syntax repacks only indexes for `orders` table in `postgres` database.

```
pg_repack -h db-instance-name.111122223333.aws-region.rds.amazonaws.com -U rds_test
--table orders --only-indexes -k postgres
```

**Monitoring the new table during the repack**

- The size of the database is increased by the total size of the table minus bloat, until swap-and-drop phase of repack. You can monitor the growth rate of the database size, calculate the speed of the repack, and roughly estimate the time it takes to complete initial data transfer.

As an example, consider the total size of the table as 2TB, the size of the database as 4TB, and total bloat in the table as 1TB. The database total size value returned by the calculation at the end of the repack operation is the following:

\[
2\text{TB (Table size)} + 4\text{ TB (Database size)} - 1\text{TB (Table bloat)} = 5\text{TB}
\]

You can roughly estimate the speed of the repack operation by sampling the growth rate in bytes between two points in time. If the growth rate is 1GB per minute, it can take 1000 minutes or 16.6 hours approximately to complete the initial table build operation. In addition to the initial table build, `pg_repack` also needs to apply accrued changes. The time it takes depends on the rate of applying ongoing changes plus accrued changes.

**Note**

You can use `pgstattuple` extension to calculate the bloat in the table. For more information, see `pgstattuple`.

- The number of rows in the `pg_repack` 's log table, under the repack schema represents the volume of changes pending to be applied to the new table after the initial load.
You can check the pg_repack's log table in pg_stat_all_tables to monitor the changes applied to the new table. pg_stat_all_tables.n_live_tup indicates the number of records that are pending to be applied to the new table. For more information, see pg_stat_all_tables.

```
postgres=>SELECT relname, n_live_tup FROM pg_stat_all_tables WHERE schemaname = 'repack' AND relname ILIKE '%log%';

-[ RECORD 1 ]---------
relname    | log_16490
n_live_tup | 2000000
```

- You can use the pg_stat_statements extension to find out the time taken by each step in the repack operation. This is helpful in preparation for applying the same repack operation in a production environment. You may adjust the LIMIT clause for extending the output further.

```
postgres=>SELECT
    SUBSTR(query, 1, 100) query,
    round((round(total_exec_time::numeric, 6) / 1000 / 60),4) total_exec_time_in_minutes
FROM
    pg_stat_statements
WHERE
    query ILIKE '%repack%'
ORDER BY
    total_exec_time DESC LIMIT 5;

query                                                                 | total_exec_time_in_minutes
-----------------------------------------------------------------------+-----------------------------
+-----------------------------+-----------------------------
CREATE UNIQUE INDEX index_16493 ON repack.table_16490 USING btree (a)  | 6.8627
INSERT INTO repack.table_16490 SELECT a FROM ONLY public.t1           | 6.4150
SELECT repack.repack_apply($1, $2, $3, $4, $5, $6)                    | 0.5395
SELECT repack.repack_drop($1, $2)                                     | 0.0004
SELECT repack.repack_swap($1)                                         | 0.0004
(5 rows)
```
Repacking is completely an out-of-place operation so the original table is not impacted and we do not anticipate any unexpected challenges that require recovery of the original table. If repack fails unexpectedly, you must inspect the cause of the error and resolve it.

After the issue is resolved, drop and recreate the `pg_repack` extension in the database where the table exists, and retry the `pg_repack` step. In addition, the availability of compute resources and concurrent accessibility of the table plays a crucial role in the timely completion of the repack operation.
Upgrading and using the PLV8 extension

PLV8 is a trusted Javascript language extension for PostgreSQL. You can use it for stored procedures, triggers, and other procedural code that's callable from SQL. This language extension is supported by all current releases of PostgreSQL.

If you use PLV8 and upgrade PostgreSQL to a new PLV8 version, you immediately take advantage of the new extension. Take the following steps to synchronize your catalog metadata with the new version of PLV8. These steps are optional, but we highly recommend that you complete them to avoid metadata mismatch warnings.

The upgrade process drops all your existing PLV8 functions. Thus, we recommend that you create a snapshot of your RDS for PostgreSQL DB instance before upgrading. For more information, see Creating a DB snapshot for a Single-AZ DB instance.

To synchronize your catalog metadata with a new version of PLV8

1. Verify that you need to update. To do this, run the following command while connected to your instance.

   ```sql
   SELECT * FROM pg_available_extensions WHERE name IN ('plv8','plls','plcoffee');
   ```

   If your results contain values for an installed version that is a lower number than the default version, continue with this procedure to update your extensions. For example, the following result set indicates that you should update.

<table>
<thead>
<tr>
<th>name</th>
<th>default_version</th>
<th>installed_version</th>
<th>comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>plls</td>
<td>2.1.0</td>
<td>1.5.3</td>
<td>PL/LiveScript (v8) trusted</td>
</tr>
<tr>
<td>plcoffee</td>
<td>2.1.0</td>
<td>1.5.3</td>
<td>PL/CoffeeScript (v8) trusted</td>
</tr>
<tr>
<td>plv8</td>
<td>2.1.0</td>
<td>1.5.3</td>
<td>PL/JavaScript (v8) trusted</td>
</tr>
</tbody>
</table>

2. Create a snapshot of your RDS for PostgreSQL DB instance if you haven't done so yet. You can continue with the following steps while the snapshot is being created.
3. Get a count of the number of PLV8 functions in your DB instance so you can validate that they are all in place after the upgrade. For example, the following SQL query returns the number of functions written in plv8, plcoffee, and plls.

```sql
SELECT proname, nspname, lanname
FROM pg_proc p, pg_language l, pg_namespace n
WHERE p.prolang = l.oid
AND n.oid = p.pronamespace
AND lanname IN ('plv8','plcoffee','plls');
```

4. Use pg_dump to create a schema-only dump file. For example, create a file on your client machine in the /tmp directory.

```
./pg_dump -Fc --schema-only -U master postgres >/tmp/test.dmp
```

This example uses the following options:

- `-Fc` – Custom format
- `--schema-only` – Dump only the commands necessary to create schema (functions in this case)
- `-U` – The RDS master user name
- `database` – The database name for our DB instance

For more information on pg_dump, see [pg_dump](https://www.postgresql.org/docs/current/pg-dump.html) in the PostgreSQL documentation.

5. Extract the "CREATE FUNCTION" DDL statement that is present in the dump file. The following example uses the `grep` command to extract the DDL statement that creates the functions and save them to a file. You use this in subsequent steps to recreate the functions.

```
./pg_restore -l /tmp/test.dmp | grep FUNCTION > /tmp/function_list/
```

For more information on pg_restore, see [pg_restore](https://www.postgresql.org/docs/current/pg-restore.html) in the PostgreSQL documentation.

6. Drop the functions and extensions. The following example drops any PLV8 based objects. The cascade option ensures that any dependent are dropped.

```
DROP EXTENSION plv8 CASCADE;
```
If your PostgreSQL instance contains objects based on plcoffee or plls, repeat this step for those extensions.

7. Create the extensions. The following example creates the plv8, plcoffee, and plls extensions.

```
CREATE EXTENSION plv8;
CREATE EXTENSION plcoffee;
CREATE EXTENSION plls;
```

8. Create the functions using the dump file and "driver" file.

The following example recreates the functions that you extracted previously.

```
./pg_restore -U master -d postgres -Fc -L /tmp/function_list /tmp/test.dmp
```

9. Verify that all your functions have been recreated by using the following query.

```
SELECT * FROM pg_available_extensions WHERE name IN ('plv8', 'plls', 'plcoffee');
```

The PLV8 version 2 adds the following extra row to your result set:

<table>
<thead>
<tr>
<th>pronom</th>
<th>nspname</th>
<th>lanname</th>
</tr>
</thead>
<tbody>
<tr>
<td>plv8_version</td>
<td>pg_catalog</td>
<td>plv8</td>
</tr>
</tbody>
</table>

**Using PL/Rust to write PostgreSQL functions in the Rust language**

PL/Rust is a trusted Rust language extension for PostgreSQL. You can use it for stored procedures, functions, and other procedural code that's callable from SQL. The PL/Rust language extension is available in the following versions:

- RDS for PostgreSQL 16.1 and higher 16 versions
- RDS for PostgreSQL 15.2-R2 and higher 15 versions
- RDS for PostgreSQL 14.9 and higher 14 versions
- RDS for PostgreSQL 13.12 and higher 13 versions

For more information, see [PL/Rust on GitHub](https://github.com/postgresr/PLRust).
Topics

• Setting up PL/Rust
• Creating functions with PL/Rust
• Using crates with PL/Rust
• PL/Rust limitations

Setting up PL/Rust

To install the plrust extension on your DB instance, add plrust to the shared_preload_libraries parameter in the DB parameter group associated with your DB instance. With the plrust extension installed, you can create functions.

To modify the shared_preload_libraries parameter, your DB instance must be associated with a custom parameter group. For information about creating a custom DB parameter group, see Working with parameter groups.

You can install the plrust extension using the AWS Management Console or the AWS CLI.

The following steps assume that your DB instance is associated with a custom DB parameter group.

Console

Install the plrust extension in the shared_preload_libraries parameter

Complete the following steps using an account that is a member of the rds_superuser group (role).

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of your DB instance to display its details.
4. Open the Configuration tab for your DB instance and find the DB instance parameter group link.
5. Choose the link to open the custom parameters associated with your DB instance.
6. In the Parameters search field, type shared_pre to find the shared_preload_libraries parameter.
7. Choose Edit parameters to access the property values.
8. Add plrust to the list in the **Values** field. Use a comma to separate items in the list of values.

9. Reboot the DB instance so that your change to the `shared_preload_libraries` parameter takes effect. The initial reboot may require additional time to complete.

10. When the instance is available, verify that plrust has been initialized. Use `psql` to connect to the DB instance, and then run the following command:

    ```
    SHOW shared_preload_libraries;
    ```

    Your output should look similar to the following:

    ```
    shared_preload_libraries
    --------------------------
    rdsutils,plrust
    (1 row)
    ```

**AWS CLI**

**Install the plrust extension in the shared_preload_libraries parameter**

Complete the following steps using an account that is a member of the `rds_superuser` group (role).

1. Use the `modify-db-parameter-group` AWS CLI command to add plrust to the `shared_preload_libraries` parameter.

   ```
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=shared_preload_libraries,ParameterValue=plrust,ApplyMethod=pending-reboot" \
   --region aws-region
   ```

2. Use the `reboot-db-instance` AWS CLI command to reboot the DB instance and initialize the plrust library. The initial reboot may require additional time to complete.

   ```
   aws rds reboot-db-instance \
   --db-instance-identifier your-instance \
   --region aws-region
   ```
3. When the instance is available, you can verify that `plrust` has been initialized. Use `psql` to connect to the DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
```

Your output should look similar to the following:

```
shared_preload_libraries
--------------------------
rdsutils,plrust
(1 row)
```

**Creating functions with PL/Rust**

PL/Rust will compile the function as a dynamic library, load it, and execute it.

The following Rust function filters multiples out of an array.

```
postgres=> CREATE LANGUAGE plrust;
CREATE EXTENSION

CREATE OR REPLACE FUNCTION filter_multiples(a BIGINT[], multiple BIGINT) RETURNS BIGINT[]
    IMMUTABLE STRICT
    LANGUAGE PLRUST AS
$$
Ok(Some(a.into_iter().filter(|x| x.unwrap() % multiple != 0).collect()))
$$;

WITH gen_values AS (SELECT ARRAY(SELECT * FROM generate_series(1,100)) as arr)
SELECT filter_multiples(arr, 3)
from gen_values;
```

**Using crates with PL/Rust**

Starting with Amazon RDS for PostgreSQL versions 15.4, 14.9, and 13.12, PL/Rust supports the following crates:

- aes
• ctr
• rand

Starting with RDS for PostgreSQL versions 15.5-R2, 14.10-R2, and 13.13-R2, PL/Rust supports two additional crates:

• croaring-rs
• num-bigint

Only the default features are supported for these crates. New RDS for PostgreSQL versions might contain updated versions of crates, and older versions of crates may no longer be supported.

Follow the best practices for performing a major version upgrade to test whether your PL/Rust functions are compatible with the new major version. For more information, see the blog **Best practices for upgrading Amazon RDS to major and minor versions of PostgreSQL** and **Upgrading the PostgreSQL DB engine for Amazon RDS** in the Amazon RDS User Guide.

Examples of using dependencies when creating a PL/Rust function are available at **Use dependencies**.

**PL/Rust limitations**

By default, database users can't use PL/Rust. To provide access to PL/Rust, connect as a user with rds_superuser privilege, and run the following command:

```
postgres=> GRANT USAGE ON LANGUAGE PLRUST TO user;
```
Managing spatial data with the PostGIS extension

PostGIS is an extension to PostgreSQL for storing and managing spatial information. To learn more about PostGIS, see PostGIS.net.

Starting with version 10.5, PostgreSQL supports the libprotobuf 1.3.0 library used by PostGIS for working with map box vector tile data.

Setting up the PostGIS extension requires rds_superuser privileges. We recommend that you create a user (role) to manage the PostGIS extension and your spatial data. The PostGIS extension and its related components add thousands of functions to PostgreSQL. Consider creating the PostGIS extension in its own schema if that makes sense for your use case. The following example shows how to install the extension in its own database, but this isn't required.

Topics

- Step 1: Create a user (role) to manage the PostGIS extension
- Step 2: Load the PostGIS extensions
- Step 3: Transfer ownership of the extensions
- Step 4: Transfer ownership of the PostGIS objects
- Step 5: Test the extensions
- Step 6: Upgrade the PostGIS extension
- PostGIS extension versions
- Upgrading PostGIS 2 to PostGIS 3

Step 1: Create a user (role) to manage the PostGIS extension

First, connect to your RDS for PostgreSQL DB instance as a user that has rds_superuser privileges. If you kept the default name when you set up your instance, you connect as postgres.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

Create a separate role (user) to administer the PostGIS extension.

```
postgres=> CREATE ROLE gis_admin LOGIN PASSWORD 'change_me';
```
CREATE ROLE

Grant this role `rds_superuser` privileges, to allow the role to install the extension.

```
postgres=> GRANT rds_superuser TO gis_admin;
```

Create a database to use for your PostGIS artifacts. This step is optional. Or you can create a schema in your user database for the PostGIS extensions, but this also isn't required.

```
postgres=> CREATE DATABASE lab_gis;
```

Give the `gis_admin` all privileges on the `lab_gis` database.

```
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_gis TO gis_admin;
```

Exit the session and reconnect to your RDS for PostgreSQL DB instance as `gis_admin`.

```
postgres=> psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=gis_admin --password --dbname=lab_gis
Password for user gis_admin:...
```

Continue setting up the extension as detailed in the next steps.

**Step 2: Load the PostGIS extensions**

The PostGIS extension includes several related extensions that work together to provide geospatial functionality. Depending on your use case, you might not need all the extensions created in this step.

Use `CREATE EXTENSION` statements to load the PostGIS extensions.

```
CREATE EXTENSION postgis;
CREATE EXTENSION postgis_raster;
CREATE EXTENSION fuzzystrmatch;
```
CREATE EXTENSION postgis_tiger_geocoder;
CREATE EXTENSION postgis_topology;
CREATE EXTENSION address_standardizer_data_us;

You can verify the results by running the SQL query shown in the following example, which lists the extensions and their owners.

```
SELECT n.nspname AS "Name",
    pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
FROM pg_catalog.pg_namespace n
WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
ORDER BY 1;
```

List of schemas

<table>
<thead>
<tr>
<th>Name</th>
<th>Owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>postgres</td>
</tr>
<tr>
<td>tiger</td>
<td>rdsadmin</td>
</tr>
<tr>
<td>tiger_data</td>
<td>rdsadmin</td>
</tr>
<tr>
<td>topology</td>
<td>rdsadmin</td>
</tr>
</tbody>
</table>

(4 rows)

**Step 3: Transfer ownership of the extensions**

Use the ALTER SCHEMA statements to transfer ownership of the schemas to the gis_admin role.

```
ALTER SCHEMA tiger OWNER TO gis_admin;
ALTER SCHEMA tiger_data OWNER TO gis_admin;
ALTER SCHEMA topology OWNER TO gis_admin;
```

You can confirm the ownership change by running the following SQL query. Or you can use the `\dn` metacommand from the psql command line.

```
SELECT n.nspname AS "Name",
```
Step 4: Transfer ownership of the PostGIS objects

Use the following function to transfer ownership of the PostGIS objects to the gis_admin role. Run the following statement from the psql prompt to create the function.

```sql
CREATE FUNCTION exec(text) returns text language plpgsql volatile AS $f$
BEGIN EXECUTE $1; RETURN $1; END; $f$;
CREATE FUNCTION
```

Next, run the following query to run the `exec` function that in turn runs the statements and alters the permissions.

```sql
SELECT exec('ALTER TABLE ' || quote_ident(s.nspname) || '.' || quote_ident(s.relname) || ' OWNER TO gis_admin;')
FROM (SELECT nspname, relname
      FROM pg_class c JOIN pg_namespace n ON (c.relnamespace = n.oid)
      WHERE nspname in ('tiger','topology') AND
        relkind IN ('r','S','v') ORDER BY relkind = 'S') s;
```

Step 5: Test the extensions
