The Lifecycle rule applies to objects that have both of the tags specified. Amazon S3 performs a logical AND. Note the following:

- Each tag must match *both* the key and value exactly. If you specify only a <Key> element and no <Value> element, the rule will apply only to objects that match the tag key and that do *not* have a value specified.
- The rule applies to a subset of objects that has all the tags specified in the rule. If an object has additional tags specified, the rule will still apply.

> **Note**
>
> When you specify multiple tags in a filter, each tag key must be unique.

- **Specifying a filter based on both the prefix and one or more tags** – In a Lifecycle rule, you can specify a filter based on both the key prefix and one or more tags. Again, you must wrap all of these filter elements in the <And> element, as follows:

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
          <And>
             <Prefix>key-prefix</Prefix>
             <Tag>
                <Key>key1</Key>
                <Value>value1</Value>
```

```
            </Tag>
            <Tag>
               <Key>key2</Key>
               <Value>value2</Value>
            </Tag>
             ...
          </And>
        </Filter>
        <Status>Enabled</Status>
        transition/expiration actions
    </Rule>
</LifecycleConfiguration>
```

Amazon S3 combines these filters by using a logical AND. That is, the rule applies to the subset of objects with the specified key prefix and the specified tags. A filter can have only one prefix, and zero or more tags.

- **Specifying an empty filter** – You can specify an empty filter, in which case the rule applies to all objects in the bucket.

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
        </Filter>
        <Status>Enabled</Status>
        transition/expiration actions
    </Rule>
</LifecycleConfiguration>
```

- **>Specifying an object size filter** – To filter a rule by object size, you can specify a minimum size (ObjectSizeGreaterThan) or a maximum size (ObjectSizeLessThan), or you can specify a range of object sizes.

  Object size values are in bytes. Maximum filter size is 5 TB. Some storage classes have minimum object size limitations. For more information, see Comparing the Amazon S3 storage classes.

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
            <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
        </Filter>
        <Status>Enabled</Status>
```

```
        transition/expiration actions
    </Rule>
</LifecycleConfiguration>
```

> **Note**
>
> The `ObjectSizeGreaterThan` and `ObjectSizeLessThan` filters exclude the specified values. For example, if you set objects sized 128 KB to 1024 KB to move from the S3 Standard storage class to the S3 Standard-IA storage class, objects that are exactly 1024 KB and 128 KB won't transition to S3 Standard-IA. Instead, the rule will apply only to objects that are greater than 128 KB and less than 1024 KB in size.

If you're specifying an object size range, the `ObjectSizeGreaterThan` integer must be less than the `ObjectSizeLessThan` value. When using more than one filter, you must wrap the filters in an <And> element. The following example shows how to specify objects in a range between 500 bytes and 64,000 bytes.

```
<LifecycleConfiguration>
    <Rule>
        <Filter>
            <And>
                <Prefix>key-prefix</Prefix>
                <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
                <ObjectSizeLessThan>64000</ObjectSizeLessThan>
            </And>
        </Filter>
        <Status>Enabled</Status>
        transition/expiration actions
    </Rule>
</LifecycleConfiguration>
```

How Amazon S3 handles conflicts in lifecycle configurations

Generally, Amazon S3 Lifecycle optimizes for cost. For example, if two expiration policies overlap, the shorter expiration policy is honored so that data is not stored for longer than expected. Likewise, if two transition policies overlap, S3 Lifecycle transitions your objects to the lower-cost storage class.

In both cases, S3 Lifecycle tries to choose the path that is least expensive for you. An exception to this general rule is with the S3 Intelligent-Tiering storage class. S3 Intelligent-Tiering is favored by S3 Lifecycle over any storage class, aside from the S3 Glacier and S3 Glacier Deep Archive storage classes.

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both an S3 Glacier Flexible Retrieval and an S3 Standard-IA (or an S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

Examples of overlapping filters and conflicting lifecycle actions

You might specify an S3 Lifecycle configuration in which you specify overlapping prefixes, or actions. The following examples show how Amazon S3 resolves potential conflicts.

Example 1: Overlapping prefixes (no conflict)

The following example configuration has two rules that specify overlapping prefixes as follows:

- The first rule specifies an empty filter, indicating all objects in the bucket.
- The second rule specifies a key name prefix (`logs/`), indicating only a subset of objects.

Rule 1 requests Amazon S3 to delete all objects one year after creation. Rule 2 requests Amazon S3 to transition a subset of objects to the S3 Standard-IA storage class 30 days after creation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
    </Filter>
    <Status>Enabled</Status>
    <Expiration>
      <Days>365</Days>
    </Expiration>
  </Rule>
```

```
  <Rule>
    <ID>Rule 2</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <StorageClass>STANDARD_IA</StorageClass>
      <Days>30</Days>
    </Transition>
   </Rule>
</LifecycleConfiguration>
```

Since there is no conflict in this case, Amazon S3 will transition the objects with the `logs/` prefix to the S3 Standard-IA storage class 30 days after creation. When any object reaches one year after creation, it will be deleted.

Example 2: Conflicting lifecycle actions

In this example configuration, there are two rules that direct Amazon S3 to perform two different actions on the same set of objects at the same time in the objects' lifetime:

- Both rules specify the same key name prefix, so both rules apply to the same set of objects.
- Both rules specify the same 365 days after object creation when the rules apply.
- One rule directs Amazon S3 to transition objects to the S3 Standard-IA storage class and another rule wants Amazon S3 to expire the objects at the same time.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Expiration>
      <Days>365</Days>
    </Expiration>
  </Rule>
  <Rule>
    <ID>Rule 2</ID>
    <Filter>
```

```
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <StorageClass>STANDARD_IA</StorageClass>
      <Days>365</Days>
    </Transition>
   </Rule>
</LifecycleConfiguration>
```

In this case, because you want objects to expire (to be removed), there is no point in changing the storage class, so Amazon S3 chooses the expiration action on these objects.

Example 3: Overlapping prefixes resulting in conflicting lifecycle actions

In this example, the configuration has two rules, which specify overlapping prefixes as follows:

- Rule 1 specifies an empty prefix (indicating all objects).
- Rule 2 specifies a key name prefix (`logs/`) that identifies a subset of all objects.

For the subset of objects with the `logs/` key name prefix, S3 Lifecycle actions in both rules apply. One rule directs Amazon S3 to transition objects 10 days after creation, and another rule directs Amazon S3 to transition objects 365 days after creation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
      <Prefix></Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <StorageClass>STANDARD_IA</StorageClass>
      <Days>10</Days>
    </Transition>
  </Rule>
  <Rule>
    <ID>Rule 2</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
```

```
    <Transition>
      <StorageClass>STANDARD_IA</StorageClass>
      <Days>365</Days>
    </Transition>
   </Rule>
</LifecycleConfiguration>
```

In this case, Amazon S3 chooses to transition them 10 days after creation.

Example 4: Tag-based filtering and resulting conflicting lifecycle actions

Suppose that you have the following S3 Lifecycle configuration that has two rules, each specifying a tag filter:

- Rule 1 specifies a tag-based filter (`tag1/value1`). This rule directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class 365 days after creation.
- Rule 2 specifies a tag-based filter (`tag2/value2`). This rule directs Amazon S3 to expire objects 14 days after creation.

The S3 Lifecycle configuration is shown in following example.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Rule 1</ID>
    <Filter>
      <Tag>
         <Key>tag1</Key>
         <Value>value1</Value>
      </Tag>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <StorageClass>GLACIER</StorageClass>
      <Days>365</Days>
    </Transition>
  </Rule>
  <Rule>
    <ID>Rule 2</ID>
    <Filter>
      <Tag>
         <Key>tag2</Key>
         <Value>value2</Value>
```

```
      </Tag>
    </Filter>
    <Status>Enabled</Status>
    <Expiration>
      <Days>14</Days>
    </Expiration>
   </Rule>
</LifecycleConfiguration>
```

If an object has both tags, then Amazon S3 has to decide which rule to follow. In this case, Amazon S3 expires the object 14 days after creation. The object is removed, and therefore the transition action does not apply.

Examples of S3 Lifecycle configurations

This section provides examples of S3 Lifecycle configuration. Each example shows how you can specify the XML in each of the example scenarios.

Topics

- Archiving all objects within one day after creation
- Disabling Lifecycle rules temporarily
- Tiering down the storage class over an object's lifetime
- Specifying multiple rules
- Specifying a lifecycle rule for a versioning-enabled bucket
- Removing expired object delete markers in a versioning-enabled bucket
- Lifecycle configuration to abort multipart uploads
- Expiring noncurrent objects that have no data
- Example: Allowing objects smaller than 128 KB to be transitioned

Archiving all objects within one day after creation

Each S3 Lifecycle rule includes a filter that you can use to identify a subset of objects in your bucket to which the S3 Lifecycle rule applies. The following S3 Lifecycle configurations show examples of how you can specify a filter.

- In this S3 Lifecycle configuration rule, the filter specifies a key prefix (`tax/`). Therefore, the rule applies to objects with the key name prefix `tax/`, such as `tax/doc1.txt` and `tax/doc2.txt`.

  The rule specifies two actions that direct Amazon S3 to do the following:

  - Transition objects to the S3 Glacier Flexible Retrieval storage class 365 days (one year) after creation.
  - Delete objects (the `Expiration` action) 3,650 days (10 years) after creation.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Transition and Expiration Rule</ID>
    <Filter>
       <Prefix>tax/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>365</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
    <Expiration>
      <Days>3650</Days>
    </Expiration>
  </Rule>
</LifecycleConfiguration>
```

  Instead of specifying the object age in terms of days after creation, you can specify a date for each action. However, you can't use both `Date` and `Days` in the same rule.

- If you want the S3 Lifecycle rule to apply to all objects in the bucket, specify an empty prefix. In the following configuration, the rule specifies a `Transition` action that directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class 0 days after creation. This rule means that the objects are eligible for archival to S3 Glacier Flexible Retrieval at midnight UTC following creation. For more information about lifecycle constraints, see Constraints and considerations for transitions.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Archive all object same-day upon creation</ID>
    <Filter>
      <Prefix></Prefix>
    </Filter>
```

```
    <Status>Enabled</Status>
    <Transition>
      <Days>0</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

- You can specify zero or one key name prefix and zero or more object tags in a filter. The following example code applies the S3 Lifecycle rule to a subset of objects with the `tax/` key prefix and to objects that have two tags with specific key and value. When you specify more than one filter, you must include the <And> element as shown (Amazon S3 applies a logical AND to combine the specified filter conditions).

```
...
<Filter>
   <And>
      <Prefix>tax/</Prefix>
      <Tag>
         <Key>key1</Key>
         <Value>value1</Value>
      </Tag>
      <Tag>
         <Key>key2</Key>
         <Value>value2</Value>
      </Tag>
    </And>
</Filter>
...
```

- You can filter objects based only on tags. For example, the following S3 Lifecycle rule applies to objects that have the two specified tags (it does not specify any prefix).

```
...
<Filter>
   <And>
      <Tag>
         <Key>key1</Key>
         <Value>value1</Value>
      </Tag>
      <Tag>
         <Key>key2</Key>
```

```
          <Value>value2</Value>
      </Tag>
    </And>
</Filter>
...
```

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both an S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see Examples of overlapping filters and conflicting lifecycle actions.

Disabling Lifecycle rules temporarily

You can temporarily disable an S3 Lifecycle rule using the `status` element. This can be useful if you want to test new rules or troubleshoot issues with your configuration, without overwriting your existing rules. The following S3 Lifecycle configuration specifies two rules:

- Rule 1 directs Amazon S3 to transition objects with the `logs/` prefix to the S3 Glacier Flexible Retrieval storage class soon after creation.
- Rule 2 directs Amazon S3 to transition objects with the `documents/` prefix to the S3 Glacier Flexible Retrieval storage class soon after creation.

In the configuration, Rule 1 is enabled and Rule 2 is disabled. Amazon S3 ignores the disabled rule.

```
<LifecycleConfiguration>
```

```
  <Rule>
    <ID>Rule1</ID>
    <Filter>
      <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>0</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
  </Rule>
  <Rule>
    <ID>Rule2</ID>
    <Filter>
      <Prefix>documents/</Prefix>
    </Filter>
    <Status>Disabled</Status>
    <Transition>
      <Days>0</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

Tiering down the storage class over an object's lifetime

In this example, you use S3 Lifecycle configuration to tier down the storage class of objects over their lifetime. Tiering down can help reduce storage costs. For more information about pricing, see Amazon S3 pricing.

The following S3 Lifecycle configuration specifies a rule that applies to objects with the key name prefix `logs/`. The rule specifies the following actions:

- Two transition actions:
  - Transition objects to the S3 Standard-IA storage class 30 days after creation.
  - Transition objects to the S3 Glacier Flexible Retrieval storage class 90 days after creation.
- One expiration action that directs Amazon S3 to delete objects a year after creation.

```
<LifecycleConfiguration>
  <Rule>
```

```
    <ID>example-id</ID>
    <Filter>
       <Prefix>logs/</Prefix>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>30</Days>
      <StorageClass>STANDARD_IA</StorageClass>
    </Transition>
    <Transition>
      <Days>90</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
    <Expiration>
      <Days>365</Days>
    </Expiration>
  </Rule>
</LifecycleConfiguration>
```

Note

You can use one rule to describe all S3 Lifecycle actions if all actions apply to the same set of objects (identified by the filter). Otherwise, you can add multiple rules with each specifying a different filter.

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both an S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see Examples of overlapping filters and conflicting lifecycle actions.

Specifying multiple rules

You can specify multiple rules if you want different S3 Lifecycle actions of different objects. The following S3 Lifecycle configuration has two rules:

- Rule 1 applies to objects with the key name prefix `classA/`. It directs Amazon S3 to transition objects to the S3 Glacier Flexible Retrieval storage class one year after creation and expire these objects 10 years after creation.
- Rule 2 applies to objects with key name prefix `classB/`. It directs Amazon S3 to transition objects to the S3 Standard-IA storage class 90 days after creation and delete them one year after creation.

```
<LifecycleConfiguration>
    <Rule>
        <ID>ClassADocRule</ID>
        <Filter>
           <Prefix>classA/</Prefix>
        </Filter>
        <Status>Enabled</Status>
        <Transition>
           <Days>365</Days>
           <StorageClass>GLACIER</StorageClass>
        </Transition>
        <Expiration>
             <Days>3650</Days>
        </Expiration>
    </Rule>
    <Rule>
        <ID>ClassBDocRule</ID>
        <Filter>
            <Prefix>classB/</Prefix>
        </Filter>
        <Status>Enabled</Status>
        <Transition>
           <Days>90</Days>
           <StorageClass>STANDARD_IA</StorageClass>
        </Transition>
        <Expiration>
             <Days>365</Days>
        </Expiration>
```

```
    </Rule>
</LifecycleConfiguration>
```

Important

When you have multiple rules in an S3 Lifecycle configuration, an object can become eligible for multiple S3 Lifecycle actions on the same day. In such cases, Amazon S3 follows these general rules:

- Permanent deletion takes precedence over transition.
- Transition takes precedence over creation of delete markers.
- When an object is eligible for both an S3 Glacier Flexible Retrieval and S3 Standard-IA (or S3 One Zone-IA) transition, Amazon S3 chooses the S3 Glacier Flexible Retrieval transition.

For examples, see Examples of overlapping filters and conflicting lifecycle actions.

Specifying a lifecycle rule for a versioning-enabled bucket

Suppose that you have a versioning-enabled bucket, which means that for each object, you have a current version and zero or more noncurrent versions. (For more information about S3 Versioning, see Retaining multiple versions of objects with S3 Versioning.)

In the following example, you want to maintain one year's worth of history, and retain 5 noncurrent versions. S3 Lifecycle configurations support keeping 1 to 100 versions of any object. Be aware that more than 5 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the `NoncurrentDays` and the `NewerNoncurrentVersions` values must be exceeded.

To save storage costs, you want to move noncurrent versions to S3 Glacier Flexible Retrieval 30 days after they become noncurrent (assuming that these noncurrent objects are cold data for which you don't need real-time access). In addition, you expect the frequency of access of the current versions to diminish 90 days after creation, so you might choose to move these objects to the S3 Standard-IA storage class.

```
<LifecycleConfiguration>
```

```
    <Rule>
        <ID>sample-rule</ID>
        <Filter>
           <Prefix></Prefix>
        </Filter>
        <Status>Enabled</Status>
        <Transition>
           <Days>90</Days>
           <StorageClass>STANDARD_IA</StorageClass>
        </Transition>
        <NoncurrentVersionTransition>
            <NoncurrentDays>30</NoncurrentDays>
            <StorageClass>GLACIER</StorageClass>
        </NoncurrentVersionTransition>
       <NoncurrentVersionExpiration>
            <NewerNoncurrentVersions>5</NewerNoncurrentVersions>
            <NoncurrentDays>365</NoncurrentDays>
       </NoncurrentVersionExpiration>
    </Rule>
</LifecycleConfiguration>
```

Removing expired object delete markers in a versioning-enabled bucket

A versioning-enabled bucket has one current version and zero or more noncurrent versions for each object. When you delete an object, note the following:

- If you don't specify a version ID in your delete request, Amazon S3 adds a delete marker instead of deleting the object. The current object version becomes noncurrent, and the delete marker becomes the current version.
- If you specify a version ID in your delete request, Amazon S3 deletes the object version permanently (a delete marker isn't created).
- A delete marker with zero noncurrent versions is referred to as an *expired object delete marker*.

This example shows a scenario that can create expired object delete markers in your bucket, and how you can use S3 Lifecycle configuration to direct Amazon S3 to remove the expired object delete markers.

Suppose that you write an S3 Lifecycle configuration that uses the `NoncurrentVersionExpiration` action to remove noncurrent versions 30 days after they become noncurrent and to retain 10 noncurrent versions, as shown in the following example. Be

aware that more than 10 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the `NoncurrentDays` and the `NewerNoncurrentVersions` values must be exceeded.

```
<LifecycleConfiguration>
    <Rule>
        ...
        <NoncurrentVersionExpiration>
            <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
            <NoncurrentDays>30</NoncurrentDays>
        </NoncurrentVersionExpiration>
    </Rule>
</LifecycleConfiguration>
```

The `NoncurrentVersionExpiration` action doesn't apply to the current object versions. It removes only the noncurrent versions.

For current object versions, you have the following options to manage their lifetime, depending on whether the current object versions follow a well-defined lifecycle:

- **The current object versions follow a well-defined lifecycle.**

  In this case, you can use an S3 Lifecycle configuration with the `Expiration` action to direct Amazon S3 to remove the current versions, as shown in the following example.

  ```
  <LifecycleConfiguration>
      <Rule>
          ...
          <Expiration>
             <Days>60</Days>
          </Expiration>
          <NoncurrentVersionExpiration>
              <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
              <NoncurrentDays>30</NoncurrentDays>
          </NoncurrentVersionExpiration>
      </Rule>
  </LifecycleConfiguration>
  ```

  In this example, Amazon S3 removes current versions 60 days after they're created by adding a delete marker for each of the current object versions. This process makes the current version

noncurrent, and the delete marker becomes the current version. For more information, see Retaining multiple versions of objects with S3 Versioning.

> **Note**
>
> You can't specify both a `Days` and an `ExpiredObjectDeleteMarker` tag on the same rule. When you specify the `Days` tag, Amazon S3 automatically performs `ExpiredObjectDeleteMarker` cleanup when the delete markers are old enough to satisfy the age criteria. To clean up delete markers as soon as they become the only version, create a separate rule with only the `ExpiredObjectDeleteMarker` tag.

The `NoncurrentVersionExpiration` action in the same S3 Lifecycle configuration removes noncurrent objects 30 days after they become noncurrent. Thus, in this example, all object versions are permanently removed 90 days after object creation. Be aware that in this example, more than 10 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the `NoncurrentDays` and the `NewerNoncurrentVersions` values must be exceeded.

Although expired object delete markers are created during this process, Amazon S3 detects and removes the expired object delete markers for you.

- **The current object versions don't have a well-defined lifecycle.**

  In this case, you might remove the objects manually when you don't need them, creating a delete marker with one or more noncurrent versions. If your S3 Lifecycle configuration with the `NoncurrentVersionExpiration` action removes all the noncurrent versions, you now have expired object delete markers.

  Specifically for this scenario, S3 Lifecycle configuration provides an `Expiration` action that you can use to remove the expired object delete markers.

```
<LifecycleConfiguration>
    <Rule>
       <ID>Rule 1</ID>
        <Filter>
          <Prefix>logs/</Prefix>
        </Filter>
```

```
        <Status>Enabled</Status>
        <Expiration>
           <ExpiredObjectDeleteMarker>true</ExpiredObjectDeleteMarker>
        </Expiration>
        <NoncurrentVersionExpiration>
            <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
            <NoncurrentDays>30</NoncurrentDays>
        </NoncurrentVersionExpiration>
    </Rule>
</LifecycleConfiguration>
```

By setting the `ExpiredObjectDeleteMarker` element to `true` in the `Expiration` action, you direct Amazon S3 to remove the expired object delete markers.

> **Note**
>
> When you use the `ExpiredObjectDeleteMarker` S3 Lifecycle action, the rule cannot specify a tag-based filter.

Lifecycle configuration to abort multipart uploads

You can use the Amazon S3 multipart upload REST API operations to upload large objects in parts. For more information about multipart uploads, see Uploading and copying objects using multipart upload in Amazon S3.

By using an S3 Lifecycle configuration, you can direct Amazon S3 to stop incomplete multipart uploads (identified by the key name prefix specified in the rule) if they aren't completed within a specified number of days after initiation. When Amazon S3 aborts a multipart upload, it deletes all the parts associated with the multipart upload. This process helps control your storage costs by ensuring that you don't have incomplete multipart uploads with parts that are stored in Amazon S3.

> **Note**
>
> When you use the `AbortIncompleteMultipartUpload` S3 Lifecycle action, the rule cannot specify a tag-based filter.

The following is an example S3 Lifecycle configuration that specifies a rule with the `AbortIncompleteMultipartUpload` action. This action directs Amazon S3 to stop incomplete multipart uploads seven days after initiation.

```
<LifecycleConfiguration>
    <Rule>
        <ID>sample-rule</ID>
        <Filter>
           <Prefix>SomeKeyPrefix/</Prefix>
        </Filter>
        <Status>rule-status</Status>
        <AbortIncompleteMultipartUpload>
          <DaysAfterInitiation>7</DaysAfterInitiation>
        </AbortIncompleteMultipartUpload>
    </Rule>
</LifecycleConfiguration>
```

Expiring noncurrent objects that have no data

You can create rules that transition objects based only on their size. You can specify a minimum size (`ObjectSizeGreaterThan`) or a maximum size (`ObjectSizeLessThan`), or you can specify a range of object sizes in bytes. When using more than one filter, such as a prefix and size rule, you must wrap the filters in an <And> element.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Transition with a prefix and based on size</ID>
    <Filter>
       <And>
          <Prefix>tax/</Prefix>
          <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
       </And>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>365</Days>
      <StorageClass>GLACIER</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

If you're specifying a range by using both the `ObjectSizeGreaterThan` and `ObjectSizeLessThan` elements, the maximum object size must be larger than the minimum object size. When using more than one filter, you must wrap the filters in an <And> element. The following example shows how to specify objects in a range between 500 bytes and 64,000 bytes. When you're specifying a range, the `ObjectSizeGreaterThan` and `ObjectSizeLessThan` filters exclude the specified values. For more information, see the section called “Filter element”.

```
<LifecycleConfiguration>
    <Rule>
        ...
          <And>
             <ObjectSizeGreaterThan>500</ObjectSizeGreaterThan>
             <ObjectSizeLessThan>64000</ObjectSizeLessThan>
          </And>
    </Rule>
</LifecycleConfiguration>
```

You can also create rules to specifically expire noncurrent objects that have no data, including noncurrent delete marker objects created in a versioning-enabled bucket. The following example uses the `NoncurrentVersionExpiration` action to remove noncurrent versions 30 days after they become noncurrent and to retain 10 noncurrent versions. This example also uses the `ObjectSizeLessThan` element to filter only objects with no data.

Be aware that more than 10 newer noncurrent versions must exist before Amazon S3 can expire a given version. Amazon S3 will permanently delete any additional noncurrent versions beyond the specified number to retain. For the deletion to occur, both the `NoncurrentDays` and the `NewerNoncurrentVersions` values must be exceeded.

```
<LifecycleConfiguration>
  <Rule>
    <ID>Expire noncurrent with size less than 1 byte</ID>
    <Filter>
       <ObjectSizeLessThan>1</ObjectSizeLessThan>
    </Filter>
    <Status>Enabled</Status>
    <NoncurrentVersionExpiration>
       <NewerNoncurrentVersions>10</NewerNoncurrentVersions>
       <NoncurrentDays>30</NoncurrentDays>
    </NoncurrentVersionExpiration>
  </Rule>
```

```
</LifecycleConfiguration>
```

Example: Allowing objects smaller than 128 KB to be transitioned

Amazon S3 applies a default behavior to your Lifecycle configuration that prevents objects smaller than 128 KB from being transitioned to any storage class. You can allow smaller objects to transition by adding a minimum size (`ObjectSizeGreaterThan`) or a maximum size (`ObjectSizeLessThan`) filter that specifies a smaller size to the configuration. The following example allows any object smaller than 128 KB to transition to the S3 Glacier Instant Retrieval storage class:

```
<LifecycleConfiguration>
  <Rule>
    <ID>Allow small object transitions</ID>
    <Filter>
          <ObjectSizeGreaterThan>1</ObjectSizeGreaterThan>
    </Filter>
    <Status>Enabled</Status>
    <Transition>
      <Days>365</Days>
      <StorageClass>GLACIER_IR</StorageClass>
    </Transition>
  </Rule>
</LifecycleConfiguration>
```

Note

In September 2024, Amazon S3 updated the default transition behavior for small objects, as follows:

- **Updated default transition behavior** — Starting September 2024, the default behavior prevents objects smaller than 128 KB from being transitioned to any storage class.
- **Previous default transition behavior** — Before September 2024, the default behavior allowed objects smaller than 128 KB to be transitioned only to the S3 Glacier and S3 Glacier Deep Archive storage classes.

Configurations created before September 2024 retain the previous transition behavior unless you modify them. That is, if you create, edit, or delete rules, the default transition behavior for your configuration changes to the updated behavior. If your use case

requires, you can change the default transition behavior so that objects smaller than 128KB will transition to S3 Glacier and S3 Glacier Deep Archive. To do this, use the optional `x-amz-transition-object-size-minimum-default` header in a PutBucketLifecycleConfiguration request.

The following example shows how to use the `x-amz-transition-object-size-minimum-default` header in a PutBucketLifecycleConfiguration request to apply the `varies_by_storage_class` default transition behavior to an S3 Lifecycle configuration. This behavior allows object smaller than 128 KB to transition to the S3 Glacier or S3 Glacier Deep Archive storage classes. By default, all other storage classes will prevent transitions smaller than 128 KB. You can still use custom filters to change the minimum transition size for any storage class. Custom filters always take precedence over the default transition behavior:

```
HTTP/1.1 200
x-amz-transition-object-size-minimum-default: varies_by_storage_class
<?xml version="1.0" encoding="UTF-8"?>
...
```

Troubleshooting Amazon S3 Lifecycle issues

The following information can help you troubleshoot common issues with Amazon S3 Lifecycle rules.

Topics

- I ran a list operation on my bucket and saw objects that I thought were expired or transitioned by a lifecycle rule.
- How do I monitor the actions taken by my lifecycle rules?
- My S3 object count still increases, even after setting up lifecycle rules on a versioning-enabled bucket.
- How do I empty my S3 bucket by using lifecycle rules?
- My Amazon S3 bill increased after transitioning objects to a lower-cost storage class.
- I've updated my bucket policy, but my S3 objects are still being deleted by expired lifecycle rules.
- Can I recover S3 objects that are expired by S3 Lifecycle rules?
- Why are my expiration and transition lifecycle actions not occurring?

- How can I exclude a prefix from my lifecycle rule?
- How can I include multiple prefixes in my lifecycle rule?

I ran a list operation on my bucket and saw objects that I thought were expired or transitioned by a lifecycle rule.

S3 Lifecycle object transitions and object expirations are asynchronous operations. Therefore, there might be a delay between the time that the objects are eligible for expiration or transition and the time that they are actually transitioned or expired. Changes in billing are applied as soon as the lifecycle rule is satisfied, even if the action isn't complete. The exception to this behavior is if you have a lifecycle rule set to transition to the S3 Intelligent-Tiering storage class. In that case, billing changes don't occur until the object has transitioned to S3 Intelligent-Tiering. For more information about changes in billing, see Setting lifecycle configuration on a bucket.

> **Note**
>
> Amazon S3 doesn't transition objects that are smaller than 128 KB from the S3 Standard or S3 Standard-IA storage class to the S3 Intelligent-Tiering, S3 Standard-IA, or S3 One Zone-IA storage class.

How do I monitor the actions taken by my lifecycle rules?

To monitor actions taken by lifecycle rules, you can use the following features:

- **S3 Event Notifications** – You can set up S3 Event Notifications so that you're notified of any S3 Lifecycle expiration or transition events.
- **S3 server access logs** – You can enable server access logs for your S3 buckets to capture S3 Lifecycle actions, such as object transitions to another storage class or object expirations. For more information, see Lifecycle and logging.

To view the changes in your storage caused by lifecycle actions on a daily basis, we recommend using S3 Storage Lens dashboards instead of using Amazon CloudWatch metrics. In your Storage Lens dashboard, you can view the following metrics, which monitor the object count or size:

- **Current version bytes**
- **Current version object count**

- **Noncurrent version bytes**
- **Noncurrent version object count**
- **Delete marker object count**
- **Delete marker storage bytes**
- **Incomplete multipart upload bytes**
- **Incomplete multipart upload object count**

My S3 object count still increases, even after setting up lifecycle rules on a versioning-enabled bucket.

In a versioning-enabled bucket, when an object is expired, the object isn't completely deleted from the bucket. Instead, a delete marker is created as the newest version of the object. Delete markers are still counted as objects. Therefore, if a lifecycle rule is created to expire only the current versions, then the object count in the S3 bucket actually increases instead of going down.

For example, let's say an S3 bucket is versioning-enabled with 100 objects, and a lifecycle rule is set to expire current versions of the object after 7 days. After the seventh day, the object count increases to 200 because 100 delete markers are created in addition to the 100 original objects, which are now the noncurrent versions. For more information about S3 Lifecycle configuration rule actions for versioning-enabled buckets, see Setting lifecycle configuration on a bucket.

To permanently remove objects, add an additional lifecycle configuration to delete the previous versions of the objects, expired delete markers, and incomplete multipart uploads. For instructions on how to create new lifecycle rules, see Setting lifecycle configuration on a bucket.

Note

- Amazon S3 rounds the transition or expiration date of an object to midnight UTC the next day.

  When evaluating objects for lifecycle actions, Amazon S3 uses the object creation time in UTC. For example, consider a nonversioned bucket with a lifecycle rule that's configured to expire objects after one day. Suppose that an object was created on January 1 at 17:05 Pacific Daylight Time (PDT), which corresponds to January 2 at 00:05 UTC. The object becomes one day old at 00:05 UTC on January 3, which makes it eligible for expiration when S3 Lifecycle evaluates objects at 00:00 UTC on January 4.

Because Amazon S3 lifecycle actions occur asynchronously, there might be some delay between the date specified in the lifecycle rule and the actual physical transition of the object. For more information, see Transition or expiration delay.

For more information, see Lifecycle rules: Based on an object's age.

- For S3 objects that are protected by Object Lock, current versions are not permanently deleted. Instead, a delete marker is added to the objects, making them noncurrent. Noncurrent versions are then preserved and are not permanently expired.

How do I empty my S3 bucket by using lifecycle rules?

S3 Lifecycle rules are an effective tool to empty an S3 bucket with millions of objects. To delete a large number of objects from your S3 bucket, make sure to use these two pairs of lifecycle rules:

- **Expire current versions of objects** and **Permanently delete previous versions of objects**
- **Delete expired delete markers** and **Delete incomplete multipart uploads**

For steps on how to create a lifecycle configuration rule, see Setting lifecycle configuration on a bucket.

Note

For S3 objects that are protected by Object Lock, current versions are not permanently deleted. Instead, a delete marker is added to the objects, making them noncurrent. Noncurrent versions are then preserved and are not permanently expired.

My Amazon S3 bill increased after transitioning objects to a lower-cost storage class.

There are several reasons that your bill might increase after transitioning objects to a lower-cost storage class:

- S3 Glacier overhead charges for small objects

  For each object that is transitioned to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive, a total overhead of 40 KB is associated with this storage update. As part of the 40 KB overhead, 8

KB is used to store metadata and the name of the object. This 8 KB is charged according to S3 Standard rates. The remaining 32 KB is used for indexing and related metadata. This 32 KB is charged according to S3 Glacier Flexible Retrieval or S3 Glacier Deep Archive pricing.

Therefore, if you're storing many smaller sized objects, we don't recommend using lifecycle transitions. Instead, to reduce any overhead charges, consider aggregating many smaller objects into a smaller number of large objects before storing them in Amazon S3. For more information about cost considerations, see Transitioning to the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes (object archival).

- Minimum storage charges

  Some S3 storage classes have minimum storage-duration requirements. Objects that are deleted, overwritten, or transitioned from those classes before the minimum duration is satisfied are charged a prorated early transition or deletion fee. These minimum storage-duration requirements are as follows:

  - S3 Standard-IA and S3 One Zone-IA – 30 days
  - S3 Glacier Flexible Retrieval and S3 Glacier Instant Retrieval – 90 days
  - S3 Glacier Deep Archive – 180 days

  For more information about these requirements, see the *Constraints* section of Transitioning objects using S3 Lifecycle. For general S3 pricing information, see Amazon S3 pricing and the AWS Pricing Calculator.

- Lifecycle transition costs

  Each time an object is transitioned to a different storage class by a lifecycle rule, Amazon S3 counts that transition as one transition request. The costs for these transition requests are in addition to the costs of these storage classes. If you plan to transition a large number of objects, consider the request costs when transitioning to a lower tier. For more information, see Amazon S3 pricing.

I've updated my bucket policy, but my S3 objects are still being deleted by expired lifecycle rules.

`Deny` statements in a bucket policy don't prevent the expiration of the objects defined in a lifecycle rule. Lifecycle actions (such as transitions or expirations) don't use the S3 `DeleteObject` operation. Instead, S3 Lifecycle actions are performed by using internal S3 endpoints. (For more information, see Lifecycle and logging.)

To prevent your lifecycle rule from taking any action, you must edit, delete, or disable the rule.

Can I recover S3 objects that are expired by S3 Lifecycle rules?

The only way to recover objects that are expired by S3 Lifecycle is through versioning, which must be in place before the objects become eligible for expiration. You cannot undo the expiration operations that are performed by lifecycle rules. If objects are permanently deleted by the S3 Lifecycle rules that are in place, you cannot recover these objects. To enable versioning on a bucket, see the section called "Retaining multiple versions of objects".

If you have applied versioning to the bucket and the noncurrent versions of the objects are still intact, you can restore previous versions of the expired objects. For more information about the behavior of S3 Lifecycle rule actions and versioning states, see the *Lifecycle actions and bucket versioning state* table in Elements to describe lifecycle actions.

> **Note**
>
> If the S3 bucket is protected by AWS Backup or S3 Replication, you might also be able to use these features to recover your expired objects.

Why are my expiration and transition lifecycle actions not occurring?

For a versioning-enabled or versioning-suspended bucket, the following considerations guide how Amazon S3 handles the Expiration action:

- Object expiration applies only to an object's current version (it has no impact on noncurrent object versions).
- Amazon S3 doesn't take any action if there are one or more object versions and the delete marker is the current version.
- Amazon S3 doesn't take any action on noncurrent versions of objects that have S3 Object Lock applied.
- For objects with a `PENDING` replication status, Amazon S3 doesn't take any action current or noncurrent versions of objects.

Lifecycle storage class transitions have the following constraints:

- By default, objects smaller than 128 KB won't transition to any storage class.

- Objects must be stored for at least 30 days before transitioning to S3 Standard-IA or S3 One Zone-IA.
- For versioning enabled or versioning suspended buckets, objects with a `PENDING` replication status can't be transitioned.

How can I exclude a prefix from my lifecycle rule?

S3 Lifecycle doesn't support excluding prefixes in your rules. Instead, use tags to tag all of the objects that you want to include in the rule. For more information about using tags in your lifecycle rules, see the section called “Archiving all objects within one day after creation”.

How can I include multiple prefixes in my lifecycle rule?

S3 Lifecycle doesn't support including multiple prefixes in your rules. Instead, use tags to tag all of the objects that you want to include in the rule. For more information about using tags in your lifecycle rules, see the section called “Archiving all objects within one day after creation”.

However, if you have one or more prefixes that start with the same characters, you can include all of those prefixes in your rule by specifying a partial prefix with no trailing slash (/) in the filter. For example, suppose that you have these prefixes:

```
sales1999/
sales2000/
sales2001/
```

To include all three prefixes in your rule, specify `<Prefix>sales</Prefix>` in your lifecycle rule.

Logging and monitoring in Amazon S3

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 and your AWS solutions. We recommend collecting monitoring data from all of the parts of your AWS solution so that you can more easily debug a multipoint failure if one occurs. Before you start monitoring Amazon S3, create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

For more information about logging and monitoring in Amazon S3, see the following topics.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see S3 Express One Zone and Working with directory buckets.

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon S3 resources and responding to potential incidents.

Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods. For more information, see Monitoring metrics with Amazon CloudWatch.

AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon S3. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Logging Amazon S3 API calls using AWS CloudTrail.

Amazon GuardDuty

Amazon GuardDuty is a threat detection service that continuously monitors your accounts, containers, workloads, and the data within your AWS environment to identify potential threats or security risks to your S3 buckets. GuardDuty also provides rich context about the threats that it detects. GuardDuty monitors AWS CloudTrail management logs for threats and surfaces security relevant information. For example, GuardDuty will include factors of an API request, such as the user that made the request, the location the request was made from, and the specific API requested, that could be unusual in your environment. GuardDuty S3 Protection monitors the S3 data events collected by CloudTrail and identifies potentially anomalous and malicious behavior in all the S3 buckets in your environment.

Amazon S3 Access Logs

Server access logs provide detailed records about requests that are made to a bucket. Server access logs are useful for many applications. For example, access log information can be useful in security and access audits. For more information, see Logging requests with server access logging.

AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon S3-related checks:

- Logging configuration of Amazon S3 buckets.
- Security checks for Amazon S3 buckets that have open access permissions.
- Fault tolerance checks for Amazon S3 buckets that don't have versioning enabled, or have versioning suspended.

For more information, see AWS Trusted Advisor in the *Support User Guide*.

Amazon S3 Storage Lens

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security best practices, and improve the performance of application workloads.

S3 Storage Lens aggregates your metrics and displays the information in the Account snapshot section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. For more information, see Understanding Amazon S3 Storage Lens.

Amazon S3 Inventory

Amazon S3 Inventory generates a list of objects and metadata that you can use to query and manage your objects. You can use this inventory report to generate granular data such as object size, last modified date, encryption status and other fields. Those reports are available daily or weekly to automatically give the latest list.

For example, you can use Amazon S3 Inventory to audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs. You can also use Amazon S3 Inventory to simplify and speed up business workflows and big data jobs, which provides a scheduled alternative to the Amazon S3 synchronous `List` API operations. Amazon S3 Inventory doesn't use the `List` API operations to audit your objects and does not affect the request rate of your bucket. For more information, see Cataloging and analyzing your data with S3 Inventory.

Amazon S3 Event Notifications

With the Amazon S3 Event Notifications feature, you receive notifications when certain events happen in your S3 bucket. To enable notifications, add a notification configuration that identifies the events that you want Amazon S3 to publish. For more information, see Amazon S3 Event Notifications.

Amazon S3 and AWS X-Ray

AWS X-Ray integrates with Amazon S3 to trace upstream requests to update your application's S3 buckets. If a service traces requests by using the X-Ray SDK, Amazon S3 can send the tracing headers to downstream event subscribers such as Λ, Amazon SQS, and Amazon SNS. X-Ray enables trace messages for Amazon S3 event notifications. You can use the X-Ray trace map to view the connections between Amazon S3 and other services that your application uses. For more information, see Amazon S3 and X-Ray.

The following security best practices also address logging and monitoring:

- Identify and audit all your Amazon S3 buckets
- Implement monitoring using Amazon Web Services monitoring tools
- Enable AWS Config
- Enable Amazon S3 server access logging
- Use CloudTrail
- Monitor Amazon Web Services security advisories

Topics

- Monitoring tools
- Logging options for Amazon S3
- Logging Amazon S3 API calls using AWS CloudTrail
- Logging requests with server access logging
- Monitoring metrics with Amazon CloudWatch
- Amazon S3 Event Notifications
- Assessing your storage activity and usage with Amazon S3 Storage Lens
- Cataloging and analyzing your data with S3 Inventory

Monitoring tools

AWS provides various tools that you can use to monitor Amazon S3. You can configure some of these tools to do the monitoring for you, while some of the tools require manual intervention. We recommend that you automate monitoring tasks as much as possible.

Automated monitoring tools

You can use the following automated monitoring tools to watch Amazon S3 and report when something is wrong:

- **Amazon CloudWatch Alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state. The state must have changed and been maintained for a specified number of periods. For more information, see Monitoring metrics with Amazon CloudWatch.
- **AWS CloudTrail Log Monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see Logging Amazon S3 API calls using AWS CloudTrail.

Manual monitoring tools

Another important part of monitoring Amazon S3 involves manually monitoring those items that the CloudWatch alarms don't cover. The Amazon S3, CloudWatch, Trusted Advisor, and other AWS Management Console dashboards provide an at-a-glance view of the state of your AWS environment. You might want to enable *server access logging*, which tracks requests for access to your bucket. Each access log record provides details about a single access request, such as the requester, bucket name, request time, request action, response status, and error code, if any. For more information, see Logging requests with server access logging.

- The Amazon S3 dashboard shows the following:
  - Your buckets and the objects and properties they contain
- The CloudWatch home page shows the following:
  - Current alarms and status
  - Graphs of alarms and resources
  - Service health status

  In addition, you can use CloudWatch to do the following:
  - Create customized dashboards to monitor the services you care about.

- Graph metric data to troubleshoot issues and discover trends.
- Search and browse all your AWS resource metrics.
- Create and edit alarms to be notified of problems.

- AWS Trusted Advisor can help you monitor your AWS resources to improve performance, reliability, security, and cost effectiveness. Four Trusted Advisor checks are available to all users; more than 50 checks are available to users with a Business or Enterprise support plan. For more information, see AWS Trusted Advisor.

  Trusted Advisor has these checks that relate to Amazon S3:

  - Checks of the logging configuration of Amazon S3 buckets.
  - Security checks for Amazon S3 buckets that have open access permissions.
  - Fault tolerance checks for Amazon S3 buckets that do not have versioning enabled, or have versioning suspended.

Logging options for Amazon S3

You can record the actions that are taken by users, roles, or AWS services on Amazon S3 resources and maintain log records for auditing and compliance purposes. To do this, you can use server-access logging, AWS CloudTrail logging, or a combination of both. We recommend that you use CloudTrail for logging bucket-level and object-level actions for your Amazon S3 resources. For more information about each option, see the following sections:

- Logging requests with server access logging
- Logging Amazon S3 API calls using AWS CloudTrail

The following table lists the key properties of CloudTrail logs and Amazon S3 server-access logs. To make sure that CloudTrail meets your security requirements, review the table and notes.

Log properties	AWS CloudTrail	Amazon S3 server logs
Can be forwarded to other systems (Amazon CloudWatch Logs, Amazon CloudWatch Events)	Yes	No

Log properties	AWS CloudTrail	Amazon S3 server logs
Deliver logs to more than one destination (for example, send the same logs to two different buckets)	Yes	No
Turn on logs for a subset of objects (prefix)	Yes	No
Cross-account log delivery (target and source bucket owned by different accounts)	Yes	No
Integrity validation of log file by using digital signature or hashing	Yes	No
Default or choice of encryptio n for log files	Yes	No
Object operations (by using Amazon S3 APIs)	Yes	Yes
Bucket operations (by using Amazon S3 APIs)	Yes	Yes
Searchable UI for logs	Yes	No
Fields for Object Lock parameters, Amazon S3 Select properties for log records	Yes	No
Fields for `Object Size`, `Total Time`, `Turn-Around Time`, and `HTTP Referer` for log records	No	Yes

Log properties	AWS CloudTrail	Amazon S3 server logs
Lifecycle transitions, expirations, restores	No	Yes
Logging of keys in a batch delete operation	Yes	Yes
Authentication failures[1]	No	Yes
Accounts where logs get delivered	Bucket owner[2], and requester	Bucket owner only
Performance and Cost	**AWS CloudTrail**	**Amazon S3 Server Logs**
Price	Management events (first delivery) are free; data events incur a fee, in addition to storage of logs	No other cost in addition to storage of logs
Speed of log delivery	Data events every 5 minutes; management events every 15 minutes	Within a few hours
Log format	JSON	Log file with space-separated, newline-delimited records

Notes

1. CloudTrail does not deliver logs for requests that fail authentication (in which the provided credentials are not valid) or that fail due to redirection (error code `301 Moved Permanently`). However, it does include logs for requests in which authorization fails (`AccessDenied`) and requests that are made by anonymous users.
2. The S3 bucket owner receives CloudTrail logs when the account does not have full access to the object in the request. For more information, see Amazon S3 object-level actions in cross-account scenarios.

3. S3 does not support delivery of CloudTrail logs or server access logs to the requester or the bucket owner for VPC endpoint requests when the VPC endpoint policy denies them or for requests that fail before the VPC policy is evaluated.

Logging Amazon S3 API calls using AWS CloudTrail

Amazon S3 is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls for Amazon S3 as events. The calls captured include calls from the Amazon S3 console and code calls to the Amazon S3 API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon S3, the IP address from which the request was made, when it was made, and additional details.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made on behalf of an IAM Identity Center user.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

CloudTrail is active in your AWS account when you create the account and you automatically have access to the CloudTrail **Event history**. The CloudTrail **Event history** provides a viewable, searchable, downloadable, and immutable record of the past 90 days of recorded management events in an AWS Region. For more information, see Working with CloudTrail Event history in the *AWS CloudTrail User Guide*. There are no CloudTrail charges for viewing the **Event history**.

For an ongoing record of events in your AWS account past 90 days, create a trail or a CloudTrail Lake event data store.

CloudTrail trails

A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. All trails created using the AWS Management Console are multi-Region. You can create a single-Region or a multi-Region trail by using the AWS CLI. Creating a multi-Region trail is recommended because you capture activity in all AWS Regions in your account. If you create a single-Region trail, you can view only the events logged in the trail's AWS Region. For more information about trails, see Creating a

trail for your AWS account and Creating a trail for an organization in the *AWS CloudTrail User Guide*.

You can deliver one copy of your ongoing management events to your Amazon S3 bucket at no charge from CloudTrail by creating a trail, however, there are Amazon S3 storage charges. For more information about CloudTrail pricing, see AWS CloudTrail Pricing. For information about Amazon S3 pricing, see Amazon S3 Pricing.

CloudTrail Lake event data stores

CloudTrail Lake lets you run SQL-based queries on your events. CloudTrail Lake converts existing events in row-based JSON format to Apache ORC format. ORC is a columnar storage format that is optimized for fast retrieval of data. Events are aggregated into *event data stores*, which are immutable collections of events based on criteria that you select by applying advanced event selectors. The selectors that you apply to an event data store control which events persist and are available for you to query. For more information about CloudTrail Lake, see Working with AWS CloudTrail Lake in the *AWS CloudTrail User Guide*.

CloudTrail Lake event data stores and queries incur costs. When you create an event data store, you choose the pricing option you want to use for the event data store. The pricing option determines the cost for ingesting and storing events, and the default and maximum retention period for the event data store. For more information about CloudTrail pricing, see AWS CloudTrail Pricing.

You can store your log files in your bucket for as long as you want, but you can also define Amazon S3 Lifecycle rules to archive or delete log files automatically. By default, your log files are encrypted by using Amazon S3 server-side encryption (SSE).

Using CloudTrail logs with Amazon S3 server access logs and CloudWatch Logs

AWS CloudTrail logs provide a record of actions taken by a user, role, or an AWS service in Amazon S3, while Amazon S3 server access logs provide detailed records for the requests that are made to an S3 bucket. For more information about how the different logs work, and their properties, performance, and costs, see the section called “Logging options”.

You can use AWS CloudTrail logs together with server access logs for Amazon S3. CloudTrail logs provide you with detailed API tracking for Amazon S3 bucket-level and object-level operations. Server access logs for Amazon S3 provide you with visibility into object-level operations on your

data in Amazon S3. For more information about server access logs, see Logging requests with server access logging.

You can also use CloudTrail logs together with Amazon CloudWatch for Amazon S3. CloudTrail integration with CloudWatch Logs delivers S3 bucket-level API activity captured by CloudTrail to a CloudWatch log stream in the CloudWatch log group that you specify. You can create CloudWatch alarms for monitoring specific API activity and receive email notifications when the specific API activity occurs. For more information about CloudWatch alarms for monitoring specific API activity, see the AWS CloudTrail User Guide. For more information about using CloudWatch with Amazon S3, see Monitoring metrics with Amazon CloudWatch.

Note

S3 does not support delivery of CloudTrail logs to the requester or the bucket owner for VPC endpoint requests when the VPC endpoint policy denies them.

CloudTrail tracking with Amazon S3 SOAP API calls

CloudTrail tracks Amazon S3 SOAP API calls. Amazon S3 SOAP support over HTTP is deprecated, but it is still available over HTTPS. For more information about Amazon S3 SOAP support, see Appendix: SOAP API in the *Amazon S3 API Reference*.

Important

Newer Amazon S3 features are not supported for SOAP. We recommend that you use either the REST API or the AWS SDKs.

The following table shows Amazon S3 SOAP actions tracked by CloudTrail logging.

SOAP API name	API event name used in CloudTrail log
ListAllMyBuckets	`ListBuckets`
CreateBucket	`CreateBucket`
DeleteBucket	`DeleteBucket`

SOAP API name	API event name used in CloudTrail log
GetBucketAccessControlPolicy	GetBucketAcl
SetBucketAccessControlPolicy	PutBucketAcl
GetBucketLoggingStatus	GetBucketLogging
SetBucketLoggingStatus	PutBucketLogging

For more information about CloudTrail and Amazon S3, see the following topics:

Topics

- Amazon S3 CloudTrail events
- CloudTrail log file entries for Amazon S3 and S3 on Outposts
- Enabling CloudTrail event logging for S3 buckets and objects
- Identifying Amazon S3 requests using CloudTrail

Amazon S3 CloudTrail events

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

This section provides information about the events that S3 logs to CloudTrail.

Amazon S3 data events in CloudTrail

Data events provide information about the resource operations performed on or in a resource (for example, reading or writing to an Amazon S3 object). These are also known as data plane operations. Data events are often high-volume activities. By default, CloudTrail doesn't log data events. The CloudTrail **Event history** doesn't record data events.

Additional charges apply for data events. For more information about CloudTrail pricing, see AWS CloudTrail Pricing.

You can log data events for the Amazon S3 resource types by using the CloudTrail console, AWS CLI, or CloudTrail API operations. For more information about how to log data events, see Logging data events with the AWS Management Console and Logging data events with the AWS Command Line Interface in the *AWS CloudTrail User Guide*.

The following table lists the Amazon S3 resource types for which you can log data events. The **Data event type (console)** column shows the value to choose from the **Data event type** list on the CloudTrail console. The **resources.type value** column shows the `resources.type` value, which you would specify when configuring advanced event selectors using the AWS CLI or CloudTrail APIs. The **Data APIs logged to CloudTrail** column shows the API calls logged to CloudTrail for the resource type.

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
S3	`AWS::S3::Object`	• AbortMultipartUpload • CompleteMultipartUpload • CopyObject • CreateMultipartUpload • DeleteObject • DeleteObjectTagging • DeleteObjects • GetObject • GetObjectAcl • GetObjectAttributes • GetObjectLegalHold

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
		• GetObjectRetention • GetObjectTagging • GetObjectTorrent • HeadObject • HeadBucket • ListObjectVersions • ListObjects • ListParts • PutObject • PutObjectAcl • PutObjectLegalHold • PutObjectRetention • PutObjectTagging • RestoreObject • SelectObjectContent • UploadPart • UploadPartCopy

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
S3 Express One Zone	`AWS::S3Express::Object`	• AbortMultipartUpload • CompleteMultipartUpload • CreateSession • CopyObject • CreateMultipartUpload • DeleteObject • DeleteObjects • GetObject • GetObjectAttributes • HeadBucket • HeadObject • ListObjectsV2 • ListParts • PutObject • UploadPart • UploadPartCopy

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
S3 Access Point	`AWS::S3::Access Point`	• AbortMultipartUpload • CompleteMultipartUpload • CopyObject (same-region copies only) • CreateMultipartUpload • DeleteObject • DeleteObjectTagging • GetBucketAcl • GetBucketCors • GetBucketLocation • GetBucketNotificationConfiguration • GetBucketPolicy • GetObject • GetObjectAcl • GetObjectAttributes • GetObjectLegalHold • GetObjectRetention • GetObjectTagging • HeadBucket • HeadObject • ListObjects • ListObjectsV2 • ListObjectVersions • ListParts • Presign • PutObject • PutObjectLegalHold

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
		• PutObjectRetention • PutObjectAcl • PutObjectTagging • RestoreObject • UploadPart • UploadPartCopy (same-region copies only)

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
S3 Object Lambda	`AWS::S3ObjectLambda::AccessPoint`	• AbortMultipartUpload • CompleteMultipartUpload • CopyObject (same-region copies only) • CreateMultipartUpload • DeleteObject • DeleteObjectTagging • GetObject • GetObjectAcl • GetObjectLegalHold • GetObjectRetention • GetObjectTagging • HeadObject • ListObjects • ListObjectVersions • ListParts • PutObject • PutObjectLegalHold • PutObjectRetention • PutObjectAcl • PutObjectTagging • RestoreObject • UploadPart • WriteGetObjectResponse

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
S3 Outposts	`AWS::S3Outposts::Object`	• AbortMultipartUpload • CompleteMultipartUpload • CopyObject (same-region copies only) • CreateMultipartUpload • DeleteObject • DeleteObjectTagging • GetObject • GetObjectTagging • HeadObject • ListObjects • ListObjectsV2 • ListParts • PutObject • PutObjectTagging • UploadPart • UploadPartCopy

You can configure advanced event selectors to filter on the `eventName`, `readOnly`, and `resources.ARN` fields to log only those events that are important to you. For more information about these fields, see AdvancedFieldSelector in the *AWS CloudTrail API Reference*.

Amazon S3 management events in CloudTrail

Amazon S3 logs all control plane operations as management events. For more information about S3 API operations, see the Amazon S3 API Reference.

How CloudTrail captures requests made to Amazon S3

By default, CloudTrail logs S3 bucket-level API calls that were made in the last 90 days, but not log requests made to objects. Bucket-level calls include events such as `CreateBucket`,

`DeleteBucket`, `PutBucketLifecycle`, `PutBucketPolicy`, and so on. You can see bucket-level events on the CloudTrail console. However, you can't view data events (Amazon S3 object-level calls) there—you must parse or query CloudTrail logs for them.

If you are logging data activity with AWS CloudTrail, the event record for an Amazon S3 `DeleteObjects` data event includes both the `DeleteObjects` event and a `DeleteObject` event for each object deleted as part of that operation. You can exclude the additional visibility about deleted objects from the event record. For more information, see AWS CLI examples for filtering data events in the *AWS CloudTrail User Guide.*

Amazon S3 account-level actions tracked by CloudTrail logging

CloudTrail logs account-level actions. Amazon S3 records are written together with other AWS service records in a log file. CloudTrail determines when to create and write to a new file based on a time period and file size.

The tables in this section list the Amazon S3 account-level actions that are supported for logging by CloudTrail.

Amazon S3 account-level API actions tracked by CloudTrail logging appear as the following event names. The CloudTrail event names differ from the API action name. For example, DeletePublicAccessBlock is DeleteAccountPublicAccessBlock.

- DeleteAccountPublicAccessBlock
- GetAccountPublicAccessBlock
- PutAccountPublicAccessBlock

Amazon S3 bucket-level actions that are tracked by CloudTrail logging

By default, CloudTrail logs bucket-level actions for general purpose buckets. Amazon S3 records are written together with other AWS service records in a log file. CloudTrail determines when to create and write to a new file based on a time period and file size.

This section lists the Amazon S3 bucket-level actions that are supported for logging by CloudTrail.

Amazon S3 bucket-level API actions tracked by CloudTrail logging appear as the following event names. In some cases, the CloudTrail event name differs from the API action name. For example, `PutBucketLifecycleConfiguration` is `PutBucketLifecycle`.

- CreateBucket
- CreateBucketMetadataConfiguration (V2 API operation)
- CreateBucketMetadataTableConfiguration (V1 API operation)
- DeleteBucket
- DeleteBucketAnalyticsConfiguration
- DeleteBucketCors
- DeleteBucketEncryption
- DeleteBucketIntelligentTieringConfiguration
- DeleteBucketInventoryConfiguration
- DeleteBucketLifecycle
- DeleteBucketMetadataConfiguration (V2 API operation)
- DeleteBucketMetadataTableConfiguration (V1 API operation)
- DeleteBucketMetricsConfiguration
- DeleteBucketOwnershipControls
- DeleteBucketPolicy
- DeleteBucketPublicAccessBlock
- DeleteBucketReplication
- DeleteBucketTagging
- GetAccelerateConfiguration
- GetBucketAcl
- GetBucketAnalyticsConfiguration
- GetBucketCors
- GetBucketEncryption
- GetBucketIntelligentTieringConfiguration
- GetBucketInventoryConfiguration
- GetBucketLifecycle
- GetBucketLocation
- GetBucketLogging

- GetBucketMetadataConfiguration (V2 API operation)
- GetBucketMetadataTableConfiguration (V1 API operation)
- GetBucketMetricsConfiguration
- GetBucketNotification
- GetBucketObjectLockConfiguration
- GetBucketOwnershipControls
- GetBucketPolicy
- GetBucketPolicyStatus
- GetBucketPublicAccessBlock
- GetBucketReplication
- GetBucketRequestPayment
- GetBucketTagging
- GetBucketVersioning
- GetBucketWebsite
- HeadBucket
- ListBuckets
- PutAccelerateConfiguration
- PutBucketAcl
- PutBucketAnalyticsConfiguration
- PutBucketCors
- PutBucketEncryption
- PutBucketIntelligentTieringConfiguration
- PutBucketInventoryConfiguration
- PutBucketLifecycle
- PutBucketLogging
- PutBucketMetricsConfiguration
- PutBucketNotification
- PutBucketObjectLockConfiguration

- PutBucketOwnershipControls
- PutBucketPolicy
- PutBucketPublicAccessBlock
- PutBucketReplication
- PutBucketRequestPayment
- PutBucketTagging
- PutBucketVersioning
- PutBucketWebsite
- UpdateBucketMetadataJournalTableConfiguration
- UpdateBucketMetadataInventoryTableConfiguration

In addition to these API operations, you can also use the OPTIONS object object-level action. This action is treated like a bucket-level action in CloudTrail logging because the action checks the CORS configuration of a bucket.

Amazon S3 Express One Zone bucket-level (Regional API endpoint) actions tracked by CloudTrail logging

By default, CloudTrail logs bucket-level actions for directory buckets as management events. The `eventsource` for CloudTrail management events for S3 Express One Zone is `s3express.amazonaws.com`.

These following Regional endpoint API operations are logged to CloudTrail.

- CreateBucket
- DeleteBucket
- DeleteBucketPolicy
- GetBucketPolicy
- PutBucketPolicy
- ListDirectoryBuckets
- PutBucketEncryption
- GetBucketEncryption

- DeleteBucketEncryption

For more information, see Logging with AWS CloudTrail for S3 Express One Zone

Amazon S3 object-level actions in cross-account scenarios

The following are special use cases involving the object-level API calls in cross-account scenarios and how CloudTrail logs are reported. CloudTrail delivers logs to the requester (the account that made the API call), except in some access denied cases where log entries are redacted or omitted. When setting up cross-account access, consider the examples in this section.

> **Note**
>
> The examples assume that CloudTrail logs are appropriately configured.

Example 1: CloudTrail delivers logs to the bucket owner

CloudTrail delivers logs to the bucket owner even if the bucket owner does not have permissions for the same object API operation. Consider the following cross-account scenario:

- Account A owns the bucket.
- Account B (the requester) tries to access an object in that bucket.
- Account C owns the object. Account C might or might not be the same account as Account A.

> **Note**
>
> CloudTrail always delivers object-level API logs to the requester (Account B). In addition, CloudTrail also delivers the same logs to the bucket owner (Account A) even when the bucket owner does not own the object (Account C) or have permissions for those same API operations on that object.

Example 2: CloudTrail does not proliferate email addresses that are used in setting object ACLs

Consider the following cross-account scenario:

- Account A owns the bucket.

- Account B (the requester) sends a request to set an object ACL grant by using an email address. For more information about ACLs, see Access control list (ACL) overview.

The requester gets the logs along with the email information. However, the bucket owner—if they are eligible to receive logs, as in example 1—gets the CloudTrail log reporting the event. However, the bucket owner doesn't get the ACL configuration information, specifically the grantee email address and the grant. The only information that the log tells the bucket owner is that an ACL API call was made by Account B.

CloudTrail log file entries for Amazon S3 and S3 on Outposts

Important

Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

An event represents a single request from any source and includes information about the requested API operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so events don't appear in any specific order.

Note

To view CloudTrail log file examples for Amazon S3 Express One Zone, see CloudTrail log file examples for S3 Express One Zone.

For more information, see the following examples.

Topics

        }
        }
    ]
}
```

Enabling CloudTrail event logging for S3 buckets and objects

You can use CloudTrail data events to get information about bucket and object-level requests in Amazon S3. To enable CloudTrail data events for all of your buckets or for a list of specific buckets, you must create a trail manually in CloudTrail.

> **Note**
>
> - The default setting for CloudTrail is to find only management events. Check to ensure that you have the data events enabled for your account.
> - With an S3 bucket that is generating a high workload, you could quickly generate thousands of logs in a short amount of time. Be mindful of how long you choose to enable CloudTrail data events for a busy bucket.

CloudTrail stores Amazon S3 data event logs in an S3 bucket of your choosing. Consider using a bucket in a separate AWS account to better organize events from multiple buckets that you might own into a central place for easier querying and analysis. AWS Organizations helps you create an AWS account that is linked to the account that owns the bucket that you're monitoring. For more information, see What is AWS Organizations? in the *AWS Organizations User Guide*.

When you log data events for a trail in CloudTrail, you can choose to use advanced event selectors or basic event selectors to log data events for objects stored in general purpose buckets. To log

data events for objects stored in directory buckets, you must use advanced event selectors. For more information, see Logging with AWS CloudTrail for S3 Express One Zone.

When you create a trail in the CloudTrail console using advanced event selectors, in the data events section, you can choose **Log all events** for the **Log selector template** to log all object-level events. When you create a trail in the CloudTrail console using basic event selectors, in the data events section, you can select the **Select all S3 buckets in your account** check box to log all object-level events.

Note

- It's a best practice to create a lifecycle configuration for your AWS CloudTrail data event bucket. Configure the lifecycle configuration to periodically remove log files after the period of time you believe you need to audit them. Doing so reduces the amount of data that Athena analyzes for each query. For more information, see Setting an S3 Lifecycle configuration on a bucket.
- For more information about logging format, see Logging Amazon S3 API calls using AWS CloudTrail.
- For examples of how to query CloudTrail logs, see the *AWS Big Data Blog* post Analyze Security, Compliance, and Operational Activity Using AWS CloudTrail and Amazon Athena.

Enable logging for objects in a bucket using the console

You can use the Amazon S3 console to configure an AWS CloudTrail trail to log data events for objects in an S3 bucket. CloudTrail supports logging Amazon S3 object-level API operations such as `GetObject`, `DeleteObject`, and `PutObject`. These events are called *data events*.

By default, CloudTrail trails don't log data events, but you can configure trails to log data events for S3 buckets that you specify, or to log data events for all the Amazon S3 buckets in your AWS account. For more information, see Logging Amazon S3 API calls using AWS CloudTrail.

CloudTrail does not populate data events in the CloudTrail event history. Additionally, not all bucket-level actions are populated in the CloudTrail event history. For more information about the Amazon S3 bucket–level API actions tracked by CloudTrail logging, see Amazon S3 bucket-level actions that are tracked by CloudTrail logging. For more information about how to query CloudTrail

logs, see the AWS Knowledge Center article about using Amazon CloudWatch Logs filter patterns and Amazon Athena to query CloudTrail logs.

> **Note**
>
> If you are logging data activity with AWS CloudTrail, the event record for an Amazon S3 `DeleteObjects` data event includes both the `DeleteObjects` event and a `DeleteObject` event for each object deleted as part of that operation. You can exclude the additional visibility about deleted objects from the event record. For more information, see AWS CLI examples for filtering data events in the *AWS CloudTrail User Guide*.

To configure a trail to log data events for an S3 bucket, you can use either the AWS CloudTrail console or the Amazon S3 console. If you are configuring a trail to log data events for all the Amazon S3 buckets in your AWS account, it's easier to use the CloudTrail console. For information about using the CloudTrail console to configure a trail to log S3 data events, see Data events in the *AWS CloudTrail User Guide*.

> **Important**
>
> Additional charges apply for data events. For more information, see AWS CloudTrail pricing.

The following procedure shows how to use the Amazon S3 console to configure a CloudTrail trail to log data events for an S3 bucket.

To enable CloudTrail data events logging for objects in an S3 general purpose bucket or in an S3 directory bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket.
3. Choose **Properties**.
4. Under **AWS CloudTrail data events**, choose **Configure in CloudTrail**.

   You can create a new CloudTrail trail or reuse an existing trail and configure Amazon S3 data events to be logged in your trail. For information about how to create trails in the CloudTrail console, see Creating and updating a trail with the console in the *AWS CloudTrail User Guide*.

For information about how to configure Amazon S3 data event logging in the CloudTrail console, see Logging data events for Amazon S3 Objects in the *AWS CloudTrail User Guide*.

> **Note**
>
> If you use the CloudTrail console or the Amazon S3 console to configure a trail to log data events for an S3 bucket, the Amazon S3 console shows that object-level logging is enabled for the bucket.

To disable CloudTrail data events logging for objects in an S3 bucket

1. Sign in to the AWS Management Console and open the CloudTrail console at https://console.aws.amazon.com/cloudtrail/.
2. In the left navigation pane, choose **Trails**.
3. Choose the name of the trail that you created to log events for your bucket.
4. On the details page for your trail, choose **Stop logging** in the upper-right corner.
5. In the dialog box that appears, choose **Stop logging**.

For information about enabling object-level logging when you create an S3 bucket, see Creating a general purpose bucket.

For more information about CloudTrail logging with S3 buckets, see the following topics:

- Viewing the properties for an S3 general purpose bucket
- Logging Amazon S3 API calls using AWS CloudTrail
- Working with CloudTrail Log Files in the *AWS CloudTrail User Guide*

Identifying Amazon S3 requests using CloudTrail

In Amazon S3, you can identify requests using an AWS CloudTrail event log. AWS CloudTrail is the preferred way of identifying Amazon S3 requests, but if you are using Amazon S3 server access logs, see the section called “Identifying S3 requests”.

Topics

- Identifying requests made to Amazon S3 in a CloudTrail log

- Identifying Amazon S3 Signature Version 2 requests by using CloudTrail
- Identifying access to S3 objects by using CloudTrail

Identifying requests made to Amazon S3 in a CloudTrail log

After you set up CloudTrail to deliver events to a bucket, you should start to see objects go to your destination bucket on the Amazon S3 console. These are formatted as follows:

`s3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/Region/yyyy/mm/dd`

Events logged by CloudTrail are stored as compressed, gzipped JSON objects in your S3 bucket. To efficiently find requests, you should use a service like Amazon Athena to index and query the CloudTrail logs.

For more information about CloudTrail and Athena, see Creating the table for AWS CloudTrail logs in Athena using partition projection in the *Amazon Athena User Guide*.

Identifying Amazon S3 Signature Version 2 requests by using CloudTrail

You can use a CloudTrail event log to identify which API signature version was used to sign a request in Amazon S3. This capability is important because support for Signature Version 2 will be turned off (deprecated). After that, Amazon S3 will no longer accept requests that use Signature Version 2, and all requests must use *Signature Version 4* signing.

We *strongly* recommend that you use CloudTrail to help determine whether any of your workflows are using Signature Version 2 signing. Remediate them by upgrading your libraries and code to use Signature Version 4 instead to prevent any impact to your business.

For more information, see Announcement: AWS CloudTrail for Amazon S3 adds new fields for enhanced security auditing in AWS re:Post.

> **Note**
>
> CloudTrail events for Amazon S3 include the signature version in the request details under the key name of `'additionalEventData`. To find the signature version on requests made for objects in Amazon S3 such as `GET`, `PUT`, and `DELETE` requests, you must enable CloudTrail data events. (This feature is turned off by default.)

AWS CloudTrail is the preferred method for identifying Signature Version 2 requests. If you're using Amazon S3 server-access logs, see Identifying Signature Version 2 requests by using Amazon S3 access logs.

Topics

- Athena query examples for identifying Amazon S3 Signature Version 2 requests
- Partitioning Signature Version 2 data

Athena query examples for identifying Amazon S3 Signature Version 2 requests

Example — Select all Signature Version 2 events, and print only `EventTime`, `S3_Action`, `Request_Parameters`, `Region`, `SourceIP`, and `UserAgent`

In the following Athena query, replace *`s3_cloudtrail_events_db.cloudtrail_table`* with your Athena details, and increase or remove the limit as needed.

```
SELECT EventTime, EventName as S3_Action, requestParameters as Request_Parameters,
 awsregion as AWS_Region, sourceipaddress as Source_IP, useragent as User_Agent
FROM s3_cloudtrail_events_db.cloudtrail_table
WHERE eventsource='s3.amazonaws.com'
AND json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'
LIMIT 10;
```

Example — Select all requesters that are sending Signature Version 2 traffic

```
SELECT useridentity.arn, Count(requestid) as RequestCount
FROM s3_cloudtrail_events_db.cloudtrail_table
WHERE eventsource='s3.amazonaws.com'
    and json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'
Group by useridentity.arn
```

Partitioning Signature Version 2 data

If you have a large amount of data to query, you can reduce the costs and running time of Athena by creating a partitioned table.

To do this, create a new table with partitions as follows.

```
CREATE EXTERNAL TABLE s3_cloudtrail_events_db.cloudtrail_table_partitioned(
     eventversion STRING,
     userIdentity STRUCT<
         type:STRING,
         principalid:STRING,
         arn:STRING,
         accountid:STRING,
         invokedby:STRING,
         accesskeyid:STRING,
         userName:STRING,
      sessioncontext:STRUCT<
                 attributes:STRUCT<
                 mfaauthenticated:STRING,
                 creationdate:STRING>,
                 sessionIssuer:STRUCT<
                 type:STRING,
                 principalId:STRING,
                 arn:STRING,
                 accountId:STRING,
                 userName:STRING>
             >
          >,
     eventTime STRING,
     eventSource STRING,
     eventName STRING,
     awsRegion STRING,
     sourceIpAddress STRING,
     userAgent STRING,
     errorCode STRING,
     errorMessage STRING,
     requestParameters STRING,
     responseElements STRING,
     additionalEventData STRING,
     requestId STRING,
     eventId STRING,
     resources ARRAY<STRUCT<ARN:STRING,accountId: STRING,type:STRING>>,
     eventType STRING,
     apiVersion STRING,
     readOnly STRING,
     recipientAccountId STRING,
     serviceEventDetails STRING,
```

```
        sharedEventID STRING,
        vpcEndpointId STRING
    )
    PARTITIONED BY (region string, year string, month string, day string)
    ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.orc.OrcSerde'
    STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'
    OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
    LOCATION 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/';
```

Then, create the partitions individually. You can't get results from dates that you haven't created.

```
ALTER TABLE s3_cloudtrail_events_db.cloudtrail_table_partitioned ADD
    PARTITION (region= 'us-east-1', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/us-east-1/2019/02/19/'
    PARTITION (region= 'us-west-1', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/us-west-1/2019/02/19/'
    PARTITION (region= 'us-west-2', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/us-west-2/2019/02/19/'
    PARTITION (region= 'ap-southeast-1', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/ap-southeast-1/2019/02/19/'
    PARTITION (region= 'ap-southeast-2', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/ap-southeast-2/2019/02/19/'
    PARTITION (region= 'ap-northeast-1', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/ap-northeast-1/2019/02/19/'
    PARTITION (region= 'eu-west-1', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/eu-west-1/2019/02/19/'
    PARTITION (region= 'sa-east-1', year= '2019', month= '02', day= '19') LOCATION
 's3://amzn-s3-demo-bucket1/AWSLogs/111122223333/CloudTrail/sa-east-1/2019/02/19/';
```

You can then make the request based on these partitions, and you don't need to load the full bucket.

```
SELECT useridentity.arn,
Count(requestid) AS RequestCount
FROM s3_cloudtrail_events_db.cloudtrail_table_partitioned
WHERE eventsource='s3.amazonaws.com'
AND json_extract_scalar(additionalEventData, '$.SignatureVersion')='SigV2'
AND region='us-east-1'
AND year='2019'
```

```
AND month='02'
AND day='19'
Group by useridentity.arn
```

Identifying access to S3 objects by using CloudTrail

You can use your AWS CloudTrail event logs to identify Amazon S3 object access requests for data events such as `GetObject`, `DeleteObject`, and `PutObject`, and discover additional information about those requests.

> **Note**
>
> If you are logging data activity with AWS CloudTrail, the event record for an Amazon S3 `DeleteObjects` data event includes both the `DeleteObjects` event and a `DeleteObject` event for each object deleted as part of that operation. You can exclude the additional visibility about deleted objects from the event record. For more information, see AWS CLI examples for filtering data events in the *AWS CloudTrail User Guide.*

The following example shows how to get all PUT object requests for Amazon S3 from an AWS CloudTrail event log.

Topics

- Athena query examples for identifying Amazon S3 object access requests

Athena query examples for identifying Amazon S3 object access requests

In the following Athena query examples, replace *`s3_cloudtrail_events_db.cloudtrail_table`* with your Athena details, and modify the date range as needed.

Example — Select all events that have PUT object access requests, and print only `EventTime`, `EventSource`, `SourceIP`, `UserAgent`, `BucketName`, `object`, and `UserARN`

```
SELECT
  eventTime,
  eventName,
  eventSource,
```

```
  sourceIpAddress,
  userAgent,
  json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
  json_extract_scalar(requestParameters, '$.key') as object,
  userIdentity.arn as userArn
FROM
  s3_cloudtrail_events_db.cloudtrail_table
WHERE
  eventName = 'PutObject'
  AND eventTime BETWEEN '2019-07-05T00:00:00Z' and '2019-07-06T00:00:00Z'
```

Example — Select all events that have GET object access requests, and print only EventTime, EventSource, SourceIP, UserAgent, BucketName, object, and UserARN

```
SELECT
  eventTime,
  eventName,
  eventSource,
  sourceIpAddress,
  userAgent,
  json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
  json_extract_scalar(requestParameters, '$.key') as object,
  userIdentity.arn as userArn
FROM
  s3_cloudtrail_events_db.cloudtrail_table
WHERE
  eventName = 'GetObject'
  AND eventTime BETWEEN '2019-07-05T00:00:00Z' and '2019-07-06T00:00:00Z'
```

Example — Select all anonymous requester events to a bucket in a certain period and print only EventTime, EventName, EventSource, SourceIP, UserAgent, BucketName, UserARN, and AccountID

```
SELECT
  eventTime,
  eventName,
  eventSource,
  sourceIpAddress,
  userAgent,
  json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
  userIdentity.arn as userArn,
```

```
  userIdentity.accountId
FROM
  s3_cloudtrail_events_db.cloudtrail_table
WHERE
  userIdentity.accountId = 'anonymous'
  AND eventTime BETWEEN '2019-07-05T00:00:00Z' and '2019-07-06T00:00:00Z'
```

Example — Identify all requests that required an ACL for authorization

The following Amazon Athena query example shows how to identify all requests to your S3 buckets that required an access control list (ACL) for authorization. If the request required an ACL for authorization, the `aclRequired` value in `additionalEventData` is `Yes`. If no ACLs were required, `aclRequired` is not present. You can use this information to migrate those ACL permissions to the appropriate bucket policies. After you've created these bucket policies, you can disable ACLs for these buckets. For more information about disabling ACLs, see Prerequisites for disabling ACLs.

```
SELECT
  eventTime,
  eventName,
  eventSource,
  sourceIpAddress,
  userAgent,
  userIdentity.arn as userArn,
  json_extract_scalar(requestParameters, '$.bucketName') as bucketName,
  json_extract_scalar(requestParameters, '$.key') as object,
  json_extract_scalar(additionalEventData, '$.aclRequired') as aclRequired
FROM
  s3_cloudtrail_events_db.cloudtrail_table
WHERE
  json_extract_scalar(additionalEventData, '$.aclRequired') = 'Yes'
  AND eventTime BETWEEN '2022-05-10T00:00:00Z' and '2022-08-10T00:00:00Z'
```

Note

- These query examples can also be useful for security monitoring. You can review the results for `PutObject` or `GetObject` calls from unexpected or unauthorized IP addresses or requesters and for identifying any anonymous requests to your buckets.
- This query only retrieves information from the time at which logging was enabled.

If you are using Amazon S3 server access logs, see Identifying object access requests by using Amazon S3 access logs.

Logging requests with server access logging

Server access logging provides detailed records for the requests that are made to a bucket. Server access logs are useful for many applications. For example, access log information can be useful in security and access audits. This information can also help you learn about your customer base and understand your Amazon S3 bill.

> **Note**
>
> Server access logs don't record information about wrong-Region redirect errors for Regions that launched after March 20, 2019. Wrong-Region redirect errors occur when a request for an object or bucket is made outside the Region in which the bucket exists.

How do I enable log delivery?

To enable log delivery, perform the following basic steps. For details, see Enabling Amazon S3 server access logging.

1. **Provide the name of the destination bucket** (also known as a *target bucket*). This bucket is where you want Amazon S3 to save the access logs as objects. Both the source and destination buckets must be in the same AWS Region and owned by the same account. The destination bucket must not have an S3 Object Lock default retention period configuration. The destination bucket must also not have Requester Pays enabled.

   You can have logs delivered to any bucket that you own that is in the same Region as the source bucket, including the source bucket itself. But for simpler log management, we recommend that you save access logs in a different bucket.

   When your source bucket and destination bucket are the same bucket, additional logs are created for the logs that are written to the bucket, which creates an infinite loop of logs. We do not recommend doing this because it could result in a small increase in your storage billing. In addition, the extra logs about logs might make it harder to find the log that you are looking for.

   If you choose to save access logs in the source bucket, we recommend that you specify a destination prefix (also known as a *target prefix*) for all log object keys. When you specify a

prefix, all the log object names begin with a common string, which makes the log objects easier to identify.

2. **(Optional) Assign a destination prefix to all Amazon S3 log object keys.** The destination prefix (also known as a *target prefix*) makes it simpler for you to locate the log objects. For example, if you specify the prefix value `logs/`, each log object that Amazon S3 creates begins with the `logs/` prefix in its key, for example:

   ```
   logs/2013-11-01-21-32-16-E568B2907131C0C0
   ```

   If you specify the prefix value `logs`, the log object appears as follows:

   ```
   logs2013-11-01-21-32-16-E568B2907131C0C0
   ```

   Prefixes are also useful to distinguish between source buckets when multiple buckets log to the same destination bucket.

   This prefix can also help when you delete the logs. For example, you can set a lifecycle configuration rule for Amazon S3 to delete objects with a specific prefix. For more information, see Deleting Amazon S3 log files.

3. **(Optional) Set permissions so that others can access the generated logs.** By default, only the bucket owner always has full access to the log objects. If your destination bucket uses the Bucket owner enforced setting for S3 Object Ownership to disable access control lists (ACLs), you can't grant permissions in destination grants (also known as *target grants*) that use ACLs. However, you can update your bucket policy for the destination bucket to grant access to others. For more information, see Identity and Access Management for Amazon S3 and Permissions for log delivery.

4. **(Optional) Set a log object key format for the log files.** You have two options for the log object key format (also known as the *target object key format*):

   - **Non-date-based partitioning** – This is the original log object key format. If you choose this format, the log file key format appears as follows:

     ```
     [DestinationPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
     ```

     For example, if you specify `logs/` as the prefix, your log objects are named like this:

     ```
     logs/2013-11-01-21-32-16-E568B2907131C0C0
     ```

- **Date-based partitioning** – If you choose date-based partitioning, you can choose the event time or delivery time for the log file as the date source used in the log format. This format makes it easier to query the logs.

  If you choose date-based partitioning, the log file key format appears as follows:

  ```
  [DestinationPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/
  [DD]/[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
  ```

  For example, if you specify `logs/` as the target prefix, your log objects are named like this:

  ```
  logs/123456789012/us-west-2/amzn-s3-demo-source-
  bucket/2023/03/01/2023-03-01-21-32-16-E568B2907131C0C0
  ```

  For delivery time delivery, the time in the log file names corresponds to the delivery time for the log files.

  For event time delivery, the year, month, and day correspond to the day on which the event occurred, and the hour, minutes and seconds are set to `00` in the key. The logs delivered in these log files are for a specific day only.

If you're configuring your logs through the AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API, use `TargetObjectKeyFormat` to specify the log object key format. To specify non-date-based partitioning, use `SimplePrefix`. To specify data-based partitioning, use `PartitionedPrefix`. If you use `PartitionedPrefix`, use `PartitionDateSource` to specify either `EventTime` or `DeliveryTime`.

For `SimplePrefix`, the log file key format appears as follows:

```
[TargetPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

For `PartitionedPrefix` with event time or delivery time, the log file key format appears as follows:

```
[TargetPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/
[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

Log object key format

Amazon S3 uses the following object key formats for the log objects that it uploads in the destination bucket:

- **Non-date-based partitioning** – This is the original log object key format. If you choose this format, the log file key format appears as follows:

```
[DestinationPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

- **Date-based partitioning** – If you choose date-based partitioning, you can choose the event time or delivery time for the log file as the date source used in the log format. This format makes it easier to query the logs.

  If you choose date-based partitioning, the log file key format appears as follows:

```
[DestinationPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/
[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]
```

In the log object key, YYYY, MM, DD, hh, mm, and ss are the digits of the year, month, day, hour, minute, and seconds (respectively). These dates and times are in Coordinated Universal Time (UTC).

A log file delivered at a specific time can contain records written at any point before that time. There is no way to know whether all log records for a certain time interval have been delivered or not.

The UniqueString component of the key is there to prevent overwriting of files. It has no meaning, and log processing software should ignore it.

How are logs delivered?

Amazon S3 periodically collects access log records, consolidates the records in log files, and then uploads log files to your destination bucket as log objects. If you enable logging on multiple source buckets that identify the same destination bucket, the destination bucket will have access logs for all those source buckets. However, each log object reports access log records for a specific source bucket.

Amazon S3 uses a special log delivery account to write server access logs. These writes are subject to the usual access control restrictions. We recommend that you update the bucket policy on the

destination bucket to grant access to the logging service principal (`logging.s3.amazonaws.com`) for access log delivery. You can also grant access for access log delivery to the S3 log delivery group through your bucket access control list (ACL). However, granting access to the S3 log delivery group by using your bucket ACL is not recommended.

When you enable server access logging and grant access for access log delivery through your destination bucket policy, you must update the policy to allow `s3:PutObject` access for the logging service principal. If you use the Amazon S3 console to enable server access logging, the console automatically updates the destination bucket policy to grant these permissions to the logging service principal. For more information about granting permissions for server access log delivery, see Permissions for log delivery.

> **Note**
>
> S3 does not support delivery of CloudTrail logs or server access logs to the requester or the bucket owner for VPC endpoint requests when the VPC endpoint policy denies them or for requests that fail before the VPC policy is evaluated.

Bucket owner enforced setting for S3 Object Ownership

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, ACLs are disabled and no longer affect permissions. You must update the bucket policy on the destination bucket to grant access to the logging service principal. For more information about Object Ownership, see Grant access to the S3 log delivery group for server access logging.

Best-effort server log delivery

Server access log records are delivered on a best-effort basis. Most requests for a bucket that is properly configured for logging result in a delivered log record. Most log records are delivered within a few hours of the time that they are recorded, but they can be delivered more frequently.

The completeness and timeliness of server logging is not guaranteed. The log record for a particular request might be delivered long after the request was actually processed, or *it might not be delivered at all*. It is possible that you might even see a duplication of a log record. The purpose of server logs is to give you an idea of the nature of traffic against your bucket. Although log records are rarely lost or duplicated, be aware that server logging is not meant to be a complete accounting of all requests.

Because of the best-effort nature of server logging, your usage reports might include one or more access requests that do not appear in a delivered server log. You can find these usage reports under **Cost & usage reports** in the AWS Billing and Cost Management console.

Bucket logging status changes take effect over time

Changes to the logging status of a bucket take time to actually affect the delivery of log files. For example, if you enable logging for a bucket, some requests made in the following hour might be logged, and others might not. Suppose that you change the destination bucket for logging from bucket A to bucket B. For the next hour, some logs might continue to be delivered to bucket A, whereas others might be delivered to the new destination bucket B. In all cases, the new settings eventually take effect without any further action on your part.

For more information about logging and log files, see the following sections:

Topics

- Enabling Amazon S3 server access logging
- Amazon S3 server access log format
- Deleting Amazon S3 log files
- Using Amazon S3 server access logs to identify requests
- Troubleshoot server access logging

Enabling Amazon S3 server access logging

Server access logging provides detailed records for the requests that are made to an Amazon S3 bucket. Server access logs are useful for many applications. For example, access log information can be useful in security and access audits. This information can also help you learn about your customer base and understand your Amazon S3 bill.

By default, Amazon S3 doesn't collect server access logs. When you enable logging, Amazon S3 delivers access logs for a source bucket to a destination bucket (also known as a *target bucket*) that you choose. The destination bucket must be in the same AWS Region and AWS account as the source bucket.

An access log record contains details about the requests that are made to a bucket. This information can include the request type, the resources that are specified in the request, and the time and date that the request was processed. For more information about logging basics, see Logging requests with server access logging.

Important

- There is no extra charge for enabling server access logging on an Amazon S3 bucket. However, any log files that the system delivers to you will accrue the usual charges for storage. (You can delete the log files at any time.) We do not assess data-transfer charges for log file delivery, but we do charge the normal data-transfer rate for accessing the log files.
- Your destination bucket should not have server access logging enabled. You can have logs delivered to any bucket that you own that is in the same Region as the source bucket, including the source bucket itself. However, delivering logs to the source bucket will cause an infinite loop of logs and is not recommended. For simpler log management, we recommend that you save access logs in a different bucket. For more information, see How do I enable log delivery?
- S3 buckets that have S3 Object Lock enabled can't be used as destination buckets for server access logs. Your destination bucket must not have a default retention period configuration.
- The destination bucket must not have Requester Pays enabled.
- You can use default bucket encryption on the destination bucket *only* if you use server-side encryption with Amazon S3 managed keys (SSE-S3), which uses the 256-bit Advanced Encryption Standard (AES-256). Default server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) is not supported.

You can enable or disable server access logging by using the Amazon S3 console, Amazon S3 API, the AWS Command Line Interface (AWS CLI), or AWS SDKs.

Permissions for log delivery

Amazon S3 uses a special log delivery account to write server access logs. These writes are subject to the usual access control restrictions. For access log delivery, you must grant the logging service principal (`logging.s3.amazonaws.com`) access to your destination bucket.

To grant permissions to Amazon S3 for log delivery, you can use either a bucket policy or bucket access control lists (ACLs), depending on your destination bucket's S3 Object Ownership settings. However, we recommend that you use a bucket policy instead of ACLs.

Bucket owner enforced setting for S3 Object Ownership

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, ACLs are disabled and no longer affect permissions. In this case, you must update the bucket policy for the destination bucket to grant access to the logging service principal. You can't update your bucket ACL to grant access to the S3 log delivery group. You also can't include destination grants (also known as *target grants*) in your PutBucketLogging configuration.

For information about migrating existing bucket ACLs for access log delivery to a bucket policy, see Grant access to the S3 log delivery group for server access logging. For more information about Object Ownership, see Controlling ownership of objects and disabling ACLs for your bucket. When you create new buckets, ACLs are disabled by default.

Granting access by using a bucket policy

To grant access by using the bucket policy on the destination bucket, update the bucket policy to grant the `s3:PutObject` permission to the logging service principal. If you use the Amazon S3 console to enable server access logging, the console automatically updates the bucket policy on the destination bucket to grant this permission to the logging service principal. If you enable server access logging programmatically, you must manually update the bucket policy for the destination bucket to grant access to the logging service principal.

For an example bucket policy that grants access to the logging service principal, see the section called "Grant permissions to the logging service principal by using a bucket policy".

Granting access by using bucket ACLs

You can alternately use bucket ACLs to grant access for access log delivery. You add a grant entry to the bucket ACL that grants `WRITE` and `READ_ACP` permissions to the S3 log delivery group. However, granting access to the S3 log delivery group by using bucket ACLs is not recommended. For more information, see Controlling ownership of objects and disabling ACLs for your bucket. For information about migrating existing bucket ACLs for access log delivery to a bucket policy, see Grant access to the S3 log delivery group for server access logging. For an example ACL that grants access to the logging service principal, see the section called "Grant permissions to the log delivery group by using a bucket ACL".

Grant permissions to the logging service principal by using a bucket policy

This example bucket policy grants the `s3:PutObject` permission to the logging service principal (`logging.s3.amazonaws.com`). To use this bucket policy, replace the *`user input placeholders`* with your own information. In the following policy, *`amzn-s3-demo-`*

destination-bucket is the destination bucket where server access logs will be delivered, and *amzn-s3-demo-source-bucket* is the source bucket. *EXAMPLE-LOGGING-PREFIX* is the optional destination prefix (also known as a *target prefix*) that you want to use for your log objects. *SOURCE-ACCOUNT-ID* is the AWS account that owns the source bucket.

> **Note**
>
> If there are Deny statements in your bucket policy, make sure that they don't prevent Amazon S3 from delivering access logs.

        }
    ]
}
```

Grant permissions to the log delivery group by using a bucket ACL

> **Note**
>
> As a security best practice, Amazon S3 disables access control lists (ACLs) by default in all new buckets. For more information about ACL permissions in the Amazon S3 console, see Configuring ACLs.

Although we do not recommend this approach, you can grant permissions to the log delivery group by using a bucket ACL. However, if the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination grants (also known as *target grants*) in your PutBucketLogging configuration. Instead, you must use a bucket policy to grant access to the logging service principal (`logging.s3.amazonaws.com`). For more information, see Permissions for log delivery.

In the bucket ACL, the log delivery group is represented by the following URL:

```
http://acs.amazonaws.com/groups/s3/LogDelivery
```

To grant `WRITE` and `READ_ACP` (ACL read) permissions, add the following grants to the destination bucket ACL:

```
<Grant>
    <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"  xsi:type="Group">
        <URI>http://acs.amazonaws.com/groups/s3/LogDelivery</URI>
    </Grantee>
    <Permission>WRITE</Permission>
</Grant>
<Grant>
    <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"  xsi:type="Group">
        <URI>http://acs.amazonaws.com/groups/s3/LogDelivery</URI>
    </Grantee>
    <Permission>READ_ACP</Permission>
</Grant>
```

For examples of adding ACL grants programmatically, see Configuring ACLs.

Important

When you enable Amazon S3 server access logging by using AWS CloudFormation on a bucket and you're using ACLs to grant access to the S3 log delivery group, you must also add `"AccessControl": "LogDeliveryWrite"` to your CloudFormation template. Doing so is important because you can grant those permissions only by creating an ACL for the bucket, but you can't create custom ACLs for buckets in CloudFormation. You can use only canned ACLs with CloudFormation.

To enable server access logging

To enable server access logging by using the Amazon S3 console, Amazon S3 REST API, AWS SDKs, and AWS CLI, use the following procedures.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable server access logging for.
4. Choose **Properties**.
5. In the **Server access logging** section, choose **Edit**.
6. Under **Server access logging**, choose **Enable**.
7. Under **Destination bucket**, specify a bucket and an optional prefix. If you specify a prefix, we recommend including a forward slash (/) after the prefix to make it easier to find your logs.

Note

Specifying a prefix with a slash (/) makes it simpler for you to locate the log objects. For example, if you specify the prefix value `logs/`, each log object that Amazon S3 creates begins with the `logs/` prefix in its key, as follows:

```
logs/2013-11-01-21-32-16-E568B2907131C0C0
```

If you specify the prefix value `logs`, the log object appears as follows:

```
logs2013-11-01-21-32-16-E568B2907131C0C0
```

8. Under **Log object key format**, do one of the following:

   - To choose non-date-based partitioning, choose **[DestinationPrefix][YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]**.
   - To choose date-based partitioning, choose **[DestinationPrefix][SourceAccountId]/[SourceRegion]/[SourceBucket]/[YYYY]/[MM]/[DD]/[YYYY]-[MM]-[DD]-[hh]-[mm]-[ss]-[UniqueString]**, then choose **S3 event time** or **Log file delivery time**.

9. Choose **Save changes**.

   When you enable server access logging on a bucket, the console both enables logging on the source bucket and updates the bucket policy for the destination bucket to grant the `s3:PutObject` permission to the logging service principal (`logging.s3.amazonaws.com`). For more information about this bucket policy, see Grant permissions to the logging service principal by using a bucket policy.

   You can view the logs in the destination bucket. After you enable server access logging, it might take a few hours before the logs are delivered to the target bucket. For more information about how and when logs are delivered, see How are logs delivered?

For more information, see Viewing the properties for an S3 general purpose bucket.

Using the REST API

To enable logging, you submit a PutBucketLogging request to add the logging configuration on the source bucket. The request specifies the destination bucket (also known as a *target bucket*) and, optionally, the prefix to be used with all log object keys.

The following example identifies *amzn-s3-demo-destination-bucket* as the destination bucket and *logs/* as the prefix.

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">
  <LoggingEnabled>
    <TargetBucket>amzn-s3-demo-destination-bucket</TargetBucket>
    <TargetPrefix>logs/</TargetPrefix>
  </LoggingEnabled>
</BucketLoggingStatus>
```

The following example identifies *amzn-s3-demo-destination-bucket* as the destination bucket, *logs/* as the prefix, and `EventTime` as the log object key format.

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">
  <LoggingEnabled>
    <TargetBucket>amzn-s3-demo-destination-bucket</TargetBucket>
    <TargetPrefix>logs/</TargetPrefix>
    <TargetObjectKeyFormat>
      <PartitionedPrefix>
         <PartitionDateSource>EventTime</PartitionDateSource>
      </PartitionedPrefix>
  </TargetObjectKeyFormat>
  </LoggingEnabled>
</BucketLoggingStatus>
```

The log objects are written and owned by the S3 log delivery account, and the bucket owner is granted full permissions on the log objects. You can optionally use destination grants (also known as *target grants*) to grant permissions to other users so that they can access the logs. For more information, see PutBucketLogging.

> **Note**
>
> If the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't use destination grants to grant permissions to other users. To grant permissions to others, you can update the bucket policy on the destination bucket. For more information, see Permissions for log delivery.

To retrieve the logging configuration on a bucket, use the GetBucketLogging API operation.

To delete the logging configuration, you send a `PutBucketLogging` request with an empty `BucketLoggingStatus`:

```
<BucketLoggingStatus xmlns="http://doc.s3.amazonaws.com/2006-03-01">
</BucketLoggingStatus>
```

To enable logging on a bucket, you can use either the Amazon S3 API or the AWS SDK wrapper libraries.

Using the AWS SDKs

The following examples enable logging on a bucket. You must create two buckets, a source bucket and a destination (target) bucket. The examples update the bucket ACL on the destination bucket first. They then grant the log delivery group the necessary permissions to write logs to the destination bucket, and then they enable logging on the source bucket.

These examples won't work on destination buckets that use the Bucket owner enforced setting for Object Ownership.

If the destination (target) bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination (target) grants in your PutBucketLogging configuration. You must use a bucket policy to grant access to the logging service principal (`logging.s3.amazonaws.com`). For more information, see Permissions for log delivery.

"\"\n" +
                "                }\n" +
                "            }\n" +
                "        }\n" +
                "    ]\n" +
                "}";
        s3Client.putBucketPolicy(b -> b.bucket(targetBucketName).policy(policy));
    }

    // Function to enable server access logging on the source S3 bucket.
    public void enableServerAccessLogging(String sourceBucketName, String
targetBucketName,
            String targetPrefix) {
        TargetObjectKeyFormat targetObjectKeyFormat =
TargetObjectKeyFormat.builder()

.partitionedPrefix(PartitionedPrefix.builder().partitionDateSource("EventTime").build())
                .build();
        LoggingEnabled loggingEnabled = LoggingEnabled.builder()
                .targetBucket(targetBucketName)
                .targetPrefix(targetPrefix)
                .targetObjectKeyFormat(targetObjectKeyFormat)
                .build();
        BucketLoggingStatus bucketLoggingStatus = BucketLoggingStatus.builder()
                .loggingEnabled(loggingEnabled)
                .build();
        s3Client.putBucketLogging(PutBucketLoggingRequest.builder()
                .bucket(sourceBucketName)
                .bucketLoggingStatus(bucketLoggingStatus)
                .build());
    }

}
```

Using the AWS CLI

We recommend that you create a dedicated logging bucket in each AWS Region that you have S3 buckets in. Then have your Amazon S3 access logs delivered to that S3 bucket. For more information and examples, see put-bucket-logging in the *AWS CLI Reference*.

If the destination (target) bucket uses the Bucket owner enforced setting for Object Ownership, you can't set bucket or object ACLs. You also can't include destination (target) grants in your PutBucketLogging configuration. You must use a bucket policy to grant access to the logging service principal (`logging.s3.amazonaws.com`). For more information, see Permissions for log delivery.

Example — Enable access logs with five buckets across two Regions

In this example, you have the following five buckets:

- *amzn-s3-demo-source-bucket*-us-east-1
- *amzn-s3-demo-source-bucket1*-us-east-1
- *amzn-s3-demo-source-bucket2*-us-east-1
- *amzn-s3-demo-bucket1*-us-west-2
- *amzn-s3-demo-bucket2*-us-west-2

> **Note**
>
> The final step of the following procedure provides example bash scripts that you can use to create your logging buckets and enable server access logging on these buckets. To use those scripts, you must create the `policy.json` and `logging.json` files, as described in the following procedure.

1. Create two logging destination buckets in the US West (Oregon) and US East (N. Virginia) Regions and give them the following names:
   - *amzn-s3-demo-destination-bucket*-logs-us-east-1
   - *amzn-s3-demo-destination-bucket1*-logs-us-west-2
2. Later in these steps, you will enable server access logging as follows:
   - *amzn-s3-demo-source-bucket*-us-east-1 logs to the S3 bucket *amzn-s3-demo-destination-bucket*-logs-us-east-1 with the prefix *amzn-s3-demo-source-bucket*-us-east-1
   - *amzn-s3-demo-source-bucket1*-us-east-1 logs to the S3 bucket *amzn-s3-demo-destination-bucket*-logs-us-east-1 with the prefix *amzn-s3-demo-source-bucket1*-us-east-1

- *amzn-s3-demo-source-bucket2*-us-east-1 logs to the S3 bucket *amzn-s3-demo-destination-bucket*-logs-us-east-1 with the prefix *amzn-s3-demo-source-bucket2*-us-east-1
- *amzn-s3-demo-bucket1*-us-west-2 logs to the S3 bucket *amzn-s3-demo-destination-bucket1*-logs-us-west-2 with the prefix *amzn-s3-demo-bucket1*-us-west-2
- *amzn-s3-demo-bucket2*-us-west-2 logs to the S3 bucket *amzn-s3-demo-destination-bucket1*-logs-us-west-2 with the prefix *amzn-s3-demo-bucket2*-us-west-2

3. For each destination logging bucket, grant permissions for server access log delivery by using a bucket ACL *or* a bucket policy:

   - **Update the bucket policy** (Recommended) – To grant permissions to the logging service principal, use the following `put-bucket-policy` command. Replace *amzn-s3-demo-destination-bucket*-logs with the name of your destination bucket.

     ```
     aws s3api put-bucket-policy --bucket amzn-s3-demo-destination-bucket-logs --
     policy file://policy.json
     ```

     `Policy.json` is a JSON document in the current folder that contains the following bucket policy. To use this bucket policy, replace the *user input placeholders* with your own information. In the following policy, *amzn-s3-demo-destination-bucket-logs* is the destination bucket where server access logs will be delivered, and *amzn-s3-demo-source-bucket* is the source bucket. *SOURCE-ACCOUNT-ID* is the AWS account that owns the source bucket.

     JSON

     ```
     {
         "Version": "2012-10-17",
         "Statement": [
             {
                 "Sid": "S3ServerAccessLogsPolicy",
                 "Effect": "Allow",
                 "Principal": {
                     "Service": "logging.s3.amazonaws.com"
                 },
     ```

```
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-destination-bucket-logs/
*",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3:::amzn-s3-demo-source-
bucket"
                },
                "StringEquals": {
                    "aws:SourceAccount": "SOURCE-ACCOUNT-ID"
                }
            }
        }
    ]
}
```

- **Update the bucket ACL** – To grant permissions to the S3 log delivery group, use the following `put-bucket-acl` command. Replace *amzn-s3-demo-destination-bucket-logs* with the name of your destination (target) bucket.

```
aws s3api put-bucket-acl --bucket amzn-s3-demo-destination-bucket-logs  --
grant-write URI=http://acs.amazonaws.com/groups/s3/LogDelivery --grant-read-acp
 URI=http://acs.amazonaws.com/groups/s3/LogDelivery
```

4. Then, create a `logging.json` file that contains your logging configuration (based on one of the three examples that follow). After you create the `logging.json` file, you can apply the logging configuration by using the following `put-bucket-logging` command. Replace *amzn-s3-demo-destination-bucket-logs* with the name of your destination (target) bucket.

```
aws s3api put-bucket-logging --bucket amzn-s3-demo-destination-bucket-logs --
bucket-logging-status file://logging.json
```

> **Note**
>
> Instead of using this `put-bucket-logging` command to apply the logging configuration on each destination bucket, you can use one of the bash scripts provided in the next step. To use those scripts, you must create the `policy.json` and `logging.json` files, as described in this procedure.

The `logging.json` file is a JSON document in the current folder that contains your logging configuration. If a destination bucket uses the Bucket owner enforced setting for Object Ownership, your logging configuration can't contain destination (target) grants. For more information, see Permissions for log delivery.

Example – `logging.json` without destination (target) grants

The following example `logging.json` file doesn't contain destination (target) grants. Therefore, you can apply this configuration to a destination (target) bucket that uses the Bucket owner enforced setting for Object Ownership.

```
{
    "LoggingEnabled": {
        "TargetBucket": "amzn-s3-demo-destination-bucket-logs",
        "TargetPrefix": "amzn-s3-demo-destination-bucket/"
     }
 }
```

Example – `logging.json` with destination (target) grants

The following example `logging.json` file contains destination (target) grants.

If the destination bucket uses the Bucket owner enforced setting for Object Ownership, you can't include destination (target) grants in your PutBucketLogging configuration. For more information, see Permissions for log delivery.

```
{
    "LoggingEnabled": {
```

```
        "TargetBucket": "amzn-s3-demo-destination-bucket-logs",
        "TargetPrefix": "amzn-s3-demo-destination-bucket/",
        "TargetGrants": [
             {
                "Grantee": {
                    "Type": "AmazonCustomerByEmail",
                    "EmailAddress": "user@example.com"
                 },
                "Permission": "FULL_CONTROL"
             }
         ]
     }
 }
```

Grantee values

You can specify the person (grantee) to whom you're assigning access rights (by using request elements) in the following ways:

- By the person's ID:

```
{
  "Grantee": {
    "Type": "CanonicalUser",
    "ID": "ID",
    "DisplayName": "GranteesEmail"
  }
}
```

  `DisplayName` is optional and is ignored in the request.

- By email address:

```
{
  "Grantee": {
    "Type": "AmazonCustomerByEmail",
    "EmailAddress": "username@example.com"
  }
}
```

The grantee is resolved to the `CanonicalUser` and, in a response to a `GetObjectAcl` request, appears as the `CanonicalUser`.

> **Note**
>
> Using email addresses to specify a grantee is supported only in some AWS Regions. For more information, see Grantee in the *Amazon S3 API Reference*.

- By URI:

```
{
  "Grantee": {
    "Type": "Group",
    "URI": "http://acs.amazonaws.com/groups/global/AuthenticatedUsers"
  }
}
```

Example – `logging.json` with the log object key format set to S3 event time

The following `logging.json` file changes the log object key format to S3 event time. For more information about setting the log object key format, see the section called "How do I enable log delivery?"

```
  {
    "LoggingEnabled": {
        "TargetBucket": "amzn-s3-demo-destination-bucket-logs",
        "TargetPrefix": "amzn-s3-demo-destination-bucket/",
        "TargetObjectKeyFormat": {
            "PartitionedPrefix": {
                "PartitionDateSource": "EventTime"
            }
         }
    }
}
```

5. Use one of the following bash scripts to add access logging for all the buckets in your account. Replace *amzn-s3-demo-destination-bucket-logs* with the name of your destination

(target) bucket, and replace *us-west-2* with the name of the Region that your buckets are located in.

> **Note**
>
> This script works only if all of your buckets are in the same Region. If you have buckets in multiple Regions, you must adjust the script.

Example – Grant access with bucket policies and add logging for the buckets in your account

```
loggingBucket='amzn-s3-demo-destination-bucket-logs'
region='us-west-2'

# Create the logging bucket.
aws s3 mb s3://$loggingBucket --region $region

aws s3api put-bucket-policy --bucket $loggingBucket --policy file://policy.json

# List the buckets in this account.
buckets="$(aws s3 ls | awk '{print $3}')"

# Put a bucket logging configuration on each bucket.
for bucket in $buckets
    do
      # This if statement excludes the logging bucket.
      if [ "$bucket" == "$loggingBucket" ] ; then
          continue;
      fi
      printf '{
        "LoggingEnabled": {
          "TargetBucket": "%s",
          "TargetPrefix": "%s/"
      }
    }' "$loggingBucket" "$bucket"  > logging.json
    aws s3api put-bucket-logging --bucket $bucket --bucket-logging-status file://
logging.json
    echo "$bucket done"
done
```

```
  rm logging.json

  echo "Complete"
```

Example – Grant access with bucket ACLs and add logging for the buckets in your account

```
  loggingBucket='amzn-s3-demo-destination-bucket-logs'
  region='us-west-2'

  # Create the logging bucket.
  aws s3 mb s3://$loggingBucket --region $region

  aws s3api put-bucket-acl --bucket $loggingBucket --grant-write URI=http://
acs.amazonaws.com/groups/s3/LogDelivery --grant-read-acp URI=http://
acs.amazonaws.com/groups/s3/LogDelivery

  # List the buckets in this account.
  buckets="$(aws s3 ls | awk '{print $3}')"

  # Put a bucket logging configuration on each bucket.
  for bucket in $buckets
      do
        # This if statement excludes the logging bucket.
        if [ "$bucket" == "$loggingBucket" ] ; then
            continue;
        fi
        printf '{
          "LoggingEnabled": {
            "TargetBucket": "%s",
            "TargetPrefix": "%s/"
        }
      }' "$loggingBucket" "$bucket"  > logging.json
      aws s3api put-bucket-logging --bucket $bucket --bucket-logging-status file://
logging.json
      echo "$bucket done"
  done

  rm logging.json

  echo "Complete"
```

Verifying your server access logs setup

After you enable server access logging, complete the following steps:

- Access the destination bucket and verify that the log files are being delivered. After the access logs are set up, Amazon S3 immediately starts capturing requests and logging them. However, it might take a few hours before the logs are delivered to the destination bucket. For more information, see the section called "Bucket logging status changes take effect over time" and the section called "Best-effort server log delivery".

  You can also automatically verify log delivery by using Amazon S3 request metrics and setting up Amazon CloudWatch alarms for these metrics. For more information, see Monitoring metrics with Amazon CloudWatch.
- Verify that you are able to open and read the contents of the log files.

For server access logging troubleshooting information, see Troubleshoot server access logging.

Amazon S3 server access log format

Server access logging provides detailed records for the requests that are made to an Amazon S3 bucket. You can use server access logs for the following purposes:

- Performing security and access audits
- Learning about your customer base
- Understanding your Amazon S3 bill

This section describes the format and other details about Amazon S3 server access log files.

Server access log files consist of a sequence of newline-delimited log records. Each log record represents one request and consists of space-delimited fields.

The following is an example log consisting of five log records.

> **Note**
>
> Any field can be set to `-` to indicate that the data was unknown or unavailable, or that the field was not applicable to this request.

```

Topics

- Log record fields
- Additional logging for copy operations
- Custom access log information
- Programming considerations for extensible server access log format

Log record fields

The following list describes the log record fields.

Bucket Owner

The canonical user ID of the owner of the source bucket. The canonical user ID is another form of the AWS account ID. For more information about the canonical user ID, see AWS account identifiers in the *AWS General Reference*. For information about how to find the canonical user ID for your account, see Finding the canonical user ID for your AWS account.

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

Bucket

The name of the bucket that the request was processed against. If the system receives a malformed request and cannot determine the bucket, the request will not appear in any server access log.

Example entry

```
amzn-s3-demo-bucket1
```

Time

The time at which the request was received; these dates and times are in Coordinated Universal Time (UTC). The format, using `strftime()` terminology, is as follows: `[%d/%b/%Y:%H:%M:%S %z]`

Example entry

```
[06/Feb/2019:00:00:38 +0000]
```

Remote IP

The apparent IP address of the requester. Intermediate proxies and firewalls might obscure the actual IP address of the machine that's making the request.

Example entry

```
192.0.2.3
```

Requester

The canonical user ID of the requester, or a - for unauthenticated requests. If the requester was an IAM user, this field returns the requester's IAM user name along with the AWS account that the IAM user belongs to. This identifier is the same one used for access control purposes.

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

If the requester is using an assumed role, this field returns the assumed IAM role.

Example entry

```
arn:aws:sts::123456789012:assumed-role/roleName/test-role
```

Request ID

A string generated by Amazon S3 to uniquely identify each request. For **Compute checksum** job requests, the **Request ID** field displays the associated job ID. For more information, see Compute checksums.

Example entry

```
3E57427F33A59F07
```

Operation

The operation listed here is declared as `SOAP.operation`, `REST.HTTP_method.resource_type`, `WEBSITE.HTTP_method.resource_type`, or `BATCH.DELETE.OBJECT`, or `S3.action.resource_type` for S3 Lifecycle and logging. For Compute checksum job requests, the operation is listed as `S3.COMPUTE.OBJECT.CHECKSUM`.

Example entry

```
REST.PUT.OBJECT
S3.COMPUTE.OBJECT.CHECKSUM
```

Key

The key (object name) part of the request.

Example entry

```
/photos/2019/08/puppy.jpg
```

Request-URI

The `Request-URI` part of the HTTP request message.

Example Entry

```
"GET /amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg?x-foo=bar HTTP/1.1"
```

HTTP status

The numeric HTTP status code of the response.

Example entry

```
200
```

Error Code

The Amazon S3 Error responses , or `-` if no error occurred.

Example entry

```
NoSuchBucket
```

Bytes Sent

The number of response bytes sent, excluding HTTP protocol overhead, or - if zero.

Example entry

```
2662992
```

Object Size

The total size of the object in question.

Example entry

```
3462992
```

Total Time

The number of milliseconds that the request was in flight from the server's perspective. This value is measured from the time that your request is received to the time that the last byte of the response is sent. Measurements made from the client's perspective might be longer because of network latency.

Example entry

```
70
```

Turn-Around Time

The number of milliseconds that Amazon S3 spent processing your request. This value is measured from the time that the last byte of your request was received until the time that the first byte of the response was sent.

Example entry

```
10
```

Referer

The value of the HTTP `Referer` header, if present. HTTP user-agents (for example, browsers) typically set this header to the URL of the linking or embedding page when making a request.

Example entry

```
"http://www.example.com/webservices"
```

User-Agent

The value of the HTTP `User-Agent` header.

Example entry

```
"curl/7.15.1"
```

Version Id

The version ID in the request, or `-` if the operation doesn't take a `versionId` parameter.

Example entry

```
3HL4kqtJvjVBH40Nrjfkd
```

Host Id

The `x-amz-id-2` or Amazon S3 extended request ID.

Example entry

```
s9lzHYrFp76ZVxRcpX9+5cjAnEH2ROuNkd2BHfIa6UkFVdtjf5mKR3/eTPFvsiP/XV/VLi31234=
```

Signature Version

The signature version, `SigV2` or `SigV4`, that was used to authenticate the request or a `-` for unauthenticated requests.

Example entry

```
SigV2
```

Cipher Suite

The Transport Layer Security (TLS) cipher that was negotiated for an HTTPS request or a `-` for HTTP.

Example entry

```
ECDHE-RSA-AES128-GCM-SHA256
```

Authentication Type

The type of request authentication used: `AuthHeader` for authentication headers, `QueryString` for query string (presigned URL), or a `-` for unauthenticated requests.

Example entry

```
AuthHeader
```

Host Header

The endpoint used to connect to Amazon S3.

Example entry

```
s3.us-west-2.amazonaws.com
```

Some earlier Regions support legacy endpoints. You might see these endpoints in your server access logs or AWS CloudTrail logs. For more information, see Legacy endpoints. For a complete list of Amazon S3 Regions and endpoints, see Amazon S3 endpoints and quotas in the *Amazon Web Services General Reference*.

TLS version

The Transport Layer Security (TLS) version negotiated by the client. The value is one of following: `TLSv1.1`, `TLSv1.2`, `TLSv1.3`, or `-` if TLS wasn't used.

Example entry

```
TLSv1.2
```

Access Point ARN

The Amazon Resource Name (ARN) of the access point of the request. If the access point ARN is malformed or not used, the field will contain a `-`. For more information about access points, see Using Amazon S3 access points for general purpose buckets. For more information about ARNs, see Amazon Resource Name (ARN) in the *AWS Reference Guide*.

Example entry

```
arn:aws:s3:us-east-1:123456789012:accesspoint/example-AP
```

aclRequired

A string that indicates whether the request required an access control list (ACL) for authorization. If the request required an ACL for authorization, the string is `Yes`. If no ACLs were required, the string is `-`. For more information about ACLs, see Access control list (ACL) overview. For more information about using the `aclRequired` field to disable ACLs, see Controlling ownership of objects and disabling ACLs for your bucket.

Example entry

```
Yes
```

Additional logging for copy operations

A copy operation involves a `GET` and a `PUT`. For that reason, we log two records when performing a copy operation. The previous section describes the fields related to the `PUT` part of the operation. The following list describes the fields in the record that relate to the `GET` part of the copy operation.

Bucket Owner

The canonical user ID of the bucket that stores the object being copied. The canonical user ID is another form of the AWS account ID. For more information about the canonical user ID, see AWS account identifiers in the *AWS General Reference*. For information about how to find the canonical user ID for your account, see Finding the canonical user ID for your AWS account.

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

Bucket

The name of the bucket that stores the object that's being copied.

Example entry

```
amzn-s3-demo-bucket1
```

Time

The time at which the request was received; these dates and times are in Coordinated Universal Time (UTC). The format, using `strftime()` terminology, is as follows: `[%d/%B/%Y:%H:%M:%S %z]`

Example entry

```
[06/Feb/2019:00:00:38 +0000]
```

Remote IP

The apparent IP address of the requester. Intermediate proxies and firewalls might obscure the actual IP address of the machine that's making the request.

Example entry

```
192.0.2.3
```

Requester

The canonical user ID of the requester, or a `-` for unauthenticated requests. If the requester was an IAM user, this field will return the requester's IAM user name along with the AWS account root user that the IAM user belongs to. This identifier is the same one used for access control purposes.

Example entry

```
79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be
```

If the requester is using an assumed role, this field returns the assumed IAM role.

Example entry

```
arn:aws:sts::123456789012:assumed-role/roleName/test-role
```

Request ID

A string generated by Amazon S3 to uniquely identify each request. For **Compute checksum** job requests, the **Request ID** field displays the associated job ID. For more information, see Compute checksums.

Example entry

```
3E57427F33A59F07
```

Operation

The operation listed here is declared as `SOAP.operation`, `REST.HTTP_method.resource_type`, `WEBSITE.HTTP_method.resource_type`, or `BATCH.DELETE.OBJECT`.

Example entry

```
REST.COPY.OBJECT_GET
```

Key

The key (object name) of the object being copied, or `-` if the operation doesn't take a key parameter.

Example entry

```
/photos/2019/08/puppy.jpg
```

Request-URI

The `Request-URI` part of the HTTP request message.

Example entry

```
"GET /amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg?x-foo=bar"
```

HTTP status

The numeric HTTP status code of the GET portion of the copy operation.

Example entry

```
200
```

Error Code

The Amazon S3 Error responses of the GET portion of the copy operation, or - if no error occurred.

Example entry

```
NoSuchBucket
```

Bytes Sent

The number of response bytes sent, excluding the HTTP protocol overhead, or - if zero.

Example entry

```
2662992
```

Object Size

The total size of the object in question.

Example entry

```
3462992
```

Total Time

The number of milliseconds that the request was in flight from the server's perspective. This value is measured from the time that your request is received to the time that the last byte of the response is sent. Measurements made from the client's perspective might be longer because of network latency.

Example entry

```
70
```

Turn-Around Time

The number of milliseconds that Amazon S3 spent processing your request. This value is measured from the time that the last byte of your request was received until the time that the first byte of the response was sent.

Example entry

```
10
```

Referer

The value of the HTTP `Referer` header, if present. HTTP user-agents (for example, browsers) typically set this header to the URL of the linking or embedding page when making a request.

Example entry

```
"http://www.example.com/webservices"
```

User-Agent

The value of the HTTP `User-Agent` header.

Example entry

```
"curl/7.15.1"
```

Version Id

The version ID of the object being copied, or `-` if the `x-amz-copy-source` header didn't specify a `versionId` parameter as part of the copy source.

Example Entry

```
3HL4kqtJvjVBH40Nrjfkd
```

Host Id

The `x-amz-id-2` or Amazon S3 extended request ID.

Example entry

```
s9lzHYrFp76ZVxRcpX9+5cjAnEH2ROuNkd2BHfIa6UkFVdtjf5mKR3/eTPFvsiP/XV/VLi31234=
```

Signature Version

The signature version, `SigV2` or `SigV4`, that was used to authenticate the request, or a `-` for unauthenticated requests.

Example entry

```
SigV4
```

Cipher Suite

The Transport Layer Security (TLS) cipher that was negotiated for an HTTPS request, or a `-` for HTTP.

Example entry

```
ECDHE-RSA-AES128-GCM-SHA256
```

Authentication Type

The type of request authentication used: `AuthHeader` for authentication headers, `QueryString` for query strings (presigned URLs), or a `-` for unauthenticated requests.

Example entry

```
AuthHeader
```

Host Header

The endpoint that was used to connect to Amazon S3.

Example entry

```
s3.us-west-2.amazonaws.com
```

Some earlier Regions support legacy endpoints. You might see these endpoints in your server access logs or AWS CloudTrail logs. For more information, see Legacy endpoints. For a complete

list of Amazon S3 Regions and endpoints, see Amazon S3 endpoints and quotas in the *Amazon Web Services General Reference*.

TLS version

The Transport Layer Security (TLS) version negotiated by the client. The value is one of following: `TLSv1.1`, `TLSv1.2`, `TLSv1.3`, or `-` if TLS wasn't used.

Example entry

```
TLSv1.2
```

Access Point ARN

The Amazon Resource Name (ARN) of the access point of the request. If the access point ARN is malformed or not used, the field will contain a `-`. For more information about access points, see Using Amazon S3 access points for general purpose buckets. For more information about ARNs, see Amazon Resource Name (ARN) in the *AWS Reference Guide*.

Example entry

```
arn:aws:s3:us-east-1:123456789012:accesspoint/example-AP
```

aclRequired

A string that indicates whether the request required an access control list (ACL) for authorization. If the request required an ACL for authorization, the string is `Yes`. If no ACLs were required, the string is `-`. For more information about ACLs, see Access control list (ACL) overview. For more information about using the `aclRequired` field to disable ACLs, see Controlling ownership of objects and disabling ACLs for your bucket.

Example entry

```
Yes
```

Custom access log information

You can include custom information to be stored in the access log record for a request. To do this, add a custom query-string parameter to the URL for the request. Amazon S3 ignores query-string

parameters that begin with `x-`, but includes those parameters in the access log record for the request, as part of the `Request-URI` field of the log record.

For example, a `GET` request for `"s3.amazonaws.com/amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg?x-user=johndoe"` works the same as the request for `"s3.amazonaws.com/amzn-s3-demo-bucket1/photos/2019/08/puppy.jpg"`, except that the `"x-user=johndoe"` string is included in the `Request-URI` field for the associated log record. This functionality is available in the REST interface only.

Programming considerations for extensible server access log format

Occasionally, we might extend the access log record format by adding new fields to the end of each line. Therefore, make sure that any of your code that parses server access logs can handle trailing fields that it might not understand.

Deleting Amazon S3 log files

An Amazon S3 bucket with server access logging enabled can accumulate many server log objects over time. Your application might need these access logs for a specific period after they are created, and after that, you might want to delete them. You can use Amazon S3 Lifecycle configuration to set rules so that Amazon S3 automatically queues these objects for deletion at the end of their life.

You can define a lifecycle configuration for a subset of objects in your S3 bucket by using a shared prefix. If you specified a prefix in your server access logging configuration, you can set a lifecycle configuration rule to delete log objects that have that prefix.

For example, suppose that your log objects have the prefix `logs/`. You can set a lifecycle configuration rule to delete all objects in the bucket that have the prefix `logs/` after a specified period of time.

For more information about lifecycle configuration, see Managing the lifecycle of objects.

For general information about server access logging, see Logging requests with server access logging.

Using Amazon S3 server access logs to identify requests

You can identify Amazon S3 requests by using Amazon S3 server access logs.

Note

- To identify Amazon S3 requests, we recommend that you use AWS CloudTrail data events instead of Amazon S3 server access logs. CloudTrail data events are easier to set up and contain more information. For more information, see Identifying Amazon S3 requests using CloudTrail.
- Depending on how many access requests you get, analyzing your logs might require more resources or time than using CloudTrail data events.

Topics

- Querying access logs for requests by using Amazon Athena
- Identifying Signature Version 2 requests by using Amazon S3 access logs
- Identifying object access requests by using Amazon S3 access logs

Querying access logs for requests by using Amazon Athena

You can identify Amazon S3 requests with Amazon S3 access logs by using Amazon Athena.

Amazon S3 stores server access logs as objects in an S3 bucket. It is often easier to use a tool that can analyze the logs in Amazon S3. Athena supports analysis of S3 objects and can be used to query Amazon S3 access logs.

Example

The following example shows how you can query Amazon S3 server access logs in Amazon Athena. Replace the *`user input placeholders`* used in the following examples with your own information.

Note

To specify an Amazon S3 location in an Athena query, you must provide an S3 URI for the bucket where your logs are delivered to. This URI must include the bucket name and prefix in the following format: `s3://`*`amzn-s3-demo-bucket1-logs/prefix/`*

1. Open the Athena console at https://console.aws.amazon.com/athena/.

2. In the Query Editor, run a command similar to the following. Replace *s3_access_logs_db* with the name that you want to give to your database.

```
CREATE DATABASE s3_access_logs_db
```

> **Note**
>
> It's a best practice to create the database in the same AWS Region as your S3 bucket.

3. In the Query Editor, run a command similar to the following to create a table schema in the database that you created in step 2. Replace *s3_access_logs_db.mybucket_logs* with the name that you want to give to your table. The `STRING` and `BIGINT` data type values are the access log properties. You can query these properties in Athena. For `LOCATION`, enter the S3 bucket and prefix path as noted earlier.

   Date-based partitioning

```
CREATE EXTERNAL TABLE s3_access_logs_db.mybucket_logs(
 `bucketowner` STRING,
 `bucket_name` STRING,
 `requestdatetime` STRING,
 `remoteip` STRING,
 `requester` STRING,
 `requestid` STRING,
 `operation` STRING,
 `key` STRING,
 `request_uri` STRING,
 `httpstatus` STRING,
 `errorcode` STRING,
 `bytessent` BIGINT,
 `objectsize` BIGINT,
 `totaltime` STRING,
 `turnaroundtime` STRING,
 `referrer` STRING,
 `useragent` STRING,
 `versionid` STRING,
 `hostid` STRING,
 `sigv` STRING,
 `ciphersuite` STRING,
 `authtype` STRING,
 `endpoint` STRING,
```

```
 `tlsversion` STRING,
 `accesspointarn` STRING,
 `aclrequired` STRING)
 PARTITIONED BY (
   `timestamp` string)
ROW FORMAT SERDE
 'org.apache.hadoop.hive.serde2.RegexSerDe'
WITH SERDEPROPERTIES (
 'input.regex'='([^ ]*) ([^ ]*) \\[(.*?)\\] ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
 ([^ ]*) (\"[^\"]*\"|-) (-|[0-9]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
 ([^ ]*) (\"[^\"]*\"|-) ([^ ]*)(?: ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
 ([^ ]*) ([^ ]*) ([^ ]*))?.*$')
STORED AS INPUTFORMAT
 'org.apache.hadoop.mapred.TextInputFormat'
OUTPUTFORMAT
 'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'

  'projection.timestamp.type'='date',
  'storage.location.template'='s3://bucket-name/prefix-name/account-id/region/
source-bucket-name/${timestamp}')
```

Non-date-based partitioning

```
CREATE EXTERNAL TABLE `s3_access_logs_db.mybucket_logs`(
  `bucketowner` STRING,
  `bucket_name` STRING,
  `requestdatetime` STRING,
  `remoteip` STRING,
  `requester` STRING,
  `requestid` STRING,
  `operation` STRING,
  `key` STRING,
  `request_uri` STRING,
  `httpstatus` STRING,
  `errorcode` STRING,
  `bytessent` BIGINT,
```

```
  `objectsize` BIGINT,
  `totaltime` STRING,
  `turnaroundtime` STRING,
  `referrer` STRING,
  `useragent` STRING,
  `versionid` STRING,
  `hostid` STRING,
  `sigv` STRING,
  `ciphersuite` STRING,
  `authtype` STRING,
  `endpoint` STRING,
  `tlsversion` STRING,
  `accesspointarn` STRING,
  `aclrequired` STRING)
ROW FORMAT SERDE
  'org.apache.hadoop.hive.serde2.RegexSerDe'
WITH SERDEPROPERTIES (
  'input.regex'='([^ ]*) ([^ ]*) \\[(.*?)\\] ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
 ([^ ]*) (\"[^\"]*\"|-) (-|[0-9]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
 ([^ ]*) (\"[^\"]*\"|-) ([^ ]*)(?: ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*) ([^ ]*)
 ([^ ]*) ([^ ]*) ([^ ]*))?.*$')
STORED AS INPUTFORMAT
  'org.apache.hadoop.mapred.TextInputFormat'
OUTPUTFORMAT
  'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION
  's3://amzn-s3-demo-bucket1-logs/prefix/'
```

4. In the navigation pane, under **Database**, choose your database.
5. Under **Tables**, choose **Preview table** next to your table name.

   In the **Results** pane, you should see data from the server access logs, such as `bucketowner`, `bucket`, `requestdatetime`, and so on. This means that you successfully created the Athena table. You can now query the Amazon S3 server access logs.

Example — Show who deleted an object and when (timestamp, IP address, and IAM user)

```
SELECT requestdatetime, remoteip, requester, key
FROM s3_access_logs_db.mybucket_logs
WHERE key = 'images/picture.jpg' AND operation like '%DELETE%';
```

Example — Show all operations that were performed by an IAM user

```
SELECT *
FROM s3_access_logs_db.mybucket_logs
WHERE requester='arn:aws:iam::123456789123:user/user_name';
```

Example — Show all operations that were performed on an object in a specific time period

```
SELECT *
FROM s3_access_logs_db.mybucket_logs
WHERE Key='prefix/images/picture.jpg'
AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2017-02-18:07:00:00','yyyy-MM-dd:HH:mm:ss')
AND parse_datetime('2017-02-18:08:00:00','yyyy-MM-dd:HH:mm:ss');
```

Example — Show how much data was transferred to a specific IP address in a specific time period

```
SELECT coalesce(SUM(bytessent), 0) AS bytessenttotal
FROM s3_access_logs_db.mybucket_logs
WHERE remoteip='192.0.2.1'
AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2022-06-01','yyyy-MM-dd')
AND parse_datetime('2022-07-01','yyyy-MM-dd');
```

Example — Find request IDs for HTTP 5xx errors in a specific time period

```
SELECT requestdatetime, key, httpstatus, errorcode, requestid, hostid
FROM s3_access_logs_db.mybucket_logs
WHERE httpstatus like '5%' AND timestamp
BETWEEN '2024/01/29'
AND '2024/01/30'
```

Note

To reduce the time that you retain your logs, you can create an S3 Lifecycle configuration for your server access logs bucket. Create lifecycle configuration rules to remove log files periodically. Doing so reduces the amount of data that Athena analyzes for each query. For more information, see Setting an S3 Lifecycle configuration on a bucket.

Identifying Signature Version 2 requests by using Amazon S3 access logs

Amazon S3 support for Signature Version 2 will be turned off (deprecated). After that, Amazon S3 will no longer accept requests that use Signature Version 2, and all requests must use Signature Version 4 signing. You can identify Signature Version 2 access requests by using Amazon S3 access logs.

> **Note**
>
> To identify Signature Version 2 requests, we recommend that you use AWS CloudTrail data events instead of Amazon S3 server access logs. CloudTrail data events are easier to set up and contain more information than server access logs. For more information, see Identifying Amazon S3 Signature Version 2 requests by using CloudTrail.

Example — Show all requesters that are sending Signature Version 2 traffic

```
SELECT requester, sigv, Count(sigv) as sigcount
FROM s3_access_logs_db.mybucket_logs
GROUP BY requester, sigv;
```

Identifying object access requests by using Amazon S3 access logs

You can use queries on Amazon S3 server access logs to identify Amazon S3 object access requests, for operations such as GET, PUT, and DELETE, and discover further information about those requests.

The following Amazon Athena query example shows how to get all PUT object requests for Amazon S3 from a server access log.

Example — Show all requesters that are sending PUT object requests in a certain period

```
SELECT bucket_name, requester, remoteip, key, httpstatus, errorcode, requestdatetime
FROM s3_access_logs_db.mybucket_logs
WHERE operation='REST.PUT.OBJECT'
AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2019-07-01:00:42:42',yyyy-MM-dd:HH:mm:ss')
AND parse_datetime('2019-07-02:00:42:42','yyyy-MM-dd:HH:mm:ss')
```

The following Amazon Athena query example shows how to get all GET object requests for Amazon S3 from the server access log.

Example — Show all requesters that are sending GET object requests in a certain period

```
SELECT bucket_name, requester, remoteip, key, httpstatus, errorcode, requestdatetime
FROM s3_access_logs_db.mybucket_logs
WHERE operation='REST.GET.OBJECT'
AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2019-07-01:00:42:42','yyyy-MM-dd:HH:mm:ss')
AND parse_datetime('2019-07-02:00:42:42','yyyy-MM-dd:HH:mm:ss')
```

The following Amazon Athena query example shows how to get all anonymous requests to your S3 buckets from the server access log.

Example — Show all anonymous requesters that are making requests to a bucket during a certain period

```
SELECT bucket_name, requester, remoteip, key, httpstatus, errorcode, requestdatetime
FROM s3_access_logs_db.mybucket_logs
WHERE requester IS NULL
AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2019-07-01:00:42:42','yyyy-MM-dd:HH:mm:ss')
AND parse_datetime('2019-07-02:00:42:42','yyyy-MM-dd:HH:mm:ss')
```

The following Amazon Athena query shows how to identify all requests to your S3 buckets that required an access control list (ACL) for authorization. You can use this information to migrate those ACL permissions to the appropriate bucket policies and disable ACLs. After you've created these bucket policies, you can disable ACLs for these buckets. For more information about disabling ACLs, see Prerequisites for disabling ACLs.

Example — Identify all requests that required an ACL for authorization

```
SELECT bucket_name, requester, key, operation, aclrequired, requestdatetime
FROM s3_access_logs_db.mybucket_logs
WHERE aclrequired = 'Yes'
AND parse_datetime(requestdatetime,'dd/MMM/yyyy:HH:mm:ss Z')
BETWEEN parse_datetime('2022-05-10:00:00:00','yyyy-MM-dd:HH:mm:ss')
AND parse_datetime('2022-08-10:00:00:00','yyyy-MM-dd:HH:mm:ss')
```

Note

- You can modify the date range as needed to suit your needs.
- These query examples might also be useful for security monitoring. You can review the results for `PutObject` or `GetObject` calls from unexpected or unauthorized IP addresses or requesters and for identifying any anonymous requests to your buckets.
- This query only retrieves information from the time at which logging was enabled.
- If you are using AWS CloudTrail logs, see Identifying access to S3 objects by using CloudTrail.

Troubleshoot server access logging

The following topics can help you troubleshoot issues that you might encounter when setting up logging with Amazon S3.

Topics

- Common error messages when setting up logging
- Troubleshooting delivery failures

Common error messages when setting up logging

The following common error messages can appear when you're enabling logging through the AWS Command Line Interface (AWS CLI) and AWS SDKs:

Error: Cross S3 location logging not allowed

If the destination bucket (also known as a *target bucket*) is in a different Region than the source bucket, a Cross S3 location logging not allowed error occurs. To resolve this error, make sure that the destination bucket configured to receive the access logs is in the same AWS Region and AWS account as the source bucket.

Error: The owner for the bucket to be logged and the target bucket must be the same

When you're enabling server access logging, this error occurs if the specified destination bucket belongs to a different account. To resolve this error, make sure that the destination bucket is in the same AWS account as the source bucket.

> **Note**
>
> We recommend that you choose a destination bucket that's different from the source bucket. When the source bucket and destination bucket are the same, additional logs are created for the logs that are written to the bucket, which can increase your storage bill. These extra logs about logs can also make it difficult to find the particular logs that you're looking for. For simpler log management, we recommend saving access logs in a different bucket. For more information, see the section called “How do I enable log delivery?”.

Error: The target bucket for logging does not exist

The destination bucket must exist prior to setting the configuration. This error indicates that the destination bucket doesn't exist or can't be found. Make sure that the bucket name is spelled correctly, and then try again.

Error: Target grants not allowed for bucket owner enforced buckets

This error indicates that the destination bucket uses the Bucket owner enforced setting for S3 Object Ownership. The Bucket owner enforced setting doesn't support destination (target) grants. For more information, see Permissions for log delivery.

Troubleshooting delivery failures

To avoid server access logging issues, make sure that you're following these best practices:

- **The S3 log delivery group has write access to the destination bucket** – The S3 log delivery group delivers server access logs to the destination bucket. A bucket policy or bucket access control list (ACL) can be used to grant write access to the destination bucket. However, we recommend that you use a bucket policy instead of an ACL. For more information about how to grant write access to your destination bucket, see Permissions for log delivery.

  > **Note**
  >
  > If the destination bucket uses the Bucket owner enforced setting for Object Ownership, be aware of the following:
  >
  > - ACLs are disabled and no longer affect permissions. This means that you can't update your bucket ACL to grant access to the S3 log delivery group. Instead, to grant access

to the logging service principal, you must update the bucket policy for the destination bucket.

- You can't include destination grants in your `PutBucketLogging` configuration.

- **The bucket policy for the destination bucket allows access to the logs** – Check the bucket policy of the destination bucket. Search the bucket policy for any statements that contain `"Effect": "Deny"`. Then, verify that the `Deny` statement isn't preventing access logs from being written to the bucket.
- **S3 Object Lock isn't enabled on the destination bucket** – Check if the destination bucket has Object Lock enabled. Object Lock blocks server access log delivery. You must choose a destination bucket that doesn't have Object Lock enabled.
- **Amazon S3 managed keys (SSE-S3) is selected if default encryption is enabled on the destination bucket** – You can use default bucket encryption on the destination bucket only if you use server-side encryption with Amazon S3 managed keys (SSE-S3). Default server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) is not supported for server access logging destination buckets. For more information about how to enable default encryption, see Configuring default encryption.
- **The destination bucket does not have Requester Pays enabled** – Using a Requester Pays bucket as the destination bucket for server access logging is not supported. To allow delivery of server access logs, disable the Requester Pays option on the destination bucket.
- **Review your AWS Organizations service control policies (SCPs) and resource control policies (RCPs)** – When you're using AWS Organizations, check the service control policies and resource control policies to make sure that Amazon S3 access is allowed. These policies specify the maximum permissions for principals and resources in the affected accounts. Search the policies for any statements that contain `"Effect": "Deny"` and verify that `Deny` statements aren't preventing any access logs from being written to the bucket. For more information, see Authorization policies in AWS Organizations in the *AWS Organizations User Guide*.
- **Allow some time for recent logging configuration changes to take effect** – Enabling server access logging for the first time, or changing the destination bucket for logs, requires time to fully take effect. It might take longer than an hour for all requests to be properly logged and delivered.

  To check for log delivery failures, enable request metrics in Amazon CloudWatch. If the logs are not delivered within a few hours, look for the `4xxErrors` metric, which can indicate log delivery failures. For more information about enabling request metrics, see the section called “Creating a metrics configuration for all objects”.

Monitoring metrics with Amazon CloudWatch

Amazon CloudWatch metrics for Amazon S3 can help you understand and improve the performance of applications that use Amazon S3. There are several ways that you can use CloudWatch with Amazon S3.

Daily storage metrics for buckets

Monitor bucket storage using CloudWatch, which collects and processes storage data from Amazon S3 into readable, daily metrics. These storage metrics for Amazon S3 are reported once per day and are provided to all customers at no additional cost.

Request metrics

Monitor Amazon S3 requests to quickly identify and act on operational issues. The metrics are available at 1-minute intervals after some latency for processing. These CloudWatch metrics are billed at the same rate as the Amazon CloudWatch custom metrics. For information about CloudWatch pricing, see Amazon CloudWatch pricing. To learn how to opt in to getting these metrics, see CloudWatch metrics configurations.

When enabled, request metrics are reported for all object operations. By default, these 1-minute metrics are available at the Amazon S3 bucket level. You can also define a filter for the metrics using a shared prefix, object tag, or access point:

- **Access point** – Access points are named network endpoints that are attached to buckets and simplify managing data access at scale for shared datasets in S3. With the access point filter, you can gain insights into your access point usage. For more information about access points, see Monitoring and logging access points.
- **Prefix** – Although the Amazon S3 data model is a flat structure, you can use prefixes to infer a hierarchy. A prefix is similar to a directory name that enables you to group similar objects together in a bucket. The S3 console supports prefixes with the concept of folders. If you filter by prefix, objects that have the same prefix are included in the metrics configuration. For more information about prefixes, see Organizing objects using prefixes.
- **Tags** – Tags are key-value name pairs that you can add to objects. Tags help you find and organize objects easily. You can also use tags as a filter for metrics configurations so that only objects with those tags are included in the metrics configuration. For more information about object tags, see Categorizing your objects using tags.

To align these metrics to specific business applications, workflows, or internal organizations, you can filter on a shared prefix, object tag, or access point.

Replication metrics

Monitor the total number of S3 API operations that are pending replication, the total size of objects pending replication, the maximum replication time to the destination AWS Region, and the total number of operations that failed replication. Replication rules that have S3 Replication Time Control (S3 RTC) or S3 Replication metrics enabled will publish replication metrics.

For more information, see Monitoring replication with metrics, event notifications, and statuses or Meeting compliance requirements with S3 Replication Time Control.

Amazon S3 Storage Lens metrics

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. S3 Storage Lens metrics are available in the `AWS/S3/Storage-Lens` namespace. The CloudWatch publishing option is available for S3 Storage Lens dashboards upgraded to *advanced metrics and recommendations*. You can enable the CloudWatch publishing option for a new or existing dashboard configuration in S3 Storage Lens.

For more information, see Monitor S3 Storage Lens metrics in CloudWatch.

All CloudWatch statistics are retained for a period of 15 months so that you can access historical information and gain a better perspective on how your web application or service is performing. For more information about CloudWatch, see What is Amazon CloudWatch? in the *Amazon CloudWatch User Guide*. You may need some additional configurations to your CloudWatch alarms, depending on your use cases. For example, you can use metric math expression to create an alarm. For more information, see Use CloudWatch metrics, Use metric math, Using Amazon CloudWatch alarms, and Create a CloudWatch alarm based on a metric math expression in the *Amazon CloudWatch User Guide*.

Best-effort CloudWatch metrics delivery

CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.

The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the

nature of traffic against your bucket in near-real time. It is not meant to be a complete accounting of all requests.

It follows from the best-effort nature of this feature that the reports available at the Billing & Cost Management Dashboard might include one or more access requests that do not appear in the bucket metrics.

For more information, see the following topics.

Topics

- Metrics and dimensions
- Accessing CloudWatch metrics
- CloudWatch metrics configurations

Metrics and dimensions

The storage metrics and dimensions that Amazon S3 sends to Amazon CloudWatch are listed in the following tables.

Best-effort CloudWatch metrics delivery

CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.

The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the nature of traffic against your bucket in near-real time. It is not meant to be a complete accounting of all requests.

It follows from the best-effort nature of this feature that the reports available at the Billing & Cost Management Dashboard might include one or more access requests that do not appear in the bucket metrics.

Amazon S3 daily storage metrics for buckets in CloudWatch

The AWS/S3 namespace includes the following daily storage metrics for buckets.

Metric	Description
BucketSizeBytes	The amount of data in bytes that is stored in a bucket in the following storage classes: • Reduced Redundancy Storage (RRS) (REDUCED_REDUNDANCY) • S3 Express One Zone (EXPRESS_ONEZONE) • S3 Glacier Deep Archive (DEEP_ARCHIVE) • S3 Glacier Flexible Retrieval (GLACIER) • S3 Glacier Instant Retrieval (GLACIER_IR) • S3 Intelligent-Tiering (INTELLIGENT_TIERING) • S3 One Zone-Infrequent Access (ONEZONE_IA) • S3 Standard (STANDARD) • S3 Standard-Infrequent Access (STANDARD_IA) This value is calculated by summing the size of all objects and metadata (such as bucket names) in the bucket (both current and noncurrent objects), including the size of all parts for all incomplete multipart uploads to the bucket.

Metric	Description
	Note The S3 Express One Zone storage class is available only for directory buckets. Valid storage-type filters (see the `StorageType` dimension): • Reduced Redundancy Storage (RRS): `ReducedRedundancyStorage` • S3 Express One Zone: `ExpressOneZoneStorage` • S3 Glacier Deep Archive: `DeepArchiveObjectOverhead`, `DeepArchiveS3ObjectOverhead`, `DeepArchiveStagingStorage`, `DeepArchiveStorage` • S3 Glacier Flexible Retrieval: `GlacierObjectOverhead`, `GlacierS3ObjectOverhead`, `GlacierStagingStorage`, `GlacierStorage` • S3 Glacier Instant Retrieval: `GlacierInstantRetrievalStorage`, `GlacierIRSizeOverhead` • S3 Intelligent-Tiering: `IntelligentTieringAAStorage`, `IntelligentTieringAIAStorage`, `IntelligentTieringDAAStorage`, `IntelligentTieringFAStorage`, `IntelligentTieringIAStorage` • S3 One Zone-Infrequent Access: `OneZoneIASizeOverhead`, `OneZoneIAStorage` • S3 Standard: `StandardStorage` • S3 Standard-Infrequent Access: `StandardIAObjectOverhead`, `StandardIASizeOverhead`, `StandardIAStorage` Units: Bytes Valid statistics: Average

Metric	Description
	For more information about the `StorageType` dimensions, see the section called "Amazon S3 dimensions in CloudWatch".
`NumberOfObjects`	The total number of objects stored in a general purpose bucket for all storage classes. This value is calculated by counting all objects in the bucket, which includes current and noncurrent objects, delete markers, and the total number of parts for all incomplete multipart uploads to the bucket. For directory buckets with objects in the S3 Express One Zone storage class, this value is calculated by counting all objects in the bucket, but it doesn't include incomplete multiple uploads to the bucket. Valid storage type filters: `AllStorageTypes` (see the `StorageType` dimension) Units: Count Valid statistics: Average

Amazon S3 request metrics in CloudWatch

The `AWS/S3` namespace includes the following request metrics. These metrics include non-billable requests (in the case of `GET` requests from `CopyObject` and Replication).

> **Note**
>
> Amazon S3 request metrics in CloudWatch aren't supported for directory buckets.

Metric	Description
`AllRequests`	The total number of HTTP requests made to an Amazon S3 bucket, regardless of type. If you're using a metrics configuration with a filter, then this metric returns only the HTTP requests that meet the filter's requirements.

Metric	Description
	Units: Count Valid statistics: Sum
`GetRequests`	The number of HTTP `GET` requests made for objects in an Amazon S3 bucket. This doesn't include list operations. This metric is incremented for the source of each `CopyObject` request. Units: Count Valid statistics: Sum **Note** Paginated list-oriented requests, such as ListMultipartUploads, ListParts, ListObjectVersions, and others, are not included in this metric.
`PutRequests`	The number of HTTP `PUT` requests made for objects in an Amazon S3 bucket. This metric is incremented for the destination of each `CopyObject` request. Units: Count Valid statistics: Sum
`DeleteRequests`	The number of HTTP `DELETE` requests made for objects in an Amazon S3 bucket. This metric also includes DeleteObjects requests. This metric shows the number of requests made, not the number of objects deleted. Units: Count Valid statistics: Sum

Metric	Description
HeadRequests	The number of HTTP HEAD requests made to an Amazon S3 bucket. Units: Count Valid statistics: Sum
PostRequests	The number of HTTP POST requests made to an Amazon S3 bucket. Units: Count Valid statistics: Sum **Note** DeleteObjects and SelectObjectContent requests are not included in this metric.
SelectRequests	The number of Amazon S3 SelectObjectContent requests made for objects in an Amazon S3 bucket. Units: Count Valid statistics: Sum
SelectBytesScanned	The number of bytes of data scanned with Amazon S3 SelectObjectContent requests in an Amazon S3 bucket. Units: Bytes Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9

Metric	Description
`SelectBytesReturned`	The number of bytes of data returned with Amazon S3 SelectObjectContent requests in an Amazon S3 bucket. Units: Bytes Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9
`ListRequests`	The number of HTTP requests that list the contents of a bucket. Units: Count Valid statistics: Sum
`BytesDownloaded`	The number of bytes downloaded for requests made to an Amazon S3 bucket, where the response includes a body. Units: Bytes Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9
`BytesUploaded`	The number of bytes uploaded for requests made to an Amazon S3 bucket, where the request includes a body. Units: Bytes Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9

Metric	Description
`4xxErrors`	The number of HTTP 4*xx* client error status code requests made to an Amazon S3 bucket with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period. Units: Count Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count
`5xxErrors`	The number of HTTP 5*xx* server error status code requests made to an Amazon S3 bucket with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period. Units: Count Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count
`FirstByteLatency`	The per-request time from the complete request being received by an Amazon S3 bucket to when the response starts to be returned. Units: Milliseconds Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100
`TotalRequestLatency`	The elapsed per-request time from the first byte received to the last byte sent to an Amazon S3 bucket. This metric includes the time taken to receive the request body and send the response body, which is not included in `FirstByteLatency` . Units: Milliseconds Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100

S3 Replication metrics in CloudWatch

You can monitor the progress of replication with S3 Replication metrics by tracking bytes pending, operations pending, and replication latency. For more information, see Monitoring progress with replication metrics.

> **Note**
>
> You can enable alarms for your replication metrics in Amazon CloudWatch. When you set up alarms for your replication metrics, set the **Missing data treatment** field to **Treat missing data as ignore (maintain the alarm state)**.

Metric	Description
`ReplicationLatency`	The maximum number of seconds by which the replication destination AWS Region is behind the source AWS Region for a given replication rule. Units: Seconds Valid statistics: Max
`BytesPendingReplication`	The total number of bytes of objects pending replication for a given replication rule. Units: Bytes Valid statistics: Max
`OperationsPendingReplication`	The number of operations pending replication for a given replication rule. Units: Count Valid statistics: Max
`OperationsFailedReplication`	The number of operations that failed to replicate for a given replication rule.

Metric	Description
	Units: Count Valid statistics: Sum (total number of failed operations), Average (failure rate), Sample Count (total number of replication operations)

S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. S3 Storage Lens metrics are published to the `AWS/S3/Storage-Lens` namespace in CloudWatch. The CloudWatch publishing option is available for S3 Storage Lens dashboards that have been upgraded to advanced metrics and recommendations.

For a list of S3 Storage Lens metrics that are published to CloudWatch, see Amazon S3 Storage Lens metrics glossary. For a complete list of dimensions, see Dimensions.

S3 Object Lambda request metrics in CloudWatch

S3 Object Lambda includes the following request metrics.

Metric	Description
`AllRequests`	The total number of HTTP requests made to an Amazon S3 bucket by using an Object Lambda Access Point. Units: Count Valid statistics: Sum
`GetRequests`	The number of HTTP `GET` requests made for objects by using an Object Lambda Access Point. This metric does not include list operations. Units: Count Valid statistics: Sum
`BytesUploaded`	The number of bytes uploaded to an Amazon S3 bucket by using an Object Lambda Access Point, where the request includes a body.

Metric	Description
	Units: Bytes Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9
`PostRequests`	The number of HTTP POST requests made to an Amazon S3 bucket by using an Object Lambda Access Point. Units: Count Valid statistics: Sum
`PutRequests`	The number of HTTP PUT requests made for objects in an Amazon S3 bucket by using an Object Lambda Access Point. Units: Count Valid statistics: Sum
`DeleteRequests`	The number of HTTP DELETE requests made for objects in an Amazon S3 bucket by using an Object Lambda Access Point. This metric includes DeleteObjects requests. This metric shows the number of requests made, not the number of objects deleted. Units: Count Valid statistics: Sum
`BytesDownloaded`	The number of bytes downloaded for requests made to an Amazon S3 bucket by using an Object Lambda Access Point, where the response includes a body. Units: Bytes Valid statistics: Average (bytes per request), Sum (bytes per period), Sample Count, Min, Max (same as p100), any percentile between p0.0 and p99.9

Metric	Description
`FirstByteLatency`	The per-request time from the complete request being received by an Amazon S3 bucket through an Object Lambda Access Point to when the response starts to be returned. This metric is dependent on the AWS Lambda function's running time to transform the object before the function returns the bytes to the Object Lambda Access Point. Units: Milliseconds Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100
`TotalRequestLatency`	The elapsed per-request time from the first byte received to the last byte sent to an Object Lambda Access Point. This metric includes the time taken to receive the request body and send the response body, which is not included in `FirstByteLatency` . Units: Milliseconds Valid statistics: Average, Sum, Min, Max (same as p100), Sample Count, any percentile between p0.0 and p100
`HeadRequests`	The number of HTTP `HEAD` requests made to an Amazon S3 bucket by using an Object Lambda Access Point. Units: Count Valid statistics: Sum
`ListRequests`	The number of HTTP `GET` requests that list the contents of an Amazon S3 bucket. This metric includes both `ListObjects` and `ListObjectsV2` operations. Units: Count Valid statistics: Sum

Metric	Description
4xxErrors	The number of HTTP 4*xx* client error status code requests made to an Amazon S3 bucket by using an Object Lambda Access Point with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period. Units: Count Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count
5xxErrors	The number of HTTP 5*xx* server error status code requests made to an Amazon S3 bucket by using an Object Lambda Access Point with a value of either 0 or 1. The Average statistic shows the error rate, and the Sum statistic shows the count of that type of error, during each period. Units: Count Valid statistics: Average (reports per request), Sum (reports per period), Min, Max, Sample Count
ProxiedRequests	The number of HTTP requests to an Object Lambda Access Point that return the standard Amazon S3 API response. (Such requests do not have a Lambda function configured.) Units: Count Valid statistics: Sum
InvokedLambda	The number of HTTP requests to an S3 object where a Lambda function was invoked. Units: Count Valid statistics: Sum

Metric	Description
LambdaResponseRequests	The number of WriteGetObjectResponse requests made by the Lambda function. This metric applies only to GetObject requests.
LambdaResponse4xx	The number of HTTP 4*xx* client errors that occur when calling WriteGetObjectResponse from a Lambda function. This metric provides the same information as 4xxErrors, but only for WriteGetObjectResponse calls.
LambdaResponse5xx	The number of HTTP 5*xx* server errors that occur when calling WriteGetObjectResponse from a Lambda function. This metric provides the same information as 5xxErrors, but only for WriteGetObjectResponse calls.

Amazon S3 dimensions in CloudWatch

The following dimensions are used to filter Amazon S3 metrics.

Dimension	Description
BucketName	This dimension filters the data that you request for the identified bucket only.
StorageType	This dimension filters the data that you have stored in a bucket by the following types of storage: • DeepArchiveObjectOverhead – For each archived object, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Deep Archive rates for this additional storage. • DeepArchiveS3ObjectOverhead – For each object archived to S3 Glacier Deep Archive, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. You are charged S3 Standard rates for this additional storage.

Dimension	Description
	• `DeepArchiveStagingStorage` – The number of bytes used for parts of multipart upload objects before the `CompleteMultipartUpload` request is completed on objects in the S3 Glacier Deep Archive storage class. • `DeepArchiveStorage` – The number of bytes used for objects in the S3 Glacier Deep Archive storage class. • `ExpressOneZoneStorage` – The number of bytes used for objects in the S3 Express One Zone storage class. • `GlacierInstantRetrievalStorage` – The number of bytes used for objects in the S3 Glacier Instant Retrieval storage class. • `GlacierIRSizeOverhead` – For objects smaller than 128 KB stored in the S3 Glacier Instant Retrieval storage class, this storage type represents the additional bytes charged to meet the minimum object size requirement. • `GlacierObjectOverhead` – For each archived object, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Flexible Retrieval rates for this additional storage. • `GlacierS3ObjectOverhead` – For each object archived to S3 Glacier Flexible Retrieval, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. You are charged S3 Standard rates for this additional storage. • `GlacierStagingStorage` – The number of bytes used for parts of multipart upload objects before the `CompleteMultipartUpload` request is completed on objects in the S3 Glacier Flexible Retrieval storage class. • `GlacierStorage` – The number of bytes used for objects in the S3 Glacier Flexible Retrieval storage class. • `IntAAObjectOverhead` – For each object in the `INTELLIGENT_TIERING` storage class in the Archive Access tier, S3 Glacier adds 32 KB of storage for index and

Dimension	Description
	related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Flexible Retrieval rates for this additional storage. • `IntAAS3ObjectOverhead` – For each object in the `INTELLIGENT_TIERING` storage class in the Archive Access tier, Amazon S3 uses 8 KB of storage for the name of the object and other metadata. You are charged S3 Standard rates for this additional storage. • `IntDAAObjectOverhead` – For each object in the `INTELLIGENT_TIERING` storage class in the Deep Archive Access tier, S3 Glacier adds 32 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Glacier Deep Archive storage rates for this additional storage. • `IntDAAS3ObjectOverhead` – For each object in the `INTELLIGENT_TIERING` storage class in the Deep Archive Access tier, Amazon S3 adds 8 KB of storage for index and related metadata. This extra data is necessary to identify and restore your object. You are charged S3 Standard rates for this additional storage. • `IntelligentTieringAAStorage` – The number of bytes used for objects in the Archive Access tier of the `INTELLIGENT_TIERING` storage class. • `IntelligentTieringAIAStorage` – The number of bytes used for objects in the Archive Instant Access tier of the `INTELLIGENT_TIERING` storage class. • `IntelligentTieringDAAStorage` – The number of bytes used for objects in the Deep Archive Access tier of the `INTELLIGENT_TIERING` storage class. • `IntelligentTieringFAStorage` – The number of bytes used for objects in the Frequent Access tier of the `INTELLIGENT_TIERING` storage class.

Dimension	Description
	• `IntelligentTieringIAStorage` – The number of bytes used for objects in the Infrequent Access tier of the `INTELLIGENT_TIERING` storage class. • `OneZoneIASizeOverhead` – For objects smaller than 128 KB stored in the S3 One Zone-Infrequent Access (`ONEZONE_IA`) storage class, this storage type represents the additional bytes charged to meet the minimum object size requirement. • `OneZoneIAStorage` – The number of bytes used for objects in the S3 One Zone-Infrequent Access (`ONEZONE_IA`) storage class. • `ReducedRedundancyStorage` – The number of bytes used for objects in the Reduced Redundancy Storage (RRS) class. • `StandardIASizeOverhead` – For objects smaller than 128 KB stored in the `STANDARD_IA` storage class, this storage type represents the additional bytes charged to meet the minimum object size requirement. • `StandardIAStorage` – The number of bytes used for objects in the S3 Standard-Infrequent Access (`STANDARD_IA`) storage class. • `StandardStorage` – The number of bytes used for objects in the `STANDARD` storage class.
`FilterId`	This dimension filters metrics configurations that you specify for the request metrics on a bucket. When you create a metrics configuration, you specify a filter ID (for example, a prefix, a tag, or an access point). For more information, see Creating a metrics configuration.

S3 Replication dimensions in CloudWatch

The following dimensions are used to filter S3 Replication metrics.

Dimension	Description
SourceBucket	The name of the bucket objects are replicated from.
DestinationBucket	The name of the bucket objects are replicated to.
RuleId	A unique identifier for the rule that triggered this replication metric to update.

S3 Storage Lens dimensions in CloudWatch

For a list of dimensions that are used to filter S3 Storage Lens metrics in CloudWatch, see Dimensions.

S3 Object Lambda request dimensions in CloudWatch

The following dimensions are used to filter data from an Object Lambda Access Point.

Dimension	Description
AccessPointName	The name of the access point of which requests are being made.
DataSourceARN	The source the Object Lambda Access Point is retrieving the data from. If the request invokes a Lambda function this refers to the Lambda Amazon Resource Name (ARN). Otherwise this refers to the access point ARN.

Amazon S3 usage metrics

You can use CloudWatch usage metrics to provide visibility into your account's usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

Amazon S3 usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about CloudWatch integration with service quotas, see AWS usage metrics in the *Amazon CloudWatch User Guide*.

Amazon S3 publishes the following metrics in the AWS/Usage namespace.

Metric	Description
ResourceCount	The number of the specified resources running in your account. The resources are defined by the dimensions associated with the metric.

The following dimensions are used to refine the usage metrics that are published by Amazon S3.

Dimension	Description
Service	The name of the AWS service containing the resource. For Amazon S3 usage metrics, the value for this dimension is S3.
Type	The type of entity that is being reported. Currently, the only valid value for Amazon S3 usage metrics is Resource.
Resource	The type of resource that is running. Currently, the only valid value for Amazon S3 usage metrics is GeneralPurposeBuckets , which returns the number of general purpose buckets in an AWS account. General purpose buckets allow objects that are stored across all storage classes, except S3 Express One Zone.

Accessing CloudWatch metrics

You can use the following procedures to view the storage metrics for Amazon S3. To get the Amazon S3 metrics involved, you must set a start and end timestamp. For metrics for any given 24-hour period, set the time period to 86400 seconds, the number of seconds in a day. Also, remember to set the BucketName and StorageType dimensions.

Using the AWS CLI

For example, if you want to use the AWS CLI to get the average of a specific bucket's size in bytes, you could use the following command:

```
aws cloudwatch get-metric-statistics --metric-name BucketSizeBytes --namespace AWS/S3
 --start-time 2016-10-19T00:00:00Z --end-time 2016-10-20T00:00:00Z --statistics Average
```

```
 --unit Bytes --region us-west-2 --dimensions Name=BucketName,Value=amzn-s3-demo-bucket
 Name=StorageType,Value=StandardStorage --period 86400 --output json
```

This example produces the following output.

```
{
    "Datapoints": [
        {
            "Timestamp": "2016-10-19T00:00:00Z",
            "Average": 1025328.0,
            "Unit": "Bytes"
        }
    ],
    "Label": "BucketSizeBytes"
}
```

Using the S3 console

To view metrics by using the Amazon CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, choose **Metrics**.
3. Choose the **S3** namespace.
4. (Optional) To view a metric, enter the metric name in the search box.
5. (Optional) To filter by the **StorageType** dimension, enter the name of the storage class in the search box.

To view a list of valid metrics stored for your AWS account by using the AWS CLI

- At a command prompt, use the following command.

```
aws cloudwatch list-metrics --namespace "AWS/S3"
```

For more information about the permissions required to access CloudWatch dashboards, see Amazon CloudWatch dashboard permissions in the *Amazon CloudWatch User Guide*.

CloudWatch metrics configurations

With Amazon CloudWatch request metrics for Amazon S3, you can receive 1-minute CloudWatch metrics, set CloudWatch alarms, and access CloudWatch dashboards to view near-real-time operations and performance of your Amazon S3 storage. For applications that depend on cloud storage, these metrics let you quickly identify and act on operational issues. When enabled, these 1-minute metrics are available at the Amazon S3 bucket-level, by default.

If you want to get the CloudWatch request metrics for the objects in a bucket, you must create a metrics configuration for the bucket. For more information, see Creating a CloudWatch metrics configuration for all the objects in your bucket.

You can also use a shared prefix, object tags, or an access point to define a filter for the metrics collected. This method of defining a filter allows you to align metrics filters to specific business applications, workflows, or internal organizations. For more information, see Creating a metrics configuration that filters by prefix, object tag, or access point. For more information about the CloudWatch metrics that are available and the differences between storage and request metrics, see Monitoring metrics with Amazon CloudWatch.

Keep the following in mind when using metrics configurations:

- You can have a maximum of 1,000 metrics configurations per bucket.
- You can choose which objects in a bucket to include in metrics configurations by using filters. You can filter on a shared prefix, object tag, or access point to align metrics filters to specific business applications, workflows, or internal organizations. To request metrics for the entire bucket, create a metrics configuration without a filter.
- Metrics configurations are necessary only to enable request metrics. Bucket-level daily storage metrics are always turned on, and are provided at no additional cost. Currently, it's not possible to get daily storage metrics for a filtered subset of objects.
- Each metrics configuration enables the full set of available request metrics. Operation-specific metrics (such as `PostRequests`) are reported only if there are requests of that type for your bucket or your filter.
- Request metrics are reported for object-level operations. They are also reported for operations that list bucket contents, like GET Bucket (List Objects), GET Bucket Object Versions, and List Multipart Uploads, but they are not reported for other operations on buckets.
- Request metrics support filtering by prefix, object tags, or access point, but storage metrics do not.

Best-effort CloudWatch metrics delivery

CloudWatch metrics are delivered on a best-effort basis. Most requests for an Amazon S3 object that have request metrics result in a data point being sent to CloudWatch.

The completeness and timeliness of metrics are not guaranteed. The data point for a particular request might be returned with a timestamp that is later than when the request was actually processed. The data point for a minute might be delayed before being available through CloudWatch, or it might not be delivered at all. CloudWatch request metrics give you an idea of the nature of traffic against your bucket in near-real time. It is not meant to be a complete accounting of all requests.

It follows from the best-effort nature of this feature that the reports available at the Billing & Cost Management Dashboard might include one or more access requests that do not appear in the bucket metrics.

For more information about working with CloudWatch metrics in Amazon S3, see the following topics.

Topics

- Creating a CloudWatch metrics configuration for all the objects in your bucket
- Creating a metrics configuration that filters by prefix, object tag, or access point
- Deleting a metrics filter

Creating a CloudWatch metrics configuration for all the objects in your bucket

When you configure request metrics, you can create a CloudWatch metrics configuration for all the objects in your bucket, or you can filter by prefix, object tag, or access point. The procedures in this topic show you how to create a configuration for all the objects in your bucket. To create a configuration that filters by object tag, prefix, or access point, see Creating a metrics configuration that filters by prefix, object tag, or access point.

There are three types of Amazon CloudWatch metrics for Amazon S3: storage metrics, request metrics, and replication metrics. Storage metrics are reported once per day and are provided to all customers at no additional cost. Request metrics are available at one-minute intervals after some latency for processing. Request metrics are billed at the standard CloudWatch rate. You must opt in to request metrics by configuring them in the console or using the Amazon S3 API. S3 Replication metrics provide detailed metrics for the replication rules in your replication configuration. With

replication metrics, you can monitor minute-by-minute progress by tracking bytes pending, operations pending, operations that failed replication, and replication latency.

For more information about CloudWatch metrics for Amazon S3, see Monitoring metrics with Amazon CloudWatch.

You can add metrics configurations to a bucket using the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the Amazon S3 REST API.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that contains the objects you want request metrics for.
4. Choose the **Metrics** tab.
5. Under **Bucket metrics**, choose **View additional charts**.
6. Choose the **Request metrics** tab.
7. Choose **Create filter**.
8. In the **Filter name** box, enter your filter name.

   Names can only contain letters, numbers, periods, dashes, and underscores. We recommend using the name `EntireBucket` for a filter that applies to all objects.
9. Under **Filter scope**, choose **This filter applies to all objects in the bucket**.

   You can also define a filter so that the metrics are only collected and reported on a subset of objects in the bucket. For more information, see Creating a metrics configuration that filters by prefix, object tag, or access point.
10. Choose **Save changes**.
11. On the **Request metrics** tab, under **Filters**, choose the filter that you just created.

    After about 15 minutes, CloudWatch begins tracking these request metrics. You can see them on the **Request metrics** tab. You can see graphs for the metrics on the Amazon S3 or CloudWatch console. Request metrics are billed at the standard CloudWatch rate. For more information, see Amazon CloudWatch pricing.

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- PUT Bucket Metric Configuration
- GET Bucket Metric Configuration
- List Bucket Metric Configuration
- DELETE Bucket Metric Configuration

Using the AWS CLI

1. Install and set up the AWS CLI. For instructions, see Installing, updating, and uninstalling the AWS CLI in the *AWS Command Line Interface User Guide*.
2. Open a terminal.
3. Run the following command to add a metrics configuration.

```
aws s3api put-bucket-metrics-configuration --endpoint https://s3.us-
west-2.amazonaws.com --bucket bucket-name --id metrics-config-id --metrics-
configuration '{"Id":"metrics-config-id"}'
```

Creating a metrics configuration that filters by prefix, object tag, or access point

There are three types of Amazon CloudWatch metrics for Amazon S3: storage metrics, request metrics, and replication metrics. Storage metrics are reported once per day and are provided to all customers at no additional cost. Request metrics are available at one-minute intervals after some latency for processing. Request metrics are billed at the standard CloudWatch rate. You must opt in to request metrics by configuring them in the console or using the Amazon S3 API. S3 Replication metrics provide detailed metrics for the replication rules in your replication configuration. With replication metrics, you can monitor minute-by-minute progress by tracking bytes pending, operations pending, operations that failed replication, and replication latency.

For more information about CloudWatch metrics for Amazon S3, see Monitoring metrics with Amazon CloudWatch.

When you configure CloudWatch metrics, you can create a filter for all the objects in your bucket, or you can filter the configuration into groups of related objects within a single bucket. You can filter objects in a bucket for inclusion in a metrics configuration based on one or more of the following filter types:

- **Object key name prefix** – Although the Amazon S3 data model is a flat structure, you can infer a hierarchy by using a prefix. The Amazon S3 console supports these prefixes with the concept of folders. If you filter by prefix, objects that have the same prefix are included in the metrics configuration. For more information about prefixes, see Organizing objects using prefixes.
- **Tag** – You can add tags, which are key-value name pairs, to objects. Tags help you find and organize objects easily. You can also use tags as filters for metrics configurations. For more information about object tags, see Categorizing your objects using tags.
- **Access point** – S3 Access Points are named network endpoints that are attached to buckets and simplify managing data access at scale for shared datasets in S3. When you create an access point filter, Amazon S3 includes requests to the access point that you specify in the metrics configuration. For more information, see Monitoring and logging access points.

> **Note**
>
> When you create a metrics configuration that filters by access point, you must use the access point Amazon Resource Name (ARN), not the access point alias. Make sure that you use the ARN for the access point itself, not the ARN for a specific object. For more information about access point ARNs, see Using Amazon S3 access points for general purpose buckets.

If you specify a filter, only requests that operate on single objects can match the filter and be included in the reported metrics. Requests like DeleteObjects and `ListObjects` requests don't return any metrics for configurations with filters.

To request more complex filtering, choose two or more elements. Only objects that have all of those elements are included in the metrics configuration. If you don't set filters, all of the objects in the bucket are included in the metrics configuration.

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **General purpose buckets**
3. In the buckets list, choose the name of the bucket that contains the objects that you want request metrics for.
4. Choose the **Metrics** tab.
5. Under **Bucket metrics**, choose **View additional charts**.
6. Choose the **Request metrics** tab.
7. Choose **Create filter**.
8. In the **Filter name** box, enter your filter name.

   Names can contain only letters, numbers, periods, dashes, and underscores.
9. Under **Filter scope**, choose **Limit the scope of this filter using a prefix, object tags, and an S3 Access Point, or a combination of all three**.
10. Under **Filter type**, choose at least one filter type: **Prefix**, **Object tags**, or **Access Point**.
11. To define a prefix filter and limit the scope of the filter to a single path, in the **Prefix** box, enter a prefix.
12. To define an object tags filter, under **Object tags**, choose **Add tag**, and then enter a tag **Key** and **Value**.
13. To define an access point filter, in the **S3 Access Point** field, enter the access point ARN, or choose **Browse S3** to navigate to the access point.

    > **Important**
    >
    > You cannot enter an access point alias. You must enter the ARN for the access point itself, not the ARN for a specific object.
14. Choose **Save changes**.

    Amazon S3 creates a filter that uses the prefix, tags, or access point that you specified.
15. On the **Request metrics** tab, under **Filters**, choose the filter that you just created.

    You have now created a filter that limits the request metrics scope by prefix, object tags, or access point. About 15 minutes after CloudWatch begins tracking these request metrics, you can see charts for the metrics on both the Amazon S3 and CloudWatch consoles. Request metrics are billed at the standard CloudWatch rate. For more information, see Amazon CloudWatch pricing.

You can also configure request metrics at the bucket level. For information, see Creating a CloudWatch metrics configuration for all the objects in your bucket.

Using the AWS CLI

1. Install and set up the AWS CLI. For instructions, see Installing, updating, and uninstalling the AWS CLI in the *AWS Command Line Interface User Guide*.
2. Open a terminal.
3. To add a metrics configuration, run one of the following commands:

Example : To filter by prefix

```
aws s3api put-bucket-metrics-configuration --bucket amzn-s3-demo-bucket --
id metrics-config-id --metrics-configuration '{"Id":"metrics-config-id", "Filter":
{"Prefix":"prefix1"}} '
```

Example : To filter by tags

```
aws s3api put-bucket-metrics-configuration --bucket amzn-s3-demo-bucket --
id metrics-config-id --metrics-configuration '{"Id":"metrics-config-id", "Filter":
{"Tag": {"Key": "string", "Value": "string"}} '
```

Example : To filter by access point

```
aws s3api put-bucket-metrics-configuration --bucket amzn-s3-demo-bucket --
id metrics-config-id --metrics-configuration '{"Id":"metrics-config-id", "Filter":
{"AccessPointArn":"arn:aws:s3:Region:account-id:accesspoint/access-point-name"}} '
```

Example : To filter by prefix, tags, and access point

```
aws s3api put-bucket-metrics-configuration --endpoint https://
s3.Region.amazonaws.com --bucket amzn-s3-demo-bucket --id metrics-config-id --
metrics-configuration '
{
    "Id": "metrics-config-id",
    "Filter": {
        "And": {
            "Prefix": "string",
```

```
            "Tags": [
                {
                    "Key": "string",
                    "Value": "string"
                }
            ],
            "AccessPointArn": "arn:aws:s3:Region:account-id:accesspoint/access-
point-name"
        }
    }
}'
```

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- PUT Bucket Metric Configuration
- GET Bucket Metric Configuration
- List Bucket Metric Configuration
- DELETE Bucket Metric Configuration

Deleting a metrics filter

You can delete an Amazon CloudWatch request metrics filter if you no longer need it. When you delete a filter, you are no longer charged for request metrics that use that *specific filter*. However, you will continue to be charged for any other filter configurations that exist.

When you delete a filter, you can no longer use the filter for request metrics. Deleting a filter cannot be undone.

For information about creating a request metrics filter, see the following topics:

- Creating a CloudWatch metrics configuration for all the objects in your bucket
- Creating a metrics configuration that filters by prefix, object tag, or access point

Using the S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket you want to delete a request metrics filter for.
4. Choose the **Metrics** tab.
5. Under **Bucket metrics**, choose **View additional charts**.
6. Choose the **Request metrics** tab.
7. Choose **Manage filters**.
8. Choose your filter.

   > **Important**
   >
   > Deleting a filter cannot be undone.

9. Choose **Delete**.

   Amazon S3 deletes your filter.

Using the REST API

You can also add metrics configurations programmatically with the Amazon S3 REST API. For more information about adding and working with metrics configurations, see the following topics in the *Amazon Simple Storage Service API Reference*:

- PUT Bucket Metric Configuration
- GET Bucket Metric Configuration
- List Bucket Metric Configuration
- DELETE Bucket Metric Configuration

Amazon S3 Event Notifications

You can use the Amazon S3 Event Notifications feature to receive notifications when certain events happen in your S3 bucket. To enable notifications, add a notification configuration that

identifies the events that you want Amazon S3 to publish. Make sure that it also identifies the destinations where you want Amazon S3 to send the notifications. You store this configuration in the *notification* subresource that's associated with a bucket. For more information, see General purpose buckets configuration options. Amazon S3 provides an API for you to manage this subresource.

> **Important**
>
> Amazon S3 event notifications are designed to be delivered at least once. Typically, event notifications are delivered in seconds but can sometimes take a minute or longer.

Overview of Amazon S3 Event Notifications

Currently, Amazon S3 can publish notifications for the following events:

- New object created events
- Object removal events
- Restore object events
- Reduced Redundancy Storage (RRS) object lost events
- Replication events
- S3 Lifecycle expiration events
- S3 Lifecycle transition events
- S3 Intelligent-Tiering automatic archival events
- Object tagging events
- Object ACL PUT events

For full descriptions of all the supported event types, see Supported event types for SQS, SNS, and Lambda.

Amazon S3 can send event notification messages to the following destinations. You specify the Amazon Resource Name (ARN) value of these destinations in the notification configuration.

- Amazon Simple Notification Service (Amazon SNS) topics
- Amazon Simple Queue Service (Amazon SQS) queues
- AWS Lambda function

- Amazon EventBridge

For more information, see Supported event destinations.

> **Note**
>
> Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see Enabling Amazon EventBridge.

> **Warning**
>
> If your notification writes to the same bucket that triggers the notification, it could cause an execution loop. For example, if the bucket triggers a Lambda function each time an object is uploaded, and the function uploads an object to the bucket, then the function indirectly triggers itself. To avoid this, use two buckets, or configure the trigger to only apply to a prefix used for incoming objects.
>
> For more information and an example of using Amazon S3 notifications with AWS Lambda, see Using AWS Lambda with Amazon S3 in the *AWS Lambda Developer Guide*.

For more information about the number of event notification configurations that you can create per bucket, see Amazon S3 service quotas in *AWS General Reference*.

For more information about event notifications, see the following sections.

Topics

- Event notification types and destinations
- Using Amazon SQS, Amazon SNS, and Lambda
- Using EventBridge

Event notification types and destinations

Amazon S3 supports several event notification types and destinations where the notifications can be published. You can specify the event type and destination when configuring your event

notifications. Only one destination can be specified for each event notification. Amazon S3 event notifications send one event entry for each notification message.

Topics

- Supported event destinations
- Supported event types for SQS, SNS, and Lambda
- Supported event types for Amazon EventBridge
- Event ordering and duplicate events

Supported event destinations

Amazon S3 can send event notification messages to the following destinations.

- Amazon Simple Notification Service (Amazon SNS) topics
- Amazon Simple Queue Service (Amazon SQS) queues
- AWS Lambda
- Amazon EventBridge

However, only one destination type can be specified for each event notification.

> **Note**
>
> You must grant Amazon S3 permissions to post messages to an Amazon SNS topic or an Amazon SQS queue. You must also grant Amazon S3 permission to invoke an AWS Lambda function on your behalf. For instructions on how to grant these permissions, see Granting permissions to publish event notification messages to a destination.

Amazon SNS topic

Amazon SNS is a flexible, fully managed push messaging service. You can use this service to push messages to mobile devices or distributed services. With SNS, you can publish a message once, and deliver it one or more times. Currently, Standard SNS is only allowed as an S3 event notification destination, whereas SNS FIFO is not allowed.

Amazon SNS both coordinates and manages sending and delivering messages to subscribing endpoints or clients. You can use the Amazon SNS console to create an Amazon SNS topic that your notifications can be sent to.

The topic must be in the same AWS Region as your Amazon S3 bucket. For instructions on how to create an Amazon SNS topic, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide* and the Amazon SNS FAQ.

Before you can use the Amazon SNS topic that you created as an event notification destination, you need the following:

- The Amazon Resource Name (ARN) for the Amazon SNS topic
- A valid Amazon SNS topic subscription. With it, topic subscribers are notified when a message is published to your Amazon SNS topic.

Amazon SQS queue

Amazon SQS offers reliable and scalable hosted queues for storing messages as they travel between computers. You can use Amazon SQS to transmit any volume of data without requiring other services to be always available. You can use the Amazon SQS console to create an Amazon SQS queue that your notifications can be sent to.

The Amazon SQS queue must be in the same AWS Region as your Amazon S3 bucket. For instructions on how to create an Amazon SQS queue, see What is Amazon Simple Queue Service and Getting started with Amazon SQS in the *Amazon Simple Queue Service Developer Guide*.

Before you can use the Amazon SQS queue as an event notification destination, you need the following:

- The Amazon Resource Name (ARN) for the Amazon SQS queue

> **Note**
>
> Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see Enabling Amazon EventBridge.

Lambda function

You can use AWS Lambda to extend other AWS services with custom logic, or create your own backend that operates at AWS scale, performance, and security. With Lambda, you can create discrete, event-driven applications that run only when needed. You can also use it to scale these applications automatically from a few requests a day to thousands a second.

Lambda can run custom code in response to Amazon S3 bucket events. You upload your custom code to Lambda and create what's called a Lambda function. When Amazon S3 detects an event of a specific type, it can publish the event to AWS Lambda and invoke your function in Lambda. In response, Lambda runs your function. One event type it might detect, for example, is an object created event.

You can use the AWS Lambda console to create a Lambda function that uses the AWS infrastructure to run the code on your behalf. The Lambda function must be in the same Region as your S3 bucket. You must also have the name or the ARN of a Lambda function to set up the Lambda function as an event notification destination.

Warning

If your notification writes to the same bucket that triggers the notification, it could cause an execution loop. For example, if the bucket triggers a Lambda function each time an object is uploaded, and the function uploads an object to the bucket, then the function indirectly triggers itself. To avoid this, use two buckets, or configure the trigger to only apply to a prefix used for incoming objects.
For more information and an example of using Amazon S3 notifications with AWS Lambda, see Using AWS Lambda with Amazon S3 in the *AWS Lambda Developer Guide*.

Amazon EventBridge

Amazon EventBridge is a serverless event bus, which receives events from AWS services. You can set up rules to match events and deliver them to targets, such as an AWS service or an HTTP endpoint. For more information, see What is EventBridge in the *Amazon EventBridge User Guide*.

Unlike other destinations, you can either enable or disable events to be delivered to EventBridge for a bucket. If you enable delivery, all events are sent to EventBridge. Moreover, you can use EventBridge rules to route events to additional targets.

Supported event types for SQS, SNS, and Lambda

Amazon S3 can publish events of the following types. You specify these event types in the notification configuration.

Event types	Description
`s3:TestEvent`	When a notification is enabled, Amazon S3 publishes a test notification. This is to ensure that the topic exists and that the bucket owner has permission to publish the specified topic. If enabling the notification fails, you don't receive a test notification.

`s3:ObjectCreated:*`
 	
`s3:ObjectCreated:Put`
 	
`s3:ObjectCreated:Post`
 	
`s3:ObjectCreated:Copy`
 	
`s3:ObjectCreated:CompleteMultipartUpload`
	Amazon S3 API operations such as PUT, POST, and COPY can create an object. With these event types, you can enable notifications when an object is created using a specific API operation. Alternatively, you can use the `s3:ObjectCreated:*` event type to request notification regardless of the API that was used to create an object.
	
	`s3:ObjectCreated:CompleteMultipartUpload` includes objects that are created using UploadPartCopy for Copy operations.

`s3:ObjectRemoved:*`
 	
`s3:ObjectRemoved:Delete`
 	
`s3:ObjectRemoved:DeleteMarkerCreated`
	By using the `ObjectRemoved` event types, you can enable notification when an object or a batch of objects is removed from a bucket.
	
	You can request notification when an object is deleted or a versioned object is permanently deleted by using the `s3:ObjectRemoved:Delete` event type. Alternatively, you can request notification when a delete marker is created for a versioned object using `s3:ObjectRemoved:DeleteMarkerCreated`. For instructions on how to delete versioned objects, see Deleting

Event types	Description
	object versions from a versioning-enabled bucket. You can also use a wildcard `s3:ObjectRemoved:*` to request notification anytime an object is deleted. These event notifications don't alert you for automatic deletes from lifecycle configurations or from failed operations.

`s3:ObjectRestore:*`
 	
`s3:ObjectRestore:Post`
 	
`s3:ObjectRestore:Completed`
 	
`s3:ObjectRestore:Delete`
	By using the `ObjectRestore` event types, you can receive notifications for event initiation and completion when restoring objects from the S3 Glacier Flexible Retrieval storage class, S3 Glacier Deep Archive storage class, S3 Intelligent-Tiering Archive Access tier, and S3 Intelligent-Tiering Deep Archive Access tier. You can also receive notifications for when the restored copy of an object expires.
	
	The `s3:ObjectRestore:Post` event type notifies you of object restoration initiation. The `s3:ObjectRestore:Completed` event type notifies you of restoration completion. The `s3:ObjectRestore:Delete` event type notifies you when the temporary copy of a restored object expires.

`s3:ReducedRedundancyLostObject`	You receive this notification event when Amazon S3 detects that an object of the RRS storage class is lost.

Event types	Description

`s3:Replication:*`
 	
`s3:Replication:OperationFailedReplication`
 	
`s3:Replication:OperationMissedThreshold`
 	
`s3:Replication:OperationReplicatedAfterThreshold`
 	
`s3:Replication:OperationNotTracked`
	By using the `Replication` event types, you can receive notifications for replication configurations that have S3 Replication metrics or S3 Replication Time Control (S3 RTC) enabled. You can monitor the minute-by-minute progress of replication events by tracking bytes pending, operations pending, and replication latency. For information about replication metrics, see Monitoring replication with metrics, event notifications, and statuses.
	
	• The `s3:Replication:OperationFailedReplication` event type notifies you when an object that was eligible for replication failed to replicate.
	• The `s3:Replication:OperationMissedThreshold` event type notifies you when an object that was eligible for replication that uses S3 RTC exceeds the 15-minute threshold for replication.
	• The `s3:Replication:OperationReplicatedAfterThreshold` event type notifies you when an object that was eligible for replication that uses S3 RTC replicates after the 15-minute threshold.
	• The `s3:Replication:OperationNotTracked` event type notifies you when an object that was eligible for live replication (either Same-Region Replication [SRR] or Cross-Region Replication [CRR]) is no longer being tracked by replication metrics.

Event types	Description
s3:LifecycleExpiration:* s3:LifecycleExpiration:Delete s3:LifecycleExpiration:DeleteMarkerCreated	By using the LifecycleExpiration event types, you can receive a notification when Amazon S3 deletes an object based on your S3 Lifecycle configuration. The s3:LifecycleExpiration:Delete event type notifies you when an object in an unversioned bucket is deleted. It also notifies you when an object version is permanently deleted by an S3 Lifecycle configuration. The s3:LifecycleExpiration:DeleteMarkerCreated event type notifies you when S3 Lifecycle creates a delete marker when a current version of an object in versioned bucket is deleted.
s3:LifecycleTransition	You receive this notification event when an object is transitioned to another Amazon S3 storage class by an S3 Lifecycle configuration.
s3:IntelligentTiering	You receive this notification event when an object within the S3 Intelligent-Tiering storage class moved to the Archive Access tier or Deep Archive Access tier.
s3:ObjectTagging:* s3:ObjectTagging:Put s3:ObjectTagging:Delete	By using the ObjectTagging event types, you can enable notification when an object tag is added or deleted from an object. The s3:ObjectTagging:Put event type notifies you when a tag is PUT on an object or an existing tag is updated. The s3:ObjectTagging:Delete event type notifies you when a tag is removed from an object.
s3:ObjectAcl:Put	You receive this notification event when an ACL is PUT on an object or when an existing ACL is changed. An event is not generated when a request results in no change to an object's ACL.

Supported event types for Amazon EventBridge

For a list of event types Amazon S3 will send to Amazon EventBridge, see Using EventBridge.

Event ordering and duplicate events

Amazon S3 Event Notifications is designed to deliver notifications at least once, but they aren't guaranteed to arrive in the same order that the events occurred. On rare occasions, Amazon S3's retry mechanism might cause duplicate S3 Event Notifications for the same object event. For more about handling duplicate or out of order events, see Manage event ordering and duplicate events with Amazon S3 Event Notifications on the *AWS Storage Blog*.

Using Amazon SQS, Amazon SNS, and Lambda

Enabling notifications is a bucket-level operation. You store notification configuration information in the *notification* subresource that's associated with a bucket. After you create or change the bucket notification configuration, it usually takes about five minutes for the changes to take effect. When the notification is first enabled, an `s3:TestEvent` occurs. You can use any of the following methods to manage notification configuration:

- **Using the Amazon S3 console** — You can use the console UI to set a notification configuration on a bucket without having to write any code. For more information, see Enabling and configuring event notifications using the Amazon S3 console.
- **Programmatically using the AWS SDKs** — Internally, both the console and the SDKs call the Amazon S3 REST API to manage *notification* subresources that are associated with the bucket. For examples of notification configurations that use AWS SDK, see Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue).

> **Note**
>
> You can also make the Amazon S3 REST API calls directly from your code. However, this can be cumbersome because to do so you must write code to authenticate your requests.

Regardless of the method that you use, Amazon S3 stores the notification configuration as XML in the *notification* subresource that's associated with a bucket. For information about bucket subresources, see General purpose buckets configuration options.

> **Note**
>
> If you have multiple failed event notifications due to deleted destinations you may receive the **Unable to validate the following destination configurations** when trying to delete them. You can resolve this in the S3 console by deleting all the failed notifications at the same time.

Topics

- Granting permissions to publish event notification messages to a destination
- Enabling and configuring event notifications using the Amazon S3 console
- Configuring event notifications programmatically
- Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue)
- Configuring event notifications using object key name filtering
- Event message structure

Granting permissions to publish event notification messages to a destination

You must grant the Amazon S3 principal the necessary permissions to call the relevant API to publish messages to an SNS topic, an SQS queue, or a Lambda function. This is so that Amazon S3 can publish event notification messages to a destination.

To troubleshoot publishing event notification messages to a destination, see Troubleshoot to publish Amazon S3 event notifications to an Amazon Simple Notification Service topic .

Topics

- Granting permissions to invoke an AWS Lambda function
- Granting permissions to publish messages to an SNS topic or an SQS queue

Granting permissions to invoke an AWS Lambda function

Amazon S3 publishes event messages to AWS Lambda by invoking a Lambda function and providing the event message as an argument.

When you use the Amazon S3 console to configure event notifications on an Amazon S3 bucket for a Lambda function, the console sets up the necessary permissions on the Lambda function. This is

so that Amazon S3 has permissions to invoke the function from the bucket. For more information, see Enabling and configuring event notifications using the Amazon S3 console.

You can also grant Amazon S3 permissions from AWS Lambda to invoke your Lambda function. For more information, see Tutorial: Using AWS Lambda with Amazon S3 in the *AWS Lambda Developer Guide*.

Granting permissions to publish messages to an SNS topic or an SQS queue

To grant Amazon S3 permissions to publish messages to the SNS topic or SQS queue, attach an AWS Identity and Access Management (IAM) policy to the destination SNS topic or SQS queue.

For an example of how to attach a policy to an SNS topic or an SQS queue, see Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue). For more information about permissions, see the following topics:

- Example cases for Amazon SNS access control in the *Amazon Simple Notification Service Developer Guide*
- Identity and access management in Amazon SQS in the *Amazon Simple Queue Service Developer Guide*

IAM policy for a destination SNS topic

The following is an example of an AWS Identity and Access Management (IAM) policy that you attach to the destination SNS topic. For instructions on how to use this policy to set up a destination Amazon SNS topic for event notifications, see Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue).

JSON

IAM policy for a destination SQS queue

The following is an example of an IAM policy that you attach to the destination SQS queue. For instructions on how to use this policy to set up a destination Amazon SQS queue for event notifications, see Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue).

To use this policy, you must update the Amazon SQS queue ARN, bucket name, and bucket owner's AWS account ID.

                    "aws:SourceAccount": "bucket-owner-account-id"
                }
            }
        }
    ]
}
```

For both the Amazon SNS and Amazon SQS IAM policies, you can specify the `StringLike` condition in the policy instead of the `ArnLike` condition.

When `ArnLike` is used, the partition, service, account-id, resource-type, and partial resource-id portions of the ARN must have exact matching to the ARN in the request context. Only the region and resource path allow partial matching.

When `StringLike` is used instead of `ArnLike`, matching ignores the ARN structure and allows partial matching, regardless of the portion that was wildcarded. For more information, see IAM JSON policy elements in the *IAM User Guide*.

```
"Condition": {
  "StringLike": { "aws:SourceArn": "arn:aws:s3:*:*:amzn-s3-demo-bucket" }
  }
```

AWS KMS key policy

If the SQS queue or SNS topics are encrypted with an AWS Key Management Service (AWS KMS) customer managed key, you must grant the Amazon S3 service principal permission to work with the encrypted topics or queue. To grant the Amazon S3 service principal permission, add the following statement to the key policy for the customer managed key.

JSON

```
{
    "Version": "2012-10-17",
    "Id": "example-ID",
    "Statement": [
        {
            "Sid": "example-statement-ID",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": [
                "kms:GenerateDataKey",
                "kms:Decrypt"
            ],
            "Resource": "*"
        }
    ]
}
```

For more information about AWS KMS key policies, see Using key policies in AWS KMS in the *AWS Key Management Service Developer Guide*.

For more information about using server-side encryption with AWS KMS for Amazon SQS and Amazon SNS, see the following:

- Key management in the *Amazon Simple Notification Service Developer Guide*.
- Key management in the *Amazon Simple Queue Service Developer Guide*.
- Encrypting messages published to Amazon SNS with AWS KMS in the *AWS Compute Blog*.

Enabling and configuring event notifications using the Amazon S3 console

You can enable certain Amazon S3 general purpose bucket events to send a notification message to a destination whenever those events occur. This section explains how to use the Amazon S3 console to enable event notifications. For information about how to use event notifications with the AWS SDKs and the Amazon S3 REST APIs, see Configuring event notifications programmatically.

Prerequisites: Before you can enable event notifications for your bucket, you must set up one of the destination types and then configure permissions. For more information, see Supported event destinations and Granting permissions to publish event notification messages to a destination.

> **Note**
>
> Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see Enabling Amazon EventBridge.

Topics

- Enabling Amazon SNS, Amazon SQS, or Lambda notifications using the Amazon S3 console

Enabling Amazon SNS, Amazon SQS, or Lambda notifications using the Amazon S3 console

To enable and configure event notifications for an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.

3. In the buckets list, choose the name of the bucket that you want to enable events for.
4. Choose **Properties**.
5. Navigate to the **Event Notifications** section and choose **Create event notification**.
6. In the **General configuration** section, specify descriptive event name for your event notification. Optionally, you can also specify a prefix and a suffix to limit the notifications to objects with keys ending in the specified characters.

   a. Enter a description for the **Event name**.

      If you don't enter a name, a globally unique identifier (GUID) is generated and used for the name.

   b. (Optional) To filter event notifications by prefix, enter a **Prefix**.

      For example, you can set up a prefix filter so that you receive notifications only when files are added to a specific folder (for example, `images/`).

   c. (Optional) To filter event notifications by suffix, enter a **Suffix**.

      For more information, see Configuring event notifications using object key name filtering.
7. In the **Event types** section, select one or more event types that you want to receive notifications for.

   For a list of the different event types, see Supported event types for SQS, SNS, and Lambda.
8. In the **Destination** section, choose the event notification destination.

   > **Note**
   >
   > Before you can publish event notifications, you must grant the Amazon S3 principal the necessary permissions to call the relevant API. This is so that it can publish notifications to a Lambda function, SNS topic, or SQS queue.

   a. Select the destination type: **Lambda Function**, **SNS Topic**, or **SQS Queue**.

   b. After you choose your destination type, choose a function, topic, or queue from the list.

   c. Or, if you prefer to specify an Amazon Resource Name (ARN), select **Enter ARN** and enter the ARN.

For more information, see Supported event destinations.

9. Choose **Save changes**, and Amazon S3 sends a test message to the event notification destination.

Configuring event notifications programmatically

By default, notifications aren't enabled for any type of event. Therefore, the *notification* subresource initially stores an empty configuration.

```
<NotificationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
</NotificationConfiguration>
```

To enable notifications for events of specific types, you replace the XML with the appropriate configuration that identifies the event types you want Amazon S3 to publish and the destination where you want the events published. For each destination, you add a corresponding XML configuration.

To publish event messages to an SQS queue

To set an SQS queue as the notification destination for one or more event types, add the `QueueConfiguration`.

```
<NotificationConfiguration>
  <QueueConfiguration>
    <Id>optional-id-string</Id>
    <Queue>sqs-queue-arn</Queue>
    <Event>event-type</Event>
    <Event>event-type</Event>
     ...
  </QueueConfiguration>
   ...
</NotificationConfiguration>
```

To publish event messages to an SNS topic

To set an SNS topic as the notification destination for specific event types, add the `TopicConfiguration`.

```
<NotificationConfiguration>
  <TopicConfiguration>
     <Id>optional-id-string</Id>
     <Topic>sns-topic-arn</Topic>
     <Event>event-type</Event>
     <Event>event-type</Event>
      ...
  </TopicConfiguration>
   ...
</NotificationConfiguration>
```

To invoke the AWS Lambda function and provide an event message as an argument

To set a Lambda function as the notification destination for specific event types, add the `CloudFunctionConfiguration`.

```
<NotificationConfiguration>
  <CloudFunctionConfiguration>
     <Id>optional-id-string</Id>
     <CloudFunction>cloud-function-arn</CloudFunction>
     <Event>event-type</Event>
     <Event>event-type</Event>
      ...
  </CloudFunctionConfiguration>
   ...
</NotificationConfiguration>
```

To remove all notifications configured on a bucket

To remove all notifications configured on a bucket, save an empty `<NotificationConfiguration/>` element in the *notification* subresource.

When Amazon S3 detects an event of the specific type, it publishes a message with the event information. For more information, see Event message structure.

For more information about configuring event notifications, see the following topics:

- Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue).
- Configuring event notifications using object key name filtering

Walkthrough: Configuring a bucket for notifications (SNS topic or SQS queue)

You can receive Amazon S3 notifications using Amazon Simple Notification Service (Amazon SNS) or Amazon Simple Queue Service (Amazon SQS). In this walkthrough, you add a notification configuration to your bucket using an Amazon SNS topic and an Amazon SQS queue.

> **Note**
>
> Amazon Simple Queue Service FIFO (First-In-First-Out) queues aren't supported as an Amazon S3 event notification destination. To send a notification for an Amazon S3 event to an Amazon SQS FIFO queue, you can use Amazon EventBridge. For more information, see Enabling Amazon EventBridge.

Topics

- Walkthrough summary
- Step 1: Create an Amazon SQS queue
- Step 2: Create an Amazon SNS topic
- Step 3: Add a notification configuration to your bucket
- Step 4: Test the setup

Walkthrough summary

This walkthrough helps you do the following:

- Publish events of the `s3:ObjectCreated:*` type to an Amazon SQS queue.
- Publish events of the `s3:ReducedRedundancyLostObject` type to an Amazon SNS topic.

For information about notification configuration, see Using Amazon SQS, Amazon SNS, and Lambda.

You can do all these steps using the console, without writing any code. In addition, code examples using AWS SDKs for Java and .NET are also provided to help you add notification configurations programmatically.

The procedure includes the following steps:

1. Create an Amazon SQS queue.

Using the Amazon SQS console, create an SQS queue. You can access any messages Amazon S3 sends to the queue programmatically. But, for this walkthrough, you verify notification messages in the console.

You attach an access policy to the queue to grant Amazon S3 permission to post messages.

2. Create an Amazon SNS topic.

   Using the Amazon SNS console, create an SNS topic and subscribe to the topic. That way, any events posted to it are delivered to you. You specify email as the communications protocol. After you create a topic, Amazon SNS sends an email. You use the link in the email to confirm the topic subscription.

   You attach an access policy to the topic to grant Amazon S3 permission to post messages.

3. Add notification configuration to a bucket.

Step 1: Create an Amazon SQS queue

Follow the steps to create and subscribe to an Amazon Simple Queue Service (Amazon SQS) queue.

1. Using the Amazon SQS console, create a queue. For instructions, see Getting Started with Amazon SQS in the *Amazon Simple Queue Service Developer Guide*.
2. Replace the access policy that's attached to the queue with the following policy.

   a. In the Amazon SQS console, in the **Queues** list, choose the queue name.

   b. On the **Access policy** tab, choose **Edit**.

   c. Replace the access policy that's attached to the queue. In it, provide your Amazon SQS ARN, source bucket name, and bucket owner account ID.

   JSON

```
{
    "Version": "2012-10-17",
    "Id": "example-ID",
    "Statement": [
        {
            "Sid": "example-statement-ID",
            "Effect": "Allow",
            "Principal": {
```

```
                "Service": "s3.amazonaws.com"
            },
            "Action": [
                "SQS:SendMessage"
            ],
            "Resource": "arn:aws:sqs:us-west-2:111122223333:s3-
notification-queue",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3:*:*:awsexamplebucket1"
                },
                "StringEquals": {
                    "aws:SourceAccount": "bucket-owner-account-id"
                }
            }
        }
    ]
}
```

d. Choose **Save**.

3. (Optional) If the Amazon SQS queue or the Amazon SNS topic is server-side encryption enabled with AWS Key Management Service (AWS KMS), add the following policy to the associated symmetric encryption customer managed key.

   You must add the policy to a customer managed key because you cannot modify the AWS managed key for Amazon SQS or Amazon SNS.

   JSON

```
{
    "Version": "2012-10-17",
    "Id": "example-ID",
    "Statement": [
        {
            "Sid": "example-statement-ID",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": [
                "kms:GenerateDataKey",
                "kms:Decrypt"
```

```
            ],
            "Resource": "*"
        }
    ]
}
```

For more information about using SSE for Amazon SQS and Amazon SNS with AWS KMS, see the following:

- Key management in the *Amazon Simple Notification Service Developer Guide*.
- Key management in the *Amazon Simple Queue Service Developer Guide*.

4. Note the queue ARN.

   The SQS queue that you created is another resource in your AWS account. It has a unique Amazon Resource Name (ARN). You need this ARN in the next step. The ARN is of the following format:

   ```
   arn:aws:sqs:aws-region:account-id:queue-name
   ```

Step 2: Create an Amazon SNS topic

Follow the steps to create and subscribe to an Amazon SNS topic.

1. Using Amazon SNS console, create a topic. For instructions, see Creating an Amazon SNS topic in the *Amazon Simple Notification Service Developer Guide*.
2. Subscribe to the topic. For this exercise, use email as the communications protocol. For instructions, see Subscribing to an Amazon SNS topic in the *Amazon Simple Notification Service Developer Guide*.

   You get an email requesting you to confirm your subscription to the topic. Confirm the subscription.
3. Replace the access policy attached to the topic with the following policy. In it, provide your SNS topic ARN, bucket name, and bucket owner's account ID.

JSON

```
```

4. Note the topic ARN.

   The SNS topic you created is another resource in your AWS account, and it has a unique ARN. You will need this ARN in the next step. The ARN will be of the following format:

   ```
   arn:aws:sns:aws-region:account-id:topic-name
   ```

Step 3: Add a notification configuration to your bucket

You can enable bucket notifications either by using the Amazon S3 console or programmatically by using AWS SDKs. Choose any one of the options to configure notifications on your bucket. This section provides code examples using the AWS SDKs for Java and .NET.

Option A: Enable notifications on a bucket using the console

Using the Amazon S3 console, add a notification configuration requesting Amazon S3 to do the following:

- Publish events of the **All object create events** type to your Amazon SQS queue.
- Publish events of the **Object in RRS lost** type to your Amazon SNS topic.

After you save the notification configuration, Amazon S3 posts a test message, which you get via email.

For instructions, see Enabling and configuring event notifications using the Amazon S3 console.

Option B: Enable notifications on a bucket using the AWS SDKs

.NET

The following C# code example provides a complete code listing that adds a notification configuration to a bucket. You must update the code and provide your bucket name and SNS topic ARN. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class EnableNotificationsTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string snsTopic = "*** SNS topic ARN ***";
        private const string sqsQueue = "*** SQS topic ARN ***";
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 client;

        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            EnableNotificationAsync().Wait();
        }

        static async Task EnableNotificationAsync()
        {
            try
            {
               PutBucketNotificationRequest request = new
 PutBucketNotificationRequest
                {
                    BucketName = bucketName
                };

                TopicConfiguration c = new TopicConfiguration
                {
                    Events = new List<EventType> { EventType.ObjectCreatedCopy },
                    Topic = snsTopic
                };
                request.TopicConfigurations = new List<TopicConfiguration>();
                request.TopicConfigurations.Add(c);
                request.QueueConfigurations = new List<QueueConfiguration>();
```

```
                request.QueueConfigurations.Add(new QueueConfiguration()
                {
                    Events = new List<EventType> { EventType.ObjectCreatedPut },
                    Queue = sqsQueue
                });

                PutBucketNotificationResponse response = await
 client.PutBucketNotificationAsync(request);
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered on server. Message:'{0}' ",
 e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown error encountered on server.
 Message:'{0}' ", e.Message);
            }
        }
    }
}
```

Java

For examples of how to configure bucket notifications with the AWS SDK for Java, see Process S3 event notifications in the *Amazon S3 API Reference*.

Step 4: Test the setup

Now, you can test the setup by uploading an object to your bucket and verifying the event notification in the Amazon SQS console. For instructions, see Receiving a Message in the *Amazon Simple Queue Service Developer Guide "Getting Started" section*.

Configuring event notifications using object key name filtering

When configuring an Amazon S3 event notification, you must specify which supported Amazon S3 event types cause Amazon S3 to send the notification. If an event type that you didn't specify occurs in your S3 bucket, Amazon S3 doesn't send the notification.

You can configure notifications to be filtered by the prefix and suffix of the key name of objects. For example, you can set up a configuration where you're sent a notification only when image files

with a "`.jpg`" file name extension are added to a bucket. Or, you can have a configuration that delivers a notification to an Amazon SNS topic when an object with the prefix "`images/`" is added to the bucket, while having notifications for objects with a "`logs/`" prefix in the same bucket delivered to an AWS Lambda function.

> **Note**
>
> A wildcard character ("*") can't be used in filters as a prefix or suffix. If your prefix or suffix contains a space, you must replace it with the "+" character. If you use any other special characters in the value of the prefix or suffix, you must enter them in URL-encoded (percent-encoded) format. For a complete list of special characters that must be converted to URL-encoded format when used in a prefix or suffix for event notifications, see Safe characters.

You can set up notification configurations that use object key name filtering in the Amazon S3 console. You can do so by using Amazon S3 APIs through the AWS SDKs or the REST APIs directly. For information about using the console UI to set a notification configuration on a bucket, see Enabling and configuring event notifications using the Amazon S3 console.

Amazon S3 stores the notification configuration as XML in the *notification* subresource associated with a bucket as described in Using Amazon SQS, Amazon SNS, and Lambda. You use the `Filter` XML structure to define the rules for notifications to be filtered by the prefix or suffix of an object key name. For information about the `Filter` XML structure, see PUT Bucket notification in the *Amazon Simple Storage Service API Reference*.

Notification configurations that use `Filter` cannot define filtering rules with overlapping prefixes, overlapping suffixes, or prefix and suffix overlapping. The following sections have examples of valid notification configurations with object key name filtering. They also contain examples of notification configurations that are not valid because of prefix and suffix overlapping.

Topics

- Examples of valid notification configurations with object key name filtering
- Examples of notification configurations with invalid prefix and suffix overlapping

Examples of valid notification configurations with object key name filtering

The following notification configuration contains a queue configuration identifying an Amazon SQS queue for Amazon S3 to publish events to of the `s3:ObjectCreated:Put` type. The events are published whenever an object that has a prefix of `images/` and a `jpg` suffix is PUT to a bucket.

```
<NotificationConfiguration>
  <QueueConfiguration>
      <Id>1</Id>
      <Filter>
          <S3Key>
              <FilterRule>
                  <Name>prefix</Name>
                  <Value>images/</Value>
              </FilterRule>
              <FilterRule>
                  <Name>suffix</Name>
                  <Value>jpg</Value>
              </FilterRule>
          </S3Key>
     </Filter>
     <Queue>arn:aws:sqs:us-west-2:444455556666:s3notificationqueue</Queue>
     <Event>s3:ObjectCreated:Put</Event>
  </QueueConfiguration>
</NotificationConfiguration>
```

The following notification configuration has multiple non-overlapping prefixes. The configuration defines that notifications for PUT requests in the `images/` folder go to queue-A, while notifications for PUT requests in the `logs/` folder go to queue-B.

```
<NotificationConfiguration>
  <QueueConfiguration>
     <Id>1</Id>
     <Filter>
            <S3Key>
                <FilterRule>
                    <Name>prefix</Name>
                    <Value>images/</Value>
                </FilterRule>
            </S3Key>
     </Filter>
     <Queue>arn:aws:sqs:us-west-2:444455556666:sqs-queue-A</Queue>
```

```
     <Event>s3:ObjectCreated:Put</Event>
  </QueueConfiguration>
  <QueueConfiguration>
     <Id>2</Id>
     <Filter>
            <S3Key>
                <FilterRule>
                    <Name>prefix</Name>
                    <Value>logs/</Value>
                </FilterRule>
            </S3Key>
     </Filter>
     <Queue>arn:aws:sqs:us-west-2:444455556666:sqs-queue-B</Queue>
     <Event>s3:ObjectCreated:Put</Event>
  </QueueConfiguration>
</NotificationConfiguration>
```

The following notification configuration has multiple non-overlapping suffixes. The configuration defines that all `.jpg` images newly added to the bucket are processed by Lambda cloud-function-A, and all newly added `.png` images are processed by cloud-function-B. The `.png` and `.jpg` suffixes aren't overlapping even though they have the same last letter. If a given string can end with both suffixes, the two suffixes are considered overlapping. A string can't end with both `.png` and `.jpg`, so the suffixes in the example configuration aren't overlapping suffixes.

```
<NotificationConfiguration>
  <CloudFunctionConfiguration>
     <Id>1</Id>
     <Filter>
            <S3Key>
                <FilterRule>
                    <Name>suffix</Name>
                    <Value>.jpg</Value>
                </FilterRule>
            </S3Key>
     </Filter>
     <CloudFunction>arn:aws:lambda:us-west-2:444455556666:cloud-function-A</
CloudFunction>
     <Event>s3:ObjectCreated:Put</Event>
  </CloudFunctionConfiguration>
  <CloudFunctionConfiguration>
     <Id>2</Id>
     <Filter>
```

```
            <S3Key>
                <FilterRule>
                    <Name>suffix</Name>
                    <Value>.png</Value>
                </FilterRule>
            </S3Key>
     </Filter>
     <CloudFunction>arn:aws:lambda:us-west-2:444455556666:cloud-function-B</
CloudFunction>
     <Event>s3:ObjectCreated:Put</Event>
  </CloudFunctionConfiguration>
</NotificationConfiguration>
```

Your notification configurations that use `Filter` can't define filtering rules with overlapping prefixes for the same event types. They can only do so, if the overlapping prefixes that are used with suffixes that don't overlap. The following example configuration shows how objects created with a common prefix but non-overlapping suffixes can be delivered to different destinations.

```
<NotificationConfiguration>
  <CloudFunctionConfiguration>
     <Id>1</Id>
     <Filter>
            <S3Key>
                <FilterRule>
                    <Name>prefix</Name>
                    <Value>images</Value>
                </FilterRule>
                <FilterRule>
                    <Name>suffix</Name>
                    <Value>.jpg</Value>
                </FilterRule>
            </S3Key>
     </Filter>
     <CloudFunction>arn:aws:lambda:us-west-2:444455556666:cloud-function-A</
CloudFunction>
     <Event>s3:ObjectCreated:Put</Event>
  </CloudFunctionConfiguration>
  <CloudFunctionConfiguration>
     <Id>2</Id>

Examples of notification configurations with invalid prefix and suffix overlapping

For the most part, your notification configurations that use `Filter` can't define filtering rules with overlapping prefixes, overlapping suffixes, or overlapping combinations of prefixes and suffixes for the same event types. You can have overlapping prefixes as long as the suffixes don't overlap. For an example, see Configuring event notifications using object key name filtering.

You can use overlapping object key name filters with different event types. For example, you can create a notification configuration that uses the prefix `image/` for the `ObjectCreated:Put` event type and the prefix `image/` for the `ObjectRemoved:*` event type.

You get an error if you try to save a notification configuration that has invalid overlapping name filters for the same event types when using the Amazon S3 console or API. This section shows examples of notification configurations that aren't valid because of overlapping name filters.

Any existing notification configuration rule is assumed to have a default prefix and suffix that match any other prefix and suffix, respectively. The following notification configuration isn't valid because it has overlapping prefixes. Specifically, the root prefix overlaps with any other prefix. The same thing is true if you use a suffix instead of a prefix in this example. The root suffix overlaps with any other suffix.

```
<NotificationConfiguration>
     <TopicConfiguration>
         <Topic>arn:aws:sns:us-west-2:444455556666:sns-notification-one</Topic>
         <Event>s3:ObjectCreated:*</Event>
    </TopicConfiguration>
    <TopicConfiguration>
```

```
        <Topic>arn:aws:sns:us-west-2:444455556666:sns-notification-two</Topic>
        <Event>s3:ObjectCreated:*</Event>
        <Filter>
            <S3Key>
                <FilterRule>
                    <Name>prefix</Name>
                    <Value>images</Value>
                </FilterRule>
           </S3Key>
        </Filter>
    </TopicConfiguration>
</NotificationConfiguration>
```

The following notification configuration isn't valid because it has overlapping suffixes. If a given string can end with both suffixes, the two suffixes are considered overlapping. A string can end with `jpg` and `pg`. So, the suffixes overlap. The same is true for prefixes. If a given string can begin with both prefixes, the two prefixes are considered overlapping.

            </S3Key>
        </Filter>
    </TopicConfiguration>
</NotificationConfiguration>
```

Event message structure

The notification message that Amazon S3 sends to publish an event is in the JSON format.

For a general overview and instructions on configuring event notifications, see Amazon S3 Event Notifications.

This example shows *version 2.2* of the event notification JSON structure. Amazon S3 uses *versions 2.1*, *2.2*, and *2.3* of this event structure. Amazon S3 uses version 2.2 for cross-Region replication event notifications. It uses version 2.3 for S3 Lifecycle, S3 Intelligent-Tiering, object ACL, object tagging, and object restoration delete events. These versions contain extra information specific to these operations. Versions 2.2 and 2.3 are otherwise compatible with version 2.1, which Amazon S3 currently uses for all other event notification types.

```
{
   "Records":[
      {
         "eventVersion":"2.2",
         "eventSource":"aws:s3",
         "awsRegion":"us-west-2",
         "eventTime":"The time, in ISO-8601 format, for example,
 1970-01-01T00:00:00.000Z, when Amazon S3 finished processing the request",
         "eventName":"event-type",
         "userIdentity":{
            "principalId":"Amazon-customer-ID-of-the-user-who-caused-the-event"
         },
         "requestParameters":{
            "sourceIPAddress":"ip-address-where-request-came-from"
         },
         "responseElements":{
            "x-amz-request-id":"Amazon S3 generated request ID",
            "x-amz-id-2":"Amazon S3 host that processed the request"
         },
         "s3":{
            "s3SchemaVersion":"1.0",
            "configurationId":"ID found in the bucket notification configuration",
            "bucket":{
               "name":"amzn-s3-demo-bucket",
               "ownerIdentity":{
                  "principalId":"Amazon-customer-ID-of-the-bucket-owner"
               },
               "arn":"bucket-ARN"
            },
            "object":{
               "key":"object-key",
               "size":"object-size in bytes",
               "eTag":"object eTag",
               "versionId":"object version if bucket is versioning-enabled, otherwise
 null",
```

```
                "sequencer": "a string representation of a hexadecimal value used to
 determine event sequence, only used with PUTs and DELETEs"
             }
          },
          "glacierEventData": {
             "restoreEventData": {
                "lifecycleRestorationExpiryTime": "The time, in ISO-8601 format, for
 example, 1970-01-01T00:00:00.000Z, of Restore Expiry",
                "lifecycleRestoreStorageClass": "Source storage class for restore"
             }
          }
       }
    ]
}
```

Note the following about the event message structure:

- The `eventVersion` key value contains a major and minor version in the form `<major>.<minor>`.

  The major version is incremented if Amazon S3 makes a change to the event structure that's not backward compatible. This includes removing a JSON field that's already present or changing how the contents of a field are represented (for example, a date format).

  The minor version is incremented if Amazon S3 adds new fields to the event structure. This might occur if new information is provided for some or all existing events. This might also occur if new information is provided on only newly introduced event types. Applications should ignore new fields to stay forward compatible with new minor versions of the event structure.

  If new event types are introduced but the structure of the event is otherwise unmodified, the event version doesn't change.

  To ensure that your applications can parse the event structure correctly, we recommend that you do an equal-to comparison on the major version number. To ensure that the fields that are expected by your application are present, we also recommend doing a greater-than-or-equal-to comparison on the minor version.
- The `eventName` references the list of event notification types but doesn't contain the `s3:` prefix.
- The `responseElements` key value is useful if you want to trace a request by following up with AWS Support. Both `x-amz-request-id` and `x-amz-id-2` help Amazon S3 trace an individual

request. These values are the same as those that Amazon S3 returns in the response to the request that initiates the events. This is so they can be used to match the event to the request.

- The `s3` key provides information about the bucket and object involved in the event. The object key name value is URL encoded. For example, "red flower.jpg" becomes "red+flower.jpg" (Amazon S3 returns "`application/x-www-form-urlencoded`" as the content type in the response).
- The `sequencer` key provides a way to determine the sequence of events. Event notifications aren't guaranteed to arrive in the same order that the events occurred. However, notifications from events that create objects (PUTs) and delete objects contain a `sequencer`. It can be used to determine the order of events for a given object key.

  If you compare the `sequencer` strings from two event notifications on the same object key, the event notification with the greater `sequencer` hexadecimal value is the event that occurred later. If you're using event notifications to maintain a separate database or index of your Amazon S3 objects, we recommend that you compare and store the `sequencer` values as you process each event notification.

  Note the following:

  - You can't use `sequencer` to determine order for events on different object keys.
  - The sequencers can be of different lengths. So, to compare these values, first left pad the shorter value with zeros, and then do a lexicographical comparison.
- The `glacierEventData` key is only visible for `s3:ObjectRestore:Completed` events.
- The `restoreEventData` key contains attributes that are related to your restore request.
- The `replicationEventData` key is only visible for replication events.
- The `intelligentTieringEventData` key is only visible for S3 Intelligent-Tiering events.
- The `lifecycleEventData` key is only visible for S3 Lifecycle transition events.

Example messages

The following are examples of Amazon S3 event notification messages.

Amazon S3 test message

After you configure an event notification on a bucket, Amazon S3 sends the following test message.

```
{
   "Service":"Amazon S3",
```

```
   "Event":"s3:TestEvent",
   "Time":"2014-10-13T15:57:02.089Z",
   "Bucket":"amzn-s3-demo-bucket",
   "RequestId":"5582815E1AEA5ADF",
   "HostId":"8cLeGAmw098X5cv4Zkwcmo8vvZa3eH3eKxsPzbB9wrR+YstdA6Knx4Ip8EXAMPLE"
}
```

> **Note**
>
> The `s3:TestEvent` message uses a different format than regular S3 event notifications. Unlike other event notifications that use the `Records` array structure shown above, the test event uses a simplified format with direct fields. When implementing event handling, ensure your code can distinguish between and properly handle both message formats.

Example message when an object is created using a PUT request

The following message is an example of a message Amazon S3 sends to publish an `s3:ObjectCreated:Put` event.

```
{
   "Records":[
      {
         "eventVersion":"2.1",
         "eventSource":"aws:s3",
         "awsRegion":"us-west-2",
         "eventTime":"1970-01-01T00:00:00.000Z",
         "eventName":"ObjectCreated:Put",
         "userIdentity":{
            "principalId":"AIDAJDPLRKLG7UEXAMPLE"
         },
         "requestParameters":{
            "sourceIPAddress":"127.0.0.1"
         },
         "responseElements":{
            "x-amz-request-id":"C3D13FE58DE4C810",
            "x-amz-id-2":"FMyUVURIY8/IgAtTv8xRjskZQpcIZ9KG4V5Wp6S7S/
JRWeUWerMUE5JgHvANOjpD"
         },
         "s3":{
            "s3SchemaVersion":"1.0",
            "configurationId":"testConfigRule",
```

```
            "bucket":{
               "name":"amzn-s3-demo-bucket",
               "ownerIdentity":{
                  "principalId":"A3NL1KOZZKExample"
               },
               "arn":"arn:aws:s3:::amzn-s3-demo-bucket"
            },
            "object":{
               "key":"HappyFace.jpg",
               "size":1024,
               "eTag":"d41d8cd98f00b204e9800998ecf8427e",
               "versionId":"096fKKXTRTtl3on89fVO.nfljtsv6qko",
               "sequencer":"0055AED6DCD90281E5"
            }
         }
      }
   ]
}
```

For a definition of each IAM identification prefix (for example, AIDA, AROA, AGPA), see IAM identifiers in the *IAM User Guide*.

Using EventBridge

Amazon S3 can send events to Amazon EventBridge whenever certain events happen in your bucket. Unlike other destinations, you don't need to select which event types you want to deliver. After EventBridge is enabled, all events below are sent to EventBridge. You can use EventBridge rules to route events to additional targets. The following lists the events Amazon S3 sends to EventBridge.

Event type	Description
Object Created	An object was created. The reason field in the event message structure indicates which S3 API was used to create the object: PutObject, POST Object, CopyObject, or CompleteMultipartUpload.
Object Deleted (DeleteObject) *Object Deleted (Lifecycle expiration)*	An object was deleted.

Event type	Description
	When an object is deleted using an S3 API call, the reason field is set to DeleteObject. When an object is deleted by an S3 Lifecycle expiration rule, the reason field is set to Lifecycle Expiration. For more information, see Expiring objects. When an unversioned object is deleted, or a versioned object is permanently deleted, the deletion-type field is set to Permanently Deleted. When a delete marker is created for a versioned object, the deletion-type field is set to Delete Marker Created. For more information, see Deleting object versions from a versioning-enabled bucket.
Object Restore Initiated	An object restore was initiated from S3 Glacier or S3 Glacier Deep Archive storage class or from S3 Intellige nt-Tiering Archive Access or Deep Archive Access tier. For more information, see Working with archived objects.
Object Restore Completed	An object restore was completed.
Object Restore Expired	The temporary copy of an object restored from S3 Glacier or S3 Glacier Deep Archive expired and was deleted.
Object Storage Class Changed	An object was transitioned to a different storage class. For more information, see Transitioning objects using Amazon S3 Lifecycle.
Object Access Tier Changed	An object was transitioned to the S3 Intelligent-Tiering Archive Access tier or Deep Archive Access tier. For more information, see Managing storage costs with Amazon S3 Intelligent-Tiering.
Object ACL Updated	An object's access control list (ACL) was set using PutObjectACL. An event is not generated when a request results in no change to an object's ACL. For more informati on, see Access control list (ACL) overview.

Event type	Description
Object Tags Added	A set of tags was added to an object using PutObject Tagging. For more information, see Categorizing your objects using tags.
Object Tags Deleted	All tags were removed from an object using DeleteObj ectTagging. For more information, see Categorizing your objects using tags.

> **Note**
>
> For more information about how Amazon S3 event types map to EventBridge event types, see Amazon EventBridge mapping and troubleshooting.

You can use Amazon S3 Event Notifications with EventBridge to write rules that take actions when an event occurs in your bucket. For example, you can have it send you a notification. For more information, see What is EventBridge in the *Amazon EventBridge User Guide*.

For more information about the actions and data types you can interact with using the EventBridge API, see the Amazon EventBridge API Reference in the *Amazon EventBridge API Reference*.

For information about pricing, see Amazon EventBridge pricing.

Topics

- Amazon EventBridge permissions
- Enabling Amazon EventBridge
- EventBridge event message structure
- Amazon EventBridge mapping and troubleshooting

Amazon EventBridge permissions

Amazon S3 does not require any additional permissions to deliver events to Amazon EventBridge.

Enabling Amazon EventBridge

You can enable Amazon EventBridge using the S3 console, AWS Command Line Interface (AWS CLI), or Amazon S3 REST API.

> **Note**
>
> After you enable EventBridge, it takes around five minutes for the changes to take effect.

Using the S3 console

To enable EventBridge event delivery in the S3 console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable events for.
4. Choose **Properties**.
5. Navigate to the **Event Notifications** section and find the **Amazon EventBridge** subsection. Choose **Edit**.
6. Under **Send notifications to Amazon EventBridge for all events in this bucket** choose **On**.

Using the AWS CLI

The following example creates a bucket notification configuration for bucket `amzn-s3-demo-bucket1` with Amazon EventBridge enabled.

```
aws s3api put-bucket-notification-configuration --bucket amzn-s3-demo-bucket1 --
notification-configuration='{ "EventBridgeConfiguration": {} }'
```

Using the REST API

You can programmatically enable Amazon EventBridge on a bucket by calling the Amazon S3 REST API. For more information, see see PutBucketNotificationConfiguration in the *Amazon Simple Storage Service API Reference*.

The following example shows the XML used to create a bucket notification configuration with Amazon EventBridge enabled.

```
<NotificationConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <EventBridgeConfiguration>
  </EventBridgeConfiguration>
</NotificationConfiguration>
```

Creating EventBridge rules

Once enabled you can create Amazon EventBridge rules for certain tasks. For example, you can send email notifications when an object is created. For a full tutorial, see Tutorial: Send a notification when an Amazon S3 object is created in the *Amazon EventBridge User Guide*.

EventBridge event message structure

The notification message that Amazon S3 sends to publish an event is in the JSON format. When Amazon S3 sends an event to Amazon EventBridge, the following fields are present.

- **version** — Currently 0 (zero) for all events.
- **id** — A UUID generated for every event.
- **detail-type** — The type of event that's being sent. See Using EventBridge for a list of event types.
- **source** — Identifies the service that generated the event.
- **account** — The 12-digit AWS account ID of the bucket owner.
- **time** — The time the event occurred.
- **region** — Identifies the AWS Region of the bucket.
- **resources** — A JSON array that contains the Amazon Resource Name (ARN) of the bucket.
- **detail** — A JSON object that contains information about the event. For more information about what can be included in this field, see Event message detail field.

Event message structure examples

The following are examples of some of the Amazon S3 event notification messages that can be sent to Amazon EventBridge.

Object created

```
{
  "version": "0",
```

```

Event message detail field

The detail field contains a JSON object with information about the event. The following fields may be present in the detail field.

- **version** — Currently 0 (zero) for all events.
- **bucket** — Information about the Amazon S3 bucket involved in the event.
- **object** — Information about the Amazon S3 object involved in the event.
- **request-id** — Request ID in S3 response.
- **requester** — AWS account ID or AWS service principal of requester.
- **source-ip-address** — Source IP address of S3 request. Only present for events triggered by an S3 request.
- **reason** — For **Object Created** events, the S3 API used to create the object: PutObject, POST Object, CopyObject, or CompleteMultipartUpload. For **Object Deleted** events, this is set to **DeleteObject** when an object is deleted by an S3 API call, or **Lifecycle Expiration** when an object is deleted by an S3 Lifecycle expiration rule. For more information, see Expiring objects.
- **deletion-type** — For **Object Deleted** events, when an unversioned object is deleted, or a versioned object is permanently deleted, this is set to **Permanently Deleted**. When a delete marker is created for a versioned object, this is set to **Delete Marker Created**. For more information, see Deleting object versions from a versioning-enabled bucket.

  > **Note**
  >
  > Some object attributes (such as `etag` and `size`) are present only when a delete marker is created.

- **restore-expiry-time** — For **Object Restore Completed** events, the time when the temporary copy of the object will be deleted from S3. For more information, see Working with archived objects.
- **source-storage-class** — For **Object Restore Initiated** and **Object Restore Completed** events, the storage class of the object being restored. For more information, see Working with archived objects.
- **destination-storage-class** — For **Object Storage Class Changed** events, the new storage class of the object. For more information, see Transitioning objects using Amazon S3 Lifecycle.
- **destination-access-tier** — For **Object Access Tier Changed** events, the new access tier of the object. For more information, see Managing storage costs with Amazon S3 Intelligent-Tiering.

Amazon EventBridge mapping and troubleshooting

The following table describes how Amazon S3 event types are mapped to Amazon EventBridge event types.

S3 event type	Amazon EventBridge detail type
ObjectCreated:Put ObjectCreated:Post ObjectCreated:Copy ObjectCreated:CompleteMultipartUpload	Object Created
ObjectRemoved:Delete ObjectRemoved:DeleteMarkerCreated LifecycleExpiration:Delete LifecycleExpiration:DeleteMarkerCreated	Object Deleted
ObjectRestore:Post	Object Restore Initiated
ObjectRestore:Completed	Object Restore Completed
ObjectRestore:Delete	Object Restore Expired
LifecycleTransition	Object Storage Class Changed
IntelligentTiering	Object Access Tier Changed
ObjectTagging:Put	Object Tags Added
ObjectTagging:Delete	Object Tags Deleted
ObjectAcl:Put	Object ACL Updated

Amazon EventBridge troubleshooting

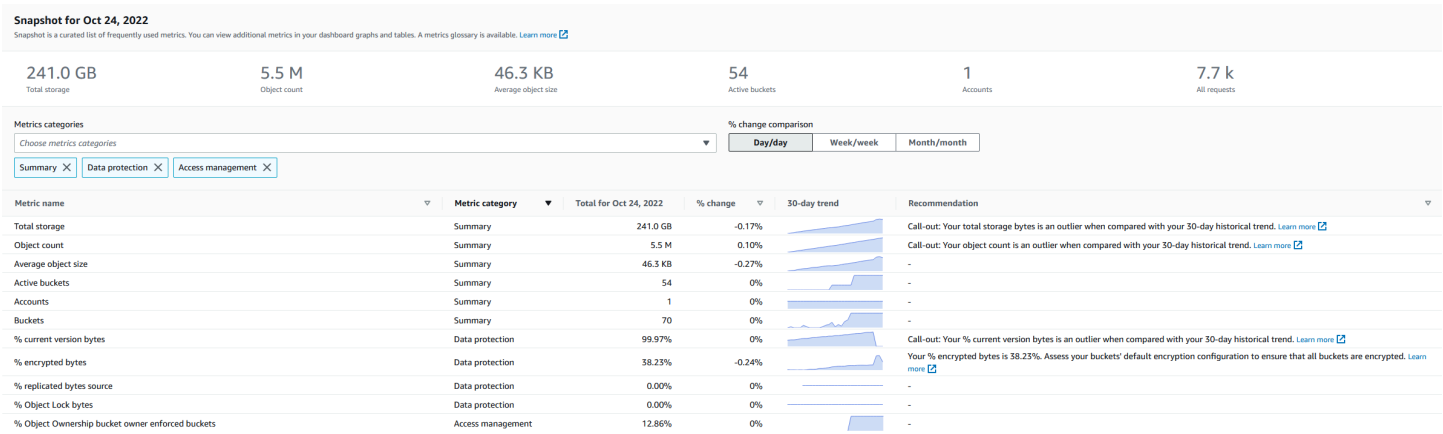
For information about how to troubleshoot EventBridge, see Troubleshooting Amazon EventBridge in the *Amazon EventBridge User Guide*.

Assessing your storage activity and usage with Amazon S3 Storage Lens

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object storage and activity. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

You can use S3 Storage Lens metrics to generate summary insights. For example, you can find out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and access-management best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules set up to expire incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket.



S3 Storage Lens metrics and features

S3 Storage Lens provides an interactive *default dashboard* that is updated daily. S3 Storage Lens preconfigures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. Metrics from this dashboard are also summarized in your account snapshot on the **Buckets** page. For more information, see Default dashboard.

To create other dashboards and scope them by AWS Regions, S3 buckets, or accounts (for AWS Organizations), you create an S3 Storage Lens dashboard configuration. You can create and manage S3 Storage Lens dashboard configurations by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API. When you create or edit an S3 Storage Lens dashboard, you define your dashboard scope and metrics selection.

S3 Storage Lens offers free metrics and advanced metrics and recommendations, which you can upgrade to for an additional charge. With advanced metrics and recommendations, you can access additional metrics and features for gaining insight into your storage. These features include advanced metric categories, prefix aggregation, contextual recommendations, and Amazon CloudWatch publishing. Prefix aggregation and contextual recommendations are available only in the Amazon S3 console. For information about S3 Storage Lens pricing, see Amazon S3 pricing.

Metrics categories

Within the free and advanced tiers, metrics are organized into categories that align with key use cases, such as cost optimization and data protection. Free metrics include summary, cost optimization, data protection, access management, performance, and event metrics. When you upgrade to advanced metrics and recommendations, you can enable advanced cost-optimization and data-protection metrics. You can use these advanced metrics to further reduce your S3 storage

costs and improve your data-protection stance. You can also enable activity metrics and detailed status-code metrics to improve the performance of application workloads that are accessing your S3 buckets. For more information about the free and advanced metrics categories, see Metrics selection.

You can assess your storage based on S3 best practices, such as analyzing the percentage of your buckets that have encryption or S3 Object Lock or S3 Versioning enabled. You can also identify potential cost-savings opportunities. For example, you can use S3 Lifecycle rule count metrics to identify buckets that are missing lifecycle expiration or transition rules. You can also analyze your request activity per bucket to find buckets where objects could be transitioned to a lower-cost storage class. For more information, see Amazon S3 Storage Lens metrics use cases.

Metrics export

Amazon CloudWatch publishing

You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. The CloudWatch publishing option is available for dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations. For more information about support for S3 Storage Lens metrics in CloudWatch, see Monitor S3 Storage Lens metrics in CloudWatch.

For more information about using S3 Storage Lens, see the following topics.

Understanding Amazon S3 Storage Lens

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket. You can create and manage S3 Storage Lens dashboards by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or Amazon S3 REST API.

S3 Storage Lens concepts and terminology

This section contains the terminology and concepts that are essential for successfully understanding and using Amazon S3 Storage Lens.

Topics

- Dashboard configuration
- Default dashboard
- Dashboards
- Account snapshot
- Metrics export
- Home Region
- Retention period
- Metrics categories
- Recommendations
- Metrics selection
- S3 Storage Lens and AWS Organizations

Dashboard configuration

S3 Storage Lens requires a dashboard configuration that contains the properties required to aggregate metrics on your behalf for a single dashboard or export. When you create a configuration, you choose the dashboard name and the home Region, which you can't change after you create the dashboard. You can optionally add tags and configure a metrics export in CSV or Parquet format.

In the dashboard configuration, you also define the dashboard scope and the metrics selection. The scope can include all the storage for your organization account or sections that are filtered by Region, bucket, and account. When you configure the metrics selection, you choose between free metrics and advanced metrics and recommendations, which you can upgrade to for an additional charge. With advanced metrics and recommendations, you can access additional metrics and features. These features include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing. For information about S3 Storage Lens pricing, see Amazon S3 pricing.

Default dashboard

The S3 Storage Lens default dashboard on the console is named **default-account-dashboard**. S3 preconfigures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. You can't modify the configuration scope of the default dashboard, but you can upgrade the metrics selection from free metrics to advanced metrics and recommendations. You can configure the optional metrics export or even disable the dashboard. However, you can't delete the default dashboard.

> **Note**
>
> If you disable your default dashboard, it is no longer updated. You'll no longer receive any new daily metrics in your S3 Storage Lens dashboard, your metrics export, or the account snapshot on the S3 **Buckets** page. If your dashboard uses advanced metrics and recommendations, you'll no longer be charged. You can still see historic data in the dashboard until the 14-day period for data queries expires. This period is 15 months if you've enabled advanced metrics and recommendations. To access historic data, you can re-enable the dashboard within the expiration period.

Dashboards

You can create additional S3 Storage Lens dashboards and scope them by AWS Regions, S3 buckets, or accounts (for AWS Organizations). When you create or edit a S3 Storage Lens dashboard, you define your dashboard scope and metrics selection. S3 Storage Lens offers free metrics and advanced metrics and recommendations, which you can upgrade to for an additional charge. With advanced metrics and recommendations, you can access additional metrics and features for gaining insight into your storage. These include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing. For information about S3 Storage Lens pricing, see Amazon S3 pricing.

You can also disable or delete dashboards. If you disable a dashboard, it is no longer updated, and you will no longer receive any new daily metrics. You can still see historic data until the 14-day expiration period. If you enabled advanced metrics and recommendations for that dashboard, this period is 15 months. To access historic data, you can re-enable the dashboard within the expiration period.

If you delete your dashboard, you lose all your dashboard configuration settings. You will no longer receive any new daily metrics, and you also lose access to the historical data associated with

that dashboard. If you want to access the historic data for a deleted dashboard, you must create another dashboard with the same name in the same home Region.

> **Note**
>
> - You can use S3 Storage Lens to create up to 50 dashboards per home Region.
> - Organization-level dashboards can be limited only to a Regional scope.

Account snapshot

The S3 Storage Lens **Account snapshot** summarizes metrics from your default dashboard and displays your total storage, object count, and average object size on the S3 console **Buckets** page. This account snapshot gives you quick access to insights about your storage without having to leave the **Buckets** page. The account snapshot also provides one-click access to your interactive S3 Storage Lens dashboard.

You can use your dashboard to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate insights at the organization, account, bucket, object, or prefix level. You can also send a once-daily metrics export to an S3 bucket in CSV or Parquet format.

You can't modify the dashboard scope of the **default-account dashboard** because it's linked to the **Account snapshot**. However, you can upgrade the metrics selection in your **default-account-dashboard** from free metrics to paid advanced metrics and recommendations. After upgrading, you can then display all requests, bytes uploaded, and bytes downloaded in the S3 Storage Lens **Account snapshot**.

> **Note**
>
> If you disable your default dashboard, your **Account snapshot** is no longer updated. To continue displaying metrics in the **Account snapshot**, you can re-enable the **default-account-dashboard**.

Metrics export

An S3 Storage Lens metrics export is a file that contains all the metrics identified in your S3 Storage Lens configuration. This information is generated daily in CSV or Parquet format and is sent to an S3 bucket. You can use the metrics export for further analysis by using the metrics tool of your choice. The S3 bucket for your metrics export must be in the same Region as your S3 Storage Lens configuration. You can generate an S3 Storage Lens metrics export from the S3 console by editing your dashboard configuration. You can also configure a metrics export by using the AWS CLI and AWS SDKs.

Home Region

The home Region is the AWS Region where all S3 Storage Lens metrics for a given dashboard configuration are stored. You must choose a home Region when you create your S3 Storage Lens dashboard configuration. After you choose a home Region, you can't change it. Also, if you're creating a Storage Lens group, we recommend that you choose the same home Region as your Storage Lens dashboard.

Note

You can choose one of the following Regions as your home Region:

- US East (N. Virginia) – `us-east-1`
- US East (Ohio) – `us-east-2`
- US West (N. California) – `us-west-1`
- US West (Oregon) – `us-west-2`
- Asia Pacific (Mumbai) – `ap-south-1`
- Asia Pacific (Seoul) – `ap-northeast-2`
- Asia Pacific (Singapore) – `ap-southeast-1`
- Asia Pacific (Sydney) – `ap-southeast-2`
- Asia Pacific (Tokyo) – `ap-northeast-1`
- Canada (Central) – `ca-central-1`
- China (Beijing) – `cn-north-1`
- China (Ningxia) – `cn-northwest-1`
- Europe (Frankfurt) – `eu-central-1`
- Europe (Ireland) – `eu-west-1`

- Europe (London) – `eu-west-2`
- Europe (Paris) – `eu-west-3`
- Europe (Stockholm) – `eu-north-1`
- South America (São Paulo) – `sa-east-1`

Retention period

S3 Storage Lens metrics are retained so that you can see historical trends and compare differences in your storage and activity over time. You can use Amazon S3 Storage Lens metrics for queries so that you can see historical trends and compare differences in your storage usage and activity over time.

All S3 Storage Lens metrics are retained for a period of 15 months. However, metrics are only available for queries for a specific duration, which depends on your metrics selection. This duration can't be modified. Free metrics are available for queries for a 14-day period, and advanced metrics are available for queries for a 15-month period.

Metrics categories

Within the free and advanced tiers, S3 Storage Lens metrics are organized into categories that align with key use cases, such as cost optimization and data protection. Free metrics include summary, cost optimization, data protection, access management, performance, and event metrics. When you upgrade to advanced metrics and recommendations, you can enable additional cost-optimization and data-protection metrics that you can use to further reduce your S3 storage costs and ensure your data is protected. You can also enable activity metrics and detailed status-code metrics that you can use to improve the performance of application workflows.

The following list shows all of the free and advanced metric categories. For a complete list of the individual metrics included in each category, see Metrics glossary.

Summary metrics

Summary metrics provide general insights about your S3 storage, including your total storage bytes and object count.

Cost-optimization metrics

Cost-optimization metrics provide insights that you can use to manage and optimize your storage costs. For example, you can identify buckets that have incomplete multipart uploads that are more than 7-days old.

With advanced metrics and recommendations, you can enable advanced cost-optimization metrics. These metrics include S3 Lifecycle rule count metrics that you can use to get per-bucket expiration and transition S3 Lifecycle rule counts.

Data-protection metrics

Data-protection metrics provide insights for data-protection features, such as encryption and S3 Versioning. You can use these metrics to identify buckets that are not following data-protection best practices. For example, you can identify buckets that are not using default encryption with AWS Key Management Service keys (SSE-KMS) or S3 Versioning.

With advanced metrics and recommendations, you can enable advanced data-protection metrics. These metrics include per-bucket replication rule count metrics.

Access-management metrics

Access-management metrics provide insights for S3 Object Ownership. You can use these metrics to see which Object Ownership settings your buckets use.

Event metrics

Event metrics provide insights for S3 Event Notifications. With event metrics, you can see which buckets have S3 Event Notifications configured.

Performance metrics

Performance metrics provide insights for S3 Transfer Acceleration. With performance metrics, you can see which buckets have Transfer Acceleration enabled.

Activity metrics (advanced)

If you upgrade your dashboard to **Advanced metrics and recommendations**, you can enable activity metrics. Activity metrics provide details about how your storage is requested (for example, All requests, Get requests, Put requests), Bytes uploaded or downloaded, and errors.

Prefix-level activity metrics can be used to help you determine which prefixes are being used infrequently, so that you can transition to a more optimal storage class using S3 Lifecycle.

Detailed status code metrics (advanced)

If you upgrade your dashboard to **Advanced metrics and recommendations**, you can enable detailed status code metrics. Detailed status code metrics provide insights for HTTP status codes, such as 403 Forbidden and 503 Service Unavailable, that you can use to troubleshoot access or performance issues. For example, you can look at the **403 Forbidden error count** metric to identify workloads that are accessing buckets without the correct permissions applied.

Prefix-level detailed status code metrics can be used to gain a better understanding of the HTTP status code occurrences by prefix. For example, 503 error count metrics enable you to identify prefixes receiving throttling requests during data ingestion.

Recommendations

S3 Storage Lens provides automated recommendations to help you optimize your storage. Recommendations are placed contextually alongside relevant metrics in the S3 Storage Lens dashboard. Historical data is not eligible for recommendations because recommendations are relevant to what is happening in the most recent period. Recommendations appear only when they are relevant.

S3 Storage Lens recommendations come in the following forms:

- **Suggestions**

  Suggestions alert you to trends within your storage and activity that might indicate a storage-cost optimization opportunity or a data-protection best practice. You can use the suggested topics in the *Amazon S3 User Guide* and the S3 Storage Lens dashboard to drill down for more details about the specific Regions, buckets, or prefixes.
- **Call-outs**

  Call-outs are recommendations that alert you to interesting anomalies within your storage and activity over a period that might need further attention or monitoring.
  - **Outlier call-outs**

    S3 Storage Lens provides call-outs for metrics that are outliers, based on your recent 30-day trend. The outlier is calculated by using a standard score, also known as a *z-score*. In this score, the current day's metric is subtracted from the average of the last 30 days for that metric. The current day's metric is then divided by the standard deviation for that metric over the last 30 days. The resulting score is usually between -3 and +3. This number represents the number of standard deviations that the current day's metric is from the mean.

S3 Storage Lens considers metrics with a score >2 or <-2 to be outliers because they are higher or lower than 95 percent of normally distributed data.

- **Significant change call-outs**

  The significant change call-out applies to metrics that are expected to change less frequently. Therefore, it is set to a higher sensitivity than the outlier calculation, which is typically in the range of +/- 20 percent versus the prior day, week, or month.

  Addressing call-outs in your storage and activity – If you receive a significant change call-out, it's not necessarily a problem. The call-out could be the result of an anticipated change in your storage. For example, you might have recently added a large number of new objects, deleted a large number of objects, or made similar planned changes.

  If you see a significant change call-out on your dashboard, take note of it and determine whether it can be explained by recent circumstances. If not, use the S3 Storage Lens dashboard to drill down for more details to understand the specific Regions, buckets, or prefixes that are driving the fluctuation.

- **Reminders**

  Reminders provide insights into how Amazon S3 works. They can help you learn more about ways to use S3 features to reduce storage costs or apply data-protection best practices.

Metrics selection

S3 Storage Lens offers two metrics selections that you can choose for your dashboard and export: *free metrics* and *advanced metrics and recommendations*.

- **Free metrics**

  S3 Storage Lens offers free metrics for all dashboards and configurations. Free metrics contain metrics that are relevant to your storage, such as the number of buckets and the objects in your account. Free metrics also include use-case based metrics (for example, cost-optimization and data-protection metrics) that you can use to investigate whether your storage is configured according to S3 best practices. All free metrics are collected daily. Data is available for queries for 14 days. For more information about which metrics are available with free metrics, see the Amazon S3 Storage Lens metrics glossary.

- **Advanced metrics and recommendations**

S3 Storage Lens offers free metrics for all dashboards and configurations with the option to upgrade to advanced metrics and recommendations. Additional charges apply. For more information, see Amazon S3 pricing.

Advanced metrics and recommendations include all the metrics in free metrics along with additional metrics, such as advanced data-protection and cost-optimization metrics, activity metrics, and detailed status-code metrics. Advanced metrics and recommendations also provide recommendations to help you optimize your storage. Recommendations are placed contextually alongside relevant metrics in the dashboard.

Advanced metrics and recommendations include the following features:

- **Advanced metrics** – Generate additional metrics. For a complete list of advanced metric categories, see Metrics categories. For a complete list of metrics, see the Amazon S3 Storage Lens metrics glossary.
- **Amazon CloudWatch publishing** – Publishes S3 Storage Lens metrics to CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch API operations and features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. For more information, see Monitor S3 Storage Lens metrics in CloudWatch.
- **Prefix aggregation** – Collects metrics at the prefix level. Note that metrics that are applicable at the prefix level are available with **Prefix aggregation**, except for bucket-level settings and rule count metrics. Prefix-level metrics are not published to CloudWatch.
- **Storage Lens group aggregation** – Collects metrics at the Storage Lens group level. After you enable **Advanced metrics and recommendations** and **Storage Lens group aggregation**, you can specify which Storage Lens groups to include or exclude from your Storage Lens dashboard. At least one Storage Lens group must be specified. Storage Lens groups that are specified must also reside within the designated home Region in the dashboard account. Storage Lens group-level metrics are not published to CloudWatch.

All advanced metrics are collected daily. Data is available for querying for up to 15 months. For more information about the storage metrics that are aggregated by S3 Storage Lens, see Amazon S3 Storage Lens metrics glossary.

> **Note**
>
> Recommendations are available only when you use the S3 Storage Lens dashboard on the Amazon S3 console.

S3 Storage Lens and AWS Organizations

AWS Organizations is an AWS service that helps you aggregate all of your AWS accounts under one organization hierarchy. Amazon S3 Storage Lens works with AWS Organizations to provide a single view of object storage and activity across your Amazon S3 storage.

For more information, see Using Amazon S3 Storage Lens with AWS Organizations.

- **Trusted access**

  Using your organization's management account, you must enable *trusted access* for S3 Storage Lens to aggregate storage metrics and usage data for all member accounts in your organization. You can then create dashboards or exports for your organization by using your management account or by giving delegated administrator access to other accounts in your organization.

  You can disable trusted access for S3 Storage Lens at any time, which stops S3 Storage Lens from aggregating metrics for your organization.

- **Delegated administrator**

  You can create dashboards and metrics for S3 Storage Lens for your organization by using your AWS Organizations management account, or by giving *delegated administrator* access to other accounts in your organization. You can deregister delegated administrators at any time. Deregistering a delegated administrator also automatically stops all organization-level dashboards created by that delegated administrator from aggregating new storage metrics.

For more information, see Amazon S3 Storage Lens and AWS Organizations in the *AWS Organizations User Guide*.

Amazon S3 Storage Lens service-linked roles

Along with AWS Organizations trusted access, Amazon S3 Storage Lens uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role

that is linked directly to S3 Storage Lens. Service-linked roles are predefined by S3 Storage Lens and include all the permissions that it requires to collect daily storage and activity metrics from member accounts in your organization.

For more information, see Using service-linked roles for Amazon S3 Storage Lens.

Amazon S3 Storage Lens metrics glossary

The Amazon S3 Storage Lens metrics glossary provides a complete list of free and advanced metrics for S3 Storage Lens.

S3 Storage Lens offers free metrics for all dashboards and configurations, with the option to upgrade to advanced metrics.

- **Free metrics** contain metrics that are relevant to your storage usage, such as the number of buckets and the objects in your account. Free metrics also include use-case based metrics, such as cost-optimization and data-protection metrics. All free metrics are collected daily, and data is available for queries for up to 14 days.
- **Advanced metrics and recommendations** include all the metrics in free metrics along with additional metrics, such as advanced data-protection and cost-optimization metrics. Advanced metrics also include additional metric categories, such as activity metrics and detailed status-code metrics. Advanced metrics data is available for queries for 15 months.

  There are additional charges when you use S3 Storage Lens with advanced metrics and recommendations. For more information, see Amazon S3 pricing. For more information about advanced metrics and recommendations features, see Metrics selection.

  > **Note**
  >
  > For Storage Lens groups, only free tier storage metrics are available. Advanced tier metrics are not available at the Storage Lens group level.

Metric names

The **Metric name** column in the following table provides the name of each S3 Storage Lens in the S3 console. The **CloudWatch and export** column provides the name of each metric in Amazon CloudWatch and the metrics export file that you can configure in your S3 Storage Lens dashboard.

Derived metric formulas

Derived metrics are not available for the metrics export and the CloudWatch publishing option. However, you can use the metrics formulas shown in the **Derived metrics formula** column to compute them.

Interpreting the Amazon S3 Storage Lens prefix symbols for metrics unit multiples (K, M, G, and so on)

S3 Storage Lens metrics unit multiples are written with prefix symbols. These prefix symbols match the International System of Units (SI) symbols that are standardized by the International Bureau of Weights and Measures (BIPM). These symbols are also used in the Unified Code for Units of Measure (UCUM). For more information, see List of SI prefix symbols.

Note

- The unit of measurement for S3 storage bytes is in binary gigabytes (GB), where 1 GB is 2^{30} bytes, 1 TB is 2^{40} bytes, and 1 PB is 2^{50} bytes. This unit of measurement is also known as a gibibyte (GiB), as defined by the International Electrotechnical Commission (IEC).
- When an object reaches the end of its lifetime based on its lifecycle configuration, Amazon S3 queues the object for removal and removes it asynchronously. Therefore, there might be a delay between the expiration date and the date when Amazon S3 removes an object. S3 Storage Lens doesn't include metrics for objects that have expired but haven't been removed. For more information about expiration actions in S3 Lifecycle, see Expiring objects.

The following table shows the S3 Storage Lens metrics glossary.

Metric name	CloudWatch and export	Description	Tier[1]	Cate	D	Deri metr form
Total storage	StorageBytes	The total storage, inclusive of incomplet e multipart uploads, object	Free	Sum	N	-

Metric name	CloudWatch and export	Description	Tier[1]	Cate	D	Deri metr form
		metadata, and delete markers				
Object count	ObjectCount	The total object count	Free	Sum	N	-
Average object size	-	The average object size	Free	Sum	Y	sum(StorageBytes)/ sum(ObjectCount)
Active buckets	-	The total number of buckets with storage > 0 bytes	Free	Sum	Y	-
Buckets	-	The total number of buckets	Free	Sum	Y	-
Accounts	-	The number of accounts whose storage is in scope	Free	Sum	Y	-
Current version bytes	CurrentVersionStorageBytes	The number of bytes that are a current version of an object	Free	Cost optimization	N	-
% current version bytes	-	The percentage of bytes in scope that are current versions of objects	Free	Cost optimization	Y	sum(CurrentVersionStorageBytes)/ sum(StorageBytes)

Metric name	CloudWatch and export	Description	Tier[1]	Cate	D	Deri metr form
Current version object count	CurrentVersionObjectCount	The count of current version objects	Free	Data prot n	N	-
% current version objects	-	The percentage of objects in scope that are a current version	Free	Cost opti ion	Y	sum(CurrentVersionObjectCount)/ sum(ObjectCount)
Noncurrent version bytes	NonCurrentVersionStorageBytes	The number of noncurrent version bytes	Free	Cost opti ion	N	-
% noncurrent version bytes	-	The percentage of bytes in scope that are noncurrent versions	Free	Cost opti ion	Y	sum(NonCurrentVersionStorageBytes)/ sum(StorageBytes)

[1] All free tier storage metrics are available at the Storage Lens group level. Advanced tier metrics are not available at the Storage Lens group level.

[2] Rule count metrics and bucket settings metrics aren't available at the prefix level.

Setting Amazon S3 Storage Lens permissions

Amazon S3 Storage Lens requires new permissions in AWS Identity and Access Management (IAM) to authorize access to S3 Storage Lens actions. To grant these permissions, you can use an identity-based IAM policy. You can attach this policy to IAM users, groups, or roles to grant them permissions. Such permissions can include the ability to enable or disable S3 Storage Lens, or to access any S3 Storage Lens dashboard or configuration.

The IAM user or role must belong to the account that created or owns the dashboard or configuration, unless both of the following conditions are true:

- Your account is a member of AWS Organizations.
- You were given access to create organization-level dashboards by your management account as a delegated administrator.

Note

- You can't use your account's root user credentials to view Amazon S3 Storage Lens dashboards. To access S3 Storage Lens dashboards, you must grant the required IAM

permissions to a new or existing IAM user. Then, sign in with those user credentials to access S3 Storage Lens dashboards. For more information, see Security best practices in IAM in the *IAM User Guide*.

- Using S3 Storage Lens on the Amazon S3 console can require multiple permissions. For example, to edit a dashboard on the console, you need the following permissions:
  - `s3:ListStorageLensConfigurations`
  - `s3:GetStorageLensConfiguration`
  - `s3:PutStorageLensConfiguration`

Topics

- Setting account permissions to use S3 Storage Lens
- Setting account permissions to use S3 Storage Lens groups
- Setting permissions to use S3 Storage Lens with AWS Organizations

Setting account permissions to use S3 Storage Lens

To create and manage S3 Storage Lens dashboards and Storage Lens dashboard configurations, you must have the following permissions, depending on which actions you want to perform:

The following table shows Amazon S3 Storage Lens related IAM permissions.

Action	IAM permissions

Create or update an S3 Storage Lens dashboard in the Amazon S3 console.	`s3:ListStorageLensConfigurations`
	`s3:GetStorageLensConfiguration`
	`s3:GetStorageLensConfigurationTagging`
	`s3:PutStorageLensConfiguration`
	`s3:PutStorageLensConfigurationTagging`

Action	IAM permissions
Get the tags of an S3 Storage Lens dashboard on the Amazon S3 console.	`s3:ListStorageLensConfigurations` `s3:GetStorageLensConfigurationTagging`

View an S3 Storage Lens dashboard on the Amazon S3 console.	`s3:ListStorageLensConfigurations`
	`s3:GetStorageLensConfiguration`
	`s3:GetStorageLensDashboard`

Delete an S3 Storage Lens dashboard on Amazon S3 console.	`s3:ListStorageLensConfigurations`
	`s3:GetStorageLensConfiguration`
	`s3:DeleteStorageLensConfiguration`

Create or update an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	`s3:PutStorageLensConfiguration` `s3:PutStorageLensConfigurationTagging`
Get the tags of an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	`s3:GetStorageLensConfigurationTagging`
View an S3 Storage Lens configuration by using the AWS CLI or an AWS SDK.	`s3:GetStorageLensConfiguration`
Delete an S3 Storage Lens configuration by using the AWS CLI or AWS SDK.	`s3:DeleteStorageLensConfiguration`

Note

- You can use resource tags in an IAM policy to manage permissions.
- An IAM user or role with these permissions can see metrics from buckets and prefixes that they might not have direct permission to read or list objects from.

- For S3 Storage Lens dashboards with prefix-level metrics enabled, if a selected prefix path matches with an object key, the dashboard might display the object key as another prefix.
- For metrics exports, which are stored in a bucket in your account, permissions are granted by using the existing `s3:GetObject` permission in the IAM policy. Similarly, for an AWS Organizations entity, the organization's management account or delegated administrator accounts can use IAM policies to manage access permissions for organization-level dashboard and configurations.

Setting account permissions to use S3 Storage Lens groups

You can use S3 Storage Lens groups to understand the distribution of your storage within buckets based on prefix, suffix, object tag, object size, or object age. You can attach Storage Lens groups to your dashboards to view their aggregated metrics.

To work with Storage Lens groups, you need certain permissions. For more information, see the section called “Storage Lens groups permissions”.

Setting permissions to use S3 Storage Lens with AWS Organizations

You can use Amazon S3 Storage Lens to collect storage metrics and usage data for all accounts that are part of your AWS Organizations hierarchy. The following table shows the actions and permissions related to using S3 Storage Lens with Organizations.

Action	IAM Permissions
Enable trusted access for S3 Storage Lens for your organization.	`organizations:EnableAWSServiceAccess`
Disable trusted access for S3 Storage Lens for your organization.	`organizations:DisableAWSServiceAccess`
Register a delegated administrator to create S3 Storage Lens dashboards or configurations for your organization.	`organizations:RegisterDelegatedAdministrator`

Action	IAM Permissions
Deregister a delegated administrator so that they can no longer create S3 Storage Lens dashboards or configurations for your organization.	`organizations:DeregisterDelegatedAdministrator`

Additional permissions to create S3 Storage Lens organization-wide configurations.	`organizations:DescribeOrganization`
	`organizations:ListAccounts`
	`organizations:ListAWSServiceAccessForOrganization`
	`organizations:ListDelegatedAdministrators`
	`iam:CreateServiceLinkedRole`

Working with Amazon S3 Storage Lens by using the console and API

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use S3 Storage Lens metrics to identify cost-optimization opportunities, implement data-protection and security best practices, and improve the performance of application workloads. For example, you can identify buckets that don't have S3 Lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. You can also identify buckets that aren't following data-protection best practices, such as using S3 Replication or S3 Versioning. S3 Storage Lens also analyzes metrics to deliver contextual recommendations that you can use to optimize storage costs and apply best practices for protecting your data.

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your

dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket.

The following sections contain examples of creating, updating, and viewing S3 Storage Lens configurations and performing operations related to the feature. If you are using S3 Storage Lens with AWS Organizations, these examples also cover those use cases. In the examples, replace any variable values with those that are specific to you.

Topics

- Create an Amazon S3 Storage Lens dashboard
- Update an Amazon S3 Storage Lens dashboard
- Disable an Amazon S3 Storage Lens dashboard
- Delete an Amazon S3 Storage Lens dashboard
- List Amazon S3 Storage Lens dashboards
- View an Amazon S3 Storage Lens dashboard configuration details
- Managing AWS resource tags with S3 Storage Lens
- Helper files for using Amazon S3 Storage Lens

Create an Amazon S3 Storage Lens dashboard

You can create additional S3 Storage Lens custom dashboards that can be scoped to your organization in AWS Organizations or to specific AWS Regions or buckets within an account.

> **Note**
>
> Any updates to your dashboard configuration can take up to 48 hours to accurately display or visualize.

Using the S3 console

Use the following steps to create an Amazon S3 Storage Lens dashboard on the Amazon S3 console.

Step 1: Define the dashboard scope

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to switch to.
3. In the left navigation pane, under **S3 Storage Lens**, choose **Dashboards**.
4. Choose **Create dashboard**.
5. On the **Dashboard** page, in the **General** section, do the following:

   a. View the **Home Region** for your dashboard. The home Region is the AWS Region where the configuration and metrics for this Storage Lens dashboard are stored.

   b. Enter a dashboard name.

      Dashboard names must be fewer than 65 characters and must not contain special characters or spaces.

      > **Note**
      >
      > You can't change this dashboard name after the dashboard is created.

   c. You can optionally choose to add **Tags** to your dashboard. You can use tags to manage permissions for your dashboard and track costs for S3 Storage Lens.

      For more information, see Controlling access using resource tags in the *IAM User Guide* and AWS-Generated Cost Allocation Tags in the *AWS Billing User Guide*.

      > **Note**
      >
      > You can add up to 50 tags to your dashboard configuration.

6. In the **Dashboard scope** section, do the following:

   a. Choose the Regions and buckets that you want S3 Storage Lens to include or exclude in the dashboard.

   b. Choose the buckets in your selected Regions that you want S3 Storage Lens to include or exclude. You can either include or exclude buckets, but not both. This option is not available when you create organization-level dashboards.

> **Note**
>
> - You can either include or exclude Regions and buckets. This option is limited to Regions only when creating organization-level dashboards across member accounts in your organization.
> - You can choose up to 50 buckets to include or exclude.

Step 2: Configure the metrics selection

1. In the **Metrics selection** section, choose the type of metrics that you want to aggregate for this dashboard.

   - To include free metrics aggregated at the bucket level and available for queries for 14 days, choose **Free metrics**.
   - To enable advanced metrics and other advanced options, choose **Advanced metrics and recommendations**. These options include advanced prefix aggregation, Amazon CloudWatch publishing, and contextual recommendations. Data is available for queries for 15 months. Advanced metrics and recommendations have an additional cost. For more information, see Amazon S3 pricing.

   For more information about advanced metrics and free metrics, see Metrics selection.

2. Under **Advanced metrics and recommendations features**, select the options that you want to enable:

   - **Advanced metrics**
   - **CloudWatch publishing**
   - **Prefix aggregation**

> **Important**
>
> If you enable prefix aggregation for your S3 Storage Lens configuration, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

3. If you enabled **Advanced metrics**, select the **Advanced metrics categories** that you want to display in your S3 Storage Lens dashboard:

   - **Activity metrics**
   - **Detailed status code metrics**
   - **Advanced cost optimization metrics**
   - **Advanced data protection metrics**

   For more information about metrics categories, see Metrics categories. For a complete list of metrics, see Amazon S3 Storage Lens metrics glossary.

4. If you chose to enable prefix aggregation, configure the following:

   a. Choose the minimum prefix threshold size for this dashboard.

      For example, a prefix threshold of 5 percent indicates that prefixes that make up 5 percent or more of the bucket's total storage size will be aggregated.

   b. Choose the prefix depth.

      This setting indicates the maximum number of levels up to which the prefixes are evaluated. The prefix depth must be less than 10.

   c. Enter a prefix delimiter character.

      This value is used to identify each prefix level. The default value in Amazon S3 is the `/` character, but your storage structure might use other delimiter characters.

(Optional) Step 3: Export metrics for the dashboard

1. In the **Metrics export** section, to create a metrics export that will be placed daily in a destination bucket of your choice, choose **Enable**.
2. If you enabled the metrics export, choose the output format of your daily metrics export: **CSV** or **Apache Parquet**.

   Parquet is an open source file format for Hadoop that stores nested data in a flat columnar format.

3. Choose the destination S3 bucket for your metrics export.
4. Choose the destination S3 bucket (format: `s3://`*`bucket-name`*`/`*`prefix`*).

The bucket must be in the home Region of your S3 Storage Lens dashboard. The S3 console shows you the **Destination bucket permission** that will be added by Amazon S3 to the destination bucket policy. Amazon S3 updates the bucket policy on the destination bucket to allow S3 to place data in that bucket.

5. (Optional) To enable server-side encryption for your metrics export, choose **Specify an encryption key**. Then, choose the **Encryption type**: **Amazon S3 managed keys (SSE-S3)** or **AWS Key Management Service key (SSE-KMS)**.

   You can choose between an Amazon S3 managed key (SSE-S3) and an AWS Key Management Service (AWS KMS) key (SSE-KMS).

6. (Optional) To specify an AWS KMS key, you must choose a KMS key or enter a key Amazon Resource Name (ARN).

   If you choose a customer managed key, you must grant S3 Storage Lens permission to encrypt in the AWS KMS key policy. For more information, see Using an AWS KMS key to encrypt your metrics exports.

7. Choose **Create dashboard**.

Using the AWS CLI

Example

The following example command creates a Amazon S3 Storage Lens configuration with tags. To use these examples, replace the *`user input placeholders`* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=111122223333 --
config-id=example-dashboard-configuration-id --region=us-east-1 --storage-lens-
configuration=file://./config.json --tags=file://./tags.json
```

Example

The following example command creates a Amazon S3 Storage Lens configuration without tags. To use these examples, replace the *`user input placeholders`* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=222222222222 --config-
id=your-configuration-id --region=us-east-1 --storage-lens-configuration=file://./
config.json
```

Using the AWS SDK for Java

Example – Create and update an Amazon S3 Storage Lens configuration

The following example creates and updates an Amazon S3 Storage Lens configuration in SDK for Java:

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.ActivityMetrics;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.CloudWatchMetrics;
import com.amazonaws.services.s3control.model.Format;
import com.amazonaws.services.s3control.model.Include;
import com.amazonaws.services.s3control.model.OutputSchemaVersion;
import com.amazonaws.services.s3control.model.PrefixLevel;
import com.amazonaws.services.s3control.model.PrefixLevelStorageMetrics;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.S3BucketDestination;
import com.amazonaws.services.s3control.model.SSES3;
import com.amazonaws.services.s3control.model.SelectionCriteria;
import com.amazonaws.services.s3control.model.StorageLensAwsOrg;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensDataExport;
import com.amazonaws.services.s3control.model.StorageLensDataExportEncryption;
import com.amazonaws.services.s3control.model.StorageLensTag;

import java.util.Arrays;
import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateAndUpdateDashboard {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";
        String exportAccountId = "Destination Account ID";
```

```
        String exportBucketArn = "arn:aws:s3:::destBucketName"; // The destination
 bucket for your metrics export must be in the same Region as your S3 Storage Lens
 configuration.
        String awsOrgARN = "arn:aws:organizations::123456789012:organization/o-
abcdefgh";
        Format exportFormat = Format.CSV;

        try {

        StorageLensDataExport dataExport = new StorageLensDataExport()
                .withCloudWatchMetrics(cloudWatchMetrics)
                .withS3BucketDestination(s3BucketDestination);

        StorageLensAwsOrg awsOrg = new StorageLensAwsOrg()
                .withArn(awsOrgARN);

        StorageLensConfiguration configuration = new StorageLensConfiguration()
                .withId(configurationId)
                .withAccountLevel(accountLevel)
                .withInclude(include)
                .withDataExport(dataExport)
                .withAwsOrg(awsOrg)
                .withIsEnabled(true);

        List<StorageLensTag> tags = Arrays.asList(
                new StorageLensTag().withKey("key-1").withValue("value-1"),
                new StorageLensTag().withKey("key-2").withValue("value-2")
        );

        AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(US_WEST_2)
                .build();

        s3ControlClient.putStorageLensConfiguration(new
PutStorageLensConfigurationRequest()
                .withAccountId(sourceAccountId)
                .withConfigId(configurationId)
                .withStorageLensConfiguration(configuration)
                .withTags(tags)
        );
    } catch (AmazonServiceException e) {
        // The call was transmitted successfully, but Amazon S3 couldn't process
        // it and returned an error response.
        e.printStackTrace();
```

```
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

To gain further visibility into your storage, you can create one or more S3 Storage Lens groups and attach them to your dashboard. An S3 Storage Lens group is a custom defined filter for objects based on prefixes, suffixes, object tags, object size, object age, or a combination of these filters.

You can use S3 Storage Lens groups to gain granular visibility into large shared buckets, such as data lakes, to make better-informed business decisions. For example, you can streamline storage allocation and optimize cost reporting by breaking down storage usage to specific groups of objects for individual projects and cost centers within a bucket or across multiple buckets.

To use S3 Storage Lens groups, you must upgrade your dashboard to use advanced metrics and recommendations. For more information about S3 Storage Lens groups, see the section called "Working with Storage Lens groups".

Update an Amazon S3 Storage Lens dashboard

The Amazon S3 Storage Lens default dashboard is `default-account-dashboard`. This dashboard is preconfigured by Amazon S3 to help you visualize summarized insights and trends for your entire account's aggregated free and advanced metrics on the console. You can't modify the default dashboard's configuration scope, but you can upgrade the metrics selection from the free metrics to the paid advanced metrics and recommendations, configure the optional metrics export, or even disable the default dashboard. The default dashboard can't be deleted, and can only be disabled. For more information, see Using the S3 console.

Using the S3 console

Use the following steps to update an Amazon S3 Storage Lens dashboard on the Amazon S3 console.

Step 1: Update the dashboard scope

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **Storage Lens, Dashboards**.
3. Choose the dashboard that you want to edit, and then choose **Edit**.

   The **Edit dashboard** page opens.

   > **Note**
   >
   > You can't change the following:
   >
   > - The dashboard name
   > - The home Region
   > - The dashboard scope of the default dashboard, which is scoped to your entire account's storage

4. (Optional) On the dashboard configuration page, in the **General** section, update and add tags to your dashboard.

   You can use tags to manage permissions for your dashboard and to track costs for S3 Storage Lens. For more information, see Controlling access using resource tags in the *IAM User Guide* and AWS-Generated Cost Allocation Tags in the *AWS Billing User Guide*.

   > **Note**
   >
   > You can add up to 50 tags to your dashboard configuration.

5. In the **Dashboard scope** section, do the following:

   a. Update the Regions and buckets that you want S3 Storage Lens to include or exclude in the dashboard.

      > **Note**
      >
      > - You can either include or exclude Regions and buckets. This option is limited to Regions only when creating organization-level dashboards across member accounts in your organization.
      > - You can choose up to 50 buckets to include or exclude.

b. Update the buckets in your selected Regions that you want S3 Storage Lens to include or exclude. You can either include or exclude buckets, but not both. This option is not present when creating organization-level dashboards.

Step 2: Update the metrics selection

1. In the **Metrics selection** section, choose the type of metrics that you want to aggregate for this dashboard.

   - To include free metrics aggregated at the bucket level and available for queries for 14 days, choose **Free metrics**.
   - To enable advanced metrics and other advanced options, choose **Advanced metrics and recommendations**. These options include advanced prefix aggregation, Amazon CloudWatch publishing, and contextual recommendations. Data is available for queries for 15 months. Advanced metrics and recommendations have an additional cost. For more information, see Amazon S3 pricing.

   For more information about advanced metrics and free metrics, see Metrics selection.

2. Under **Advanced metrics and recommendations features**, select the options that you want to enable:

   - **Advanced metrics**
   - **CloudWatch publishing**
   - **Prefix aggregation**

   > **Important**
   >
   > If you enable prefix aggregation for your S3 Storage Lens configuration, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

3. If you enabled **Advanced metrics**, select the **Advanced metrics categories** that you want to display in your S3 Storage Lens dashboard:

   - **Activity metrics**
   - **Detailed status code metrics**

- **Advanced cost optimization metrics**
- **Advanced data protection metrics**

For more information metrics categories, see Metrics categories. For a complete list of metrics, see Amazon S3 Storage Lens metrics glossary.

4. If you chose to enable prefix aggregation, configure the following:

   a. Choose the minimum prefix threshold size for this dashboard.

      For example, a prefix threshold of 5 percent indicates that prefixes that make up 5 percent or more of the bucket's total storage size will be aggregated.

   b. Choose the prefix depth.

      This setting indicates the maximum number of levels up to which the prefixes are evaluated. The prefix depth must be less than 10.

   c. Enter a prefix delimiter character.

      This is the value used to identify each prefix level. The default value in Amazon S3 is the `/` character, but your storage structure might use other delimiter characters.

(Optional) Step 3: Export metrics for the dashboard

1. In the **Metrics export** section, to create a metrics export that will be placed daily in a destination bucket of your choice, choose **Enable**. To disable the metrics export, choose **Disable**.

   The metrics export is in CSV or Apache Parquet format. It represents the same scope of data as your S3 Storage Lens dashboard data without the recommendations.

2. If enabled, choose the output format of your daily metrics export: **CSV** or **Apache Parquet**.

   Parquet is an open source file format for Hadoop that stores nested data in a flat columnar format.

3. Choose the destination S3 bucket for your metrics export.

   You can choose a bucket in the current account of the S3 Storage Lens dashboard. Or you can choose another AWS account if you have the destination bucket permissions and the destination bucket owner's account ID.

4. Choose the destination S3 bucket (format: `s3://bucket-name/prefix`).

   The bucket must be in the home Region of your S3 Storage Lens dashboard. The S3 console shows you the **Destination bucket permission** that will be added by Amazon S3 to the destination bucket policy. Amazon S3 updates the bucket policy on the destination bucket to allow S3 to place data in that bucket.

5. (Optional) To enable server-side encryption for your metrics export, choose **Specify an encryption key**. Then, choose the **Encryption type**: **Amazon S3 managed keys (SSE-S3)** or **AWS Key Management Service key (SSE-KMS)**.

   You can choose between an Amazon S3 managed key (SSE-S3) and an AWS Key Management Service (AWS KMS) key (SSE-KMS).

6. (Optional) To specify an AWS KMS key, you must choose a KMS key or enter a key Amazon Resource Name (ARN). Under **AWS KMS key**, specify your KMS key in one of the following ways:

   - To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose your **KMS key** from the list of available keys.

     Both the AWS managed key (`aws/s3`) and your customer managed keys appear in this list. For more information about customer managed keys, see Customer keys and AWS keys in the *AWS Key Management Service Developer Guide*.

     > **Note**
     >
     > The AWS managed key (`aws/S3`) is not supported for SSE-KMS encryption with S3 Storage Lens.

   - To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
   - To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

     If you choose a customer managed key, you must grant S3 Storage Lens permission to encrypt in the AWS KMS key policy. For more information, see Using an AWS KMS key to encrypt your metrics exports.

     For more information about creating an AWS KMS key, see Creating Keys in the *AWS Key Management Service Developer Guide*.

7. Choose **Save changes**.

To gain further visibility into your storage, you can create one or more S3 Storage Lens groups and attach them to your dashboard. An S3 Storage Lens group is a custom defined filter for objects based on prefixes, suffixes, object tags, object size, object age, or a combination of these filters.

You can use S3 Storage Lens groups to gain granular visibility into large shared buckets, such as data lakes, to make better-informed business decisions. For example, you can streamline storage allocation and optimize cost reporting by breaking down storage usage to specific groups of objects for individual projects and cost centers within a bucket or across multiple buckets.

To use S3 Storage Lens groups, you must upgrade your dashboard to use advanced metrics and recommendations. For more information about S3 Storage Lens groups, see the section called "Working with Storage Lens groups".

Using the AWS CLI

Example

The following example command updates a Amazon S3 Storage Lens dashboard configuration. To use these examples, replace the *`user input placeholders`* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=111122223333 --
config-id=example-dashboard-configuration-id --region=us-east-1 --storage-lens-
configuration=file://./config.json --tags=file://./tags.json
```

Using the AWS SDK for Java

Example – Update a Amazon S3 Storage Lens configuration with advanced metrics and recommendations

The following examples shows you how to update the default S3 Storage Lens configuration with advanced metrics and recommendations in SDK for Java:

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
```

```
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.ActivityMetrics;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.Format;
import com.amazonaws.services.s3control.model.Include;
import com.amazonaws.services.s3control.model.OutputSchemaVersion;
import com.amazonaws.services.s3control.model.PrefixLevel;
import com.amazonaws.services.s3control.model.PrefixLevelStorageMetrics;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.S3BucketDestination;
import com.amazonaws.services.s3control.model.SSES3;
import com.amazonaws.services.s3control.model.SelectionCriteria;
import com.amazonaws.services.s3control.model.StorageLensAwsOrg;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensDataExport;
import com.amazonaws.services.s3control.model.StorageLensDataExportEncryption;
import com.amazonaws.services.s3control.model.StorageLensTag;

import java.util.Arrays;
import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class UpdateDefaultConfigWithPaidFeatures {

    public static void main(String[] args) {
        String configurationId = "default-account-dashboard"; // This configuration ID
 cannot be modified.
        String sourceAccountId = "111122223333";

        try {
            SelectionCriteria selectionCriteria = new SelectionCriteria()
                    .withDelimiter("/")
                    .withMaxDepth(5)
                    .withMinStorageBytesPercentage(10.0);
            PrefixLevelStorageMetrics prefixStorageMetrics = new
 PrefixLevelStorageMetrics()
                    .withIsEnabled(true)
                    .withSelectionCriteria(selectionCriteria);
            BucketLevel bucketLevel = new BucketLevel()
                    .withActivityMetrics(new ActivityMetrics().withIsEnabled(true))
                    .withPrefixLevel(new
 PrefixLevel().withStorageMetrics(prefixStorageMetrics));
            AccountLevel accountLevel = new AccountLevel()
```

```
                    .withActivityMetrics(new ActivityMetrics().withIsEnabled(true))
                    .withBucketLevel(bucketLevel);

            StorageLensConfiguration configuration = new StorageLensConfiguration()
                    .withId(configurationId)
                    .withAccountLevel(accountLevel)
                    .withIsEnabled(true);

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            s3ControlClient.putStorageLensConfiguration(new
 PutStorageLensConfigurationRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
                    .withStorageLensConfiguration(configuration)
            );

        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Note

Additional charges apply for advanced metrics and recommendations. For more information, see advanced metrics and recommendations.

Disable an Amazon S3 Storage Lens dashboard

You can disable an Amazon S3 Storage Lens dashboard from the Amazon S3 console. Disabling a dashboard prevents it from generating metrics in the future. A disabled dashboard still retains its

configuration information, so that it can be easily resumed when re-enabled. A disabled dashboard retains its historical data until it's no longer available for queries.

Using the S3 console

Use the following steps to disable an Amazon S3 Storage Lens dashboard on the Amazon S3 console.

To disable an Amazon S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to disable, and then choose **Disable** at the top of the list.
4. On the confirmation page, confirm that you want to disable the dashboard by entering the name of dashboard in the text field, and then choose **Confirm**.

Delete an Amazon S3 Storage Lens dashboard

You can't delete the default dashboard. However, you can disable it. Before deleting a dashboard that you've created, consider the following:

- As an alternative to deleting a dashboard, you can *disable* the dashboard so that it is available to be re-enabled in the future. For more information, see Using the S3 console.
- Deleting the dashboard deletes all the configuration settings that are associated with it.
- Deleting a dashboard makes all the historic metrics data unavailable. This historical data is still retained for 15 months. If you want to access this data again, create a dashboard with the same name in the same home Region as the one that was deleted.

Using the S3 console

You can delete an Amazon S3 Storage Lens dashboard from the Amazon S3 console. However, deleting a dashboard prevents it from generating metrics in the future.

Deleting an Amazon S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to delete, and then choose **Delete** at the top of the list.
4. On the **Delete dashboards** page, confirm that you want to delete the dashboard by entering the name of dashboard in the text field. Then choose **Confirm**.

Using the AWS CLI

Example

The following example deletes a S3 Storage Lens configuration. To use these examples, replace the *`user input placeholders`* with your own information.

```
aws s3control delete-storage-lens-configuration --account-id=222222222222 --region=us-east-1 --config-id=your-configuration-id
```

Using the AWS SDK for Java

Example – Delete an Amazon S3 Storage Lens dashboard configuration

The following example shows you how to delete an S3 Storage Lens configuration using SDK for Java:

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.DeleteStorageLensConfigurationRequest;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class DeleteDashboard {
```

```
    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";
        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            s3ControlClient.deleteStorageLensConfiguration(new
 DeleteStorageLensConfigurationRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

List Amazon S3 Storage Lens dashboards

Using the S3 console

To list S3 Storage Lens dashboards

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**. You can now view the dashboards in your AWS account.

Using the AWS CLI

Example

The following example command lists the S3 Storage Lens dashboards in your AWS account. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control list-storage-lens-configurations --account-id=222222222222 --region=us-east-1 --next-token=abcdefghij1234
```

Example

The following example lists S3 Storage Lens configurations without a next token. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control list-storage-lens-configurations --account-id=222222222222 --region=us-east-1
```

Using the AWS SDK for Java

Example – List S3 Storage Lens dashboard configurations

The following examples shows you how to list S3 Storage Lens configurations in SDK for Java. To use this example, replace the *user input placeholders* with your own information." to each example description.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.ListStorageLensConfigurationEntry;
import com.amazonaws.services.s3control.model.ListStorageLensConfigurationsRequest;

import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class ListDashboard {
```

```
    public static void main(String[] args) {
        String sourceAccountId = "111122223333";
        String nextToken = "nextToken";

        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            final List<ListStorageLensConfigurationEntry> configurations =
                    s3ControlClient.listStorageLensConfigurations(new
 ListStorageLensConfigurationsRequest()
                            .withAccountId(sourceAccountId)
                            .withNextToken(nextToken)
                    ).getStorageLensConfigurationList();

            System.out.println(configurations.toString());
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

View an Amazon S3 Storage Lens dashboard configuration details

You can view a Amazon S3 Storage Lens dashboard from the Amazon S3 console, AWS CLI, and SDK for Java.

Using the S3 console

To view S3 Storage Lens dashboard configuration details

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. On the left navigation pane, navigate to **Storage Lens**.

3. Choose **Dashboards**.
4. From the **Dashboards** list, click on the dashboard that you want to view. You can now view the details of your Storage Lens dashboard.

Using the AWS CLI

Example

The following example retrieves an S3 Storage Lens configuration so that you can view the configuration details. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-configuration --account-id=222222222222 --config-
id=your-configuration-id --region=us-east-1
```

Using the AWS SDK for Java

Example – Retrieve and view an S3 Storage Lens configuration

The following example shows you how to retrieve an S3 Storage Lens configuration in SDK for Java so that you can view the configuration details. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.GetStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.GetStorageLensConfigurationResult;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class GetDashboard {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
```

```
        String sourceAccountId = "111122223333";

        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            final StorageLensConfiguration configuration =
                    s3ControlClient.getStorageLensConfiguration(new
 GetStorageLensConfigurationRequest()
                            .withAccountId(sourceAccountId)
                            .withConfigId(configurationId)
                    ).getStorageLensConfiguration();

            System.out.println(configuration.toString());
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Managing AWS resource tags with S3 Storage Lens

Each Amazon S3 Storage Lens dashboard is counted as an AWS resource with its own Amazon Resource Name (ARN). Therefore, when you configure your Storage Lens dashboard, you can optionally add AWS resource tags to the dashboard. You can add up to 50 tags for each Storage Lens dashboard. To create a Storage Lens dashboard with tags, you must have the following S3 Storage Lens permissions:

- `s3:ListStorageLensConfigurations`
- `s3:GetStorageLensConfiguration`
- `s3:GetStorageLensConfigurationTagging`
- `s3:PutStorageLensConfiguration`
- `s3:PutStorageLensConfigurationTagging`

You can use AWS resource tags to categorize resources according to department, line of business, or project. This is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific S3 Storage Lens dashboard based on the tags that you've assigned to it. You can also use tags to track and allocate costs.

In addition, when you add an AWS resource tag to your Storage Lens dashboard, you activate attribute-based access control (ABAC). ABAC is an authorization strategy that defines permissions based on attributes such as tags. You can also use conditions that specify resource tags in your IAM policies to control access to AWS resources.

You can edit tag keys and values, and you can remove tags from a resource at any time. Also, be aware of the following limitations:

- Tag keys and tag values are case sensitive.
- If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value.
- If you delete a resource, any tags for the resource are also deleted.
- Don't include private or sensitive data in your AWS resource tags.
- System tags (with tag keys that begin with `aws:`) aren't supported.
- The length of each tag key can't exceed 128 characters. The length of each tag value can't exceed 256 characters.

The following examples demonstrate how to use AWS resource tags with Storage Lens dashboard.

Topics

- Add AWS resource tags to a Storage Lens dashboard
- Retrieve AWS resource tags for a Storage Lens dashboard
- Updating Storage Lens dashboard tags
- Deleting AWS resource tags from a S3 Storage Lens dashboard

Add AWS resource tags to a Storage Lens dashboard

The following examples demonstrate how to add AWS resource tags to an S3 Storage Lens dashboard. You can add resource tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To add AWS resource tags to a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, navigate to **Storage Lens** on the left navigation panel.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard that you want to update. Then, choose **Edit**.
5. Under **General**, choose **Add tag**.
6. On the **Add tag** page, add the new key-value pair.

   > **Note**
   >
   > Adding a new tag with the same key as an existing tag overwrites the previous tag value.

7. (Optional) To add more than one new tag, choose **Add tag** again to continue adding new entries. You can add up to 50 AWS resource tags to your Storage Lens dashboard.
8. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
9. Choose **Save changes**.

Using the AWS CLI

Example

The following example command adds tags to a S3 Storage Lens dashboard configuration. To use these examples, replace the *`user input placeholders`* with your own information.

```
aws s3control put-storage-lens-configuration-tagging --account-id=222222222222 --
region=us-east-1 --config-id=your-configuration-id --tags=file://./tags.json
```

Using the AWS SDK for Java

The following example adds tags to an Amazon S3 Storage Lens configuration in SDK for Java. To use this example, replace the *`user input placeholders`* with your own information.

Example – Add tags to an S3 Storage Lens configuration

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import
 com.amazonaws.services.s3control.model.PutStorageLensConfigurationTaggingRequest;
import com.amazonaws.services.s3control.model.StorageLensTag;

import java.util.Arrays;
import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class PutDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";

        try {
            List<StorageLensTag> tags = Arrays.asList(
                    new StorageLensTag().withKey("key-1").withValue("value-1"),
                    new StorageLensTag().withKey("key-2").withValue("value-2")
            );

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            s3ControlClient.putStorageLensConfigurationTagging(new
 PutStorageLensConfigurationTaggingRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
                    .withTags(tags)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
```

```
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Retrieve AWS resource tags for a Storage Lens dashboard

The following examples demonstrate how to retrieve AWS resource tags for a S3 Storage Lens dashboard. You can get resource tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To retrieve the AWS resource tags for a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard configuration that you want to view. Then, choose **View dashboard configuration**.
5. Under **Tags**, review the tags associated with the dashboard.
6. (Optional) If you want to add a new tag, choose **Edit**. Then, choose **Add tag**. On the **Add tag** page, add the new key-value pair.

   > **Note**
   >
   > Adding a new tag with the same key as an existing tag overwrites the previous tag value.

7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
8. Choose **Save changes**.

Using the AWS CLI

Example

The following example command retrieves tags for a S3 Storage Lens dashboard configuration. To use these examples, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-configuration-tagging --account-id=222222222222 --
region=us-east-1 --config-id=your-configuration-id --tags=file://./tags.json
```

Using the AWS SDK for Java

Example – Get tags for an S3 Storage Lens dashboard configuration

The following example shows you how to retrieve tags for an S3 Storage Lens dashboard configuration in SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.DeleteStorageLensConfigurationRequest;
import
 com.amazonaws.services.s3control.model.GetStorageLensConfigurationTaggingRequest;
import com.amazonaws.services.s3control.model.StorageLensTag;

import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class GetDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";
        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
```

```
                    .withRegion(US_WEST_2)
                    .build();

            final List<StorageLensTag> s3Tags = s3ControlClient
                    .getStorageLensConfigurationTagging(new
 GetStorageLensConfigurationTaggingRequest()
                            .withAccountId(sourceAccountId)
                            .withConfigId(configurationId)
                    ).getTags();

            System.out.println(s3Tags.toString());
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Updating Storage Lens dashboard tags

The following examples demonstrate how to update Storage Lens dashboard tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To update an AWS resource tag for a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard configuration that you want to view. Then, choose **View dashboard configuration**.
5. Under **Tags**, review the tags associated with the dashboard.
6. (Optional) If you want to add a new tag, choose **Edit**. Then, choose **Add tag**. On the **Add tag** page, add the new key-value pair.

> **Note**
>
> Adding a new tag with the same key as an existing tag overwrites the previous tag value.

7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
8. Choose **Save changes**.

Using the AWS CLI

Example

The following example command adds or replaces tags on an existing Amazon S3 Storage Lens dashboard configuration. To use these examples, replace the *`user input placeholders`* with your own information.

```
aws s3control put-storage-lens-configuration-tagging --account-id=111122223333 --
config-id=example-dashboard-configuration-id --region=us-east-1 --config-id=your-
configuration-id
```

Using the AWS SDK for Java

The following AWS SDK for Java example updates the AWS resource tags on an existing Storage Lens dashboard. To use this example, replace the *`user input placeholders`* with your own information.

Example – Update tags on an existing Storage Lens dashboard configuration

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import
 com.amazonaws.services.s3control.model.PutStorageLensConfigurationTaggingRequest;
import com.amazonaws.services.s3control.model.StorageLensTag;
```

```
import java.util.Arrays;
import java.util.List;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class PutDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";

        try {
            List<StorageLensTag> tags = Arrays.asList(
                    new StorageLensTag().withKey("key-1").withValue("value-1"),
                    new StorageLensTag().withKey("key-2").withValue("value-2")
            );

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            s3ControlClient.putStorageLensConfigurationTagging(new
 PutStorageLensConfigurationTaggingRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
                    .withTags(tags)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Deleting AWS resource tags from a S3 Storage Lens dashboard

The following examples demonstrate how to delete AWS resource tags from an existing Storage Lens dashboard. You can delete tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To delete AWS resource tags from an existing Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, navigate to **Storage Lens**.
3. Choose **Dashboards**.
4. Choose the radio button for the Storage Lens dashboard configuration that you want to view. Then, choose **View dashboard configuration**.
5. Under **Tags**, review the tags associated with the dashboard.
6. Choose **Remove** next to the tag that you want to remove.
7. Choose **Save changes**.

Using the AWS CLI

The following AWS CLI command deletes AWS resource tags from an existing Storage Lens dashboard. To use this example command, replace the *`user input placeholders`* with your own information.

Example

```
aws s3control delete-storage-lens-configuration-tagging --account-id=222222222222 --
config-id=your-configuration-id --region=us-east-1
```

Using the AWS SDK for Java

The following AWS SDK for Java example deletes an AWS resource tag from the Storage Lens dashboard using the Amazon Resource Name (ARN) that you specify in account *`111122223333`*. To use this example, replace the *`user input placeholders`* with your own information.

Example – Delete tags for an S3 Storage Lens dashboard configuration

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import
 com.amazonaws.services.s3control.model.DeleteStorageLensConfigurationTaggingRequest;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class DeleteDashboardTagging {

    public static void main(String[] args) {
        String configurationId = "ConfigurationId";
        String sourceAccountId = "111122223333";
        try {
            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            s3ControlClient.deleteStorageLensConfigurationTagging(new
 DeleteStorageLensConfigurationTaggingRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Helper files for using Amazon S3 Storage Lens

Use the following JSON files and its key inputs for your examples.

S3 Storage Lens example configuration in JSON

Example `config.json`

The `config.json` file contains the details of a S3 Storage Lens Organizations-level *advanced metrics and recommendations* configuration. To use the following example, replace the *`user input placeholders`* with your own information.

> **Note**
>
> Additional charges apply for advanced metrics and recommendations. For more information, see advanced metrics and recommendations.

```
{

S3 Storage Lens example configuration with Storage Lens groups in JSON

Example `config.json`

The `config.json` file contains the details that you want to apply to your Storage Lens configuration when using Storage Lens groups. To use the example, replace the *`user input placeholders`* with your own information.

To attach all Storage Lens groups to your dashboard, update your Storage Lens configuration with the following syntax:

```
{
  "Id": "ExampleS3StorageLensConfiguration",
  "AccountLevel": {
    "ActivityMetrics": {
      "IsEnabled":true
    },
    "AdvancedCostOptimizationMetrics": {
      "IsEnabled":true
    },
    "AdvancedDataProtectionMetrics": {
      "IsEnabled":true
    },
    "BucketLevel": {
      "ActivityMetrics": {
      "IsEnabled":true
      },
    "StorageLensGroupLevel": {},
  "IsEnabled": true
}
```

To include only two Storage Lens groups in your Storage Lens dashboard configuration (*`slg-1`* and *`slg-2`*), use the following syntax:

```
{
  "Id": "ExampleS3StorageLensConfiguration",
  "AccountLevel": {
```

```
    "ActivityMetrics": {
      "IsEnabled":true
    },
    "AdvancedCostOptimizationMetrics": {
      "IsEnabled":true
    },
    "AdvancedDataProtectionMetrics": {
      "IsEnabled":true
    },
    "BucketLevel": {
      "ActivityMetrics": {
      "IsEnabled":true
      },
   "StorageLensGroupLevel": {
        "SelectionCriteria": {
            "Include": [
                "arn:aws:s3:us-east-1:111122223333:storage-lens-group/slg-1",
                "arn:aws:s3:us-east-1:444455556666:storage-lens-group/slg-2"
            ]
    },
  "IsEnabled": true
}
```

To exclude only certain Storage Lens groups from being attached to your dashboard configuration, use the following syntax:

```
{
  "Id": "ExampleS3StorageLensConfiguration",
  "AccountLevel": {
    "ActivityMetrics": {
      "IsEnabled":true
    },
    "AdvancedCostOptimizationMetrics": {
      "IsEnabled":true
    },
    "AdvancedDataProtectionMetrics": {
      "IsEnabled":true
    },
    "BucketLevel": {
      "ActivityMetrics": {
      "IsEnabled":true
      },
   "StorageLensGroupLevel": {
```

```
        "SelectionCriteria": {
            "Exclude": [
                "arn:aws:s3:us-east-1:111122223333:storage-lens-group/slg-1",
                "arn:aws:s3:us-east-1:444455556666:storage-lens-group/slg-2"
            ]
    },
  "IsEnabled": true
}
```

S3 Storage Lens example tags configuration in JSON

Example `tags.json`

The `tags.json` file contains the tags that you want to apply to your S3 Storage Lens configuration. To use this example, replace the *`user input placeholders`* with your own information.

```
[
    {
        "Key": "key1",
        "Value": "value1"
    },
    {
        "Key": "key2",
        "Value": "value2"
    }
]
```

S3 Storage Lens example configuration IAM permissions

Example `permissions.json` – Specific dashboard name

This example policy shows an S3 Storage Lens IAM `permissions.json` file with a specific dashboard name specified. Replace *`value1`*, *`us-east-1`*, *`your-dashboard-name`*, and *`example-account-id`* with your own values.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetStorageLensConfiguration",
                "s3:DeleteStorageLensConfiguration",
                "s3:PutStorageLensConfiguration"
            ],
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/key1": "value1"
                }
            },
            "Resource": "arn:aws:s3:us-east-1:111122223333:storage-lens/your-
dashboard-name"
        }
    ]
}
```

Example `permissions.json` – No specific dashboard name

This example policy shows an S3 Storage Lens IAM `permissions.json` file without a specific dashboard name specified. Replace *value1*, *us-east-1*, and *example-account-id* with your own values.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetStorageLensConfiguration",
                "s3:DeleteStorageLensConfiguration",
                "s3:PutStorageLensConfiguration"
            ],
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/key1": "value1"
                }
            },
```

```
            "Resource": "arn:aws:s3:us-east-1:111122223333:storage-lens/*"
        }
    ]
}
```

Viewing metrics with Amazon S3 Storage Lens

S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket.

By default, all dashboards are configured with free metrics, which include metrics that you can use to understand usage and activity across your S3 storage, optimize your storage costs, and implement data-protection and access-management best practices. Free metrics are aggregated down to the bucket level. With free metrics, data is available for queries for up to 14 days.

Advanced metrics and recommendations include the following additional features that you can use to gain further insight into usage and activity across your storage and best practices for optimizing your storage:

- Contextual recommendations (available only in the dashboard)
- Advanced metrics (including activity metrics aggregated by bucket)
- Prefix aggregation
- Storage Lens group aggregation
- Storage Lens group aggregation
- Amazon CloudWatch publishing

Advanced metrics data is available for queries for 15 months. There are additional charges for using S3 Storage Lens with advanced metrics. For more information, see Amazon S3 pricing. For more information about free and advanced metrics, see Metrics selection.

Topics

- Viewing S3 Storage Lens metrics on the dashboards
- Viewing Amazon S3 Storage Lens metrics using a data export
- Monitor S3 Storage Lens metrics in CloudWatch
- Amazon S3 Storage Lens metrics use cases

Viewing S3 Storage Lens metrics on the dashboards

In the Amazon S3 console, S3 Storage Lens provides an interactive default dashboard that you can use to visualize insights and trends in your data. You can also use this dashboard to flag outliers and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate insights at the account, bucket, AWS Region, prefix, or Storage Lens group level. If you've enabled S3 Storage Lens to work with AWS Organizations, you can also generate insights at the organization level (such as data for all accounts that are part of your AWS Organizations hierarchy). The dashboard always loads for the latest date that has metrics available.

The S3 Storage Lens default dashboard on the console is named **default-account-dashboard**. Amazon S3 pre-configures this dashboard to visualize the summarized insights and trends for your entire account and updates them daily in the S3 console. You can't modify the configuration scope of the default dashboard, but you can upgrade the metrics selection from the free metrics to the paid advanced metrics and recommendations. With advanced metrics and recommendations, you can access additional metrics and features. These features include advanced metric categories, prefix-level aggregation, contextual recommendations, and Amazon CloudWatch publishing.

You can disable the default dashboard, but you can't delete it. If you disable your default dashboard, it is no longer updated. You also will no longer receive any new daily metrics in S3 Storage Lens or in the **Account snapshot** section on the **Buckets** page. You can still see historic data in the default dashboard until the 14-day period for data queries expires. This period is 15 months if you've enabled advanced metrics and recommendations. To access this data, you can re-enable the default dashboard within the expiration period.

You can create additional S3 Storage Lens dashboards and scope them by AWS Regions, S3 buckets, or accounts. You can also scope your dashboards by organization if you've enabled Storage Lens to work with AWS Organizations. When you create or edit an S3 Storage Lens dashboard, you define your dashboard scope and metrics selection.

You can disable or delete any additional dashboards that you create.

- If you disable a dashboard, it is no longer updated, and you will no longer receive any new daily metrics. You can still see historic data for free metrics until the 14-day expiration period. If you enabled advanced metrics and recommendations for that dashboard, this period is 15 months. To access this data, you can re-enable the dashboard within the expiration period.
- If you delete your dashboard, you lose all your dashboard configuration settings. You will no longer receive any new daily metrics, and you also lose access to the historical data associated with that dashboard. If you want to access the historic data for a deleted dashboard, you must create another dashboard with the same name in the same home Region.

- Understanding your S3 Storage Lens dashboard

Viewing an Amazon S3 Storage Lens dashboard

The following procedure shows how to view an S3 Storage Lens dashboard in the S3 console. For use-case based walkthroughs that show how to use your dashboard to optimize costs, implement best practices, and improve the performance of applications that access your S3 buckets, see Amazon S3 Storage Lens metrics use cases.

> **Note**
>
> You can't use your account's root user credentials to view Amazon S3 Storage Lens dashboards. To access S3 Storage Lens dashboards, you must grant the required AWS Identity and Access Management (IAM) permissions to a new or existing IAM user. Then, sign in with those user credentials to access S3 Storage Lens dashboards. For more information, see Setting Amazon S3 Storage Lens permissions and Security best practices in IAM in the *IAM User Guide*.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.

Your dashboard opens in S3 Storage Lens. The **Snapshot for *date*** section shows the latest date that S3 Storage Lens has collected metrics for. Your dashboard always loads the latest date that has metrics available.

4. (Optional) To change the date for your S3 Storage Lens dashboard, in the top-right date selector, choose a new date.
5. (Optional) To apply temporary filters to further limit the scope of your dashboard data, do the following:

   a. Expand the **Filters** section.

   b. To filter by specific accounts, AWS Regions, storage classes, buckets, prefixes, or Storage Lens groups, choose the options to filter by.

   > **Note**
   >
   > The **Prefixes** filter and the **Storage Lens groups** filter can't be applied at the same time.

   c. To update a filter, choose **Apply**.

   d. To remove a filter, click on the **X** next to the filter.
6. In any section in your S3 Storage Lens dashboard, to see data for a specific metric, for **Metric**, choose the metric name.
7. In any chart or visualization in your S3 Storage Lens dashboard, you can drill down into deeper levels of aggregation by using the **Accounts**, **AWS Regions**, **Storage classes**, **Buckets**, **Prefixes**, or **Storage Lens groups** tabs. For an example, see Uncover cold Amazon S3 buckets.

Understanding your S3 Storage Lens dashboard

Your S3 Storage Lens dashboard has a primary **Overview** tab, and up to five additional tabs that represent each aggregation level:

- **Accounts**
- **AWS Regions**
- **Storage classes**
- **Buckets**
- **Prefixes**

- **Storage Lens groups**

On the **Overview** tab, your dashboard data is aggregated into three different sections: **Snapshot for *date***, **Trends and distributions**, and **Top N overview**.

For more information about your S3 Storage Lens dashboard, see the following sections.

Snapshot

The **Snapshot for *date*** section shows summary metrics that S3 Storage Lens has aggregated for the date selected. These summary metrics include the following metrics:

- **Total storage** – The total amount of storage used in bytes.
- **Object count** – The total number of objects in your AWS account.
- **Average object size** – The average object size.
- **Active buckets** – The total number of active buckets in active usage with storage > 0 bytes in your account.
- **Accounts** – The number of accounts whose storage is in scope. This value is **1** unless you are using AWS Organizations and your S3 Storage Lens has trusted access with a valid service-linked role. For more information, see Using service-linked roles for Amazon S3 Storage Lens.
- **Buckets** – The total number of buckets in your account.

Metric data

For each metric that appears in the snapshot, you can see the following data:

- **Metric name** – The name of the metric.
- **Metric category** – The category that the metric is organized into.
- **Total for *date*** – The total count for the date selected.
- **% change** – The percentage change from the last snapshot date.
- **30-day trend** – A trend-line showing the changes for the metric over a 30-day period.
- **Recommendation** – A contextual recommendation based on the data that's provided in the snapshot. Recommendations are available with advanced metrics and recommendations. For more information, see Recommendations.

Metrics categories

You can optionally update your dashboard **Snapshot for *date*** section to display metrics for other categories. If you want to see snapshot data for additional metrics, you can choose from the following **Metrics categories**:

- **Cost optimization**
- **Data protection**
- **Activity** (available with advanced metrics)
- **Access management**
- **Performance**
- **Events**

The **Snapshot for *date*** section displays only a selection of metrics for each category. To see all metrics for a specific category, choose the metric in the **Trends and distributions** or **Top N overview** sections. For more information about metric categories, see Metrics categories. For a complete list of S3 Storage Lens metrics, see Amazon S3 Storage Lens metrics glossary.

Trends and distributions

The second section of the **Overview** tab is **Trends and distributions**. In the **Trends and distributions** section, you can choose two metrics to compare over a date range that you define. The **Trends and distributions** section shows the relationship between two metrics over time. This section displays charts that you can use to see the **Storage class** and **Region** distribution between the two trends that you are tracking. You can optionally drill down into a data point in one of the charts for deeper analysis.

For a walkthrough that uses the **Trends and distributions** section, see Identify buckets that don't use server-side encryption with AWS KMS for default encryption (SSE-KMS).

Top N overview

The third section of the S3 Storage Lens dashboard is **Top N overview** (sorted in ascending or descending order). This section displays your selected metrics across the top number of accounts, AWS Regions, buckets, prefixes, or Storage Lens groups. If you enabled S3 Storage Lens to work with AWS Organizations, you can also see your selected metrics across your organization.

For a walkthrough that uses the **Top N overview** section, see Identify your largest S3 buckets.

Drill down and analyze by options

To provide a fluid experience for analysis, the S3 Storage Lens dashboard provides an action menu, which appears when you choose any chart value. To use this menu, choose any chart value to see the associated metrics values, and then choose from two options in the box that appears:

- The **Drill down** action applies the selected value as a filter across all tabs of your dashboard. You can then drill down into that value for deeper analysis.
- The **Analyze by** action takes you to the **Dimension** tab that you select and applies that tab value as a filter. These tabs include **Accounts**, **AWS Regions**, **Storage classes**, **Buckets**, **Prefixes** (for dashboards that have **Advanced metrics** and **Prefix aggregation** enabled), and **Storage Lens groups** (for dashboards that have **Advanced metrics** and **Storage Lens group aggregation** enabled). With **Analyze by**, you can view the data in the context of the new dimension for deeper analysis.

The **Drill down** and **Analyze by** actions might be disabled if the outcome would yield illogical results or would not have any value. Both the **Drill down** and **Analyze by** actions apply filters on top of any existing filters across all tabs of the dashboard. You can also remove the filters as needed.

Tabs

The dimension-level tabs provide a detailed view of all values within a particular dimension. For example, the **AWS Regions** tab shows metrics for all AWS Regions, and the **Buckets** tab shows metrics for all buckets. Each dimension tab contains an identical layout consisting of four sections:

- A trend chart that displays your top *N* items within the dimension over the last 30 days for the selected metric. By default, this chart displays the top 10 items, but you can decrease it to at least 3 items or increase it up to 50 items.
- A histogram chart that shows a vertical bar chart for the selected date and metric. If you have a large number of items to display in this chart, you might need to scroll horizontally.
- A bubble analysis chart that plots all items within the dimension. This chart represents the first metric on the x axis and the second metric on the y axis. The third metric is represented by the size of the bubble.
- A metric grid view that contains each item in the dimension listed in rows. The columns represent each available metric, arranged in metrics category tabs for easier navigation.

Viewing Amazon S3 Storage Lens metrics using a data export

Amazon S3 Storage Lens metrics are generated daily in CSV or Apache Parquet-formatted metrics export files and placed in an S3 bucket in your account. From there, you can ingest the metrics export into the analytics tools of your choice, such as Amazon QuickSight and Amazon Athena, where you can analyze storage usage and activity trends.

Topics

- Using an AWS KMS key to encrypt your metrics exports
- What is an S3 Storage Lens export manifest?
- Understanding the Amazon S3 Storage Lens export schema

Using an AWS KMS key to encrypt your metrics exports

To grant Amazon S3 Storage Lens permission to encrypt your metrics exports by using a customer managed key, you must use a key policy. To update your key policy so that you can use a KMS key to encrypt your S3 Storage Lens metrics exports, follow these steps.

To grant S3 Storage Lens permissions to encrypt data by using your KMS key

1. Sign into the AWS Management Console by using the AWS account that owns the customer managed key.
2. Open the AWS KMS console at https://console.aws.amazon.com/kms.
3. To change the AWS Region, use the **Region selector** in the upper-right corner of the page.
4. In the left navigation pane, choose **Customer managed keys**.
5. Under **Customer managed keys**, choose the key that you want to use to encrypt the metrics exports. AWS KMS keys are Region-specific and must be in the same Region as the metrics export destination S3 bucket.
6. Under **Key policy**, choose **Switch to policy view**.
7. To update the key policy, choose **Edit**.
8. Under **Edit key policy**, add the following key policy to the existing key policy. To use this policy, replace the *`user input placeholders`* with your information.

```
{
    "Sid": "Allow Amazon S3 Storage Lens use of the KMS key",
     "Effect": "Allow",
```

```
    "Principal": {
        "Service": "storage-lens.s3.amazonaws.com"
    },
    "Action": [
        "kms:GenerateDataKey"
    ],
    "Resource": "*",
    "Condition": {
       "StringEquals": {
           "aws:SourceArn": "arn:aws:s3:us-east-1:source-account-id:storage-
lens/your-dashboard-name",
           "aws:SourceAccount": "source-account-id"
        }
     }
}
```

9. Choose **Save changes**.

For more information about creating customer managed keys and using key policies, see the following topics in the *AWS Key Management Service Developer Guide*:

- Getting started
- Using key policies in AWS KMS

You can also use the AWS KMS PUT key policy API operation (PutKeyPolicy) to copy the key policy to the customer managed keys that you want to use to encrypt the metrics exports by using the REST API, AWS CLI, and SDKs.

What is an S3 Storage Lens export manifest?

Given the large amount of data aggregated, an S3 Storage Lens daily metrics export can be split into multiple files. The manifest file `manifest.json` describes where the metrics export files for that day are located. Whenever a new export is delivered, it is accompanied by a new manifest. Each manifest contained in the `manifest.json` file provides metadata and other basic information about the export.

The manifest information includes the following properties:

- `sourceAccountId` – The account ID of the configuration owner.
- `configId` – A unique identifier for the dashboard.

- `destinationBucket` – The destination bucket Amazon Resource Name (ARN) that the metrics export is placed in.
- `reportVersion` – The version of the export.
- `reportDate` – The date of the report.
- `reportFormat` – The format of the report.
- `reportSchema` – The schema of the report.
- `reportFiles` – The actual list of the export report files that are in the destination bucket.

The following is an example of a manifest in a `manifest.json` file for a CSV-formatted export.

```
{
   "sourceAccountId":"123456789012",
   "configId":"my-dashboard-configuration-id",
   "destinationBucket":"arn:aws:s3:::amzn-s3-demo-destination-bucket",
   "reportVersion":"V_1",
   "reportDate":"2020-11-03",
   "reportFormat":"CSV",

 "reportSchema":"version_number,configuration_id,report_date,aws_account_number,aws_region,stor
   "reportFiles":[
        {
            "key":"DestinationPrefix/StorageLens/123456789012/my-dashboard-
configuration-id/V_1/reports/dt=2020-11-03/a38f6bc4-2e3d-4355-ac8a-e2fdcf3de158.csv",
            "size":1603959,
            "md5Checksum":"2177e775870def72b8d84febe1ad3574"
        }
      ]
}
```

The following is an example of a manifest in a `manifest.json` file for a Parquet-formatted export.

```
{
   "sourceAccountId":"123456789012",
   "configId":"my-dashboard-configuration-id",
   "destinationBucket":"arn:aws:s3:::amzn-s3-demo-destination-bucket",
   "reportVersion":"V_1",
   "reportDate":"2020-11-03",
   "reportFormat":"Parquet",
```

```
   "reportSchema":"message s3.storage.lens { required string version_number;
 required string configuration_id; required string report_date; required string
 aws_account_number; required string aws_region; required string storage_class;
 required string record_type; required string record_value; required string
 bucket_name; required string metric_name; required long metric_value; }",
   "reportFiles":[
      {
         "key":"DestinationPrefix/StorageLens/123456789012/my-dashboard-configuration-

```

You can configure your metrics export to be generated as part of your dashboard configuration in the Amazon S3 console or by using the Amazon S3 REST API, AWS CLI, and SDKs.

Understanding the Amazon S3 Storage Lens export schema

The following table contains the schema of your S3 Storage Lens metrics export.

Attribute name	Data type	Column name	Description
`VersionNumber`	String	`version_number`	The version of the S3 Storage Lens metrics being used.
`ConfigurationId`	String	`configuration_id`	The `configuration_id` of your S3 Storage Lens configuration.
`ReportDate`	String	`report_date`	The date that the metrics were tracked.
`AwsAccountNumber`	String	`aws_account_number`	Your AWS account number.
`AwsRegion`	String	`aws_region`	The AWS Region for which the metrics are being tracked.

Attribute name	Data type	Column name	Description
StorageClass	String	storage_class	The storage class of the bucket in question.
RecordType	ENUM	record_type	The type of artifact that is being reported (ACCOUNT, BUCKET, or PREFIX).
RecordValue	String	record_value	The value of the RecordType artifact. **Note** The record_value is URL-encoded.
BucketName	String	bucket_name	The name of the bucket that is being reported.
MetricName	String	metric_name	The name of the metric that is being reported.
MetricValue	Long	metric_value	The value of the metric that is being reported.

Example of an S3 Storage Lens metrics export

The following is an example of an S3 Storage Lens metrics export based on this schema.

> **Note**
>
> You can identify metrics for Storage Lens groups by looking for the `STORAGE_LENS_GROUP_BUCKET` or `STORAGE_LENS_GROUP_ACCOUNT` values in the `record_type` column. The `record_value` column will display the Amazon Resource Name (ARN) for the Storage Lens group, for example, `arn:aws:s3:us-east-1:123456789012:storage-lens-group/slg-1`.

version_r	configuration_id	report_date	aws_account_number	aws_region	storage_class	record_type	record_value	bucket_name	metric_name	metric_value

Monitor S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the Amazon CloudWatch User Guide.

You can enable the CloudWatch publishing option for new or existing dashboard configurations by using the Amazon S3 console, Amazon S3 REST API, AWS CLI, and AWS SDKs. Dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations can use the CloudWatch publishing option. For S3 Storage Lens advanced metrics and recommendations pricing, see Amazon S3 pricing. No additional CloudWatch metrics publishing charges apply; however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply. For more information, see Amazon CloudWatch pricing.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

> **Note**
>
> S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

After you enable the CloudWatch publishing option, you can use the following CloudWatch features to monitor and analyze your S3 Storage LensStorage Lens data:

- Dashboards – Use CloudWatch dashboards to create customized S3 Storage Lens dashboards. Share your CloudWatch dashboard with people who don't have direct access to your AWS account, across teams, with stakeholders, and with people external to your organizations.

- Alarms and triggered actions – Configure alarms that watch metrics and take action when a threshold is breached. For example, you can configure an alarm that sends an Amazon SNS notification when the **Incomplete Multipart Upload Bytes** metric exceeds 1 GB for three consecutive days.
- Anomaly detection – Enable anomaly detection to continuously analyze metrics, determine normal baselines, and surface anomalies. You can create an anomaly detection alarm based on the expected value of a metric. For example, you can monitor anomalies for the **Object Lock Enabled Bytes** metric to detect unauthorized removal of Object Lock settings.
- Metric math – You can also use metric math to query multiple S3 Storage Lens metrics and use math expressions to create new time series based on these metrics. For example, you can create a new metric to get the average object size by dividing `StorageBytes` by `ObjectCount`.

For more information about the CloudWatch publishing option for S3 Storage Lens metrics, see the following topics.

- Enabling CloudWatch publishing for S3 Storage Lens
- Working with S3 Storage Lens metrics in CloudWatch

S3 Storage Lens metrics and dimensions

To send S3 Storage Lens metrics to CloudWatch, you must enable the CloudWatch publishing option within S3 Storage Lens advanced metrics and recommendations. After advanced metrics are enabled, you can use CloudWatch dashboards to monitor S3 Storage Lens metrics alongside other application metrics and create a unified view of your operational health. You can use dimensions to filter your S3 Storage Lens metrics in CloudWatch by organization, account, bucket, storage class, Region, and metrics configuration ID.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

Note

S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.

For more information about S3 Storage Lens metrics and dimensions in CloudWatch, see the following topics.

Topics

- Metrics
- Dimensions

Metrics

S3 Storage Lens metrics are available as metrics within CloudWatch. S3 Storage Lens metrics are published to the `AWS/S3/Storage-Lens` namespace. This namespace is only for S3 Storage Lens metrics. Amazon S3 bucket, request, and replication metrics are published to the `AWS/S3` namespace.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

In S3 Storage Lens, metrics are aggregated and stored only in the designated home Region. S3 Storage Lens metrics are also published to CloudWatch in the home Region that you specify in the S3 Storage Lens configuration.

For a complete list of S3 Storage Lens metrics, including a list of those metrics available in CloudWatch, see Amazon S3 Storage Lens metrics glossary.

> **Note**
>
> The valid statistic for S3 Storage Lens metrics in CloudWatch is Average. For more information about statistics in CloudWatch, see CloudWatch statistics definitions in the *Amazon CloudWatch User Guide*.

Granularity of S3 Storage Lens metrics in CloudWatch

S3 Storage Lens offers metrics at organization, account, bucket, and prefix granularity. S3 Storage Lens publishes organization, account, and bucket-level S3 Storage Lens metrics to CloudWatch. Prefix-level S3 Storage Lens metrics are not available in CloudWatch.

For more information about the granularity of S3 Storage Lens metrics available in CloudWatch, see the following list:

- **Organization** – Metrics aggregated across the member accounts in your organization. S3 Storage Lens publishes metrics for member accounts to CloudWatch in the management account.
  - **Organization and account** – Metrics for the member accounts in your organization.
  - **Organization and bucket** – Metrics for Amazon S3 buckets in the member accounts of your organization.
- **Account** (Non-organization level) – Metrics aggregated across the buckets in your account.
- **Bucket** (Non-organization level) – Metrics for a specific bucket. In CloudWatch, S3 Storage Lens publishes these metrics to the AWS account that created the S3 Storage Lens configuration. S3 Storage Lens publishes these metrics only for non-organization configurations.

Dimensions

When S3 Storage Lens sends data to CloudWatch, dimensions are attached to each metric. Dimensions are categories that describe the characteristics of metrics. You can use dimensions to filter the results that CloudWatch returns.

For example, all S3 Storage Lens metrics in CloudWatch have the `configuration_id` dimension. You can use this dimension to differentiate between metrics associated with a specific S3 Storage Lens configuration. The `organization_id` identifies organization-level metrics. For more information about dimensions in CloudWatch, see Dimensions in the *CloudWatch User Guide*.

Different dimensions are available for S3 Storage Lens metrics depending on the granularity of the metrics. For example, you can use the `organization_id` dimension to filter organization-level metrics by the AWS Organizations ID. However, you can't use this dimension for bucket and account-level metrics. For more information, see Filtering metrics using dimensions.

To see which dimensions are available for your S3 Storage Lens configuration, see the following table.

Dimension	Description	Bucket	Account	Organization	Organization and account	Organization and bucket
`configuration_id`	The dashboard name for the S3 Storage Lens configuration reported in the metrics					
`metrics_version`	The version of the S3 Storage Lens metrics. The metrics version has a fixed value of `1.0`.					
`organization_id`	The AWS Organizations ID for the metrics					
`aws_account_number`	The AWS account that's associated with the metrics					
`aws_region`	The AWS Region for the metrics					
`bucket_name`	The name of the S3 bucket that's reported in the metrics					
`storage_class`	The storage class for the bucket that's reported in the metrics					
`record_type`	The granularity of the metrics: ORGANIZATION, ACCOUNT, BUCKET	BUCKET	ACCOUNT	ORGANIZATION		

Enabling CloudWatch publishing for S3 Storage Lens

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the Amazon CloudWatch User Guide.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

You can enable CloudWatch support for new or existing dashboard configurations by using the S3 console, Amazon S3 REST APIs, AWS CLI, and AWS SDKs. The CloudWatch publishing option is available for dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations. For S3 Storage Lens advanced metrics and recommendations pricing, see Amazon S3 pricing. No additional CloudWatch metrics publishing charges apply; however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply.

To enable the CloudWatch publishing option for S3 Storage Lens metrics, see the following topics.

> **Note**
>
> S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.
>
> Currently, S3 Storage Lens metrics cannot be consumed through CloudWatch streams.

Using the S3 console

When you update an S3 Storage Lens dashboard, you can't change the dashboard name or home Region. You also can't change the scope of the default dashboard, which is scoped to your entire account's storage.

To update an S3 Storage Lens dashboard to enable CloudWatch publishing

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **S3 Storage Lens**, **Dashboards**.
3. Choose the dashboard that you want to edit, and then choose **Edit.**
4. Under **Metrics selection**, choose **Advanced metrics and recommendations**.

   Advanced metrics and recommendations are available for an additional charge. Advanced metrics and recommendations include a 15-month period for data queries, usage metrics aggregated at the prefix level, activity metrics aggregated by bucket, the CloudWatch publishing option, and contextual recommendations that help you optimize storage costs and apply data-protection best practices. For more information, see Amazon S3 pricing.
5. Under **Select Advanced metrics and recommendations features**, select **CloudWatch publishing**.

   > **Important**
   >
   > If your configuration enables prefix aggregation for usage metrics, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.
6. Choose **Save changes**.

To create a new S3 Storage Lens dashboard that enables CloudWatch support

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. Choose **Create dashboard**.
4. Under **General**, define the following configuration options:

a. For **Dashboard name**, enter your dashboard name.

   Dashboard names must be fewer than 65 characters and must not contain special characters or spaces. You can't change the dashboard name after you create your dashboard.

b. Choose the **Home Region** for your dashboard.

   Metrics for all Regions included in this dashboard scope are stored centrally in the designated home Region. In CloudWatch, S3 Storage Lens metrics are also available in the home Region. You can't change the home Region after you create your dashboard.

5. (Optional) To add tags, choose **Add tag** and enter the tag **Key** and **Value**.

> **Note**
>
> You can add up to 50 tags to your dashboard configuration.

6. Define the scope for your configuration:

a. If you're creating an organization-level configuration, choose the accounts to include in the configuration: **Include all accounts in your configuration** or **Limit the scope to your signed-in account**.

> **Note**
>
> When you create an organization-level configuration that includes all accounts, you can include or exclude only Regions, not buckets.

b. Choose the Regions and buckets that you want S3 Storage Lens to include in the dashboard configuration by doing the following:

- To include all Regions, choose **Include Regions and buckets**.
- To include specific Regions, clear **Include all Regions**. Under **Choose Regions to include**, choose the Regions that you want S3 Storage Lens to include in the dashboard.
- To include specific buckets, clear **Include all buckets**. Under **Choose buckets to include**, choose the buckets that you want S3 Storage Lens to include in the dashboard.

> **Note**
>
> You can choose up to 50 buckets.

7. For **Metrics selection**, choose **Advanced metrics and recommendations**.

   For more information about advanced metrics and recommendations pricing, see Amazon S3 pricing.

8. Under **Advanced metrics and recommendations features**, select the options that you want to enable:

   - **Advanced metrics**
   - **CloudWatch publishing**

   > **Important**
   >
   > If you enable prefix aggregation for your S3 Storage Lens configuration, prefix-level metrics will not be published to CloudWatch. Only bucket, account, and organization-level S3 Storage Lens metrics are published to CloudWatch.

   - **Prefix aggregation**

   > **Note**
   >
   > For more information about advanced metrics and recommendations features, see Metrics selection.

9. If you enabled **Advanced metrics**, select the **Advanced metrics categories** that you want to display in your S3 Storage Lens dashboard:

   - **Activity metrics**
   - **Detailed status code metrics**
   - **Advanced cost optimization metrics**
   - **Advanced data protection metrics**

For more information about metrics categories, see Metrics categories. For a complete list of metrics, see Amazon S3 Storage Lens metrics glossary.

10. (Optional) Configure your metrics export.

    For more information about how to configure a metrics export, see step Using the S3 console.

11. Choose **Create dashboard**.

Using the AWS CLI

The following AWS CLI example enables the CloudWatch publishing option by using a S3 Storage Lens organization-level advanced metrics and recommendations configuration. To use this example, replace the *`user input placeholders`* with your own information.

```
aws s3control put-storage-lens-configuration --account-id=555555555555 --config-
id=your-configuration-id --region=us-east-1 --storage-lens-configuration=file://./
config.json

config.json
{
  "Id": "SampleS3StorageLensConfiguration", //Use this property to identify your S3
 Storage Lens configuration.
  "AwsOrg": { //Use this property when enabling S3 Storage Lens for AWS Organizations.
    "Arn": "arn:aws:organizations::123456789012:organization/o-abcdefgh"
  },

            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Using the REST API

To enable the CloudWatch publishing option by using the Amazon S3 REST API, you can use PutStorageLensConfiguration.

Next steps

After you enable the CloudWatch publishing option, you can access your S3 Storage Lens metrics in CloudWatch. You also can leverage CloudWatch features to monitor and analyze your S3 Storage Lens data in CloudWatch. For more information, see the following topics:

- S3 Storage Lens metrics and dimensions
- Working with S3 Storage Lens metrics in CloudWatch

Working with S3 Storage Lens metrics in CloudWatch

You can publish S3 Storage Lens metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch features, such as alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, CloudWatch API operations enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information about CloudWatch features, see the Amazon CloudWatch User Guide.

You can enable the CloudWatch publishing option for new or existing dashboard configurations by using the Amazon S3 console, Amazon S3 REST APIs, AWS CLI, and AWS SDKs. The CloudWatch publishing option is available for dashboards that are upgraded to S3 Storage Lens advanced metrics and recommendations. For S3 Storage Lens advanced metrics and recommendations pricing, see Amazon S3 pricing. No additional CloudWatch metrics publishing charges apply;

however, other CloudWatch charges, such as dashboards, alarms, and API calls, do apply. For more information, see Amazon CloudWatch pricing.

S3 Storage Lens metrics are published to CloudWatch in the account that owns the S3 Storage Lens configuration. After you enable the CloudWatch publishing option within advanced metrics and recommendations, you can access organization, account, and bucket-level metrics in CloudWatch. Prefix-level metrics are not available in CloudWatch.

> **Note**
>
> S3 Storage Lens metrics are daily metrics and are published to CloudWatch once per day. When you query S3 Storage Lens metrics in CloudWatch, the period for the query must be 1 day (86400 seconds). After your daily S3 Storage Lens metrics appear in your S3 Storage Lens dashboard in the Amazon S3 console, it can take a few hours for these same metrics to appear in CloudWatch. When you enable the CloudWatch publishing option for S3 Storage Lens metrics for the first time, it can take up to 24 hours for your metrics to publish to CloudWatch.
> Currently, S3 Storage Lens metrics cannot be consumed through CloudWatch streams.

For more information about working with S3 Storage Lens metrics in CloudWatch, see the following topics.

Topics

- Working with CloudWatch dashboards
- Setting alarms, triggering actions, and using anomaly detection
- Filtering metrics using dimensions
- Calculating new metrics with metric math
- Using search expressions in graphs

Working with CloudWatch dashboards

You can use CloudWatch dashboards to monitor S3 Storage Lens metrics alongside other application metrics and create a unified view of your operational health. Dashboards are customizable home pages in the CloudWatch console that you can use to monitor your resources in a single view.

CloudWatch has broad permissions control that doesn't support limiting access to a specific set of metrics or dimensions. Users in your account or organization who have access to CloudWatch will have access to metrics for all S3 Storage Lens configurations where the CloudWatch support option is enabled. You can't manage permissions for specific dashboards as you can in S3 Storage Lens. For more information about CloudWatch permissions, see Managing access permissions to your CloudWatch resources in the *Amazon CloudWatch User Guide*.

For more information about using CloudWatch dashboards and configuring permissions, see Using Amazon CloudWatch dashboards and Sharing CloudWatch dashboards in the *Amazon CloudWatch User Guide*.

Setting alarms, triggering actions, and using anomaly detection

You can configure CloudWatch alarms that watch S3 Storage Lens metrics in CloudWatch and take action when a threshold is breached. For example, you can configure an alarm that sends an Amazon SNS notification when the **Incomplete Multipart Upload Bytes** metric exceeds 1 GB for three consecutive days.

You can also enable anomaly detection to continuously analyze your S3 Storage Lens metrics, determine normal baselines, and surface anomalies. You can create an anomaly detection alarm based on a metric's expected value. For example, you can monitor anomalies for the **Object Lock Enabled Bytes** metric to detect unauthorized removal of Object Lock settings.

For more information and examples, see Using Amazon CloudWatch alarms and Creating an alarm from a metric on a graph in the *Amazon CloudWatch User Guide*.

Filtering metrics using dimensions

You can use dimensions to filter S3 Storage Lens metrics in the CloudWatch console. For example, you can filter by `configuration_id`, `aws_account_number`, `aws_region`, `bucket_name`, and more.

S3 Storage Lens supports multiple dashboard configurations per account. This means that different configurations can include the same bucket. When these metrics are published to CloudWatch, the bucket will have duplicate metrics within CloudWatch. To view metrics only for a specific S3 Storage Lens configuration in CloudWatch, you can use the `configuration_id` dimension. When you filter by `configuration_id`, you see only the metrics that are associated with the configuration that you identify.

For more information about filtering by configuration ID, see Searching for available metrics in the *Amazon CloudWatch User Guide*.

Calculating new metrics with metric math

You can use metric math to query multiple S3 Storage Lens metrics and use math expressions to create new time series based on these metrics. For example, you can create a new metric for unencrypted objects by subtracting Encrypted Objects from Object Count. You can also create a metric to get the average object size by dividing `StorageBytes` by `ObjectCount` or the number bytes accessed on one day by dividing `BytesDownloaded` by `StorageBytes`.

For more information, see Using metric math in the *Amazon CloudWatch User Guide*.

Using search expressions in graphs

With S3 Storage Lens metrics, you can create a search expression. For example, you can create a search expression for all metrics that are named **IncompleteMultipartUploadStorageBytes** and add SUM to the expression. With this search expression, you can see your total incomplete multipart upload bytes across all dimensions of your storage in a single metric.

This example shows the syntax that you would use to create a search expression for all metrics named **IncompleteMultipartUploadStorageBytes**.

```
SUM(SEARCH('{AWS/S3/Storage-
Lens,aws_account_number,aws_region,configuration_id,metrics_version,record_type,storage_class}
 MetricName="IncompleteMultipartUploadStorageBytes"', 'Average',86400))
```

For more information about this syntax, see CloudWatch search expression syntax in the *Amazon CloudWatch User Guide*. To create a CloudWatch graph with a search expression, see Creating a CloudWatch graph with a search expressionin the *Amazon CloudWatch User Guide*.

Amazon S3 Storage Lens metrics use cases

You can use your Amazon S3 Storage Lens dashboard to visualize insights and trends, flag outliers, and receive recommendations. S3 Storage Lens metrics are organized into categories that align with key use cases. You can use these metrics to do the following:

- Identify cost-optimization opportunities
- Apply data-protection best practices
- Apply access-management best practices
- Improve the performance of application workloads

For example, with cost-optimization metrics, you can identify opportunities to reduce your Amazon S3 storage costs. You can identify buckets with multipart uploads that are more than 7-days old or buckets that are accumulating noncurrent versions.

Similarly, you can use data-protection metrics to identify buckets that aren't following data-protection best practices within your organization. For example, you can identify buckets that don’t use AWS Key Management Service keys (SSE-KMS) for default encryption or don't have S3 Versioning enabled.

With S3 Storage Lens access-management metrics, you can identify bucket settings for S3 Object Ownership so that you can migrate access control list (ACL) permissions to bucket policies and disable ACLs.

If you have S3 Storage Lens advanced metrics enabled, you can use detailed status-code metrics to get counts for successful or failed requests that you can use to troubleshoot access or performance issues.

With advanced metrics, you can also access additional cost-optimization and data-protection metrics that you can use to identify opportunities to further reduce your overall S3 storage costs and better align with best practices for protecting your data. For example, advanced cost-optimization metrics include lifecycle rule counts that you can use to identify buckets that don't have lifecycle rules to expire incomplete multipart uploads that are more than 7 days old. Advanced data-protection metrics include replication rule counts.

For more information about metrics categories, see Metrics categories. For a complete list of S3 Storage Lens metrics, see Amazon S3 Storage Lens metrics glossary.

Topics

- Using Amazon S3 Storage Lens to optimize your storage costs
- Using S3 Storage Lens to protect your data
- Using S3 Storage Lens to audit Object Ownership settings
- Using S3 Storage Lens metrics to improve performance

Using Amazon S3 Storage Lens to optimize your storage costs

You can use S3 Storage Lens cost-optimization metrics to reduce the overall cost of your S3 storage. Cost-optimization metrics can help you confirm that you've configured Amazon S3 cost

effectively and according to best practices. For example, you can identify the following cost-optimization opportunities:

- Buckets with incomplete multipart uploads older than 7 days
- Buckets that are accumulating numerous noncurrent versions
- Buckets that don't have lifecycle rules to abort incomplete multipart uploads
- Buckets that don't have lifecycle rules to expire noncurrent versions objects
- Buckets that don't have lifecycle rules to transition objects to a different storage class

You can then use this data to add additional lifecycle rules to your buckets.

The following examples show how you can use cost- optimization metrics in your S3 Storage Lens dashboard to optimize your storage costs.

Topics

- Identify your largest S3 buckets
- Uncover cold Amazon S3 buckets
- Locate incomplete multipart uploads
- Reduce the number of noncurrent versions retained
- Identify buckets that don't have lifecycle rules and review lifecycle rule counts

Identify your largest S3 buckets

You pay for storing objects in S3 buckets. The rate that you're charged depends on your objects' sizes, how long you store the objects, and their storage classes. With S3 Storage Lens, you get a centralized view of all the buckets in your account. To see all the buckets in all of your organization's accounts, you can configure an AWS Organizations-level S3 Storage Lens dashboard. From this dashboard view, you can identify your largest buckets.

Step 1: Identify your largest buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.

When the dashboard opens, you can see the latest date that S3 Storage Lens has collected metrics for. Your dashboard always loads to the latest date that has metrics available.

4. To see a ranking of your largest buckets by the **Total storage** metric for a selected date range, scroll down to the **Top N overview for *date*** section.

   You can toggle the sort order to show the smallest buckets. You can also adjust the **Metric** selection to rank your buckets by any of the available metrics. The **Top N overview for *date*** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

   > **Note**
   >
   > With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see Metrics selection.

5. For more detailed insights about your buckets, scroll up to the top of the page, and then choose the **Bucket** tab.

   On the **Bucket** tab, you can see details such as the recent growth rate, the average object size, the largest prefixes, and the number of objects.

Step 2: Navigate to your buckets and investigate

After you've identified your largest S3 buckets, you can navigate to each bucket within the S3 console to view the objects in the bucket, understand its associated workload, and identify its internal owners. You can contact the bucket owners to find out whether the growth is expected or whether the growth needs further monitoring and control.

Uncover cold Amazon S3 buckets

If you have S3 Storage Lens advanced metrics enabled, you can use activity metrics to understand how cold your S3 buckets are. A "cold" bucket is one whose storage is no longer accessed (or very rarely accessed). This lack of activity typically indicates that the bucket's objects aren't frequently accessed.

Activity metrics, such as **GET Requests** and **Download Bytes**, indicate how often your buckets are accessed each day. To understand the consistency of the access pattern and to spot buckets that

are no longer being accessed at all, you can trend this data over several months. The **Retrieval rate** metric, which is computed as **Download bytes / Total storage**, indicates the proportion of storage in a bucket that is accessed daily.

> **Note**
>
> Download bytes are duplicated in cases where the same object is downloaded multiple times during the day.

Prerequisite

To see activity metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Activity metrics**. For more information, see Using the S3 console.

Step 1: Identify active buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. Choose the **Bucket** tab, and then scroll down to the **Bubble analysis by buckets for *date*** section.

   In the **Bubble analysis by buckets for *date*** section, you can plot your buckets on multiple dimensions by using any three metrics to represent the **X-axis**, **Y-axis**, and **Size** of the bubble.
5. To find buckets that have gone cold, for **X-axis**, **Y-axis**, and **Size**, choose the **Total storage**, **% retrieval rate**, and **Average object size** metrics.
6. In the **Bubble analysis by buckets for *date*** section, locate any buckets with retrieval rates of zero (or near zero) and a larger relative storage size, and choose the bubble that represents the bucket.

   A box will appear with choices for more granular insights. Do one of the following:

   a. To update the **Bucket** tab to display metrics only for the selected bucket, choose **Drill down**, and then choose **Apply**.

b. To aggregate your bucket-level data to by account, AWS Region, storage class, or bucket, choose **Analyze by** and then make a choice for **Dimension**. For example, to aggregate by storage class, choose **Storage class** for **Dimension**.

To find buckets that have gone cold, do a bubble analysis using the **Total storage**, **% retrieval rate**, and **Average object size** metrics. Look for any buckets with retrieval rates of zero (or near zero) and a larger relative storage size.

The **Bucket** tab of your dashboard updates to display data for your selected aggregation or filter. If you aggregated by storage class or another dimension, that new tab opens in your dashboard (for example, the **Storage class** tab).

Step 2: Investigate cold buckets

From here, you can identify the owners of cold buckets in your account or organization and find out if that storage is still needed. You can then optimize costs by configuring lifecycle expiration configurations for these buckets or archiving the data in one of the Amazon S3 Glacier storage classes.

To avoid the problem of cold buckets going forward, you can automatically transition your data by using S3 Lifecycle configurations for your buckets, or you can enable auto-archiving with S3 Intelligent-Tiering.

You can also use step 1 to identify hot buckets. Then, you can ensure that these buckets use the correct S3 storage class to ensure that they serve their requests most effectively in terms of performance and cost.

Locate incomplete multipart uploads

You can use multipart uploads to upload very large objects (up to 5 TB) as a set of parts for improved throughput and quicker recovery from network issues. In cases where the multipart upload process doesn't finish, the incomplete parts remain in the bucket (in an unusable state). These incomplete parts incur storage costs until the upload process is finished, or until the incomplete parts are removed. For more information, see Uploading and copying objects using multipart upload in Amazon S3.

With S3 Storage Lens, you can identify the number of incomplete multipart upload bytes in your account or across your entire organization, including incomplete multipart uploads that are

more than 7 days old. For a complete list of incomplete multipart upload metrics, see Amazon S3 Storage Lens metrics glossary.

As a best practice, we recommend configuring lifecycle rules to expire incomplete multipart uploads that are older than a specific number of days. When you create your lifecycle rule to expire incomplete multipart uploads, we recommend 7 days as a good starting point.

Step 1: Review overall trends for incomplete multipart uploads

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In the **Snapshot for *date*** section, under **Metrics categories**, choose **Cost optimization**.

   The **Snapshot for *date*** section updates to display **Cost optimization** metrics, which include **Incomplete multipart upload bytes greater than 7 days old**.

   In any chart in your S3 Storage Lens dashboard, you can see metrics for incomplete multipart uploads. You can use these metrics to further assess the impact of incomplete multipart upload bytes on your storage, including their contribution to overall growth trends. You can also drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Bucket**, or **Storage class** tabs for a deeper analysis of your data. For an example, see Uncover cold Amazon S3 buckets.

Step 2: Identify buckets that have the most incomplete multipart upload bytes but don't have lifecycle rules to abort incomplete multipart uploads

Prerequisite

To see the **Abort incomplete multipart upload lifecycle rule count** metric in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see Using the S3 console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.

4. To identify specific buckets that are accumulating incomplete multipart uploads greater than 7 days old, go to the **Top N overview for *date*** section.

   By default, the **Top N overview for *date*** section displays metrics for the top 3 buckets. You can increase or decrease the number of buckets in the **Top N** field. The **Top N overview for *date*** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. (This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.)

   > **Note**
   >
   > With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see Metrics selection.

5. For **Metric**, choose **Incomplete multipart upload bytes greater than 7 days old** in the **Cost optimization** category.

   Under **Top *number* buckets**, you can see the buckets with the most incomplete multipart upload storage bytes that are greater than 7 days old.

6. To view more detailed bucket-level metrics for incomplete multipart uploads, scroll to the top of the page, and then choose the **Bucket** tab.

7. Scroll down to the **Buckets** section. For **Metrics categories**, select **Cost optimization**. Then clear **Summary**.

   The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.

8. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon
   ( ).

9. Clear the toggles for all cost-optimization metrics until only **Incomplete multipart upload bytes greater than 7 days old** and **Abort incomplete multipart upload lifecycle rule count** remain selected.

10. (Optional) Under **Page size**, choose the number of buckets to display in the list.

11. Choose **Confirm**.

    The **Buckets** list updates to display bucket-level metrics for incomplete multipart uploads and lifecycle rule counts. You can use this data to identify buckets that have the most incomplete

multipart upload bytes that are greater than 7 days old and are missing lifecycle rules to abort incomplete multipart uploads. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to delete abandoned incomplete multipart uploads.

Step 3: Add a lifecycle rule to delete incomplete multipart uploads after 7 days

To automatically manage incomplete multipart uploads, you can use the S3 console to create a lifecycle configuration to expire incomplete multipart upload bytes from a bucket after a specified number of days. For more information, see Configuring a bucket lifecycle configuration to delete incomplete multipart uploads.

Reduce the number of noncurrent versions retained

When enabled, S3 Versioning retains multiple distinct copies of the same object that you can use to quickly recover data if an object is accidentally deleted or overwritten. If you've enabled S3 Versioning without configuring lifecycle rules to transition or expire noncurrent versions, a large number of previous noncurrent versions can accumulate, which can have storage-cost implications. For more information, see Retaining multiple versions of objects with S3 Versioning.

Step 1: Identify buckets with the most noncurrent object versions

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In the **Snapshot for *date*** section, under **Metric categories**, choose **Cost optimization**.

   The **Snapshot for *date*** section updates to display **Cost optimization** metrics, which include the metric for **% noncurrent version bytes**. The **% noncurrent version bytes** metric represents the proportion of your total storage bytes that is attributed to noncurrent versions, within the dashboard scope and for the selected date.

   > **Note**
   >
   > If your **% noncurrent version bytes** is greater than 10 percent of your storage at the account level, you might be storing too many object versions.

5. To identify specific buckets that are accumulating a large number of noncurrent versions:

a. Scroll down to the **Top N overview for *date*** section. For **Top N**, enter the number of buckets that you would like to see data for.

b. For **Metric**, choose **% noncurrent version bytes**.

   Under **Top *number* buckets**, you can see the buckets (for the number that you specified) with the highest **% noncurrent version bytes**. The **Top N overview for *date*** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

   > **Note**
   >
   > With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see Metrics selection.

c. To view more detailed bucket-level metrics for noncurrent object versions, scroll to the top of the page, and then choose the **Bucket** tab.

   In any chart or visualization in your S3 Storage Lens dashboard, you can drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Storage class**, or **Bucket** tabs. For an example, see Uncover cold Amazon S3 buckets.

d. In the **Buckets** section, for **Metric categories**, select **Cost optimization**. Then, clear **Summary**.

   You can now see the **% noncurrent version bytes** metric, along with other metrics related to noncurrent versions.

Step 2: Identify buckets that are missing transition and expiration lifecycle rules for managing noncurrent versions

Prerequisite

To see the **Noncurrent version transition lifecycle rule count** and **Noncurrent version expiration lifecycle rule count** metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see Using the S3 console.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. For **Metrics categories**, select **Cost optimization**. Then clear **Summary**.

   The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.
6. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon ( ).
7. Clear the toggles for all cost-optimization metrics until only the following remain selected:
   - **% noncurrent version bytes**
   - **Noncurrent version transition lifecycle rule count**
   - **Noncurrent version expiration lifecycle rule count**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

   The **Buckets** list updates to display metrics for noncurrent version bytes and noncurrent version lifecycle rule counts. You can use this data to identify buckets that have a high percentage of noncurrent version bytes but are missing transition and expiration lifecycle rules. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to these buckets.

Step 3: Add lifecycle rules to transition or expire noncurrent object versions

After you've determined which buckets require further investigation, you can navigate to the buckets within the S3 console and add a lifecycle rule to expire noncurrent versions after a specified number of days. Alternatively, to reduce costs while still retaining noncurrent versions, you can configure a lifecycle rule to transition noncurrent versions to one of the Amazon S3 Glacier storage classes. For more information, see Specifying a lifecycle rule for a versioning-enabled bucket.

Identify buckets that don't have lifecycle rules and review lifecycle rule counts

S3 Storage Lens provides S3 Lifecycle rule count metrics that you can use to identify buckets that are missing lifecycle rules. To find buckets that don't have lifecycle rules, you can use the **Total buckets without lifecycle rules** metric. A bucket with no S3 Lifecycle configuration might have storage that you no longer need or can migrate to a lower-cost storage class. You can also use lifecycle rule count metrics to identify buckets that are missing specific types of lifecycle rules, such as expiration or transition rules.

Prerequisite

To see lifecycle rule count metrics and the **Total buckets without lifecycle rules** metric in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Advanced cost optimization metrics**. For more information, see Using the S3 console.

Step 1: Identify buckets without lifecycle rules

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. To identify specific buckets without lifecycle rules, scroll down to the **Top N overview for *date*** section.

   By default, the **Top N overview for *date*** section displays metrics for the top 3 buckets. In the **Top N** field, you can increase the number of buckets. The **Top N overview for *date*** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

   > **Note**
   >
   > With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see Metrics selection.

5. For **Metric**, choose **Total buckets without lifecycle rules** from the **Cost optimization** category.
6. Review the following data for **Total buckets without lifecycle rules**:

- **Top *number* accounts** - See which accounts that have the most buckets without lifecycle rules.
- **Top *number* Regions** - View a breakdown of buckets without lifecycle rules by Region.
- **Top *number* buckets** - See which buckets don't have lifecycle rules.

In any chart or visualization in your S3 Storage Lens dashboard, you can drill down to deeper levels of aggregation, using the **Account**, **AWS Region**, **Storage class**, or **Bucket** tabs. For an example, see Uncover cold Amazon S3 buckets.

After you identify which buckets don't have lifecycle rules, you can also review specific lifecycle rule counts for your buckets.

Step 2: Review lifecycle rule counts for your buckets

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the dashboard that you want to view.
4. In your S3 Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, select **Cost optimization**. Then clear **Summary**.

   The **Buckets** list updates to display all the available **Cost optimization** metrics for the buckets shown.
6. To filter the **Buckets** list to display only specific cost-optimization metrics, choose the preferences icon ( ).
7. Clear the toggles for all cost-optimization metrics until only the following remain selected:

   - **Transition lifecycle rule count**
   - **Expiration lifecycle rule count**
   - **Noncurrent version transition lifecycle rule count**
   - **Noncurrent version expiration lifecycle rule count**
   - **Abort incomplete multipart upload lifecycle rule count**

- **Total lifecycle rule count**

8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

   The **Buckets** list updates to display lifecycle rule count metrics for your buckets. You can use this data to identify buckets without lifecycle rules or buckets that are missing specific kinds of lifecycle rules, for example, expiration or transition rules. Then, you can navigate to these buckets in the S3 console and add lifecycle rules to these buckets.

Step 3: Add lifecycle rules

After you've identified buckets with no lifecycle rules, you can add lifecycle rules. For more information, see Setting an S3 Lifecycle configuration on a bucket and Examples of S3 Lifecycle configurations.

Using S3 Storage Lens to protect your data

You can use Amazon S3 Storage Lens data-protection metrics to identify buckets where data-protection best practices haven't been applied. You can use these metrics to take action and apply standard settings that align with best practices for protecting your data across the buckets in your account or organization. For example, you can use data-protection metrics to identify buckets that don't use AWS Key Management Service (AWS KMS) keys (SSE-KMS) for default encryption or requests that use AWS Signature Version 2 (SigV2).

The following use cases provide strategies for using your S3 Storage Lens dashboard to identify outliers and apply data-protection best practices across your S3 buckets.

Topics

- Identify buckets that don't use server-side encryption with AWS KMS for default encryption (SSE-KMS)
- Identify buckets that have S3 Versioning enabled
- Identify requests that use AWS Signature Version 2 (SigV2)
- Count the total number of replication rules for each bucket
- Identify percentage of Object Lock bytes

Identify buckets that don't use server-side encryption with AWS KMS for default encryption (SSE-KMS)

With Amazon S3 default encryption, you can set the default encryption behavior for an S3 bucket. For more information, see the section called “Setting default bucket encryption”.

You can use the **SSE-KMS enabled bucket count** and **% SSE-KMS enabled buckets** metrics to identify buckets that use server-side encryption with AWS KMS keys (SSE-KMS) for default encryption. S3 Storage Lens also provides metrics for unencrypted bytes, unencrypted objects, encrypted bytes, and encrypted objects. For a complete list of metrics, see Amazon S3 Storage Lens metrics glossary.

You can analyze SSE-KMS encryption metrics in the context of general encryption metrics to identify buckets that don't use SSE-KMS. If you want to use SSE-KMS for all the buckets in your account or organization, you can then update the default encryption settings for these buckets to use SSE-KMS. In addition to SSE-KMS, you can use server-side encryption with Amazon S3 managed keys (SSE-S3) or customer-provided keys (SSE-C). For more information, see Protecting data with encryption.

Step 1: Identify which buckets are using SSE-KMS for default encryption

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, choose **% SSE-KMS enabled bucket count** for the primary metric and **% encrypted bytes** for the secondary metric.

   The **Trend for *date*** chart updates to display trends for SSE-KMS and encrypted bytes.
5. To view more granular, bucket-level insights for SSE-KMS:

   a. Choose a point on the chart. A box will appear with choices for more granular insights.

   b. Choose the **Buckets** dimension. Then choose **Apply**.
6. In the **Distribution by buckets for *date*** chart, choose the **SSE-KMS enabled bucket count** metric.
7. You can now see which buckets have SSE-KMS enabled and which do not.

Step 2: Update bucket default encryption settings

Now that you've determined which buckets use SSE-KMS in the context of your **% encrypted bytes**, you can identify buckets that don't use SSE-KMS. You can then optionally navigate to these buckets within the S3 console and update their default encryption settings to use SSE-KMS or SSE-S3. For more information, see Configuring default encryption.

Identify buckets that have S3 Versioning enabled

When enabled, the S3 Versioning feature retains multiple versions of the same object that can be used to quickly recover data if an object is accidentally deleted or overwritten. You can use the **Versioning-enabled bucket count** metric to see which buckets use S3 Versioning. Then, you can take action in the S3 console to enable S3 Versioning for other buckets.

Step 1: Identify buckets that have S3 Versioning enabled

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, choose **Versioning-enabled bucket count** for the primary metric and **Buckets** for the secondary metric.

   The **Trend for *date*** chart updates to display trends for S3 Versioning enabled buckets. Right below the trends line, you can see the **Storage class distribution** and **Region distribution** subsections.
5. To view more granular insights for any of the buckets that you see in the **Trend for *date*** chart so that you can perform a deeper analysis, do the following:

   a. Choose a point on the chart. A box will appear with choices for more granular insights.

   b. Choose a dimension to apply to your data for deeper analysis: **Account**, **AWS Region**, **Storage class**, or **Bucket**. Then choose **Apply**.
6. In the **Bubble analysis by buckets for *date*** section, choose the **Versioning-enabled bucket count**, **Buckets**, and **Active buckets** metrics.

   The **Bubble analysis by buckets for *date*** section updates to display data for the metrics that you selected. You can use this data to see which buckets have S3 Versioning enabled in the context of your total bucket count. In the **Bubble analysis by buckets for *date*** section, you can

plot your buckets on multiple dimensions by using any three metrics to represent the **X-axis**, **Y-axis**, and **Size** of the bubble.

Step 2: Enable S3 Versioning

After you've identified buckets that have S3 Versioning enabled, you can identify buckets that have never had S3 Versioning enabled or are versioning suspended. Then, you can optionally enable versioning for these buckets in the S3 console. For more information, see Enabling versioning on buckets.

Identify requests that use AWS Signature Version 2 (SigV2)

You can use the **All unsupported signature requests** metric to identify requests that use AWS Signature Version 2 (SigV2). This data can help you identify specific applications that are using SigV2. You can then migrate these applications to AWS Signature Version 4 (SigV4).

SigV4 is the recommended signing method for all new S3 applications. SigV4 provides improved security and is supported in all AWS Regions. For more information, see Amazon S3 update - SigV2 deprecation period extended & modified.

Prerequisite

To see **All unsupported signature requests** in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Advanced data protection metrics**. For more information, see Using the S3 console.

Step 1: Examine SigV2 signing trends by AWS account, Region, and bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. To identify specific buckets, accounts, and Regions with requests that use SigV2:

    a. Under **Top N overview for *date***, in **Top N**, enter the number of buckets that you would like to see data for.

    b. For **Metric**, choose **All unsupported signature requests** from the **Data protection** category.

The **Top N overview for *date*** updates to display data for SigV2 requests by account, AWS Region, and bucket. The **Top N overview for *date*** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

> **Note**
>
> With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see Metrics selection.

Step 2: Identify buckets that are accessed by applications through SigV2 requests

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, choose **Data protection**. Then clear **Summary**.

   The **Buckets** list updates to display all the available **Data protection** metrics for the buckets shown.
6. To filter the **Buckets** list to display only specific data-protection metrics, choose the preferences icon ( ).
7. Clear the toggles for all data-protection metrics until only the following metrics remain selected:

   - **All unsupported signature requests**
   - **% all unsupported signature requests**
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

The **Buckets** list updates to display bucket-level metrics for SigV2 requests. You can use this data to identify specific buckets that have SigV2 requests. Then, you can use this information to migrate your applications to SigV4. For more information, see Authenticating Requests (AWS Signature Version 4) in the *Amazon Simple Storage Service API Reference*.

Count the total number of replication rules for each bucket

S3 Replication enables automatic, asynchronous copying of objects across Amazon S3 buckets. Buckets that are configured for object replication can be owned by the same AWS account or by different accounts. For more information, see Replicating objects within and across Regions.

You can use S3 Storage Lens replication rule count metrics to get detailed per-bucket information about your buckets that are configured for replication. This information includes replication rules within and across buckets and Regions.

Prerequisite

To see replication rule count metrics in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations** and then select **Advanced data protection metrics**. For more information, see Using the S3 console.

Step 1: Count the total number of replication rules for each bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. Under **Metrics categories**, choose **Data protection**. Then clear **Summary**.
6. To filter the **Buckets** list to display only replication rule count metrics, choose the preferences icon ( ).
7. Clear the toggles for all data-protection metrics until only the replication rule count metrics remain selected:

- **Same-Region Replication rule count**
- **Cross-Region Replication rule count**
- **Same-account replication rule count**
- **Cross-account replication rule count**
- **Total replication rule count**

8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

Step 2: Add replication rules

After you have a per-bucket replication rule count, you can optionally create additional replication rules. For more information, see Examples for configuring live replication.

Identify percentage of Object Lock bytes

With S3 Object Lock, you can store objects by using a *write-once-read-many (WORM)* model. You can use Object Lock to help prevent objects from being deleted or overwritten for a fixed amount of time or indefinitely. You can enable Object Lock only when you create a bucket and also enable S3 Versioning. However, you can edit the retention period for individual object versions or apply legal holds for buckets that have Object Lock enabled. For more information, see Locking objects with Object Lock.

You can use Object Lock metrics in S3 Storage Lens to see the **% Object Lock bytes** metric for your account or organization. You can use this information to identify buckets in your account or organization that aren't following your data-protection best practices.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Snapshot** section, under **Metrics categories**, choose **Data protection**.

   The **Snapshot** section updates to display data-protection metrics, including the **% Object Lock bytes** metric. You can see the overall percentage of Object Lock bytes for your account or organization.
5. To see the **% Object Lock bytes** per bucket, scroll down to the **Top N overview** section.

To get object-level data for Object Lock, you can also use the **Object Lock object count** and **% Object Lock objects** metrics.

6. For **Metric**, choose **% Object Lock bytes** from the **Data protection** category.

   By default, the **Top N overview for *date*** section displays metrics for the top 3 buckets. In the **Top N** field, you can increase the number of buckets. The **Top N overview for *date*** section also shows the percentage change from the prior day or week and a spark-line to visualize the trend. This trend is a 14-day trend for free metrics and a 30-day trend for advanced metrics and recommendations.

   > **Note**
   >
   > With S3 Storage Lens advanced metrics and recommendations, metrics are available for queries for 15 months. For more information, see Metrics selection.

7. Review the following data for **% Object Lock bytes**:

   - **Top *number* accounts** - See which accounts have the highest and lowest **% Object Lock bytes**.
   - **Top *number* Regions** - View a breakdown of **% Object Lock bytes** by Region.
   - **Top *number* buckets** - See which buckets have the highest and lowest **% Object Lock bytes**.

Using S3 Storage Lens to audit Object Ownership settings

Amazon S3 Object Ownership is an S3 bucket-level setting that you can use to disable access control lists (ACLs) and control ownership of the objects in your bucket. If you set Object Ownership to bucket owner enforced, you can disable access control lists (ACLs) and take ownership of every object in your bucket. This approach simplifies access management for data stored in Amazon S3.

By default, when another AWS account uploads an object to your S3 bucket, that account (the object writer) owns the object, has access to it, and can grant other users access to it through ACLs. You can use Object Ownership to change this default behavior.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. Therefore, we recommend that you disable ACLs, except in unusual circumstances where you must control access for each object individually. By setting Object Ownership to bucket owner enforced, you

can disable ACLs and rely on policies for access control. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

With S3 Storage Lens access-management metrics, you can identify buckets that don't have disabled ACLs. After identifying these buckets, you can migrate ACL permissions to policies and disable ACLs for these buckets.

Topics

- Step 1: Identify general trends for Object Ownership settings
- Step 2: Identify bucket-level trends for Object Ownership settings
- Step 3: Update your Object Ownership setting to bucket owner enforced to disable ACLs

Step 1: Identify general trends for Object Ownership settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Snapshot for *date*** section, under **Metrics categories**, choose **Access management**.

   The **Snapshot for *date*** section updates to display the **% Object Ownership bucket owner enforced** metric. You can see the overall percentage of buckets in your account or organization that use the bucket owner enforced setting for Object Ownership to disable ACLs.

Step 2: Identify bucket-level trends for Object Ownership settings

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. To view more detailed bucket-level metrics, choose the **Bucket** tab.
5. In the **Distribution by buckets for *date*** section, choose the **% Object Ownership bucket owner enforced** metric.

The chart updates to show a per-bucket breakdown for **% Object Ownership bucket owner enforced**. You can see which buckets use the bucket owner enforced setting for Object Ownership to disable ACLs.

6. To view the bucket owner enforced settings in context, scroll down to the **Buckets** section. For **Metrics categories**, select **Access management**. Then clear **Summary**.

   The **Buckets** list displays data for all three Object Ownership settings: bucket owner enforced, bucket owner preferred, and object writer.

7. To filter the **Buckets** list to display metrics only for a specific Object Ownership setting, choose the preferences icon ( ).

8. Clear the metrics that you don't want to see.

9. (Optional) Under **Page size**, choose the number of buckets to display in the list.

10. Choose **Confirm**.

Step 3: Update your Object Ownership setting to bucket owner enforced to disable ACLs

After you've identified buckets that use the object writer and bucket owner preferred setting for Object Ownership, you can migrate your ACL permissions to bucket policies. When you've finished migrating your ACL permissions, you can then update your Object Ownership settings to bucket owner enforced in order to disable ACLs. For more information, see Prerequisites for disabling ACLs.

Using S3 Storage Lens metrics to improve performance

If you have S3 Storage Lens advanced metrics enabled, you can use detailed status-code metrics to get counts for successful or failed requests. You can use this information to troubleshoot access or performance issues. Detailed status-code metrics show counts for HTTP status codes, such as 403 Forbidden and 503 Service Unavailable. You can examine overall trends for detailed status-code metrics across S3 buckets, accounts, and organizations. Then, you can drill down into bucket-level metrics to identify workloads that are currently accessing these buckets and causing errors.

For example, you can look at the **403 Forbidden error count** metric to identify workloads that are accessing buckets without the correct permissions applied. After you've identified these workloads, you can do a deep dive outside of S3 Storage Lens to troubleshoot your 403 Forbidden errors.

This example shows you how to do a trend analysis for the 403 Forbidden error by using the **403 Forbidden error count** and the **% 403 Forbidden errors** metrics. You can use these metrics to identify workloads that are accessing buckets without the correct permissions applied. You can do a similar trend analysis for any of the other **Detailed status code metrics**. For more information, see Amazon S3 Storage Lens metrics glossary.

Prerequisite

To see **Detailed status code metrics** in your S3 Storage Lens dashboard, you must enable S3 Storage Lens **Advanced metrics and recommendations**, and then select **Detailed status code metrics**. For more information, see Using the S3 console.

Topics

- Step 1: Do a trend analysis for an individual HTTP status code
- Step 2: Analyze error counts by bucket
- Step 3: Troubleshoot errors

Step 1: Do a trend analysis for an individual HTTP status code

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In the **Trends and distributions** section, for **Primary metric**, choose **403 Forbidden error count** from the **Detailed status codes** category. For **Secondary metric**, choose **% 403 Forbidden errors**.
5. Scroll down to the **Top N overview for *date*** section. For **Metrics**, choose **403 Forbidden error count** or **% 403 Forbidden errors** from the **Detailed status codes** category.

   The **Top N overview for *date*** section updates to display the top 403 Forbidden error counts by account, AWS Region, and bucket.

Step 2: Analyze error counts by bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **Storage Lens**, **Dashboards**.
3. In the **Dashboards** list, choose the name of the dashboard that you want to view.
4. In your Storage Lens dashboard, choose the **Bucket** tab.
5. Scroll down to the **Buckets** section. For **Metrics categories**, select **Detailed status code** metrics. Then clear **Summary**.

   The **Buckets** list updates to display all the available detailed status code metrics. You can use this information to see which buckets have a large proportion of certain HTTP status codes and which status codes are common across buckets.
6. To filter the **Buckets** list to display only specific detailed status-code metrics, choose the preferences icon
   ( ).
7. Clear the toggles for any detailed status-code metrics that you don't want to view in the **Buckets** list.
8. (Optional) Under **Page size**, choose the number of buckets to display in the list.
9. Choose **Confirm**.

   The **Buckets** list displays error count metrics for the number of buckets that you specified. You can use this information to identify specific buckets that are experiencing many errors and troubleshoot errors by bucket.

Step 3: Troubleshoot errors

After you identify buckets with a high proportion of specific HTTP status codes, you can troubleshoot these errors. For more information, see the following:

- Why am I getting a 403 Forbidden error when I try to upload files in Amazon S3?
- Why am I getting a 403 Forbidden error when I try to modify a bucket policy in Amazon S3?
- How do I troubleshoot 403 Forbidden errors from my Amazon S3 bucket where all the resources are from the same AWS account?
- How do I troubleshoot an HTTP 500 or 503 error from Amazon S3?

Using Amazon S3 Storage Lens with AWS Organizations

Amazon S3 Storage Lens is a cloud-storage analytics feature that you can use to gain organization-wide visibility into object-storage usage and activity. You can use S3 Storage Lens metrics to generate summary insights, such as finding out how much storage you have across your entire organization or which are the fastest-growing buckets and prefixes. You can also use Amazon S3 Storage Lens to collect storage metrics and usage data for all AWS accounts that are part of your AWS Organizations hierarchy. To do this, you must be using AWS Organizations, and you must enable S3 Storage Lens trusted access by using your AWS Organizations management account.

After enabling trusted access, add delegated administrator access to accounts in your organization. The delegated administrator accounts are used to create S3 Storage Lens configurations and dashboards that collect organization-wide storage metrics and user data. For more information about enabling trusted access, see Amazon S3 Storage Lens and AWS Organizations in the *AWS Organizations User Guide*.

Topics

- Enabling trusted access for S3 Storage Lens
- Disabling trusted access for S3 Storage Lens
- Registering a delegated administrator for S3 Storage Lens
- Deregistering a delegated administrator for S3 Storage Lens

Enabling trusted access for S3 Storage Lens

By enabling trusted access, you allow Amazon S3 Storage Lens to access your AWS Organizations hierarchy, membership, and structure through AWS Organizations API operations. S3 Storage Lens then becomes a trusted service for your entire organization's structure.

Whenever a dashboard configuration is created, S3 Storage Lens creates service-linked roles in your organization's management or delegated administrator accounts. The service-linked role grants S3 Storage Lens permission to perform the following actions:

- Describe organizations
- List accounts
- Verify a list of AWS service access for the organizations
- Get delegated administrators for the organizations

S3 Storage Lens can then ensure that it has access to collect the cross-account metrics for the accounts in your organization. For more information, see Using service-linked roles for Amazon S3 Storage Lens.

After enabling trusted access, you can assign delegated administrator access to accounts in your organization. When an account is marked as a delegated administrator for a service, the account receives authorization to access all read-only organization API operations. This access provides the delegated administrator visibility to the members and structures of your organization so that they too can create S3 Storage Lens dashboards.

Note

- Trusted access can only be enabled by the management account.
- Only the management account and delegated administrators can create S3 Storage Lens dashboards or configurations for your organization.

Using the S3 console

To enable S3 Storage Lens to have AWS Organizations trusted access

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**. The **AWS Organizations access for Storage Lens** page displays.
4. Under **AWS Organizations trusted access**, choose **Edit**.

   The **AWS Organizations access** page displays.
5. Choose **Enable** to enable trusted access for your S3 Storage Lens dashboard.
6. Choose **Save changes**.

Using the AWS CLI

Example

The following example shows you how to enable AWS Organizations trusted access for S3 Storage Lens in AWS CLI.

```
aws organizations enable-aws-service-access --service-principal storage-
lens.s3.amazonaws.com
```

Using the AWS SDK for Java

Example – Enable AWS Organizations trusted access for S3 Storage Lens using SDK for Java

The following example shows you how to enable trusted access for S3 Storage Lens in SDK for Java. To use this example, replace the *`user input placeholders`* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import com.amazonaws.services.organizations.model.EnableAWSServiceAccessRequest;

public class EnableOrganizationsTrustedAccess {
 private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

 public static void main(String[] args) {
  try {
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            organizationsClient.enableAWSServiceAccess(new
 EnableAWSServiceAccessRequest()
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
 process
            // it and returned an error response.
```

```
            e.printStackTrace();
        } catch (SdkClientException e) {
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
 }
}
```

Disabling trusted access for S3 Storage Lens

Removing an account as a delegated administrator or disabling trusted access limits the account owner's S3 Storage Lens dashboard metrics to work only on an account level. Each account holder is then only be able to see the benefits of S3 Storage Lens through the limited scope of their account, and not their entire organization.

When you disable trusted access in S3 Storage Lens, any dashboards requiring trusted access are no longer updated. Any organizational dashboards that are created are also no longer updated. Instead, you're only able to query historic data for the S3 Storage Lens dashboard, while the data is still available.

Note

- Disabling trusted access for S3 Storage Lens also automatically stops all organization-level dashboards from collecting and aggregating storage metrics. This is because S3 Storage Lens no longer has trusted access to the organization accounts.
- Your management and delegate administrator accounts can still see the historic data for any disabled dashboards. They can also query this historic data while it is still available.

Using the S3 console

To disable trusted access for S3 Storage Lens

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**. The **AWS Organizations access for Storage Lens** page displays.

4. Under **AWS Organizations trusted access**, choose **Edit**.

   The **AWS Organizations access** page displays.
5. Choose **Disable** to disable trusted access for your S3 Storage Lens dashboard.
6. Choose **Save changes**.

Using the AWS CLI

Example

The following example disables trusted access for S3 Storage Lens using the AWS CLI.

```
aws organizations disable-aws-service-access --service-principal storage-
lens.s3.amazonaws.com
```

Using the AWS SDK for Java

Example – Disable AWS Organizations trusted access for S3 Storage Lens

The following example shows you how to disable AWS Organizations trusted access for S3 Storage Lens in SDK for Java. To use this example, replace the *`user input placeholders`* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import com.amazonaws.services.organizations.model.DisableAWSServiceAccessRequest;

public class DisableOrganizationsTrustedAccess {
 private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

 public static void main(String[] args) {
  try {
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();
```

```
            // Make sure to remove any existing delegated administrator for S3 Storage
 Lens
            // before disabling access; otherwise, the request will fail.
            organizationsClient.disableAWSServiceAccess(new
 DisableAWSServiceAccessRequest()
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
 process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
 }
}
```

Registering a delegated administrator for S3 Storage Lens

You can create organization-level dashboards by using your organization's management account or delegated administrator accounts. Delegated administrator accounts allow other accounts besides your management account to create organization-level dashboards. Only the management account of an organization can register and deregister other accounts as delegated administrators for the organization.

After enabling trusted access, you can register delegate administrator access to accounts in your organization by using the AWS Organizations REST API, AWS CLI, or SDKs from the management account. (For more information, see RegisterDelegatedAdministrator in the *AWS Organizations API Reference*.) When an account is registered as a delegated administrator, the account receives authorization to access all read-only AWS Organizations API operations. This provides visibility to the members and structures of your organization so that they can create S3 Storage Lens dashboards on your behalf.

> **Note**
>
> Before you can designate a delegated administrator by using the AWS Organizations REST API, AWS CLI, or SDKs, you must call the EnableAWSOrganizationsAccess operation.

Using the S3 console

To register delegated administrators for S3 Storage Lens

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**.
4. Under **Delegated administrators**, choose **Register account**.
5. Add an AWS account ID to register the account as a delegated administrator. The delegated administrator is able to create organization-level dashboards for all accounts and storage in your organization.
6. Choose **Register account**.

Using the AWS CLI

Example

The following example shows you how to register Organizations delegated administrators for S3 Storage Lens using the AWS CLI. To use this example, replace the *`user input placeholders`* with your own information.

```
aws organizations register-delegated-administrator --service-principal storage-
lens.s3.amazonaws.com --account-id 111122223333
```

Using the AWS SDK for Java

Example – Register Organizations delegated administrators for S3 Storage Lens

The following example shows you how to register AWS Organizations delegated administrators for S3 Storage Lens in SDK for Java. To use this example, replace the *`user input placeholders`* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
```

```
import
 com.amazonaws.services.organizations.model.RegisterDelegatedAdministratorRequest;

public class RegisterOrganizationsDelegatedAdministrator {
 private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

 public static void main(String[] args) {
  try {
            String delegatedAdminAccountId = "111122223333"; // Account Id for the
 delegated administrator.
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            organizationsClient.registerDelegatedAdministrator(new
 RegisterDelegatedAdministratorRequest()
                .withAccountId(delegatedAdminAccountId)
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
 process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
 }
}
```

Deregistering a delegated administrator for S3 Storage Lens

After enabling trusted access, you can also deregister delegate administrator access to accounts in your organization. Delegated administrator accounts allow other accounts besides your management account to create organization-level dashboards. Only the management account of an organization can deregister accounts as delegated administrators for the organization.

You can deregister a delegated administrator by using the AWS Organizations AWS Management Console, REST API, AWS CLI, or AWS SDKS from the management account. For more information, see DeregisterDelegatedAdministrator in the *AWS Organizations API Reference*.

When an account is deregistered as a delegated administrator, the account loses access to the following:

- All read-only AWS Organizations API operations that provide visibility to the members and structures of your organization.
- All organization-level dashboards created by the delegated administrator. Deregistering a delegated administrator also automatically stops all organization-level dashboards created by that delegated administrator from aggregating new storage metrics.

> **Note**
>
> The deregistered delegated administrator will still be able to see the historic data for the disabled dashboards that they created if data is still available for querying.

Using the S3 console

To deregister delegated administrators for S3 Storage Lens

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. On the left navigation pane, navigate to **Storage Lens**.
3. Choose **AWS Organizations settings**.
4. Under **Delegated administrators**, choose the account that you wish to deregister.
5. Choose **De-register account**. The deregistered account is no longer a delegated administrator and is now unable to create organization-level dashboards for all accounts and storage in your organization.
6. Choose **Register account**.

Using the AWS CLI

Example

The following example shows you how to deregister Organizations delegated administrators for S3 Storage Lens using the AWS CLI. To use this example, replace *111122223333* with your own AWS account ID.

```
aws organizations deregister-delegated-administrator --service-principal storage-
lens.s3.amazonaws.com --account-id 111122223333
```

Using the AWS SDK for Java

Example – Deregister Organizations delegated administrators for S3 Storage Lens

The following example shows you how to deregister Organizations delegated administrators for S3 Storage Lens using SDK for Java. To use this example, replace the *user input placeholders* with your own information.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.organizations.AWSOrganizations;
import com.amazonaws.services.organizations.AWSOrganizationsClient;
import
 com.amazonaws.services.organizations.model.DeregisterDelegatedAdministratorRequest;

public class DeregisterOrganizationsDelegatedAdministrator {
 private static final String S3_STORAGE_LENS_SERVICE_PRINCIPAL = "storage-
lens.s3.amazonaws.com";

 public static void main(String[] args) {
  try {
            String delegatedAdminAccountId = "111122223333"; // Account Id for the
 delegated administrator.
            AWSOrganizations organizationsClient = AWSOrganizationsClient.builder()
                .withCredentials(new ProfileCredentialsProvider())
                .withRegion(Regions.US_EAST_1)
                .build();

            organizationsClient.deregisterDelegatedAdministrator(new
 DeregisterDelegatedAdministratorRequest()
                .withAccountId(delegatedAdminAccountId)
                .withServicePrincipal(S3_STORAGE_LENS_SERVICE_PRINCIPAL));
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but AWS Organizations couldn't
 process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
```

```
            // AWS Organizations couldn't be contacted for a response, or the client
            // couldn't parse the response from AWS Organizations.
            e.printStackTrace();
        }
 }
}
```

Working with S3 Storage Lens groups to filter and aggregate metrics

An Amazon S3 Storage Lens group aggregates metrics using custom filters based on object metadata. Storage Lens groups help you drill down into characteristics of your data, such as distribution of objects by age, your most common file types, and more. For example, you can filter metrics by object tag to identify your fastest-growing datasets, or visualize your storage based on object size and age to inform your storage archive strategy. As a result, Amazon S3 Storage Lens groups helps you to better understand and optimize your S3 storage.

When you use Storage Lens groups, you can analyze and filter S3 Storage Lens metrics using object metadata such as prefixes, suffixes, object tags, object size, or object age. You can also apply a combination of these filters. After you attach your Storage Lens group to your S3 Storage Lens dashboard, you can view S3 Storage Lens metrics aggregated by Amazon S3 Storage Lens groups directly in your dashboard.

For example, you can also filter your metrics by object size or age bands to determine which portion of your storage consists of small objects. You can then use this information with S3 Intelligent-Tiering or S3 Lifecycle to transition small objects to different storage classes for cost and storage optimization.

- Using Storage Lens groups

How S3 Storage Lens groups work

You can use Storage Lens groups to aggregate metrics using custom filters based on object metadata. When you define a custom filter, you can use prefixes, suffixes, object tags, object sizes, object age, or a combination of these custom filters. During Storage Lens group creation, you can also include a single filter or multiple filter conditions. To specify multiple filter conditions, you use And or `Or` logical operators.

When you create and configure a Storage Lens group, the Storage Lens group itself acts as a custom filter in the dashboard that you attach the group to. In your dashboard, you can then use the Storage Lens group filter to obtain storage metrics based on the custom filter that you defined in the group.

To view the data for your Storage Lens group in your S3 Storage Lens dashboard, you must attach the group to the dashboard after you've created the group. After your Storage Lens group is attached to your Storage Lens dashboard, your dashboard will collect storage usage metrics within 48 hours. You can then visualize this data in the Storage Lens dashboard or export it through a metrics export. If you forget to attach a Storage Lens group to a dashboard, your Storage Lens group data won't be captured or displayed anywhere.

Note

- When you create a S3 Storage Lens group, you're creating an AWS resource. Therefore, each Storage Lens group has its own Amazon Resource Name (ARN), which you can specify when attaching it to or excluding it from a S3 Storage Lens dashboard.
- If your Storage Lens group isn't attached to a dashboard, you won't incur any additional charges for creating a Storage Lens group.
- S3 Storage Lens aggregates usage metrics for an object under all matching Storage Lens groups. Therefore, if an object matches the filter conditions for two or more Storage Lens groups, you will see repeated counts for the same object across your storage usage.

You can create a Storage Lens group at the account level in a specified home Region (from the list of supported AWS Regions). Then, you can attach your Storage Lens group to multiple Storage Lens dashboards, as long as the dashboards are in the same AWS account and home Region. You can create up to 50 Storage Lens groups per home Region in each AWS account.

You can create and manage S3 Storage Lens groups by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), AWS SDKs, or the Amazon S3 REST API.

- Storage Lens groups metrics export

Viewing Storage Lens group aggregated metrics

You can view the aggregated metrics for your Storage Lens groups by attaching the groups to a dashboard. The Storage Lens groups that you want to attach must reside within the designated home Region in the dashboard account.

To attach a Storage Lens group to a dashboard, you must specify the group in the **Storage Lens group aggregation** section of your dashboard configuration. If you have several Storage Lens groups, you can filter the **Storage Lens group aggregation** results to include or exclude only the groups that you want. For more information about attaching groups to your dashboards, see the section called "Attach or remove a Storage Lens group".

After you've attached your groups, you will see the additional Storage Lens group aggregation data in your dashboard within 48 hours.

> **Note**
>
> To view aggregated metrics for your Storage Lens group, you must attach the group to an S3 Storage Lens dashboard.

Storage Lens groups permissions

Storage Lens groups require certain permissions in AWS Identity and Access Management (IAM) to authorize access to S3 Storage Lens group actions. To grant these permissions, you can use an identity-based IAM policy. You can attach this policy to IAM users, groups, or roles to grant them permissions. Such permissions can include the ability to create or delete Storage Lens groups, view their configurations, or manage their tags.

The IAM user or role that you grant permissions to must belong to the account that created or owns the Storage Lens group.

To use Storage Lens groups and to view your Storage Lens groups metrics, you must first have the appropriate permissions to use S3 Storage Lens. For more information, see the section called "Setting permissions".

To create and manage S3 Storage Lens groups, you must have the following IAM permissions, depending on which actions you want to perform:

Action	IAM permissions
Create a new Storage Lens group	`s3:CreateStorageLensGroup`
Create a new Storage Lens group with tags	`s3:CreateStorageLensGroup` , `s3:TagResource`
Update an existing Storage Lens group	`s3:UpdateStorageLensGroup`
Return the details of a Storage Lens group configuration	`s3:GetStorageLensGroup`
List all Storage Lens groups in your home Region	`s3:ListStorageLensGroups`
Delete a Storage Lens group	`s3:DeleteStorageLensGroup`
List the tags that were added to your Storage Lens group	`s3:ListTagsForResource`
Add or update a Storage Lens group tag for an existing Storage Lens group	`s3:TagResource`
Delete a tag from a Storage Lens group	`s3:UntagResource`

Here's an example of how to configure your IAM policy in the account that creates the Storage Lens group. To use this policy, replace *`us-east-1`* with the home Region that your Storage Lens group is located in. Replace *`111122223333`* with your AWS account ID, and replace *`example-storage-lens-group`* with the name of your Storage Lens group. To apply these permissions to all Storage Lens groups, replace *`example-storage-lens-group`* with an *`*`*.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EXAMPLE-Statement-ID",
```

```
            "Effect": "Allow",
            "Action": [
                "s3:CreateStorageLensGroup",
                "s3:UpdateStorageLensGroup",
                "s3:GetStorageLensGroup",
                "s3:ListStorageLensGroups",
                "s3:DeleteStorageLensGroup,
                "s3:TagResource",
                "s3:UntagResource",
                "s3:ListTagsForResource"
                ],
            "Resource": "arn:aws:s3:us-east-1:111122223333:storage-lens-group/example-storage-lens-group"
        }
    ]
}
```

For more information about S3 Storage Lens permissions, see Setting Amazon S3 Storage Lens permissions. For more information about IAM policy language, see Policies and permissions in Amazon S3.

Storage Lens groups configuration

S3 Storage Lens group name

We recommend giving your Storage Lens groups names that indicate their purpose so that you can easily determine which groups you want to attach to your dashboards. To attach a Storage Lens group to a dashboard, you must specify the group in the **Storage Lens group aggregation** section of the dashboard configuration.

Storage Lens group names must be unique within the account. They must not exceed 64 characters, and can contain only letters (a-z, A-Z), numbers (0-9), hyphens (-), and underscores (_).

Home Region

The home Region is the AWS Region where your Storage Lens group is created and maintained. Your Storage Lens group is created in the same home Region as your Amazon S3 Storage Lens dashboard. The Storage Lens group configuration and metrics are also stored in this Region. You can create up to 50 Storage Lens groups in a home Region.

After you create your Storage Lens group, you can't edit the home Region.

Scope

To include objects in your Storage Lens group, they must be in scope for your Amazon S3 Storage Lens dashboard. The scope of your Storage Lens dashboard is determined by the buckets that you included in the **Dashboard scope** of your S3 Storage Lens dashboard configuration.

You can use different filters for your objects to define the scope of your Storage Lens group. To view these Storage Lens group metrics in your S3 Storage Lens dashboard, objects must match the filters that you include in your Storage Lens groups. For example, suppose that your Storage Lens group includes objects with the prefix `marketing` and the suffix `.png`, but no objects match those criteria. In this case, metrics for this Storage Lens group won't be generated in your daily metrics export, and no metrics for this group will be visible in your dashboard.

Filters

You can use the following filters in an S3 Storage Lens group:

- **Prefixes** – Specifies the prefix of included objects, which is a string of characters at the beginning of the object key name. For example, a value of `images` for the **Prefixes** filter includes objects with any of the following prefixes: `images/`, `images-marketing`, and `images/production`. The maximum length of a prefix is 1,024 bytes.
- **Suffixes** – Specifies the suffix of included objects (for example, `.png`, `.jpeg`, or `.csv`). The maximum length of a suffix is 1,024 bytes.
- **Object tags** – Specifies the list of object tags that you want to filter on. A tag key can't exceed 128 Unicode characters, and a tag value can’t exceed 256 Unicode characters. Note that if the object tag value field is left empty, S3 Storage Lens groups only matches the object to other objects that also have empty tag values.
- **Age** – Specifies the object age range of included objects in days. Only integers are supported.
- **Size** – Specifies the object size range of included objects in bytes. Only integers are supported. The maximum allowable value is 5 TB.

Storage Lens group object tags

You can create a Storage Lens group that includes up to 10 object tag filters. The following example includes two object tag key-value pairs as filters for a Storage Lens group that's named *`Marketing-Department`*. To use this example, replace *`Marketing-Department`* with the name of your group, and replace *`object-tag-key-1`*, *`object-tag-value-1`*, and so on with the object tag key-value pairs that you want to filter on.

```
{
    "Name": "Marketing-Department",
    "Filter": {
     "MatchAnyTag":[
                {
                    "Key": "object-tag-key-1",
                    "Value": "object-tag-value-1"
                },
                {
                    "Key": "object-tag-key-2",
                    "Value": "object-tag-value-2"
                }
            ]
    }
}
```

Logical operators (And or Or)

To include multiple filter conditions in your Storage Lens group, you can use logical operators (either And or Or). In the following example, the Storage Lens group that's named *Marketing-Department* has an And operator that contains Prefix, ObjectAge, and ObjectSize filters. Because an And operator is used, only objects that match **all** of these filter conditions will be included the Storage Lens group's scope.

To use this example, replace the *user input placeholders* with the values that you want to filter on.

```
{
    "Name": "Marketing-Department",
    "Filter": {
        "And": {
            "MatchAnyPrefix": [
                "prefix-1",
                "prefix-2",
                "prefix-3/sub-prefix-1"
            ],
             "MatchObjectAge": {
                "DaysGreaterThan": 10,
                "DaysLessThan": 60
            },
            "MatchObjectSize": {
                "BytesGreaterThan": 10,
```

```
                "BytesLessThan": 60
            }
        }
    }
}
```

> **Note**
>
> If you want to include objects that match **any** of the conditions in the filters, replace the And logical operator with the `Or` logical operator in this example.

AWS resource tags

Each S3 Storage Lens group is counted as an AWS resource with its own Amazon Resource Name (ARN). Therefore, when you configure your Storage Lens group, you can optionally add AWS resource tags to the group. You can add up to 50 tags for each Storage Lens group. To create a Storage Lens group with tags, you must have the `s3:CreateStorageLensGroup` and `s3:TagResource` permissions.

You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it. You can also use tags to track and allocate costs.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate attribute-based access control (ABAC). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to control access to AWS resources.

You can edit tag keys and values, and you can remove tags from a resource at any time. Also, be aware of the following limitations:

- Tag keys and tag values are case sensitive.
- If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value.
- If you delete a resource, any tags for the resource are also deleted.
- Don't include private or sensitive data in your AWS resource tags.

- System tags (or tags with tag keys that begin with `aws:`) aren't supported.
- The length of each tag key can't exceed 128 characters. The length of each tag value can't exceed 256 characters.

Storage Lens groups metrics export

S3 Storage Lens group metrics are included in the Amazon S3 Storage Lens metrics export for the dashboard that the Storage Lens group is attached to. For general information about the Storage Lens metrics export feature, see Viewing Amazon S3 Storage Lens metrics using a data export.

Your metrics export for Storage Lens groups includes any S3 Storage Lens metrics that are in scope for the dashboard that you attached the Storage Lens group to. The export also includes additional metrics data for Storage Lens groups.

After you create your Storage Lens group, your metrics export is sent daily to the bucket that you selected when you configured the metrics export for the dashboard that your group is attached to. It can take up to 48 hours for you to receive the first metrics export.

To generate metrics in the daily export, objects must match the filters that you include in your Storage Lens groups. If no objects match the filters that you included in your Storage Lens group, then no metrics will be generated. However, if an object matches two or more Storage Lens groups, the object is listed separately for each group when it appears in the metrics export.

You can identify metrics for Storage Lens groups by looking for one of the following values in the `record_type` column of the metrics export for your dashboard:

- `STORAGE_LENS_GROUP_BUCKET`
- `STORAGE_LENS_GROUP_ACCOUNT`

The `record_value` column displays the resource ARN for the Storage Lens group (for example, `arn:aws:s3:us-east-1:111122223333:storage-lens-group/Marketing-Department`).

Using Storage Lens groups

Amazon S3 Storage Lens groups aggregates metrics using custom filters based on object metadata. You can analyze and filter S3 Storage Lens metrics using prefixes, suffixes, object tags, object size, or object age. With Amazon S3 Storage Lens groups, you can also categorize your usage within and across Amazon S3 buckets. As a result, you'll be able to better understand and optimize your S3 storage.

To start visualizing the data for a Storage Lens group, you must first attach your Storage Lens group to an S3 Storage Lens dashboard. If you need to manage Storage Lens groups in the dashboard, you can edit the dashboard configuration. To check which Storage Lens groups are under your account, you can list them. To check which Storage Lens groups are attached to your dashboard, you can always check the **Storage Lens groups** tab in the dashboard. To review or update the scope of an existing Storage Lens group, you can view its details. You can also permanently delete a Storage Lens group.

To manage permissions, you can create and add user-defined AWS resource tags to your Storage Lens groups. You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate attribute-based access control (ABAC). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to control access to AWS resources.

Creating a Storage Lens group

The following examples demonstrate how to create an Amazon S3 Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To create a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region that you want to switch to.
3. In the left navigation pane, choose **Storage Lens groups**.
4. Choose **Create Storage Lens group**.
5. Under **General**, view your **Home Region** and enter your **Storage Lens group name**.
6. Under **Scope**, choose the filter that you want to apply to your Storage Lens group. To apply multiple filters, choose your filters, and then choose the **AND** or **OR** logical operator.

   - For the **Prefixes** filter, choose **Prefixes**, and enter a prefix string. To add multiple prefixes, choose **Add prefix**. To remove a prefix, choose **Remove** next to the prefix that you want to remove.
   - For the **Object tags** filter, choose **Object tags**, and enter the key-value pair for your object. Then, choose **Add tag**. To remove a tag, choose **Remove** next to the tag that you want to remove.
   - For the **Suffixes** filter, choose **Suffixes**, and enter a suffix string. To add multiple suffixes, choose **Add suffix**. To remove a suffix, choose **Remove** next to the suffix that you want to remove.
   - For the **Age** filter, specify the object age range in days. Choose **Specify minimum object age**, and enter the minimum object age. Then, choose **Specify maximum object age**, and enter the maximum object age.
   - For the **Size** filter, specify the object size range and unit of measurement. Choose **Specify minimum object size**, and enter the minimum object size. Choose **Specify maximum object size**, and enter the maximum object size.
7. (Optional) For AWS resource tags, add the key-value pair, and then choose **Add tag**.
8. Choose **Create Storage Lens group**.

Using the AWS CLI

The following example AWS CLI command creates a Storage Lens group. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control create-storage-lens-group --account-id 111122223333 \
--region us-east-1 --storage-lens-group=file://./marketing-department.json
```

The following example AWS CLI command creates a Storage Lens group with two AWS resource tags. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control create-storage-lens-group --account-id 111122223333 \
--region us-east-1 --storage-lens-group=file://./marketing-department.json \
--tags Key=k1,Value=v1 Key=k2,Value=v2
```

For example JSON configurations, see Storage Lens groups configuration.

Using the AWS SDK for Java

The following AWS SDK for Java example creates a Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

Example – Create a Storage Lens group with a single filter

The following example creates a Storage Lens group named *Marketing-Department*. This group has an object age filter that specifies the age range as *30* to *90* days. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectAge;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;

public class CreateStorageLensGroupWithObjectAge {
```

```
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            StorageLensGroupFilter objectAgeFilter = StorageLensGroupFilter.builder()
                    .matchObjectAge(MatchObjectAge.builder()
                            .daysGreaterThan(30)
                            .daysLessThan(90)
                            .build())
                    .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
                    .name(storageLensGroupName)
                    .filter(objectAgeFilter)
                    .build();

            CreateStorageLensGroupRequest createStorageLensGroupRequest =
 CreateStorageLensGroupRequest.builder()
                    .storageLensGroup(storageLensGroup)
                    .accountId(accountId).build();

            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Example – Create a Storage Lens group with an AND operator that includes multiple filters

The following example creates a Storage Lens group named *Marketing-Department*. This group uses the AND operator to indicate that objects must match **all** of the filter conditions. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectAge;
import software.amazon.awssdk.services.s3control.model.MatchObjectSize;
import software.amazon.awssdk.services.s3control.model.S3Tag;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupAndOperator;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;

public class CreateStorageLensGroupWithAndFilter {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            // Create object tags.
            S3Tag tag1 = S3Tag.builder()
                    .key("object-tag-key-1")
                    .value("object-tag-value-1")
                    .build();
            S3Tag tag2 = S3Tag.builder()
                    .key("object-tag-key-2")
                    .value("object-tag-value-2")
                    .build();

            StorageLensGroupAndOperator andOperator =
 StorageLensGroupAndOperator.builder()
                    .matchAnyPrefix("prefix-1", "prefix-2", "prefix-3/sub-prefix-1")
                    .matchAnySuffix(".png", ".gif", ".jpg")
                    .matchAnyTag(tag1, tag2)
```

```
                    .matchObjectAge(MatchObjectAge.builder()
                            .daysGreaterThan(30)
                            .daysLessThan(90).build())
                    .matchObjectSize(MatchObjectSize.builder()
                            .bytesGreaterThan(1000L)
                            .bytesLessThan(6000L).build())
                    .build();

            StorageLensGroupFilter andFilter = StorageLensGroupFilter.builder()
                    .and(andOperator)
                    .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
                    .name(storageLensGroupName)
                    .filter(andFilter)
                    .build();

            CreateStorageLensGroupRequest createStorageLensGroupRequest =
 CreateStorageLensGroupRequest.builder()
                    .storageLensGroup(storageLensGroup)
                    .accountId(accountId).build();

            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Example – Create a Storage Lens group with an OR operator that includes multiple filters

The following example creates a Storage Lens group named *Marketing-Department*. This group uses an OR operator to apply a prefix filter (*prefix-1*, *prefix-2*, *prefix3/sub-prefix-1*) or

an object size filter with a size range between *1000* bytes and *6000* bytes. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.MatchObjectSize;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupOrOperator;

public class CreateStorageLensGroupWithOrFilter {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            StorageLensGroupOrOperator orOperator =
 StorageLensGroupOrOperator.builder()
                    .matchAnyPrefix("prefix-1", "prefix-2", "prefix-3/sub-prefix-1")
                    .matchObjectSize(MatchObjectSize.builder()
                            .bytesGreaterThan(1000L)
                            .bytesLessThan(6000L)
                            .build())
                    .build();

            StorageLensGroupFilter orFilter = StorageLensGroupFilter.builder()
                    .or(orOperator)
                    .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
                    .name(storageLensGroupName)
                    .filter(orFilter)
                    .build();

            CreateStorageLensGroupRequest createStorageLensGroupRequest =
 CreateStorageLensGroupRequest.builder()
                    .storageLensGroup(storageLensGroup)
```

```
                    .accountId(accountId).build();

            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Example – Create a Storage Lens group with a single filter and two AWS resource tags

The following example creates a Storage Lens group named *Marketing-Department* that has a suffix filter. This example also adds two AWS resource tags to the Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.CreateStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;
import software.amazon.awssdk.services.s3control.model.Tag;

public class CreateStorageLensGroupWithResourceTags {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
```

```
            // Create AWS resource tags.
            Tag resourceTag1 = Tag.builder()
                    .key("resource-tag-key-1")
                    .value("resource-tag-value-1")
                    .build();
            Tag resourceTag2 = Tag.builder()
                    .key("resource-tag-key-2")
                    .value("resource-tag-value-2")
                    .build();

            StorageLensGroupFilter suffixFilter = StorageLensGroupFilter.builder()
                    .matchAnySuffix(".png", ".gif", ".jpg")
                    .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
                    .name(storageLensGroupName)
                    .filter(suffixFilter)
                    .build();

            CreateStorageLensGroupRequest createStorageLensGroupRequest =
 CreateStorageLensGroupRequest.builder()
                    .storageLensGroup(storageLensGroup)
                    .tags(resourceTag1, resourceTag2)
                    .accountId(accountId).build();

            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.createStorageLensGroup(createStorageLensGroupRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

For example JSON configurations, see Storage Lens groups configuration.

Attaching or removing S3 Storage Lens groups to or from your dashboard

After you've upgraded to the advanced tier in Amazon S3 Storage Lens, you can attach a Storage Lens group to your dashboard. If you have several Storage Lens groups, you can include or exclude the groups that you want.

Your Storage Lens groups must reside within the designated home Region in the dashboard account. After you attach a Storage Lens group to your dashboard, you'll receive the additional Storage Lens group aggregation data in your metrics export within 48 hours.

> **Note**
>
> If you want to view aggregated metrics for your Storage Lens group, you must attach it to your Storage Lens dashboard. For examples of Storage Lens group JSON configuration files, see S3 Storage Lens example configuration with Storage Lens groups in JSON.

Using the S3 console

To attach a Storage Lens group to a Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, under **Storage Lens**, choose **Dashboards**.
3. Choose the option button for the Storage Lens dashboard that you want to attach a Storage Lens group to.
4. Choose **Edit**.
5. Under **Metrics selection**, choose **Advanced metrics and recommendations**.
6. Select **Storage Lens group aggregation**.

   > **Note**
   >
   > By default, **Advanced metrics** is also selected. However, you can also deselect this setting as it's not required to aggregate Storage Lens groups data.

7. Scroll down to **Storage Lens group aggregation** and specify the Storage Lens group or groups that you either want to include or exclude in the data aggregation. You can use the following filtering options:

- If you want to include certain Storage Lens groups, choose **Include Storage Lens groups**. Under **Storage Lens groups to include**, select your Storage Lens groups.
- If you want to include all Storage Lens groups, select **Include all Storage Lens groups in home Region in this account**.
- If you want to exclude certain Storage Lens groups, choose **Exclude Storage Lens groups**. Under **Storage Lens groups to exclude**, select the Storage Lens groups that you want to exclude.

8. Choose **Save changes**. If you've configured your Storage Lens groups correctly, you will see the additional Storage Lens group aggregation data in your dashboard within 48 hours.

To remove a Storage Lens group from an S3 Storage Lens dashboard

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, under **Storage Lens**, choose **Dashboards**.
3. Choose the option button for the Storage Lens dashboard that you want to remove a Storage Lens group from.
4. Choose **View dashboard configuration**.
5. Choose **Edit**.
6. Scroll down to the **Metrics selection** section.
7. Under **Storage Lens group aggregation**, choose the **X** next to the Storage Lens group that you want to remove. This removes your Storage Lens group.

   If you included all of your Storage Lens groups in your dashboard, clear the check box next to **Include all Storage Lens groups in home Region in this account**.
8. Choose **Save changes**.

> **Note**
>
> It will take up to 48 hours for your dashboard to reflect the configuration updates.

Using the AWS SDK for Java

Example – Attach all Storage Lens groups to a dashboard

The following SDK for Java example attaches all Storage Lens groups in the account *111122223333* to the *DashBoardConfigurationId* dashboard:

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateDashboardWithStorageLensGroups {
    public static void main(String[] args) {
        String configurationId = "ExampleDashboardConfigurationId";
        String sourceAccountId = "111122223333";

        try {
            StorageLensGroupLevel storageLensGroupLevel = new StorageLensGroupLevel();

            AccountLevel accountLevel = new AccountLevel()
                    .withBucketLevel(new BucketLevel())
                    .withStorageLensGroupLevel(storageLensGroupLevel);

            StorageLensConfiguration configuration = new StorageLensConfiguration()
                    .withId(configurationId)
                    .withAccountLevel(accountLevel)
                    .withIsEnabled(true);

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();
```

```
            s3ControlClient.putStorageLensConfiguration(new
 PutStorageLensConfigurationRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
                    .withStorageLensConfiguration(configuration)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Example – Attach two Storage Lens groups to a dashboard

The following AWS SDK for Java example attaches two Storage Lens groups (*StorageLensGroupName1* and *StorageLensGroupName2*) to the *ExampleDashboardConfigurationId* dashboard.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;
import com.amazonaws.services.s3control.model.StorageLensGroupLevelSelectionCriteria;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateDashboardWith2StorageLensGroups {
    public static void main(String[] args) {
```

```
        String configurationId = "ExampleDashboardConfigurationId";
        String storageLensGroupName1 = "StorageLensGroupName1";
        String storageLensGroupName2 = "StorageLensGroupName2";
        String sourceAccountId = "111122223333";

        try {
            StorageLensGroupLevelSelectionCriteria selectionCriteria = new
StorageLensGroupLevelSelectionCriteria()
                    .withInclude(
                            "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
+ ":storage-lens-group/" + storageLensGroupName1,
                            "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
+ ":storage-lens-group/" + storageLensGroupName2);

            System.out.println(selectionCriteria);
            StorageLensGroupLevel storageLensGroupLevel = new StorageLensGroupLevel()
                    .withSelectionCriteria(selectionCriteria);

            AccountLevel accountLevel = new AccountLevel()
                    .withBucketLevel(new BucketLevel())
                    .withStorageLensGroupLevel(storageLensGroupLevel);

            StorageLensConfiguration configuration = new StorageLensConfiguration()
                    .withId(configurationId)
                    .withAccountLevel(accountLevel)
                    .withIsEnabled(true);

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            s3ControlClient.putStorageLensConfiguration(new
PutStorageLensConfigurationRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
                    .withStorageLensConfiguration(configuration)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
```

```
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Example – Attach all Storage Lens groups with exclusions

The following SDK for Java example attaches all Storage Lens groups to the *ExampleDashboardConfigurationId* dashboard, excluding the two specified (*StorageLensGroupName1* and *StorageLensGroupName2*):

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.s3control.AWSS3Control;
import com.amazonaws.services.s3control.AWSS3ControlClient;
import com.amazonaws.services.s3control.model.AccountLevel;
import com.amazonaws.services.s3control.model.BucketLevel;
import com.amazonaws.services.s3control.model.PutStorageLensConfigurationRequest;
import com.amazonaws.services.s3control.model.StorageLensConfiguration;
import com.amazonaws.services.s3control.model.StorageLensGroupLevel;
import com.amazonaws.services.s3control.model.StorageLensGroupLevelSelectionCriteria;

import static com.amazonaws.regions.Regions.US_WEST_2;

public class CreateDashboardWith2StorageLensGroupsExcluded {
    public static void main(String[] args) {
        String configurationId = "ExampleDashboardConfigurationId";
        String storageLensGroupName1 = "StorageLensGroupName1";
        String storageLensGroupName2 = "StorageLensGroupName2";
        String sourceAccountId = "111122223333";

        try {
            StorageLensGroupLevelSelectionCriteria selectionCriteria = new
 StorageLensGroupLevelSelectionCriteria()
                    .withInclude(
                            "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
 + ":storage-lens-group/" + storageLensGroupName1,
```

```
                            "arn:aws:s3:" + US_WEST_2.getName() + ":" + sourceAccountId
 + ":storage-lens-group/" + storageLensGroupName2);

            System.out.println(selectionCriteria);
            StorageLensGroupLevel storageLensGroupLevel = new StorageLensGroupLevel()
                    .withSelectionCriteria(selectionCriteria);

            AccountLevel accountLevel = new AccountLevel()
                    .withBucketLevel(new BucketLevel())
                    .withStorageLensGroupLevel(storageLensGroupLevel);

            StorageLensConfiguration configuration = new StorageLensConfiguration()
                    .withId(configurationId)
                    .withAccountLevel(accountLevel)
                    .withIsEnabled(true);

            AWSS3Control s3ControlClient = AWSS3ControlClient.builder()
                    .withCredentials(new ProfileCredentialsProvider())
                    .withRegion(US_WEST_2)
                    .build();

            s3ControlClient.putStorageLensConfiguration(new
 PutStorageLensConfigurationRequest()
                    .withAccountId(sourceAccountId)
                    .withConfigId(configurationId)
                    .withStorageLensConfiguration(configuration)
            );
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Visualizing your Storage Lens groups data

You can visualize your Storage Lens groups data by attaching the group to your Amazon S3 Storage Lens dashboard. After you've included the Storage Lens group in the Storage Lens group

aggregation in your dashboard configuration, it can take up to 48 hours for the Storage Lens group data to display in your dashboard.

After the dashboard configuration has been updated, any newly attached Storage Lens groups appear in the list of available resources under the **Storage Lens groups** tab. You can also further analyze storage usage in your **Overview** tab by slicing the data by another dimension. For example, you can choose one of the items listed under the **Top 3** categories and choose **Analyze by** to slice the data by another dimension. You can't apply the same dimension as the filter itself.

> **Note**
>
> You can't apply a Storage Lens group filter along with a prefix filter, or the reverse. You also can't further analyze a Storage Lens group by using a prefix filter.

You can use the **Storage Lens groups** tab in the Amazon S3 Storage Lens dashboard to customize the data visualization for the Storage Lens groups that are attached to your dashboard. You can either visualize the data for some Storage Lens groups that are attached to your dashboard, or all of them.

When visualizing Storage Lens group data in your S3 Storage Lens dashboard, be aware of the following:

- S3 Storage Lens aggregates usage metrics for an object under all matching Storage Lens groups. Therefore, if an object matches the filter conditions for two or more Storage Lens groups, you will see repeated counts for the same object across your storage usage.
- Objects must match the filters that you include in your Storage Lens groups. If no objects match the filters that you include in your Storage Lens group, then no metrics are generated. To determine if there are any unassigned objects, check your total object count in the dashboard at the account level and bucket level.

Updating a Storage Lens group

The following examples demonstrate how to update an Amazon S3 Storage Lens group. You can update a Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To update a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **Scope**, choose **Edit**.
5. On the **Scope** page, select the filter that you want to apply to your Storage Lens group. To apply multiple filters, select your filters, and choose the **AND** or **OR** logical operator.

   - For the **Prefixes** filter, select **Prefixes**, and enter a prefix string. To add multiple prefixes, choose **Add prefix**. To remove a prefix, choose **Remove** next to the prefix that you want to remove.
   - For the **Object tags** filter, enter the key-value pair for your object. Then, choose **Add tag**. To remove a tag, choose **Remove** next to the tag that you want to remove.
   - For the **Suffixes** filter, select **Suffixes**, and enter a suffix string. To add multiple suffixes, choose **Add suffix**. To remove a suffix, choose **Remove** next to the suffix that you want to remove.
   - For the **Age** filter, specify the object age range in days. Choose **Specify minimum object age**, and enter the minimum object age. For **Specify maximum object age**, enter the maximum object age.
   - For the **Size** filter, specify the object size range and unit of measurement. Choose **Specify minimum object size**, and enter the minimum object size. For **Specify maximum object size**, enter the maximum object size.
6. Choose **Save changes**. The details page for the Storage Lens group appears.
7. (Optional) If you want to add a new AWS resource tag, scroll to the **AWS resource tags** section, then choose **Add tags**. The **Add tags** page appears.

   Add the new key-value pair, then choose **Save changes**. The details page for the Storage Lens group appears.
8. (Optional) If you want to remove an existing AWS resource tag, scroll to the **AWS resource tags** section, and select the resource tag. Then, choose **Delete**. The **Delete AWS tags** dialog box appears.

Choose **Delete** again to permanently delete the AWS resource tag.

> **Note**
>
> After you permanently delete an AWS resource tag, it can't be restored.

Using the AWS CLI

The following AWS CLI example command returns the configuration details for a Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-group --account-id 111122223333 \
--region us-east-1 --name marketing-department
```

The following AWS CLI example updates a Storage Lens group. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control update-storage-lens-group --account-id 111122223333 \
--region us-east-1 --storage-lens-group=file://./marketing-department.json
```

For example JSON configurations, see Storage Lens groups configuration.

Using the AWS SDK for Java

The following AWS SDK for Java example returns the configuration details for the *Marketing-Department* Storage Lens group in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupResponse;
```

```
public class GetStorageLensGroup {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            GetStorageLensGroupRequest getRequest =
 GetStorageLensGroupRequest.builder()
                    .name(storageLensGroupName)
                    .accountId(accountId).build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            GetStorageLensGroupResponse response =
 s3ControlClient.getStorageLensGroup(getRequest);
            System.out.println(response);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

The following example updates the Storage Lens group named *Marketing-Department* in account *111122223333*. This example updates the dashboard scope to include objects that match any of the following suffixes: *.png*, *.gif*, *.jpg*, or *.jpeg*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.StorageLensGroup;
import software.amazon.awssdk.services.s3control.model.StorageLensGroupFilter;
```

```
import software.amazon.awssdk.services.s3control.model.UpdateStorageLensGroupRequest;

public class UpdateStorageLensGroup {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            // Create updated filter.
            StorageLensGroupFilter suffixFilter = StorageLensGroupFilter.builder()
                    .matchAnySuffix(".png", ".gif", ".jpg", ".jpeg")
                    .build();

            StorageLensGroup storageLensGroup = StorageLensGroup.builder()
                    .name(storageLensGroupName)
                    .filter(suffixFilter)
                    .build();

            UpdateStorageLensGroupRequest updateStorageLensGroupRequest =
 UpdateStorageLensGroupRequest.builder()
                    .name(storageLensGroupName)
                    .storageLensGroup(storageLensGroup)
                    .accountId(accountId)
                    .build();

            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.updateStorageLensGroup(updateStorageLensGroupRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

For example JSON configurations, see Storage Lens groups configuration.

Managing AWS resource tags with Storage Lens groups

Each Amazon S3 Storage Lens group is counted as an AWS resource with its own Amazon Resource Name (ARN). Therefore, when you configure your Storage Lens group, you can optionally add AWS resource tags to the group. You can add up to 50 tags for each Storage Lens group. To create a Storage Lens group with tags, you must have the `s3:CreateStorageLensGroup` and `s3:TagResource` permissions.

You can use AWS resource tags to categorize resources according to department, line of business, or project. Doing so is useful when you have many resources of the same type. By applying tags, you can quickly identify a specific Storage Lens group based on the tags that you've assigned to it. You can also use tags to track and allocate costs.

In addition, when you add an AWS resource tag to your Storage Lens group, you activate attribute-based access control (ABAC). ABAC is an authorization strategy that defines permissions based on attributes, in this case tags. You can also use conditions that specify resource tags in your IAM policies to control access to AWS resources.

You can edit tag keys and values, and you can remove tags from a resource at any time. Also, be aware of the following limitations:

- Tag keys and tag values are case sensitive.
- If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value.
- If you delete a resource, any tags for the resource are also deleted.
- Don't include private or sensitive data in your AWS resource tags.
- System tags (with tag keys that begin with `aws:`) aren't supported.
- The length of each tag key can't exceed 128 characters. The length of each tag value can't exceed 256 characters.

The following examples demonstrate how to use AWS resource tags with Storage Lens groups.

Topics

- Adding an AWS resource tag to a Storage Lens group
- Updating Storage Lens group tag values
- Deleting an AWS resource tag from a Storage Lens group
- Listing Storage Lens group tags

Adding an AWS resource tag to a Storage Lens group

The following examples demonstrate how to add AWS resource tags to an Amazon S3 Storage Lens group. You can add resource tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To add an AWS resource tag to a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, choose **Add tags**.
5. On the **Add tags** page, add the new key-value pair.

   > **Note**
   >
   > Adding a new tag with the same key as an existing tag overwrites the previous tag value.

6. (Optional) To add more than one new tag, choose **Add tag** again to continue adding new entries. You can add up to 50 AWS resource tags to your Storage Lens group.
7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove.
8. Choose **Save changes**.

Using the AWS CLI

The following example AWS CLI command adds two resource tags to an existing Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control tag-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-department \
```

```
--region us-east-1 --tags Key=k1,Value=v1 Key=k2,Value=v2
```

Using the AWS SDK for Java

The following AWS SDK for Java example adds two AWS resource tags to an existing Storage Lens group. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.Tag;
import software.amazon.awssdk.services.s3control.model.TagResourceRequest;

public class TagResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            Tag resourceTag1 = Tag.builder()
                .key("resource-tag-key-1")
                .value("resource-tag-value-1")
                .build();
            Tag resourceTag2 = Tag.builder()
                    .key("resource-tag-key-2")
                    .value("resource-tag-value-2")
                    .build();
            TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                    .resourceArn(resourceARN)
                    .tags(resourceTag1, resourceTag2)
                    .accountId(accountId)
                    .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.tagResource(tagResourceRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
```

```
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Updating Storage Lens group tag values

The following examples demonstrate how to update Storage Lens group tag values by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To update an AWS resource tag for a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, select the tag that you want to update.
5. Add the new tag value, using the same key of the key-value pair that you want to update. Choose the checkmark icon to update the tag value.

   > **Note**
   >
   > Adding a new tag with the same key as an existing tag overwrites the previous tag value.

6. (Optional) If you want to add new tags, choose **Add tag** to add new entries. The **Add tags** page appears.

   You can add up to 50 AWS resource tags for your Storage Lens group. When you're finished adding new tags, choose **Save changes**.
7. (Optional) If you want to remove a newly added entry, choose **Remove** next to the tag that you want to remove. When you're finished removing tags, choose **Save changes**.

Using the AWS CLI

The following example AWS CLI command updates two tag values for the Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control tag-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-department \
--region us-east-1 --tags Key=k1,Value=v3 Key=k2,Value=v4
```

Using the AWS SDK for Java

The following AWS SDK for Java example updates two Storage Lens group tag values. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.Tag;
import software.amazon.awssdk.services.s3control.model.TagResourceRequest;

public class UpdateTagsForResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            Tag updatedResourceTag1 = Tag.builder()
                .key("resource-tag-key-1")
                .value("resource-tag-updated-value-1")
                .build();
            Tag updatedResourceTag2 = Tag.builder()
                    .key("resource-tag-key-2")
                    .value("resource-tag-updated-value-2")
                    .build();
            TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                    .resourceArn(resourceARN)
                    .tags(updatedResourceTag1, updatedResourceTag2)
```

```
                    .accountId(accountId)
                    .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.tagResource(tagResourceRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Deleting an AWS resource tag from a Storage Lens group

The following examples demonstrate how to delete an AWS resource tag from a Storage Lens group. You can delete tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To delete an AWS resource tag from a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you want to update.
4. Under **AWS resource tags**, select the key-value pair that you want to delete.
5. Choose **Delete**. The **Delete AWS resource tags** dialog box appears.

> **Note**
>
> If tags are used to control access, proceeding with this action can affect related resources. After you permanently delete a tag, it can't be restored.

6. Choose **Delete** to permanently delete the key-value pair.

Using the AWS CLI

The following AWS CLI command deletes two AWS resource tags from an existing Storage Lens group: To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control untag-resource --account-id 111122223333 \
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/Marketing-Department \
--region us-east-1 --tag-keys k1 k2
```

Using the AWS SDK for Java

The following AWS SDK for Java example deletes two AWS resource tags from the Storage Lens group Amazon Resource Name (ARN) that you specify in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.UntagResourceRequest;

public class UntagResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            String tagKey1 = "resource-tag-key-1";
            String tagKey2 = "resource-tag-key-2";
            UntagResourceRequest untagResourceRequest = UntagResourceRequest.builder()
                    .resourceArn(resourceARN)
                    .tagKeys(tagKey1, tagKey2)
                    .accountId(accountId)
                    .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
```

```
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.untagResource(untagResourceRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Listing Storage Lens group tags

The following examples demonstrate how to list the AWS resource tags associated with a Storage Lens group. You can list tags by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To review the list of tags and tag values for a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the Storage Lens group that you're interested in.
4. Scroll down to the **AWS resource tags** section. All of the user-defined AWS resource tags that are added to your Storage Lens group are listed along with their tag values.

Using the AWS CLI

The following AWS CLI example command lists all the Storage Lens group tag values for the Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control list-tags-for-resource --account-id 111122223333 \
```

```
--resource-arn arn:aws:s3:us-east-1:111122223333:storage-lens-group/marketing-
department \
--region us-east-1
```

Using the AWS SDK for Java

The following AWS SDK for Java example lists the Storage Lens group tag values for the Storage Lens group Amazon Resource Name (ARN) that you specify. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceRequest;
import software.amazon.awssdk.services.s3control.model.ListTagsForResourceResponse;

public class ListTagsForResource {
    public static void main(String[] args) {
        String resourceARN = "Resource_ARN";
        String accountId = "111122223333";

        try {
            ListTagsForResourceRequest listTagsForResourceRequest =
 ListTagsForResourceRequest.builder()
                    .resourceArn(resourceARN)
                    .accountId(accountId)
                    .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            ListTagsForResourceResponse response =
 s3ControlClient.listTagsForResource(listTagsForResourceRequest);
            System.out.println(response);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
```

```
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Listing all Storage Lens groups

The following examples demonstrate how to list all Amazon S3 Storage Lens groups in an AWS account and home Region. These examples show how list all Storage Lens groups by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To list all Storage Lens groups in an account and home Region

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, the list of Storage Lens groups in your account is displayed.

Using the AWS CLI

The following AWS CLI example lists all of the Storage Lens groups for your account. To use this example command, replace the *`user input placeholders`* with your own information.

```
aws s3control list-storage-lens-groups --account-id 111122223333 \
--region us-east-1
```

Using the AWS SDK for Java

The following AWS SDK for Java example lists the Storage Lens groups for account *`111122223333`*. To use this example, replace the *`user input placeholders`* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
```

```
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.ListStorageLensGroupsRequest;
import software.amazon.awssdk.services.s3control.model.ListStorageLensGroupsResponse;

public class ListStorageLensGroups {
    public static void main(String[] args) {
        String accountId = "111122223333";

        try {
            ListStorageLensGroupsRequest listStorageLensGroupsRequest =
 ListStorageLensGroupsRequest.builder()
                    .accountId(accountId)
                    .build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            ListStorageLensGroupsResponse response =
 s3ControlClient.listStorageLensGroups(listStorageLensGroupsRequest);
            System.out.println(response);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Viewing Storage Lens group details

The following examples demonstrate how to view Amazon S3 Storage Lens group configuration details. You can view these details by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To view Storage Lens group configuration details

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the option button next to the Storage Lens group that you're interested in.
4. Choose **View details**. You can now review the details of your Storage Lens group.

Using the AWS CLI

The following AWS CLI example returns the configuration details for a Storage Lens group. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control get-storage-lens-group --account-id 111122223333 \
--region us-east-1 --name marketing-department
```

Using the AWS SDK for Java

The following AWS SDK for Java example returns the configuration details for the Storage Lens group named *Marketing-Department* in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupRequest;
import software.amazon.awssdk.services.s3control.model.GetStorageLensGroupResponse;

public class GetStorageLensGroup {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
```

```
            GetStorageLensGroupRequest getRequest =
 GetStorageLensGroupRequest.builder()
                    .name(storageLensGroupName)
                    .accountId(accountId).build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            GetStorageLensGroupResponse response =
 s3ControlClient.getStorageLensGroup(getRequest);
            System.out.println(response);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Deleting a Storage Lens group

The following examples demonstrate how to delete an Amazon S3 Storage Lens group by using the Amazon S3 console, AWS Command Line Interface (AWS CLI), and AWS SDK for Java.

Using the S3 console

To delete a Storage Lens group

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Storage Lens groups**.
3. Under **Storage Lens groups**, choose the option button next to the Storage Lens group that you want to delete.
4. Choose **Delete**. A **Delete Storage Lens group** dialog box displays.
5. Choose **Delete** again to permanently delete your Storage Lens group.

> **Note**
>
> After you delete a Storage Lens group, it can't be restored.

Using the AWS CLI

The following AWS CLI example deletes the Storage Lens group named *marketing-department*. To use this example command, replace the *user input placeholders* with your own information.

```
aws s3control delete-storage-lens-group --account-id 111122223333 \
--region us-east-1 --name marketing-department
```

Using the AWS SDK for Java

The following AWS SDK for Java example deletes the Storage Lens group named *Marketing-Department* in account *111122223333*. To use this example, replace the *user input placeholders* with your own information.

```
package aws.example.s3control;

import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3control.S3ControlClient;
import software.amazon.awssdk.services.s3control.model.DeleteStorageLensGroupRequest;

public class DeleteStorageLensGroup {
    public static void main(String[] args) {
        String storageLensGroupName = "Marketing-Department";
        String accountId = "111122223333";

        try {
            DeleteStorageLensGroupRequest deleteStorageLensGroupRequest =
 DeleteStorageLensGroupRequest.builder()
                    .name(storageLensGroupName)
                    .accountId(accountId).build();
            S3ControlClient s3ControlClient = S3ControlClient.builder()
                    .region(Region.US_WEST_2)
```

```
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .build();
            s3ControlClient.deleteStorageLensGroup(deleteStorageLensGroupRequest);
        } catch (AmazonServiceException e) {
            // The call was transmitted successfully, but Amazon S3 couldn't process
            // it and returned an error response.
            e.printStackTrace();
        } catch (SdkClientException e) {
            // Amazon S3 couldn't be contacted for a response, or the client
            // couldn't parse the response from Amazon S3.
            e.printStackTrace();
        }
    }
}
```

Cataloging and analyzing your data with S3 Inventory

You can use Amazon S3 Inventory to help manage your storage. For example, you can use it to audit and report on the replication and encryption status of your objects for business, compliance, and regulatory needs. You can also simplify and speed up business workflows and big data jobs by using Amazon S3 Inventory, which provides a scheduled alternative to the Amazon S3 synchronous `List` API operations. Amazon S3 Inventory does not use the `List` API operations to audit your objects and does not affect the request rate of your bucket.

Amazon S3 Inventory provides comma-separated values (CSV), Apache optimized row columnar (ORC) or Apache Parquet output files that list your objects and their corresponding metadata on a daily or weekly basis for an S3 bucket or objects with a shared prefix (that is, objects that have names that begin with a common string). If you set up a weekly inventory, a report is generated every Sunday (UTC time zone) after the initial report. For information about Amazon S3 Inventory pricing, see Amazon S3 pricing.

You can configure multiple inventory lists for a bucket. When you're configuring an inventory list, you can specify the following:

- What object metadata to include in the inventory
- Whether to list all object versions or only current versions
- Where to store the inventory list file output
- Whether to generate the inventory on a daily or weekly basis
- Whether to encrypt the inventory list file

You can query Amazon S3 Inventory with standard SQL queries by using Amazon Athena, Amazon Redshift Spectrum, and other tools, such as Presto, Apache Hive, and Apache Spark. For more information about using Athena to query your inventory files, see the section called "Querying inventory with Athena".

> **Note**
>
> It might take up to 48 hours for Amazon S3 to deliver the first inventory report.

Source and destination buckets

The bucket that the inventory lists objects for is called the *source bucket*. The bucket where the inventory list file is stored is called the *destination bucket*.

Source bucket

The inventory lists the objects that are stored in the source bucket. You can get an inventory list for an entire bucket, or you can filter the list by object key name prefix.

The source bucket:

- Contains the objects that are listed in the inventory
- Contains the configuration for the inventory

Destination bucket

Amazon S3 Inventory list files are written to the destination bucket. To group all the inventory list files in a common location in the destination bucket, you can specify a destination prefix in the inventory configuration.

The destination bucket:

- Contains the inventory file lists.
- Contains the manifest files that list all the inventory list files that are stored in the destination bucket. For more information, see Inventory manifest.
- Must have a bucket policy to give Amazon S3 permission to verify ownership of the bucket and permission to write files to the bucket.
- Must be in the same AWS Region as the source bucket.

- Can be the same as the source bucket.
- Can be owned by a different AWS account than the account that owns the source bucket.

Amazon S3 Inventory list

An inventory list file contains a list of the objects in the source bucket and metadata for each object. An inventory list file is stored in the destination bucket with one of the following formats:

- As a CSV file compressed with GZIP
- As an Apache optimized row columnar (ORC) file compressed with ZLIB
- As an Apache Parquet file compressed with Snappy

> **Note**
>
> Objects in Amazon S3 Inventory reports aren't guaranteed to be sorted in any order.

An inventory list file contains a list of the objects in the source bucket and metadata for each listed object:

- **Bucket name** – The name of the bucket that the inventory is for.
- **Key name** – The object key name (or key) that uniquely identifies the object in the bucket. When you're using the CSV file format, the key name is URL-encoded and must be decoded before you can use it.
- **Version ID** – The object version ID. When you enable versioning on a bucket, Amazon S3 assigns a version number to objects that are added to the bucket. For more information, see Retaining multiple versions of objects with S3 Versioning. (This field is not included if the list is configured only for the current version of the objects.)
- **IsLatest** – Set to `True` if the object is the current version of the object. (This field is not included if the list is configured only for the current version of the objects.)
- **Delete marker** – Set to `True` if the object is a delete marker. For more information, see Retaining multiple versions of objects with S3 Versioning. (This field is automatically added to your report if you've configured the report to include all versions of your objects).
- **Size** – The object size in bytes, not including the size of incomplete multipart uploads, object metadata, and delete markers.

- **Last modified date** – The object creation date or the last modified date, whichever is the latest.
- **ETag** – The entity tag (ETag) is a hash of the object. The ETag reflects changes only to the contents of an object, not to its metadata. The ETag can be an MD5 digest of the object data. Whether it is depends on how the object was created and how it is encrypted. For more information, see Object in the *Amazon Simple Storage Service API Reference*.
- **Storage class** – The storage class that's used for storing the object. Set to `STANDARD`, `REDUCED_REDUNDANCY`, `STANDARD_IA`, `ONEZONE_IA`, `INTELLIGENT_TIERING`, `GLACIER`, `DEEP_ARCHIVE`, `OUTPOSTS`, `GLACIER_IR`, or `SNOW`. For more information, see Understanding and managing Amazon S3 storage classes.

  > **Note**
  >
  > S3 Inventory does not support S3 Express One Zone.

- **Multipart upload flag** – Set to `True` if the object was uploaded as a multipart upload. For more information, see Uploading and copying objects using multipart upload in Amazon S3.
- **Replication status** – Set to `PENDING`, `COMPLETED`, `FAILED`, or `REPLICA`. For more information, see Getting replication status information.
- **Encryption status** – The server-side encryption status, depending on what kind of encryption key is used— server-side encryption with Amazon S3 managed keys (SSE-S3), server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), dual-layer server-side encryption with AWS KMS keys (DSSE-KMS), or server-side encryption with customer-provided keys (SSE-C). Set to `SSE-S3`, `SSE-KMS`, `DSSE-KMS`, `SSE-C`, or `NOT-SSE`. A status of `NOT-SSE` means that the object is not encrypted with server-side encryption. For more information, see Protecting data with encryption.
- **S3 Object Lock retain until date** – The date until which the locked object cannot be deleted. For more information, see Locking objects with Object Lock.
- **S3 Object Lock retention mode** – Set to `Governance` or `Compliance` for objects that are locked. For more information, see Locking objects with Object Lock.
- **S3 Object Lock legal hold status** – Set to `On` if a legal hold has been applied to an object. Otherwise, it is set to `Off`. For more information, see Locking objects with Object Lock.
- **S3 Intelligent-Tiering access tier** – Access tier (frequent or infrequent) of the object if it is stored in the S3 Intelligent-Tiering storage class. Set to `FREQUENT`, `INFREQUENT`, `ARCHIVE_INSTANT_ACCESS`, `ARCHIVE`, or `DEEP_ARCHIVE`. For more information, see Storage class for automatically optimizing data with changing or unknown access patterns.

- **S3 Bucket Key status** – Set to `ENABLED` or `DISABLED`. Indicates whether the object uses an S3 Bucket Key for SSE-KMS. For more information, see Using Amazon S3 Bucket Keys.
- **Checksum algorithm** – Indicates the algorithm that's used to create the checksum for the object. For more information, see Using supported checksum algorithms.
- **Object access control list** – An access control list (ACL) for each object that defines which AWS accounts or groups are granted access to this object and the type of access that is granted. The Object ACL field is defined in JSON format. An S3 Inventory report includes ACLs that are associated with objects in your source bucket, even when ACLs are disabled for the bucket. For more information, see Working with the Object ACL field and Access control list (ACL) overview.

> **Note**
>
> The Object ACL field is defined in JSON format. An inventory report displays the value for the Object ACL field as a base64-encoded string.
> For example, suppose that you have the following Object ACL field in JSON format:
>
> ```
> {
>         "version": "2022-11-10",
>         "status": "AVAILABLE",
>         "grants": [{
>             "canonicalId": "example-canonical-user-ID",
>             "type": "CanonicalUser",
>             "permission": "READ"
>         }]
> }
> ```
>
> The Object ACL field is encoded and shown as the following base64-encoded string:
>
> ```
> eyJ2ZXJzaW9uIjoiMjAyMi0xMS0xMCIsInN0YXR1cyI6IkFWQUlMQUJMRSIsImdyYW50cyI6W3siY2Fub25pY2Fs
> ```
>
> To get the decoded value in JSON for the Object ACL field, you can query this field in Amazon Athena. For query examples, see Querying Amazon S3 Inventory with Amazon Athena.

- **Object owner** – The canonical user ID of the owner of the object. For more information, see Find the canonical user ID for your AWS account in the *AWS Account Management Reference Guide*.

> **Note**
>
> When an object reaches the end of its lifetime based on its lifecycle configuration, Amazon S3 queues the object for removal and removes it asynchronously. Therefore, there might be a delay between the expiration date and the date when Amazon S3 removes an object. The inventory report includes the objects that have expired but haven't been removed yet. For more information about expiration actions in S3 Lifecycle, see Expiring objects.

The following is an example inventory report with additional metadata fields consisting of four records.

```
amzn-s3-demo-bucket1    example-object-1    EXAMPLEDC8l.XJCENlF7LePaNIIvs001    TRUE

```

We recommend that you create a lifecycle policy that deletes old inventory lists. For more information, see Managing the lifecycle of objects.

The `s3:PutInventoryConfiguration` permission allows a user to both select all the metadata fields that are listed earlier for each object when configuring an inventory list and to specify the destination bucket to store the inventory. A user with read access to objects in the destination bucket can access all object metadata fields that are available in the inventory list. To restrict access to an inventory report, see Grant permissions for S3 Inventory and S3 analytics.

Inventory consistency

All of your objects might not appear in each inventory list. The inventory list provides eventual consistency for PUT requests (of both new objects and overwrites) and for DELETE requests. Each inventory list for a bucket is a snapshot of bucket items. These lists are eventually consistent (that is, a list might not include recently added or deleted objects).

To validate the state of an object before you take action on the object, we recommend that you perform a `HeadObject` REST API request to retrieve metadata for the object, or to check the object's properties in the Amazon S3 console. You can also check object metadata with the AWS CLI or the AWS SDKS. For more information, see `HeadObject` in the *Amazon Simple Storage Service API Reference*.

For more information about working with Amazon S3 Inventory, see the following topics.

Topics

- Configuring Amazon S3 Inventory
- Locating your inventory list
- Setting up Amazon S3 Event Notifications for inventory completion
- Querying Amazon S3 Inventory with Amazon Athena
- Converting empty version ID strings in Amazon S3 Inventory reports to null strings
- Working with the Object ACL field

Configuring Amazon S3 Inventory

Amazon S3 Inventory provides a flat file list of your objects and metadata, on a schedule that you define. You can use S3 Inventory as a scheduled alternative to the Amazon S3 synchronous `List` API operation. S3 Inventory provides comma-separated values (CSV), Apache optimized row columnar (ORC), or Apache Parquet (Parquet) output files that list your objects and their corresponding metadata.

You can configure S3 Inventory to create inventory lists on a daily or weekly basis for an S3 bucket or for objects that share a prefix (objects that have names that begin with the same string). For more information, see Cataloging and analyzing your data with S3 Inventory.

This section describes how to configure an inventory, including details about the inventory source and destination buckets.

Topics

- Overview
- Creating a destination bucket policy
- Granting Amazon S3 permission to use your customer managed key for encryption
- Configuring inventory by using the S3 console
- Using the REST API to work with S3 Inventory

Overview

Amazon S3 Inventory helps you manage your storage by creating lists of the objects in an S3 bucket on a defined schedule. You can configure multiple inventory lists for a bucket. The inventory lists are published to CSV, ORC, or Parquet files in a destination bucket.

The easiest way to set up an inventory is by using the Amazon S3 console, but you can also use the Amazon S3 REST API, AWS Command Line Interface (AWS CLI), or AWS SDKs. The console performs the first step of the following procedure for you: adding a bucket policy to the destination bucket.

To set up Amazon S3 Inventory for an S3 bucket

1. **Add a bucket policy for the destination bucket.**

   You must create a bucket policy on the destination bucket that grants permissions to Amazon S3 to write objects to the bucket in the defined location. For an example policy, see Grant permissions for S3 Inventory and S3 analytics.
2. **Configure an inventory to list the objects in a source bucket and publish the list to a destination bucket.**

   When you configure an inventory list for a source bucket, you specify the destination bucket where you want the list to be stored, and whether you want to generate the list daily or weekly. You can also configure whether to list all object versions or only current versions and what object metadata to include.

Some object metadata fields in S3 Inventory report configurations are optional, meaning that they're available by default but they can be restricted when you grant a user the `s3:PutInventoryConfiguration` permission. You can control whether users can include these optional metadata fields in their reports by using the `s3:InventoryAccessibleOptionalFields` condition key.

For more information about the optional metadata fields available in S3 Inventory, see OptionalFields in the *Amazon Simple Storage Service API Reference*. For more information about restricting access to certain optional metadata fields in an inventory configuration, see Control S3 Inventory report configuration creation.

You can specify that the inventory list file be encrypted by using server-side encryption with an Amazon S3 managed key (SSE-S3) or an AWS Key Management Service (AWS KMS) customer managed key (SSE-KMS).

> **Note**
>
> The AWS managed key (`aws/s3`) is not supported for SSE-KMS encryption with S3 Inventory.

For more information about SSE-S3 and SSE-KMS, see Protecting data with server-side encryption. If you plan to use SSE-KMS encryption, see Step 3.

- For information about how to use the console to configure an inventory list, see Configuring inventory by using the S3 console.
- To use the Amazon S3 API to configure an inventory list, use the PutBucketInventoryConfiguration REST API operation or the equivalent from the AWS CLI or AWS SDKs.

3. **To encrypt the inventory list file with SSE-KMS, grant Amazon S3 permission to use the AWS KMS key.**

   You can configure encryption for the inventory list file by using the Amazon S3 console, Amazon S3 REST API, AWS CLI, or AWS SDKs. Whichever way you choose, you must grant Amazon S3 permission to use the customer managed key to encrypt the inventory file. You grant Amazon S3 permission by modifying the key policy for the customer managed key that you want to use to encrypt the inventory file. Make sure that you've provided a KMS key ARN in the S3 Inventory

configuration or the destination bucket's encryption settings. If no KMS key ARN has been specified and the default encryption settings are being used, you won't be able to access your S3 Inventory report.

The destination bucket that stores the inventory list file can be owned by a different AWS account than the account that owns the source bucket. If you use SSE-KMS encryption for the cross-account operations of Amazon S3 Inventory, we recommend that you use a fully qualified KMS key ARN when you configure S3 inventory. For more information, see Using SSE-KMS encryption for cross-account operations and ServerSideEncryptionByDefault in the *Amazon Simple Storage Service API Reference*.

> **Note**
>
> If you can't access your S3 Inventory report, use the GetBucketEncryption API, and check whether the destination bucket has the default SSE-KMS encryption enabled. If no KMS key ARN has been specified and the default encryption settings are being used, you won't be able to access your S3 Inventory report. To access S3 Inventory reports again, either provide a KMS key ARN in the S3 Inventory configuration or in the destination bucket's encryption settings.

Creating a destination bucket policy

If you create your inventory configuration through the Amazon S3 console, Amazon S3 automatically creates a bucket policy on the destination bucket that grants Amazon S3 write permission to the bucket. However, if you create your inventory configuration through the AWS CLI, AWS SDKs, or the Amazon S3 REST API, you must manually add a bucket policy on the destination bucket. The S3 Inventory destination bucket policy allows Amazon S3 to write data for the inventory reports to the bucket.

The following is the example bucket policy.

JSON

```
{
      "Version": "2012-10-17",
      "Statement": [
        {
```

```
            "Sid": "InventoryExamplePolicy",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": "s3:PutObject",
            "Resource": [
                "arn:aws:s3:::DOC-EXAMPLE-DESTINATION-BUCKET/*"
            ],
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:s3:::DOC-EXAMPLE-SOURCE-BUCKET"
                },
                "StringEquals": {
                    "aws:SourceAccount": "source-account-id",
                    "s3:x-amz-acl": "bucket-owner-full-control"
                }
            }
        }
    ]
}
```

For more information, see Grant permissions for S3 Inventory and S3 analytics.

If an error occurs when you try to create the bucket policy, you are given instructions on how to fix it. For example, if you choose a destination bucket in another AWS account and don't have permissions to read and write to the bucket policy, you see an error message.

In this case, the destination bucket owner must add the bucket policy to the destination bucket. If the policy is not added to the destination bucket, you won't get an inventory report because Amazon S3 doesn't have permission to write to the destination bucket. If the source bucket is owned by a different account than that of the current user, the correct account ID of the source bucket owner must be substituted in the policy.

Note

Ensure that there are no Deny statements added to the destination bucket policy that would prevent the delivery of inventory reports into this bucket. For more information, see Why can't I generate an Amazon S3 Inventory Report? .

Granting Amazon S3 permission to use your customer managed key for encryption

To grant Amazon S3 permission to use your AWS Key Management Service (AWS KMS) customer managed key for server-side encryption, you must use a key policy. To update your key policy so that you can use your customer managed key, use the following procedure.

To grant Amazon S3 permissions to encrypt by using your customer managed key

1. Using the AWS account that owns the customer managed key, sign into the AWS Management Console.
2. Open the AWS KMS console at https://console.aws.amazon.com/kms.
3. To change the AWS Region, use the Region selector in the upper-right corner of the page.
4. In the left navigation pane, choose **Customer managed keys**.
5. Under **Customer managed keys**, choose the customer managed key that you want to use to encrypt your inventory files.
6. In the **Key policy** section, choose **Switch to policy view**.
7. To update the key policy, choose **Edit**.
8. On the **Edit key policy** page, add the following lines to the existing key policy. For *source-account-id* and *amzn-s3-demo-source-bucket*, supply the appropriate values for your use case.

```
{
    "Sid": "Allow Amazon S3 use of the customer managed key",
    "Effect": "Allow",
    "Principal": {
        "Service": "s3.amazonaws.com"
    },
    "Action": [
        "kms:GenerateDataKey"
    ],
    "Resource": "*",
    "Condition":{
      "StringEquals":{
         "aws:SourceAccount":"source-account-id"
     },
      "ArnLike":{
        "aws:SourceARN": "arn:aws:s3:::amzn-s3-demo-source-bucket"
     }
```

```
    }
}
```

9. Choose **Save changes**.

For more information about creating customer managed keys and using key policies, see the following links in the *AWS Key Management Service Developer Guide*:

- Managing keys
- Key policies in AWS KMS

> **Note**
>
> Ensure that there are no Deny statements added to the destination bucket policy that would prevent the delivery of inventory reports into this bucket. For more information, see Why can't I generate an Amazon S3 Inventory Report? .

Configuring inventory by using the S3 console

Use these instructions to configure inventory by using the S3 console.

> **Note**
>
> It might take up to 48 hours for Amazon S3 to deliver the first inventory report.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to configure Amazon S3 Inventory for.
4. Choose the **Management** tab.
5. Under **Inventory configurations**, choose **Create inventory configuration**.
6. For **Inventory configuration name**, enter a name.
7. For **Inventory scope**, do the following:

- Enter an optional prefix.
- Choose which object versions to include, either **Current versions only** or **Include all versions**.

8. Under **Report details**, choose the location of the AWS account that you want to save the reports to: **This account** or **A different account**.
9. Under **Destination**, choose the destination bucket where you want the inventory reports to be saved.

   The destination bucket must be in the same AWS Region as the bucket for which you are setting up the inventory. The destination bucket can be in a different AWS account. When specifying the destination bucket, you can also include an optional prefix to group your inventory reports together.

   Under the **Destination** bucket field, you see the **Destination bucket permission** statement that is added to the destination bucket policy to allow Amazon S3 to place data in that bucket. For more information, see Creating a destination bucket policy.
10. Under **Frequency**, choose how often the report will be generated, **Daily** or **Weekly**.
11. For **Output format**, choose one of the following formats for the report:

    - **CSV** – If you plan to use this inventory report with S3 Batch Operations or if you want to analyze this report in another tool, such as Microsoft Excel, choose **CSV**.
    - **Apache ORC**
    - **Apache Parquet**
12. Under **Status**, choose **Enable** or **Disable**.
13. To configure server-side encryption, under **Inventory report encryption**, follow these steps:

    a. Under **Server-side encryption**, choose either **Do not specify an encryption key** or **Specify an encryption key** to encrypt data.

       - To keep the bucket settings for default server-side encryption of objects when storing them in Amazon S3, choose **Do not specify an encryption key**. As long as the bucket destination has S3 Bucket Keys enabled, the copy operation applies an S3 Bucket Key at the destination bucket.

> **Note**
>
> If the bucket policy for the specified destination requires objects to be encrypted before storing them in Amazon S3, you must choose **Specify an encryption key**. Otherwise, copying objects to the destination will fail.

- To encrypt objects before storing them in Amazon S3, choose **Specify an encryption key**.

b. If you chose **Specify an encryption key**, under **Encryption type**, you must choose either **Amazon S3 managed key (SSE-S3)** or **AWS Key Management Service key (SSE-KMS)**.

SSE-S3 uses one of the strongest block ciphers—256-bit Advanced Encryption Standard (AES-256) to encrypt each object. SSE-KMS provides you with more control over your key. For more information about SSE-S3, see Using server-side encryption with Amazon S3 managed keys (SSE-S3). For more information about SSE-KMS, see Using server-side encryption with AWS KMS keys (SSE-KMS).

> **Note**
>
> To encrypt the inventory list file with SSE-KMS, you must grant Amazon S3 permission to use the customer managed key. For instructions, see Grant Amazon S3 Permission to Encrypt Using Your KMS Keys.

c. If you chose **AWS Key Management Service key (SSE-KMS)**, under **AWS KMS key**, you can specify your AWS KMS key through one of the following options.

> **Note**
>
> If the destination bucket that stores the inventory list file is owned by a different AWS account, make sure that you use a fully qualified KMS key ARN to specify your KMS key.

- To choose from a list of available KMS keys, choose **Choose from your AWS KMS keys**, and choose a symmetric encryption KMS key from the list of available keys. Make sure the KMS key is in the same Region as your bucket.

> **Note**
>
> Both the AWS managed key (`aws/s3`) and your customer managed keys appear in the list. However, the AWS managed key (`aws/s3`) is not supported for SSE-KMS encryption with S3 Inventory.

- To enter the KMS key ARN, choose **Enter AWS KMS key ARN**, and enter your KMS key ARN in the field that appears.
- To create a new customer managed key in the AWS KMS console, choose **Create a KMS key**.

14. For **Additional metadata fields**, select one or more of the following to add to the inventory report:

- **Size** – The object size in bytes, not including the size of incomplete multipart uploads, object metadata, and delete markers.
- **Last modified date** – The object creation date or the last modified date, whichever is the latest.
- **Multipart upload** – Specifies that the object was uploaded as a multipart upload. For more information, see Uploading and copying objects using multipart upload in Amazon S3.
- **Replication status** – The replication status of the object. For more information, see Getting replication status information.
- **Encryption status** – The server-side encryption type that's used to encrypt the object. For more information, see Protecting data with server-side encryption.
- **Bucket Key status** – Indicates whether a bucket-level key generated by AWS KMS applies to the object. For more information, see Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys.
- **Object access control list** – An access control list (ACL) for each object that defines which AWS accounts or groups are granted access to this object and the type of access that is granted. For more information about this field, see Working with the Object ACL field. For more information about ACLs, see Access control list (ACL) overview.
- **Object owner** – The owner of the object.
- **Storage class** – The storage class that's used for storing the object.

- **Intelligent-Tiering: Access tier** – Indicates the access tier (frequent or infrequent) of the object if it was stored in the S3 Intelligent-Tiering storage class. For more information, see Storage class for automatically optimizing data with changing or unknown access patterns.
- **ETag** – The entity tag (ETag) is a hash of the object. The ETag reflects changes only to the contents of an object, not to its metadata. The ETag might or might not be an MD5 digest of the object data. Whether it is depends on how the object was created and how it is encrypted. For more information, see Object in the *Amazon Simple Storage Service API Reference*.
- **Checksum algorithm** – Indicates the algorithm that is used to create the checksum for the object. For more information, see Using supported checksum algorithms.
- **All Object Lock configurations** – The Object Lock status of the object, including the following settings:
  - **Object Lock: Retention mode** – The level of protection applied to the object, either *Governance* or *Compliance*.
  - **Object Lock: Retain until date** – The date until which the locked object cannot be deleted.
  - **Object Lock: Legal hold status** – The legal hold status of the locked object.

  For information about S3 Object Lock, see How S3 Object Lock works.

For more information about the contents of an inventory report, see Amazon S3 Inventory list.

For more information about restricting access to certain optional metadata fields in an inventory configuration, see Control S3 Inventory report configuration creation.

15. Choose **Create**.

Using the REST API to work with S3 Inventory

The following are the REST operations that you can use to work with Amazon S3 Inventory.

- DeleteBucketInventoryConfiguration
- GetBucketInventoryConfiguration
- ListBucketInventoryConfigurations
- PutBucketInventoryConfiguration

Locating your inventory list

When an inventory list is published, the manifest files are published to the following location in the destination bucket.

```
destination-prefix/amzn-s3-demo-source-bucket/config-ID/YYYY-MM-DDTHH-MMZ/manifest.json
 destination-prefix/amzn-s3-demo-source-bucket/config-ID/YYYY-MM-DDTHH-MMZ/
manifest.checksum
 destination-prefix/amzn-s3-demo-source-bucket/config-ID/hive/dt=YYYY-MM-DD-HH-MM/
symlink.txt
```

- *destination-prefix* is the object key name prefix that is optionally specified in the inventory configuration. You can use this prefix to group all the inventory list files in a common location within the destination bucket.
- *amzn-s3-demo-source-bucket* is the source bucket that the inventory list is for. The source bucket name is added to prevent collisions when multiple inventory reports from different source buckets are sent to the same destination bucket.
- *config-ID* is added to prevent collisions with multiple inventory reports from the same source bucket that are sent to the same destination bucket. The *config-ID* comes from the inventory report configuration, and is the name for the report that is defined during setup.
- *YYYY-MM-DDTHH-MMZ* is the timestamp that consists of the start time and the date when the inventory report generation process begins scanning the bucket; for example, `2016-11-06T21-32Z`.
- `manifest.json` is the manifest file.
- `manifest.checksum` is the MD5 hash of the content of the `manifest.json` file.
- `symlink.txt` is the Apache Hive-compatible manifest file.

The inventory lists are published daily or weekly to the following location in the destination bucket.

```
destination-prefix/amzn-s3-demo-source-bucket/config-ID/data/example-file-name.csv.gz
...
destination-prefix/amzn-s3-demo-source-bucket/config-ID/data/example-file-name-1.csv.gz
```

- *destination-prefix* is the object key name prefix that is optionally specified in the inventory configuration. You can use this prefix to group all the inventory list files in a common location in the destination bucket.

- *amzn-s3-demo-source-bucket* is the source bucket that the inventory list is for. The source bucket name is added to prevent collisions when multiple inventory reports from different source buckets are sent to the same destination bucket.
- *example-file-name*.csv.gz is one of the CSV inventory files. ORC inventory names end with the file name extension .orc, and Parquet inventory names end with the file name extension .parquet.

Inventory manifest

The manifest files manifest.json and symlink.txt describe where the inventory files are located. Whenever a new inventory list is delivered, it is accompanied by a new set of manifest files. These files might overwrite each other. In versioning-enabled buckets, Amazon S3 creates new versions of the manifest files.

Each manifest contained in the manifest.json file provides metadata and other basic information about an inventory. This information includes the following:

- The source bucket name
- The destination bucket name
- The version of the inventory
- The creation timestamp in the epoch date format that consists of the start time and the date when the inventory report generation process begins scanning the bucket
- The format and schema of the inventory files
- A list of the inventory files that are in the destination bucket

Whenever a manifest.json file is written, it is accompanied by a manifest.checksum file that is the MD5 hash of the content of the manifest.json file.

Example Inventory manifest in a manifest.json file

The following examples show an inventory manifest in a manifest.json file for CSV, ORC, and Parquet-formatted inventories.

CSV

The following is an example of a manifest in a manifest.json file for a CSV-formatted inventory.

```
{
    "sourceBucket": "amzn-s3-demo-source-bucket",
    "destinationBucket": "arn:aws:s3:::example-inventory-destination-bucket",
    "version": "2016-11-30",
    "creationTimestamp" : "1514944800000",
    "fileFormat": "CSV",
    "fileSchema": "Bucket, Key, VersionId, IsLatest, IsDeleteMarker,
 Size, LastModifiedDate, ETag, StorageClass, IsMultipartUploaded,
 ReplicationStatus, EncryptionStatus, ObjectLockRetainUntilDate, ObjectLockMode,
 ObjectLockLegalHoldStatus, IntelligentTieringAccessTier, BucketKeyStatus,
 ChecksumAlgorithm, ObjectAccessControlList, ObjectOwner",
    "files": [
        {
            "key": "Inventory/amzn-s3-demo-source-bucket/2016-11-06T21-32Z/
files/939c6d46-85a9-4ba8-87bd-9db705a579ce.csv.gz",
            "size": 2147483647,
            "MD5checksum": "f11166069f1990abeb9c97ace9cdfabc"
        }
    ]
}
```

ORC

The following is an example of a manifest in a `manifest.json` file for an ORC-formatted inventory.

```
{
    "sourceBucket": "amzn-s3-demo-source-bucket",
    "destinationBucket": "arn:aws:s3:::example-destination-bucket",
    "version": "2016-11-30",
    "creationTimestamp" : "1514944800000",
    "fileFormat": "ORC",
    "fileSchema":
 "struct<bucket:string,key:string,version_id:string,is_latest:boolean,is_delete_marker:boole
    "files": [
        {
            "key": "inventory/amzn-s3-demo-source-bucket/data/
d794c570-95bb-4271-9128-26023c8b4900.orc",
            "size": 56291,
            "MD5checksum": "5925f4e78e1695c2d020b9f6eexample"
        }
    ]
```

```
}
```

Parquet

The following is an example of a manifest in a `manifest.json` file for a Parquet-formatted inventory.

```
{
    "sourceBucket": "amzn-s3-demo-source-bucket",
    "destinationBucket": "arn:aws:s3:::example-destination-bucket",
    "version": "2016-11-30",
    "creationTimestamp" : "1514944800000",
    "fileFormat": "Parquet",
    "fileSchema": "message s3.inventory { required binary bucket (UTF8);
 required binary key (UTF8); optional binary version_id (UTF8); optional boolean
 is_latest; optional boolean is_delete_marker; optional int64 size; optional
 int64 last_modified_date (TIMESTAMP_MILLIS); optional binary e_tag (UTF8);
 optional binary storage_class (UTF8); optional boolean is_multipart_uploaded;
 optional binary replication_status (UTF8); optional binary encryption_status
 (UTF8); optional int64 object_lock_retain_until_date (TIMESTAMP_MILLIS); optional
 binary object_lock_mode (UTF8); optional binary object_lock_legal_hold_status
 (UTF8); optional binary intelligent_tiering_access_tier (UTF8); optional binary
 bucket_key_status (UTF8); optional binary checksum_algorithm (UTF8); optional
 binary object_access_control_list (UTF8); optional binary object_owner (UTF8);}",
    "files": [
        {
           "key": "inventory/amzn-s3-demo-source-bucket/data/
d754c470-85bb-4255-9218-47023c8b4910.parquet",
            "size": 56291,
            "MD5checksum": "5825f2e18e1695c2d030b9f6eexample"
        }
    ]
}
```

The `symlink.txt` file is an Apache Hive-compatible manifest file that allows Hive to automatically discover inventory files and their associated data files. The Hive-compatible manifest works with the Hive-compatible services Athena and Amazon Redshift Spectrum. It also works with Hive-compatible applications, including Presto, Apache Hive, Apache Spark, and many others.

Important

The `symlink.txt` Apache Hive-compatible manifest file does not currently work with AWS Glue.
Reading the `symlink.txt` file with Apache Hive and Apache Spark is not supported for ORC and Parquet-formatted inventory files.

Setting up Amazon S3 Event Notifications for inventory completion

You can set up an Amazon S3 event notification to receive notice when the manifest checksum file is created, which indicates that an inventory list has been added to the destination bucket. The manifest is an up-to-date list of all the inventory lists at the destination location.

Amazon S3 can publish events to an Amazon Simple Notification Service (Amazon SNS) topic, an Amazon Simple Queue Service (Amazon SQS) queue, or an AWS Lambda function. For more information, see Amazon S3 Event Notifications.

The following notification configuration defines that all `manifest.checksum` files newly added to the destination bucket are processed by the AWS Lambda `cloud-function-list-write`.

```
<NotificationConfiguration>
  <QueueConfiguration>
      <Id>1</Id>
      <Filter>
          <S3Key>
              <FilterRule>
                  <Name>prefix</Name>
                  <Value>destination-prefix/source-bucket</Value>
              </FilterRule>
              <FilterRule>
                  <Name>suffix</Name>
                  <Value>checksum</Value>
              </FilterRule>
          </S3Key>
     </Filter>
     <CloudFunction>arn:aws:lambda:us-west-2:222233334444:cloud-function-list-write</
CloudFunction>
     <Event>s3:ObjectCreated:*</Event>
  </QueueConfiguration>
  </NotificationConfiguration>
```

For more information, see Using AWS Lambda with Amazon S3 in the *AWS Lambda Developer Guide*.

Querying Amazon S3 Inventory with Amazon Athena

You can query Amazon S3 Inventory files with standard SQL queries by using Amazon Athena in all Regions where Athena is available. To check for AWS Region availability, see the AWS Region Table.

Athena can query Amazon S3 Inventory files in Apache optimized row columnar (ORC), Apache Parquet, or comma-separated values (CSV) format. When you use Athena to query inventory files, we recommend that you use ORC-formatted or Parquet-formatted inventory files. The ORC and Parquet formats provide faster query performance and lower query costs. ORC and Parquet are self-describing, type-aware columnar file formats designed for Apache Hadoop. The columnar format lets the reader read, decompress, and process only the columns that are required for the current query. The ORC and Parquet formats for Amazon S3 Inventory are available in all AWS Regions.

To use Athena to query Amazon S3 Inventory files

1. Create an Athena table. For information about creating a table, see Creating Tables in Amazon Athena in the *Amazon Athena User Guide*.
2. Create your query by using one of the following sample query templates, depending on whether you're querying an ORC-formatted, a Parquet-formatted, or a CSV-formatted inventory report.

   - When you're using Athena to query an ORC-formatted inventory report, use the following sample query as a template.

     The following sample query includes all the optional fields in an ORC-formatted inventory report.

     To use this sample query, do the following:

     - Replace *`your_table_name`* with the name of the Athena table that you created.
     - Remove any optional fields that you did not choose for your inventory so that the query corresponds to the fields chosen for your inventory.
     - Replace the following bucket name and inventory location (the configuration ID) as appropriate for your configuration.

       `s3://`*`amzn-s3-demo-bucket`*`/`*`config-ID`*`/hive/`

- Replace the *2022-01-01-00-00* date under `projection.dt.range` with the first day of the time range within which you partition the data in Athena. For more information, see Partitioning data in Athena.

```
CREATE EXTERNAL TABLE your_table_name(
         bucket string,
         key string,
         version_id string,
         is_latest boolean,
         is_delete_marker boolean,
         size bigint,
         last_modified_date timestamp,
         e_tag string,
         storage_class string,
         is_multipart_uploaded boolean,
         replication_status string,
         encryption_status string,
         object_lock_retain_until_date bigint,
         object_lock_mode string,
         object_lock_legal_hold_status string,
         intelligent_tiering_access_tier string,
         bucket_key_status string,
         checksum_algorithm string,
         object_access_control_list string,
         object_owner string
) PARTITIONED BY (
        dt string
)
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.orc.OrcSerde'
  STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'
  OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat'
  LOCATION 's3://source-bucket/config-ID/hive/'
  TBLPROPERTIES (
    "projection.enabled" = "true",
    "projection.dt.type" = "date",
    "projection.dt.format" = "yyyy-MM-dd-HH-mm",
    "projection.dt.range" = "2022-01-01-00-00,NOW",
    "projection.dt.interval" = "1",
    "projection.dt.interval.unit" = "HOURS"
  );
```

- When you're using Athena to query a Parquet-formatted inventory report, use the sample query for an ORC-formatted report. However, use the following Parquet SerDe in place of the ORC SerDe in the `ROW FORMAT SERDE` statement.

```
ROW FORMAT SERDE 'org.apache.hadoop.hive.ql.io.parquet.serde.ParquetHiveSerDe'
```

- When you're using Athena to query a CSV-formatted inventory report, use the following sample query as a template.

  The following sample query includes all the optional fields in an CSV-formatted inventory report.

  To use this sample query, do the following:

  - Replace *`your_table_name`* with the name of the Athena table that you created.
  - Remove any optional fields that you did not choose for your inventory so that the query corresponds to the fields chosen for your inventory.
  - Replace the following bucket name and inventory location (the configuration ID) as appropriate for your configuration.

    `s3://`*`amzn-s3-demo-bucket`*`/`*`config-ID`*`/hive/`

  - Replace the *`2022-01-01-00-00`* date under `projection.dt.range` with the first day of the time range within which you partition the data in Athena. For more information, see Partitioning data in Athena.

```
CREATE EXTERNAL TABLE your_table_name(
         bucket string,
         key string,
         version_id string,
         is_latest boolean,
         is_delete_marker boolean,
         size string,
         last_modified_date string,
         e_tag string,
         storage_class string,
         is_multipart_uploaded boolean,
         replication_status string,
         encryption_status string,
         object_lock_retain_until_date string,
         object_lock_mode string,
         object_lock_legal_hold_status string,
```

```
         intelligent_tiering_access_tier string,
         bucket_key_status string,
         checksum_algorithm string,
         object_access_control_list string,
         object_owner string
) PARTITIONED BY (
        dt string
)
ROW FORMAT SERDE 'org.apache.hadoop.hive.serde2.OpenCSVSerde'
  STORED AS INPUTFORMAT 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat'
  OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat'
  LOCATION 's3://source-bucket/config-ID/hive/'
  TBLPROPERTIES (
    "projection.enabled" = "true",
    "projection.dt.type" = "date",
    "projection.dt.format" = "yyyy-MM-dd-HH-mm",
    "projection.dt.range" = "2022-01-01-00-00,NOW",
    "projection.dt.interval" = "1",
    "projection.dt.interval.unit" = "HOURS"
  );
```

3. You can now run various queries on your inventory, as shown in the following examples. Replace each *user input placeholder* with your own information.

```
# Get a list of the latest inventory report dates available.
SELECT DISTINCT dt FROM your_table_name ORDER BY 1 DESC limit 10;

# Get the encryption status for a provided report date.
SELECT encryption_status, count(*) FROM your_table_name WHERE dt = 'YYYY-MM-DD-HH-
MM' GROUP BY encryption_status;

# Get the encryption status for inventory report dates in the provided range.
SELECT dt, encryption_status, count(*) FROM your_table_name
WHERE dt > 'YYYY-MM-DD-HH-MM' AND dt < 'YYYY-MM-DD-HH-MM' GROUP BY dt,
 encryption_status;
```

When you configure S3 Inventory to add the Object Access Control List (Object ACL) field to an inventory report, the report displays the value for the Object ACL field as a base64-encoded string. To get the decoded value in JSON for the Object ACL field, you can query this field by using Athena. See the following query examples. For more information about the Object ACL field, see Working with the Object ACL field.

```
# Get the S3 keys that have Object ACL grants with public access.
WITH grants AS (
    SELECT key,
        CAST(
            json_extract(from_utf8(from_base64(object_access_control_list)),
 '$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))
        ) AS grants_array
    FROM your_table_name
)
SELECT key,
       grants_array,
       grant
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE element_at(grant, 'uri') = 'http://acs.amazonaws.com/groups/global/AllUsers'
```

```
# Get the S3 keys that have Object ACL grantees in addition to the object owner.
WITH grants AS
    (SELECT key,
    from_utf8(from_base64(object_access_control_list)) AS
 object_access_control_list,
         object_owner,
         CAST(json_extract(from_utf8(from_base64(object_access_control_list)),
         '$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))) AS grants_array
    FROM your_table_name)
SELECT key,
       grant,
       objectowner
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE cardinality(grants_array) > 1 AND element_at(grant, 'canonicalId') !=
 object_owner;
```

```
# Get the S3 keys with READ permission that is granted in the Object ACL.
WITH grants AS (
    SELECT key,
        CAST(
            json_extract(from_utf8(from_base64(object_access_control_list)),
 '$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))
        ) AS grants_array
    FROM your_table_name
```

```
)
SELECT key,
       grants_array,
       grant
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE element_at(grant, 'permission') = 'READ';
```

```
# Get the S3 keys that have Object ACL grants to a specific canonical user ID.
WITH grants AS (
    SELECT key,
        CAST(
            json_extract(from_utf8(from_base64(object_access_control_list)),
 '$.grants') AS ARRAY(MAP(VARCHAR, VARCHAR))
        ) AS grants_array
    FROM your_table_name
)
SELECT key,
       grants_array,
       grant
FROM grants, UNNEST(grants_array) AS t(grant)
WHERE element_at(grant, 'canonicalId') = 'user-canonical-id';
```

```
# Get the number of grantees on the Object ACL.
SELECT key,
       object_access_control_list,
       json_array_length(json_extract(object_access_control_list,'$.grants')) AS
 grants_count
FROM your_table_name;
```

For more information about using Athena, see the Amazon Athena User Guide.

Converting empty version ID strings in Amazon S3 Inventory reports to null strings

> **Note**
>
> **The following procedure applies only to Amazon S3 Inventory reports that include all versions, and only if the "all versions" reports are used as manifests for S3 Batch Operations on buckets that have S3 Versioning enabled.** You are not required to convert strings for S3 Inventory reports that specify the current version only.

You can use S3 Inventory reports as manifests for S3 Batch Operations. However, when S3 Versioning is enabled on a bucket, S3 Inventory reports that include all versions mark any null-versioned objects with empty strings in the version ID field. When an Inventory Report includes all object version IDs, Batch Operations recognizes `null` strings as version IDs, but not empty strings.

When an S3 Batch Operations job uses an "all versions" S3 Inventory report as a manifest, it fails all tasks on objects that have an empty string in the version ID field. To convert empty strings in the version ID field of the S3 Inventory report to `null` strings for Batch Operations, use the following procedure.

Update an Amazon S3 Inventory report for use with Batch Operations

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Navigate to your S3 Inventory report. The inventory report is located in the destination bucket that you specified while configuring your inventory report. For more information about locating inventory reports, see Locating your inventory list.
   a. Choose the destination bucket.
   b. Choose the folder. The folder is named after the original source bucket.
   c. Choose the folder named after the inventory configuration.
   d. Select the check box next to the folder named **hive**. At the top of the page, choose **Copy S3 URI** to copy the S3 URI for the folder.
3. Open the Amazon Athena console at https://console.aws.amazon.com/athena/.
4. In the query editor, choose **Settings**, then choose **Manage**. On the **Manage settings** page, for **Location of query result**, choose an S3 bucket to store your query results in.

5. In the query editor, create an Athena table to hold the data in the inventory report using the following command. Replace *table_name* with a name of your choosing, and in the LOCATION clause, insert the S3 URI that you copied earlier. Then choose **Run** to run the query.

```
CREATE EXTERNAL TABLE table_name(bucket string, key string,
 version_id string) PARTITIONED BY (dt string)ROW FORMAT SERDE
 'org.apache.hadoop.hive.serde2.OpenCSVSerde'STORED AS INPUTFORMAT
 'org.apache.hadoop.hive.ql.io.SymlinkTextInputFormat' OUTPUTFORMAT
 'org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat' LOCATION 'Copied S3 URI';
```

6. To clear the query editor, choose **Clear**. Then load the inventory report into the table using the following command. Replace *table_name* with the one that you chose in the prior step. Then choose **Run** to run the query.

```
MSCK REPAIR TABLE table_name;
```

7. To clear the query editor, choose **Clear**. Run the following SELECT query to retrieve all entries in the original inventory report and replace any empty version IDs with null strings. Replace *table_name* with the one that you chose earlier, and replace *YYYY-MM-DD-HH-MM* in the WHERE clause with the date of the inventory report that you want this tool to run on. Then choose **Run** to run the query.

```
SELECT bucket as Bucket, key as Key, CASE WHEN version_id = '' THEN 'null' ELSE
 version_id END as VersionId FROM table_name WHERE dt = 'YYYY-MM-DD-HH-MM';
```

8. Return to the Amazon S3 console (https://console.aws.amazon.com/s3/), and navigate to the S3 bucket that you chose for **Location of query result** earlier. Inside, there should be a series of folders ending with the date.

   For example, you should see something like **s3://*amzn-s3-demo-bucket*/*query-result-location*/Unsaved/2021/10/07/**. You should see .csv files containing the results of the SELECT query that you ran.

   Choose the CSV file with the latest modified date. Download this file to your local machine for the next step.

9. The generated CSV file contains a header row. To use this CSV file as input for an S3 Batch Operations job, you must remove the header row, because Batch Operations doesn't support header rows on CSV manifests.

To remove the header row, you can run one of the following commands on the file. Replace *file.csv* with the name of your CSV file.

For macOS and Linux machines, run the `tail` command in a Terminal window.

```
tail -n +2 file.csv > tmp.csv && mv tmp.csv file.csv
```

For Windows machines, run the following script in a Windows PowerShell window. Replace *File-location* with the path to your file, and *file.csv* with the file name.

```
$ins = New-Object System.IO.StreamReader File-location\file.csv
$outs = New-Object System.IO.StreamWriter File-location\temp.csv
try {
    $skip = 0
    while ( !$ins.EndOfStream ) {
        $line = $ins.ReadLine();
        if ( $skip -ne 0 ) {
            $outs.WriteLine($line);
        } else {
            $skip = 1
        }
    }
} finally {
    $outs.Close();
    $ins.Close();
}
Move-Item File-location\temp.csv File-location\file.csv -Force
```

10. After removing the header row from the CSV file, you are ready to use it as a manifest in an S3 Batch Operations job. Upload the CSV file to an S3 bucket or location of your choosing, and then create a Batch Operations job using the CSV file as the manifest.

    For more information about creating a Batch Operations job, see Creating an S3 Batch Operations job.

Working with the Object ACL field

An Amazon S3 Inventory report contains a list of the objects in the S3 source bucket and metadata for each object. The Object access control list (ACL) field is a metadata field that is available in

Amazon S3 Inventory. Specifically, the Object ACL field contains the access control list (ACL) for each object. The ACL for an object defines which AWS accounts or groups are granted access to this object and the type of access that is granted. For more information, see Access control list (ACL) overview and Amazon S3 Inventory list.

The Object ACL field in Amazon S3 Inventory reports is defined in JSON format. The JSON data includes the following fields:

- `version` – The version of the Object ACL field format in the inventory reports. It's in date format `yyyy-mm-dd`.
- `status` – Possible values are `AVAILABLE` or `UNAVAILABLE` to indicate whether an Object ACL is available for an object. When the status for the Object ACL is `UNAVAILABLE`, the value of the Object Owner field in the inventory report is also `UNAVAILABLE`.
- `grants` – Grantee-permission pairs that list the permission status of each grantee that is granted by the Object ACL. The available values for a grantee are `CanonicalUser` and `Group`. For more information about grantees, see Grantees in access control lists.

  For a grantee with the `Group` type, a grantee-permission pair includes the following attributes:

  - `uri` – A predefined Amazon S3 group.
  - `permission` – The ACL permissions that are granted on the object. For more information, see ACL permissions on an object.
  - `type` – The type `Group`, which denotes that the grantee is group.

  For a grantee with the `CanonicalUser` type, a grantee-permission pair includes the following attributes:

  - `canonicalId` – An obfuscated form of the AWS account ID. The canonical user ID for an AWS account is specific to that account. You can retrieve the canonical user ID. For more information, see Find the canonical user ID for your AWS account in the *AWS Account Management Reference Guide*.

    Note

    If a grantee in an ACL is the email address of an AWS account, S3 Inventory uses the `canonicalId` of that AWS account and the `CanonicalUser` type to specify this grantee. For more information, see Grantees in access control lists.

- `permission` – The ACL permissions that are granted on the object. For more information, see ACL permissions on an object.
- `type` – The type `CanonicalUser`, which denotes that the grantee is an AWS account.

The following example shows possible values for the Object ACL field in JSON format:

```
{
    "version": "2022-11-10",
    "status": "AVAILABLE",
    "grants": [{
        "uri": "http://acs.amazonaws.com/groups/global/AllUsers",
        "permission": "READ",
        "type": "Group"
    }, {
        "canonicalId": "example-canonical-id",
        "permission": "FULL_CONTROL",
        "type": "CanonicalUser"
    }]
}
```

Note

The Object ACL field is defined in JSON format. An inventory report displays the value for the Object ACL field as a base64-encoded string.
For example, suppose that you have the following Object ACL field in JSON format:

```
{
        "version": "2022-11-10",
        "status": "AVAILABLE",
        "grants": [{
            "canonicalId": "example-canonical-user-ID",
            "type": "CanonicalUser",
            "permission": "READ"
        }]
}
```

The Object ACL field is encoded and shown as the following base64-encoded string:

```
eyJ2ZXJzaW9uIjoiMjAyMi0xMS0xMCIsInN0YXR1cyI6IkFWQUlMQUJMRSIsImdyYW50cyI6W3siY2Fub25pY2FsSW
```

To get the decoded value in JSON for the Object ACL field, you can query this field in Amazon Athena. For query examples, see Querying Amazon S3 Inventory with Amazon Athena.

Best practices design patterns: optimizing Amazon S3 performance

Your applications can easily achieve thousands of transactions per second in request performance when uploading and retrieving storage from Amazon S3. Amazon S3 automatically scales to high request rates. For example, your application can achieve at least 3,500 PUT/COPY/POST/DELETE or 5,500 GET/HEAD requests per second per partitioned Amazon S3 prefix. There are no limits to the number of prefixes in a bucket. You can increase your read or write performance by using parallelization. For example, if you create 10 prefixes in an Amazon S3 bucket to parallelize reads, you could scale your read performance to 55,000 read requests per second. Similarly, you can scale write operations by writing to multiple prefixes. The scaling, in the case of both read and write operations, happens gradually and is not instantaneous, and actual performance will vary based on your specific workload characteristics, usage patterns, and system configuration. While Amazon S3 is scaling to your new higher request rate, you may see some 503 (Slow Down) errors. These errors will dissipate when the scaling is complete. For more information about creating and using prefixes, see Organizing objects using prefixes.

Some data lake applications on Amazon S3 scan millions or billions of objects for queries that run over petabytes of data. These data lake applications achieve single-instance transfer rates that maximize the network interface use for their Amazon EC2 instance, which can be up to 100 Gb/s on a single instance. These applications then aggregate throughput across multiple instances to get multiple terabits per second.

Other applications are sensitive to latency, such as social media messaging applications. These applications can achieve consistent small object latencies (and first-byte-out latencies for larger objects) of roughly 100–200 milliseconds.

Other AWS services can also help accelerate performance for different application architectures. For example, if you want higher transfer rates over a single HTTP connection or single-digit millisecond latencies, use Amazon CloudFront or Amazon ElastiCache for caching with Amazon S3.

Additionally, if you want fast data transport over long distances between a client and an S3 bucket, use Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration. Transfer Acceleration uses the globally distributed edge locations in CloudFront to accelerate data transport over geographical distances. If your Amazon S3 workload uses server-side encryption with AWS KMS, see AWS KMS Limits in the AWS Key Management Service Developer Guide for information about the request rates supported for your use case.

The following topics describe best practice guidelines and design patterns for optimizing performance for applications that use Amazon S3. Refer to the Performance guidelines for Amazon S3 and Performance design patterns for Amazon S3 for the most current information about performance optimization for Amazon S3.

> **Note**
>
> For more information about using the Amazon S3 Express One Zone storage class with directory buckets, see S3 Express One Zone and Working with directory buckets.

Performance guidelines for Amazon S3

When building applications that upload and retrieve objects from Amazon S3, follow our best practices guidelines to optimize performance. We also offer more detailed Performance design patterns for Amazon S3 .

To obtain the best performance for your application on Amazon S3, we recommend the following guidelines.

Topics

- Measure performance
- Scale storage connections horizontally
- Use byte-range fetches
- Retry requests for latency-sensitive applications
- Combine Amazon S3 (Storage) and Amazon EC2 (compute) in the same AWS Region
- Use Amazon S3 Transfer Acceleration to minimize latency caused by distance
- Use the latest version of the AWS SDKs

Measure performance

When optimizing performance, look at network throughput, CPU, and DRAM requirements. Depending on the mix of demands for these different resources, it might be worth evaluating different Amazon EC2 instance types. For more information about instance types, see Instance Types in the *Amazon EC2 User Guide*.

It's also helpful to look at DNS lookup time, latency, and data transfer speed using HTTP analysis tools when measuring performance.

To understand the performance requirements and optimize the performance of your application, you can also monitor the 503 error responses that you receive. Monitoring certain performance metrics may incur additional expenses. For more information, see Amazon S3 pricing.

Monitor the number of 503 (Slow Down) status error responses

To monitor the number of 503 status error responses that you get, you can use one of the following options:

- Use Amazon CloudWatch request metrics for Amazon S3. The CloudWatch request metrics include a metric for 5xx status responses. For more information about CloudWatch request metrics, see Monitoring metrics with Amazon CloudWatch.
- Use the 503 (Service Unavailable) error count available in the advanced metrics section of Amazon S3 Storage Lens. For more information, see Using S3 Storage Lens metrics to improve performance.
- Use Amazon S3 server access logging. With server access logging, you can filter and review all requests that receive 503 (Internal Error) responses. You can also use Amazon Athena to parse logs. For more information about server access logging, see Logging requests with server access logging.

By monitoring the number of HTTP 503 status error code, you can often gain valuable insights into which prefixes, keys, or buckets are getting the most throttling requests.

Scale storage connections horizontally

Spreading requests across many connections is a common design pattern to horizontally scale performance. When you build high performance applications, think of Amazon S3 as a very large

distributed system, not as a single network endpoint like a traditional storage server. You can achieve the best performance by issuing multiple concurrent requests to Amazon S3. Spread these requests over separate connections to maximize the accessible bandwidth from Amazon S3. Amazon S3 doesn't have any limits for the number of connections made to your bucket.

Use byte-range fetches

Using the `Range` HTTP header in a GET Object request, you can fetch a byte-range from an object, transferring only the specified portion. You can use concurrent connections to Amazon S3 to fetch different byte ranges from within the same object. This helps you achieve higher aggregate throughput versus a single whole-object request. Fetching smaller ranges of a large object also allows your application to improve retry times when requests are interrupted. For more information, see Downloading objects.

Typical sizes for byte-range requests are 8 MB or 16 MB. If objects are PUT using a multipart upload, it's a good practice to GET them in the same part sizes (or at least aligned to part boundaries) for best performance. GET requests can directly address individual parts; for example, `GET ?partNumber=N`.

Retry requests for latency-sensitive applications

Aggressive timeouts and retries help drive consistent latency. Given the large scale of Amazon S3, if the first request is slow, a retried request is likely to take a different path and quickly succeed. The AWS SDKs have configurable timeout and retry values that you can tune to the tolerances of your specific application.

Combine Amazon S3 (Storage) and Amazon EC2 (compute) in the same AWS Region

Although S3 bucket names are globally unique, each bucket is stored in a Region that you select when you create the bucket. To learn more about bucket naming guidelines, see Buckets overview and Bucket naming rules. To optimize performance, we recommend that you access the bucket from Amazon EC2 instances in the same AWS Region when possible. This helps reduce network latency and data transfer costs.

For more information about data transfer costs, see Amazon S3 Pricing.

Use Amazon S3 Transfer Acceleration to minimize latency caused by distance

Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration manages fast, easy, and secure transfers of files over long geographic distances between the client and an S3 bucket. Transfer Acceleration takes advantage of the globally distributed edge locations in Amazon CloudFront. As the data arrives at an edge location, it is routed to Amazon S3 over an optimized network path. Transfer Acceleration is ideal for transferring gigabytes to terabytes of data regularly across continents. It's also useful for clients that upload to a centralized bucket from all over the world.

You can use the Amazon S3 Transfer Acceleration Speed comparison tool to compare accelerated and non-accelerated upload speeds across Amazon S3 Regions. The Speed Comparison tool uses multipart uploads to transfer a file from your browser to various Amazon S3 Regions with and without using Amazon S3 Transfer Acceleration.

Use the latest version of the AWS SDKs

The AWS SDKs provide built-in support for many of the recommended guidelines for optimizing Amazon S3 performance. The SDKs provide a simpler API for taking advantage of Amazon S3 from within an application and are regularly updated to follow the latest best practices. For example, the SDKs include logic to automatically retry requests on HTTP 503 errors and are investing in code to respond and adapt to slow connections.

The SDKs also provide the Transfer Manager, which automates horizontally scaling connections to achieve thousands of requests per second, using byte-range requests where appropriate. It's important to use the latest version of the AWS SDKs to obtain the latest performance optimization features.

You can also optimize performance when you are using HTTP REST API requests. When using the REST API, you should follow the same best practices that are part of the SDKs. Allow for timeouts and retries on slow requests, and multiple connections to allow fetching of object data in parallel. For information about using the REST API, see the Amazon Simple Storage Service API Reference.

Performance design patterns for Amazon S3

When designing applications to upload and retrieve objects from Amazon S3, use our best practices design patterns for achieving the best performance for your application. We also offer

Performance guidelines for Amazon S3 for you to consider when planning your application architecture.

To optimize performance, you can use the following design patterns.

Topics

- Using caching for frequently accessed content
- Timeouts and retries for latency-sensitive applications
- Horizontal scaling and request parallelization for high throughput
- Optimizing for high-request rate workloads
- Using Amazon S3 Transfer Acceleration to accelerate geographically disparate data transfers
- Optimizing for high-request rate workloads

Using caching for frequently accessed content

Many applications that store data in Amazon S3 serve a "working set" of data that is repeatedly requested by users. If a workload is sending repeated GET requests for a common set of objects, you can use a cache such as Amazon CloudFront, Amazon ElastiCache, or AWS Elemental MediaStore to optimize performance. Successful cache adoption can result in low latency and high data transfer rates. Applications that use caching also send fewer direct requests to Amazon S3, which can help reduce request costs.

Amazon CloudFront is a fast content delivery network (CDN) that transparently caches data from Amazon S3 in a large set of geographically distributed points of presence (PoPs). When objects might be accessed from multiple Regions, or over the internet, CloudFront allows data to be cached close to the users that are accessing the objects. This can result in high performance delivery of popular Amazon S3 content. For information about CloudFront, see the Amazon CloudFront Developer Guide.

Amazon ElastiCache is a managed, in-memory cache. With ElastiCache, you can provision Amazon EC2 instances that cache objects in memory. This caching results in orders of magnitude reduction in GET latency and substantial increases in download throughput. To use ElastiCache, you modify application logic to both populate the cache with hot objects and check the cache for hot objects before requesting them from Amazon S3. For examples of using ElastiCache to improve Amazon S3 GET performance, see the blog post Turbocharge Amazon S3 with Amazon ElastiCache for Redis.

AWS Elemental MediaStore is a caching and content distribution system specifically built for video workflows and media delivery from Amazon S3. MediaStore provides end-to-end storage APIs specifically for video, and is recommended for performance-sensitive video workloads. For information about MediaStore, see the AWS Elemental MediaStore User Guide.

Timeouts and retries for latency-sensitive applications

There are certain situations where an application receives a response from Amazon S3 indicating that a retry is necessary. Amazon S3 maps bucket and object names to the object data associated with them. If an application generates high request rates (typically sustained rates of over 5,000 requests per second to a small number of objects), it might receive HTTP 503 *slowdown* responses. If these errors occur, each AWS SDK implements automatic retry logic using exponential backoff. If you are not using an AWS SDK, you should implement retry logic when receiving the HTTP 503 error. For information about back-off techniques, see Retry behavior in the *AWS SDKs and Tools Reference Guide*.

Amazon S3 automatically scales in response to sustained new request rates, dynamically optimizing performance. While Amazon S3 is internally optimizing for a new request rate, you will receive HTTP 503 request responses temporarily until the optimization completes. After Amazon S3 internally optimizes performance for the new request rate, all requests are generally served without retries.

For latency-sensitive applications, Amazon S3 advises tracking and aggressively retrying slower operations. When you retry a request, we recommend using a new connection to Amazon S3 and performing a fresh DNS lookup.

When you make large variably sized requests (for example, more than 128 MB), we advise tracking the throughput being achieved and retrying the slowest 5 percent of the requests. When you make smaller requests (for example, less than 512 KB), where median latencies are often in the tens of milliseconds range, a good guideline is to retry a GET or PUT operation after 2 seconds. If additional retries are needed, the best practice is to back off. For example, we recommend issuing one retry after 2 seconds and a second retry after an additional 4 seconds.

If your application makes fixed-size requests to Amazon S3, you should expect more consistent response times for each of these requests. In this case, a simple strategy is to identify the slowest 1 percent of requests and to retry them. Even a single retry is frequently effective at reducing latency.

If you are using AWS Key Management Service (AWS KMS) for server-side encryption, see Quotas in the *AWS Key Management Service Developer Guide* for information about the request rates that are supported for your use case.

Horizontal scaling and request parallelization for high throughput

Amazon S3 is a very large distributed system. To help you take advantage of its scale, we encourage you to horizontally scale parallel requests to the Amazon S3 service endpoints. In addition to distributing the requests within Amazon S3, this type of scaling approach helps distribute the load over multiple paths through the network.

For high-throughput transfers, Amazon S3 advises using applications that use multiple connections to GET or PUT data in parallel. For example, this is supported by Amazon S3 Transfer Manager in the AWS Java SDK, and most of the other AWS SDKs provide similar constructs. For some applications, you can achieve parallel connections by launching multiple requests concurrently in different application threads, or in different application instances. The best approach to take depends on your application and the structure of the objects that you are accessing.

You can use the AWS SDKs to issue GET and PUT requests directly rather than employing the management of transfers in the AWS SDK. This approach lets you tune your workload more directly, while still benefiting from the SDK's support for retries and its handling of any HTTP 503 responses that might occur. As a general rule, when you download large objects within a Region from Amazon S3 to Amazon EC2, we suggest making concurrent requests for byte ranges of an object at the granularity of 8–16 MB. Make one concurrent request for each 85–90 MB/s of desired network throughput. To saturate a 10 Gb/s network interface card (NIC), you might use about 15 concurrent requests over separate connections. You can scale up the concurrent requests over more connections to saturate faster NICs, such as 25 Gb/s or 100 Gb/s NICs.

Measuring performance is important when you tune the number of requests to issue concurrently. We recommend starting with a single request at a time. Measure the network bandwidth being achieved and the use of other resources that your application uses in processing the data. You can then identify the bottleneck resource (that is, the resource with the highest usage), and hence the number of requests that are likely to be useful. For example, if processing one request at a time leads to a CPU usage of 25 percent, it suggests that up to four concurrent requests can be accommodated. Measurement is essential, and it is worth confirming resource use as the request rate is increased.

If your application issues requests directly to Amazon S3 using the REST API, we recommend using a pool of HTTP connections and re-using each connection for a series of requests. Avoiding per-

request connection setup removes the need to perform TCP slow-start and Secure Sockets Layer (SSL) handshakes on each request. For information about using the REST API, see the Amazon Simple Storage Service API Reference.

Finally, it's worth paying attention to DNS and double-checking that requests are being spread over a wide pool of Amazon S3 IP addresses. DNS queries for Amazon S3 cycle through a large list of IP endpoints. But caching resolvers or application code that reuses a single IP address do not benefit from address diversity and the load balancing that follows from it. Network utility tools such as the `netstat` command line tool can show the IP addresses being used for communication with Amazon S3, and we provide guidelines for DNS configurations to use. For more information about these guidelines, see Making requests in the *Amazon S3 API Reference*.

Optimizing for high-request rate workloads

Using Amazon S3 Transfer Acceleration to accelerate geographically disparate data transfers

Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration is effective at minimizing or eliminating the latency caused by geographic distance between globally dispersed clients and a regional application using Amazon S3. Transfer Acceleration uses the globally distributed edge locations in CloudFront for data transport. The AWS edge network has points of presence in more than 50 locations. Today, it is used to distribute content through CloudFront and to provide rapid responses to DNS queries made to Amazon Route 53.

The edge network also helps to accelerate data transfers into and out of Amazon S3. It is ideal for applications that transfer data across or between continents, have a fast internet connection, use large objects, or have a lot of content to upload. As the data arrives at an edge location, data is routed to Amazon S3 over an optimized network path. In general, the farther away you are from an Amazon S3 Region, the higher the speed improvement you can expect from using Transfer Acceleration.

You can set up Transfer Acceleration on new or existing buckets. You can use a separate Amazon S3 Transfer Acceleration endpoint to use the AWS edge locations. The best way to test whether Transfer Acceleration helps client request performance is to use the Amazon S3 Transfer Acceleration Speed Comparison tool. Network configurations and conditions vary from time to time and from location to location. So you are charged only for transfers where Amazon S3 Transfer Acceleration can potentially improve your upload performance. For information

about using Transfer Acceleration with different AWS SDKs, see Enabling and using S3 Transfer Acceleration.

Optimizing for high-request rate workloads

Applications that generate high request rates to Amazon S3 require specific design patterns to achieve optimal performance. When your application consistently generates more than 3,500 PUT/COPY/POST/DELETE or 5,500 GET/HEAD requests per second per prefix, you should implement strategies to distribute requests and handle scaling behavior.

Amazon S3 automatically scales to accommodate higher request rates, but this scaling happens gradually. During the scaling process, you might receive HTTP 503 (Slow Down) responses. These responses are temporary and indicate that Amazon S3 is optimizing its internal systems for your new request pattern. Once scaling is complete, your requests will be served without throttling.

To optimize performance for high-request rate workloads, consider the following strategies:

- **Distribute requests across multiple prefixes** – Use a randomized or sequential prefix pattern to spread requests across multiple partitions. For example, instead of using sequential object names like `log-2024-01-01.txt`, use randomized prefixes like `a1b2/log-2024-01-01.txt`. This helps Amazon S3 distribute the load more effectively.
- **Implement exponential backoff for 503 errors** – When you receive HTTP 503 responses, implement retry logic with exponential backoff. Start with a short delay and gradually increase the wait time between retries. The AWS SDKs include built-in retry logic that handles this automatically.
- **Monitor request patterns** – Use Amazon CloudWatch metrics to monitor your request rates and error rates. Pay particular attention to 5xx error metrics, which can indicate when your application is approaching or exceeding current scaling limits.
- **Gradually ramp up request rates** – When launching new applications or significantly increasing request rates, gradually increase your traffic over time rather than immediately jumping to peak rates. This allows Amazon S3 to scale proactively and reduces the likelihood of throttling.
- **Use multiple connections** – Distribute your requests across multiple HTTP connections to maximize throughput and reduce the impact of any single connection issues.

For applications that require consistent high performance, consider using Amazon S3 Express One Zone, which is designed for applications that require single-digit millisecond latencies and can

support hundreds of thousands of requests per second. For more information, see S3 Express One Zone.

Hosting a static website using Amazon S3

You can use Amazon S3 to host a static website. On a *static* website, individual webpages include static content. They might also contain client-side scripts.

> **Note**
>
> We recommend that you use AWS Amplify Hosting to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting.
> With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. For more information about Amplify Hosting, see Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket and Deploying a static website from S3 using the Amplify console in the *AWS Amplify Console User Guide*.

For more information about hosting a static website on Amazon S3, including instructions and step-by-step walkthroughs, see the following topics.

Topics

- Website endpoints
- Enabling website hosting
- Configuring an index document
- Configuring a custom error document
- Setting permissions for website access
- (Optional) Logging web traffic
- (Optional) Configuring a webpage redirect
- Using cross-origin resource sharing (CORS)
- Static website tutorials

Website endpoints

When you configure your bucket as a static website, the website is available at the AWS Region-specific website endpoint of the bucket. Website endpoints are different from the endpoints where you send REST API requests. For more information about the differences between the endpoints, see Key differences between a website endpoint and a REST API endpoint.

Depending on your Region, your Amazon S3 website endpoint follows one of these two formats.

- **s3-website dash (-) Region** - `http://bucket-name.s3-website-Region.amazonaws.com`
- **s3-website dot (.) Region** - `http://bucket-name.s3-website.Region.amazonaws.com`

These URLs return the default index document that you configure for the website. For a complete list of Amazon S3 website endpoints, see Amazon S3 Website Endpoints.

Note

To augment the security of your Amazon S3 static websites, the Amazon S3 website endpoint domains (for example, *s3-website-us-east-1.amazonaws.com* or *s3-website.ap-south-1.amazonaws.com*) are registered in the Public Suffix List (PSL). For further security, we recommend that you use cookies with a `__Host-` prefix if you ever need to set sensitive cookies in the domain name for your Amazon S3 static websites. This practice will help to defend your domain against cross-site request forgery attempts (CSRF). For more information see the Set-Cookie page in the Mozilla Developer Network.

If you want your website to be public, you must make all your content publicly readable for your customers to be able to access it at the website endpoint. For more information, see Setting permissions for website access.

Important

- Amazon S3 website endpoints do not support HTTPS or access points. If you want to use HTTPS, you can do one of the following:
  - (Recommended) Use AWS Amplify Hosting to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your

websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting.

With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. For more information about Amplify Hosting, see Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket and Deploying a static website from S3 using the Amplify console in the *AWS Amplify Console User Guide*.

- Use Amazon CloudFront to serve a static website hosted on Amazon S3. For more information, see How do I use CloudFront to serve HTTPS requests for my Amazon S3 bucket? To use HTTPS with a custom domain, see Configuring a static website using a custom domain registered with Route 53.

- Requester Pays buckets do not allow access through a website endpoint. Any request to such a bucket receives a 403 Access Denied response. For more information, see Using Requester Pays general purpose buckets for storage transfers and usage.

Topics

- Website endpoint examples
- Adding a DNS CNAME
- Using a custom domain with Route 53
- Key differences between a website endpoint and a REST API endpoint

Website endpoint examples

The following examples show how you can access an Amazon S3 bucket that is configured as a static website.

Example — Requesting an object at the root level

To request a specific object that is stored at the root level in the bucket, use the following URL structure.

```
http://bucket-name.s3-website.Region.amazonaws.com/object-name
```

For example, the following URL requests the `photo.jpg` object that is stored at the root level in the bucket.

```
http://example-bucket.s3-website.us-west-2.amazonaws.com/photo.jpg
```

Example — Requesting an object in a prefix

To request an object that is stored in a folder in your bucket, use this URL structure.

```
http://bucket-name.s3-website.Region.amazonaws.com/folder-name/object-name
```

The following URL requests the `docs/doc1.html` object in your bucket.

```
http://example-bucket.s3-website.us-west-2.amazonaws.com/docs/doc1.html
```

Adding a DNS CNAME

If you have a registered domain, you can add a DNS CNAME entry to point to the Amazon S3 website endpoint. For example, if you registered the domain `www.example-bucket.com`, you could create a bucket `www.example-bucket.com`, and add a DNS CNAME record that points to `www.example-bucket.com.s3-website.Region.amazonaws.com`. All requests to `http://www.example-bucket.com` are routed to `www.example-bucket.com.s3-website.Region.amazonaws.com`.

For more information, see Customizing Amazon S3 URLs with CNAME records.

Using a custom domain with Route 53

Instead of accessing the website using an Amazon S3 website endpoint, you can use your own domain registered with Amazon Route 53 to serve your content—for example, `example.com`. You can use Amazon S3 with Route 53 to host a website at the root domain. For example, if you have the root domain `example.com` and you host your website on Amazon S3, your website visitors can access the site from their browser by entering either `http://www.example.com` or `http://example.com`.

For an example walkthrough, see Tutorial: Configuring a static website using a custom domain registered with Route 53.

Key differences between a website endpoint and a REST API endpoint

An Amazon S3 website endpoint is optimized for access from a web browser. The following table summarizes the key differences between a REST API endpoint and a website endpoint.

Key difference	REST API endpoint	Website endpoint
Access control	Supports both public and private content	Supports only publicly readable content
Error message handling	Returns an XML-formatted error response	Returns an HTML document
Redirection support	Not applicable	Supports both object-level and bucket-level redirects
Requests supported	Supports all bucket and object operations	Supports only `GET` and `HEAD` requests on objects
Responses to `GET` and `HEAD` requests at the root of a bucket	Returns a list of the object keys in the bucket	Returns the index document that is specified in the website configuration
Secure Sockets Layer (SSL) support	Supports SSL connections	Does not support SSL connections

For a complete list of Amazon S3 endpoints, see Amazon S3 endpoints and quotas in the *AWS General Reference*.

Enabling website hosting

When you configure a bucket as a static website, you must enable static website hosting, configure an index document, and set permissions.

You can enable static website hosting using the Amazon S3 console, REST API, the AWS SDKs, the AWS CLI, or AWS CloudFormation.

To configure your website with a custom domain, see Tutorial: Configuring a static website using a custom domain registered with Route 53.

Using the S3 console

To enable static website hosting

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable static website hosting for.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. Choose **Use this bucket to host a website**.
7. Under **Static website hosting**, choose **Enable**.
8. In **Index document**, enter the file name of the index document, typically `index.html`.

   The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see Configuring an index document.
9. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

   The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see Configuring a custom error document.
10. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see Configure redirection rules to use advanced conditional redirects.

11. Choose **Save changes**.

    Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.

12. Under **Static website hosting**, note the **Endpoint**.

    The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

Using the REST API

For more information about sending REST requests directly to enable static website hosting, see the following sections in the Amazon Simple Storage Service API Reference:

- PUT Bucket website
- GET Bucket website
- DELETE Bucket website

Using the AWS SDKs

To host a static website on Amazon S3, you configure an Amazon S3 bucket for website hosting and then upload your website content to the bucket. You can also use the AWS SDKs to create, update, and delete the website configuration programmatically. The SDKs provide wrapper classes around the Amazon S3 REST API. If your application requires it, you can send REST API requests directly from your application.

.NET

The following example shows how to use the AWS SDK for .NET to manage website configuration for a bucket. To add a website configuration to a bucket, you provide a bucket name and a website configuration. The website configuration must include an index document and can contain an optional error document. These documents must be stored in the bucket. For more information, see PUT Bucket website. For more information about the Amazon S3 website feature, see Hosting a static website using Amazon S3.

The following C# code example adds a website configuration to the specified bucket. The configuration specifies both the index document and the error document names. For information about setting up and running the code examples, see Getting Started with the AWS SDK for .NET in the *AWS SDK for .NET Developer Guide*.

```
using Amazon;
using Amazon.S3;
using Amazon.S3.Model;
using System;
using System.Threading.Tasks;

namespace Amazon.DocSamples.S3
{
    class WebsiteConfigTest
    {
        private const string bucketName = "*** bucket name ***";
        private const string indexDocumentSuffix = "*** index object key ***"; //
 For example, index.html.
        private const string errorDocument = "*** error object key ***"; // For
 example, error.html.
        // Specify your bucket region (an example region is shown).
        private static readonly RegionEndpoint bucketRegion =
 RegionEndpoint.USWest2;
        private static IAmazonS3 client;
        public static void Main()
        {
            client = new AmazonS3Client(bucketRegion);
            AddWebsiteConfigurationAsync(bucketName, indexDocumentSuffix,
 errorDocument).Wait();
        }

        static async Task AddWebsiteConfigurationAsync(string bucketName,
                                                string indexDocumentSuffix,
                                                string errorDocument)
        {
            try
            {
                // 1. Put the website configuration.
                PutBucketWebsiteRequest putRequest = new PutBucketWebsiteRequest()
                {
                    BucketName = bucketName,
                    WebsiteConfiguration = new WebsiteConfiguration()
                    {
```

```
                        IndexDocumentSuffix = indexDocumentSuffix,
                        ErrorDocument = errorDocument
                    }
                };
                PutBucketWebsiteResponse response = await
 client.PutBucketWebsiteAsync(putRequest);

                // 2. Get the website configuration.
                GetBucketWebsiteRequest getRequest = new GetBucketWebsiteRequest()
                {
                    BucketName = bucketName
                };
                GetBucketWebsiteResponse getResponse = await
 client.GetBucketWebsiteAsync(getRequest);
                Console.WriteLine("Index document: {0}",
 getResponse.WebsiteConfiguration.IndexDocumentSuffix);
                Console.WriteLine("Error document: {0}",
 getResponse.WebsiteConfiguration.ErrorDocument);
            }
            catch (AmazonS3Exception e)
            {
                Console.WriteLine("Error encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
            catch (Exception e)
            {
                Console.WriteLine("Unknown encountered on server. Message:'{0}' when
 writing an object", e.Message);
            }
        }
    }
}
```

PHP

The following PHP example adds a website configuration to the specified bucket. The `create_website_config` method explicitly provides the index document and error document names. The example also retrieves the website configuration and prints the response. For more information about the Amazon S3 website feature, see Hosting a static website using Amazon S3.

For more information about the AWS SDK for Ruby API, go to AWS SDK for Ruby - Version 2.

```
 require 'vendor/autoload.php';

use Aws\S3\S3Client;

$bucket = '*** Your Bucket Name ***';

$s3 = new S3Client([
    'version' => 'latest',
    'region'  => 'us-east-1'
]);

// Add the website configuration.
$s3->putBucketWebsite([
    'Bucket'                => $bucket,
    'WebsiteConfiguration'  => [
        'IndexDocument' => ['Suffix' => 'index.html'],
        'ErrorDocument' => ['Key' => 'error.html']
    ]
]);

// Retrieve the website configuration.
$result = $s3->getBucketWebsite([
    'Bucket' => $bucket
]);
echo $result->getPath('IndexDocument/Suffix');

// Delete the website configuration.
$s3->deleteBucketWebsite([
    'Bucket' => $bucket
]);
```

Using the AWS CLI

For more information about using the AWS CLI to configure an S3 bucket as a static website, see website in the *AWS CLI Command Reference*.

Next, you must configure your index document and set permissions. For information, see Configuring an index document and Setting permissions for website access.

You can also optionally configure an error document, web traffic logging, or a redirect.

Configuring an index document

When you enable website hosting, you must also configure and upload an index document. An *index document* is a webpage that Amazon S3 returns when a request is made to the root of a website or any subfolder. For example, if a user enters `http://www.example.com` in the browser, the user is not requesting any specific page. In that case, Amazon S3 serves up the index document, which is sometimes referred to as the *default page*.

When you enable static website hosting for your bucket, you enter the name of the index document (for example, `index.html`). After you enable static website hosting for your bucket, you upload an HTML file with the index document name to your bucket.

The trailing slash at the root-level URL is optional. For example, if you configure your website with `index.html` as the index document, either of the following URLs returns `index.html`.

```
http://example-bucket.s3-website.Region.amazonaws.com/
http://example-bucket.s3-website.Region.amazonaws.com
```

For more information about Amazon S3 website endpoints, see Website endpoints.

Index document and folders

In Amazon S3, a bucket is a flat container of objects. It does not provide any hierarchical organization as the file system on your computer does. However, you can create a logical hierarchy by using object key names that imply a folder structure.

For example, consider a bucket with three objects that have the following key names. Although these are stored with no physical hierarchical organization, you can infer the following logical folder structure from the key names:

- `sample1.jpg` — Object is at the root of the bucket.
- `photos/2006/Jan/sample2.jpg` — Object is in the `photos/2006/Jan` subfolder.
- `photos/2006/Feb/sample3.jpg` — Object is in the `photos/2006/Feb` subfolder.

In the Amazon S3 console, you can also create a folder in a bucket. For example, you can create a folder named `photos`. You can upload objects to the bucket or to the `photos` folder within the bucket. If you add the object `sample.jpg` to the bucket, the key name is `sample.jpg`. If you upload the object to the `photos` folder, the object key name is `photos/sample.jpg`.

If you create a folder structure in your bucket, you must have an index document at each level. In each folder, the index document must have the same name, for example, `index.html`. When a user specifies a URL that resembles a folder lookup, the presence or absence of a trailing slash determines the behavior of the website. For example, the following URL, with a trailing slash, returns the `photos/index.html` index document.

```
http://bucket-name.s3-website.Region.amazonaws.com/photos/
```

However, if you exclude the trailing slash from the preceding URL, Amazon S3 first looks for an object `photos` in the bucket. If the `photos` object is not found, it searches for an index document, `photos/index.html`. If that document is found, Amazon S3 returns a `302 Found` message and points to the `photos/` key. For subsequent requests to `photos/`, Amazon S3 returns `photos/index.html`. If the index document is not found, Amazon S3 returns an error.

Configure an index document

To configure an index document using the S3 console, use the following procedure. You can also configure an index document using the REST API, the AWS SDKs, the AWS CLI, or AWS CloudFormation.

> **Note**
>
> In a versioning-enabled bucket, you may upload multiple copies of the `index.html` but only the newest version will be resolved to. For more information about using S3 Versioning see, Retaining multiple versions of objects with S3 Versioning.

When you enable static website hosting for your bucket, you enter the name of the index document (for example, **`index.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

To configure the index document

1. Create an `index.html` file.

   If you don't have an `index.html` file, you can use the following HTML to create one:

   ```
   <html xmlns="http://www.w3.org/1999/xhtml" >
   ```

```
<head>
    <title>My Website Home Page</title>
</head>
<body>
  <h1>Welcome to my website</h1>
  <p>Now hosted on Amazon S3!</p>
</body>
</html>
```

2. Save the index file locally.

   The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see Enabling website hosting.

   After enabling static website hosting, proceed to step 6.

7. To upload the index document to your bucket, do one of the following:

   - Drag and drop the index file into the console bucket listing.
   - Choose **Upload**, and follow the prompts to choose and upload the index file.

   For step-by-step instructions, see Uploading objects.

8. (Optional) Upload other website content to your bucket.

Next, you must set permissions for website access. For information, see Setting permissions for website access.

You can also optionally configure an error document, web traffic logging, or a redirect.

Configuring a custom error document

After you configure your bucket as a static website, when an error occurs, Amazon S3 returns an HTML error document. You can optionally configure your bucket with a custom error document so that Amazon S3 returns that document when an error occurs.

> **Note**
>
> Some browsers display their own error message when an error occurs, ignoring the error document that Amazon S3 returns. For example, when an HTTP 404 Not Found error occurs, Google Chrome might ignore the error document that Amazon S3 returns and display its own error.

Topics

- Amazon S3 HTTP response codes
- Configuring a custom error document

Amazon S3 HTTP response codes

The following table lists the subset of HTTP response codes that Amazon S3 returns when an error occurs.

HTTP error code	Description
301 Moved Permanently	When a user sends a request directly to the Amazon S3 website endpoint (`http://s3-website.` *`Region`*`.amazonaws.com/`), Amazon S3 returns a **301 Moved Permanently** response and redirects those requests to `https://aws.amazon.com/s3/`.
302 Found	When Amazon S3 receives a request for a key `x`, `http://`*`bucket-name`*`.s3-website.` *`Region`*`.amazonaws.com/x`, without a trailing slash, it first looks for the object with the key name `x`. If the object is not found, Amazon S3 determines that the request is for subfolder `x` and redirects the request by adding a slash at the end, and returns **302 Found**.

HTTP error code	Description
304 Not Modified	Amazon S3 uses request headers `If-Modified-Since` , `If-Unmodified-Since` , `If-Match` and/or `If-None-Match` to determine whether the requested object is same as the cached copy held by the client. If the object is the same, the website endpoint returns a **304 Not Modified** response.
400 Malformed Request	The website endpoint responds with a **400 Malformed Request** when a user attempts to access a bucket through the incorrect regional endpoint.
403 Forbidden	The website endpoint responds with a **403 Forbidden** when a user request translates to an object that is not publicly readable. The object owner must make the object publicly readable using a bucket policy or an ACL.

HTTP error code	Description
404 Not Found	The website endpoint responds with **404 Not Found** for the following reasons: • Amazon S3 determines that the URL of the website refers to an object key that does not exist. • Amazon S3 infers that the request is for an index document that does not exist. • A bucket specified in the URL does not exist. • A bucket specified in the URL exists, but isn't configured as a website. You can create a custom document that is returned for **404 Not Found**. Make sure that the document is uploaded to the bucket configured as a website, and that the website hosting configuration is set to use the document. For information on how Amazon S3 interprets the URL as a request for an object or an index document, see Configuring an index document.
500 Service Error	The website endpoint responds with a **500 Service Error** when an internal server error occurs.
503 Service Unavailable	The website endpoint responds with a **503 Service Unavailable** when Amazon S3 determines that you need to reduce your request rate.

For each of these errors, Amazon S3 returns a predefined HTML message. The following is an example HTML message that is returned for a **403 Forbidden** response.

Configuring a custom error document

When you configure your bucket as a static website, you can provide a custom error document that contains a user-friendly error message and additional help. Amazon S3 returns your custom error document for only the HTTP 4XX class of error codes.

To configure a custom error document using the S3 console, follow the steps below. You can also configure an error document using the REST API, the AWS SDKs, the AWS CLI, or AWS CloudFormation. For more information, see the following:

- PutBucketWebsite in the *Amazon Simple Storage Service API Reference*
- AWS::S3::Bucket WebsiteConfiguration in the *AWS CloudFormation User Guide*
- put-bucket-website in the *AWS CLI Command Reference*

When you enable static website hosting for your bucket, you enter the name of the error document (for example, **`404.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

To configure an error document

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

   The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error**

document name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, `404.html`). For more information, see Enabling website hosting and Configuring a custom error document.

   After enabling static website hosting, proceed to step 6.
7. To upload the error document to your bucket, do one of the following:

   - Drag and drop the error document file into the console bucket listing.
   - Choose **Upload**, and follow the prompts to choose and upload the index file.

   For step-by-step instructions, see Uploading objects.

Setting permissions for website access

When you configure a bucket as a static website, if you want your website to be public, you can grant public read access. To make your bucket publicly readable, you must disable block public access settings for the bucket and write a bucket policy that grants public read access. If your bucket contains objects that are not owned by the bucket owner, you might also need to add an object access control list (ACL) that grants everyone read access.

If you don't want to disable block public access settings for your bucket but you still want your website to be public, you can create a Amazon CloudFront distribution to serve your static website. For more information, see Speeding up your website with Amazon CloudFront or Use an Amazon CloudFront distribution to serve a static website in the *Amazon Route 53 Developer Guide*.

> **Note**
>
> On the website endpoint, if a user requests an object that doesn't exist, Amazon S3 returns HTTP response code `404 (Not Found)`. If the object exists but you haven't granted

read permission on it, the website endpoint returns HTTP response code `403 (Access Denied)`. The user can use the response code to infer whether a specific object exists. If you don't want this behavior, you should not enable website support for your bucket.

Topics

- Step 1: Edit S3 Block Public Access settings
- Step 2: Add a bucket policy
- Object access control lists

Step 1: Edit S3 Block Public Access settings

If you want to configure an existing bucket as a static website that has public access, you must edit Block Public Access settings for that bucket. You might also have to edit your account-level Block Public Access settings. Amazon S3 applies the most restrictive combination of the bucket-level and account-level block public access settings.

For example, if you allow public access for a bucket but block all public access at the account level, Amazon S3 will continue to block public access to the bucket. In this scenario, you would have to edit your bucket-level and account-level Block Public Access settings. For more information, see Blocking public access to your Amazon S3 storage.

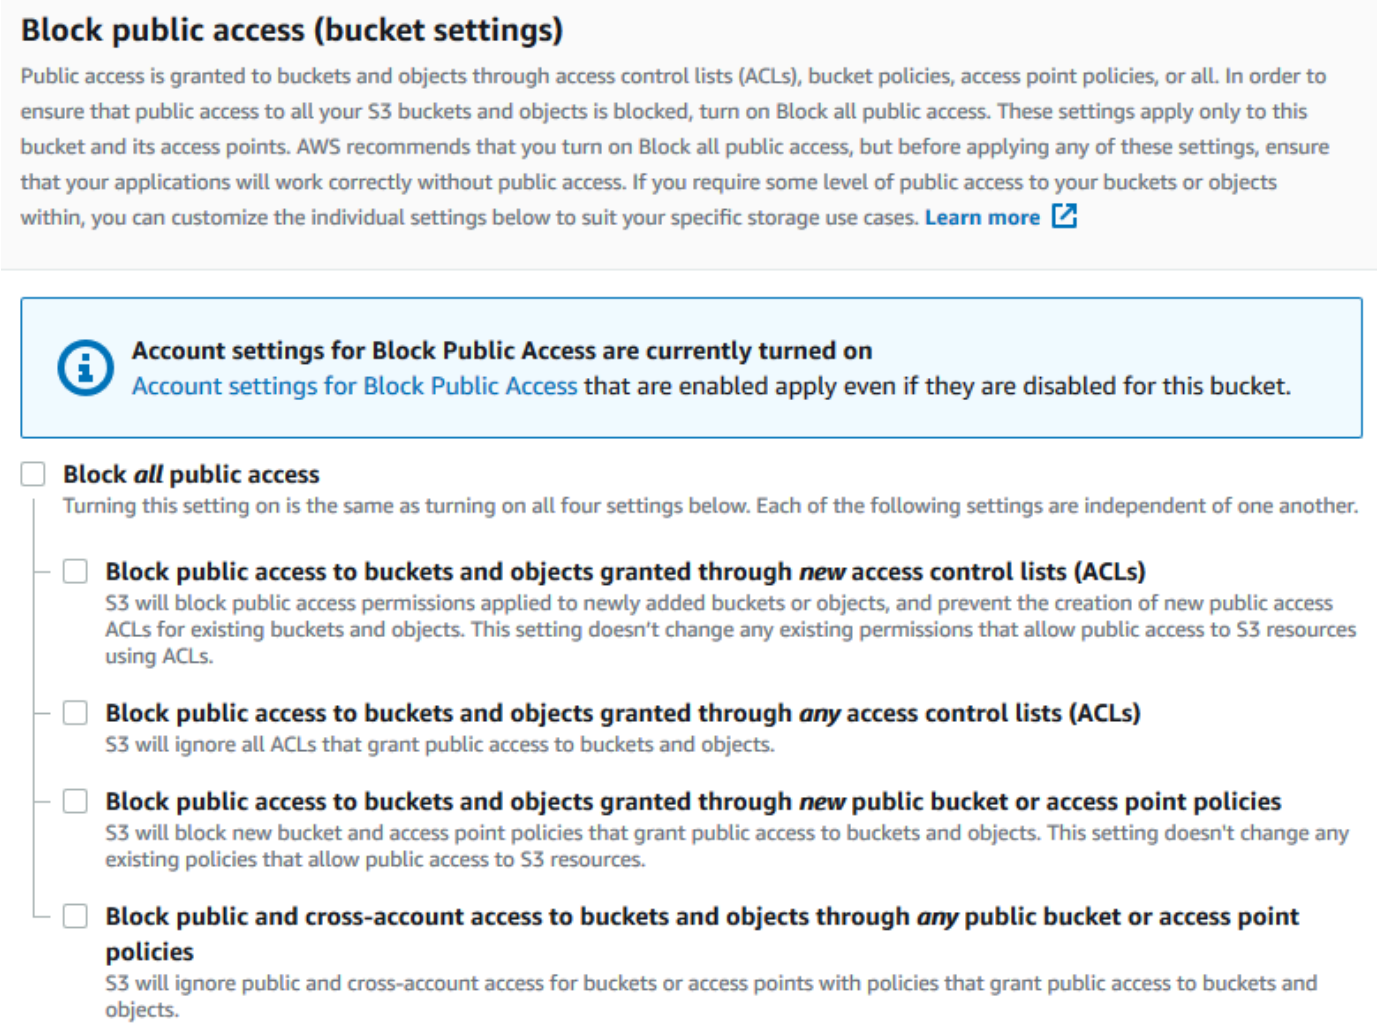
By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

Warning

Before you complete these steps, review Blocking public access to your Amazon S3 storage to ensure that you understand and accept the risks involved with allowing public access. When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the bucket that you have configured as a static website.

3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block *all* public access**, and choose **Save changes**.



Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to edit the Block Public Access settings for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

Step 2: Add a bucket policy

To make the objects in your bucket publicly readable, you must write a bucket policy that grants everyone `s3:GetObject` permission.

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

> **Important**
>
> The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review How can I secure the files in my Amazon S3 bucket? to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PublicReadGetObject",
            "Effect": "Allow",
            "Principal": "*",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::Bucket-Name/*"
            ]
        }
    ]
}
```

5. Update the `Resource` to your bucket name.

   In the preceding example bucket policy, *`Bucket-Name`* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

   A message appears indicating that the bucket policy has been successfully added.

   If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see How do I add an S3 bucket policy?

   If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

Object access control lists

You can use a bucket policy to grant public read permission to your objects. However, the bucket policy applies only to objects that are owned by the bucket owner. If your bucket contains objects that aren't owned by the bucket owner, the bucket owner should use the object access control list (ACL) to grant public READ permission on those objects.

S3 Object Ownership is an Amazon S3 bucket-level setting that you can use to both control ownership of the objects that are uploaded to your bucket and to disable or enable ACLs. By default, Object Ownership is set to the Bucket owner enforced setting, and all ACLs are disabled. When ACLs are disabled, the bucket owner owns all the objects in the bucket and manages access to them exclusively by using access-management policies.

A majority of modern use cases in Amazon S3 no longer require the use of ACLs. We recommend that you keep ACLs disabled, except in unusual circumstances where you need to control access for each object individually. With ACLs disabled, you can use policies to control access to all objects in your bucket, regardless of who uploaded the objects to your bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

> **Important**
>
> If your general purpose bucket uses the Bucket owner enforced setting for S3 Object Ownership, you must use policies to grant access to your general purpose bucket and the objects in it. With the Bucket owner enforced setting enabled, requests to set access control lists (ACLs) or update ACLs fail and return the `AccessControlListNotSupported` error code. Requests to read ACLs are still supported.

To make an object publicly readable using an ACL, grant READ permission to the `AllUsers` group, as shown in the following grant element. Add this grant element to the object ACL. For information about managing ACLs, see Access control list (ACL) overview.

```
<Grant>
  <Grantee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
           xsi:type="Group">
    <URI>http://acs.amazonaws.com/groups/global/AllUsers</URI>
  </Grantee>
  <Permission>READ</Permission>
</Grant>
```

(Optional) Logging web traffic

You can optionally enable Amazon S3 server access logging for a bucket that is configured as a static website. Server access logging provides detailed records for the requests that are made to your bucket. For more information, see Logging requests with server access logging. If you plan to use Amazon CloudFront to speed up your website, you can also use CloudFront logging. For more information, see Configuring and Using Access Logs in the *Amazon CloudFront Developer Guide*.

To enable server access logging for your static website bucket

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the same Region where you created the bucket that is configured as a static website, create a general purpose bucket for logging, for example `logs.example.com`.
3. Create a folder for the server access logging log files (for example, `logs`).
4. (Optional) If you want to use CloudFront to improve your website performance, create a folder for the CloudFront log files (for example, `cdn`).

   For more information, see Speeding up your website with Amazon CloudFront.
5. In the **Buckets** list, choose your bucket.
6. Choose **Properties**.
7. Under **Server access logging**, choose **Edit**.
8. Choose **Enable**.
9. Under the **Target bucket**, choose the bucket and folder destination for the server access logs:

   - Browse to the folder and bucket location:

1. Choose **Browse S3**.
2. Choose the bucket name, and then choose the logs folder.
3. Choose **Choose path**.

- Enter the S3 bucket path, for example, **`s3://logs.example.com/logs/`**.

10. Choose **Save changes**.

    In your log bucket, you can now access your logs. Amazon S3 writes website access logs to your log bucket every 2 hours.

(Optional) Configuring a webpage redirect

If your Amazon S3 bucket is configured for static website hosting, you can configure redirects for your bucket or the objects in it. You have the following options for configuring redirects.

Topics

- Redirect requests for your bucket's website endpoint to another bucket or domain
- Configure redirection rules to use advanced conditional redirects
- Redirect requests for an object

Redirect requests for your bucket's website endpoint to another bucket or domain

You can redirect all requests to a website endpoint for a bucket to another bucket or domain. If you redirect all requests, any request made to the website endpoint is redirected to the specified bucket or domain.

For example, if your root domain is `example.com`, and you want to serve requests for both `http://example.com` and `http://www.example.com`, you must create two buckets named `example.com` and `www.example.com`. Then, maintain the content in the `example.com` bucket, and configure the other `www.example.com` bucket to redirect all requests to the `example.com` bucket. For more information, see Configuring a Static Website Using a Custom Domain Name.

To redirect requests for a bucket website endpoint

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. Under **Buckets**, choose the name of the bucket that you want to redirect requests from (for example, `www.example.com`).
3. Choose **Properties**.
4. Under **Static website hosting**, choose **Edit**.
5. Choose **Redirect requests for an object**.
6. In the **Host name** box, enter the website endpoint for your bucket or your custom domain.

   For example, if you are redirecting to a root domain address, you would enter **`example.com`**.
7. For **Protocol**, choose the protocol for the redirected requests (**none**,**http**, or **https**).

   If you do not specify a protocol, the default option is **none**.
8. Choose **Save changes**.

Configure redirection rules to use advanced conditional redirects

Using advanced redirection rules, you can route requests conditionally according to specific object key names, prefixes in the request, or response codes. For example, suppose that you delete or rename an object in your bucket. You can add a routing rule that redirects the request to another object. If you want to make a folder unavailable, you can add a routing rule to redirect the request to another webpage. You can also add a routing rule to handle error conditions by routing requests that return the error to another domain when the error is processed.

When enabling static website hosting for your bucket, you can optionally specify advanced redirection rules. Amazon S3 has a limitation of 50 routing rules per website configuration. If you require more than 50 routing rules, you can use object redirect. For more information, see Using the S3 console.

For more information about configuring routing rules using the REST API, see PutBucketWebsite in the *Amazon Simple Storage Service API Reference*.

> **Important**
>
> To create redirection rules in the new Amazon S3 console, you must use JSON. For JSON examples, see Redirection rules examples.

To configure redirection rules for a static website

To add redirection rules for a bucket that already has static website hosting enabled, follow these steps.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of a bucket that you have configured as a static website.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. In **Redirection rules** box, enter your redirection rules in JSON.

   In the S3 console you describe the rules using JSON. For JSON examples, see Redirection rules examples. Amazon S3 has a limitation of 50 routing rules per website configuration.
7. Choose **Save changes**.

Routing rule elements

The following is general syntax for defining the routing rules in a website configuration in JSON and XML To configure redirection rules in the new S3 console, you must use JSON. For JSON examples, see Redirection rules examples.

JSON

```
[
    {
      "Condition": {
        "HttpErrorCodeReturnedEquals": "string",
        "KeyPrefixEquals": "string"
      },
      "Redirect": {
        "HostName": "string",
        "HttpRedirectCode": "string",
        "Protocol": "http"|"https",
        "ReplaceKeyPrefixWith": "string",
        "ReplaceKeyWith": "string"
      }
    }
  ]
```

```
Note: Redirect must each have at least one child element. You can have either
 ReplaceKeyPrefix with or ReplaceKeyWith but not both.
```

XML

```
<RoutingRules> =
    <RoutingRules>
         <RoutingRule>...</RoutingRule>
         [<RoutingRule>...</RoutingRule>
         ...]
    </RoutingRules>

<RoutingRule> =
   <RoutingRule>
      [ <Condition>...</Condition> ]
      <Redirect>...</Redirect>
   </RoutingRule>

<Condition> =
   <Condition>
      [ <KeyPrefixEquals>...</KeyPrefixEquals> ]
      [ <HttpErrorCodeReturnedEquals>...</HttpErrorCodeReturnedEquals> ]
   </Condition>
    Note: <Condition> must have at least one child element.

<Redirect> =
   <Redirect>
      [ <HostName>...</HostName> ]
      [ <Protocol>...</Protocol> ]
      [ <ReplaceKeyPrefixWith>...</ReplaceKeyPrefixWith>  ]
      [ <ReplaceKeyWith>...</ReplaceKeyWith> ]
      [ <HttpRedirectCode>...</HttpRedirectCode> ]
   </Redirect>

Note: <Redirect> must have at least one child element. You can have either
 ReplaceKeyPrefix with or ReplaceKeyWith but not both.
```

The following table describes the elements in the routing rule.

Name	Description
RoutingRules	Container for a collection of RoutingRule elements.
RoutingRule	A rule that identifies a condition and the redirect that is applied when the condition is met. Condition: • A RoutingRules container must contain at least one routing rule.
Condition	Container for describing a condition that must be met for the specified redirect to be applied. If the routing rule does not include a condition, the rule is applied to all requests.
KeyPrefixEquals	The prefix of the object key name from which requests are redirected. KeyPrefixEquals is required if HttpErrorCodeReturnedEquals is not specified. If both KeyPrefixEquals and HttpErrorCodeReturnedEquals are specified, both must be true for the condition to be met.
HttpErrorCodeReturnedEquals	The HTTP error code that must match for the redirect to apply. If an error occurs, and if the error code meets this value, then the specified redirect applies. HttpErrorCodeReturnedEquals is required if KeyPrefixEquals is not specified. If both KeyPrefixEquals and HttpErrorCodeReturnedEquals are specified, both must be true for the condition to be met.
Redirect	

Name	Description
	Container element that provides instructions for redirecting the request. You can redirect requests to another host or another page, or you can specify another protocol to use. A `RoutingRule` must have a `Redirect` element. A `Redirect` element must contain at least one of the following sibling elements: `Protocol`, `HostName`, `ReplaceKeyPrefixWith`, `ReplaceKeyWith`, or `HttpRedirectCode`.
`Protocol`	The protocol, `http` or `https`, to be used in the `Location` header that is returned in the response. If one of its siblings is supplied, `Protocol` is not required.
`HostName`	The hostname to be used in the `Location` header that is returned in the response. If one of its siblings is supplied, `HostName` is not required.
`ReplaceKeyPrefixWith`	The prefix of the object key name that replaces the value of `KeyPrefixEquals` in the redirect request. If one of its siblings is supplied, `ReplaceKeyPrefixWith` is not required. It can be supplied only if `ReplaceKeyWith` is not supplied.
`ReplaceKeyWith`	The object key to be used in the `Location` header that is returned in the response. If one of its siblings is supplied, `ReplaceKeyWith` is not required. It can be supplied only if `ReplaceKeyPrefixWith` is not supplied.

Name	Description
`HttpRedirectCode`	The HTTP redirect code to be used in the `Location` header that is returned in the response. If one of its siblings is supplied, `HttpRedirectCode` is not required.

Redirection rules examples

The following examples explain common redirection tasks:

> **Important**
>
> To create redirection rules in the new Amazon S3 console, you must use JSON.

Example 1: Redirect after renaming a key prefix

Suppose that your bucket contains the following objects:

- index.html
- docs/article1.html
- docs/article2.html

You decide to rename the folder from `docs/` to `documents/`. After you make this change, you need to redirect requests for prefix `docs/` to `documents/`. For example, request for `docs/article1.html` will be redirected to `documents/article1.html`.

In this case, you add the following routing rule to the website configuration.

JSON

```
[
    {
        "Condition": {
            "KeyPrefixEquals": "docs/"
        },
```

```
        "Redirect": {
            "ReplaceKeyPrefixWith": "documents/"
        }
    }
]
```

XML

```
  <RoutingRules>
    <RoutingRule>
    <Condition>
      <KeyPrefixEquals>docs/</KeyPrefixEquals>
    </Condition>
    <Redirect>
      <ReplaceKeyPrefixWith>documents/</ReplaceKeyPrefixWith>
    </Redirect>
    </RoutingRule>
  </RoutingRules>
```

Example 2: Redirect requests for a deleted folder to a page

Suppose that you delete the `images/` folder (that is, you delete all objects with the key prefix `images/`). You can add a routing rule that redirects requests for any object with the key prefix `images/` to a page named `folderdeleted.html`.

JSON

```
[
    {
        "Condition": {
            "KeyPrefixEquals": "images/"
        },
        "Redirect": {
            "ReplaceKeyWith": "folderdeleted.html"
        }
    }
]
```

XML

```
  <RoutingRules>
```

```
    <RoutingRule>
    <Condition>
       <KeyPrefixEquals>images/</KeyPrefixEquals>
    </Condition>
    <Redirect>
      <ReplaceKeyWith>folderdeleted.html</ReplaceKeyWith>
    </Redirect>
    </RoutingRule>
  </RoutingRules>
```

Example 3: Redirect for an HTTP error

Suppose that when a requested object is not found, you want to redirect requests to an Amazon Elastic Compute Cloud (Amazon EC2) instance. Add a redirection rule so that when an HTTP status code 404 (Not Found) is returned, the site visitor is redirected to an Amazon EC2 instance that handles the request.

The following example also inserts the object key prefix `report-404/` in the redirect. For example, if you request a page `ExamplePage.html` and it results in an HTTP 404 error, the request is redirected to a page `report-404/ExamplePage.html` on the specified Amazon EC2 instance. If there is no routing rule and the HTTP error 404 occurs, the error document that is specified in the configuration is returned.

JSON

```
[
    {
        "Condition": {
            "HttpErrorCodeReturnedEquals": "404"
        },
        "Redirect": {
            "HostName": "ec2-11-22-333-44.compute-1.amazonaws.com",
            "ReplaceKeyPrefixWith": "report-404/"
        }
    }
]
```

XML

```
  <RoutingRules>
    <RoutingRule>
```

```
    <Condition>
      <HttpErrorCodeReturnedEquals>404</HttpErrorCodeReturnedEquals >
    </Condition>
    <Redirect>
      <HostName>ec2-11-22-333-44.compute-1.amazonaws.com</HostName>
      <ReplaceKeyPrefixWith>report-404/</ReplaceKeyPrefixWith>
    </Redirect>
    </RoutingRule>
  </RoutingRules>
```

Redirect requests for an object

You can redirect requests for an object to another object or URL by setting the website redirect location in the metadata of the object. You set the redirect by adding the `x-amz-website-redirect-location` property to the object metadata. On the Amazon S3 console, you set the **Website Redirect Location** in the metadata of the object. If you use the Amazon S3 API, you set `x-amz-website-redirect-location`. The website then interprets the object as a 301 redirect.

To redirect a request to another object, you set the redirect location to the key of the target object. To redirect a request to an external URL, you set the redirect location to the URL that you want. For more information about object metadata, see System-defined object metadata.

When you set a page redirect, you can either keep or delete the source object content. For example, if you have a `page1.html` object in your bucket, you can redirect any requests for this page to another object, `page2.html`. You have two options:

- Keep the content of the `page1.html` object and redirect page requests.
- Delete the content of `page1.html` and upload a zero-byte object named `page1.html` to replace the existing object and redirect page requests.

Using the S3 console

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you have configured as a static website (for example, `example.com`).
3. Under **Objects**, select your object.
4. Choose **Actions**, and choose **Edit metadata**.

5. Choose **Metadata**.
6. Choose **Add Metadata**.
7. Under **Type**, choose **System Defined**.
8. In **Key**, choose **x-amz-website-redirect-location**.
9. In **Value**, enter the key name of the object that you want to redirect to, for example, `/page2.html`.

   For another object in the same bucket, the `/` prefix in the value is required. You can also set the value to an external URL, for example, `http://www.example.com`.
10. Choose **Edit metadata**.

Using the REST API

The following Amazon S3 API actions support the `x-amz-website-redirect-location` header in the request. Amazon S3 stores the header value in the object metadata as `x-amz-website-redirect-location`.

- PUT Object
- Initiate Multipart Upload
- POST Object
- PUT Object - Copy

A bucket configured for website hosting has both the website endpoint and the REST endpoint. A request for a page that is configured as a 301 redirect has the following possible outcomes, depending on the endpoint of the request:

- **Region-specific website endpoint –** Amazon S3 redirects the page request according to the value of the `x-amz-website-redirect-location` property.
- **REST endpoint –** Amazon S3 doesn't redirect the page request. It returns the requested object.

For more information about the endpoints, see Key differences between a website endpoint and a REST API endpoint.

When setting a page redirect, you can either keep or delete the object content. For example, suppose that you have a `page1.html` object in your bucket.

- To keep the content of `page1.html` and only redirect page requests, you can submit a PUT Object - Copy request to create a new `page1.html` object that uses the existing `page1.html` object as the source. In your request, you set the `x-amz-website-redirect-location` header. When the request is complete, you have the original page with its content unchanged, but Amazon S3 redirects any requests for the page to the redirect location that you specify.
- To delete the content of the `page1.html` object and redirect requests for the page, you can send a PUT Object request to upload a zero-byte object that has the same object key: `page1.html`. In the PUT request, you set `x-amz-website-redirect-location` for `page1.html` to the new object. When the request is complete, `page1.html` has no content, and requests are redirected to the location that is specified by `x-amz-website-redirect-location`.

When you retrieve the object using the GET Object action, along with other object metadata, Amazon S3 returns the `x-amz-website-redirect-location` header in the response.

Using cross-origin resource sharing (CORS)

Cross-origin resource sharing (CORS) defines a way for client web applications that are loaded in one domain to interact with resources in a different domain. With CORS support, you can build rich client-side web applications with Amazon S3 and selectively allow cross-origin access to your Amazon S3 resources.

This section provides an overview of CORS. The subtopics describe how you can enable CORS using the Amazon S3 console, or programmatically by using the Amazon S3 REST API and the AWS SDKs.

Cross-origin resource sharing: Use-case scenarios

The following are example scenarios for using CORS.

Scenario 1

Suppose that you are hosting a website in an Amazon S3 bucket named `website` as described in Hosting a static website using Amazon S3. Your users load the website endpoint:

```
http://website.s3-website.us-east-1.amazonaws.com
```

Now you want to use JavaScript on the webpages that are stored in this bucket to be able to make authenticated GET and PUT requests against the same bucket by using the Amazon S3

API endpoint for the bucket, `website.s3.us-east-1.amazonaws.com`. A browser would normally block JavaScript from allowing those requests, but with CORS you can configure your bucket to explicitly enable cross-origin requests from `website.s3-website.us-east-1.amazonaws.com`.

Scenario 2

Suppose that you want to host a web font from your S3 bucket. Again, browsers require a CORS check (also called a preflight check) for loading web fonts. You would configure the bucket that is hosting the web font to allow any origin to make these requests.

How does Amazon S3 evaluate the CORS configuration on a bucket?

When Amazon S3 receives a preflight request from a browser, it evaluates the CORS configuration for the bucket and uses the first `CORSRule` rule that matches the incoming browser request to enable a cross-origin request. For a rule to match, the following conditions must be met:

- The `Origin` header in a CORS request to your bucket must match the origins in the `AllowedOrigins` element in your CORS configuration.
- The HTTP methods that are specified in the `Access-Control-Request-Method` in a CORS request to your bucket must match the method or methods listed in the `AllowedMethods` element in your CORS configuration.
- The headers listed in the `Access-Control-Request-Headers` header in a pre-flight request must match the headers in the `AllowedHeaders` element in your CORS configuration.

> **Note**
>
> The ACLs and policies continue to apply when you enable CORS on your bucket.

How Object Lambda Access Point supports CORS

When S3 Object Lambda receives a request from a browser or the request includes an `Origin` header, S3 Object Lambda always adds an `"AllowedOrigins":"*"` header field.

For more information about using CORS, see the following topics.

Topics

- Elements of a CORS configuration
- Configuring cross-origin resource sharing (CORS)
- Testing CORS
- Troubleshooting CORS

Elements of a CORS configuration

To configure your bucket to allow cross-origin requests, you create a CORS configuration. The CORS configuration is a document with elements that identify the origins that you will allow to access your bucket, the operations (HTTP methods) that you will support for each origin, and other operation-specific information. You can add up to 100 rules to the configuration. You can add the CORS configuration as the `cors` subresource to the bucket.

If you are configuring CORS in the S3 console, you must use JSON to create a CORS configuration. The new S3 console only supports JSON CORS configurations.

For more information about the CORS configuration and the elements in it, see the topics below. For instructions on how to add a CORS configuration, see Configuring cross-origin resource sharing (CORS).

> **Important**
>
> In the S3 console, the CORS configuration must be JSON.

Topics

- AllowedMethods element
- AllowedOrigins element
- AllowedHeaders element
- ExposeHeaders element
- MaxAgeSeconds element
- Examples of CORS configurations

`AllowedMethods` element

In the CORS configuration, you can specify the following values for the `AllowedMethods` element.

- GET
- PUT
- POST
- DELETE
- HEAD

`AllowedOrigins` element

In the `AllowedOrigins` element, you specify the origins that you want to allow cross-domain requests from, for example, `http://www.example.com`. The origin string can contain only one `*` wildcard character, such as `http://*.example.com`. You can optionally specify `*` as the origin to enable all the origins to send cross-origin requests. You can also specify `https` to enable only secure origins.

`AllowedHeaders` element

The `AllowedHeaders` element specifies which headers are allowed in a preflight request through the `Access-Control-Request-Headers` header. Each header name in the `Access-Control-Request-Headers` header must match a corresponding entry in the element. Amazon S3 will send only the allowed headers in a response that were requested. For a sample list of headers that can be used in requests to Amazon S3, go to Common Request Headers in the *Amazon Simple Storage Service API Reference* guide.

Each AllowedHeaders string in your configuration can contain at most one * wildcard character. For example, `<AllowedHeader>x-amz-*</AllowedHeader>` will enable all Amazon-specific headers.

`ExposeHeaders` element

Each `ExposeHeader` element identifies a header in the response that you want customers to be able to access from their applications (for example, from a JavaScript `XMLHttpRequest` object). For a list of common Amazon S3 response headers, go to Common Response Headers in the *Amazon Simple Storage Service API Reference* guide.

`MaxAgeSeconds` element

The `MaxAgeSeconds` element specifies the time in seconds that your browser can cache the response for a preflight request as identified by the resource, the HTTP method, and the origin.

Examples of CORS configurations

Instead of accessing a website by using an Amazon S3 website endpoint, you can use your own domain, such as `example1.com` to serve your content. For information about using your own domain, see Tutorial: Configuring a static website using a custom domain registered with Route 53.

The following example CORS configuration has three rules, which are specified as `CORSRule` elements:

- The first rule allows cross-origin PUT, POST, and DELETE requests from the `http://www.example1.com` origin. The rule also allows all headers in a preflight OPTIONS request through the `Access-Control-Request-Headers` header. In response to preflight OPTIONS requests, Amazon S3 returns requested headers.
- The second rule allows the same cross-origin requests as the first rule, but the rule applies to another origin, `http://www.example2.com`.
- The third rule allows cross-origin GET requests from all origins. The `*` wildcard character refers to all origins.

JSON

```
[
    {
        "AllowedHeaders": [
            "*"
        ],
        "AllowedMethods": [
            "PUT",
            "POST",
            "DELETE"
        ],
        "AllowedOrigins": [
            "http://www.example1.com"
        ],
        "ExposeHeaders": []
    },
    {
        "AllowedHeaders": [
            "*"
        ],
        "AllowedMethods": [
```

```
            "PUT",
            "POST",
            "DELETE"
        ],
        "AllowedOrigins": [
            "http://www.example2.com"
        ],
        "ExposeHeaders": []
    },
    {
        "AllowedHeaders": [],
        "AllowedMethods": [
            "GET"
        ],
        "AllowedOrigins": [
            "*"
        ],
        "ExposeHeaders": []
    }
]
```

XML

```
<CORSConfiguration>
 <CORSRule>
   <AllowedOrigin>http://www.example1.com</AllowedOrigin>

   <AllowedMethod>PUT</AllowedMethod>
   <AllowedMethod>POST</AllowedMethod>
   <AllowedMethod>DELETE</AllowedMethod>

   <AllowedHeader>*</AllowedHeader>
 </CORSRule>
 <CORSRule>
   <AllowedOrigin>http://www.example2.com</AllowedOrigin>

   <AllowedMethod>PUT</AllowedMethod>
   <AllowedMethod>POST</AllowedMethod>
   <AllowedMethod>DELETE</AllowedMethod>

   <AllowedHeader>*</AllowedHeader>
 </CORSRule>
 <CORSRule>
```

```
   <AllowedOrigin>*</AllowedOrigin>
   <AllowedMethod>GET</AllowedMethod>
 </CORSRule>
</CORSConfiguration>
```

The CORS configuration also allows optional configuration parameters, as shown in the following CORS configuration. In this example, the CORS configuration allows cross-origin PUT, POST, and DELETE requests from the `http://www.example.com` origin.

JSON

```
[
    {
        "AllowedHeaders": [
            "*"
        ],
        "AllowedMethods": [
            "PUT",
            "POST",
            "DELETE"
        ],
        "AllowedOrigins": [
            "http://www.example.com"
        ],
        "ExposeHeaders": [
            "x-amz-server-side-encryption",
            "x-amz-request-id",
            "x-amz-id-2"
        ],
        "MaxAgeSeconds": 3000
    }
]
```

XML

```
<CORSConfiguration>
 <CORSRule>
   <AllowedOrigin>http://www.example.com</AllowedOrigin>
   <AllowedMethod>PUT</AllowedMethod>
   <AllowedMethod>POST</AllowedMethod>
   <AllowedMethod>DELETE</AllowedMethod>
   <AllowedHeader>*</AllowedHeader>
```

```
  <MaxAgeSeconds>3000</MaxAgeSeconds>
  <ExposeHeader>x-amz-server-side-encryption</
ExposeHeader>
  <ExposeHeader>x-amz-request-id</
ExposeHeader>
  <ExposeHeader>x-amz-id-2</ExposeHeader>
 </CORSRule>
</CORSConfiguration>
```

The `CORSRule` element in the preceding configuration includes the following optional elements:

- `MaxAgeSeconds`—Specifies the amount of time in seconds (in this example, 3000) that the browser caches an Amazon S3 response to a preflight OPTIONS request for the specified resource. By caching the response, the browser does not have to send preflight requests to Amazon S3 if the original request will be repeated.
- `ExposeHeaders`—Identifies the response headers (in this example, `x-amz-server-side-encryption`, `x-amz-request-id`, and `x-amz-id-2`) that customers are able to access from their applications (for example, from a JavaScript `XMLHttpRequest` object).

Configuring cross-origin resource sharing (CORS)

Cross-origin resource sharing (CORS) defines a way for client web applications that are loaded in one domain to interact with resources in a different domain. With CORS support, you can build rich client-side web applications with Amazon S3 and selectively allow cross-origin access to your Amazon S3 resources.

This section shows you how to enable CORS using the Amazon S3 console, the Amazon S3 REST API, and the AWS SDKs. To configure your bucket to allow cross-origin requests, you add a CORS configuration to the bucket. A CORS configuration is a document that defines rules that identify the origins that you will allow to access your bucket, the operations (HTTP methods) supported for each origin, and other operation-specific information. In the S3 console, the CORS configuration must be a JSON document.

For example CORS configurations in JSON and XML, see Elements of a CORS configuration.

Using the S3 console

This section explains how to use the Amazon S3 console to add a cross-origin resource sharing (CORS) configuration to an S3 bucket.

When you enable CORS on the bucket, the access control lists (ACLs) and other access permission policies continue to apply.

> **Important**
>
> In the S3 console, the CORS configuration must be JSON. For examples CORS configurations in JSON and XML, see Elements of a CORS configuration.

To add a CORS configuration to an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to create a bucket policy for.
4. Choose **Permissions**.
5. In the **Cross-origin resource sharing (CORS)** section, choose **Edit**.
6. In the **CORS configuration editor** text box, type or copy and paste a new CORS configuration, or edit an existing configuration.

   The CORS configuration is a JSON file. The text that you type in the editor must be valid JSON. For more information, see Elements of a CORS configuration.
7. Choose **Save changes**.

   > **Note**
   >
   > Amazon S3 displays the Amazon Resource Name (ARN) for the bucket next to the **CORS configuration editor** title. For more information about ARNs, see Amazon Resource Names (ARNs) and AWS Service Namespaces in the *Amazon Web Services General Reference*.

Using the AWS SDKs

You can use the AWS SDK to manage cross-origin resource sharing (CORS) for a bucket. For more information about CORS, see Using cross-origin resource sharing (CORS).

The following examples:

- Creates a CORS configuration and sets the configuration on a bucket
- Retrieves the configuration and modifies it by adding a rule
- Adds the modified configuration to the bucket
- Deletes the configuration

Java

Example

Example

For instructions on how to create and test a working sample, see Getting Started in the AWS SDK for Java Developer Guide.

```
import com.amazonaws.AmazonServiceException;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;

            var configuration = response.Configuration;
            PrintCORSRules(configuration);
```

```
            return configuration;
        }

        static async Task DeleteCORSConfigurationAsync()
        {
            DeleteCORSConfigurationRequest request = new
 DeleteCORSConfigurationRequest
            {
                BucketName = bucketName
            };
            await s3Client.DeleteCORSConfigurationAsync(request);
        }

        static void PrintCORSRules(CORSConfiguration configuration)
        {
            Console.WriteLine();

            if (configuration == null)
            {
                Console.WriteLine("\nConfiguration is null");
                return;
            }

            Console.WriteLine("Configuration has {0} rules:",
 configuration.Rules.Count);
            foreach (CORSRule rule in configuration.Rules)
            {
                Console.WriteLine("Rule ID: {0}", rule.Id);
                Console.WriteLine("MaxAgeSeconds: {0}", rule.MaxAgeSeconds);
                Console.WriteLine("AllowedMethod: {0}", string.Join(", ",
 rule.AllowedMethods.ToArray()));
                Console.WriteLine("AllowedOrigins: {0}", string.Join(", ",
 rule.AllowedOrigins.ToArray()));
                Console.WriteLine("AllowedHeaders: {0}", string.Join(", ",
 rule.AllowedHeaders.ToArray()));
                Console.WriteLine("ExposeHeader: {0}", string.Join(", ",
 rule.ExposeHeaders.ToArray()));
            }
        }
    }
}
```

Using the REST API

To set a CORS configuration on your bucket, you can use the AWS Management Console. If your application requires it, you can also send REST requests directly. The following sections in the *Amazon Simple Storage Service API Reference* describe the REST API actions related to the CORS configuration:

- PutBucketCors
- GetBucketCors
- DeleteBucketCors
- OPTIONS object

Testing CORS

To test your CORS configuration, a CORS preflight request can be sent with the `OPTIONS` method so that the server can respond if it is acceptable to send the request. When Amazon S3 receives a preflight request, S3 evaluates the CORS configuration for the bucket and uses the first `CORSRule` rule that matches the incoming request to enable a cross-origin request. For a rule to match, the following conditions must be met:

- The `Origin` header in a CORS request to your bucket must match the origins in the `AllowedOrigins` element in your CORS configuration.
- The HTTP methods that are specified in the `Access-Control-Request-Method` in a CORS request to your bucket must match the method or methods listed in the `AllowedMethods` element in your CORS configuration.
- The headers listed in the `Access-Control-Request-Headers` header in a preflight request must match the headers in the `AllowedHeaders` element in your CORS configuration.

The following is an example of a CORS configuration. To create a CORS Configuration, see Configuring CORS. For more examples of a CORS configuration, see Elements of a CORS configuration.

For guidance on configuring and troubleshooting CORS rules, see How do I configure CORS in Amazon S3 and confirm the CORS rules using cURL? in the AWS re:Post Knowledge Center.

JSON

```
[
    {
        "AllowedHeaders": [
            "Authorization"
        ],
        "AllowedMethods": [
            "GET",
            "PUT",
            "POST",
            "DELETE"
        ],
        "AllowedOrigins": [
            "http://www.example1.com"
        ],
        "ExposeHeaders":  [
             "x-amz-meta-custom-header"
        ]

    }
]
```

To test the CORS configuration, you can send a preflight `OPTIONS` check by using the following CURL command. CURL is a command-line tool that can be used to interact with S3. For more information, see CURL.

```
curl -v -X OPTIONS \
 -H "Origin: http://www.example1.com" \
 -H "Access-Control-Request-Method: PUT" \
 -H "Access-Control-Request-Headers: Authorization" \
 -H "Access-Control-Expose-Headers: x-amz-meta-custom-header"\
    "http://bucket_name.s3.amazonaws.com/object_prefix_name"
```

In the above example, the `curl -v -x OPTIONS` command is used to send a preflight request to S3 to inquire if it is allowed by S3 to send a PUT request on an object from the cross origin `http://www.example1.com`. The headers `Access-Control-Request-Headers` and `Access-Control-Expose-Headers` are optional.

- In response to the `Access-Control-Request-Method` header in the preflight `OPTIONS` request, Amazon S3 returns the list of allowed methods if the requested methods match.
- In response to the `Access-Control-Request-Headers` header in the preflight `OPTIONS` request, Amazon S3 returns the list of allowed headers if the requested headers match.
- In response to the `Access-Control-Expose-Headers` header in the preflight `OPTIONS` request, Amazon S3 returns a list of allowed headers if the requested headers match the allowed headers that can be accessed by scripts running in the browser.

> **Note**
>
> When sending a preflight request, if any of the CORS request headers are not allowed, none of the response CORS headers are returned.

In response to this preflight `OPTIONS` request, you will receive a `200 OK` response. For common error codes received when testing CORS and more information to solve CORS related issues, see Troubleshooting CORS.

```
< HTTP/1.1 200 OK
< Date: Fri, 12 Jul 2024 00:23:51 GMT
< Access-Control-Allow-Origin: http://www.example1.com
< Access-Control-Allow-Methods: GET, PUT, POST, DELETE
< Access-Control-Allow-Headers: Authorization
< Access-Control-Expose-Headers: x-amz-meta-custom-header
< Access-Control-Allow-Credentials: true
< Vary: Origin, Access-Control-Request-Headers, Access-Control-Request-Method
< Server: AmazonS3

```

Troubleshooting CORS

The following topics can help you troubleshoot some common CORS issues related to S3.

Topics

- 403 Forbidden error: CORS is not enabled for this bucket
- 403 Forbidden error: This CORS request is not allowed
- Headers not found in CORS response

- Considerations of CORS on S3 proxy integrations

403 Forbidden error: CORS is not enabled for this bucket

The following `403 Forbidden` error occurs when a cross-origin request is sent to Amazon S3 but CORS is not configured on your S3 bucket.

Error: HTTP/1.1 403 Forbidden CORS Response: CORS is not enabled for this bucket.

The CORS configuration is a document or policy with rules that identify the origins that you will allow to access your bucket, the operations (HTTP methods) that you will support for each origin, and other operation-specific information. See how to configure CORS on S3 by using the Amazon S3 console, AWS SDKs, and REST API. For more information on CORS and examples of a CORS configuration, see Elements of CORS.

403 Forbidden error: This CORS request is not allowed

The following `403 Forbidden` error is received when a CORS rule in your CORS configuration doesn't match the data in your request.

Error: HTTP/1.1 403 Forbidden CORS Response: This CORS request is not allowed.

As a result, this `403 Forbidden` error can occur for multiple reasons:

- Origin is not allowed.
- Methods are not allowed.
- Requested headers are not allowed.

For each request that Amazon S3 receives, you must have a CORS rule in your CORS configuration that matches the data in your request.

Origin is not allowed

The `Origin` header in a CORS request to your bucket must match the origins in the `AllowedOrigins` element in your CORS configuration. A wildcard character ("`*`") in the `AllowedOrigins` element would match all HTTP methods. For more information on how to update the `AllowedOrigins` element, see Configuring cross-origin resource sharing (CORS).

For example, if only the `http://www.example1.com` domain is included in the `AllowedOrigins` element, then a CORS request sent from the `http://www.example2.com` domain would receive the `403 Forbidden` error.

The following example shows part of a CORS configuration that includes the `http://www.example1.com` domain in the `AllowedOrigins` element.

```
"AllowedOrigins":[
   "http://www.example1.com"
]
```

For a CORS request sent from the `http://www.example2.com` domain to be successful, the `http://www.example2.com` domain should be included in the `AllowedOrigins` element of CORS configuration.

```
"AllowedOrigins":[
   "http://www.example1.com"
   "http://www.example2.com"
]
```

Methods are not allowed

The HTTP methods that are specified in the `Access-Control-Request-Method` in a CORS request to your bucket must match the method or methods listed in the `AllowedMethods` element in your CORS configuration. A wildcard character ("`*`") in `AllowedMethods` would match all HTTP methods. For more information on how to update the `AllowedOrigins` element, see Configuring cross-origin resource sharing (CORS).

In a CORS configuration, you can specify the following methods in the `AllowedMethods` element:

- `GET`
- `PUT`
- `POST`
- `DELETE`
- `HEAD`

The following example shows part of a CORS configuration that includes the `GET` method in the `AllowedMethods` element. Only requests including the `GET` method would succeed.

```
"AllowedMethods":[
   "GET"
]
```

If an HTTP method (for example, PUT) was used in a CORS request or included in a pre-flight CORS request to your bucket but the method isn't present in your CORS configuration, the request would result in a `403 Forbidden` error. To allow this CORS request or CORS pre-flight request, the PUT method must be added to your CORS configuration.

```
"AllowedMethods":[
   "GET"
   "PUT"
]
```

Requested headers are not allowed

The headers listed in the `Access-Control-Request-Headers` header in a pre-flight request must match the headers in the `AllowedHeaders` element in your CORS configuration. For a list of common headers that can be used in requests to Amazon S3, see Common Request Headers. For more information on how to update the `AllowedHeaders` element, see Configuring cross-origin resource sharing (CORS).

The following example shows part of a CORS configuration that includes the `Authorization` header in the `AllowedHeaders` element. Only requests for the `Authorization` header would succeed.

```
"AllowedHeaders":  [
    "Authorization"
]
```

If a header (for example `Content-MD5` was included in a CORS request but the header isn't present in your CORS configuration, the request would result in a `403 Forbidden` error. To allow this CORS request , the `Content-MD5` header must be added to your CORS configuration. If you want to pass both `Authorization` and `Content-MD5` headers in a CORS request to your bucket, confirm that both headers are included in the `AllowedHeaders` element in your CORS configuration.

```
"AllowedHeaders":  [
    "Authorization"
```

```
    "Content-MD5"
]
```

Headers not found in CORS response

The `ExposeHeaders` element in your CORS configuration identifies which response headers that you would like to make accessible to scripts and applications running in browsers, in response to a CORS request.

If your objects stored in your S3 bucket have user-defined metadata (for example, `x-amz-meta-custom-header`) along with the response data, this custom header could contain additional metadata or information that you want to access from your client-side JavaScript code. However, by default, browsers block access to custom headers for security reasons. To allow your client-side JavaScript to access custom headers, you need to include the header in your CORS configuration.

In the example below, the `x-amz-meta-custom-header1` header is included in the `ExposeHeaders` element. The `x-amz-meta-custom-header2` isn't included in the `ExposeHeaders` element and is missing from the CORS configuration. In the response, only the values included in the `ExposeHeaders` element would be returned. If the request included the `x-amz-meta-custom-header2` header in the `Access-Control-Expose-Headers` header, the response would still return a `200 OK`. However, only the permitted header, For example `x-amz-meta-custom-header` would be returned and show in the response.

```
"ExposeHeaders":  [
    "x-amz-meta-custom-header1"
]
```

To ensure all headers appear in the response, add all permitted headers to the `ExposeHeaders` element in your CORS configuration as shown below.

```
"ExposeHeaders":  [
    "x-amz-meta-custom-header1",
    "x-amz-meta-custom-header2"
]
```

Considerations of CORS on S3 proxy integrations

If you are experiencing errors and have already checked the CORS configuration on your S3 bucket, and the cross-origin request is sent to proxies such as AWS CloudFront, try the following:

- Configure the settings to allow the `OPTIONS` method for HTTP requests.
- Configure the proxy to forward the following headers: `Origin`, `Access-Control-Request-Headers`, and `Access-Control-Request-Method`.
- Configure the proxy settings to include the origin header in its cache key. This is important because caching proxies that don't include the origin header in their cache key may serve cached responses that don't include the appropriate CORS headers for different origins.

Some proxies provide pre-defined features for CORS requests. For example, in CloudFront, you can configure a policy that includes the headers

that enable cross-origin resource sharing (CORS) requests when the origin is an Amazon S3 bucket.

This policy has the following settings:

- Headers included in origin requests:

  `Origin`

  `Access-Control-Request-Headers`

  `Access-Control-Request-Method`
- Cookies included in origin requests: None
- Query strings included in origin requests: None

For more information, see Control origin requests with a policy and Use managed origin request policies in the *CloudFront Developer Guide*.

Static website tutorials

The following tutorials or walkthroughs present complete procedures for how to create and configure an Amazon S3 general purpose bucket for static website hosting and hosting on-demand video streaming. The purpose of these tutorials is to provide general guidance. These tutorials are intended for a lab-type environment, and they use example bucket names, user names, and so on. They are not intended for direct use in a production environment without careful review and adaptation to meet the unique needs of your organization's environment.

- Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53 – You can use Amazon S3 with Amazon CloudFront to host videos for on-demand viewing in

a secure and scalable way. After your video is packaged into the right formats, you can store it on a server or in an S3 general purpose bucket, and then deliver it with CloudFront as viewers request it. In this tutorial, you will learn how to configure your general purpose bucket to host on-demand video streaming using CloudFront for delivery and Amazon Route 53 for Domain Name System (DNS) and custom domain management. CloudFront serves the video from its cache, retrieving it from your general purpose bucket only if it is not already cached. This caching management feature accelerates the delivery of your video to viewers globally with low latency, high throughput, and high transfer speeds. For more information about CloudFront caching management, see Optimizing caching and availability in the *Amazon CloudFront Developer Guide*.

- Configuring a static website – You can configure a general purpose bucket to function like a website. This tutorial walks you through the steps of hosting a website on Amazon S3 including creating a bucket, enabling static website hosting in the S3 console, creating an index document and creating an error document. For more information, see Hosting a static website using Amazon S3.
- Configuring a static website using a custom domain registered with Route 53 – You can create and configure a general purpose bucket to host a static website and create redirects on S3 for a website with a custom domain name that is registered with Amazon Route 53. You use Route 53 to register domains and to define where you want to route internet traffic for your domain. This tutorial shows how to create Route 53 alias records that routes traffic for your domain and subdomain to your general purpose bucket that contains an HTML file. For more information, see Use your domain for a static website in an Amazon S3 bucket in the *Amazon Route 53 Developer Guide*. After you complete this tutorial, you can optionally use CloudFront to improve the performance of your website. For more information, see Speeding up your website with Amazon CloudFront.
- Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket – We recommend that you use AWS Amplify Hosting to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting without extensive setup. With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. For more information, see Deploying a static website from S3 using the Amplify console in the *AWS Amplify Hosting User Guide*.

Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53

You can use Amazon S3 with Amazon CloudFront to host videos for on-demand viewing in a secure and scalable way. Video on demand (VOD) streaming means that your video content is stored on a server and viewers can watch it at any time.

CloudFront is a fast, highly secure, and programmable content delivery network (CDN) service. CloudFront can deliver your content securely over HTTPS from all of the CloudFront edge locations around the globe. For more information about CloudFront, see What is Amazon CloudFront? in the *Amazon CloudFront Developer Guide*.

CloudFront caching reduces the number of requests that your origin server must respond to directly. When a viewer (end user) requests a video that you serve with CloudFront, the request is routed to a nearby edge location closer to where the viewer is located. CloudFront serves the video from its cache, retrieving it from the S3 bucket only if it is not already cached. This caching management feature accelerates the delivery of your video to viewers globally with low latency, high throughput, and high transfer speeds. For more information about CloudFront caching management, see Optimizing caching and availability in the *Amazon CloudFront Developer Guide*.

Objective

In this tutorial, you configure an S3 bucket to host on-demand video streaming using CloudFront for delivery and Amazon Route 53 for Domain Name System (DNS) and custom domain management.

Topics

- Prerequisites: Register and configure a custom domain with Route 53
- Step 1: Create an S3 bucket
- Step 2: Upload a video to the S3 bucket
- Step 3: Create a CloudFront origin access identity
- Step 4: Create a CloudFront distribution
- Step 5: Access the video through the CloudFront distribution
- Step 6: Configure your CloudFront distribution to use your custom domain name
- Step 7: Access the S3 video through the CloudFront distribution with the custom domain name
- (Optional) Step 8: View data about requests received by your CloudFront distribution
- Step 9: Clean up
- Next steps

Prerequisites: Register and configure a custom domain with Route 53

Before you start this tutorial, you must register and configure a custom domain (for example, **`example.com`**) with Route 53 so that you can configure your CloudFront distribution to use a custom domain name later.

Without a custom domain name, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

```
https://CloudFront distribution domain name/Path to an S3 video
```

For example, **`https://d111111abcdef8.cloudfront.net/sample.mp4`**.

After you configure your CloudFront distribution to use a custom domain name configured with Route 53, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

```
https://CloudFront distribution alternate domain name/Path to an S3 video
```

For example, **`https://www.example.com/sample.mp4`**. A custom domain name is simpler and more intuitive for your viewers to use.

To register a custom domain, see Registering a new domain using Route 53 in the *Amazon Route 53 Developer Guide*.

When you register a domain name with Route 53, Route 53 creates the hosted zone for you, which you will use later in this tutorial. This hosted zone is where you store information about how to route traffic for your domain, for example, to an Amazon EC2 instance or a CloudFront distribution.

There are fees associated with domain registration, your hosted zone, and DNS queries received by your domain. For more information, see Amazon Route 53 Pricing.

> **Note**
>
> When you register a domain, it costs money immediately and it's irreversible. You can choose not to auto-renew the domain, but you pay up front and own it for the year. For more information, see Registering a new domain in the *Amazon Route 53 Developer Guide*.

Step 1: Create an S3 bucket

Create a bucket to store the original video that you plan to stream.

To create a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

   > **Note**
   >
   > To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see AWS service endpoints in the *Amazon Web Services General Reference*.

3. In the left navigation pane, choose **General purpose buckets**.
4. Choose **Create bucket**. The **Create bucket** page opens.
5. For **Bucket name**, enter a name for your bucket (for example, **`tutorial-bucket`**).

   For more information about naming buckets in Amazon S3, see General purpose bucket naming rules.
6. For **Region**, choose the AWS Region where you want the bucket to reside.

   If possible, you should pick the Region that is closest to the majority of your viewers. For more information about the bucket Region, see General purpose buckets overview.
7. For **Block Public Access settings for this bucket**, keep the default settings (**Block *all* public access** is enabled).

   Even with **Block *all* public access** enabled, viewers can still access the uploaded video through CloudFront. This feature is a major advantage of using CloudFront to host a video stored in S3.

   We recommend that you keep all settings enabled unless you need to turn off one or more of them for your use case. For more information about blocking public access, see Blocking public access to your Amazon S3 storage.
8. For the remaining settings, keep the defaults.

   (Optional) If you want to configure additional bucket settings for your specific use case, see Creating a general purpose bucket.
9. Choose **Create bucket**.

Step 2: Upload a video to the S3 bucket

The following procedure describes how to upload a video file to an S3 bucket by using the console. If you're uploading many large video files to S3, you might want to use Amazon S3 Transfer Acceleration to configure fast and secure file transfers. Transfer Acceleration can speed up video uploading to your S3 bucket for long-distance transfer of larger videos. For more information, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.

To upload a file to the bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the left navigation pane, choose **General purpose buckets**.
3. In the **General purpose buckets** list, choose the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**) to upload your file to.
4. On the **Objects** tab for your bucket, choose **Upload**.
5. On the **Upload** page, under **Files and folders**, choose **Add files**.
6. Choose a file to upload, and then choose **Open**.

   For example, you can upload a video file named `sample.mp4`.
7. Choose **Upload**.

Step 3: Create a CloudFront origin access identity

To restrict direct access to the video from your S3 bucket, create a special CloudFront user called an origin access identity (OAI). You will associate the OAI with your distribution later in this tutorial. By using an OAI, you make sure that viewers can't bypass CloudFront and get the video directly from the S3 bucket. Only the CloudFront OAI can access the file in the S3 bucket. For more information, see Restricting access to Amazon S3 content by using an OAI in the *Amazon CloudFront Developer Guide*.

To create a CloudFront OAI

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, under the **Security** section, choose **Origin access**.
3. Under the **Identities** tab, choose **Create origin access identity**.
4. Enter a name (for example, **`S3-OAI`**) for the new origin access identity.
5. Choose **Create**.

Step 4: Create a CloudFront distribution

To use CloudFront to serve and distribute the video in your S3 bucket, you must create a CloudFront distribution.

Substeps

- Create a CloudFront distribution

- Review the bucket policy

Create a CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.
3. Choose **Create distribution**.
4. In the **Origin** section, for **Origin domain**, choose the domain name of your S3 origin, which starts with the name of the S3 bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
5. For **Origin access**, choose **Legacy access identities**.
6. Under **Origin access identity**, choose the origin access identity that you created in Step 3 (for example, **`S3-OAI`**).
7. Under **Bucket policy**, choose **Yes, update the bucket policy**.
8. In the **Default cache behavior** section, under **Viewer protocol policy**, choose **Redirect HTTP to HTTPS**.

   When you choose this feature, HTTP requests are automatically redirected to HTTPS to secure your website and protect your viewers' data.
9. For the other settings in the **Default cache behaviors** section, keep the default values.

   (Optional) You can control how long your file stays in a CloudFront cache before CloudFront forwards another request to your origin. Reducing the duration allows you to serve dynamic content. Increasing the duration means that your viewers get better performance because your files are more likely to be served directly from the edge cache. A longer duration also reduces the load on your origin. For more information, see Managing how long content stays in the cache (expiration) in the *Amazon CloudFront Developer Guide*.
10. For the other sections, keep the remaining settings set to the defaults.

    For more information about the different settings options, see Values That You Specify When You Create or Update a Distribution in the *Amazon CloudFront Developer Guide*.
11. At the bottom of the page, choose **Create distribution**.

12. On the **General** tab for your CloudFront distribution, under **Details**, the value of the **Last modified** column for your distribution changes from **Deploying** to the timestamp when the distribution was last modified. This process typically takes a few minutes.

Review the bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the name of the bucket that you used earlier as the origin of your CloudFront distribution (for example, **`tutorial-bucket`**).
4. Choose the **Permissions** tab.
5. In the **Bucket policy** section, confirm that you see a statement similar to the following in the bucket policy text:

```
{
    "Version": "2008-10-17",
    "Id": "PolicyForCloudFrontPrivateContent",
    "Statement": [
        {
            "Sid": "1",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::cloudfront:user/CloudFront Origin Access
 Identity EH1HDMB1FH2TC"
            },
            "Action": "s3:GetObject",
            "Resource": "arn:aws:s3:::tutorial-bucket/*"
        }
    ]
}
```

This is the statement that your CloudFront distribution added to your bucket policy when you chose **Yes, update the bucket policy** earlier.

This bucket policy update indicates that you successfully configured the CloudFront distribution to restrict access to the S3 bucket. Because of this restriction, objects in the bucket can be accessed only through your CloudFront distribution.

Step 5: Access the video through the CloudFront distribution

Now, CloudFront can serve the video stored in your S3 bucket. To access your video through CloudFront, you must combine your CloudFront distribution domain name with the path to the video in the S3 bucket.

To create a URL to the S3 video using the CloudFront distribution domain name

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.
3. To get the distribution domain name, do the following:
   a. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
   b. After finding the distribution in the list, widen the **Domain name** column to copy the domain name value for your CloudFront distribution.
4. In a new browser tab, paste the distribution domain name that you copied.
5. Return to the previous browser tab, and open the S3 console at https://console.aws.amazon.com/s3/.
6. In the left navigation pane, choose **Buckets**.
7. In the **Buckets** list, choose the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
8. In the **Objects** list, choose the name of the video that you uploaded in Step 2 (for example, `sample.mp4`).
9. On the object detail page, in the **Object overview** section, copy the value of the **Key**. This value is the path to the uploaded video object in the S3 bucket.
10. Return to the browser tab where you previously pasted the distribution domain name, enter a forward slash (**/**) after the distribution domain name, and then paste the path to the video that you copied earlier (for example, `sample.mp4`).

    Now, your S3 video is publicly accessible and hosted through CloudFront at a URL that looks similar to the following:

    ```
    https://CloudFront distribution domain name/Path to the S3 video
    ```

Replace *CloudFront distribution domain name* and *Path to the S3 video* with the appropriate values. An example URL is **https://d111111abcdef8.cloudfront.net/sample.mp4**.

Step 6: Configure your CloudFront distribution to use your custom domain name

To use your own domain name instead of the CloudFront domain name in the URL to access the S3 video, add an alternate domain name to your CloudFront distribution.

Substeps

- Request an SSL certificate
- Add the alternate domain name to your CloudFront distribution
- Create a DNS record to route traffic from your alternate domain name to your CloudFront distribution's domain name
- Check whether IPv6 is enabled for your distribution and create another DNS record if needed

Request an SSL certificate

To allow your viewers to use HTTPS and your custom domain name in the URL for your video streaming, use AWS Certificate Manager (ACM) to request a Secure Sockets Layer (SSL) certificate. The SSL certificate establishes an encrypted network connection to the website.

1. Sign in to the AWS Management Console and open the ACM console at https://console.aws.amazon.com/acm/.
2. If the introductory page appears, under **Provision certificates**, choose **Get Started**.
3. On the **Request a certificate** page, choose **Request a public certificate**, and then choose **Request a certificate**.
4. On the **Add domain names** page, enter the fully qualified domain name (FQDN) of the site that you want to secure with an SSL/TLS certificate. You can use an asterisk (*) to request a wildcard certificate to protect several site names in the same domain. For this tutorial, enter ***** and the custom domain name that you configured in Prerequisites. For example, enter ***.example.com**, and then choose **Next**.

   For more information, see To request an ACM public certificate (console) in the *AWS Certificate Manager User Guide*.

5. On the **Select validation method** page, choose **DNS validation**. Then, choose **Next**.

   If you are able to edit your DNS configuration, we recommend that you use DNS domain validation rather than email validation. DNS validation has multiple benefits over email validation. For more information, see Option 1: DNS validation in the *AWS Certificate Manager User Guide*.

6. (Optional) On the **Add tags** page, tag your certificate with metadata.
7. Choose **Review**.
8. On the **Review** page, verify that the information under **Domain name** and **Validation method** are correct. Then, choose **Confirm and request**.

   The **Validation** page shows that your request is being processed and that the certificate domain is being validated. The certificate awaiting validation is in the **Pending validation** status.

9. On the **Validation** page, choose the down arrow to the left of your custom domain name, and then choose **Create record in Route 53** to validate your domain ownership through DNS.

   Doing this adds a CNAME record provided by AWS Certificate Manager to your DNS configuration.

10. In the **Create record in Route 53** dialog box, choose **Create**.

    The **Validation** page should display a status notification of **Success** at the bottom.

11. Choose **Continue** to view the **Certificates** list page.

    The **Status** for your new certificate changes from **Pending validation** to **Issued** within 30 minutes.

Add the alternate domain name to your CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.
3. Choose the ID for the distribution that you created in Step 4.
4. On the **General** tab, go to the **Settings** section, and choose **Edit**.

5. On the **Edit settings** page, for **Alternate domain name (CNAME) - *optional***, choose **Add item** to add the custom domain names that you want to use in the URL for the S3 video served by this CloudFront distribution.

   In this tutorial, for example, if you want to route traffic for a subdomain, such as `www.example.com`, enter the subdomain name (`www`) with the domain name (`example.com`). Specifically, enter **`www.example.com`**.

   > **Note**
   >
   > The alternate domain name (CNAME) that you add must be covered by the SSL certificate that you previously attached to your CloudFront distribution.

6. For **Custom SSL certificate - *optional***, choose the SSL certificate that you requested earlier (for example, **`*.example.com`**).

   > **Note**
   >
   > If you don't see the SSL certificate immediately after you request it, wait 30 minutes, and then refresh the list until the SSL certificate is available for you to select.

7. Keep the remaining settings set to the defaults. Choose **Save changes**.
8. On the **General** tab for the distribution, wait for the value of **Last modified** to change from **Deploying** to the timestamp when the distribution was last modified.

Create a DNS record to route traffic from your alternate domain name to your CloudFront distribution's domain name

1. Sign in to the AWS Management Console and open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in Prerequisites (for example, **`example.com`**).
4. Choose **Create record**, and then use the **Quick create record** method.
5. For **Record name**, keep the value for the record name the same as the alternate domain name of the CloudFront distribution that you added earlier.

In this tutorial, to route traffic to a subdomain, such as `www.example.com`, enter the subdomain name without the domain name. For example, enter only **`www`** in the text field before your custom domain name.

6. For **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
7. For **Value**, choose the **Alias** toggle to enable the alias resource.
8. Under **Route traffic to**, choose **Alias to CloudFront distribution** from the dropdown list.
9. In the search box that says **Choose distribution**, choose the domain name of the CloudFront distribution that you created in Step 4.

   To find the domain name of your CloudFront distribution, do the following:

   a. In a new browser tab, sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v3/home.

   b. In the left navigation pane, choose **Distributions**.

   c. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket that you created in Step 1 (for example, **`tutorial-bucket`**).

   d. After finding the distribution in the list, widen the **Domain name** column to see the domain name value for your CloudFront distribution.
10. On the **Create record** page in the Route 53 console, for the remaining settings, keep the defaults.
11. Choose **Create records**.

Check whether IPv6 is enabled for your distribution and create another DNS record if needed

If IPv6 is enabled for your distribution, you must create another DNS record.

1. To check whether IPv6 is enabled for your distribution, do the following:

   a. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.

   b. In the left navigation pane, choose **Distributions**.

   c. Choose the ID of the CloudFront distribution that you created in Step 4.

   d. On the **General** tab, under **Settings**, check whether **IPv6** is set to **Enabled**.

If IPv6 is enabled for your distribution, you must create another DNS record.

2. If IPv6 is enabled for your distribution, do the following to create a DNS record:

   a. Sign in to the AWS Management Console and open the Route 53 console at https://console.aws.amazon.com/route53/.

   b. In the left navigation pane, choose **Hosted zones**.

   c. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in Prerequisites (for example, **`example.com`**).

   d. Choose **Create record**, and then use the **Quick create record** method.

   e. For **Record name**, in the text field before your custom domain name, type the same value that you typed when you created the IPv4 DNS record earlier. For example, in this tutorial, to route traffic for the subdomain `www.example.com`, enter only **`www`**.

   f. For **Record type**, choose **AAAA - Routes traffic to an IPv6 address and some AWS resources**.

   g. For **Value**, choose the **Alias** toggle to enable the alias resource.

   h. Under **Route traffic to**, choose **Alias to CloudFront distribution** from the dropdown list.

   i. In the search box that says **Choose distribution**, choose the domain name of the CloudFront distribution that you created in Step 4.

   j. For the remaining settings, keep the defaults.

   k. Choose **Create records**.

Step 7: Access the S3 video through the CloudFront distribution with the custom domain name

To access the S3 video using the custom URL, you must combine your alternate domain name with the path to the video in the S3 bucket.

To create a custom URL to access the S3 video through the CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.
3. To get the alternate domain name of your CloudFront distribution, do the following:

a. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket name for the bucket that you created in Step 1 (for example, **`tutorial-bucket`**).

b. After finding the distribution in the list, widen the **Alternate domain names** column to copy the value of the alternate domain name of your CloudFront distribution.

4. In a new browser tab, paste the alternate domain name of the CloudFront distribution.
5. Return to the previous browser tab, and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
6. Find the path to your S3 video, as explained in Step 5.
7. Return to the browser tab where you previously pasted the alternate domain name, enter a forward slash (**/**), and then paste the path to your S3 video (for example, `sample.mp4`).

   Now, your S3 video is publicly accessible and hosted through CloudFront at a custom URL that looks similar to the following:

   ```
   https://CloudFront distribution alternate domain name/Path to the S3 video
   ```

   Replace *`CloudFront distribution alternate domain name`* and *`Path to the S3 video`* with the appropriate values. An example URL is **`https://www.example.com/sample.mp4`**.

(Optional) Step 8: View data about requests received by your CloudFront distribution

To view data about requests received by your CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, under **Reports & analytics**, choose the reports from the console, ranging from **Cache statistics**, **Popular Objects**, **Top Referrers**, **Usage**, and **Viewers**.

   You can filter each report dashboard. For more information, see CloudFront Reports in the Console in the *Amazon CloudFront Developer Guide*.
3. To filter data, choose the ID of the CloudFront distribution that you created in Step 4.

Step 9: Clean up

If you hosted an S3 streaming video using CloudFront and Route 53 only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges.

> **Note**
>
> When you register a domain, it costs money immediately and it's irreversible. You can choose not to auto-renew the domain, but you pay up front and own it for the year. For more information, see Registering a new domain in the *Amazon Route 53 Developer Guide*.

Substeps

- Delete the CloudFront distribution
- Delete the DNS record
- Delete the public hosted zone for your custom domain
- Delete the custom domain name from Route 53
- Delete the original video in the S3 source bucket
- Delete the S3 source bucket

Delete the CloudFront distribution

1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. In the left navigation pane, choose **Distributions**.
3. In the **Origins** column, find the correct CloudFront distribution by looking for its origin name, which starts with the S3 bucket name for the bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
4. To delete the CloudFront distribution, you must disable it first.

   - If the value of the **Status** column is **Enabled** and the value of **Last modified** is the timestamp when the distribution was last modified, continue to disable the distribution before deleting it.
   - If the value of **Status** is **Enabled** and the value of **Last modified** is **Deploying**, wait until the value of **Status** changes to the timestamp when the distribution was last modified. Then continue to disable the distribution before deleting it.

5. To disable the CloudFront distribution, do the following:

   a. In the **Distributions** list, select the check box next to the ID for the distribution that you want to delete.

   b. To disable the distribution, choose **Disable**, and then choose **Disable** to confirm.

      If you disable a distribution that has an alternate domain name associated with it, CloudFront stops accepting traffic for that domain name (such as `www.example.com`), even if another distribution has an alternate domain name with a wildcard (`*`) that matches the same domain (such as `*.example.com`).

   c. The value of **Status** immediately changes to **Disabled**. Wait until the value of **Last modified** changes from **Deploying** to the timestamp when the distribution was last modified.

      Because CloudFront must propagate this change to all edge locations, it might take a few minutes before the update is complete and the **Delete** option is available for you to delete the distribution.

6. To delete the disabled distribution, do the following:

   a. Choose the check box next to the ID for the distribution that you want to delete.

   b. Choose **Delete**, and then choose **Delete** to confirm.

Delete the DNS record

If you want to delete the public hosted zone for the domain (including the DNS record), see Delete the public hosted zone for your custom domain in the *Amazon Route 53 Developer Guide*. If you only want to delete the DNS record created in Step 6, do the following:

1. Sign in to the AWS Management Console and open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that Route 53 created for you in Prerequisites (for example, **`example.com`**).
4. In the list of records, select the check box next to the records that you want to delete (the records that you created in Step 6).

> **Note**
>
> You can't delete records that have a **Type** value of **NS** or **SOA**.

5. Choose **Delete records**.
6. To confirm the deletion, choose **Delete**.

   Changes to records take time to propagate to the Route 53 DNS servers. Currently, the only way to verify that your changes have propagated is to use the GetChange API action. Changes usually propagate to all Route 53 name servers within 60 seconds.

Delete the public hosted zone for your custom domain

> **Warning**
>
> If you want to keep your domain registration but stop routing internet traffic to your website or web application, we recommend that you delete records in the hosted zone (as described in the prior section) instead of deleting the hosted zone.
> If you delete a hosted zone, someone else can use the domain and route traffic to their own resources using your domain name.
> In addition, if you delete a hosted zone, you can't undelete it. You must create a new hosted zone and update the name servers for your domain registration, which can take up to 48 hours to take effect.
> If you want to make the domain unavailable on the internet, you can first transfer your DNS service to a free DNS service and then delete the Route 53 hosted zone. This prevents future DNS queries from possibly being misrouted.
>
> 1. If the domain is registered with Route 53, see Adding or changing name servers and glue records for a domain in the *Amazon Route 53 Developer Guide* for information about how to replace Route 53 name servers with name servers for the new DNS service.
> 2. If the domain is registered with another registrar, use the method provided by the registrar to change name servers for the domain.

> **Note**
>
> If you're deleting a hosted zone for a subdomain (`www.example.com`), you don't need to change name servers for the domain (`example.com`).

1. Sign in to the AWS Management Console and open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the left navigation pane, choose **Hosted zones**.
3. On the **Hosted zones** page, choose the name of the hosted zone that you want to delete.
4. On the **Records** tab for your hosted zone, confirm that the hosted zone that you want to delete contains only an **NS** and an **SOA** record.

   If it contains additional records, delete them first.

   If you created any NS records for subdomains in the hosted zone, delete those records too.
5. On the **DNSSEC signing** tab for your hosted zone, disable DNNSSEC signing if it was enabled. For more information, see Disabling DNSSEC signing in the *Amazon Route 53 Developer Guide*.
6. At the top of the details page of the hosted zone, choose **Delete zone**.
7. To confirm the deletion, enter **`delete`**, and then choose **Delete**.

Delete the custom domain name from Route 53

For most top-level domains (TLDs), you can delete the registration if you no longer want it. If you delete a domain name registration from Route 53 before the registration is scheduled to expire, AWS does not refund the registration fee. For more information, see Deleting a domain name registration in the *Amazon Route 53 Developer Guide*.

> **Important**
>
> If you want to transfer the domain between AWS accounts or transfer the domain to another registrar, don't delete the domain and expect to immediately reregister it. Instead, see the applicable documentation in the *Amazon Route 53 Developer Guide*:
>
> - Transferring a domain to a different AWS account

- Transferring a domain from Amazon Route 53 to another registrar

Delete the original video in the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Bucket name** list, choose the name of the bucket that you uploaded the video to in Step 2 (for example, **`tutorial-bucket`**).
4. On the **Objects** tab, select the check box next to the name of the object that you want to delete (for example, `sample.mp4`).
5. Choose **Delete**.
6. Under **Permanently delete objects?**, enter **`permanently delete`** to confirm that you want to delete this object.
7. Choose **Delete objects**.

Delete the S3 source bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, select the option button next to the name of the bucket that you created in Step 1 (for example, **`tutorial-bucket`**).
4. Choose **Delete**.
5. On the **Delete bucket** page, confirm that you want to delete the bucket by entering the bucket name in the text field, and then choose **Delete bucket**.

Next steps

After you complete this tutorial, you can further explore the following related use cases:

- Transcode S3 videos into streaming formats needed by a particular television or connected device before hosting these videos with a CloudFront distribution.

To use Amazon S3 Batch Operations, AWS Lambda and AWS Elemental MediaConvert to batch-transcode a collection of videos to a variety of output media formats, see Tutorial: Batch-transcoding videos with S3 Batch Operations.

- Host other objects stored in S3, such as images, audio, motion graphics, style sheets, HTML, JavaScript, React apps, and so on, using CloudFront and Route 53.

  For example, see Tutorial: Configuring a static website using a custom domain registered with Route 53 and Speeding up your website with Amazon CloudFront.
- Use Amazon S3 Transfer Acceleration to configure fast and secure file transfers. Transfer Acceleration can speed up video uploading to your S3 bucket for long-distance transfer of larger videos. Transfer Acceleration improves transfer performance by routing traffic through the CloudFront globally distributed edge locations and over the AWS backbone networks. It also uses network protocol optimizations. For more information, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.

Tutorial: Configuring a static website on Amazon S3

> **Important**
>
> Amazon S3 now applies server-side encryption with Amazon S3 managed keys (SSE-S3) as the base level of encryption for every bucket in Amazon S3. Starting January 5, 2023, all new object uploads to Amazon S3 are automatically encrypted at no additional cost and with no impact on performance. The automatic encryption status for S3 bucket default encryption configuration and for new object uploads is available in AWS CloudTrail logs, S3 Inventory, S3 Storage Lens, the Amazon S3 console, and as an additional Amazon S3 API response header in the AWS Command Line Interface and AWS SDKs. For more information, see Default encryption FAQ.

You can configure an Amazon S3 bucket to function like a website. This example walks you through the steps of hosting a website on Amazon S3.

> **Important**
>
> The following tutorial requires disabling Block Public Access. We recommend keeping Block Public Access enabled. If you want to keep all four Block Public Access settings enabled

and host a static website, you can use Amazon CloudFront origin access control (OAC). Amazon CloudFront provides the capabilities required to set up a secure static website. Amazon S3 static websites support only HTTP endpoints. Amazon CloudFront uses the durable storage of Amazon S3 while providing additional security headers, such as HTTPS. HTTPS adds security by encrypting a normal HTTP request and protecting against common cyberattacks. For more information, see Getting started with a secure static website in the *Amazon CloudFront Developer Guide*.

Topics

- Step 1: Create a bucket
- Step 2: Enable static website hosting
- Step 3: Edit Block Public Access settings
- Step 4: Add a bucket policy that makes your bucket content publicly available
- Step 5: Configure an index document
- Step 6: Configure an error document
- Step 7: Test your website endpoint
- Step 8: Clean up

Step 1: Create a bucket

The following instructions provide an overview of how to create your buckets for website hosting. For detailed, step-by-step instructions on creating a bucket, see Creating a general purpose bucket.

To create a bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose **Create bucket**.
3. Enter the **Bucket name** (for example, **`example.com`**).
4. Choose the Region where you want to create the bucket.

   Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see Website endpoints.

5. To accept the default settings and create the bucket, choose **Create**.

Step 2: Enable static website hosting

After you create a bucket, you can enable static website hosting for your bucket. You can create a new bucket or use an existing bucket.

To enable static website hosting

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable static website hosting for.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. Choose **Use this bucket to host a website**.
7. Under **Static website hosting**, choose **Enable**.
8. In **Index document**, enter the file name of the index document, typically `index.html`.

   The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see Configuring an index document.
9. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

   The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see Configuring a custom error document.
10. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see Configure redirection rules to use advanced conditional redirects.

11. Choose **Save changes**.

    Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.

12. Under **Static website hosting**, note the **Endpoint**.

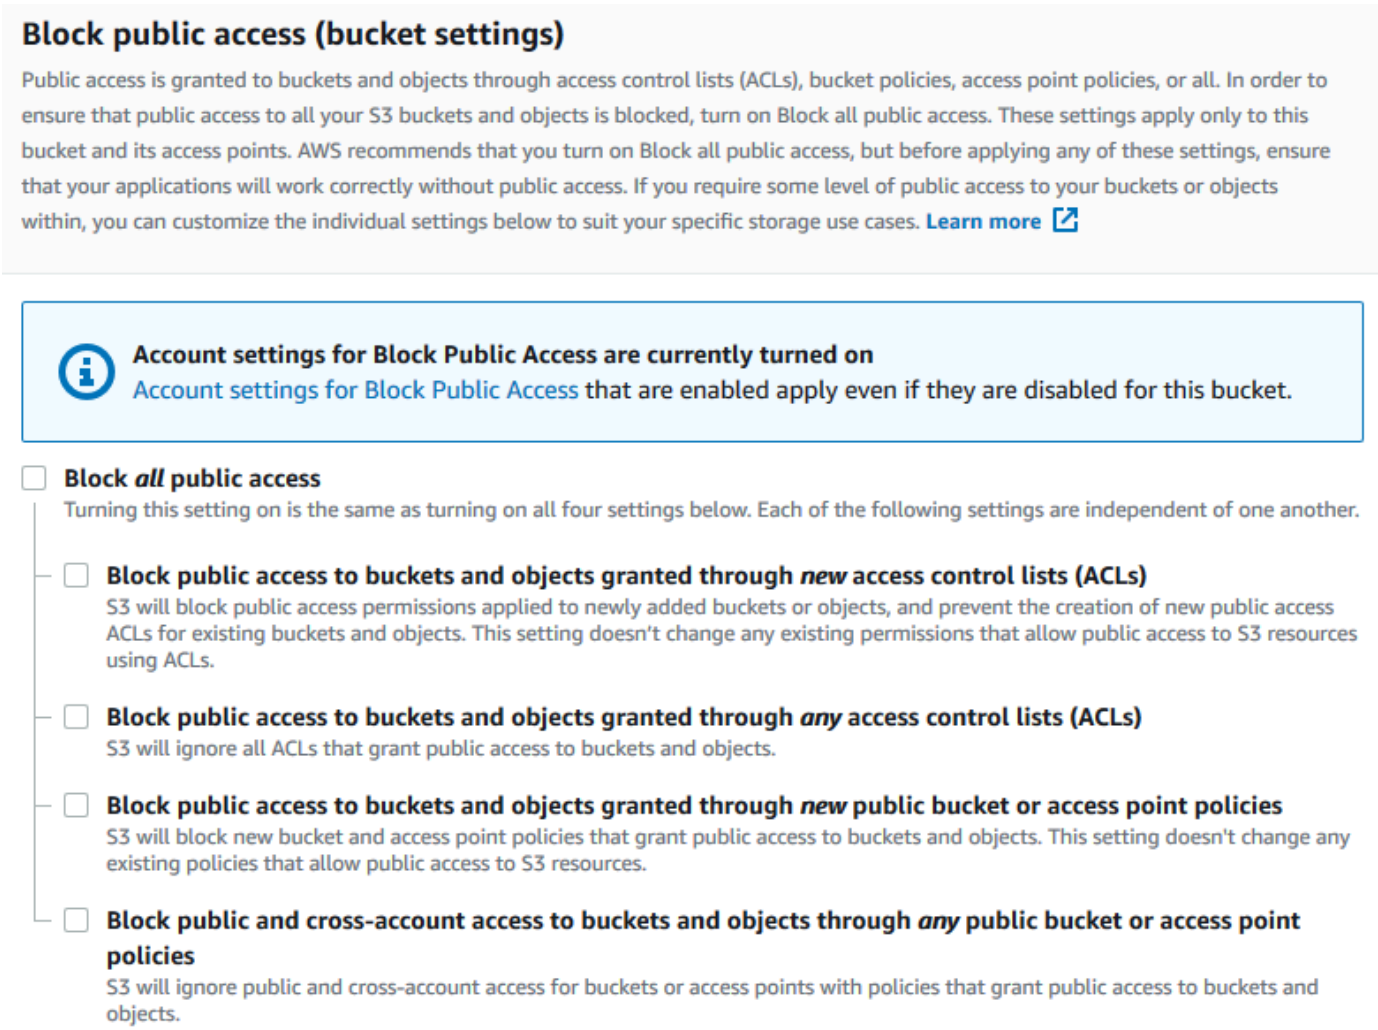
    The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

Step 3: Edit Block Public Access settings

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

> **Warning**
>
> Before you complete these steps, review Blocking public access to your Amazon S3 storage to ensure that you understand and accept the risks involved with allowing public access. When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the bucket that you have configured as a static website.
3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block *all* public access**, and choose **Save changes**.



Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to edit the Block Public Access settings for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

Step 4: Add a bucket policy that makes your bucket content publicly available

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

Important

The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review How can I secure the files in my Amazon S3 bucket? to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PublicReadGetObject",
            "Effect": "Allow",
            "Principal": "*",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::Bucket-Name/*"
            ]
        }
    ]
}
```

5. Update the `Resource` to your bucket name.

   In the preceding example bucket policy, *`Bucket-Name`* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

   A message appears indicating that the bucket policy has been successfully added.

If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see How do I add an S3 bucket policy?

If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

Step 5: Configure an index document

When you enable static website hosting for your bucket, you enter the name of the index document (for example, **`index.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

To configure the index document

1. Create an `index.html` file.

   If you don't have an `index.html` file, you can use the following HTML to create one:

   ```
   <html xmlns="http://www.w3.org/1999/xhtml" >
   <head>
       <title>My Website Home Page</title>
   </head>
   <body>
     <h1>Welcome to my website</h1>
     <p>Now hosted on Amazon S3!</p>
   </body>
   </html>
   ```

2. Save the index file locally.

   The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

4. In the left navigation pane, choose **General purpose buckets**.

5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see Enabling website hosting.

   After enabling static website hosting, proceed to step 6.
7. To upload the index document to your bucket, do one of the following:

   - Drag and drop the index file into the console bucket listing.
   - Choose **Upload**, and follow the prompts to choose and upload the index file.

   For step-by-step instructions, see Uploading objects.
8. (Optional) Upload other website content to your bucket.

Step 6: Configure an error document

When you enable static website hosting for your bucket, you enter the name of the error document (for example, **`404.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

To configure an error document

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

   The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error document** name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.
3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.

6. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, `404.html`). For more information, see Enabling website hosting and Configuring a custom error document.

   After enabling static website hosting, proceed to step 6.

7. To upload the error document to your bucket, do one of the following:

   - Drag and drop the error document file into the console bucket listing.
   - Choose **Upload**, and follow the prompts to choose and upload the index file.

   For step-by-step instructions, see Uploading objects.

Step 7: Test your website endpoint

After you configure static website hosting for your bucket, you can test your website endpoint.

> **Note**
>
> Amazon S3 does not support HTTPS access to the website. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3.
> For more information, see How do I use CloudFront to serve a static website hosted on Amazon S3? and Requiring HTTPS for communication between viewers and CloudFront.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Properties**.
3. At the bottom of the page, under **Static website hosting**, choose your **Bucket website endpoint**.

   Your index document opens in a separate browser window.

You now have a website hosted on Amazon S3. This website is available at the Amazon S3 website endpoint. However, you might have a domain, such as `example.com`, that you want to use to serve the content from the website you created. You might also want to use Amazon S3 root domain support to serve requests for both `http://www.example.com` and `http://example.com`. This requires additional steps. For an example, see Tutorial: Configuring a static website using a custom domain registered with Route 53.

Step 8: Clean up

If you created your static website only as a learning exercise, delete the AWS resources that you allocated so that you no longer accrue charges. After you delete your AWS resources, your website is no longer available. For more information, see Deleting a general purpose bucket.

Tutorial: Configuring a static website using a custom domain registered with Route 53

Suppose that you want to host a static website on Amazon S3. You've registered a domain with Amazon Route 53 (for example, `example.com`), and you want requests for `http://www.example.com` and `http://example.com` to be served from your Amazon S3 content. You can use this walkthrough to learn how to host a static website and create redirects on Amazon S3 for a website with a custom domain name that is registered with Route 53. You can work with an existing website that you want to host on Amazon S3, or use this walkthrough to start from scratch.

After you complete this walkthrough, you can optionally use Amazon CloudFront to improve the performance of your website. For more information, see Speeding up your website with Amazon CloudFront.

> **Note**
>
> Amazon S3 website endpoints do not support HTTPS or access points. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3. For a tutorial about how to host your content securely with CloudFront and Amazon S3, see Tutorial: Hosting on-demand streaming video with Amazon S3, Amazon CloudFront, and Amazon Route 53. For more information, see How do I use CloudFront to serve a static website hosted on Amazon S3? and Requiring HTTPS for communication between viewers and CloudFront.

Automating static website setup with an AWS CloudFormation template

You can use an AWS CloudFormation template to automate your static website setup. The AWS CloudFormation template sets up the components that you need to host a secure static website so that you can focus more on your website's content and less on configuring components.

The AWS CloudFormation template includes the following components:

- Amazon S3 – Creates an Amazon S3 bucket to host your static website.
- CloudFront – Creates a CloudFront distribution to speed up your static website.
- Lambda@Edge – Uses Lambda@Edge to add security headers to every server response. Security headers are a group of headers in the web server response that tell web browsers to take extra security precautions. For more information, see the blog post Adding HTTP security headers using Lambda@Edge and Amazon CloudFront.

This AWS CloudFormation template is available for you to download and use. For information and instructions, see Getting started with a secure static website in the *Amazon CloudFront Developer Guide*.

Topics

- Before you begin
- Step 1: Register a custom domain with Route 53
- Step 2: Create two buckets
- Step 3: Configure your root domain bucket for website hosting
- Step 4: Configure your subdomain bucket for website redirect
- Step 5: Configure logging for website traffic
- Step 6: Upload index and website content
- Step 7: Upload an error document
- Step 8: Edit S3 Block Public Access settings
- Step 9: Attach a bucket policy
- Step 10: Test your domain endpoint
- Step 11: Add alias records for your domain and subdomain
- Step 12: Test the website
- Speeding up your website with Amazon CloudFront
- Cleaning up your example resources

Before you begin

As you follow the steps in this example, you work with the following services:

Amazon Route 53 – You use Route 53 to register domains and to define where you want to route internet traffic for your domain. The example shows how to create Route 53 alias records that

route traffic for your domain (`example.com`) and subdomain (`www.example.com`) to an Amazon S3 bucket that contains an HTML file.

Amazon S3 – You use Amazon S3 to create buckets, upload a sample website page, configure permissions so that everyone can see the content, and then configure the buckets for website hosting.

Step 1: Register a custom domain with Route 53

If you don't already have a registered domain name, such as `example.com`, register one with Route 53. For more information, see Registering a new domain in the *Amazon Route 53 Developer Guide*. After you register your domain name, you can create and configure your Amazon S3 buckets for website hosting.

Step 2: Create two buckets

To support requests from both the root domain and subdomain, you create two buckets.

- **Domain bucket** – `example.com`
- **Subdomain bucket** – `www.example.com`

These bucket names must match your domain name exactly. In this example, the domain name is `example.com`. You host your content out of the root domain bucket (`example.com`). You create a redirect request for the subdomain bucket (`www.example.com`). If someone enters `www.example.com` in their browser, they are redirected to `example.com` and see the content that is hosted in the Amazon S3 bucket with that name.

To create your buckets for website hosting

The following instructions provide an overview of how to create your buckets for website hosting. For detailed, step-by-step instructions on creating a bucket, see Creating a general purpose bucket.

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Create your root domain bucket:

    a. In the navigation bar on the top of the page, choose the name of the currently displayed AWS Region. Next, choose the Region in which you want to create a bucket.

> **Note**
>
> To minimize latency and costs and address regulatory requirements, choose a Region close to you. Objects stored in a Region never leave that Region unless you explicitly transfer them to another Region. For a list of Amazon S3 AWS Regions, see AWS service endpoints in the *Amazon Web Services General Reference*.

b. In the left navigation pane, choose **General purpose buckets**.

c. Choose **Create bucket**. The **Create bucket** page opens.

d. Enter the **Bucket name** (for example, **`example.com`**).

e. Choose the Region where you want to create the bucket.

Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see Website endpoints.

f. To accept the default settings and create the bucket, choose **Create**.

3. Create your subdomain bucket:

a. Choose **Create bucket**.

b. Enter the **Bucket name** (for example, **`www.example.com`**).

c. Choose the Region where you want to create the bucket.

Choose a Region that is geographically close to you to minimize latency and costs, or to address regulatory requirements. The Region that you choose determines your Amazon S3 website endpoint. For more information, see Website endpoints.

d. To accept the default settings and create the bucket, choose **Create**.

In the next step, you configure `example.com` for website hosting.

Step 3: Configure your root domain bucket for website hosting

In this step, you configure your root domain bucket (`example.com`) as a website. This bucket will contain your website content. When you configure a bucket for website hosting, you can access the website using the Website endpoints.

To enable static website hosting

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **General purpose buckets**.
3. In the buckets list, choose the name of the bucket that you want to enable static website hosting for.
4. Choose **Properties**.
5. Under **Static website hosting**, choose **Edit**.
6. Choose **Use this bucket to host a website**.
7. Under **Static website hosting**, choose **Enable**.
8. In **Index document**, enter the file name of the index document, typically `index.html`.

   The index document name is case sensitive and must exactly match the file name of the HTML index document that you plan to upload to your S3 bucket. When you configure a bucket for website hosting, you must specify an index document. Amazon S3 returns this index document when requests are made to the root domain or any of the subfolders. For more information, see Configuring an index document.
9. To provide your own custom error document for 4XX class errors, in **Error document**, enter the custom error document file name.

   The error document name is case sensitive and must exactly match the file name of the HTML error document that you plan to upload to your S3 bucket. If you don't specify a custom error document and an error occurs, Amazon S3 returns a default HTML error document. For more information, see Configuring a custom error document.
10. (Optional) If you want to specify advanced redirection rules, in **Redirection rules**, enter JSON to describe the rules.

    For example, you can conditionally route requests according to specific object key names or prefixes in the request. For more information, see Configure redirection rules to use advanced conditional redirects.
11. Choose **Save changes**.

    Amazon S3 enables static website hosting for your bucket. At the bottom of the page, under **Static website hosting**, you see the website endpoint for your bucket.
12. Under **Static website hosting**, note the **Endpoint**.

The **Endpoint** is the Amazon S3 website endpoint for your bucket. After you finish configuring your bucket as a static website, you can use this endpoint to test your website.

After you edit block public access settings and add a bucket policy that allows public read access, you can use the website endpoint to access your website.

In the next step, you configure your subdomain (`www.example.com`) to redirect requests to your domain (`example.com`).

Step 4: Configure your subdomain bucket for website redirect

After you configure your root domain bucket for website hosting, you can configure your subdomain bucket to redirect all requests to the domain. In this example, all requests for `www.example.com` are redirected to `example.com`.

To configure a redirect request

1. On the Amazon S3 console, in the **General purpose buckets** list, choose your subdomain bucket name (`www.example.com` in this example).
2. Choose **Properties**.
3. Under **Static website hosting**, choose **Edit**.
4. Choose **Redirect requests for an object**.
5. In the **Target bucket** box, enter your root domain, for example, **`example.com`**.
6. For **Protocol**, choose **http**.
7. Choose **Save changes**.

Step 5: Configure logging for website traffic

If you want to track the number of visitors accessing your website, you can optionally enable logging for your root domain bucket. For more information, see Logging requests with server access logging. If you plan to use Amazon CloudFront to speed up your website, you can also use CloudFront logging.

To enable server access logging for your root domain bucket

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the same Region where you created the bucket that is configured as a static website, create a bucket for logging, for example `logs.example.com`.
3. Create a folder for the server access logging log files (for example, `logs`).
4. (Optional) If you want to use CloudFront to improve your website performance, create a folder for the CloudFront log files (for example, `cdn`).

   > **Important**
   >
   > When you create or update a distribution and enable CloudFront logging, CloudFront updates the bucket access control list (ACL) to give the `awslogsdelivery` account `FULL_CONTROL` permissions to write logs to your bucket. For more information, see Permissions required to configure standard logging and to access your log files in the *Amazon CloudFront Developer Guide*. If the bucket that stores the logs uses the Bucket owner enforced setting for S3 Object Ownership to disable ACLs, CloudFront cannot write logs to the bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

5. In the **Buckets** list, choose your root domain bucket.
6. Choose **Properties**.
7. Under **Server access logging**, choose **Edit**.
8. Choose **Enable**.
9. Under the **Target bucket**, choose the bucket and folder destination for the server access logs:

   - Browse to the folder and bucket location:
     1. Choose **Browse S3**.
     2. Choose the bucket name, and then choose the logs folder.
     3. Choose **Choose path**.
   - Enter the S3 bucket path, for example, `s3://logs.example.com/logs/`.

10. Choose **Save changes**.

    In your log bucket, you can now access your logs. Amazon S3 writes website access logs to your log bucket every 2 hours.

Step 6: Upload index and website content

In this step, you upload your index document and optional website content to your root domain bucket.

When you enable static website hosting for your bucket, you enter the name of the index document (for example, **`index.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this index document name to your bucket.

To configure the index document

1. Create an `index.html` file.

   If you don't have an `index.html` file, you can use the following HTML to create one:

   ```
   <html xmlns="http://www.w3.org/1999/xhtml" >
   <head>
       <title>My Website Home Page</title>
   </head>
   <body>
     <h1>Welcome to my website</h1>
     <p>Now hosted on Amazon S3!</p>
   </body>
   </html>
   ```

2. Save the index file locally.

   The index document file name must exactly match the index document name that you enter in the **Static website hosting** dialog box. The index document name is case sensitive. For example, if you enter `index.html` for the **Index document** name in the **Static website hosting** dialog box, your index document file name must also be `index.html` and not `Index.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your index document (for example, `index.html`). For more information, see Enabling website hosting.

After enabling static website hosting, proceed to step 6.

7. To upload the index document to your bucket, do one of the following:

   - Drag and drop the index file into the console bucket listing.
   - Choose **Upload**, and follow the prompts to choose and upload the index file.

   For step-by-step instructions, see Uploading objects.

8. (Optional) Upload other website content to your bucket.

Step 7: Upload an error document

When you enable static website hosting for your bucket, you enter the name of the error document (for example, **`404.html`**). After you enable static website hosting for the bucket, you upload an HTML file with this error document name to your bucket.

To configure an error document

1. Create an error document, for example `404.html`.
2. Save the error document file locally.

   The error document name is case sensitive and must exactly match the name that you enter when you enable static website hosting. For example, if you enter `404.html` for the **Error document** name in the **Static website hosting** dialog box, your error document file name must also be `404.html`.

3. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
4. In the left navigation pane, choose **General purpose buckets**.
5. In the buckets list, choose the name of the bucket that you want to use to host a static website.
6. Enable static website hosting for your bucket, and enter the exact name of your error document (for example, `404.html`). For more information, see Enabling website hosting and Configuring a custom error document.

   After enabling static website hosting, proceed to step 6.

7. To upload the error document to your bucket, do one of the following:

- Drag and drop the error document file into the console bucket listing.
- Choose **Upload**, and follow the prompts to choose and upload the index file.

For step-by-step instructions, see Uploading objects.

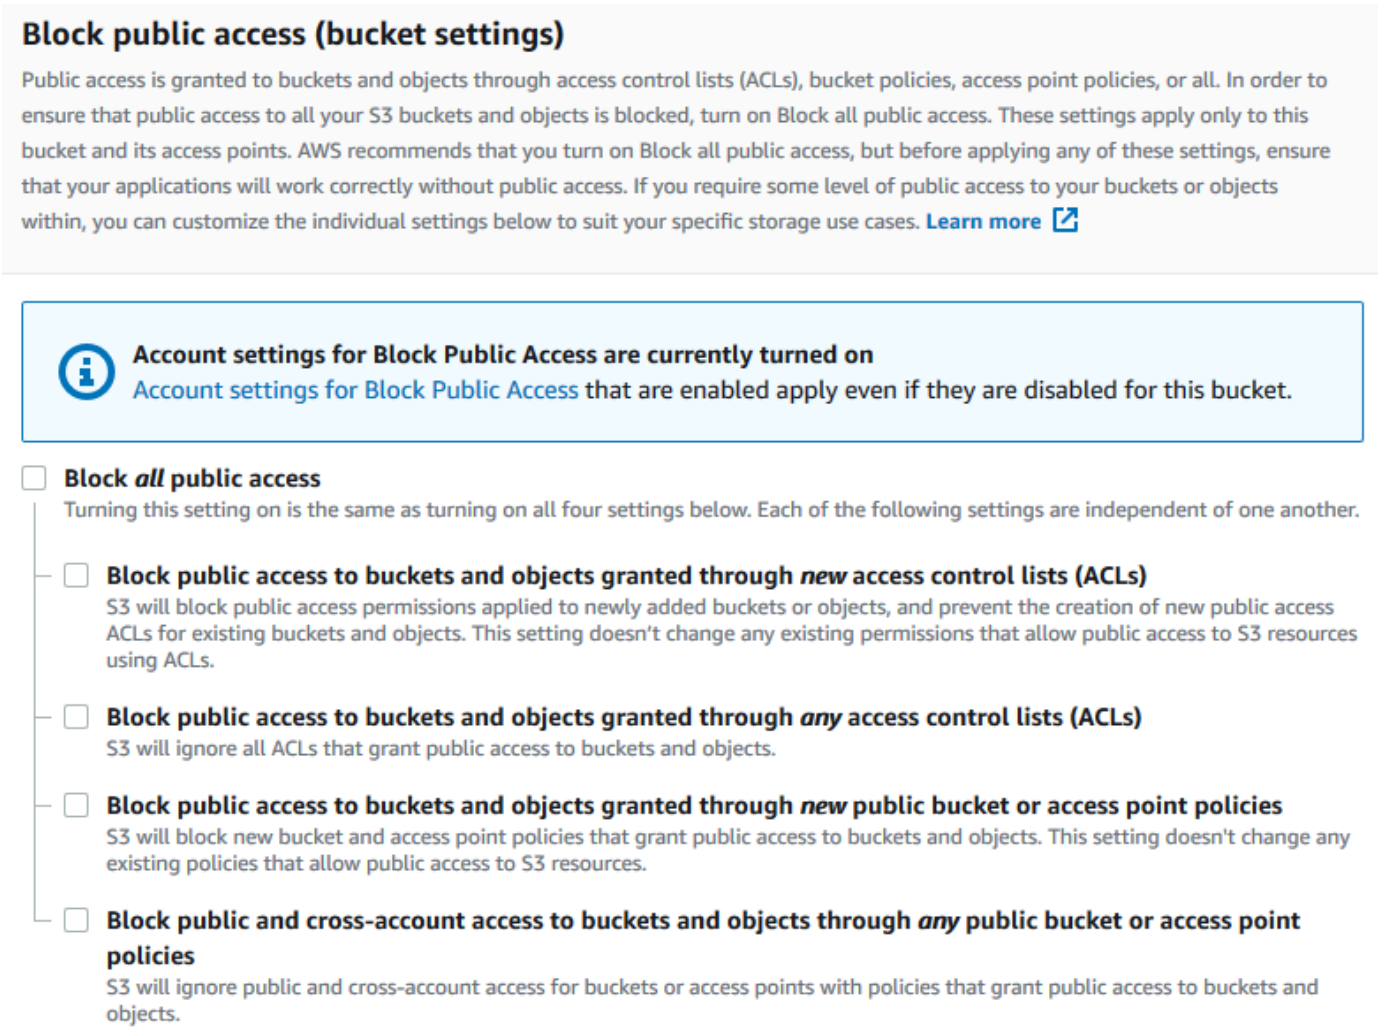
Step 8: Edit S3 Block Public Access settings

In this example, you edit block public access settings for the domain bucket (`example.com`) to allow public access.

By default, Amazon S3 blocks public access to your account and buckets. If you want to use a bucket to host a static website, you can use these steps to edit your block public access settings.

> **Warning**
>
> Before you complete these steps, review Blocking public access to your Amazon S3 storage to ensure that you understand and accept the risks involved with allowing public access. When you turn off block public access settings to make your bucket public, anyone on the internet can access your bucket. We recommend that you block all public access to your buckets.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the bucket that you have configured as a static website.
3. Choose **Permissions**.
4. Under **Block public access (bucket settings)**, choose **Edit**.
5. Clear **Block *all* public access**, and choose **Save changes**.



Amazon S3 turns off the Block Public Access settings for your bucket. To create a public static website, you might also have to edit the Block Public Access settings for your account before adding a bucket policy. If the Block Public Access settings for your account are currently turned on, you see a note under **Block public access (bucket settings)**.

Step 9: Attach a bucket policy

In this example, you attach a bucket policy to the domain bucket (`example.com`) to allow public read access. You replace the *`Bucket-Name`* in the example bucket policy with the name of your domain bucket, for example `example.com`.

After you edit S3 Block Public Access settings, you can add a bucket policy to grant public read access to your bucket. When you grant public read access, anyone on the internet can access your bucket.

Important

The following policy is an example only and allows full access to the contents of your bucket. Before you proceed with this step, review How can I secure the files in my Amazon S3 bucket? to ensure that you understand the best practices for securing the files in your S3 bucket and risks involved in granting public access.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Permissions**.
3. Under **Bucket Policy**, choose **Edit**.
4. To grant public read access for your website, copy the following bucket policy, and paste it in the **Bucket policy editor**.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PublicReadGetObject",
            "Effect": "Allow",
            "Principal": "*",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::Bucket-Name/*"
            ]
        }
    ]
}
```

5. Update the `Resource` to your bucket name.

   In the preceding example bucket policy, *Bucket-Name* is a placeholder for the bucket name. To use this bucket policy with your own bucket, you must update this name to match your bucket name.

6. Choose **Save changes**.

   A message appears indicating that the bucket policy has been successfully added.

If you see an error that says `Policy has invalid resource`, confirm that the bucket name in the bucket policy matches your bucket name. For information about adding a bucket policy, see How do I add an S3 bucket policy?

If you get an error message and cannot save the bucket policy, check your account and bucket Block Public Access settings to confirm that you allow public access to the bucket.

In the next step, you can figure out your website endpoints and test your domain endpoint.

Step 10: Test your domain endpoint

After you configure your domain bucket to host a public website, you can test your endpoint. For more information, see Website endpoints. You can only test the endpoint for your domain bucket because your subdomain bucket is set up for website redirect and not static website hosting.

> **Note**
>
> Amazon S3 does not support HTTPS access to the website. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3.
> For more information, see How do I use CloudFront to serve a static website hosted on Amazon S3? and Requiring HTTPS for communication between viewers and CloudFront.

1. Under **Buckets**, choose the name of your bucket.
2. Choose **Properties**.
3. At the bottom of the page, under **Static website hosting**, choose your **Bucket website endpoint**.

   Your index document opens in a separate browser window.

In the next step, you use Amazon Route 53 to enable customers to use both of your custom URLs to navigate to your site.

Step 11: Add alias records for your domain and subdomain

In this step, you create the alias records that you add to the hosted zone for your domain maps `example.com` and `www.example.com`. Instead of using IP addresses, the alias records use the

Amazon S3 website endpoints. Amazon Route 53 maintains a mapping between the alias records and the IP addresses where the Amazon S3 buckets reside. You create two alias records, one for your root domain and one for your subdomain.

Add an alias record for your root domain and subdomain

To add an alias record for your root domain (`example.com`)

1. Open the Route 53 console at https://console.aws.amazon.com/route53/.

   > **Note**
   >
   > If you don't already use Route 53, see Step 1: Register a domain in the *Amazon Route 53 Developer Guide*. After completing your setup, you can resume the instructions.

2. Choose **Hosted zones**.
3. In the list of hosted zones, choose the name of the hosted zone that matches your domain name.
4. Choose **Create record**.
5. Choose **Switch to wizard**.

   > **Note**
   >
   > If you want to use quick create to create your alias records, see Configuring Route 53 to route traffic to an S3 Bucket.

6. Choose **Simple routing**, and choose **Next**.
7. Choose **Define simple record**.
8. In **Record name**, accept the default value, which is the name of your hosted zone and your domain.
9. In **Value/Route traffic to**, choose **Alias to S3 website endpoint**.
10. Choose the Region.
11. Choose the S3 bucket.

    The bucket name should match the name that appears in the **Name** box. In the **Choose S3 bucket** list, the bucket name appears with the Amazon S3 website endpoint for the Region

where the bucket was created, for example, `s3-website-us-west-1.amazonaws.com (example.com)`.

Choose S3 bucket lists a bucket if:

- You configured the bucket as a static website.
- The bucket name is the same as the name of the record that you're creating.
- The current AWS account created the bucket.

If your bucket does not appear in the **Choose S3 bucket** list, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, **`s3-website-us-west-2.amazonaws.com`**. For a complete list of Amazon S3 website endpoints, see Amazon S3 Website endpoints. For more information about the alias target, see Value/route traffic to in the *Amazon Route 53 Developer Guide*.

12. In **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
13. For **Evaluate target health**, choose **No**.
14. Choose **Define simple record**.

To add an alias record for your subdomain (`www.example.com`)

1. Under **Configure records**, choose **Define simple record**.
2. In **Record name** for your subdomain, type `www`.
3. In **Value/Route traffic to**, choose **Alias to S3 website endpoint**.
4. Choose the Region.
5. Choose the S3 bucket, for example, `s3-website-us-west-2.amazonaws.com (www.example.com)`.

   If your bucket does not appear in the **Choose S3 bucket** list, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, **`s3-website-us-west-2.amazonaws.com`**. For a complete list of Amazon S3 website endpoints, see Amazon S3 Website endpoints. For more information about the alias target, see Value/route traffic to in the *Amazon Route 53 Developer Guide*.
6. In **Record type**, choose **A - Routes traffic to an IPv4 address and some AWS resources**.
7. For **Evaluate target health**, choose **No**.
8. Choose **Define simple record**.

9. On the **Configure records** page, choose **Create records**.

> **Note**
>
> Changes generally propagate to all Route 53 servers within 60 seconds. When propagation is done, you can route traffic to your Amazon S3 bucket by using the names of the alias records that you created in this procedure.

Add an alias record for your root domain and subdomain (old Route 53 console)

To add an alias record for your root domain (`example.com`)

The Route 53 console has been redesigned. In the Route 53 console you can temporarily use the old console. If you choose to work with the old Route 53 console, use the procedure below.

1. Open the Route 53 console at https://console.aws.amazon.com/route53/.

   > **Note**
   >
   > If you don't already use Route 53, see Step 1: Register a domain in the *Amazon Route 53 Developer Guide*. After completing your setup, you can resume the instructions.

2. Choose **Hosted Zones**.
3. In the list of hosted zones, choose the name of the hosted zone that matches your domain name.
4. Choose **Create Record Set**.
5. Specify the following values:

   Name

   Accept the default value, which is the name of your hosted zone and your domain.

   For the root domain, you don't need to enter any additional information in the **Name** field.

   Type

   Choose **A – IPv4 address**.

Alias

Choose **Yes**.

Alias Target

In the **S3 website endpoints** section of the list, choose your bucket name.

The bucket name should match the name that appears in the **Name** box. In the **Alias Target** listing, the bucket name is followed by the Amazon S3 website endpoint for the Region where the bucket was created, for example `example.com (s3-website-us-west-2.amazonaws.com)`. **Alias Target** lists a bucket if:

- You configured the bucket as a static website.
- The bucket name is the same as the name of the record that you're creating.
- The current AWS account created the bucket.

If your bucket does not appear in the **Alias Target** listing, enter the Amazon S3 website endpoint for the Region where the bucket was created, for example, `s3-website-us-west-2`. For a complete list of Amazon S3 website endpoints, see Amazon S3 Website endpoints. For more information about the alias target, see Value/route traffic to in the *Amazon Route 53 Developer Guide*.

Routing Policy

Accept the default value of **Simple**.

Evaluate Target Health

Accept the default value of **No**.

6. Choose **Create**.

To add an alias record for your subdomain (`www.example.com`)

1. In the hosted zone for your root domain (`example.com`), choose **Create Record Set**.
2. Specify the following values:

Name

For the subdomain, enter `www` in the box.

Type

Choose **A – IPv4 address**.

Alias

Choose **Yes**.

Alias Target

In the **S3 website endpoints** section of the list, choose the same bucket name that appears in the **Name** field—for example, `www.example.com (s3-website-us-west-2.amazonaws.com)`.

Routing Policy

Accept the default value of **Simple**.

Evaluate Target Health

Accept the default value of **No**.

3. Choose **Create**.

> **Note**
>
> Changes generally propagate to all Route 53 servers within 60 seconds. When propagation is done, you can route traffic to your Amazon S3 bucket by using the names of the alias records that you created in this procedure.

Step 12: Test the website

Verify that the website and the redirect work correctly. In your browser, enter your URLs. In this example, you can try the following URLs:

- **Domain** (`http://example.com`) – Displays the index document in the `example.com` bucket.
- **Subdomain** (`http://www.example.com`) – Redirects your request to `http://example.com`. You see the index document in the `example.com` bucket.

If your website or redirect links don't work, you can try the following:

- **Clear cache** – Clear the cache of your web browser.
- **Check name servers** – If your web page and redirect links don't work after you've cleared your cache, you can compare the name servers for your domain and the name servers for your hosted zone. If the name servers don't match, you might need to update your domain name servers to match those listed under your hosted zone. For more information, see Adding or changing name servers and glue records for a domain.

After you've successfully tested your root domain and subdomain, you can set up an Amazon CloudFront distribution to improve the performance of your website and provide logs that you can use to review website traffic. For more information, see Speeding up your website with Amazon CloudFront.

Speeding up your website with Amazon CloudFront

You can use Amazon CloudFront to improve the performance of your Amazon S3 website. CloudFront makes your website files (such as HTML, images, and video) available from data centers around the world (known as *edge locations*). When a visitor requests a file from your website, CloudFront automatically redirects the request to a copy of the file at the nearest edge location. This results in faster download times than if the visitor had requested the content from a data center that is located farther away.

CloudFront caches content at edge locations for a period of time that you specify. If a visitor requests content that has been cached for longer than the expiration date, CloudFront checks the origin server to see if a newer version of the content is available. If a newer version is available, CloudFront copies the new version to the edge location. Changes that you make to the original content are replicated to edge locations as visitors request the content.

Using CloudFront without Route 53

The tutorial on this page uses Route 53 to point to your CloudFront distribution. However, if you want to serve content hosted in an Amazon S3 bucket using CloudFront without using Route 53, see Amazon CloudFront Tutorials: Setting up a Dynamic Content Distribution for Amazon S3. When you serve content hosted in an Amazon S3 bucket using CloudFront, you can use any bucket name, and both HTTP and HTTPS are supported.

Automating set up with an AWS CloudFormation template

For more information about using an AWS CloudFormation template to configure a secure static website that creates a CloudFront distribution to serve your website, see Getting started with a secure static website in the *Amazon CloudFront Developer Guide*.

Topics

- Step 1: Create a CloudFront distribution
- Step 2: Update the record sets for your domain and subdomain
- (Optional) Step 3: Check the log files

Step 1: Create a CloudFront distribution

First, you create a CloudFront distribution. This makes your website available from data centers around the world.

To create a distribution with an Amazon S3 origin

1. Open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. Choose **Create Distribution**.
3. On the **Create Distribution** page, in the **Origin Settings** section, for **Origin Domain Name**, enter the Amazon S3 website endpoint for your bucket—for example, **`example.com.s3-website.us-west-1.amazonaws.com`**.

   CloudFront fills in the **Origin ID** for you.
4. For **Default Cache Behavior Settings**, keep the values set to the defaults.

   With the default settings for **Viewer Protocol Policy**, you can use HTTPS for your static website. For more information these configuration options, see Values that You Specify When You Create or Update a Web Distribution in the *Amazon CloudFront Developer Guide*.
5. For **Distribution Settings**, do the following:

   a. Leave **Price Class** set to **Use All Edge Locations (Best Performance)**.

   b. Set **Alternate Domain Names (CNAMEs)** to the root domain and `www` subdomain. In this tutorial, these are `example.com` and `www.example.com`.

> **Important**
>
> Before you perform this step, note the requirements for using alternate domain names, in particular the need for a valid SSL/TLS certificate.

c. For **SSL Certificate**, choose **Custom SSL Certificate (example.com)**, and choose the custom certificate that covers the domain and subdomain names.

   For more information, see SSL Certificate in the *Amazon CloudFront Developer Guide*.

d. In **Default Root Object**, enter the name of your index document, for example, `index.html`.

   If the URL used to access the distribution doesn't contain a file name, the CloudFront distribution returns the index document. The **Default Root Object** should exactly match the name of the index document for your static website. For more information, see Configuring an index document.

e. Set **Logging** to **On**.

> **Important**
>
> When you create or update a distribution and enable CloudFront logging, CloudFront updates the bucket access control list (ACL) to give the `awslogsdelivery` account `FULL_CONTROL` permissions to write logs to your bucket. For more information, see Permissions required to configure standard logging and to access your log files in the *Amazon CloudFront Developer Guide*. If the bucket that stores the logs uses the Bucket owner enforced setting for S3 Object Ownership to disable ACLs, CloudFront cannot write logs to the bucket. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

f. For **Bucket for Logs**, choose the logging bucket that you created.

   For more information about configuring a logging bucket, see (Optional) Logging web traffic.

g. If you want to store the logs that are generated by traffic to the CloudFront distribution in a folder, in **Log Prefix**, enter the folder name.

h. Keep all other settings at their default values.

6. Choose **Create Distribution**.
7. To see the status of the distribution, find the distribution in the console and check the **Status** column.

   A status of `InProgress` indicates that the distribution is not yet fully deployed.

   After your distribution is deployed, you can reference your content with the new CloudFront domain name.
8. Record the value of **Domain Name** shown in the CloudFront console, for example, `dj4p1rv6mvubz.cloudfront.net`.
9. To verify that your CloudFront distribution is working, enter the domain name of the distribution in a web browser.

   If your website is visible, the CloudFront distribution works. If your website has a custom domain registered with Amazon Route 53, you will need the CloudFront domain name to update the record set in the next step.

Step 2: Update the record sets for your domain and subdomain

Now that you have successfully created a CloudFront distribution, update the alias record in Route 53 to point to the new CloudFront distribution.

To update the alias record to point to a CloudFront distribution

1. Open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the left navigation, choose **Hosted zones**.
3. On the **Hosted Zones** page, choose the hosted zone that you created for your subdomain, for example, `www.example.com`.
4. Under **Records**, select the *A* record that you created for your subdomain.
5. Under **Record details**, choose **Edit record**.
6. Under **Route traffic to**, choose **Alias to CloudFront distribution**.
7. Under **Choose distribution**, choose the CloudFront distribution.
8. Choose **Save**.
9. To redirect the *A* record for the root domain to the CloudFront distribution, repeat this procedure for the root domain, for example, `example.com`.

The update to the record sets takes effect within 2–48 hours.

10. To see whether the new *A* records have taken effect, in a web browser, enter your subdomain URL, for example, `http://www.example.com`.

    If the browser no longer redirects you to the root domain (for example, `http://example.com`), the new A records are in place. When the new *A* record has taken effect, traffic routed by the new *A* record to the CloudFront distribution is not redirected to the root domain. Any visitors who reference the site by using `http://example.com` or `http://www.example.com` are redirected to the nearest CloudFront edge location, where they benefit from faster download times.

    > **Tip**
    >
    > Browsers can cache redirect settings. If you think the new *A* record settings should have taken effect, but your browser still redirects `http://www.example.com` to `http://example.com`, try clearing your browser history and cache, closing and reopening your browser application, or using a different web browser.

(Optional) Step 3: Check the log files

The access logs tell you how many people are visiting the website. They also contain valuable business data that you can analyze with other services, such as Amazon EMR.

CloudFront logs are stored in the bucket and folder that you choose when you create a CloudFront distribution and enable logging. CloudFront writes logs to your log bucket within 24 hours from when the corresponding requests are made.

To see the log files for your website

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the logging bucket for your website.
3. Choose the CloudFront logs folder.
4. Download the `.gzip` files written by CloudFront before opening them.

   If you created your website only as a learning exercise, you can delete the resources that you allocated so that you no longer accrue charges. To do so, see Cleaning up your example resources. After you delete your AWS resources, your website is no longer available.

Cleaning up your example resources

If you created your static website as a learning exercise, you should delete the AWS resources that you allocated so that you no longer accrue charges. After you delete your AWS resources, your website is no longer available.

Tasks

- Step 1: Delete the Amazon CloudFront distribution
- Step 2: Delete the Route 53 hosted zone
- Step 3: Disable logging and delete your S3 bucket

Step 1: Delete the Amazon CloudFront distribution

Before you delete an Amazon CloudFront distribution, you must disable it. A disabled distribution is no longer functional and does not accrue charges. You can enable a disabled distribution at any time. After you delete a disabled distribution, it is no longer available.

To disable and delete a CloudFront distribution

1. Open the CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home.
2. Select the distribution that you want to disable, and then choose **Disable**.
3. When prompted for confirmation, choose **Yes, Disable**.
4. Select the disabled distribution, and then choose **Delete**.
5. When prompted for confirmation, choose **Yes, Delete**.

Step 2: Delete the Route 53 hosted zone

Before you delete the hosted zone, you must delete the record sets that you created. You don't need to delete the NS and SOA records; these are automatically deleted when you delete the hosted zone.

To delete the record sets

1. Open the Route 53 console at https://console.aws.amazon.com/route53/.
2. In the list of domain names, select your domain name, and then choose **Go to Record Sets**.
3. In the list of record sets, select the *A* records that you created.

The type of each record set is listed in the **Type** column.

4. Choose **Delete Record Set**.
5. When prompted for confirmation, choose **Confirm**.

To delete a Route 53 hosted zone

1. Continuing from the previous procedure, choose **Back to Hosted Zones**.
2. Select your domain name, and then choose **Delete Hosted Zone**.
3. When prompted for confirmation, choose **Confirm**.

Step 3: Disable logging and delete your S3 bucket

Before you delete your S3 bucket, make sure that logging is disabled for the bucket. Otherwise, AWS continues to write logs to your bucket as you delete it.

To disable logging for a bucket

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Under **Buckets**, choose your bucket name, and then choose **Properties**.
3. From **Properties**, choose **Logging**.
4. Clear the **Enabled** check box.
5. Choose **Save**.

Now, you can delete your bucket. For more information, see Deleting a general purpose bucket.

Deploying a static website to AWS Amplify Hosting from an S3 general purpose bucket

We recommend that you use AWS Amplify Hosting to host static website content stored on S3. Amplify Hosting is a fully managed service that makes it easy to deploy your websites on a globally available content delivery network (CDN) powered by Amazon CloudFront, allowing secure static website hosting without extensive setup. With AWS Amplify Hosting, you can select the location of your objects within your general purpose bucket, deploy your content to a managed CDN, and generate a public HTTPS URL for your website to be accessible anywhere. Deploying a static website using Amplify Hosting provides you with the following benefits and features:

- **Deployment to the AWS content delivery network (CDN) powered by Amazon CloudFront** - CloudFront is a web service that speeds up distribution of your static and dynamic web content to your users. CloudFront delivers your content through a worldwide network of data centers called edge locations. When a user requests content that you're serving with CloudFront, the request is routed to the edge location that provides the lowest latency (time delay), so that content is delivered with the best possible performance, increased reliability and availability. For more information, see How CloudFront delivers content in the *Amazon CloudFront Developer Guide*.
- **HTTPS support** - Provides secure communication and data transfer between your website and a user's web browser.
- **Custom domains** - Easily connect your website to a custom URL purchased from a domain registrar such as Amazon Route 53.
- **Custom SSL certificates** - When you set up your custom domain, you can use the default managed certificate that Amplify provisions for you or you can use your own custom certificate purchased from the third-party certificate authority of your choice.
- **Built in metrics and CloudWatch monitoring** - Monitor traffic, errors, data transfer, and latency for your website.
- **Password protection** - Restrict access to your website, by setting up a username and password requirement in the Amplify console.
- **Redirects and rewrites** - Create redirect and rewrite rules in the Amplify console to enable a web server to reroute navigation from one URL to another.

When you deploy your application from an Amazon S3 general purpose bucket to Amplify Hosting, AWS charges are based on Amplify's pricing model. For more information, see AWS Amplify Pricing.

Important

Amplify Hosting is not available in all of the AWS Regions where Amazon S3 is available. To deploy a static website to Amplify Hosting, the Amazon S3 general purpose bucket containing your website must be located in a region where Amplify is available. For the list of regions where Amplify is available, see Amplify endpoints in the *Amazon Web Services General Reference*.

You can start the deployment process from the Amazon S3 console, the Amplify console, the AWS CLI, or the AWS SDKs. You can only deploy to Amplify from a general purpose bucket located in your own account. Amplify doesn't support cross-account bucket access.

Use the following instructions to deploy a static website from an Amazon S3 general purpose bucket to Amplify Hosting starting from the Amazon S3 console.

Deploying a static website to Amplify from the S3 console

To deploy a static website from the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the left navigation pane, choose **Buckets**.
3. In the **Buckets** list, choose the general purpose bucket that contains the website you want to deploy to Amplify Hosting.
4. Choose the **Properties** tab.
5. Under **Static website hosting**, choose **Create Amplify app**. At this step, the deployment process will move to the Amplify console.
6. On the **Deploy with S3** page, do the following steps.
   a. For **App name**, enter the name of your app or website.
   b. For **Branch name**, enter the name of your app's backend.
   c. For **S3 location of objects to host**, either enter the directory path to your general purpose bucket or choose **Browse S3** to locate and select it.
7. Choose **Save and deploy**.

> **Note**
>
> If you update any of the objects for a static website in your general purpose bucket hosted on Amplify, you must redeploy the application to Amplify Hosting to cause the changes to take effect. Amplify Hosting doesn't automatically detect changes to your bucket. For more information, see Updating a static website deployed to Amplify from an S3 bucket in the *AWS Amplify Hosting User Guide*.

To start directly from the Amplify console, see Deploying a static website from S3 using the Amplify console in the *AWS Amplify Hosting User Guide*.

To get started using the AWS SDKs, see Creating a bucket policy to deploy a static website from S3 using the AWS SDKs in the *AWS Amplify Hosting User Guide*.

Tagging for cost allocation or attribute-based access control (ABAC)

An AWS tag is a key-value pair that holds metadata. You attach the tags to your Amazon S3 resources, such as buckets. You can tag resources when you create them or manage tags on existing resources. There is no additional charge for using tags beyond the standard S3 API request rates. For more information, see Amazon S3 pricing.

How tags work

Amazon S3 support two types of tags:

- **AWS-generated tags:** AWS automatically applies these tags, and you cannot modify them or remove them. To learn more about AWS-generated tags, see Using AWS-generated tags.
- **User-defined tags:** You apply these tags to your S3 resources and manage them.

User-defined tags

A user-defined tag is a tag key-value pair that you use to label your resources. User-defined tags consist of a required key and an optional value. These are the main components of a user-defined tag:

The tag key

The tag key is the required name of the tag. For example, `project` is the tag key in the following tag key-value pair:

Key	Value
`project`	`Trinity`

The tag key is a case-sensitive string that must contain between 1 and 128 Unicode characters. Keys can only contain Unicode letters or numbers, white space, and the following symbols:

- _ - underscore

- `.` - period
- `:` - colon
- `/` - forward slash
- `=` - equal sign
- `+` - plus sign
- `@` - at sign
- `-` - dash

The tag value

The tag value is an optional string. For example, `Trinity` is the tag value in this tag key-value pair:

Key	Value
`project`	`Trinity`

The tag value is a case-sensitive string that can contain between 0 and 256 Unicode characters. Values can only contain Unicode letters or numbers, white space, and the following symbols:

- `_` - underscore
- `.` - period
- `:` - colon
- `/` - forward slash
- `=` - equal sign
- `+` - plus sign
- `@` - at sign
- `-` - dash

For details on the characters allowed in user-defined tags and other restrictions, see User-Defined Tag Restrictions in the *AWS Billing and Cost Management User Guide*.

The tag set

Each S3 resource has one *tag set* that contains all of the tag key and value pairs that are assigned to that bucket. A tag set can be empty, or it can contain as many as 50 user-defined tags, except in the case of tagging objects. Objects can have up to 10 tags only.

While each key must be unique in a tag set, you can use the same value multiple times. For example, you can have the same value, `Trinity`, for following two tag keys:

Key	Value
`project`	`Trinity`
`cost-center`	`Trinity`

When you add a tag that has the same key as an existing tag, the new value overwrites the old value.

AWS doesn't apply any semantic meaning to your tags. We interpret tags strictly as character strings.

To add, list, modify, or delete tags, you can use the Amazon S3 console, the AWS Command Line Interface (AWS CLI), or the Amazon S3 API.

Common ways to use tags

Use tags on your S3 resources for:

1. **Cost allocation** – Track storage costs by bucket tag in AWS Billing and Cost Management.
2. **Attribute-based access control (ABAC)** – Scale access permissions and grant access to S3 resources based on their tags.

> **Note**
>
> You can use the same tags for both cost allocation and access control.

Using tags for cost allocation

Track your Amazon S3 storage costs by applying tags to S3 resources and activating these tags for cost allocation.

To start tracking costs:

1. Add tags to your S3 resources or use existing tags. For example, you can label buckets with a tag that identifies a project or a group of projects.
2. Activate the tags for cost allocation in the AWS Billing and Cost Management console. See Activating user-defined cost allocation tags in the *AWS Billing and Cost Management User Guide*. You can activate user-defined or AWS-generated tags. For more information, see Organizing and tracking costs using AWS cost allocation tags.

AWS uses the activated tags to organize your resource costs in various billing and cost management tools, such as:

- **Cost allocation report**

  Provides a high-level view of costs organized by your activated tags. For more information, see Using the monthly cost allocation report in the *AWS Billing User Guide*.
- **Cost and Usage Report (CUR)**

  Provides the most detailed set of AWS cost and usage data, including tag-based cost breakdowns. For more information, see What are AWS Cost and Usage Reports? in the *AWS Data Export User Guide*.

Amazon S3 resources that support tracking costs with tags

The following Amazon S3 resources support storage cost tracking using tags.

- **Directory buckets**

  For more information, see Managing tags for directory buckets.
- **General purpose buckets**

  For more information, see Managing tags for general purpose buckets.

Using tags for attribute-based access control (ABAC)

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes, i.e., tags. You can attach tags to AWS Identity and Access Management (IAM) entities (users or roles) and to AWS resources, such as Amazon S3 Access Points and directory buckets. Then, you control permissions to these resources using tag-based conditions in access control policies to allow or deny operations when these conditions are met.

With ABAC, you use tag-based condition keys in your AWS organizations, IAM, and S3 resource policies. For enterprises, ABAC in Amazon S3 supports authorization across multiple AWS accounts.

In your IAM policies, you can control access to S3 resources based on the bucket's tags by using condition keys.

Supported condition keys

You can use the following AWS condition keys for all Amazon S3 resources that support ABAC.

- `aws:ResourceTag/key-name`
- `aws:RequestTag/key-name`
- `aws:TagKeys`

Some resources support additional Amazon S3 condition keys. For a complete list of condition keys that can be used for ABAC and example policies, see the following tagging topics for the resource.

Amazon S3 resources that support ABAC

The following Amazon S3 resources support attribute-based access control (ABAC) using tags.

- **Access points**

  For more information, see Using tags with S3 Access Points for general purpose buckets and Using tags with S3 Access Points for directory buckets.
- **Batch operation jobs**

  For more information, see Controlling access and labeling jobs using tags.
- **Directory buckets**

  For more information, see Using tags with S3 directory buckets.

- **Objects**

  For more information, see Categorizing your objects using tags.
- **S3 Access Grants**

  For more information, see Managing tags for S3 Access Grants.
- **S3 Storage Lens Groups**

  For more information, see Managing AWS resource tags with Storage Lens groups.

Planning your tagging strategy

We recommend that you devise a set of tag keys that meets your needs for each resource type. Using a consistent set of tag keys makes it easier for you to manage your resources. You can search and filter the resources based on the tags you add. For more information about how to implement an effective resource tagging strategy, see the Tagging Best Practices AWS Whitepaper.

Best practices for tagging Amazon S3 resources

When you use tags, we recommend that you adhere to the following best practices:

- Document conventions for tag use that are followed by all teams in your organization. In particular, ensure the names are both descriptive and consistent. For example, standardize on the format `environment:prod` rather than tagging some resources with `env:production`.

  > **Important**
  >
  > Do not store personally identifiable information (PII) or other confidential or sensitive information in tags.

- Automate tagging to ensure consistency. For example, you can include tags in an AWS CloudFormation template. When you create resources with the template, the resources are tagged automatically.
- Use tags only when necessary. Avoid unnecessary tag proliferation and complexity.
- Review tags periodically for relevance and accuracy. Remove or modify outdated tags as needed.
- Consider creating tags with the AWS Tag Editor in the AWS Management Console. You can use the Tag Editor to add tags to multiple supported AWS resources, including Amazon S3 resources, at the same time. For more information, see Tag Editor in the *AWS Resource Groups User Guide*.

Managing tags for Amazon S3 resources

For more information on how to manage tags for Amazon S3 resources, see the following:

- Managing tags for Access Points for general purpose buckets
- Managing tags for Access Points for directory buckets
- Controlling access and labeling jobs using tags
- Managing tags for directory buckets
- Managing tags for general purpose buckets
- Categorizing your objects using tags
- Managing tags for S3 Access Grants
- Managing AWS resource tags with Storage Lens groups

Quotas

Your AWS account has default quotas, formerly referred to as limits, for each AWS service. Amazon S3 quotas include number of general purpose buckets, directory buckets, access points and more. You can request an increase for some quotas, but not all quotas can be increased. These increases are not granted immediately, so it may take a couple of days for your increase to become effective.

For a list of Amazon S3 quotas and their default values see, Amazon S3 quotas in the *AWS General Reference*.

Quota increases

To request a quota increase

You can request a quota increase by using one of following options:

- From the AWS Management Console: Open the Service Quotas console. In the navigation pane, choose **AWS services**. Select **Amazon S3**, select a quota, and follow the directions to request a quota increase. For instructions, see Requesting a quota increase in the *Service Quotas User Guide*.
- From the AWS CLI: Use the request-service-quota-increase AWS CLI command. For instructions, see Requesting a quota increase in the *Service Quotas User Guide*.

Reference

In addition to the Amazon S3 console, you can work with Amazon S3 programmatically using the Amazon S3 REST APIs, AWS SDKs, or AWS Command Line Interface (AWS CLI).

- Amazon Simple Storage Service API Reference

Document history

- **Current API version:** 2006-03-01

The following table describes the important changes in each release of the *Amazon Simple Storage Service API Reference* and the *Amazon S3 User Guide*. For notification about updates to this documentation, you can subscribe to an RSS feed.

Change	Description	Date
Amazon S3 now supports Access Points tags for attribute-based access control (ABAC)	Amazon S3 now supports tagging Access Points for both general purpose and directory buckets. Add tags to access points and use attribute-based access control (ABAC) to scale access. You can get started with tagging access points using the AWS Management Console, S3 REST API, AWS CLI, or the AWS SDK. To learn more about using tags for ABAC, see Using tags for attribute-based access control (ABAC).	July 31, 2025
Amazon S3 Vectors (Preview)	Amazon S3 Vectors delivers purpose-built, cost-opti mized vector storage for your semantic search and AI applications. S3 Vectors introduces a new bucket type, the vector bucket, which is optimized for durable, low-cost vector storage. For more information, see Working	July 15, 2025

with S3 Vectors and vector buckets.

Amazon S3 Metadata now supports existing objects	Amazon S3 Metadata creates and manages metadata that provides information about datasets stored in S3, so you can more easily discover and use your S3 data. Previously, S3 Metadata supported new and updated objects. Now, S3 Metadata also creates and manages metadata for all your existing S3 data. S3 Metadata now creates and maintains two Apache Iceberg tables that give you a queryable and continuously updated view of the metadata associated with the objects in a general purpose bucket. A journal table records changes made to your data in near real time, helping you to identify new data uploaded to your bucket, track recently deleted objects, monitor S3 Lifecycle transitions, and more. A new live inventory table provides and maintains an up-to-dat e view of all objects in your bucket. Both S3 Metadata tables are stored in an AWS managed Iceberg table bucket in your account, and can be queried using standard SQL through AWS analytics services, such as Amazon Athena or Amazon EMR, and	July 15, 2025

	open source tooling, such as DuckDB and PyIceberg. For more information, see Accelerating data discovery with S3 Metadata.	
Amazon S3 Express One Zone now supports tags for cost allocation and attribute-based access control	Amazon S3 Express One Zone, a high performance S3 storage class, now supports tags for cost allocation and attribute-based access control (ABAC). You can add tags to S3 directory buckets to track and organize AWS costs using AWS Billing and Cost Management. Additionally, with ABAC support, you can scale access control to your directory buckets by using tags. S3 Express One Zone supports tags on directory buckets in all AWS Regions where the storage class is available. You can get started with tagging using the AWS Management Console, S3 REST API, AWS CLI, or the AWS SDK. To learn more about using tags to simplify cost allocation or ABAC, see Using tags with S3 directory buckets.	July 2, 2025

Access points now supports attaching to an FSx for OpenZFS volume	You can create and attach an access point to an FSx for OpenZFS volume using the Amazon FSx console, AWS CLI, or API. Once attached, you can use the S3 object APIs to access your file data. Your data continues to reside on the Amazon FSx file system and continues to be directly accessible for your existing workloads. For mor e information, see Managing access to shared datasets with access points.	June 25, 2025
S3 Tables now supports new compaction strategies for tables	S3 Tables now supports multiple compaction strategies to optimize query performance based on different data access patterns. The new strategies include Sort and Z-order. For more information, see Compaction Strategies for tables.	June 18, 2025

Enhanced access denied error messages for same-organization requests	Amazon S3 now includes additional context in access denied (HTTP `403 Forbidden`) errors for requests made to resources within the same organization in AWS Organizations. This new context includes the type of policy that denied access, the reason for denial, and information about the AWS Identity and Access Management (IAM) user or role that requested access to the resource. This context helps you to troubleshoot access issues, identify the root cause of access denied errors, and fix incorrect access controls by updating the relevant policies. This additional context is also available in AWS CloudTrail logs. Enhanced access denied error messages for same-organization requests are now available in all AWS Regions, including the AWS GovCloud (US) Regions and the China Regions. For more information, see Troubleshoot access denied (403 Forbidden) errors in Amazon S3..	June 16, 2025

S3 Tables adds new AWS managed policy for S3 Tables	S3 Tables added a new AWS-managed policy called `AmazonS3TablesLakeFormationServiceRole`. This policy grants permissions that allows the Lake Formation service role access to Amazon S3 tables and table buckets. For more information, see AWS managed policies for S3 Tables.	May 19, 2025
S3 Tables now supports SSE-KMS using customer managed keys	S3 Tables now supports server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) using customer managed keys. You can apply SSE-KMS encryption at the table bucket and table level. For more information, see Using server-side encryption with AWS KMS keys (SSE-KMS) in table buckets.	April 16, 2025

Access points for directory buckets are available in AWS Local Zones	Directory buckets now support access points to simplify managing data access at scale for shared datasets in Amazon S3. With this new feature, you can create hundreds of access points per bucket, each with a distinct name and permissions customized for each applicati on. For more information, see Managing access to shared datasets in directory buckets with access points.	March 31, 2025

S3 table bucket integration with Amazon SageMaker Lakehouse is now generally available	You can integrate S3 table buckets with Amazon SageMaker Lakehouse to access tables from AWS analytics services, such as Amazon Athena, Amazon Redshift, and QuickSigh t. Amazon SageMaker Lakehouse unifies your data across Amazon S3 data lakes and Amazon Redshift data warehouses, so you can build analytics, machine learning (ML), and generativ e AI applications on a single copy of data. The integrati on populates the AWS Glue Data Catalog with your table resources, and federates access to these resources with AWS Lake Formation. The integration enables fine-grai ned access control through Lake Formation to provide additional security. For more information about integrati ng, see Using Amazon S3 Tables with AWS analytics services. If you set up the integration with the preview release, you can continue to use your current integrati on. However, the updated integration process provides performance improvements, so we recommend migrating	March 13, 2025

	. To migrate to the updated integration, see Migrating to the updated integration process.	
S3 Tables create table and query table support added to the Amazon S3 console	S3 Tables now support create table and query table operations directly from the Amazon S3 console by using Amazon Athena. With this new feature, you can now create a table, populate it with data, and query it with just a few steps in the Amazon S3 console. For more information, see Creating an Amazon S3 table and Querying Amazon S3 tables with Athena.	March 13, 2025
S3 Tables adds support for adding schemas when creating tables	You can now use the S3 Tables `CreateTable` API operation to create tables with schemas by adding an optional metadata flag. For more information, see Creating tables.	January 30, 2025
S3 Tables adds support for adding schemas when creating tables	You can now use the S3 Tables `CreateTable` API operation to create tables with schemas by adding an optional metadata flag. For more information, see Creating tables.	January 30, 2025

S3 Metadata is now generally available	Amazon S3 Metadata is now generally available. S3 Metadata helps you easily discover and understand your S3 data with automated , queryable metadata that updates in near real-time. With S3 Metadata, you can curate, identify, and use your S3 data for business analytics , artificial intelligence and machine learning (AI/ML) model training, and more. S3 Metadata supports object metadata, which includes system-defined information like the size and the source of the object, and custom metadata, such as tags with information like product SKUs, transaction IDs, or content ratings. For more information, see Accelerating data discovery with S3 Metadata.	January 27, 2025
AWS managed policies – New policies	S3 Tables added two new AWS managed policies.	December 6, 2024

S3 Tables	Amazon S3 Tables provide S3 storage that's optimized for analytics workloads, with features that improve query performance, reduce storage costs for tables, and simplify the operation of data lakes at scale. S3 Tables introduces a new bucket type: table buckets, which are purpose-built for storing Apache Iceberg tables as subresources. Table buckets provide higher transactions per second (TPS) and better query throughput compared to self-managed tables in S3 general purpose buckets. You can automatically integrate your table buckets with AWS analytics services, such as Athena, Amazon Redshift QuickSight, and more. For more information, see Working with Amazon S3 Tables and table buckets .	December 3, 2024

S3 Metadata preview	Amazon S3 Metadata helps you easily discover and understand your S3 data with automated, queryable metadata that updates in near real-time. With S3 Metadata, you can curate, identify, and use your S3 data for business analytics, artificial intelligence and machine learning (AI/ML) model training, and more. S3 Metadata supports object metadata, which includes system-defined information like the size and the source of the object, and custom metadata, such as tags with information like product SKUs, transaction IDs, or content ratings. For more information, see Accelerating data discovery with S3 Metadata.	December 3, 2024
Storage Browser for S3	Storage Browser for S3 is an open source component that you can add to your web applications to provide your end users with a simple interface for data stored in S3. For more information, see Storage Browser for S3.	December 1, 2024

New Amazon S3 checksum algorithm and improved checksum integrity features	Amazon S3 adds the `CRC-64NVME` checksum algorithm and improved checksum integrity features. For more information, see Checking object integrity in Amazon S3.	December 1, 2024
Data residency workloads	In Dedicated Local Zones, you can create S3 directory buckets to store data for your data residency and isolation use cases. For more information, see Data residency workloads.	December 1, 2024
New condition keys to enforce conditional writes	Amazon S3 adds new condition keys `s3:if-match` and `s3:if-none-match` to use in bucket policies to force clients to use the `If-None-Match` or `If-Match` HTTP header. For more information, see Enforce conditional writes on Amazon S3 buckets.	November 25, 2024

New HTTP header for conditional writes to check if the object has changed	Amazon S3 adds the `If-Match` HTTP header to check an object's entity tag (ETag) before writing an object for some API operations. With this header, Amazon S3 compares the provided ETag value with the ETag value of the object in S3. If the ETag values don't match, the operation fails. For more information, see How to prevent object overwrites with conditional writes.	November 25, 2024
Amazon Redshift now integrates with S3 Access Grants	Amazon Redshift customers can now use S3 Access Grants to scale and manage permissions for their S3 data. This allows Amazon Redshift customers to scale S3 permissions for corporate identities by using AWS IAM Identity Center as well as for IAM users and groups. For more information, see Amazon Redshift integration with Amazon S3 Access Grants.	November 15, 2024

AWS Organizations member accounts can now regain access to accidentally locked Amazon S3 buckets	AWS Organizations member accounts can now use a simple process through AWS Identity and Access Management (IAM) to regain access to accidentally locked Amazon S3 buckets. For more information, see Perform a privileged task on an AWS Organizations member account in the *AWS Identity and Access Management User Guide*.	November 14, 2024
Resource control policies (RCPs), a new type of authorization policy in AWS Organizations is also available for Amazon S3 buckets	Resource control policies (RCPs), a new authorization policy managed in AWS Organizations can be used to set the maximum available permissions on Amazon S3 buckets within your entire organization. For more information, see Resource control policies (RCPs) in the *AWS Organizations User Guide*.	November 13, 2024
Amazon S3 now automatically approves bucket quota increases up to 1,000 buckets	Amazon S3 now automatically approves bucket quota increases up to 1,000 buckets. To view your bucket utilization or request an increase, visit the Service Quotas console.	September 30, 2024

New default minimum object size transition behavior for Amazon S3 Lifecycle con figurations	Amazon S3 now applies a default behavior to S3 Lifecycle configurations that prevents objects smaller than 128 KB from being transitio ned to any storage class. To learn how to override this behavior, see Allowing objects smaller than 128 KB to be transitioned.	September 24, 2024
Directory buckets now support SSE-KMS using customer managed keys.	Directory buckets now supports server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) using customer managed keys. You have more options to encrypt and manage the security of your data in directory buckets. For more informati on, see Data protection and encryption in directory buckets.	September 17, 2024

S3 Access Grants supports an API action that lists the caller's access grants	IAM identities and IAM Identity Center corporate directory identities can now use the `ListCallerAccessGrants` API to list all of the Amazon S3 buckets, prefixes, and objects they can access, as defined by their S3 Access Grants. Use this API to discover all of the S3 data an IAM or corporate directory identity can access through S3 Access Grants, within a particular AWS account. For more information, see List the caller's access grants.	September 5, 2024

Enhanced access denied error messages for same-account requests	Amazon S3 now includes additional context in access denied (HTTP `403 Forbidden`) errors for requests made to resources within the same AWS account. This new context includes the type of policy that denied access, the reason for denial, and information about the AWS Identity and Access Management (IAM) user or role that requested access to the resource. This context helps you to troubleshoot access issues, identify the root cause of access denied errors, and fix incorrect access controls by updating the relevant policies. This additional context is also available in AWS CloudTrail logs. Enhanced access denied error messages for same-account requests are now available in all AWS Regions, including the AWS GovCloud (US) Regions and the China Regions. For more information, see Troubleshoot access denied (403 Forbidden) errors in Amazon S3..	August 21, 2024

Amazon S3 supports using conditional writes for `PutObject` and `CompleteMultipartUpload`	You can check for the existence of an object in your bucket before creating it using a conditional write on upload operations. This can prevent overwrites of existing data. Conditional writes will validate there is no existing object with the same key name already in your bucket. For more information, see Conditional requests.	August 20, 2024
Amazon S3 no longer charges for several HTTP error codes	Amazon S3 has completed a change so unauthorized requests that customers did not initiate are free of charge. For more information, see Billing for Amazon S3 error responses.	August 19, 2024
Amazon S3 Select is no longer available to new customers	Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. Learn more.	July 25, 2024

Amazon S3 Inventory supports the s3:InventoryAccessibleOptionalFields condition key	Amazon S3 Inventory supports the s3:InventoryAccessibleOptionalFields condition key to control whether users can include optional metadata fields in their reports. For more information, see Control S3 Inventory report configuration creation.	February 20, 2024
IPv6 support for S3 on Outposts	You can now access S3 on Outposts buckets using IPv6 via S3 on Outposts dual-stack endpoints. IPv6 support for S3 on Outposts allows you to manage your S3 on Outposts buckets and control plane resources over IPv6 networks.	January 16, 2024
New high-performance, single-zone Amazon S3 storage class – S3 Express One Zone	Amazon S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that is purpose-built to deliver consistent, single-digit millisecond data access for your most latency-sensitive applications. For more information, see S3 Express One Zone.	November 28, 2023
Mountpoint for Amazon S3 adds support for S3 Express One Zone	You can now mount S3 Express One Zone directory buckets with Mountpoint.	November 28, 2023

Lambda invocation schema version	Amazon S3 Batch Operations introduces a new Lambda invocation schema version for use with Batch Operations jobs that act on directory buckets. For more information, see Using Lambda and Amazon S3 batch operations with directory buckets.	November 28, 2023
Import action for directory buckets	Amazon S3 introduces the import action. Import is a streamlined method for creating Amazon S3 Batch Operations jobs to copy objects from general purpose buckets to directory buckets. For more information, see Importing objects into a directory bucket.	November 28, 2023
Manage S3 access with S3 Access Grants	Amazon S3 Access Grants enables you to manage data permissions at scale for AWS Identity and Access Management (IAM) principals in addition to directory identities from corporate directories such as Azure AD. You can now enforce least-privilege S3 permissions and easily scale those permissions based on your business needs. For more information, see Managing access with S3 Access Grants.	November 26, 2023

Mountpoint for Amazon S3 adds caching feature	With Mountpoint, you can now configure caching for repeatedly accessed data.	November 22, 2023
Enhanced Amazon S3 Batch Operations manifest generation	You can now direct Amazon S3 Batch Operations to generate a manifest automatically based on object filter criteria that you specify when you create your job. This option is available for batch replication jobs that you create in the Amazon S3 console, or for any job type that you create by using the AWS CLI, AWS SDKs, or Amazon S3 REST API. For more information, see Creating an Amazon S3 Batch Operations job.	November 22, 2023
Existing Amazon S3 buckets can now add Object Lock configurations	You can now enable Object Lock on existing Amazon S3 bucket. You may set legal holds and retention periods for new or existing buckets. For more information, see Using Object Lock.	November 20, 2023
S3 Storage Lens request metrics for prefixes	S3 Storage Lens introduces request metrics for prefixes within an Amazon S3 bucket. For more information, see Metrics categories.	November 17, 2023

Amazon S3 Storage Lens groups	S3 Storage Lens introduces Storage Lens groups, a custom defined filter for objects based on object metadata. For more information, see Working with Amazon S3 Storage Lens groups.	November 15, 2023
New IAM policy	S3 on Outposts introduces `AWSServiceRoleForS3nOutposts`, a service-linked role to help manage network resources for you. For more information, see Using service-linked roles for S3 on Outposts.	October 3, 2023
Amazon S3 provides the `Last-Modified` time for delete markers	Amazon S3 provides the `Last-Modified` time of delete markers in the response headers of S3 `Head` and `Get` API operations. For more information, see Working with delete markers.	September 27, 2023
Amazon S3 update to AWS managed policy	Amazon S3 added `s3:Describe*` permissions to `AmazonS3ReadOnlyAccess`. For more information, see AWS managed policies for Amazon S3.	August 11, 2023

Improved start times for Standard restore requests made through S3 Batch Operations	Standard retrievals for restore requests that are made through S3 Batch Operations now can start within minutes. For more information, see Archive Retrieval Options.	August 9, 2023
Added Mountpoint, a high-throughput client for mounting an Amazon S3 bucket as a local file system.	With Mountpoint, your applications can access objects stored in Amazon S3 through file operations, giving your applications access to the elastic storage and throughput of Amazon S3 through a file interface.	August 9, 2023
Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS)	Dual-layer server-side encryption with AWS Key Management Service (AWS KMS) keys (DSSE-KMS) applies two layers of encryption to objects when they are uploaded to Amazon S3. For more information, see Using dual-layer server-side encryption with AWS KMS keys.	June 13, 2023

Amazon S3 enables S3 Block Public Access and disables S3 access control lists (ACLs) for all new buckets.	Amazon S3 now automatically enables S3 Block Public Access and disables S3 access control lists (ACLs) for all new S3 buckets in all AWS Regions. For more information, see Blocking public access to your Amazon S3 storage and Controlling ownership of objects and disabling ACLs for your bucket.	April 27, 2023
S3 Replication Operations Failed metric	Amazon S3 adds new Amazon CloudWatch metric to monitor S3 Replication failures. For more information, see Monitoring progress with replication metrics.	April 5, 2023
Private DNS	AWS PrivateLink for Amazon S3 now supports Private DNS. For more information, see Private DNS.	March 14, 2023
Cross-account access points support in the Amazon S3 console	Amazon S3 now supports creating cross-account access points with the Amazon S3 console. For more information, see Creating access points.	March 14, 2023

Amazon S3 on Outposts supports S3 Replication on Outposts	With local S3 Replication, you can automatically replicate objects to a single Outposts destination bucket or to multiple destination buckets. The destination buckets can be in different AWS Outposts or within the same Outposts as the source bucket. For more information, see Replicating objects for S3 on Outposts.	March 14, 2023
Amazon S3 Object Lambda Access Point alias	When you create an Object Lambda Access Point, Amazon S3 automatically generates a unique alias for your Object Lambda Access Point. You can use this alias instead of an Amazon S3 bucket name or the Object Lambda Access Point Amazon Resource Name (ARN) in a request for access point data plane operations. For more information, see How to use a bucket-style alias for your Object Lambda Access Point.	March 14, 2023
Amazon S3 Multi-Region Access Points cross-account support	Amazon S3 now supports creating cross-account Multi-Region Access Points with the Amazon S3 console. For more information, see Creating Multi-Region Access Points.	March 14, 2023

Cross-account access points	Amazon S3 supports creating cross-account access points. You can create a cross-account access point by using the AWS Command Line Interface (AWS CLI) or the REST API `CreateAccessPoint` operation. For more information, see Creating access points.	November 30, 2022
Amazon S3 supports failover controls for Amazon S3 Multi-Region Access Points	Amazon S3 introduces failover control for Multi-Region Access Points. These controls let you shift S3 data access request traffic routed through an Amazon S3 Multi-Region Access Point to an alternate AWS Region within minutes to test and build highly available applications. For more information, see Amazon S3 Multi-Region Access Point failover controls.	November 28, 2022
Amazon S3 Storage Lens increases organization-wide visibility with 34 new metrics	S3 Storage Lens introduces 34 additional metrics to uncover deeper cost-optimization opportunities, identify data-protection best practices, and improve the performance of application workflows. For more information, see S3 Storage Lens metrics.	November 17, 2022

Amazon S3 supports higher restore request rates for S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive	Amazon S3 supports restore requests at a rate of up to 1,000 transactions per second, per AWS account for the S3 Glacier Flexible Retrieval and S3 Glacier Deep Archive storage classes.	November 15, 2022
Amazon S3 on Outposts supports additional S3 Lifecycle actions and filters	S3 on Outposts supports additional S3 Lifecycle rules to optimize capacity mana gement. You can expire objects as they age or are replaced with newer version s. You can create a lifecycle rule for a whole bucket or a subset of objects in a bucket by filtering with prefixes, object tags, or object size. For more information, see Creating and managing a lifecycle configuration.	November 2, 2022
S3 Replication support for SSE-C objects	You can replicate objects that are created using server-side encryption with customer -provided keys. For more information about replicati ng encrypted objects, see Replicating objects created with server-side encryption (SSE-C, SSE-S3, SSE-KMS).	October 24, 2022

Amazon S3 on Outposts supports access point aliases	With S3 on Outposts, you must use access points to access any object in an Outposts bucket. Every time you create an access point for a bucket, S3 on Outposts automatically generates an access point alias. You can use this access point alias instead of an access point ARN for any data plane operation. For more information, see Using a bucket-style alias for your S3 on Outposts bucket access point.	October 21, 2022
S3 Object Lambda supports the `HeadObject`, `ListObjects`, and `ListObjectsV2` operations	You can use custom code to modify the data returned by standard S3 `GET`, `LIST`, or `HEAD` requests to filter rows, dynamically resize images, redact confidential data, and more. For more information, see Transforming objects with S3 Object Lambda.	October 4, 2022

Amazon S3 on Outposts supports S3 Versioning	When enabled, S3 Versioning saves multiple distinct copies of an object in the same bucket. You can use S3 Versioning to preserve, retrieve, and restore every version of every object stored in your Outposts buckets. S3 Versioning helps you recover from unintended user actions and application failures. For more information, see Managing S3 Versioning for your S3 on Outposts bucket.	September 21, 2022
AWS Backup for Amazon S3	AWS Backup is a fully managed, policy-based service that you can use to define a central backup policy to protect your Amazon S3 data. For more information, see Using AWS Backup for Amazon S3.	February 18, 2022

Use S3 Batch Replication to replicate existing objects	With S3 Batch Replication, you can replicate objects that existed before a replication configuration was in place. Replicating existing objects is done through the use of a Batch Operations job. S3 Batch Replication differs from live replication, which continuously and automatic ally copies new objects across Amazon S3 buckets. For more information, see Replicating existing objects with S3 Batch Replication.	February 8, 2022
Rename of S3 Glacier Flexible Retrieval	The Glacier storage class has been renamed to S3 Glacier Flexible Retrieval. This change does not impact the API.	November 30, 2021

New S3 Object Ownership setting to disable ACLs	You can apply the bucket owner enforced setting for Object Ownership to disable ACLs for your bucket and the objects in it and take ownership of every object in your bucket. The bucket owner enforced setting simplifies access management for data stored in Amazon S3. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.	November 30, 2021
New S3 Intelligent-Tiering storage class	S3 Intelligent-Tiering Archive Instant Access is an additional storage class under S3 Intelligent-Tiering. For more information, see How S3 Intelligent-Tiering works.	November 30, 2021
New S3 Glacier Instant Retrieval storage class	You can now place objects in the S3 Glacier Instant Retrieval storage class. For more information about this storage class, see Using Amazon S3 storage classes.	November 30, 2021

AWS Backup for Amazon S3 Preview	AWS Backup is a fully managed, policy-based service that you can use to define a central backup policy to protect your Amazon S3 data. For more informati on, see Using AWS Backup for Amazon S3.	November 30, 2021
AWS Identity and Access Management Access Analyzer for Amazon S3	IAM Access Analyzer runs policy checks to validate your policy against IAM policy grammar and best practices. To learn more about validatin g policies using IAM Access Analyzer, see IAM Access Analyzer policy validation in the *IAM User Guide*.	November 30, 2021
New event types	New event types added to Amazon S3 Event Notificat ions, see Amazon S3 Event Notifications.	November 29, 2021
Enable Amazon EventBridge on buckets	You can enable EventBrid ge on Amazon S3 buckets to send events to Amazon EventBridge, see Using EventBridge.	November 29, 2021
New S3 Lifecycle filters	You can create lifecycle rules based on object size or specify how many noncurre nt object versions to keep. For more information, see Examples of S3 Lifecycle configuration.	November 23, 2021

Publish Amazon S3 Storage Lens metrics to Amazon CloudWatch	You can publish S3 Storage Lens usage and activity metrics to Amazon CloudWatch to create a unified view of your operational health in CloudWatch dashboards. You can also use CloudWatch features, like alarms and triggered actions, metric math, and anomaly detection, to monitor and take action on S3 Storage Lens metrics. In addition, the CloudWatch APIs enable applications, including third-party providers, to access your S3 Storage Lens metrics. For more information, see the Monitor S3 Storage Lens metrics in CloudWatch.	November 22, 2021
Multi-Region Access Points	You can use Multi-Region Access Points to create a global endpoint that applications can use to fulfill requests from Amazon S3 buckets located in multiple AWS Regions. You can use this Multi-Region Access Point to route data to a bucket with the lowest latency. For more information about Multi-Region Access Points and how to use them, see Multi-Region Access Point in Amazon S3.	September 2, 2021

Amazon S3 on Outposts adds direct local access for applications	Run your applications outside the AWS Outposts virtual private cloud (VPC) and access your S3 on Outposts data. You can also access S3 on Outposts objects directly from your on-premises network. For more information about configuring S3 on Outposts endpoints using customer-owned IP (CoIP) addresses and accessing your objects by creating a local gateway from your on-premises network, see Accessing Amazon S3 on Outposts using VPC-only access points.	July 29, 2021
Amazon S3 access point alias	When you create an access point, Amazon S3 automatically generates an alias that you can use instead of a bucket name for data access. You can use this access point alias instead of an Amazon Resource Name (ARN) for any access point data plane operation. For more information, see Using a bucket-style alias for your access point.	July 26, 2021

Amazon S3 Inventory and S3 Batch Operations support S3 Bucket Key status	Amazon S3 Inventory and Batch Operations support identifying and copying existing objects with S3 Bucket Keys. S3 Bucket Keys accelerate the reduction of server-side encryption costs for existing objects. For more information, see Amazon S3 Inventory and Batch Operations Copy object.	June 3, 2021
Amazon S3 Storage Lens metrics account snapshot	The S3 Storage Lens account snapshot displays your total storage, object count, and average object size on the S3 console home (**Buckets**) page by summarizing metrics from your default dashboard. For more information, see S3 Storage Lens metrics account snapshot.	May 5, 2021
Increased Amazon S3 on Outposts endpoint support	S3 on Outposts now supports up to 100 endpoints per Outpost. For more information, see S3 on Outposts network restrictions.	April 29, 2021

Amazon S3 on Outposts event notifications in Amazon CloudWatch Events	You can use CloudWatch Events to create a rule to capture any S3 on Outposts API event and get notified through all supported CloudWatch targets. For more information, see Receiving S3 on Outposts event notifications using CloudWatch Events.	April 19, 2021
S3 Object Lambda	With S3 Object Lambda, you can add your own code to Amazon S3 GET requests to modify and process data as it is returned to an application. You can use custom code to modify the data returned by standard S3 GET requests to f ilter rows, dynamically resize images, redact confidential data, and more. For more information, see Transform ing objects.	March 18, 2021

AWS PrivateLink	With AWS PrivateLink for Amazon S3, you can connect directly to S3 by using an interface endpoint in your virtual private cloud (VPC) instead of connecting over the internet. Interface endpoints are directly accessible from applications that are on premises or in a different AWS Region. For more information, see AWS PrivateLink for Amazon S3.	February 2, 2021
Managing Amazon S3 on Outposts capacity with AWS CloudTrail	S3 on Outposts management events are available through CloudTrail logs. For more information, see Managing S3 on Outposts capacity with CloudTrail.	December 21, 2020
Strong consistency	Amazon S3 provides strong read-after-write consistency for PUT and DELETE requests of objects in your S3 bucket in all AWS Regions. In addition, read operations on Amazon S3 Select, Amazon S3 access control lists, Amazon S3 Object Tags, and object metadata (for example, HEAD object) are strongly consistent. For more information, see Amazon S3 data consistency model.	December 1, 2020

Amazon S3 replica modification sync	Amazon S3 replica modification sync keeps object metadata, such as tags, ACLs, and Object Lock settings, in sync between source objects and replicas. When this feature is enabled, Amazon S3 replicates metadata changes made to either the source object or the replica copies. For more information, see Replicating metadata changes with replica modification sync.	December 1, 2020
Amazon S3 Bucket Keys	Amazon S3 Bucket Keys reduce the cost of Amazon S3 server-side encryption with AWS Key Management Service (SSE-KMS). This new bucket-level key for server-side encryption can reduce AWS KMS request costs by up to 99 percent by decreasing the request traffic from Amazon S3 to AWS KMS. For more information, see Reducing the cost of SSE-KMS by using S3 Bucket Keys.	December 1, 2020

Amazon S3 Storage Lens	S3 Storage Lens aggregates your metrics and displays the information in the **Account snapshot** section on the Amazon S3 console **Buckets** page. S3 Storage Lens also provides an interactive dashboard that you can use to visualize insights and trends, flag outliers, and receive recommendations for optimizing storage costs and applying data-protection best practices. Your dashboard has drill-down options to generate and visualize insights at the organization, account, AWS Region, storage class, bucket, prefix, or Storage Lens group level. You can also send a daily metrics export in CSV or Parquet format to an S3 bucket. For more information, see Assessing your storage activity and usage with S3 Storage Lens.	November 18, 2020
Tracing S3 requests using AWS X-Ray	Amazon S3 integrates with X-Ray to propagate the trace context and give you one request chain with upstream and downstream nodes. For more information, see Tracing requests using X-Ray.	November 16, 2020

S3 Replication metrics	S3 Replication metrics provide detailed metrics for the replication rules in your replication configuration. For more information, see Replication metrics and Amazon S3 event notifications.	November 9, 2020
S3 Intelligent-Tiering Archive Access and Deep Archive Access	S3 Intelligent-Tiering Archive Access and Deep Archive Access are additional storage tiers under S3 Intelligent-Tiering. For more information, see Storage class for automatically optimizing frequently and infrequently accessed objects .	November 9, 2020
Delete marker replication	With delete marker replication, you can ensure that delete markers are copied to your destination buckets for your replication rules. For more information, see Using delete marker replication.	November 9, 2020
S3 Object Ownership	Object Ownership is an S3 bucket setting that you can use to control ownership of new objects that are uploaded to your buckets. For more information, see Using S3 Object Ownership.	October 2, 2020

Amazon S3 on Outposts	With Amazon S3 on Outposts, you can create S3 buckets on your AWS Outposts resources and easily store and retrieve objects on-premises for applications that require local data access, local data processing, and data residency. You can use S3 on Outposts through the AWS Management Console, AWS CLI, AWS SDKs, or REST API. For more information, see Using Amazon S3 on Outposts.	September 30, 2020
Bucket owner condition	You can use the Amazon S3 bucket owner condition to ensure that the buckets you use in your S3 operations belong to the AWS accounts that you expect. For more information, see Bucket owner condition.	September 11, 2020
S3 Batch Operations support for Object Lock Retention	You can now use Batch Operations with S3 Object Lock to apply retention settings to many Amazon S3 objects at once. For more information, see Setting S3 Object Lock Retention dates with S3 Batch Operations.	May 4, 2020

S3 Batch Operations support for Object Lock Legal Hold	You can now use Batch Operations with S3 Object Lock to add a legal hold to many Amazon S3 objects at once. For more information, see Using S3 Batch Operations for setting S3 Object Lock Legal Hold.	May 4, 2020
Job tags for S3 Batch Operations	You can add tags to your S3 Batch Operations jobs to control and label those jobs. For more information, see Tags for S3 Batch Operations jobs.	March 16, 2020
Amazon S3 access points	Amazon S3 access points simplify managing data access at scale for shared datasets in S3. Access points are named network endpoints that are attached to buckets that you can use to perform S3 object operations. For more information, see Managing data access with Amazon S3 access points.	December 2, 2019

Access Analyzer for Amazon S3	Access Analyzer for Amazon S3 alerts you to S3 buckets that are configured to allow access to anyone on the internet or other AWS accounts, including accounts outside of your organization. For more information, see Using Access Analyzer for Amazon S3.	December 2, 2019
S3 Replication Time Control (S3 RTC)	S3 Replication Time Control (S3 RTC) replicates most objects that you upload to Amazon S3 in seconds, and 99.99 percent of those objects within 15 minutes. For more information, see Replicating objects using S3 Replication Time Control (S3 RTC).	November 20, 2019
Same-Region Replication	You can use Same-Region Replication (SRR) to copy objects across Amazon S3 buckets in the same AWS Region. For information about both Cross-Region Replication (CRR) and Same-Region Replication, see Replication.	September 18, 2019
Cross-Region Replication support for S3 Object Lock	Cross-Region Replication now supports Object Lock. For more information, see What does Amazon S3 Replicate?.	May 28, 2019

S3 Batch Operations	By using S3 Batch Operations, you can perform large-scale Batch Operations on Amazon S3 objects. S3 Batch Operations can run a single operation on lists of objects that you specify. A single job can perform the specified operation on billions of objects containing exabytes of data. For more information, see Performing S3 Batch Operations.	April 30, 2019
Asia Pacific (Hong Kong) Region	Amazon S3 is now available in the Asia Pacific (Hong Kong) Region. For more information about Amazon S3 Regions and endpoints, see Regions and endpoints in the *AWS General Reference*.	April 24, 2019
Added a new field to the server access logs	Amazon S3 added the following new field to the server access logs: Transport Layer Security (TLS) version. For more information, see Server access log format.	March 28, 2019
New archive storage class	Amazon S3 now offers a new archive storage class, S3 Glacier Deep Archive (`DEEP_ARCHIVE`), for storing rarely accessed objects. For more information, see Storage Classes.	March 27, 2019

Added new fields to the server access logs	Amazon S3 added the following new fields to the server access logs: Host Id, Signature Version, Cipher Suite, Authentication Type, and Host Header. For more information, see Server access log format.	March 5, 2019
Support for Parquet-formatted Amazon S3 Inventory files	Amazon S3 now supports the Apache Parquet (Parquet) format in addition to the Apache optimized row columnar (ORC) and comma-separated values (CSV) file formats for inventory output files. For more information, see Inventory.	December 4, 2018
S3 Object Lock	Amazon S3 now offers Object Lock functionality that provides Write Once Read Many (WORM) protections for Amazon S3 objects. For more information, see Locking Objects.	November 26, 2018
Restore speed upgrade	Using Amazon S3 restore speed upgrade, you can change the speed of a restoration from the S3 Glacier Flexible Retrieval storage class to a faster speed while the restoration is in progress. For more information, see Restoring Archived Objects.	November 26, 2018

Restore Event Notifications	Amazon S3 Event Notifications now support initiation and completion events when restoring objects from the S3 Glacier Flexible Retrieval storage class. For more information, see Event Notifications.	November 26, 2018

PUT directly to the S3 Glacier Flexible Retrieval storage class	The Amazon S3 PUT operation now supports specifying S3 Glacier Flexible Retrieval as the storage class when creating objects. Previously, you had to transition objects to the S3 Glacier Flexible Retrieval storage class from another Amazon S3 storage class. Also, when using S3 Cross-Region Replication (CRR), you can now specify S3 Glacier Flexible Retrieval as the storage class for replicated objects. For more information about the S3 Glacier Flexible Retrieval storage class, see Storage Classes. For more information about specifying the storage class for replicated objects, Replication Configuration Overview. For more informati on about the direct PUT to S3 Glacier Flexible Retrieval REST API changes, see Document History: PUT directly to S3 Glacier Flexible Retrieval .	November 26, 2018

New storage class	Amazon S3 now offers a new storage class named S3 Intelligent-Tiering (`INTELLIGENT_TIERING`) that is designed for long-lived data with changing or unknown access patterns. For more information, see Storage Classes.	November 26, 2018
Amazon S3 Block Public Access	Amazon S3 now includes the ability to block public access to buckets and objects on a per-bucket or account-wide basis. For more information, see Using Amazon S3 Block Public Access.	November 15, 2018
Filtering enhancements in Cross-Region Replication (CRR) rules	In a CRR rule configuration, you can specify an object filter to choose a subset of objects to apply the rule to. Previously, you could filter only on an object key prefix. In this release, you can filter on an object key prefix, one or more object tags, or both. For more information, see CRR Setup: Replication Configuration Overview.	September 19, 2018

New Amazon S3 Select features	Amazon S3 Select now supports Apache Parquet input, queries on nested JSON objects, and two new Amazon CloudWatch monitoring metrics (`SelectScannedBytes` and `SelectReturnedBytes`).	September 5, 2018
Updates now available over RSS	You can now subscribe to an RSS feed to receive notifications about updates to the *Amazon S3 User Guide*.	June 19, 2018

Earlier updates

The following table describes the important changes in each release of the *Amazon S3 User Guide* before June 19, 2018.

Change	Description	Date
Code examples update	Code examples updated: • C#—Updated all of the examples to use the task-based asynchronous pattern. For more information, see Amazon Web Services Asynchronous APIs for .NET in the *AWS SDK for .NET Developer Guide*. Code examples are now compliant with version 3 of the AWS SDK for .NET. • Java—Updated all of the examples to use the client builder model. For more information about the client builder model, see Creating Service Clients. •	April 30, 2018

Change	Description	Date
	PHP—Updated all of the examples to use the AWS SDK for PHP 3.0. For more information about the AWS SDK for PHP 3.0, see AWS SDK for PHP. • Ruby—Updated example code so that the examples work with the AWS SDK for Ruby version 3.	

Amazon S3 now reports S3 Glacier Flexible Retrieval and ONEZONE_IA storage classes to Amazon CloudWatch Logs storage metrics	In addition to reporting actual bytes, these storage metrics include per-object overhead bytes for applicable storage classes (ONEZONE_IA , STANDARD_IA , and S3 Glacier Flexible Retrieval):
	• For ONEZONE_IA and STANDARD_IA storage class objects, Amazon S3 reports objects smaller than 128 KB as 128 KB. For more information, see Understanding and managing Amazon S3 storage classes.
	• For S3 Glacier Flexible Retrieval storage class objects, the storage metrics report the following overheads:
	  • A 32 KB per-object overhead, charged at S3 Glacier Flexible Retrieval storage class pricing
	  • An 8 KB per-object overhead, charged at STANDARD storage class pricing
	  For more information, see Transitioning objects using Amazon S3 Lifecycle.
	For more information about storage metrics, see Monitoring metrics with Amazon CloudWatch.
		April 30, 2018

Change	Description	Date
New storage class	Amazon S3 now offers a new storage class, `STANDARD_IA` (IA, for infrequent access) for storing objects. This storage class is optimized for long-lived and less frequently accessed data. For more information, see Understanding and managing Amazon S3 storage classes.	April 4, 2018
Amazon S3 Select	a>Amazon S3 now supports retrieving object content based on an SQL expression. For more information, see Querying data in place with Amazon S3 Select.	April 4, 2018
Asia Pacific (Osaka-Local) Region	Amazon S3 is now available in the Asia Pacific (Osaka-Local) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*. **Important** You can use the Asia Pacific (Osaka-Local) Region only in conjunction with the Asia Pacific (Tokyo) Region. To request access to Asia Pacific (Osaka-Local) Region, contact your sales representative.	February 12, 2018
Amazon S3 Inventory creation timestamp	Amazon S3 Inventory now includes a timestamp of the date and start time of the creation of the Amazon S3 Inventory report. You can use the timestamp to determine changes in your Amazon S3 storage from the start time of when the inventory report was generated.	January 16, 2018
Europe (Paris) Region	Amazon S3 is now available in the Europe (Paris) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.	December 18, 2017

Change	Description	Date
China (Ningxia) Region	Amazon S3 is now available in the China (Ningxia) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.	November 29, 2017
Support for ORC-formatted Amazon S3 Inventory files	Amazon S3 now supports the Apache optimized row columnar (ORC) format in addition to comma-separated values (CSV) file format for inventory output files. Also, you can now query Amazon S3 inventory using standard SQL by using Amazon Athena, Amazon Redshift Spectrum, and other tools such as Presto, Apache Hive, and Apache Spark. For more information, see Cataloging and analyzing your data with S3 Inventory.	November 17, 2017
Default encryption for S3 buckets	Amazon S3 default encryption provides a way to set the default encryption behavior for an S3 bucket. You can set default encryption on a bucket so that all objects are encrypted when they are stored in the bucket. The objects are encrypted using server-side encryption with either Amazon S3 managed keys (SSE-S3) or AWS managed keys (SSE-KMS). For more information, see Setting default server-side encryption behavior for Amazon S3 buckets.	November 06, 2017
Encryption status in Amazon S3 Inventory	Amazon S3 now supports including encryption status in Amazon S3 Inventory so you can see how your objects are encrypted at rest for compliance auditing or other purposes. You can also configure to encrypt Amazon S3 Inventory with server-side encryption (SSE) or SSE-KMS so that all inventory files are encrypted accordingly. For more information, see Cataloging and analyzing your data with S3 Inventory.	November 06, 2017

Change	Description	Date
Cross-Region Replication (CRR) enhancements	Cross-Region Replication now supports the following: • In a cross-account scenario, you can add a CRR configuration to change replica ownership to the AWS account that owns the destination bucket. For more information, see Changing the replica owner. • By default, Amazon S3 does not replicate objects in your source bucket that are created using server-side encryption using keys stored in AWS KMS In your CRR configuration, you can now direct Amazon S3 to replicate these objects. For more information, see Replicating encrypted objects (SSE-S3, SSE-KMS, DSSE-KMS, SSE-C).	November 06, 2017
Europe (London) Region	Amazon S3 is now available in the Europe (London) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.	December 13, 2016
Canada (Central) Region	Amazon S3 is now available in the Canada (Central) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.	December 8, 2016

Change	Description	Date
Object tagging	Amazon S3 now supports object tagging. Object tagging enables you to categorize storage. Object key name prefixes also enable you to categorize storage, object tagging adds another dimension to it. There are added benefits tagging offers. These include: • Object tags enable fine-grained access control of permissions (for example, you could grant an IAM user permissions to read-only objects with specific tags). • Fine-grained control in specifying lifecycle configuration. You can specify tags to select a subset of objects to which lifecycle rule applies. • If you have Cross-Region Replication (CRR) configured, Amazon S3 can replicate the tags. You must grant necessary permission to the IAM role created for Amazon S3 to assume to replicate objects on your behalf. • You can also customize CloudWatch metrics and CloudTrail events to display information by specific tag filters. For more information, see Categorizing your objects using tags.	November 29, 2016
Amazon S3 Lifecycle now supports tag-based filters	Amazon S3 now supports tag-based filtering in lifecycle configuration. You can now specify lifecycle rules in which you can specify a key prefix, one or more object tags, or a combination of both to select a subset of objects to which the lifecycle rule applies. For more information, see Managing the lifecycle of objects.	November 29, 2016

Change	Description	Date
CloudWatch request metrics for buckets	Amazon S3 now supports CloudWatch metrics for requests made on buckets. When you enable these metrics for a bucket, the metrics report at 1-minut e intervals. You can also configure which objects in a bucket will report these request metrics. For more information, see Monitoring metrics with Amazon CloudWatch.	November 29, 2016
Amazon S3 Inventory	Amazon S3 now supports storage inventory. Amazon S3 Inventory provides a flat-file output of your objects and their corresponding metadata on a daily or weekly basis for an S3 bucket or a shared prefix (that is, objects that have names that begin with a common string). For more information, see Cataloging and analyzing your data with S3 Inventory.	November 29, 2016
Amazon S3 Analytics – Storage Class Analysis	The new Amazon S3 analytics – storage class analysis feature observes data access patterns to help you determine when to transition less frequently accessed `STANDARD` storage to the `STANDARD_IA` (IA, for infrequent access) storage class. After storage class analysis observes the infrequent access patterns of a filtered set of data over a period of time, you can use the analysis results to help you improve your lifecycle configurations. This feature also includes a detailed daily analysis of your storage usage at the specified bucket, pr efix, or tag level that you can export to an S3 bucket.	November 29, 2016
New Expedited and Bulk data retrieval s when restoring archived objects from S3 Glacier	Amazon S3 now supports Expedited and Bulk data retrievals in addition to Standard retrievals when restoring objects archived to S3 Glacier. For more information, see Restoring an archived object.	November 21, 2016

Change	Description	Date
CloudTrail object logging	CloudTrail supports logging Amazon S3 object level API operations such as `GetObject` , `PutObject` , and `DeleteObject` . You can configure your event selectors to log object level API operations. For more information, see Logging Amazon S3 API calls using AWS CloudTrail.	November 21, 2016
US East (Ohio) Region	Amazon S3 is now available in the US East (Ohio) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.	October 17, 2016
IPv6 support for Amazon S3 Transfer Acceleration	Amazon S3 now supports Internet Protocol version 6 (IPv6) for Amazon S3 Transfer Acceleration. You can connect to Amazon S3 over IPv6 by using the new dual-stack for Transfer Acceleration endpoint. For more information, see Getting started with Amazon S3 Transfer Acceleration.	October 6, 2016
IPv6 support	Amazon S3 now supports Internet Protocol version 6 (IPv6). You can access Amazon S3 over IPv6 by using dual-stack endpoints. For more information, see Making requests to Amazon S3 over IPv6 in the *Amazon S3 API Reference*.	August 11, 2016
Asia Pacific (Mumbai) Region	Amazon S3 is now available in the Asia Pacific (Mumbai) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.	June 27, 2016

Change	Description	Date
Amazon S3 Transfer Acceleration	Amazon S3 Transfer Acceleration enables fast, easy, and secure transfers of files over long distances between your client and an S3 bucket. Transfer Acceleration takes advantage of Amazon CloudFront globally distributed edge locations. For more information, see Configuring fast, secure file transfers using Amazon S3 Transfer Acceleration.	April 19, 2016
Lifecycle support to remove expired object delete markers	Lifecycle configuration `Expiration` action now allows you to direct Amazon S3 to remove expired object delete markers in a/ versioned bucket. For more information, see Elements to describe lifecycle actions.	March 16, 2016

Change	Description	Date
Bucket lifecycle configuration now supports action to stop incomplete multipart uploads	Bucket lifecycle configuration now supports the `AbortIncompleteMultipartUpload` action that you can use to direct Amazon S3 to stop multipart uploads that don't complete within a specified number of days after being initiated. When a multipart upload becomes eligible for a stop operation, Amazon S3 deletes any uploaded parts and stops the multipart upload. For conceptual information, see the following topics in the *Amazon S3 User Guide*: • Aborting a multipart upload • Elements to describe lifecycle actions The following API operations have been updated to support the new action: • PUT Bucket lifecycle – The XML configuration now allows you to specify the `AbortIncompleteMultipartUpload` action in a lifecycle configuration rule. • List Parts and Initiate Multipart Upload – Both of these API operations now return two additional response headers (`x-amz-abort-date` , and `x-amz-abort-rule-id`) if the bucket has a lifecycle rule that specifies the `AbortIncompleteMultipartUpload` action. These headers in the response indicate when the initiated multipart upload becomes eligible for a stop operation and which lifecycle rule is applicable.	March 16, 2016

Change	Description	Date
Asia Pacific (Seoul) Region	Amazon S3 is now available in the Asia Pacific (Seoul) Region. For more information about Amazon S3 Regions and endpoints, see Regions and Endpoints in the *AWS General Reference*.	January 6, 2016
New condition key and a multipart upload change	IAM policies now support an Amazon S3 `s3:x-amz-storage-class` condition key. For more information, see Bucket policy examples using condition keys. You no longer need to be the initiator of a multipart upload to upload parts and complete the upload. For more information, see Multipart upload API and permissions.	December 14, 2015
Renamed the US Standard Region	Changed the Region name string from "US Standard" to "US East (N. Virginia)." This is only a Region name update, there is no change in the functionality.	December 11, 2015
New storage class	Amazon S3 now offers a new storage class, STANDARD_IA (IA, for infrequent access) for storing objects. This storage class is optimized for long-lived and less frequently accessed data. For more information, see Understanding and managing Amazon S3 storage classes. Lifecycle configuration feature updates now allow you to transition objects to the STANDARD_IA storage class. For more information, see Managing the lifecycle of objects. Previously, the Cross-Region Replication feature used the storage class of the source object for object replicas. Now, when you configure Cross-Region Replication, you can specify a storage class for the object replica created in the destination bucket. For more information, see Replicating objects within and across Regions.	September 16, 2015

Change	Description	Date
AWS CloudTrail integration	New AWS CloudTrail integration allows you to record Amazon S3 API activity in your S3 bucket. You can use CloudTrail to track S3 bucket creations or deletions, access control modifications, or lifecycle configuration changes. For more information, see Logging Amazon S3 API calls using AWS CloudTrail.	September 1, 2015
Bucket limit increase	Amazon S3 now supports bucket limit increases. By default, customers can create up to 100 buckets in their AWS account. Customers who need additional buckets can increase that limit by submitting a service limit increase. For information about how to increase your bucket limit, go to AWS service quotas in the *AWS General Reference*. For more information, see Using the AWS SDKs and General purpose bucket quotas, limitations, and restrictions.	August 4, 2015
Consistency model update	Amazon S3 now supports read-after-write consistency for new objects added to Amazon S3 in the US East (N. Virginia) Region. Prior to this update, all Regions except US East (N. Virginia) Region supported read-after-write consistency for new objects uploaded to Amazon S3. With this enhancement, Amazon S3 now supports read-after-write consistency in all Regions for new objects added to Amazon S3. Read-after-write consistency allows you to retrieve objects immediately after creation in Amazon S3. For more information, see Regions.	August 4, 2015
Event notifications	Amazon S3 Event Notifications have been updated to add notifications when objects are deleted and to add filtering on object names with prefix and suffix matching. For more information, see Amazon S3 Event Notifications.	July 28, 2015

Change	Description	Date
Amazon CloudWatch integration	New Amazon CloudWatch integration allows you to monitor and set alarms on your Amazon S3 usage through CloudWatch metrics for Amazon S3. Supported metrics include total bytes for Standard storage, total bytes for Reduced-Redundancy Storage, and total number of objects for a given S3 bucket. For more information, see Monitoring metrics with Amazon CloudWatch.	July 28, 2015
Support for deleting and emptying non-empty buckets	Amazon S3 now supports deleting and emptying non-empty buckets. For more information, see Emptying a general purpose bucket.	July 16, 2015
Bucket policies for Amazon VPC endpoints	Amazon S3 has added support for bucket policies for virtual private cloud (VPC) (VPC) endpoints. You can use S3 bucket policies to control access to buckets from specific VPC endpoints, or specific VPCs. VPC endpoints are easy to configure, are highly reliable, and provide a secure connection to Amazon S3 without requiring a gateway or a NAT instance. For more information, see Controlling access from VPC endpoints with bucket policies.	April 29, 2015
Event notifications	Amazon S3 Event Notifications have been updated to support the switch to resource-based permissions for AWS Lambda functions. For more information, see Amazon S3 Event Notifications.	April 9, 2015
Cross-Region Replication	Amazon S3 now supports Cross-Region Replication. Cross-Region Replication is the automatic, asynchronous copying of objects across buckets in different AWS Regions. For more information, see Replicating objects within and across Regions.	March 24, 2015

Change	Description	Date
Event notifications	Amazon S3 now supports new event types and destinations in a bucket notification configuration. Prior to this release, Amazon S3 supported only the *s3:ReducedRedundancyLostObject* event type and an Amazon SNS topic as the destination. For more information about the new event types, see Amazon S3 Event Notifications.	November 13, 2014
Server-side encryption with customer-provided encryption keys	Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS) Amazon S3 now supports server-side encryption using AWS KMS. This feature allows you to manage the envelope key through AWS KMS, and Amazon S3 calls AWS KMS to access the envelope key within the permissions you set. For more information about server-side encryption with AWS KMS, see Protecting Data Using Server-Side Encryption with AWS Key Management Service.	November 12, 2014
Europe (Frankfurt) Region	Amazon S3 is now available in the Europe (Frankfurt) Region.	October 23, 2014
Server-side encryption with customer-provided encryption keys	Amazon S3 now supports server-side encryption using customer-provided encryption keys (SSE-C). Server-side encryption enables you to request Amazon S3 to encrypt your data at rest. When using SSE-C, Amazon S3 encrypts your objects with the custom encryption keys that you provide. Since Amazon S3 performs the encryption for you, you get the benefits of using your own encryption keys without the cost of writing or executing your own encryption code. For more information about SSE-C, see Server-Side Encryption (Using Customer-Provided Encryption Keys).	June 12, 2014

Change	Description	Date
Lifecycle support for versioning	Prior to this release, lifecycle configuration was supported only on nonversioned buckets. Now you can configure lifecycle on both nonversioned and versioning-enabled buckets. For more information, see Managing the lifecycle of objects.	May 20, 2014
Access control topics revised	Revised Amazon S3 access control documentation. For more information, see Identity and Access Management for Amazon S3.	April 15, 2014
Server access logging topic revised	Revised server access logging documentation. For more information, see Logging requests with server access logging.	November 26, 2013
.NET SDK samples updated to version 2.0	.NET SDK samples in this guide are now compliant to version 2.0.	November 26, 2013
SOAP Support Over HTTP deprecated	SOAP support over HTTP is deprecated, but it is still available over HTTPS. New Amazon S3 features will not be supported for SOAP. We recommend that you use either the REST API or the AWS SDKs.	September 20, 2013
IAM policy variable support	IAM policy language now supports variables. When a policy is evaluated, any policy variables are replaced with values that are supplied by context-based information from the authenticated user's session. You can use policy variables to define general purpose policies without explicitly listing all the components of the policy. For more information about policy variables, see IAM Policy Variables Overview in the *IAM User Guide*. For examples of policy variables in Amazon S3, see Identity-based policy examples for Amazon S3.	April 3, 2013

Change	Description	Date
Console support for Requester Pays	You can now configure your bucket for Requester Pays by using the Amazon S3 console. For more information, see Using Requester Pays general purpose buckets for storage transfers and usage.	December 31, 2012
Root domain support for website hosting	Amazon S3 now supports hosting static websites at the root domain. Visitors to your website can access your site from their browser without specifying **www** in the web address (for example, they can use **example.com** instead of **www.example.com**). Many customers already host static websites on Amazon S3 that are accessible from a **www** subdomain (for example, **www.example.com**). Previously, to support root domain access, you needed to run your own web server to proxy root domain requests from browsers to your website on Amazon S3. Running a web server to proxy requests introduces additional costs, operational burden, and another potential point of failure. Now, you can take advantage of the high availability and durability of Amazon S3 for both **www** and root domain addresses. For more information, see Hosting a static website using Amazon S3.	December 27, 2012
Console revision	Amazon S3 console has been updated. The documentation topics that refer to the console have been revised accordingly.	December 14, 2012

Change	Description	Date
Support for Archiving Data to S3 Glacier	Amazon S3 now supports a storage option that enables you to utilize S3 Glacier's low-cost storage service for data archival. To archive objects, you define archival rules identifying objects and a time frame when you want Amazon S3 to archive these objects to S3 Glacier. You can easily set the rules on a bucket using the Amazon S3 console or programmatically using the Amazon S3 API or AWS SDKs. For more information, see Managing the lifecycle of objects.	November 13, 2012
Support for Website Page Redirects	For a bucket that is configured as a website, Amazon S3 now supports redirecting a request for an object to another object in the same bucket or to an external URL. For more information, see (Optional) Configuring a webpage redirect. For information about hosting websites, see Hosting a static website using Amazon S3.	October 4, 2012
Support for Cross-Origin Resource Sharing (CORS)	Amazon S3 now supports Cross-Origin Resource Sharing (CORS). CORS defines a way in which client web applications that are loaded in one domain can interact with or access resources in a different domain. With CORS support in Amazon S3, you can build rich client-side web applications on top of Amazon S3 and selectively allow cross-domain access to your Amazon S3 resources. For more information, see Using cross-origin resource sharing (CORS).	August 31, 2012
Support for Cost Allocation Tags	Amazon S3 now supports cost allocation tagging, which allows you to label S3 buckets so you can more easily track their cost against projects or other criteria. For more information about using tagging for buckets, see Using cost allocation S3 bucket tags.	August 21, 2012

Change	Description	Date
Support for MFA-protected API access in bucket policies	Amazon S3 now supports MFA-protected API access, a feature that can enforce AWS Multi-Factor Authentication for an extra level of security when accessing your Amazon S3 resources. It is a security feature that requires users to prove physical possession of an MFA device by providing a valid MFA code. For more information, go to AWS Multi-Factor Authentication. You can now require MFA authentication for any requests to access your Amazon S3 resources. To enforce MFA authentication, Amazon S3 now supports the `aws:MultiFactorAuthAge` key in a bucket policy. For an example bucket policy, see Requiring MFA.	July 10, 2012
Object Expiration support	You can use Object Expiration to schedule automatic removal of data after a configured time period. You set object expiration by adding lifecycle configuration to a bucket.	27 December 2011
New Region supported	Amazon S3 now supports the South America (São Paulo) Region. For more information, see Accessing an Amazon S3 general purpose bucket.	December 14, 2011
Multi-Object Delete	Amazon S3 now supports Multi-Object Delete API that enables you to delete multiple objects in a single request. With this feature, you can remove large numbers of objects from Amazon S3 more quickly than using multiple individual DELETE requests. For more information, see Deleting Amazon S3 objects.	December 7, 2011
New Region supported	Amazon S3 now supports the US West (Oregon) Region. For more information, see Buckets and Regions.	November 8, 2011
Documentation Update	Documentation bug fixes.	November 8, 2011

Change	Description	Date
Documentation Update	In addition to documentation bug fixes, this release includes the following enhancements: • New server-side encryption sections using the AWS SDK for PHP and the AWS SDK for Ruby (see Specifying server-side encryption with Amazon S3 managed keys (SSE-S3)).	October 17, 2011
Server-side encryption support	Amazon S3 now supports server-side encryption. It enables you to request Amazon S3 to encrypt your data at rest, that is, encrypt your object data when Amazon S3 writes your data to disks in its data centers. In addition to REST API updates, the AWS SDK for Java and .NET provide necessary functionality to request server-side encryption. You can also request server-side encryption when uploading objects using the AWS Management Console. To learn more about data encryption, go to Using Data Encryption.	October 4, 2011
Documentation Update	In addition to documentation bug fixes, this release includes the following enhancements: • Added Ruby and PHP samples to the Making requests in the *Amazon S3 API Reference* section. • Added sections describing how to generate and use presigned URLs. For more information, see Sharing objects with presigned URLs and Sharing objects with presigned URLs. • Updated an existing section to introduce AWS Explorers for Eclipse and Visual Studio. For more information, see Developing with Amazon S3 using the AWS SDKs in the *Amazon S3 API Reference*.	September 22, 2011

Change	Description	Date
Support for sending requests using temporary security credentials	In addition to using your AWS account and IAM user security credentials to send authenticated requests to Amazon S3, you can now send requests using temporary security credentials you obtain from AWS Identity and Access Management (IAM). You can use the AWS Security Token Service API or the AWS SDK wrapper libraries to request these temporary credentials from IAM. You can request these temporary security credentials for your own use or hand them out to federated users and applications. This feature enables you to manage your users outside AWS and provide them with temporary security credentials to access your AWS resources. For more information, see Making requests in the *Amazon S3 API Reference*. For more information about IAM support for temporary security credentials, see Temporary Security Credentials in the *IAM User Guide*.	August 3, 2011
Multipart Upload API extended to enable copying objects up to 5 TB	Prior to this release, Amazon S3 API supported copying objects of up to 5 GB in size. To enable copying objects larger than 5 GB, Amazon S3 now extends the multipart upload API with a new operation, `Upload Part (Copy)`. You can use this multipart upload operation to copy objects up to 5 TB in size. For more information, see Copying, moving, and renaming objects. For conceptual information about multipart upload API, see Uploading and copying objects using multipart upload in Amazon S3.	June 21, 2011
SOAP API calls over HTTP disabled	To increase security, SOAP API calls over HTTP are disabled. Authenticated and anonymous SOAP requests must be sent to Amazon S3 using SSL.	June 6, 2011

Change	Description	Date
IAM enables cross-account delegation	Previously, to access an Amazon S3 resource, an IAM user needed permissions from both the parent AWS account and the Amazon S3 resource owner. With cross-account access, the IAM user now only needs permission from the owner account. That is, If a resource owner grants access to an AWS account, the AWS account can now grant its IAM users access to these resources. For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*. For more information on specifying principals in a bucket policy, see Principals for bucket policies.	June 6, 2011
New link	This service's endpoint information is now located in the *AWS General Reference*. For more information, go to Regions and Endpoints in the AWS General Reference.	March 1, 2011
Support for hosting static websites in Amazon S3	Amazon S3 introduces enhanced support for hosting static websites. This includes support for index documents and custom error documents. When using these features, requests to the root of your bucket or a subfolder (for example, `http://mywebsite.com/subfolder`) returns your index document instead of the list of objects in your bucket. If an error is encountered, Amazon S3 returns your custom error message instead of an Amazon S3 error message. For more information, see Hosting a static website using Amazon S3.	June 6, 2011

Change	Description	Date
This service's endpoint information is now located in the *AWS General Reference*. For more information, go to Regions and Endpoints in the AWS General Reference.	March 1, 2011	
Support for hosting static websites in Amazon S3	Amazon S3 introduces enhanced support for hosting static websites. This includes support for index documents and custom error documents. When using these features, requests to the root of your bucket or a subfolder (for example, `http://mywebsite.com/subfolder`) returns your index document instead of the list of objects in your bucket. If an error is encountered, Amazon S3 returns your custom error message instead of an Amazon S3 error message. For more information, see Hosting a static website using Amazon S3.	February 17, 2011
Response Header API Support	The GET Object REST API now allows you to change the response headers of the REST GET Object request for each request. That is, you can alter object metadata in the response, without altering the object itself. For more information, see Downloading objects.	January 14, 2011
Large object support	Amazon S3 has increased the maximum size of an object you can store in an S3 bucket from 5 GB to 5 TB. If you are using the REST API, you can upload objects of up to 5 GB in a single PUT operation. For larger objects, you must use the Multipart Upload REST API to upload objects in parts. For more information, see Uploading and copying objects using multipart upload in Amazon S3.	December 9, 2010

Change	Description	Date
Multipart upload	Multipart upload enables faster, more flexible uploads into Amazon S3. It allows you to upload a single object as a set of parts. For more information, see Uploading and copying objects using multipart upload in Amazon S3.	November 10, 2010
Canonical ID support in bucket policies	You can now specify canonical IDs in bucket policies. For more information, see Principals for bucket policies	September 17, 2010
Amazon S3 works with IAM	This service now integrates with AWS Identity and Access Management (IAM). For more information, go to AWS services that work with IAM in the *IAM User Guide*.	September 2, 2010
Notifications	The Amazon S3 notifications feature enables you to configure a bucket so that Amazon S3 publishes a message to an Amazon Simple Notification Service (Amazon SNS) topic when Amazon S3 detects a key event on a bucket. For more information, see Setting Up Notification of Bucket Events.	July 14, 2010
Bucket policies	Bucket policies are an access management system that you use to set access permissions across buckets, objects, and sets of objects. This functionality supplements and in many cases replaces access control lists. For more information, see Bucket policies for Amazon S3.	July 6, 2010
Path-style syntax available in all Regions	Amazon S3 now supports the path-style syntax for any bucket in the US Classic Region, or if the bucket is in the same Region as the endpoint of the request. For more information, see Virtual Hosting.	June 9, 2010
New endpoint for Europe (Ireland)	Amazon S3 now provides an endpoint for Europe (Ireland) : `http://s3-eu-west-1.amazonaws.com` .	June 9, 2010

Change	Description	Date
Console	You can now use Amazon S3 through the AWS Management Console. You can read about all of the Amazon S3 functionality in the console in the Amazon Simple Storage Service User Guide.	June 9, 2010
Reduced Redundancy	Amazon S3 now enables you to reduce your storage costs by storing objects in Amazon S3 with reduced redundancy. For more information, see Reduced Redundancy Storage.	May 12, 2010
New Region supported	Amazon S3 now supports the Asia Pacific (Singapore) Region. For more information, see Buckets and Regions.	April 28, 2010
Object Versioning	This release introduces object versioning. All objects now can have a key and a version. If you enable versioning for a bucket, Amazon S3 gives all objects added to a bucket a unique version ID. This feature enables you to recover from unintended overwrites and deletions. For more information, see Versioning and Using Versioning.	February 8, 2010
New Region supported	Amazon S3 now supports the US West (N. California) Region. The new endpoint for requests to this Region is `s3-us-west-1.amazonaws.com`. For more information, see Buckets and Regions.	December 2, 2009
AWS SDK for .NET	AWS now provides libraries, sample code, tutorials, and other resources for software developers who prefer to build applications using .NET language-specific API operations instead of REST or SOAP. These libraries provide basic functions (not included in the REST or SOAP APIs), such as request authentication, request retries, and error handling so that it's easier to get started. For more information about language-specific libraries and resources, see Developing with Amazon S3 using the AWS SDKs in the *Amazon S3 API Reference*.	November 11, 2009
