If you're new to archival storage in Amazon Simple Storage Service (Amazon S3), we recommend that you start by learning more about the S3 Glacier storage classes in Amazon S3, **S3 Glacier Instant Retrieval**, **S3 Glacier Flexible Retrieval**, and **S3 Glacier Deep Archive**. For more information, see [S3 Glacier storage classes](https://docs.aws.amazon.com/AmazonS3/latest/dev/glacier-storage-classes-topic.html) and [Storage classes for archiving objects](https://docs.aws.amazon.com/AmazonS3/latest/dev/archiving-storage-classes.html) in the *Amazon S3 User Guide*.
What Is Amazon S3 Glacier?

If you're currently using the Amazon S3 Glacier (S3 Glacier) service and want to learn more, you'll find the information that you need in this guide. S3 Glacier is a secure and durable service for low-cost data archiving and long-term backup using vaults. For more information about S3 Glacier service pricing, see S3 Glacier pricing.

Do You Currently Use S3 Glacier?

Note

This section is about the S3 Glacier service. If you currently use the S3 Glacier storage classes (S3 Glacier Instant Retrieval, S3 Glacier Flexible Retrieval, and S3 Glacier Deep Archive), see Storage classes for archiving objects in the Amazon S3 User Guide.

If you currently use the S3 Glacier service and want to learn more, we recommend that you begin by reading the following sections:

- **What is Amazon S3 Glacier** – The rest of this section describes the underlying data model, the operations it supports, and the AWS SDKs that you can use to interact with the service.
- **Getting Started** – The Getting Started with Amazon S3 Glacier section walks you through the process of creating a vault, uploading archives, creating jobs to download archives, retrieving the job output, and deleting archives.

Important

S3 Glacier does provide a console. However, any archive operation, such as upload, download, or deletion, requires you to use the AWS Command Line Interface (AWS CLI).
or write code. There is no console support for archive operations. For example, to upload data, such as photos, videos, and other documents, you must either use the AWS CLI or write code to make requests, by using either the REST API directly or by using the AWS SDKs.

To install the AWS CLI, see [AWS Command Line Interface](https://aws.amazon.com/cli/). For more information about using S3 Glacier with the AWS CLI, see the [AWS CLI Reference for S3 Glacier](https://docs.aws.amazon.com/cli/latest/reference/gs.html). For examples of using the AWS CLI to upload archives to S3 Glacier, see [Using S3 Glacier with the AWS Command Line Interface](https://docs.aws.amazon.com/cli/latest/reference/gs.html).

Beyond the getting started section, you'll probably want to learn more about S3 Glacier operations. The following sections provide detailed information about working with S3 Glacier by using the REST API and the AWS SDKs for Java and Microsoft .NET:

- **Using the AWS SDKs with Amazon S3 Glacier**

  This section provides an overview of the AWS SDKs used in various code examples in this guide. A review of this section will help when reading the following sections. It includes an overview of the high-level and the low-level APIs that these SDKs offer, when to use them, and common steps for running the code examples provided in this guide.

- **Working with Vaults in Amazon S3 Glacier**

  This section provides details of various vault operations, such as creating a vault, retrieving vault metadata, using jobs to retrieve vault inventory, and configuring vault notifications. In addition to using the S3 Glacier console, you can use the AWS SDKs for various vault operations. This section describes the API and provides working samples by using the AWS SDK for Java and the AWS SDK for .NET.

- **Working with Archives in Amazon S3 Glacier**

  This section provides details of archive operations, such as uploading an archive in a single request or using a multipart upload operation to upload large archives in parts. The section also explains how to create jobs to download archives asynchronously. The section provides examples by using the AWS SDK for Java and the AWS SDK for .NET.

- **API Reference for Amazon S3 Glacier**
S3 Glacier is a RESTful service. This section describes the REST operations, including the syntax, and example requests and responses for all the operations. The AWS SDK libraries wrap this API, simplifying your programming tasks.

Amazon S3 Glacier Data Model

The Amazon S3 Glacier data model core components include vaults and archives. S3 Glacier is a REST-based web service. In terms of REST, vaults and archives are the resources. In addition, the S3 Glacier data model includes job and notification-configuration resources. These resources complement the core resources.

Topics

- **Vault**
- **Archive**
- **Job**
- **Notification Configuration**

Vault

In S3 Glacier, a vault is a container for storing archives. A vault is similar to an Amazon S3 bucket. When you create a vault, you specify a name and choose an AWS Region where you want to create the vault.

Each vault resource has a unique address. The general form is:

```
https://region-specific-endpoint/account-id/vaults/vault-name
```

For example, suppose that you create a vault (examplevault) in the US West (Oregon) Region in your account with the ID 111122223333. You can address this vault by using the following URI:

```
https://glacier.us-west-2.amazonaws.com/111122223333/vaults/examplevault
```

Here is what the various components of the URI mean:

- `glacier.us-west-2.amazonaws.com` identifies the US West (Oregon) Region.
- `111122223333` is the AWS account ID that owns the vault.
• **vaults** refers to the collection of vaults that are owned by the AWS account.

• **examplevault** identifies a specific vault in the vaults collection.

An AWS account can create vaults in any supported AWS Region. For list of supported AWS Regions, see [Accessing Amazon S3 Glacier](#). Within a Region, an account must use unique vault names. An AWS account can create same-named vaults in different Regions.

You can store an unlimited number of archives in a vault. Depending on your business or application needs, you can store these archives in one vault or multiple vaults.

S3 Glacier supports various vault operations. Vault operations are Region-specific. For example, when you create a vault, you create it in a specific Region. When you request a vault list, you request it from a specific AWS Region, and the resulting list includes only vaults created in that specific Region.

---

**Archive**

An **archive** can be any data, such as a photo, video, or document. An archive is similar to an Amazon S3 object, and is the base unit of storage in S3 Glacier. Each archive has a unique ID and an optional description. You can specify this optional description only during the upload of an archive. S3 Glacier assigns the archive an ID, which is unique in the AWS Region in which the archive is stored.

Each archive has a unique address. The general form is as follows:

```
https://region-specific-endpoint/account-id/vaults/vault-name/archives/archive-id
```

The following is an example URI of an archive stored in the examplevault vault in the US West (Oregon) Region in account 11112222333:

```
https://glacier.us-west-2.amazonaws.com/111122223333/vaults/examplevault/archives/NkbByEejwEggmBz2fTHgJrg0XBoDfjP4q6iu87-TjhqG6eGo0Y9Z8i1_AUyUsuhPAdTqlHy8pTl5nfCFJmD12yEZONi5L260mw12vcs01MNtHEQl8MBfGlqrEXAMPLEArchiveId
```

You can store an unlimited number of archives in a vault.

---

**Job**

An S3 Glacier job can retrieve an archive, or get an inventory of a vault.
Retrieving archives and vault inventories (lists of archives) are asynchronous operations in S3 Glacier, in which you first initiate a job, and then download the job output after S3 Glacier completes the job.

Note

S3 Glacier offers a cold-storage data-archival solution. If your application needs a storage solution that requires real-time data retrieval, you might consider using Amazon S3. For more information, see Amazon Simple Storage Service (Amazon S3).

To initiate a vault inventory job, you provide a vault name. Archive retrieval jobs require both the vault name and the archive ID. You can also provide an optional job description to help identify the jobs.

Archive retrieval and vault inventory jobs are associated with a vault. A vault can have multiple jobs in progress at any point in time. When you send a job request (initiate a job), S3 Glacier returns to you a job ID to track the job. Each job is uniquely identified by a URI of the form:

https://region-specific-endpoint/account-id/vaults/vault-name/jobs/job-id

The following is an example of a job associated with an examplevault vault in the US West (Oregon) Region in account 111122223333.

https://glacier.us-west-2.amazonaws.com/111122223333/vaults/examplevault/jobs/HkF9p6o7yjhFx-K3CGl6fuSm6VzW9T7esGQfco8nUXVYwS0j1b5gq1JZ55yHgt5vP54ZShjoQzQVVh7vEXAMPLEjobID

For each job, S3 Glacier maintains information, such as the job type, description, creation date, completion date, and job status. You can obtain information about a specific job or obtain a list of all your jobs associated with a vault. The list of jobs that S3 Glacier returns includes all the in-progress and recently finished jobs.

Notification Configuration

Because jobs take time to run, S3 Glacier supports a notification mechanism to notify you when a job is completed. You can configure a vault to send a notification to an Amazon Simple Notification Service (Amazon SNS) topic when a job is completed. You can specify one Amazon SNS topic per vault in the notification configuration.
S3 Glacier stores the notification configuration as a JSON document. The following is an example vault notification configuration:

```json
{
    "Events": ["ArchiveRetrievalCompleted", "InventoryRetrievalCompleted"]
}
```

Notification configurations are associated with vaults; you can have one for each vault. Each notification configuration resource is uniquely identified by a URI of the form:

https://region-specific-endpoint/account-id/vaults/vault-name/notification-configuration

S3 Glacier supports operations to set, get, and delete a notification configuration. When you delete a notification configuration, no notifications are sent when any data retrieval operation on the vault is completed.

**Supported Operations in S3 Glacier**

To work with vaults and archives (see Amazon S3 Glacier Data Model), Amazon S3 Glacier supports a set of operations. Among all the supported operations, only the following operations are asynchronous:

- Retrieving an archive
- Retrieving a vault inventory (list of archives)

These operations require you to first initiate a job and then download the job output. The following sections summarize the S3 Glacier operations.

**Vault Operations**

S3 Glacier provides operations to create and delete vaults. You can obtain a vault description for a specific vault or for all vaults in an AWS Region. The vault description provides information, such as the creation date, the number of archives in the vault, the total size in bytes used by all the archives in the vault, and the date that S3 Glacier generated the vault inventory. S3 Glacier also provides operations to set, retrieve, and delete a notification configuration on the vault. For more information, see Working with Vaults in Amazon S3 Glacier.
Archive Operations

S3 Glacier provides operations for you to upload and delete archives. You cannot update an existing archive; you must delete the existing archive and upload a new archive. Each time that you upload an archive, S3 Glacier generates a new archive ID. For more information, see Working with Archives in Amazon S3 Glacier.

Jobs

You can initiate an S3 Glacier job to perform a retrieval on an archive or get an inventory of a vault.

The following are the types of S3 Glacier jobs:

- archive-retrieval – Retrieve an archive.

  For more information, see Downloading an Archive in S3 Glacier.

- inventory-retrieval – Inventory a vault.

  For more information, see Downloading a Vault Inventory in Amazon S3 Glacier.

Accessing Amazon S3 Glacier

Amazon S3 Glacier is a RESTful web service that uses HTTP and HTTPS as a transport protocol and JavaScript Object Notation (JSON) as a message-serialization format. Your application code can make requests directly to the S3 Glacier web service API. When using the REST API directly, you must write the necessary code to sign and authenticate your requests. For more information about the API, see API Reference for Amazon S3 Glacier.

Alternatively, you can simplify application development by using the AWS SDKs that wrap the S3 Glacier REST API calls. You provide your credentials, and these libraries take care of authentication and request signing. For more information about using the AWS SDKs, see Using the AWS SDKs with Amazon S3 Glacier.

S3 Glacier also provides a console. However, all archive and job operations require you to write code and make requests by using either the REST API directly or the AWS SDK wrapper libraries. To access the S3 Glacier console, go to S3 Glacier Console.
Regions and Endpoints

You create a vault in a specific AWS Region. You always send your S3 Glacier requests to an endpoint specific to an AWS Region. For a list of the AWS Regions supported by S3 Glacier, see Amazon S3 Glacier endpoints and quotas in the AWS General Reference.
Getting Started with Amazon S3 Glacier

You can get started with Amazon S3 Glacier (S3 Glacier) by working with vaults and archives. A vault is a container for storing archives, and an archive is any object, such as a photo, video, or document, that you store in a vault. An archive is the base unit of storage in S3 Glacier. This getting started exercise provides instructions for you to explore basic S3 Glacier operations on vaults and archives. For more information about these resources, see the Amazon S3 Glacier Data Model section.

In the getting started exercise, you will create a vault, upload and download an archive, and then delete the archive and the vault. You can do all these operations programmatically. However, the getting started exercise uses the S3 Glacier management console to create and delete a vault. For uploading and downloading an archive, this getting started section uses the high-level API for the AWS SDK for Java and the AWS SDK for .NET. The high-level API provides a simplified programming experience when working with S3 Glacier. For more information about using the high-level API with the AWS SDKs, see Using the AWS SDKs with Amazon S3 Glacier.

⚠️ Important

S3 Glacier does provide a console. However, any archive operation, such as upload, download, or deletion, requires you to use the AWS Command Line Interface (CLI) or write code. There is no console support for archive operations. For example, to upload data, such as photos, videos, and other documents, you must either use the AWS CLI or write code to make requests, by using either the REST API directly or by using the AWS SDKs. To install the AWS CLI, see AWS Command Line Interface. For more information about using S3 Glacier with the AWS CLI, see the AWS CLI Reference for S3 Glacier. For examples of using the AWS CLI to upload archives to S3 Glacier, see Using S3 Glacier with the AWS Command Line Interface.

This getting started exercise provides code examples in Java and C# for you to upload and download an archive. The last section of the getting started exercise provides steps where you can learn more about the developer experience with S3 Glacier.

Topics

• Step 1: Before You Begin with S3 Glacier
Step 1: Before You Begin with S3 Glacier

Before you can start with this exercise, you must sign up for an AWS account (if you don't already have one), and then download one of the AWS SDKs. See the following sections for instructions.

Topics

• Set Up an AWS account and an Administrator User
• Download the Appropriate AWS SDK

Set Up an AWS account and an Administrator User

If you have not already done so, you must sign up for an AWS account and create an administrator user in the account.

To complete the setup, follow the instructions in the following topics.

Set Up an AWS account and Create an Administrator User

Sign up for AWS

When you sign up for Amazon Web Services (AWS), your AWS account is automatically signed up for all services in AWS, including S3 Glacier. You are charged only for the services that you use. For more information about S3 Glacier usage rates, see the Amazon S3 Glacier pricing page.

If you already have an AWS account, skip to Download the Appropriate AWS SDK. If you don't have an AWS account, use the following procedure to create one.

If you do not have an AWS account, complete the following steps to create one.
To sign up for an AWS account

2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an AWS account root user is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to a user, and use only the root user to perform tasks that require root user access.

To create an administrator user, choose one of the following options.

Download the Appropriate AWS SDK

To try the getting started exercise, you must decide which programming language you want to use, and then download the appropriate AWS SDK for your development platform.

The getting started exercise provides examples in Java and C#.

Downloading the AWS SDK for Java

To test the Java examples in this developer guide, you need the AWS SDK for Java. You have the following download options:

- If you are using Eclipse, you can download and install the AWS Toolkit for Eclipse by using the update site http://aws.amazon.com/eclipse/. For more information, see AWS Toolkit for Eclipse.
- If you are using any other IDE to create your application, download the AWS SDK for Java.

Downloading the AWS SDK for .NET

To test the C# examples in this developer guide, you need the AWS SDK for .NET. You have the following download options:

- If you are using Visual Studio, you can install both the AWS SDK for .NET and the AWS Toolkit for Visual Studio. The toolkit provides AWS Explorer for Visual Studio and project templates that you can use for development. To download the AWS SDK for .NET, go to http://aws.amazon.com/sdkfornet. By default, the installation script installs both the AWS SDK and the AWS Toolkit for Visual Studio. To learn more about the toolkit, see the AWS Toolkit for Visual Studio User Guide.
If you are using any other IDE to create your application, you can use the same link provided in the preceding step and install only the AWS SDK for .NET.

**Step 2: Create a Vault in S3 Glacier**

A vault is a container for storing archives. Your first step is to create a vault in one of the supported AWS Regions. For a list of the AWS Regions that are supported by Amazon S3 Glacier, see [Amazon S3 Glacier endpoints and quotas](#) in the [AWS General Reference](#).

You can create vaults programmatically or by using the S3 Glacier console. This section uses the console to create a vault.

**To create a vault**

2. In the left navigation pane, choose **Vaults**.
3. Choose **Create vault**.
   
   The **Create vault** page opens.

4. Under **Select a Region**, select an AWS Region from the Region selector. Your vault will be located in the Region that you select.

5. For **Vault name**, enter a name for your vault.
   
   The following are the vault-naming requirements:

   - A vault name must be unique within an AWS account and the AWS Region in which the vault is created.
   - A vault name must be between 1 and 255 characters long.
   - A vault name can contain only the following characters: a–z, A–Z, 0–9, _ (underscore), - (hyphen), and . (period).

6. Under **Event notifications**, to turn on or off notifications on a vault for when a job is completed, choose one of the following settings:

   - **Turn off notifications** – Notifications are turned off, and notifications are not sent to an Amazon Simple Notification Service (Amazon SNS) topic when a specified job is completed.
• Turn on notifications – Notifications are turned on, and notifications are sent to the provided Amazon SNS topic when a specified job is completed.

If you chose Turn on notifications, see Configuring Vault Notifications by Using the Amazon S3 Glacier Console.

7. If the AWS Region and vault name are correct, then choose Create vault.

Your new vault is now listed on the Vaults page in the S3 Glacier console.

Step 3: Upload an Archive to a Vault in S3 Glacier

In this step, you'll upload a sample archive to the vault that you created in the preceding step (see Step 2: Create a Vault in S3 Glacier). Depending on the development platform that you're using, choose one of the links at the end of this section.

Important

Any archive operation, such as upload, download, or deletion, requires you to use the AWS Command Line Interface (CLI) or write code. There is no console support for archive operations. For example, to upload data, such as photos, videos, and other documents, you must either use the AWS CLI or write code to make requests, by using either the REST API directly or by using the AWS SDKs.

To install the AWS CLI, see AWS Command Line Interface. For more information about using S3 Glacier with the AWS CLI, see AWS CLI Reference for S3 Glacier. For examples of using the AWS CLI to upload archives to S3 Glacier, see Using S3 Glacier with the AWS Command Line Interface.

An archive is any object, such as a photo, video, or document, that you store in a vault. An archive is the base unit of storage in S3 Glacier. You can upload an archive in a single request. For large archives, S3 Glacier provides a multipart upload API operation that enables you to upload an archive in parts.

In this getting started section, you upload a sample archive in a single request. For this exercise, you specify a file that is smaller in size. For larger files, multipart upload is suitable. For more information, see Uploading Large Archives in Parts (Multipart Upload).

Upload an Archive to a Vault in S3 Glacier by Using the AWS SDK for Java

The following Java code example uses the high-level API of the AWS SDK for Java to upload a sample archive to the vault. In the code example, note the following:

- The example creates an instance of the `AmazonGlacierClient` class.
- The example uses the `upload` API operation of the `ArchiveTransferManager` class from the high-level API of the AWS SDK for Java.
- The example uses the US West (Oregon) Region (`us-west-2`).

For step-by-step instructions on how to run this example, see Running Java Examples for Amazon S3 Glacier Using Eclipse. You must update the code as shown with the name of the archive file that you want to upload.

Note

Amazon S3 Glacier keeps an inventory of all the archives in your vaults. When you upload the archive in the following example, it will not appear in a vault in the management console until the vault inventory has been updated. This update usually happens once a day.

**Upload an Archive to a Vault in S3 Glacier by Using the AWS SDK for .NET**

The following C# code example uses the high-level API of the AWS SDK for .NET to upload a sample archive to the vault. In the code example, note the following:

• The example creates an instance of the `ArchiveTransferManager` class for the specified Amazon S3 Glacier Region endpoint.

• The code example uses the US West (Oregon) Region (`us-west-2`).
• The example uses the Upload API operation of the ArchiveTransferManager class to upload your archive. For small archives, this operation uploads the archive directly to S3 Glacier. For larger archives, this operation uses the multipart upload API operation in S3 Glacier to split the upload into multiple parts for better error recovery, if any errors are encountered while streaming the data to S3 Glacier.

For step-by-step instructions on how to run the following example, see Running Code Examples. You must update the code as shown with the name of your vault and the name of the archive file to upload.

**Note**

S3 Glacier keeps an inventory of all the archives in your vaults. When you upload the archive in the following example, the archive will not appear in a vault in the management console until the vault inventory has been updated. This update usually happens once a day.

---

Example — Uploading an Archive by Using the High-Level API of the AWS SDK for .NET

```csharp
using System;
using Amazon.Glacier;
using Amazon.Glacier.Transfer;
using Amazon.Runtime;

namespace glacier.amazon.com.docsamples
{
    class ArchiveUploadHighLevel_GettingStarted
    {
        static string vaultName = "examplevault";
        static string archiveToUpload = "*** Provide file name (with full path) to upload ***";

        public static void Main(string[] args)
        {
            try
            {
                var manager = new ArchiveTransferManager(Amazon.RegionEndpoint.USWest2);
                // Upload an archive.
            }
        }
    }
}
```
Step 4: Download an Archive from a Vault in S3 Glacier

In this step, you'll download the sample archive that you uploaded previously in Step 3: Upload an Archive to a Vault in S3 Glacier.

⚠️ Important

Amazon S3 Glacier does provide a console. However, any archive operation, such as upload, download, or deletion, requires you to use the AWS Command Line Interface (CLI) or write code. There is no console support for archive operations. For example, to upload data, such as photos, videos, and other documents, you must either use the AWS CLI or write code to make requests, by using either the REST API directly or by using the AWS SDKs.

To install the AWS CLI, see AWS Command Line Interface. For more information about using S3 Glacier with the AWS CLI, see AWS CLI Reference for S3 Glacier. For examples of using the AWS CLI to upload archives to S3 Glacier, see Using S3 Glacier with the AWS Command Line Interface.

In general, retrieving your data from S3 Glacier is a two-step process:

1. Initiate a retrieval job.
2. After the job is completed, download the bytes of data.
To retrieve an archive from S3 Glacier, you first initiate a job. After the job is completed, you download the data. For more information about archive retrievals, see [Retrieving S3 Glacier Archives Using AWS Console](#).

The access time of your request depends on the retrieval option that you choose: Expedited, Standard, or Bulk retrievals. For all but the largest archives (250 MB+), archives accessed by using Expedited retrievals are typically made available within 1–5 minutes. Archives retrieved by using Standard retrievals typically are available between 3–5 hours. Bulk retrievals typically are available within 5–12 hours. For more information about the various retrieval options, see the [S3 Glacier FAQ](#). For information about data retrieval charges, see the [S3 Glacier pricing page](#).

The code examples shown in the following topics initiate the job, wait for it to be completed, and then download the archive's data.

**Download an Archive from a Vault in S3 Glacier by Using the AWS SDK for Java**

The following Java code example uses the high-level API of the AWS SDK for Java to download the archive that you uploaded in the previous step. In the code example, note the following:

- The example creates an instance of the `AmazonGlacierClient` class.
- The code uses the US West (Oregon) Region (`us-west-2`) to match the location where you created the vault in [Step 2: Create a Vault in S3 Glacier](#).
- The example uses the `download` API operation of the `ArchiveTransferManager` class from the high-level API of the AWS SDK for Java. The example creates an Amazon Simple Notification Service (Amazon SNS) topic, and an Amazon Simple Queue Service (Amazon SQS) queue that is subscribed to that topic. If you created an AWS Identity and Access Management (IAM) admin user as instructed in [Step 1: Before You Begin with S3 Glacier](#), your user has the necessary IAM permissions for the creation and use of the Amazon SNS topic and Amazon SQS queue.

Download an Archive from a Vault in S3 Glacier by Using the AWS SDK for .NET

The following C# code example uses the high-level API of the AWS SDK for .NET to download the archive that you uploaded previously in Upload an Archive to a Vault in S3 Glacier by Using the AWS SDK for .NET. In the code example, note the following:

- The example creates an instance of the ArchiveTransferManager class for the specified Amazon S3 Glacier Region endpoint.
- The code example uses the US West (Oregon) Region (us-west-2) to match the location where you created the vault previously in Step 2: Create a Vault in S3 Glacier.
- The example uses the Download API operation of the ArchiveTransferManager class to download your archive. The example creates an Amazon Simple Notification Service (Amazon SNS) topic, and an Amazon Simple Queue Service (Amazon SQS) queue that is subscribed to that topic. If you created an AWS Identity and Access Management (IAM) admin user as instructed in Step 1: Before You Begin with S3 Glacier, your user has the necessary IAM permissions for the creation and use of the Amazon SNS topic and Amazon SQS queue.
- The example then initiates the archive retrieval job and polls the queue for the archive to be available. When the archive is available, the download begins. For information about retrieval times, see Archive Retrieval Options.

For step-by-step instructions on how to run this example, see Running Code Examples. You must update the code as shown with the archive ID of the file that you uploaded in Step 3: Upload an Archive to a Vault in S3 Glacier.

Example — Download an Archive by Using the High-Level API of the AWS SDK for .NET

```csharp
using System;
using Amazon.Glacier;
```
using Amazon.Glacier.Transfer;
using Amazon.Runtime;

namespace glacier.amazon.com.docsamples

                currentPercentage = args.PercentDone;
            }
        }
    }
}
Step 5: Delete an Archive from a Vault in S3 Glacier

In this step, you'll delete the sample archive that you uploaded in Step 3: Upload an Archive to a Vault in S3 Glacier.

**Important**

You cannot delete an archive by using the Amazon S3 Glacier console. Any archive operation, such as upload, download, or deletion, requires you to use the AWS Command Line Interface (CLI) or write code. To upload data, such as photos, videos, and other documents, you must either use the AWS CLI or write code to make requests, by using either the REST API directly or by using the AWS SDKs.

To install the AWS CLI, see [AWS Command Line Interface](https://aws.amazon.com/cli/). For more information about using S3 Glacier with the AWS CLI, see [AWS CLI Reference for S3 Glacier](https://docs.aws.amazon.com/cli/latest/reference/s3glacier/). For examples of using the AWS CLI to upload archives to S3 Glacier, see [Using S3 Glacier with the AWS Command Line Interface](https://docs.aws.amazon.com/cli/latest/reference/s3glacier/).

Delete the sample archive by following one of these SDKs or the AWS CLI:

Delete an Archive from a Vault in S3 Glacier by Using the AWS SDK for Java

The following code example uses the AWS SDK for Java to delete the archive. In the code, note the following:

- The `DeleteArchiveRequest` object describes the delete request, including the vault name where the archive is located and the archive ID.
- The `deleteArchive` API operation sends the request to Amazon S3 Glacier to delete the archive.
- The example uses the US West (Oregon) Region (`us-west-2`).

For step-by-step instructions on how to run this example, see Running Java Examples for Amazon S3 Glacier Using Eclipse. You must update the code as shown with the archive ID of the file that you uploaded in Step 3: Upload an Archive to a Vault in S3 Glacier.

Example — Deleting an Archive by Using the AWS SDK for Java

```java
import java.io.IOException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.glacier.AmazonGlacierClient;
import com.amazonaws.services.glacier.model.DeleteArchiveRequest;

public class AmazonGlacierDeleteArchive_GettingStarted {
    public static String vaultName = "examplevault";
    public static String archiveId = "*** provide archive ID***";
    public static AmazonGlacierClient client;

    public static void main(String[] args) throws IOException {
        ProfileCredentialsProvider credentials = new ProfileCredentialsProvider();
        client = new AmazonGlacierClient(credentials);
        client.setEndpoint("https://glacier.us-west-2.amazonaws.com/");

        try {
```
// Delete the archive.
client.deleteArchive(new DeleteArchiveRequest()
    .withVaultName(vaultName)
    .withArchiveId(archiveId));

System.out.println("Deleted archive successfully.");

} catch (Exception e) {
    System.err.println("Archive not deleted.");
    System.err.println(e);
}
}

Delete an Archive in S3 Glacier by Using the AWS CLI

You can delete archives in Amazon S3 Glacier by using the AWS Command Line Interface (AWS CLI).

Topics

• (Prerequisite) Setting Up the AWS CLI
• Example: Deleting an Archive by Using the AWS CLI

(Prerequisite) Setting Up the AWS CLI

1. Download and configure the AWS CLI. For instructions, see the following topics in the AWS Command Line Interface User Guide:

   - Installing the AWS Command Line Interface
   - Configuring the AWS Command Line Interface

2. Verify your AWS CLI setup by entering the following commands at the command prompt. These commands don't provide credentials explicitly, so the credentials of the default profile are used.
• Try using the help command.

```bash
aws help
```

• To get a list of S3 Glacier vaults on the configured account, use the `list-vaults` command. Replace `123456789012` with your AWS account ID.

```bash
aws glacier list-vaults --account-id 123456789012
```

• To see the current configuration data for the AWS CLI, use the `aws configure list` command.

```bash
aws configure list
```

**Example: Deleting an Archive by Using the AWS CLI**

1. Use the `initiate-job` command to start an inventory retrieval job. For more information on the `initiate-job` command, see [Initiate Job](#).  

```bash
aws glacier initiate-job --vault-name awsexamplevault --account-id 111122223333 --job-parameters "{"Type": "inventory-retrieval"}"
```

Expected output:

```json
{
   "location": "/111122223333/vaults/awsexamplevault/jobs/*** jobid ***,
   "jobId": "*** jobid ***"
}
```

2. Use the `describe-job` command to check the status of the previous retrieval job. For more information on the `describe-job` command, see [Describe Job](#).

```bash
aws glacier describe-job --vault-name awsexamplevault --account-id 111122223333 --job-id *** jobid ***
```

Expected output:

```json
{
}
```
3. Wait for the job to be completed.

You must wait until the job output is ready for you to download. If you set a notification configuration on the vault or specified an Amazon Simple Notification Service (Amazon SNS) topic when you initiated the job, S3 Glacier sends a message to the topic after it completes the job.

You can set notification configuration for specific events on the vault. For more information, see Configuring Vault Notifications in Amazon S3 Glacier. S3 Glacier sends a message to the specified Amazon SNS topic anytime the specific event occurs.

4. When the job is complete, use the `get-job-output` command to download the retrieval job to the file `output.json`. For more information on the `get-job-output` command, see Get Job Output.

   ```bash
   aws glacier get-job-output --vault-name awsexamplevault --account-id 111122223333 --job-id *** jobid *** output.json
   ```

This command produces a file with the following fields.

```json
{
   "InventoryDate": "*** job completion date ***",
   "ArchiveList": [{
      "ArchiveId": "*** archiveid ***",
      "ArchiveDescription": "*** archive description (if set) ***",
      "CreationDate": "*** archive creation date ***",
      "Size": "*** archive size (in bytes) ***",
      "SHA256TreeHash": "*** archive hash ***"
   }],
   "ArchiveId": 123456789
}
```
5. Use the `delete-archive` command to delete each archive from a vault until none remain.

```bash
aws glacier delete-archive --vault-name awsexamplevault --account-id 111122223333 --archive-id="*** archiveid ***"
```

For more information on the `delete-archive` command, see [Delete Archive](#).

## Step 6: Delete a Vault in S3 Glacier

A vault is a container for storing archives. To delete an Amazon S3 Glacier vault, you must first delete all existing archives in the vault as of the last inventory that S3 Glacier computed.

You can delete a vault programmatically or by using the S3 Glacier console. For information about deleting a vault programmatically, see [Deleting a Vault in Amazon S3 Glacier](#).

⚠️ **Important**

If you upload an archive to a vault or delete an archive from a vault within the recent 24 hours, you must wait until the last vault inventory is updated to reflect the latest information. S3 Glacier prepares an inventory for each vault periodically, every 24 hours.

### To delete an empty vault

2. From the **Select a Region** menu, choose the AWS Region for the vault that you want to delete.

   In this getting started exercise, your example vault is in the US West (Oregon) Region.

3. Select the option button next to the empty vault that you want to delete. If the vault is not empty, you must delete all archives before deleting the vault. For more information, see [Deleting an Archive in Amazon S3 Glacier](#).
Important
Deleting a vault can't be undone.

4. Choose **Delete**.
5. The **Delete vault** dialog box appears. Choose **Delete**.

To delete a nonempty vault

1. If you're deleting a nonempty vault, you must first delete all existing archives before deleting the vault. You can do this by writing code to make a delete archive request by using either the REST API, the AWS SDK for Java, the AWS SDK for .NET or the AWS CLI. For information about deleting archives, see **Step 5: Delete an Archive from a Vault in S3 Glacier**.
2. After the vault is empty, follow the steps to delete an empty vault in the preceding procedure.

Where Do I Go From Here?

Working with Vaults in Amazon S3 Glacier

A vault is a container for storing archives. When you create a vault, you specify a vault name and the AWS Region in which you want to create the vault. For a list of the AWS Regions supported by S3 Glacier, see Amazon S3 Glacier endpoints and quotas in the AWS General Reference.

You can store an unlimited number of archives in a vault.

⚠️ Important

S3 Glacier does provide a console. However, any archive operation, such as upload, download, or deletion, requires you to use the AWS Command Line Interface (AWS CLI) or write code. There is no console support for archive operations. For example, to upload data, such as photos, videos, and other documents, you must either use the AWS CLI or write code to make requests, by using either the REST API directly or by using the AWS SDKs. To install the AWS CLI, see AWS Command Line Interface. For more information about using S3 Glacier with the AWS CLI, see AWS CLI Reference for S3 Glacier. For examples of using the AWS CLI to upload archives to S3 Glacier, see Using S3 Glacier with the AWS Command Line Interface.

Vault Operations in S3 Glacier

S3 Glacier supports various vault operations. Vault operations are specific to particular AWS Regions. In other words, when you create a vault, you create it in a specific AWS Region. When you list vaults, S3 Glacier returns the vault list from the AWS Region that you specified in the request.

Creating and Deleting Vaults

An AWS account can create up to 1,000 vaults per AWS Region. For a list of the AWS Regions supported by S3 Glacier, see Amazon S3 Glacier endpoints and quotas in the AWS General Reference.

You can delete a vault only if there are no archives in the vault as of the last inventory that S3 Glacier computed and if there have been no writes to the vault since the last inventory.

Note

S3 Glacier prepares an inventory for each vault periodically, every 24 hours. Because the inventory might not reflect the latest information, S3 Glacier ensures that the vault is indeed empty by checking if there were any write operations since the last vault inventory.

For more information, see Creating a Vault in Amazon S3 Glacier and Deleting a Vault in Amazon S3 Glacier.

Retrieving Vault Metadata

You can retrieve vault information such as the vault creation date, number of archives in the vault, and the total size of all the archives in the vault. S3 Glacier provides API calls for you to retrieve this information for a specific vault or all the vaults in a specific AWS Region in your account. For more information, see Retrieving Vault Metadata in Amazon S3 Glacier.

Downloading a Vault Inventory

A vault inventory refers to the list of archives in a vault. For each archive in the list, the inventory provides archive information, such as the archive ID, creation date, and size. S3 Glacier updates the vault inventory once a day, starting on the day that the first archive is uploaded to the vault. A vault inventory must exist for you to be able to download it.
Downloading a vault inventory is an asynchronous operation. You must first initiate a job to download the inventory. After receiving the job request, S3 Glacier prepares your inventory for download. After the job is completed, you can download the inventory data.

Given the asynchronous nature of the job, you can use Amazon Simple Notification Service (Amazon SNS) notifications to notify you when the job is completed. You can specify an Amazon SNS topic for each individual job request or configure your vault to send a notification when specific vault events occur.

S3 Glacier prepares an inventory for each vault periodically, every 24 hours. If there have been no archive additions or deletions to the vault since the last inventory, the inventory date is not updated.

When you initiate a job for a vault inventory, S3 Glacier returns the last inventory that it generated, which is a point-in-time snapshot and not real-time data. You might not find it useful to retrieve vault inventory for each archive upload. However, suppose that you maintain a database on the client-side that contains metadata associated with the archives that you upload to S3 Glacier. In that case, you might find the vault inventory useful to reconcile information in your database with the actual vault inventory.

For more information about retrieving a vault inventory, see Downloading a Vault Inventory in Amazon S3 Glacier.

**Configuring Vault Notifications**

Retrieving anything from S3 Glacier, such as an archive from a vault or a vault inventory, is a two-step process. First, you initiate a job. After the job is completed, you download the output. To learn when your job is complete, you can use S3 Glacier notifications. S3 Glacier sends notification messages to an Amazon Simple Notification Service (Amazon SNS) topic that you provide.

You can configure notifications on a vault and identify vault events and the Amazon SNS topic to be notified when the event occurs. Anytime the vault event occurs, S3 Glacier sends a notification to the specified Amazon SNS topic. For more information, see Configuring Vault Notifications in Amazon S3 Glacier.

**Creating a Vault in Amazon S3 Glacier**

Creating a vault adds a vault to the set of vaults in your account. An AWS account can create up to 1,000 vaults per AWS Region. For a list of the AWS Regions supported by Amazon S3 Glacier (S3 Glacier), see Regions and Endpoints in the AWS General Reference.
When you create a vault, you must provide a vault name. The following are the vault naming requirements:

- Names can be between 1 and 255 characters long.
- Allowed characters are a–z, A–Z, 0–9, '_' (underscore), '-' (hyphen), and '.' (period).

Vault names must be unique within an account and the AWS Region in which the vault is being created. That is, an account can create vaults with the same name in different AWS Regions but not in the same AWS Region.

Creating a Vault in Amazon S3 Glacier Using the AWS SDK for Java

The low-level API provides methods for all the vault operations, including creating and deleting vaults, getting a vault description, and getting a list of vaults created in a specific AWS Region. The following are the steps to create a vault using the AWS SDK for Java.

1. Create an instance of the AmazonGlacierClient class (the client).

   You need to specify an AWS Region in which you want to create a vault. All operations you perform using this client apply to that AWS Region.

2. Provide request information by creating an instance of the CreateVaultRequest class.

   Amazon S3 Glacier (S3 Glacier) requires you to provide a vault name and your account ID. If you don't provide an account ID, then the account ID associated with the credentials you provide to sign the request is used. For more information, see Using the AWS SDK for Java with Amazon S3 Glacier.

3. Run the createVault method by providing the request object as a parameter.
The response S3 Glacier returns is available in the CreateVaultResult object.

The following Java code snippet illustrates the preceding steps. The snippet creates a vault in the us-west-2 Region. The Location it prints is the relative URI of the vault that includes your account ID, the AWS Region, and the vault name.

```java
AmazonGlacierClient client = new AmazonGlacierClient(credentials);
client.setEndpoint("https://glacier.us-west-2.amazonaws.com");

CreateVaultRequest request = new CreateVaultRequest()
    .withVaultName("*** provide vault name ***");
CreateVaultResult result = client.createVault(request);
System.out.println("Created vault successfully: " + result.getLocation());
```

**Note**
For information about the underlying REST API, see [Create Vault (PUT vault)](https://docs.aws.amazon.com/glacier/latest/dev/create-vault-api.html).

### Example: Creating a Vault Using the AWS SDK for Java

The following Java code example creates a vault in the us-west-2 Region (for more information on AWS Regions, see [Accessing Amazon S3 Glacier](https://docs.aws.amazon.com/glacier/latest/user/accessing_amazon_s3_glacier.html)). In addition, the code example retrieves the vault information, lists all vaults in the same AWS Region, and then deletes the vault created.

Creating a Vault in Amazon S3 Glacier Using the AWS SDK for .NET

Both the high-level and low-level APIs provided by the Amazon SDK for .NET provide a method to create a vault.

Topics
Creating a Vault Using the High-Level API of the AWS SDK for .NET

The ArchiveTransferManager class of the high-level API provides the CreateVault method you can use to create a vault in an AWS Region.

Example: Vault Operations Using the High-Level API of the AWS SDK for .NET

The following C# code example creates and delete a vault in the US West (Oregon) Region. For a list of AWS Regions in which you can create vaults, see Accessing Amazon S3 Glacier.

For step-by-step instructions on how to run the following example, see Running Code Examples. You need to update the code as shown with a vault name.

Example

```csharp
using System;
using Amazon.Glacier;
using Amazon.Glacier.Transfer;
using Amazon.Runtime;

namespace glacier.amazon.com.docsamples
{
    class VaultCreateDescribeListVaultsDeleteHighLevel
    {
        static string vaultName = "*** Provide vault name ***";

        public static void Main(string[] args)
        {
            try
            {
                var manager = new ArchiveTransferManager(Amazon.RegionEndpoint.USWest2);
                manager.CreateVault(vaultName);
                Console.WriteLine("Vault created. To delete the vault, press Enter");
                Console.ReadKey();
                manager.DeleteVault(vaultName);
                Console.WriteLine("\nVault deleted. To continue, press Enter");
                Console.ReadKey();
            }
            catch (AmazonGlacierException e) { Console.WriteLine(e.Message); }
        }
    }
}
```
Creating a Vault Using the Low-Level API of the AWS SDK for .NET

The low-level API provides methods for all the vault operations, including create and delete vaults, get a vault description, and get a list of vaults created in a specific AWS Region. The following are the steps to create a vault using the AWS SDK for .NET.

1. Create an instance of the AmazonGlacierClient class (the client).

   You need to specify an AWS Region in which you want to create a vault. All operations you perform using this client apply to that AWS Region.

2. Provide request information by creating an instance of the CreateVaultRequest class.

   Amazon S3 Glacier (S3 Glacier) requires you to provide a vault name and your account ID. If you don't provide an account ID, then account ID associated with the credentials you provide to sign the request is assumed. For more information, see Using the AWS SDK for .NET with Amazon S3 Glacier.

3. Run the CreateVault method by providing the request object as a parameter.

   The response S3 Glacier returns is available in the CreateVaultResponse object.

Example: Vault Operations Using the Low-Level API of the AWS SDK for .NET

The following C# example illustrates the preceding steps. The example creates a vault in the US West (Oregon) Region. In addition, the code example retrieves the vault information, lists all vaults in the same AWS Region, and then deletes the vault created. The Location printed is the relative URI of the vault that includes your account ID, the AWS Region, and the vault name.

```csharp
    catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
    catch (Exception e) { Console.WriteLine(e.Message); }
    Console.WriteLine("To continue, press Enter");
    Console.ReadKey();
}
}

1. Create an instance of the AmazonGlacierClient class (the client).

   You need to specify an AWS Region in which you want to create a vault. All operations you perform using this client apply to that AWS Region.

2. Provide request information by creating an instance of the CreateVaultRequest class.

   Amazon S3 Glacier (S3 Glacier) requires you to provide a vault name and your account ID. If you don't provide an account ID, then account ID associated with the credentials you provide to sign the request is assumed. For more information, see Using the AWS SDK for .NET with Amazon S3 Glacier.

Creating a Vault in Amazon S3 Glacier Using the REST API

To create a vault using the REST API, see Create Vault (PUT vault).

Creating a Vault Using the Amazon S3 Glacier Console

To create a vault using the Amazon S3 Glacier (S3 Glacier) console, see Step 2: Create a Vault in S3 Glacier in the Getting Started tutorial.

Creating a Vault in Amazon S3 Glacier Using the AWS Command Line Interface

Follow these steps to create a vault in Amazon S3 Glacier (S3 Glacier) using the AWS Command Line Interface (AWS CLI).

Topics

- (Prerequisite) Setting Up the AWS CLI
- Example: Creating a Vault Using the AWS CLI

(Prerequisite) Setting Up the AWS CLI

1. Download and configure the AWS CLI. For instructions, see the following topics in the AWS Command Line Interface User Guide:
2. Verify your AWS CLI setup by entering the following commands at the command prompt. These commands don't provide credentials explicitly, so the credentials of the default profile are used.

- Try using the help command.

```bash
aws help
```

- To get a list of S3 Glacier vaults on the configured account, use the `list-vaults` command. Replace `123456789012` with your AWS account ID.

```bash
aws glacier list-vaults --account-id 123456789012
```

- To see the current configuration data for the AWS CLI, use the `aws configure list` command.

```bash
aws configure list
```

**Example: Creating a Vault Using the AWS CLI**

1. Use the `create-vault` command to create a vault named `awsexamplevault` under account `111122223333`.

```bash
aws glacier create-vault --vault-name awsexamplevault --account-id 111122223333
```

Expected output:

```json
{
  "location": "/111122223333/vaults/awsexamplevault"
}
```

2. Verify creation using the `describe-vault` command.
Retrieving Vault Metadata in Amazon S3 Glacier

You can retrieve vault information such as the vault creation date, number of archives in the vault, and the total size of all the archives in the vault. Amazon S3 Glacier (S3 Glacier) provides API calls for you to retrieve this information for a specific vault or all the vaults in a specific AWS Region in your account.

If you retrieve a vault list, S3 Glacier returns the list sorted by the ASCII values of the vault names. The list contains up to 1,000 vaults. You should always check the response for a marker at which to continue the list; if there are no more items the marker field is null. You can optionally limit the number of vaults returned in the response. If there are more vaults than are returned in the response, the result is paginated. You need to send additional requests to fetch the next set of vaults.

Retrieving Vault Metadata in Amazon S3 Glacier Using the AWS SDK for Java

- Example: Retrieving Vault Metadata Using the Amazon SDK for Java
Retrieve Vault Metadata for a Vault

You can retrieve metadata for a specific vault or all the vaults in a specific AWS Region. The following are the steps to retrieve vault metadata for a specific vault using the low-level API of the Amazon SDK for Java.

1. Create an instance of the AmazonGlacierClient class (the client).

   You need to specify an AWS Region where the vault resides. All operations you perform using this client apply to that AWS Region.

2. Provide request information by creating an instance of the DescribeVaultRequest class.

   Amazon S3 Glacier (S3 Glacier) requires you to provide a vault name and your account ID. If you don't provide an account ID, then the account ID associated with the credentials you provide to sign the request is assumed. For more information, see Using the AWS SDK for Java with Amazon S3 Glacier.

3. Run the describeVault method by providing the request object as a parameter.

   The vault metadata information that S3 Glacier returns is available in the DescribeVaultResult object.

The following Java code snippet illustrates the preceding steps.

```java
DescribeVaultRequest request = new DescribeVaultRequest()
   .withVaultName("*** provide vault name***");

DescribeVaultResult result = client.describeVault(request);

System.out.print(
   "\nCreationDate: " + result.getCreationDate() + 
   "\nLastInventoryDate: " + result.getLastInventoryDate() + 
   "\nNumberOfArchives: " + result.getNumberOfArchives() + 
   "\nSizeInBytes: " + result.getSizeInBytes() + 
   "\nVaultARN: " + result.getVaultARN() + 
   "\nVaultName: " + result.getVaultName());
```
Retrieve Vault Metadata for All Vaults in a Region

You can also use the listVaults method to retrieve metadata for all the vaults in a specific AWS Region.

The following Java code snippet retrieves list of vaults in the us-west-2 Region. The request limits the number of vaults returned in the response to 5. The code snippet then makes a series of listVaults calls to retrieve the entire vault list from the AWS Region.

```java
AmazonGlacierClient client;
client.setEndpoint("https://glacier.us-west-2.amazonaws.com/");

String marker = null;
do {
    ListVaultsRequest request = new ListVaultsRequest()
        .withLimit("5")
        .withMarker(marker);
    ListVaultsResult listVaultsResult = client.listVaults(request);

    List<DescribeVaultOutput> vaultList = listVaultsResult.getVaultList();
    marker = listVaultsResult.getMarker();
    for (DescribeVaultOutput vault : vaultList) {
        System.out.println("\nCreationDate: " + vault.getCreationDate() +
        "\nLastInventoryDate: " + vault.getLastInventoryDate() +
        "\nNumberOfArchives: " + vault.getNumberOfArchives() +
        "\nSizeInBytes: " + vault.getSizeInBytes() +
        "\nVaultARN: " + vault.getVaultARN() +
        "\nVaultName: " + vault.getVaultName());
    } while (marker != null);
```

In the preceding code segment, if you don't specify the Limit value in the request, S3 Glacier returns up to 10 vaults, as set by the S3 Glacier API. If there are more vaults to list, the response marker field contains the vault Amazon Resource Name (ARN) at which to continue the list with a new request; otherwise, the marker field is null.
Note that the information returned for each vault in the list is the same as the information you get by calling the describeVault method for a specific vault.

Note
The listVaults method calls the underlying REST API (see List Vaults (GET vaults)).

• Retrieve Vault Metadata for a Vault
• Retrieve Vault Metadata for All Vaults in a Region
• Example: Retrieving Vault Metadata Using the Low-Level API of the AWS SDK for .NET

Retrieve Vault Metadata for a Vault

You can retrieve metadata for a specific vault or all the vaults in a specific AWS Region. The following are the steps to retrieve vault metadata for a specific vault using the low-level API of the AWS SDK for .NET.

1. Create an instance of the AmazonGlacierClient class (the client).
   You need to specify an AWS Region where the vault resides. All operations you perform using this client apply to that AWS Region.

2. Provide request information by creating an instance of the DescribeVaultRequest class.
   Amazon S3 Glacier (S3 Glacier) requires you to provide a vault name and your account ID. If you don't provide an account ID, then the account ID associated with the credentials you provide to sign the request is assumed. For more information, see Using the AWS SDK for .NET with Amazon S3 Glacier.
3. Run the DescribeVault method by providing the request object as a parameter.

The vault metadata information that S3 Glacier returns is available in the DescribeVaultResult object.

The following C# code snippet illustrates the preceding steps. The snippet retrieves metadata information of an existing vault in the US West (Oregon) Region.

```csharp
AmazonGlacierClient client;
client = new AmazonGlacierClient(Amazon.RegionEndpoint.USWest2);

DescribeVaultRequest describeVaultRequest = new DescribeVaultRequest()
{
    VaultName = "*** Provide vault name ***"
};
DescribeVaultResponse describeVaultResponse =
    client.DescribeVault(describeVaultRequest);
Console.WriteLine("\nVault description...\n");
Console.WriteLine("\nVaultName: " + describeVaultResponse.VaultName +
    "\nVaultARN: " + describeVaultResponse.VaultARN +
    "\nVaultCreationDate: " + describeVaultResponse.CreationDate +
    "\nNumberOfArchives: " + describeVaultResponse.NumberOfArchives +
    "\nSizeInBytes: " + describeVaultResponse.SizeInBytes +
    "\nLastInventoryDate: " + describeVaultResponse.LastInventoryDate
    ");
```

Note
For information about the underlying REST API, see Describe Vault (GET vault).

Retrieve Vault Metadata for All Vaults in a Region

You can also use the ListVaults method to retrieve metadata for all the vaults in a specific AWS Region.

The following C# code snippet retrieves list of vaults in the US West (Oregon) Region. The request limits the number of vaults returned in the response to 5. The code snippet then makes a series of ListVaults calls to retrieve the entire vault list from the AWS Region.
AmazonGlacierClient client;
client = new AmazonGlacierClient(Amazon.RegionEndpoint.USWest2);
string lastMarker = null;
Console.WriteLine("\n List of vaults in your account in the specific AWS Region ...");
do
{
    ListVaultsRequest request = new ListVaultsRequest()
    {
        Limit = 5,
        Marker = lastMarker
    };
    ListVaultsResponse response = client.ListVaults(request);

    foreach (DescribeVaultOutput output in response.VaultList)
    {
        Console.WriteLine("Vault Name: {0} \tCreation Date: {1} \t #of archives: {2}",
                output.VaultName, output.CreationDate, output.NumberOfArchives);
    }
    lastMarker = response.Marker;
} while (lastMarker != null);

In the preceding code segment, if you don't specify the Limit value in the request, S3 Glacier returns up to 10 vaults, as set by the S3 Glacier API.

Note that the information returned for each vault in the list is the same as the information you get by calling the DescribeVault method for a specific vault.

⚠️ Note

The ListVaults method calls the underlying REST API (see List Vaults (GET vaults)).

Example: Retrieving Vault Metadata Using the Low-Level API of the AWS SDK for .NET

For a working code example, see Example: Vault Operations Using the Low-Level API of the AWS SDK for .NET. The C# code example creates a vault and retrieves the vault metadata.
Retrieving Vault Metadata Using the REST API

To list vaults using the REST API, see List Vaults (GET vaults). To describe one vault, see Describe Vault (GET vault).

Retrieving Vault Metadata in Amazon S3 Glacier Using the AWS Command Line Interface

This example shows how to retrieve vault information and metadata in Amazon S3 Glacier (S3 Glacier) using the AWS Command Line Interface (AWS CLI).

Topics

• (Prerequisite) Setting Up the AWS CLI
• Example: Retrieving Vault Metadata Using the AWS CLI

(Prerequisite) Setting Up the AWS CLI

1. Download and configure the AWS CLI. For instructions, see the following topics in the AWS Command Line Interface User Guide:

   Installing the AWS Command Line Interface

   Configuring the AWS Command Line Interface

2. Verify your AWS CLI setup by entering the following commands at the command prompt. These commands don't provide credentials explicitly, so the credentials of the default profile are used.

   • Try using the help command.

     ```
     aws help
     ```

   • To get a list of S3 Glacier vaults on the configured account, use the list-vaults command. Replace 123456789012 with your AWS account ID.

     ```
     aws glacier list-vaults --account-id 123456789012
     ```

   • To see the current configuration data for the AWS CLI, use the aws configure list command.
Example: Retrieving Vault Metadata Using the AWS CLI

- Use the describe-vault command to describe a vault named `awsexamplevault` under account `111122223333`.

```bash
aws glacier describe-vault --vault-name awsexamplevault --account-id 111122223333
```

Download a Vault Inventory in Amazon S3 Glacier

After you upload your first archive to your vault, Amazon S3 Glacier (S3 Glacier) automatically creates a vault inventory and then updates it approximately once a day. After S3 Glacier creates the first inventory, it typically takes half a day and up to a day before that inventory is available for retrieval. You can retrieve a vault inventory from S3 Glacier with the following two-step process:

1. Initiate an inventory retrieval job by using the [Initiate Job (POST jobs)](https://docs.aws.amazon.com/AmazonS3/latest/API/api_v2.html#Initiate-Job) operation.

   **Important**
   
   A data retrieval policy can cause your initiate retrieval job request to fail with a PolicyEnforcedException exception. For more information about data retrieval policies, see [S3 Glacier Data Retrieval Policies](https://docs.aws.amazon.com/AmazonS3/latest/API/amazon-s3-transfer-concepts.html#transfer-policies). For more information about the PolicyEnforcedException exception, see [Error Responses](https://docs.aws.amazon.com/AmazonS3/latest/API/ErrorResponses.html).

2. After the job completes, download the bytes using the [Get Job Output (GET output)](https://docs.aws.amazon.com/AmazonS3/latest/API/amazon-s3-transfer-concepts.html#transfers-get-output) operation.

   For example, retrieving an archive or a vault inventory requires you to first initiate a retrieval job. The job request is run asynchronously. When you initiate a retrieval job, S3 Glacier creates a job and returns a job ID in the response. When S3 Glacier completes the job, you can get the job output, the archive bytes, or the vault inventory data.

   The job must complete before you can get its output. To determine the status of the job, you have the following options:
• **Wait for job completion notification**—You can specify an Amazon Simple Notification Service (Amazon SNS) topic to which S3 Glacier can post a notification after the job is completed. You can specify Amazon SNS topic using the following methods:

  • Specify an Amazon SNS topic per job basis.

  When you initiate a job, you can optionally specify an Amazon SNS topic.

  • Set notification configuration on the vault.

  You can set notification configuration for specific events on the vault (see [Configuring Vault Notifications in Amazon S3 Glacier](#)). S3 Glacier sends a message to the specified SNS topic any time the specific event occur.

  If you have notification configuration set on the vault and you also specify an Amazon SNS topic when you initiate a job, S3 Glacier sends job completion message to both the topics.

  You can configure the SNS topic to notify you via email or store the message in an Amazon Simple Queue Service (Amazon SQS) that your application can poll. When a message appears in the queue, you can check if the job is completed successfully and then download the job output.

• **Request job information explicitly**—S3 Glacier also provides a describe job operation ([Describe Job (GET JobID)](#)) that enables you to poll for job information. You can periodically send this request to obtain job information. However, using Amazon SNS notifications is the recommended option.

---

**Note**

The information you get via SNS notification is the same as what you get by calling Describe Job.

About the Inventory

S3 Glacier updates a vault inventory approximately once a day, starting on the day you first upload an archive to the vault. If there have been no archive additions or deletions to the vault since the last inventory, the inventory date is not updated. When you initiate a job for a vault inventory, S3 Glacier returns the last inventory it generated, which is a point-in-time snapshot and not real-time data. Note that after S3 Glacier creates the first inventory for the vault, it typically takes half a day and up to a day before that inventory is available for retrieval.

You might not find it useful to retrieve a vault inventory for each archive upload. However, suppose you maintain a database on the client-side associating metadata about the archives you upload to S3 Glacier. Then, you might find the vault inventory useful to reconcile information, as needed, in your database with the actual vault inventory. You can limit the number of inventory items retrieved by filtering on the archive creation date or by setting a quota. For more information about limiting inventory retrieval, see Range Inventory Retrieval.

The inventory can be returned in two formats, comma-separated values (CSV) or JSON. You can optionally specify the format when you initiate the inventory job. The default format is JSON. For more information about the data fields returned in an inventory job output, see Response Body of the Get Job Output API.

Downloading a Vault Inventory in Amazon S3 Glacier Using the AWS SDK for Java

The following are the steps to retrieve a vault inventory using the low-level API of the AWS SDK for Java. The high-level API does not support retrieving a vault inventory.

1. Create an instance of the AmazonGlacierClient class (the client).

   You need to specify an AWS Region where the vault resides. All operations you perform using this client apply to that AWS Region.

2. Initiate an inventory retrieval job by executing the initiateJob method.

   Run initiateJob by providing job information in an InitiateJobRequest object.
Note

Note that if an inventory has not been completed for the vault an error is returned. Amazon S3 Glacier (S3 Glacier) prepares an inventory for each vault periodically, every 24 hours.

S3 Glacier returns a job ID in response. The response is available in an instance of the InitiateJobResult class.

```java
InitiateJobRequest initJobRequest = new InitiateJobRequest()
    .withVaultName("*** provide vault name ***")
    .withJobParameters(
        new JobParameters()
            .withType("inventory-retrieval")
            .withSNSTopic("*** provide SNS topic ARN ****")
    );

InitiateJobResult initJobResult = client.initiateJob(initJobRequest);
String jobId = initJobResult.getJobId();
```

3. Wait for the job to complete.

You must wait until the job output is ready for you to download. If you have either set a notification configuration on the vault, or specified an Amazon Simple Notification Service (Amazon SNS) topic when you initiated the job, S3 Glacier sends a message to the topic after it completes the job.

You can also poll S3 Glacier by calling the describeJob method to determine job completion status. However, using an Amazon SNS topic for notification is the recommended approach. The code example given in the following section uses Amazon SNS for S3 Glacier to publish a message.

4. Download the job output (vault inventory data) by executing the getJobOutput method.

You provide your account ID, job ID, and vault name by creating an instance of the GetJob0utputRequest class. If you don't provide an account ID, then the account ID
associated with the credentials you provide to sign the request is used. For more information, see [Using the AWS SDK for Java with Amazon S3 Glacier](#).

The output that S3 Glacier returns is available in the `GetJobOutputResult` object.

```java
GetJobOutputRequest jobOutputRequest = new GetJobOutputRequest()
    .withVaultName("*** provide vault name ***")
    .withJobId("*** provide job ID ***");
GetJobOutputResult jobOutputResult = client.getJobOutput(jobOutputRequest);
// jobOutputResult.getBody(); provides the output stream.
```

Example: Retrieving a Vault Inventory Using the Amazon SDK for Java

The following Java code example retrieves the vault inventory for the specified vault.

The example performs the following tasks:

- Creates an Amazon Simple Notification Service (Amazon SNS) topic.
  
  S3 Glacier sends notification to this topic after it completes the job.
- Creates an Amazon Simple Queue Service (Amazon SQS) queue.
  
  The example attaches a policy to the queue to enable the Amazon SNS topic to post messages to the queue.
- Initiates a job to download the specified archive.
  
  In the job request, the Amazon SNS topic that was created is specified so that S3 Glacier can publish a notification to the topic after it completes the job.
- Checks the Amazon SQS queue for a message that contains the job ID.
  
  If there is a message, parse the JSON and check if the job completed successfully. If it did, download the archive.
• Cleans up by deleting the Amazon SNS topic and the Amazon SQS queue that it created.

Downloading a Vault Inventory in Amazon S3 Glacier Using the AWS SDK for .NET

The following are the steps to retrieve a vault inventory using the low-level API of the AWS SDK for .NET. The high-level API does not support retrieving a vault inventory.

1. Create an instance of the AmazonGlacierClient class (the client).

   You need to specify an AWS Region where the vault resides. All operations you perform using this client apply to that AWS Region.

2. Initiate an inventory retrieval job by executing the InitiateJob method.

   You provide job information in an InitiateJobRequest object. Amazon S3 Glacier (S3 Glacier) returns a job ID in response. The response is available in an instance of the InitiateJobResponse class.

```csharp
AmazonGlacierClient client;
client = new AmazonGlacierClient(Amazon.RegionEndpoint.USWest2);

InitiateJobRequest initJobRequest = new InitiateJobRequest()
{
    VaultName = vaultName,
    JobParameters = new JobParameters()
    {
        Type = "inventory-retrieval",
        SNSTopic = "*** Provide Amazon SNS topic arn ***",
    }
};
InitiateJobResponse initJobResponse = client.InitiateJob(initJobRequest);
string jobId = initJobResponse.JobId;
```

3. Wait for the job to complete.

   You must wait until the job output is ready for you to download. If you have either set a notification configuration on the vault identifying an Amazon Simple Notification Service
(Amazon SNS) topic, or specified an Amazon SNS topic when you initiated a job, S3 Glacier sends a message to that topic after it completes the job. The code example given in the following section uses Amazon SNS for S3 Glacier to publish a message.

You can also poll S3 Glacier by calling the DescribeJob method to determine job completion status. Although using Amazon SNS topic for notification is the recommended approach.

4. Download the job output (vault inventory data) by executing the GetJobOutput method.

You provide your account ID, vault name, and the job ID information by creating an instance of the GetJobOutputRequest class. If you don’t provide an account ID, then the account ID associated with the credentials you provide to sign the request is assumed. For more information, see Using the AWS SDK for .NET with Amazon S3 Glacier.

The output that S3 Glacier returns is available in the GetJobOutputResponse object.

```csharp
GetJobOutputRequest getJobOutputRequest = new GetJobOutputRequest()
{
    JobId = jobID,
    VaultName = vaultName
};

GetJobOutputResponse getJobOutputResponse = client.GetJobOutput(getJobOutputRequest);
using (Stream webStream = getJobOutputResponse.Body)
{
    using (Stream fileToSave = File.OpenWrite(fileName))
    {
        CopyStream(webStream, fileToSave);
    }
}
```

**Note**

Example: Retrieving a Vault Inventory Using the Low-Level API of the AWS SDK for .NET

The following C# code example retrieves the vault inventory for the specified vault.

The example performs the following tasks:

- Set up an Amazon SNS topic.
  
  S3 Glacier sends notification to this topic after it completes the job.

- Set up an Amazon SQS queue.
  
  The example attaches a policy to the queue to enable the Amazon SNS topic to post messages.

- Initiate a job to download the specified archive.
  
  In the job request, the example specifies the Amazon SNS topic so that S3 Glacier can send a message after it completes the job.

- Periodically check the Amazon SQS queue for a message.
  
  If there is a message, parse the JSON and check if the job completed successfully. If it did, download the archive. The code example uses the JSON.NET library (see JSON.NET) to parse the JSON.

- Clean up by deleting the Amazon SNS topic and the Amazon SQS queue it created.

**Downloading a Vault Inventory Using the REST API**

To download a vault inventory using the REST API

Downloading a vault inventory is a two-step process.

1. Initiate a job of the inventory-retrieval type. For more information, see [Initiate Job (POST jobs)](https://docs.aws.amazon.com/AmazonS3/latest/dev/InitiateJobPOSTJobs.html).
2. After the job completes, download the inventory data. For more information, see [Get Job Output (GET output)](https://docs.aws.amazon.com/AmazonS3/latest/API/REST-Inventory-Get.html).
Downloading a Vault Inventory in Amazon S3 Glacier Using the AWS Command Line Interface

Follow these steps to download a vault inventory in Amazon S3 Glacier (S3 Glacier) using the AWS Command Line Interface (AWS CLI).

Topics

- (Prerequisite) Setting Up the AWS CLI
- Example: Downloading a Vault Inventory Using the AWS CLI

(Prerequisite) Setting Up the AWS CLI

1. Download and configure the AWS CLI. For instructions, see the following topics in the AWS Command Line Interface User Guide:
   - Installing the AWS Command Line Interface
   - Configuring the AWS Command Line Interface

2. Verify your AWS CLI setup by entering the following commands at the command prompt. These commands don't provide credentials explicitly, so the credentials of the default profile are used.
   - Try using the help command.

   ```
   aws help
   ```

   - To get a list of S3 Glacier vaults on the configured account, use the list-vaults command. Replace `123456789012` with your AWS account ID.

   ```
   aws glacier list-vaults --account-id 123456789012
   ```

   - To see the current configuration data for the AWS CLI, use the `aws configure list` command.

   ```
   aws configure list
   ```
Example: Downloading a Vault Inventory Using the AWS CLI

1. Use the `initiate-job` command to start an inventory retrieval job.

   ```
   aws glacier initiate-job --vault-name awsexamplevault --account-id 111122223333 --job-parameters='{"Type": "inventory-retrieval"}'
   ```

   Expected output:

   ```
   {
   "location": "/111122223333/vaults/awsexamplevault/jobs/*** jobid ***",
   "jobId": "*** jobid ***"
   }
   ```

2. Use the `describe-job` command to check status of the previous retrieval job.

   ```
   aws glacier describe-job --vault-name awsexamplevault --account-id 111122223333 --job-id *** jobid ***
   ```

   Expected output:

   ```
   {
   "InventoryRetrievalParameters": {
   "Format": "JSON"
   },
   "VaultARN": "*** vault arn ***",
   "Completed": false,
   "JobId": "*** jobid ***",
   "Action": "InventoryRetrieval",
   "CreationDate": "*** job creation date ***",
   "StatusCode": "InProgress"
   }
   ```

3. Wait for the job to complete.

   You must wait until the job output is ready for you to download. The job ID does not expire for at least 24 hours after S3 Glacier completes the job. If you have either set a notification
configuration on the vault, or specified an Amazon Simple Notification Service (Amazon SNS) topic when you initiated the job, S3 Glacier sends a message to the topic after it completes the job.

You can set the notification configuration for specific events on the vault. For more information, see Configuring Vault Notifications in Amazon S3 Glacier. S3 Glacier sends a message to the specified SNS topic anytime the specific events occur.

4. When it's complete, use the `get-job-output` command to download the retrieval job to the file `output.json`.

```bash
aws glacier get-job-output --vault-name awsexamplevault --account-id 111122223333 --job-id *** jobid *** output.json
```

This command produces a file with the following fields.

```json
{
  "InventoryDate": "*** job completion date ***",
  "ArchiveList": [
    {"ArchiveId": "*** archiveid ***",
    "ArchiveDescription": "*** archive description (if set) ***",
    "CreationDate": "*** archive creation date ***",
    "Size": "*** archive size (in bytes) ***",
    "SHA256TreeHash": "*** archive hash ***"
  }
  ]
}
```

Configuring Vault Notifications in Amazon S3 Glacier

Retrieving anything from Amazon S3 Glacier, such as an archive from a vault or a vault inventory, is a two-step process.

1. Initiate a retrieval job.
2. After the job is completed, download the job output.
You can set a notification configuration on a vault so that when a job is completed, a message is sent to an Amazon Simple Notification Service (Amazon SNS) topic.

### Configuring Vault Notifications in S3 Glacier: General Concepts

A S3 Glacier retrieval job request is run asynchronously. You must wait until S3 Glacier completes the job before you can get its output. You can periodically poll S3 Glacier to determine the job status, but that is not an optimal approach. S3 Glacier also supports notifications. When a job is completed, the job can post a message to an Amazon Simple Notification Service (Amazon SNS) topic. Using this feature requires you to set a notification configuration on the vault. In the configuration, you identify one or more events and an Amazon SNS topic to which you want S3 Glacier to send a message when the event occurs.

S3 Glacier defines events specifically related to job completion (ArchiveRetrievalCompleted, InventoryRetrievalCompleted) that you can add to the vault's notification configuration. When a specific job is completed, S3 Glacier publishes a notification message to the SNS topic.

The notification configuration is a JSON document as shown in the following example.

```json
{
    "Events": ["ArchiveRetrievalCompleted", "InventoryRetrievalCompleted"]
}
```

You can configure only one Amazon SNS topic for a vault.
Note

Adding a notification configuration to a vault causes S3 Glacier to send a notification each time the event specified in the notification configuration occurs. You can also optionally specify an Amazon SNS topic in each job initiation request. If you add both the notification configuration on the vault and also specify an Amazon SNS topic in your initiate job request, S3 Glacier sends both notifications.

The job completion message S3 Glacier sends include information such as the type of job (InventoryRetrieval, ArchiveRetrieval), job completion status, SNS topic name, job status code, and the vault ARN. The following is an example notification S3 Glacier sent to an SNS topic after an InventoryRetrieval job is completed.

```
{
  "Action": "InventoryRetrieval",
  "ArchiveId": null,
  "ArchiveSizeInBytes": null,
  "Completed": true,
  "CompletionDate": "2012-06-12T22:20:40.790Z",
  "CreationDate": "2012-06-12T22:20:36.814Z",
  "InventorySizeInBytes": 11693,
  "JobDescription": "my retrieval job",
  "JobId": "HkF9p6o7yjhFx-K3Cg16fuSmGvzw9T7esGqfco8nUXVYwS0j1b5gq1JZ55yHgt5vP54ZShjoQzQVv27vEXAMPLEjobID",
  "SHA256TreeHash": null,
  "StatusCode": "Succeeded",
  "StatusMessage": "Succeeded",
}
```

If the Completed field is true, you must also check the StatusCode to check if the job completed successfully or failed.

Note

The Amazon SNS topic must allow the vault to publish a notification. By default, only the Amazon SNS topic owner can publish a message to the topic. However, if the Amazon SNS topic and the vault are owned by different AWS accounts, then you must configure the

### Configuring Vault Notifications in Amazon S3 Glacier Using the AWS SDK for Java

The following are the steps to configure notifications on a vault using the low-level API of the AWS SDK for Java.

1. Create an instance of the `AmazonGlacierClient` class (the client).
   
   You need to specify an AWS Region where the vault resides. All operations you perform using this client apply to that AWS Region.

2. Provide notification configuration information by creating an instance of the `SetVaultNotificationsRequest` class.
   
   You need to provide the vault name, notification configuration information, and account ID. In specifying a notification configuration, you provide the Amazon Resource Name (ARN) of an existing Amazon SNS topic and one or more events for which you want to be notified. For a list of supported events, see [Set Vault Notification Configuration (PUT notification-configuration)](#).

3. Run the `setVaultNotifications` method by providing the request object as a parameter.

The following Java code snippet illustrates the preceding steps. The snippet sets a notification configuration on a vault. The configuration requests Amazon S3 Glacier (S3 Glacier) to send a notification to the specified Amazon SNS topic when either the `ArchiveRetrievalCompleted` event or the `InventoryRetrievalCompleted` event occurs.

```java
SetVaultNotificationsRequest request = new SetVaultNotificationsRequest()
    .withAccountId("-")
    .withVaultName("*** provide vault name ***")
    .withVaultNotificationConfig(
        new VaultNotificationConfig()
        .withSNSTopic("*** provide SNS topic ARN ***")
        .withEvents("ArchiveRetrievalCompleted", "InventoryRetrievalCompleted")
    )
```

        .withEvents("ArchiveRetrievalCompleted", "InventoryRetrievalCompleted");

    SetVaultNotificationsRequest request = new SetVaultNotificationsRequest()
        .withVaultName(vaultName)
        .withVaultNotificationConfig(config);

    client.setVaultNotifications(request);
    System.out.println("Notification configured for vault: " + vaultName);
}

private static void getVaultNotifications() {
    VaultNotificationConfig notificationConfig = null;
    GetVaultNotificationsRequest request = new GetVaultNotificationsRequest()
        .withVaultName(vaultName);
    GetVaultNotificationsResult result = client.getVaultNotifications(request);
    notificationConfig = result.getVaultNotificationConfig();

    System.out.println("Notifications configuration for vault: "
        + vaultName);
    System.out.println("Topic: " + notificationConfig.getSNSTopic());
    System.out.println("Events: " + notificationConfig.getEvents());
}

Configuring Vault Notifications in Amazon S3 Glacier Using the AWS SDK for .NET

The following are the steps to configure notifications on a vault using the low-level API of the AWS SDK for .NET.

1. Create an instance of the AmazonGlacierClient class (the client).

   You need to specify an AWS Region where the vault resides. All operations you perform using this client apply to that AWS Region.

2. Provide notification configuration information by creating an instance of the SetVaultNotificationsRequest class.

   You need to provide the vault name, notification configuration information, and account ID. If you don't provide an account ID, then the account ID associated with the credentials you provide to sign the request is assumed. For more information, see Using the AWS SDK for .NET with Amazon S3 Glacier.

   In specifying a notification configuration, you provide the Amazon Resource Name (ARN) of an existing Amazon SNS topic and one or more events for which you want to be notified. For a list of supported events, see Set Vault Notification Configuration (PUT notification-configuration).

3. Run the SetVaultNotifications method by providing the request object as a parameter.

4. After setting notification configuration on a vault, you can retrieve configuration information by calling the GetVaultNotifications method, and remove it by calling the DeleteVaultNotifications method provided by the client.

Example: Setting the Notification Configuration on a Vault Using the AWS SDK for .NET

The following C# code example illustrates the preceding steps. The example sets the notification configuration on the vault ("examplevault") in the US West (Oregon) Region, retrieves the configuration, and then deletes it. The configuration requests Amazon S3
Glacier (S3 Glacier) to send a notification to the specified Amazon SNS topic when either the ArchiveRetrievalCompleted event or the InventoryRetrievalCompleted event occurs.

**Note**

For information about the underlying REST API, see [Vault Operations](#).

For step-by-step instructions to run the following example, see [Running Code Examples](#). You need to update the code as shown and provide an existing vault name and an Amazon SNS topic.

**Example**

```csharp

Configuring Vault Notifications Using .NET
Configuring Vault Notifications in S3 Glacier Using the REST API

To configure vault notifications using the REST API, see Set Vault Notification Configuration (PUT notification-configuration). Additionally, you can also get vault notifications (Get Vault Notifications (GET notification-configuration)) and delete vault notifications (Delete Vault Notifications (DELETE notification-configuration)).

Configuring Vault Notifications by Using the S3 Glacier Console

This section describes how to configure vault notifications by using the Amazon S3 Glacier console. When you configure notifications, you specify job-completion events that send a notification to an Amazon Simple Notification Service (Amazon SNS) topic. In addition to configuring notifications for the vault, you can also specify a topic to publish notifications to when you initiate a job. If your vault is configured to send a notification for a specific event and you also configure notifications in the job-initiation request, then two notifications are sent.

To configure a vault notification

1. Sign in to the AWS Management Console and open the S3 Glacier console at https://console.aws.amazon.com/glacier/home.
2. In the left navigation pane, choose Vaults.
3. In the Vaults list, choose a vault.
4. In the Notifications section, choose Edit.
5. On the Event notifications page, choose Turn on notifications.
6. In the Notifications section, choose one of the following Amazon Simple Notification Service (Amazon SNS) options, and then follow the corresponding steps:

<table>
<thead>
<tr>
<th>Amazon SNS options</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create new SNS topic</td>
<td>1. Choose Create new SNS topic.</td>
</tr>
<tr>
<td></td>
<td>2. For Topic name, enter the name of the new topic.</td>
</tr>
</tbody>
</table>
### Amazon SNS options

<table>
<thead>
<tr>
<th>Topic names can be up to 256 characters. Alphanumeric characters, hyphens (-), and underscores (_) are allowed. Topic names must be unique within the account and AWS Region.</th>
</tr>
</thead>
</table>

### Choose an existing SNS topic

| 1. Choose **Choose an existing SNS topic**. |
| 2. Under **Specify SNS topic**, choose one of the following options: |
| • **Choose from your SNS topics** |
| An **SNS topic** dropdown list appears. |
| Choose an existing topic from the dropdown list. |
| • **Enter SNS topic ARN** |
| An **Amazon SNS topic ARN** text box appears. |
| Enter the Amazon Resource Name (ARN) for your SNS topic. An SNS topic ARN has the following format: |
| `arn:aws:sns: region:account-id :topic-name` |
| You can find the SNS topic ARN in the Amazon SNS console. |
7. Under **Events**, select one or both events that you want to send notifications:

- To send a notification only when archive retrieval jobs are complete, select **Archive Retrieval Job Complete**.
- To send a notification only when vault inventory jobs are complete, select **Vault Inventory Retrieval Job Complete**.

**Configuring Vault Notifications Using the AWS Command Line Interface**

This section describes how to configure vault notifications using the AWS Command Line Interface. When you configure notifications, you specify job completion events that trigger notification to an Amazon Simple Notification Service (Amazon SNS) topic. In addition to configuring notifications for the vault, you can also specify a topic to publish notification to when you initiate a job. If your vault is configured to notify for a specific event and you specify notification in the job initiation request, then two notifications are sent.

To get a list of S3 Glacier vaults on the configured account, use the `list-vaults` command. Replace `123456789012` with your AWS account ID.

```
aws glacier list-vaults --account-id 123456789012
```

To see the current configuration data for the AWS CLI, use the `aws configure list` command.

```
aws configure list
```

**Example: Configure Vault Notifications Using the AWS CLI**

1. Use the `set-vault-notifications` command to configure notifications that will be sent when specific events happen to a vault. By default, you don’t get any notifications.

```
aws glacier set-vault-notifications --vault-name examplevault --account-id 111122223333 --vault-notification-config file://notificationconfig.json
```

2. The notification configuration is a JSON document as shown in the following example.

```json
{
   "Events": ["ArchiveRetrievalCompleted", "InventoryRetrievalCompleted"]
}
```

For more information about using Amazon SNS topics for S3 Glacier see, [Configuring Vault Notifications in S3 Glacier: General Concepts](#).

For more information about Amazon SNS, see [Getting Started with Amazon SNS](#).

**Deleting a Vault in Amazon S3 Glacier**

Amazon S3 Glacier (S3 Glacier) deletes a vault only if there are no archives in the vault as of the last inventory it computed and there have been no writes to the vault since the last inventory. For information about deleting archives, see [Deleting an Archive in Amazon S3 Glacier](#). For information about downloading a vault inventory, [Downloading a Vault Inventory in Amazon S3 Glacier](#).
S3 Glacier prepares an inventory for each vault periodically, every 24 hours. Because the inventory might not reflect the latest information, S3 Glacier ensures the vault is indeed empty by checking if there were any write operations since the last vault inventory.

### Deleting a Vault in Amazon S3 Glacier Using the AWS SDK for Java

The following are the steps to delete a vault using the low-level API of the AWS SDK for Java.

1. Create an instance of the `AmazonGlacierClient` class (the client).

   You need to specify an AWS Region from where you want to delete a vault. All operations you perform using this client apply to that AWS Region.

2. Provide request information by creating an instance of the `DeleteVaultRequest` class.

   You need to provide the vault name and account ID. If you don't provide an account ID, then account ID associated with the credentials you provide to sign the request is assumed. For more information, see [Using the AWS SDK for Java with Amazon S3 Glacier](#).

3. Run the `deleteVault` method by providing the request object as a parameter.

   Amazon S3 Glacier (S3 Glacier) deletes the vault only if it is empty. For more information, see [Delete Vault (DELETE vault)](#).

The following Java code snippet illustrates the preceding steps.

```java
try {
    // ... (code snippet)
}
```
DeleteVaultRequest request = new DeleteVaultRequest()
    .withVaultName("*** provide vault name ***");

client.deleteVault(request);
    System.out.println("Deleted vault: " + vaultName);
} catch (Exception e) {
    System.err.println(e.getMessage());
}

### Note

For information about the underlying REST API, see [Delete Vault (DELETE vault)](https://docs.aws.amazon.com/AmazonS3/latest/API/index.html#create-vault).

### Example: Deleting a Vault Using the AWS SDK for Java

For a working code example, see [Example: Creating a Vault Using the AWS SDK for Java](https://docs.aws.amazon.com/AmazonS3/latest/API/index.html#create-vault). The Java code example shows basic vault operations including create and delete vault.

### Deleting a Vault in Amazon S3 Glacier Using the AWS SDK for .NET

Both the [high-level and low-level APIs](https://docs.aws.amazon.com/AmazonS3/latest/API/index.html#create-vault) provided by the Amazon SDK for .NET provide a method to delete a vault.

### Topics

- [Deleting a Vault Using the High-Level API of the AWS SDK for .NET](https://docs.aws.amazon.com/AmazonS3/latest/API/index.html#create-vault)

### Deleting a Vault Using the High-Level API of the AWS SDK for .NET

The `ArchiveTransferManager` class of the high-level API provides the `DeleteVault` method you can use to delete a vault.

### Example: Deleting a Vault Using the High-Level API of the AWS SDK for .NET

For a working code example, see [Example: Vault Operations Using the High-Level API of the AWS SDK for .NET](https://docs.aws.amazon.com/AmazonS3/latest/API/index.html#create-vault). The C# code example shows basic vault operations including create and delete vault.
Deleting a Vault Using the Low-Level API of the AWS SDK for .NET

The following are the steps to delete a vault using the AWS SDK for .NET.

1. Create an instance of the AmazonGlacierClient class (the client).

   You need to specify an AWS Region from where you want to delete a vault. All operations you perform using this client apply to that AWS Region.

2. Provide request information by creating an instance of the DeleteVaultRequest class.

   You need to provide the vault name and account ID. If you don't provide an account ID, then account ID associated with the credentials you provide to sign the request is assumed. For more information, see Using the AWS SDK for .NET with Amazon S3 Glacier.

3. Run the DeleteVault method by providing the request object as a parameter.

   Amazon S3 Glacier (S3 Glacier) deletes the vault only if it is empty. For more information, see Delete Vault (DELETE vault).

The following C# code snippet illustrates the preceding steps. The snippet retrieves metadata information of a vault that exists in the default AWS Region.

```csharp
AmazonGlacier client;
client = new AmazonGlacierClient(Amazon.RegionEndpoint.USEast1);

DeleteVaultRequest request = new DeleteVaultRequest()
{
    VaultName = "*** provide vault name ***"
};

DeleteVaultResponse response = client.DeleteVault(request);
```

ℹ️ Note

For information about the underlying REST API, see Delete Vault (DELETE vault).
Example: Deleting a Vault Using the Low-Level API of the AWS SDK for .NET

For a working code example, see Example: Vault Operations Using the Low-Level API of the AWS SDK for .NET. The C# code example shows basic vault operations including create and delete vault.

Deleting a Vault in S3 Glacier Using the REST API

To delete a vault using the REST API, see Delete Vault (DELETE vault).

Deleting an Empty Vault by Using the S3 Glacier Console

Note
Before deleting a vault, you must delete all existing archives within the vault. You can do this by writing code to make a delete archive request by using either the REST API, the AWS SDK for Java, the AWS SDK for .NET, or by using the AWS Command Line Interface (AWS CLI). For information about deleting archives, see Step 5: Delete an Archive from a Vault in S3 Glacier.

After your vault is empty, you can delete it by using the following steps.

To delete an empty vault by using the Amazon S3 Glacier console

1. Sign into the AWS Management Console and open the S3 Glacier console at S3 Glacier Console.
2. Under Select a Region, choose the AWS Region where the vault exists.
3. In the left navigation pane, choose Vaults.
4. In the Vaults list, select the option button next to the name of the vault that you want to delete, and then choose Delete at the top of the page.
5. In the Delete vault dialog box, confirm that you want to delete the vault by choosing Delete.

Important
Deleting a vault can't be undone.

6. To verify that you've deleted the vault, open the Vaults list and enter the name of the vault that you deleted. If the vault can't be found, your deletion was successful.
Deleting a Vault in Amazon S3 Glacier Using the AWS Command Line Interface

You can delete empty and nonempty vaults in Amazon S3 Glacier (S3 Glacier) using the AWS Command Line Interface (AWS CLI).

Topics

- **(Prerequisite) Setting Up the AWS CLI**
- **Example: Deleting an Empty Vault Using the AWS CLI**
- **Example: Deleting a Nonempty Vault Using the AWS CLI**

(Prerequisite) Setting Up the AWS CLI

1. Download and configure the AWS CLI. For instructions, see the following topics in the AWS Command Line Interface User Guide:
   - **Installing the AWS Command Line Interface**
   - **Configuring the AWS Command Line Interface**

2. Verify your AWS CLI setup by entering the following commands at the command prompt. These commands don't provide credentials explicitly, so the credentials of the default profile are used.
   - Try using the help command.
     
     ```
     aws help
     ```
   - To get a list of S3 Glacier vaults on the configured account, use the `list-vaults` command. Replace `123456789012` with your AWS account ID.
     
     ```
     aws glacier list-vaults --account-id 123456789012
     ```
   - To see the current configuration data for the AWS CLI, use the `aws configure list command`.
     
     ```
     aws configure list
     ```
Example: Deleting an Empty Vault Using the AWS CLI

- Use the `delete-vault` command to delete a vault that contains no archives.
  
  ```
  aws glacier delete-vault --vault-name awsexamplevault --account-id 111122223333
  ```

Example: Deleting a Nonempty Vault Using the AWS CLI

S3 Glacier deletes a vault only if there are no archives in the vault as of the last inventory it computed, and there have been no writes to the vault since the last inventory. Deleting a nonempty vault is a three-step process: retrieving archive IDs from a vault's inventory report, deleting each archive, and then deleting the vault.

1. Use the `initiate-job` command to start an inventory retrieval job.

   ```
   aws glacier initiate-job --vault-name awsexamplevault --account-id 111122223333 --job-parameters='{"Type": "inventory-retrieval"}"
   ```

   Expected output:

   ```
   {
      "location": "/111122223333/vaults/awsexamplevault/jobs/*** jobid ***",
      "jobId": "*** jobid ***"
   }
   ```

2. Use the `describe-job` command to check status of the previous retrieval job.

   ```
   aws glacier describe-job --vault-name awsexamplevault --account-id 111122223333 --job-id *** jobid ***
   ```

   Expected output:

   ```
   {
      "InventoryRetrievalParameters": {
         "Format": "JSON"
      }
   }
   ```
3. Wait for the job to complete.

You must wait until the job output is ready for you to download. If you set a notification configuration on the vault or specified an Amazon Simple Notification Service (Amazon SNS) topic when you initiated the job, S3 Glacier sends a message to the topic after it completes the job.

You can set notification configuration for specific events on the vault. For more information, see Configuring Vault Notifications in Amazon S3 Glacier. S3 Glacier sends a message to the specified SNS topic anytime the specific event occurs.

4. When it's complete, use the `get-job-output` command to download the retrieval job to the file `output.json`.

```bash
aws glacier get-job-output --vault-name awsexamplevault --account-id 111122223333 --job-id *** jobid *** output.json
```

This command produces a file with the following fields.

```json
{
  "VaultARN": "*** vault arn ***",
  "Completed": false,
  "JobId": "*** jobid ***",
  "Action": "InventoryRetrieval",
  "CreationDate": "*** job creation date ***",
  "StatusCode": "InProgress"
}
```
5. Use the `delete-archive` command to delete each archive from a vault until none remain.

   ```bash
   aws glacier delete-archive --vault-name awsexamplevault --account-id 111122223333 --archive-id="*** archiveid ***"
   ``

   **Note**
   If your Archive ID starts with a hyphen or another special character you will need to put it in quotes in order to run this command.

6. Use the `initiate-job` command to start a new inventory retrieval job.

   ```bash
   aws glacier initiate-job --vault-name awsexamplevault --account-id 111122223333 --job-parameters='{"Type": "inventory-retrieval"}"
   ``

7. When it's complete, use the `delete-vault` command to delete a vault with no archives.

   ```bash
   aws glacier delete-vault --vault-name awsexamplevault --account-id 111122223333
   ``

### Tagging Your S3 Glacier Vaults

You can assign your own metadata to Amazon S3 Glacier vaults in the form of tags. A *tag* is a key-value pair that you define for a vault. For basic information about tagging, including restrictions on tags, see [Tagging Amazon S3 Glacier Resources](#).

The following topics describe how you can add, list, and remove tags for vaults.

**Topics**

Tagging Vaults by Using the Amazon S3 Glacier Console

You can add, list, and remove tags using the S3 Glacier console, as described in the following procedures.

To view the tags for a vault

1. Sign in to the AWS Management Console and open the S3 Glacier console at https://console.aws.amazon.com/glacier/home.
2. Under Select a Region, select an AWS Region from the Region selector.
3. In the left navigation pane, choose Vaults.
4. In the Vaults list, choose a vault.
5. Choose the Vaults properties tab. Scroll to the Tags section to view the tags associated with the vault.

To add a tag to a vault

You can associate up to 50 tags to a vault. Tags that are associated with a vault must have unique tag keys.

For more information about tag restrictions, see Tagging Amazon S3 Glacier Resources.

1. Sign in to the AWS Management Console and open the S3 Glacier console at https://console.aws.amazon.com/glacier/home.
2. Under Select a Region, select an AWS Region from the Region selector.
3. In the left navigation pane, choose Vaults.
4. In the Vaults list, choose the name of the vault that you want to add tags to.
5. Choose the Vault properties tab.
6. In the Tags section, choose Add. The Add tags page appears.
7. On the Add tags page, specify the tag key in the Key field, and optionally specify a tag value in the Value field.
8. Choose Save changes.
To edit a tag

1. Sign in to the AWS Management Console and open the S3 Glacier console at https://console.aws.amazon.com/glacier/home.
2. Under Select a Region, select an AWS Region from the Region selector.
3. In the left navigation pane, choose Vaults.
4. In the Vaults list, choose a vault name.
5. Choose the Vault properties tab, and then scroll down to the Tags section.
6. Under Tags, select the check box next to the tags that you want to change, then choose Edit. The Edit tags page appears.
7. Update the tag key in the Key field, and optionally update the tag value in the Value field.
8. Choose Save changes.

To remove a tag from a vault

1. Sign in to the AWS Management Console and open the S3 Glacier console at https://console.aws.amazon.com/glacier/home.
2. Under Select a Region, select an AWS Region from the Region selector.
3. In the left navigation pane, choose Vaults.
4. In the Vaults list, choose the name of the vault that you want to remove tags from.
5. Choose the Vault properties tab. Scroll down to the Tags section.
6. Under Tags, select the check box next to the tags that you want to remove, then choose Delete.
7. The Delete tags dialog box opens. To confirm that you want to delete the selected tags, choose Delete.

Tagging Vaults by Using the AWS CLI

Follow these steps to add, list, or remove tags by using the AWS Command Line Interface (AWS CLI).

Each tag is composed of a key and a value. Each vault can have up to 50 tags.

1. To add tags to a vault, use the add-tags-to-vault command.
aws glacier add-tags-to-vault --vault-name examplevault --account-id 111122223333 --tags id=1234,date=2020

For more information on this vault operation, see Add Tags To Vault.

2. To list all the tags attached to a vault, use the list-tags-for-vault command.

aws glacier list-tags-for-vault --vault-name examplevault --account-id 111122223333

For more information on this vault operation, see List Tags For Vault.

3. To remove one or more tags from the set of tags attached to a vault, use the remove-tags-from-vault command.

aws glacier remove-tags-from-vault --vault-name examplevault --account-id 111122223333 --tag-keys date

For more information on this vault operation, see Remove Tags From Vault.

Tagging Vaults by Using the Amazon S3 Glacier API

You can add, list, and remove tags by using the S3 Glacier API. For examples, see the following documentation:

Add Tags To Vault (POST tags add)

Adds or updates tags for the specified vault.

List Tags For Vault (GET tags)

Lists the tags for the specified vault.

Remove Tags From Vault (POST tags remove)

Removes tags from the specified vault.

S3 Glacier Vault Lock

The following topics describe how to lock a vault in Amazon S3 Glacier and how to use Vault Lock policies.

Topics

- Vault Locking Overview
- Locking a Vault by Using the S3 Glacier API
- Locking a Vault using the AWS Command Line Interface
- Locking a Vault by Using the S3 Glacier Console

Vault Locking Overview

S3 Glacier Vault Lock helps you to easily deploy and enforce compliance controls for individual S3 Glacier vaults with a Vault Lock policy. You can specify controls such as "write once read many" (WORM) in a Vault Lock policy and lock the policy from future edits.

⚠️ Important

After a Vault Lock policy is locked, the policy can no longer be changed or deleted.

S3 Glacier enforces the controls set in the Vault Lock policy to help achieve your compliance objectives. For example, you can use Vault Lock policies to enforce data retention. You can deploy a variety of compliance controls in a Vault Lock policy by using the AWS Identity and Access Management (IAM) policy language. For more information about Vault Lock policies, see Vault Lock Policies.

A Vault Lock policy is different from a vault access policy. Both policies govern access controls to your vault. However, a Vault Lock policy can be locked to prevent future changes, which provides strong enforcement for your compliance controls. You can use the Vault Lock policy to deploy regulatory and compliance controls, which typically require tight controls on data access.

⚠️ Important

We recommend that you first create a vault, complete a Vault Lock policy, and then upload your archives to the vault so that the policy will be applied to them.
In contrast, you use a vault access policy to implement access controls that are not compliance related, temporary, and subject to frequent modification. You can use Vault lock and vault access policies together. For example, you can implement time-based data-retention rules in the Vault Lock policy (deny deletes), and grant read access to designated third parties or your business partners (allow reads) in your vault access policy.

Locking a vault takes two steps:

1. Initiate the lock by attaching a Vault Lock policy to your vault, which sets the lock to an in-progress state and returns a lock ID. While the policy is in the in-progress state, you have 24 hours to validate your Vault Lock policy before the lock ID expires. To prevent your vault from exiting the in-progress state, you must complete the Vault Lock process within these 24 hours. Otherwise, your Vault Lock policy will be deleted.

2. Use the lock ID to complete the lock process. If the Vault Lock policy doesn't work as expected, you can stop the Vault Lock process and restart from the beginning. For information about how to use the S3 Glacier API to lock a vault, see Locking a Vault by Using the S3 Glacier API.

Locking a Vault by Using the S3 Glacier API

To lock your vault with the Amazon S3 Glacier API, you first call Initiate Vault Lock (POST lock-policy) with a Vault Lock policy that specifies the controls that you want to deploy. The Initiate Vault Lock operation attaches the policy to your vault, transitions the Vault Lock to the in-progress state, and returns a unique lock ID. After the Vault Lock enters the in-progress state, you have 24 hours to complete the lock by calling Complete Vault Lock (POST lockId) with the lock ID that was returned from the Initiate Vault Lock call.

Important

- We recommend that you first create a vault, complete a Vault Lock policy, and then upload your archives to the vault so that the policy will be applied to them.
- After the Vault Lock policy is locked, it cannot be changed or deleted.

If you don't complete the Vault Lock process within 24 hours after entering the in-progress state, your vault automatically exits the in-progress state, and the Vault Lock policy is removed. You can call Initiate Vault Lock again to install a new Vault Lock policy and transition into the in-progress state.
The in-progress state provides the opportunity to test your Vault Lock policy before you lock it. Your Vault Lock policy takes full effect during the in-progress state just as if the vault has been locked, except that you can remove the policy by calling `Abort Vault Lock (DELETE lock-policy)`. To fine-tune your policy, you can repeat the `Abort Vault Lock/Initiate Vault Lock` combination as many times as necessary to validate your Vault Lock policy changes.

After you validate the Vault Lock policy, you can call `Complete Vault Lock (POST lockId)` with the most recent lock ID to complete the vault locking process. Your vault transitions to a locked state, where the Vault Lock policy is unchangeable and can no longer be removed by calling `Abort Vault Lock`.

**Locking a Vault using the AWS Command Line Interface**

You can lock your vault using the AWS Command Line Interface. This will install a vault lock policy on the specified vault and return the lock ID. You must complete the vault locking process within 24 hours else the vault lock policy is removed from the vault.

**(Prerequisite) Setting Up the AWS CLI**

1. Download and configure the AWS CLI. For instructions, see the following topics in the *AWS Command Line Interface User Guide*:
   
   **Installing the AWS Command Line Interface**
   
   **Configuring the AWS Command Line Interface**

2. Verify your AWS CLI setup by entering the following commands at the command prompt. These commands don't provide credentials explicitly, so the credentials of the default profile are used.
• Try using the help command.

```
aws help
```

• To get a list of S3 Glacier vaults on the configured account, use the `list-vaults` command. Replace `123456789012` with your AWS account ID.

```
aws glacier list-vaults --account-id 123456789012
```

• To see the current configuration data for the AWS CLI, use the `aws configure list` command.

```
aws configure list
```

1. Use the `initiate-vault-lock` to install a vault lock policy and sets the lock state of the vault lock to `InProgress`.

```
aws glacier initiate-vault-lock --vault-name examplevault --account-id 111122223333 --policy file://lockconfig.json
```

2. The lock configuration is a JSON document as shown in the following example. Before using this command, replace the `VAULT_ARN` and `Principal` with the appropriate values for your use case.

To find the ARN of the vault you wish to lock, you can use the `list-vaults` command.

```json
```

3. After initiating the vault lock you should see the `lockId` returned.

```
{
  "lockId": "LOCK_ID"
}
```
To complete the vault lock you must run `complete-vault-lock` within 24 hours else the vault lock policy is removed from the vault.

```bash
aws glacier complete-vault-lock --vault-name examplevault --account-id 111122223333 --lock-id LOCK_ID
```

12. After saving your lock ID in a safe place, choose **Close**.
13. Test your Vault Lock policy within the next 24 hours. If the policy is working as intended, choose **Complete Vault Lock policy**.

14. In the **Complete Vault Lock** dialog box, select the check box to acknowledge that completing the Vault Lock policy process is irreversible.

15. Enter your provided **Lock ID** in the text box.

16. Choose **Complete Vault Lock**.
Working with Archives in Amazon S3 Glacier

An archive is any object, such as a photo, video, or document, that you store in a vault. It is a base unit of storage in Amazon S3 Glacier (S3 Glacier). Each archive has a unique ID and an optional description. When you upload an archive, S3 Glacier returns a response that includes an archive ID. This archive ID is unique in the AWS Region in which the archive is stored. The following is an example archive ID.

```
TJgHcrOSfAkV6hdPq0ATYfp_0ZaxL1pIB0c0Z0gDPMr2ig-nhwd_PafstdsIf6HSrzHnP-3p6LCJC1YytFT_CBhT9CwNxbRaM5MetS31-GqwxI3Y8QtgbJbhEQPs0mJ3KEexample
```

Archive IDs are 138 bytes long. When you upload an archive, you can provide an optional description. You can retrieve an archive using its ID but not its description.

⚠️ Important

S3 Glacier provides a management console. You can use the console to create and delete vaults. However, all other interactions with S3 Glacier require that you use the AWS Command Line Interface (CLI) or write code. For example, to upload data, such as photos, videos, and other documents, you must either use the AWS CLI or write code to make requests, using either the REST API directly or by using the Amazon SDKs. For more information about using S3 Glacier with the AWS CLI, go to AWS CLI Reference for S3 Glacier. To install the AWS CLI, go to AWS Command Line Interface.

Archive Operations in Amazon S3 Glacier

S3 Glacier supports the following basic archive operations: upload, download, and delete. Downloading an archive is an asynchronous operation.

Uploading an Archive in Amazon S3 Glacier

You can upload an archive in a single operation or upload it in parts. The API call you use to upload an archive in parts is referred as Multipart Upload. For more information, see Uploading an Archive in Amazon S3 Glacier.

Important

S3 Glacier provides a management console. You can use the console to create and delete vaults. However, all other interactions with S3 Glacier require that you use the AWS Command Line Interface (CLI) or write code. For more information about using S3 Glacier with the AWS CLI, go to AWS CLI Reference for S3 Glacier. To install the AWS CLI, go to AWS Command Line Interface.

Finding an Archive ID in Amazon S3 Glacier

You can get the archive ID by downloading the vault inventory for the vault that contains the archive. For more information about downloading the vault inventory, see Downloading a Vault Inventory in Amazon S3 Glacier.

Downloading an Archive in Amazon S3 Glacier

Downloading an archive is an asynchronous operation. You must first initiate a job to download a specific archive. After receiving the job request, S3 Glacier prepares your archive for download. After the job completes, you can download your archive data. Because of the asynchronous nature of the job, you can request S3 Glacier to send a notification to an Amazon Simple Notification Service (Amazon SNS) topic when the job completes. You can specify an SNS topic for each individual job request or configure your vault to send a notification when specific events occur. For more information about downloading an archive, see Downloading an Archive in S3 Glacier.
Deleting an Archive in Amazon S3 Glacier

S3 Glacier provides an API call that you can use to delete one archive at a time. For more information, see [Deleting an Archive in Amazon S3 Glacier](#).  

Updating an Archive in S3 Glacier

After you upload an archive, you cannot update its content or its description. The only way you can update the archive content or its description is by deleting the archive and uploading another archive. Note that each time you upload an archive, S3 Glacier returns to you a unique archive ID.

Maintaining Client-Side Archive Metadata

Except for the optional archive description, S3 Glacier does not support any additional metadata for the archives. When you upload an archive S3 Glacier assigns an ID, an opaque sequence of characters, from which you cannot infer any meaning about the archive. You might maintain metadata about the archives on the client-side. The metadata can include archive name and some other meaningful information about the archive.

Note

If you are an Amazon Simple Storage Service (Amazon S3) customer, you know that when you upload an object to a bucket, you can assign the object an object key such as `MyDocument.txt` or `SomePhoto.jpg`. In S3 Glacier, you cannot assign an object key to the archives you upload.

If you maintain client-side archive metadata, note that S3 Glacier maintains a vault inventory that includes archive IDs and any descriptions you provided during the archive upload. You might occasionally download the vault inventory to reconcile any issues in your client-side database you maintain for the archive metadata. However, S3 Glacier takes vault inventory approximately daily. When you request a vault inventory, S3 Glacier returns the last inventory it prepared, a point in time snapshot.

Uploading an Archive in Amazon S3 Glacier

Amazon S3 Glacier (S3 Glacier) provides a management console, which you can use to create and delete vaults. However, you cannot upload archives to S3 Glacier by using the management
To upload data, such as photos, videos, and other documents, you must either use the AWS CLI or write code to make requests, by using either the REST API directly or by using the Amazon SDKs.

For information about using S3 Glacier with the AWS CLI, go to AWS CLI Reference for S3 Glacier. To install the AWS CLI, go to AWS Command Line Interface. The following Uploading topics describe how to upload archives to S3 Glacier by using the Amazon SDK for Java, the Amazon SDK for .NET, and the REST API.

- Uploading an Archive in a Single Operation
- Uploading Large Archives in Parts (Multipart Upload)

Options for Uploading an Archive to Amazon S3 Glacier

Depending on the size of the data you are uploading, S3 Glacier offers the following options:

- **Upload archives in a single operation** – In a single operation, you can upload archives from 1 byte to up to 4 GB in size. However, we encourage S3 Glacier customers to use multipart upload to upload archives greater than 100 MB. For more information, see Uploading an Archive in a Single Operation.

- **Upload archives in parts** – Using the multipart upload API, you can upload large archives, up to about 40,000 GB (10,000 * 4 GB).

  The multipart upload API call is designed to improve the upload experience for larger archives. You can upload archives in parts. These parts can be uploaded independently, in any order, and in parallel. If a part upload fails, you only need to upload that part again and not the entire archive. You can use multipart upload for archives from 1 byte to about 40,000 GB in size. For more information, see Uploading Large Archives in Parts (Multipart Upload).

⚠️ **Important**

The S3 Glacier vault inventory is only updated once a day. When you upload an archive, you will not immediately see the new archive added to your vault (in the console or in your downloaded vault inventory list) until the vault inventory has been updated.
Using the AWS Snowball Service

AWS Snowball accelerates moving large amounts of data into and out of AWS using Amazon-owned devices, bypassing the internet. For more information, see AWS Snowball detail page.

To upload existing data to Amazon S3 Glacier (S3 Glacier), you might consider using one of the AWS Snowball device types to import data into Amazon S3, and then move it to the S3 Glacier storage class for archival using lifecycle rules. When you transition Amazon S3 objects to the S3 Glacier storage class, Amazon S3 internally uses S3 Glacier for durable storage at lower cost. Although the objects are stored in S3 Glacier, they remain Amazon S3 objects that you manage in Amazon S3, and you cannot access them directly through S3 Glacier.

For more information about Amazon S3 lifecycle configuration and transitioning objects to the S3 Glacier storage class, see Object Lifecycle Management and Transitioning Objects in the Amazon Simple Storage Service User Guide.

Uploading an Archive in a Single Operation

As described in Uploading an Archive in Amazon S3 Glacier, you can upload smaller archives in a single operation. However, we encourage Amazon S3 Glacier (S3 Glacier) customers to use Multipart Upload to upload archives greater than 100 MB.

Uploading an Archive in a Single Operation Using the AWS Command Line Interface

You can upload an archive in Amazon S3 Glacier (S3 Glacier) using the AWS Command Line Interface (AWS CLI).

Topics

- (Prerequisite) Setting Up the AWS CLI
- Example: Upload an Archive Using the AWS CLI
(Prerequisite) Setting Up the AWS CLI

1. Download and configure the AWS CLI. For instructions, see the following topics in the *AWS Command Line Interface User Guide*:

   **Installing the AWS Command Line Interface**

   **Configuring the AWS Command Line Interface**

2. Verify your AWS CLI setup by entering the following commands at the command prompt. These commands don't provide credentials explicitly, so the credentials of the default profile are used.

   - Try using the help command.

     ```bash
     aws help
     ```

   - To get a list of S3 Glacier vaults on the configured account, use the `list-vaults` command. Replace `123456789012` with your AWS account ID.

     ```bash
     aws glacier list-vaults --account-id 123456789012
     ```

   - To see the current configuration data for the AWS CLI, use the `aws configure list` command.

     ```bash
     aws configure list
     ```

Example: Upload an Archive Using the AWS CLI

In order to upload an archive you must have a vault created. For more information about creating vaults, see [Creating a Vault in Amazon S3 Glacier](#).

1. Use the `upload-archive` command to add an archive to an existing vault. In the below example replace the vault name and account ID. For the body parameter specify a path to the file you wish to upload.

   ```bash
   aws glacier upload-archive --vault-name awsexamplevault --account-id 123456789012 --body archive.zip
   ```

2. Expected output:
When finished the command will output the archive ID, checksum, and location in S3 Glacier. For more information about the upload-archive command, see `upload-archive` in the AWS CLI Command Reference.

## Uploading an Archive in a Single Operation Using the AWS SDK for Java

Both the high-level and low-level APIs provided by the Amazon SDK for Java provide a method to upload an archive.

- [Uploading an Archive in a Single Operation Using the Low-Level API of the AWS SDK for Java](#)

## Uploading an Archive Using the High-Level API of the AWS SDK for Java

The `ArchiveTransferManager` class of the high-level API provides the upload method, which you can use to upload an archive to a vault.

### Note

You can use the upload method to upload small or large archives. Depending on the archive size you are uploading, this method determines whether to upload it in a single operation or use the multipart upload API to upload the archive in parts.
Example: Uploading an Archive Using the High-Level API of the AWS SDK for Java

The following Java code example uploads an archive to a vault (examplevault) in the US West (Oregon) Region (us-west-2). For a list of supported AWS Regions and endpoints, see Accessing Amazon S3 Glacier.

For step-by-step instructions on how to run this example, see Running Java Examples for Amazon S3 Glacier Using Eclipse. You need to update the code as shown with the name of the vault you want to upload to and the name of the file you want to upload.

Example

```java
import java.io.File;
import java.io.IOException;
import java.util.Date;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.glacier.AmazonGlacierClient;
import com.amazonaws.services.glacier.transfer.ArchiveTransferManager;
import com.amazonaws.services.glacier.transfer.UploadResult;

public class ArchiveUploadHighLevel {
    public static String vaultName = "*** provide vault name ***";
    public static String archiveToUpload = "*** provide name of file to upload ***";

    public static AmazonGlacierClient client;

    public static void main(String[] args) throws IOException {
        ProfileCredentialsProvider credentials = new ProfileCredentialsProvider();

        client = new AmazonGlacierClient(credentials);
        client.setEndpoint("https://glacier.us-west-2.amazonaws.com/");

        try {
            ArchiveTransferManager atm = new ArchiveTransferManager(client, credentials);

            UploadResult result = atm.upload(vaultName, "my archive " + (new Date()),
                                              new File(archiveToUpload));
            System.out.println("Archive ID: " + result.getArchiveId());
        }
    }
}
```
Uploading an Archive in a Single Operation Using the Low-Level API of the AWS SDK for Java

The low-level API provides methods for all the archive operations. The following are the steps to upload an archive using the AWS SDK for Java.

1. Create an instance of the AmazonGlacierClient class (the client).

   You need to specify an AWS Region where you want to upload the archive. All operations you perform using this client apply to that AWS Region.

2. Provide request information by creating an instance of the UploadArchiveRequest class.

   In addition to the data you want to upload, you need to provide a checksum (SHA-256 tree hash) of the payload, the vault name, the content length of the data, and your account ID.

   If you don’t provide an account ID, then the account ID associated with the credentials you provide to sign the request is assumed. For more information, see Using the AWS SDK for Java with Amazon S3 Glacier.

3. Run the uploadArchive method by providing the request object as a parameter.

   In response, Amazon S3 Glacier (S3 Glacier) returns an archive ID of the newly uploaded archive.

The following Java code snippet illustrates the preceding steps.

```java
AmazonGlacierClient client;

UploadArchiveRequest request = new UploadArchiveRequest()
    .withVaultName("*** provide vault name ***")
    .withChecksum(checksum)
    .withBody(new ByteArrayInputStream(body))
    .withContentLength((long)body.length);

UploadArchiveResult uploadArchiveResult = client.uploadArchive(request);
```
Example: Uploading an Archive in a Single Operation Using the Low-Level API of the AWS SDK for Java

The following Java code example uses the AWS SDK for Java to upload an archive to a vault (examplevault). For step-by-step instructions on how to run this example, see Running Java Examples for Amazon S3 Glacier Using Eclipse. You need to update the code as shown with the name of the vault you want to upload to and the name of the file you want to upload.

```java
import java.io.ByteArrayInputStream;
import java.io.File;
import java.io.FileInputStream;
import java.io.IOException;
import java.io.InputStream;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.glacier.AmazonGlacierClient;
import com.amazonaws.services.glacier.TreeHashGenerator;
import com.amazonaws.services.glacier.model.UploadArchiveRequest;
import com.amazonaws.services.glacier.model.UploadArchiveResult;
public class ArchiveUploadLowLevel {
    public static String vaultName = "*** provide vault name ***";
    public static String archiveFilePath = "*** provide to file upload ***";
    public static AmazonGlacierClient client;

    public static void main(String[] args) throws IOException {
        ProfileCredentialsProvider credentials = new ProfileCredentialsProvider();
        client = new AmazonGlacierClient(credentials);
        client.setEndpoint("https://glacier.us-east-1.amazonaws.com/");

        try {
            // First open file and read.
            File file = new File(archiveFilePath);
            InputStream is = new FileInputStream(file);
            byte[] body = new byte[(int) file.length()];
            is.read(body);
        }
    }
}
```
// Send request.
UploadArchiveRequest request = new UploadArchiveRequest()
    .withVaultName(vaultName)
    .withChecksum(TreeHashGenerator.calculateTreeHash(new File(archiveFilePath)))
    .withBody(new ByteArrayInputStream(body))
    .withContentLength((long)body.length);

UploadArchiveResult uploadArchiveResult = client.uploadArchive(request);

System.out.println("ArchiveID: " + uploadArchiveResult.getArchiveId());

} catch (Exception e) {
    System.err.println("Archive not uploaded.");
    System.err.println(e);
}

Uploading an Archive in a Single Operation Using the AWS SDK for .NET in Amazon S3 Glacier

Both the high-level and low-level APIs provided by the Amazon SDK for .NET provide a method to upload an archive in a single operation.

Uploading an Archive Using the High-Level API of the AWS SDK for .NET

The ArchiveTransferManager class of the high-level API provides the Upload method that you can use to upload an archive to a vault.

Note

You can use the Upload method to upload small or large files. Depending on the file size you are uploading, this method determines whether to upload it in a single operation or use the multipart upload API to upload the file in parts.
Example: Uploading an Archive Using the High-Level API of the AWS SDK for .NET

The following C# code example uploads an archive to a vault (examplevault) in the US West (Oregon) Region.

For step-by-step instructions on how to run this example, see Running Code Examples. You need to update the code as shown with the name of the file you want to upload.

Example

```csharp
using System;
using Amazon.Glacier;
using Amazon.Glacier.Transfer;
using Amazon.Runtime;

namespace glacier.amazon.com.docsamples
{
    class ArchiveUploadHighLevel
    {
        static string vaultName = "examplevault";
        static string archiveToUpload = "*** Provide file name (with full path) to upload ***";

        public static void Main(string[] args)
        {
            try
            {
                var manager = new ArchiveTransferManager(Amazon.RegionEndpoint.USWest2);
                // Upload an archive.
                string archiveId = manager.Upload(vaultName, "upload archive test", archiveToUpload).ArchiveId;
                Console.WriteLine("Archive ID: (Copy and save this ID for use in other examples.) : {0}", archiveId);
                Console.WriteLine("To continue, press Enter");
                Console.ReadKey();
            }
            catch (AmazonGlacierException e) { Console.WriteLine(e.Message); }
            catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
            catch (Exception e) { Console.WriteLine(e.Message); }
            Console.WriteLine("To continue, press Enter");
            Console.ReadKey();
        }
    }
}
```
Uploading an Archive in a Single Operation Using the Low-Level API of the AWS SDK for .NET

The low-level API provides methods for all the archive operations. The following are the steps to upload an archive using the AWS SDK for .NET.

1. Create an instance of the AmazonGlacierClient class (the client).
   
   You need to specify an AWS Region where you want to upload the archive. All operations you perform using this client apply to that AWS Region.

2. Provide request information by creating an instance of the UploadArchiveRequest class.
   
   In addition to the data you want to upload, You need to provide a checksum (SHA-256 tree hash) of the payload, the vault name, and your account ID.
   
   If you don’t provide an account ID, then the account ID associated with the credentials you provide to sign the request is assumed. For more information, see Using the AWS SDK for .NET with Amazon S3 Glacier.

3. Run the UploadArchive method by providing the request object as a parameter.

   In response, S3 Glacier returns an archive ID of the newly uploaded archive.

Example: Uploading an Archive in a Single Operation Using the Low-Level API of the AWS SDK for .NET

The following C# code example illustrates the preceding steps. The example uses the AWS SDK for .NET to upload an archive to a vault (examplevault).

Note

For information about the underlying REST API to upload an archive in a single request, see Upload Archive (POST archive).

Uploading Large Archives in Parts (Multipart Upload)

- Multipart Upload Process
- Quick Facts
- Uploading Large Archives by Using the AWS CLI
- Uploading Large Archives in Parts Using the Amazon SDK for Java
- Uploading Large Archives Using the AWS SDK for .NET
- Uploading Large Archives in Parts Using the REST API

Multipart Upload Process

As described in Uploading an Archive in Amazon S3 Glacier, we encourage Amazon S3 Glacier (S3 Glacier) customers to use Multipart Upload to upload archives greater than 100 mebibytes (MiB).

1. **Initiate Multipart Upload**

   When you send a request to initiate a multipart upload, S3 Glacier returns a multipart upload ID, which is a unique identifier for your multipart upload. Any subsequent multipart upload operations require this ID. This ID doesn't expire for at least 24 hours after S3 Glacier completes the job.
In your request to start a multipart upload, specify the part size in number of bytes. Each part you upload, except the last part, must be this size.

**Note**

You don't need to know the overall archive size when using multipart uploads. This means that you can use multipart uploads in cases where you don't know the archive size when you start uploading the archive. You only need to decide the part size at the time you start the multipart upload.

In the initiate multipart upload request, you can also provide an optional archive description.

2. **Upload Parts**

For each part upload request, you must include the multipart upload ID you obtained in step 1. In the request, you must also specify the content range, in bytes, identifying the position of the part in the final archive. S3 Glacier later uses the content range information to assemble the archive in proper sequence. Because you provide the content range for each part that you upload, it determines the part's position in the final assembly of the archive, and therefore you can upload parts in any order. You can also upload parts in parallel. If you upload a new part using the same content range as a previously uploaded part, the previously uploaded part is overwritten.

3. **Complete (or stop) Multipart Upload**

After uploading all the archive parts, you use the complete operation. Again, you must specify the upload ID in your request. S3 Glacier creates an archive by concatenating parts in ascending order based on the content range you provided. S3 Glacier response to a Complete Multipart Upload request includes an archive ID for the newly created archive. If you provided an optional archive description in the Initiate Multipart Upload request, S3 Glacier associates it with the assembled archive. After you successfully complete a multipart upload, you cannot refer to the multipart upload ID. That means you cannot access parts associated with the multipart upload ID.

If you stop a multipart upload, you cannot upload any more parts using that multipart upload ID. All storage consumed by any parts associated with the stopped multipart upload is freed. If any part uploads were in-progress, they can still succeed or fail even after stopped.
Additional Multipart Upload Operations

Amazon S3 Glacier (S3 Glacier) provides the following additional multipart upload API calls.

- **List Parts**—Using this operation, you can list the parts of a specific multipart upload. It returns information about the parts that you have uploaded for a multipart upload. For each list parts request, S3 Glacier returns information for up to 1,000 parts. If there are more parts to list for the multipart upload, the result is paginated and a marker is returned in the response at which to continue the list. You need to send additional requests to retrieve subsequent parts. Note that the returned list of parts doesn't include parts that haven't completed uploading.

- **List Multipart Uploads**—Using this operation, you can obtain a list of multipart uploads in progress. An in-progress multipart upload is an upload that you have initiated, but have not yet completed or stopped. For each list multipart uploads request, S3 Glacier returns up to 1,000 multipart uploads. If there are more multipart uploads to list, then the result is paginated and a marker is returned in the response at which to continue the list. You need to send additional requests to retrieve the remaining multipart uploads.

**Quick Facts**

The following table provides multipart upload core specifications.

<table>
<thead>
<tr>
<th>Item</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum archive size</td>
<td>10,000 x 4 gibibytes (GiB)</td>
</tr>
<tr>
<td>Maximum number of parts per upload</td>
<td>10,000</td>
</tr>
<tr>
<td>Part size</td>
<td>1 MiB to 4 GiB, last part can be &lt; 1 MiB. You specify the size value in bytes.</td>
</tr>
<tr>
<td></td>
<td>The part size must be a mebibyte (1024 kibibytes [KiB]) multiplied by a power of 2. For example, 1048576 (1 MiB), 2097152 (2 MiB), 4194304 (4 MiB), 8388608 (8 MiB).</td>
</tr>
<tr>
<td>Maximum number of parts returned for a list parts request</td>
<td>1,000</td>
</tr>
</tbody>
</table>
Uploading Large Archives by Using the AWS CLI

You can upload an archive in Amazon S3 Glacier (S3 Glacier) by using the AWS Command Line Interface (AWS CLI). To improve the upload experience for larger archives, S3 Glacier provides several API operations to support multipart uploads. By using these API operations, you can upload archives in parts. These parts can be uploaded independently, in any order, and in parallel. If a part upload fails, you need to upload only that part again, not the entire archive. You can use multipart uploads for archives from 1 byte to about 40,000 gibibytes (GiB) in size.

For more information about S3 Glacier multipart uploads, see Uploading Large Archives in Parts (Multipart Upload).

Topics

- (Prerequisite) Setting Up the AWS CLI
- (Prerequisite) Install Python
- (Prerequisite) Create an S3 Glacier Vault
- Example: Uploading Large Archives in Parts by Using the AWS CLI

(Prerequisite) Setting Up the AWS CLI

1. Download and configure the AWS CLI. For instructions, see the following topics in the AWS Command Line Interface User Guide:
   
   Installing the AWS Command Line Interface
   
   Configuring the AWS Command Line Interface

2. Verify your AWS CLI setup by entering the following commands at the command prompt. These commands don't provide credentials explicitly, so the credentials of the default profile are used.
   
   • Try using the help command.
• To get a list of S3 Glacier vaults on the configured account, use the `list-vaults` command. Replace `123456789012` with your AWS account ID.

```
aws glacier list-vaults --account-id 123456789012
```

• To see the current configuration data for the AWS CLI, use the `aws configure list` command.

```
aws configure list
```

(Prerequisite) Install Python

To complete a multipart upload, you must calculate the SHA256 tree hash of the archive that you're uploading. Doing so is different than calculating the SHA256 tree hash of the file that you want to upload. To calculate the SHA256 tree hash of the archive that you're uploading, you can use Java, C# (with .NET), or Python. In this example, you will use Python. For instructions on using Java or C#, see Computing Checksums.

For more information about installing Python, see Install or update Python in the Boto3 Developer Guide.

(Prerequisite) Create an S3 Glacier Vault

To use the following example, you must have at least one S3 Glacier vault created. For more information about creating vaults, see Creating a Vault in Amazon S3 Glacier.

Example: Uploading Large Archives in Parts by Using the AWS CLI

In this example, you will create a file and use multipart upload API operations to upload this file, in parts, to Amazon S3 Glacier.

⚠️ **Important**

Before starting this procedure, make sure that you've performed all of the prerequisite steps. To upload an archive, you must have a vault created, the AWS CLI configured, and be prepared to use Java, C#, or Python to calculate a SHA256 tree hash.
The following procedure uses the initiate-multipart-upload, upload-multipart-part, and complete-multipart-upload AWS CLI commands.

For more detailed information about each of these commands, see initiate-multipart-upload, upload-multipart-part, and complete-multipart-upload in the AWS CLI Command Reference.

1. Use the initiate-multipart-upload command to create a multipart upload resource. In your request, specify the part size in number of bytes. Each part that you upload, except the last part, will be this size. You don't need to know the overall archive size when initiating an upload. However, you will need the total size, in bytes, of each part when completing the upload on the final step.

   In the following command, replace the values for the --vault-name and --account-ID parameters with your own information. This command specifies that you will upload an archive with a part size of 1 mebibyte (MiB) (1024 x 1024 bytes) per file. Replace this --part-size parameter value if needed.

```
aws glacier initiate-multipart-upload --vault-name awsexamplevault --part-size 1048576 --account-id 123456789012
```

Expected output:

```
{
  "location": "/123456789012/vaults/awsexamplevault/multipart-uploads/uploadId",
  "uploadId": "uploadId"
}
```

When finished, the command will output the multipart upload resource's upload ID and location in S3 Glacier. You will use this upload ID in subsequent steps.

2. For this example, you can use the following commands to create a 4.4 MiB file, split it into 1 MiB chunks, and upload each chunk. To upload your own files, you can follow a similar procedure of splitting your data into chunks and uploading each part.

**Linux or macOS**

The following command creates a 4.4 MiB file, named file_to_upload, on Linux or macOS.

```
mkfile -n 9000b file_to_upload
```
The following command creates a 4.4 MiB file, named file_to_upload, on Windows.

```bash
fsutil file createnew file_to_upload 4608000
```

3. Next, you will split this file into 1 MiB chunks.

```bash
split -b 1048576 file_to_upload chunk
```

You now have the following five chunks. The first four are 1 MiB, and the last is approximately 400 kibibytes (KiB).

```bash
chunkaa
chunkab
chunkac
chunkad
chunkae
```

4. Use the `upload-multipart-part` command to upload a part of an archive. You can upload archive parts in any order. You can also upload them in parallel. You can upload up to 10,000 parts for a multipart upload.

In the following command, replace the values for the `--vault-name`, `--account-ID`, and `--upload-id` parameters. The upload ID must match the ID given as output of the `initiate-multipart-upload` command. The `--range` parameter specifies that you will upload a part with a size of 1 MiB (1024 x 1024 bytes). This size must match what you specified in the `initiate-multipart-upload` command. Adjust this size value if needed. The `--body` parameter specifies the name of the part that you're uploading.

```bash
aws glacier upload-multipart-part --body chunkaa --range='bytes 0-1048575/*' --vault-name awsexamplevault --account-id 123456789012 --upload-id upload_ID
```

If successful, the command will produce output that contains the checksum for the uploaded part.

5. Run the `upload-multipart-part` command again to upload the remaining parts of your multipart upload. Update the `--range` and `--body` parameter values for each command to match the part that you're uploading.
aws glacier upload-multipart-part --body chunkab --range='bytes 1048576-2097151/*' --vault-name awsexamplevault --account-id 123456789012 --upload-id upload_ID

aws glacier upload-multipart-part --body chunkac --range='bytes 2097152-3145727/*' --vault-name awsexamplevault --account-id 123456789012 --upload-id upload_ID

aws glacier upload-multipart-part --body chunkad --range='bytes 3145728-4194303/*' --vault-name awsexamplevault --account-id 123456789012 --upload-id upload_ID

aws glacier upload-multipart-part --body chunkae --range='bytes 4194304-4607999/*' --vault-name awsexamplevault --account-id 123456789012 --upload-id upload_ID

**Note**

The final command's --range parameter value is smaller because the final part of our upload is less than 1 MiB. If successful, each command will produce output that contains the checksum for each uploaded part.

6. Next, you will assemble the archive and finish the upload. You must include the total size and SHA256 tree hash of the archive.

   To calculate the SHA256 tree hash of the archive, you can use Java, C#, or Python. In this example, you will use Python. For instructions on using Java or C#, see [Computing Checksums](#).

   Create the Python file `checksum.py` and insert the following code. If needed, replace the name of the original file.

   ```python
   from botocore.utils import calculate_tree_hash
   
   checksum = calculate_tree_hash(open('file_to_upload', 'rb'))
   print(checksum)
   ```

7. Run `checksum.py` to calculate the SHA256 tree hash. The following hash may not match your output.

   ```shell
   $ python3 checksum.py
   $ 3d760edb291bfc9d90d35809243de092aa4c47b308290ad12d084f69988ae0c
   ```
8. Use the `complete-multipart-upload` command to finish the archive upload. Replace the values for the `--vault-name`, `--account-ID`, `--upload-ID`, and `--checksum` parameters. The `--archive` parameter value specifies the total size, in bytes, of the archive. This value must be the sum of all the sizes of the individual parts that you uploaded. Replace this value if needed.

```bash
aws glacier complete-multipart-upload --archive-size 4608000 --vault-name awsexamplevault --account-id 123456789012 --upload-id upload_ID --checksum checksum
```

When finished, the command will output the archive's ID, checksum, and location in S3 Glacier.

### Uploading Large Archives in Parts Using the Amazon SDK for Java

Both the high-level and low-level APIs provided by the Amazon SDK for Java provide a method to upload a large archive (see Uploading an Archive in Amazon S3 Glacier).

- The high-level API provides a method that you can use to upload archives of any size. Depending on the file you are uploading, the method either uploads an archive in a single operation or uses the multipart upload support in Amazon S3 Glacier (S3 Glacier) to upload the archive in parts.
- The low-level API maps close to the underlying REST implementation. Accordingly, it provides a method to upload smaller archives in one operation and a group of methods that support multipart upload for larger archives. This section explains uploading large archives in parts using the low-level API.

For more information about the high-level and low-level APIs, see Using the AWS SDK for Java with Amazon S3 Glacier.

### Uploading Large Archives in Parts Using the High-Level API of the AWS SDK for Java

You use the same methods of the high-level API to upload small or large archives. Based on the archive size, the high-level API methods decide whether to upload the archive in a single operation
or use the multipart upload API provided by S3 Glacier. For more information, see Uploading an Archive Using the High-Level API of the AWS SDK for Java.

**Upload Large Archives in Parts Using the Low-Level API of the AWS SDK for Java**

For granular control of the upload you can use the low-level API where you can configure the request and process the response. The following are the steps to upload large archives in parts using the AWS SDK for Java.

1. Create an instance of the AmazonGlacierClient class (the client).

   You need to specify an AWS Region where you want to save the archive. All operations you perform using this client apply to that AWS Region.

2. Initiate multipart upload by calling the initiateMultipartUpload method.

   You need to provide vault name in which you want to upload the archive, part size you want to use to upload archive parts, and an optional description. You provide this information by creating an instance of the InitiateMultipartUploadRequest class. In response, S3 Glacier returns an upload ID.

3. Upload parts by calling the uploadMultipartPart method.

   For each part you upload, You need to provide the vault name, the byte range in the final assembled archive that will be uploaded in this part, the checksum of the part data, and the upload ID.

4. Complete multipart upload by calling the completeMultipartUpload method.

   You need to provide the upload ID, the checksum of the entire archive, the archive size (combined size of all parts you uploaded), and the vault name. S3 Glacier constructs the archive from the uploaded parts and returns an archive ID.

**Example: Uploading a Large Archive in a Parts Using the AWS SDK for Java**

The following Java code example uses the AWS SDK for Java to upload an archive to a vault (examplevault). For step-by-step instructions on how to run this example, see Running Java Examples for Amazon S3 Glacier Using Eclipse. You need to update the code as shown with the name of the file you want to upload.
Note

This example is valid for part sizes from 1 MB to 1 GB. However, S3 Glacier supports part sizes up to 4 GB.

Uploading Large Archives Using the AWS SDK for .NET

Both the high-level and low-level APIs provided by the Amazon SDK for .NET provide a method to upload large archives in parts (see Uploading an Archive in Amazon S3 Glacier).

- The high-level API provides a method that you can use to upload archives of any size. Depending on the file you are uploading, the method either uploads archive in a single operation or uses the multipart upload support in Amazon S3 Glacier (S3 Glacier) to upload the archive in parts.

Uploading Large Archives in Parts Using the High-Level API of the AWS SDK for .NET

You use the same methods of the high-level API to upload small or large archives. Based on the archive size, the high-level API methods decide whether to upload the archive in a single operation or use the multipart upload API provided by S3 Glacier. For more information, see Uploading an Archive Using the High-Level API of the AWS SDK for .NET.

Uploading Large Archives in Parts Using the Low-Level API of the AWS SDK for .NET

For granular control of the upload, you can use the low-level API, where you can configure the request and process the response. The following are the steps to upload large archives in parts using the AWS SDK for .NET.
1. Create an instance of the AmazonGlacierClient class (the client).

   You need to specify an AWS Region where you want to save the archive. All operations you perform using this client apply to that AWS Region.

2. Initiate multipart upload by calling the InitiateMultipartUpload method.

   You need to provide the vault name to which you want to upload the archive, the part size you want to use to upload archive parts, and an optional description. You provide this information by creating an instance of the InitiateMultipartUploadRequest class. In response, S3 Glacier returns an upload ID.

3. Upload parts by calling the UploadMultipartPart method.

   For each part you upload, you need to provide the vault name, the byte range in the final assembled archive that will be uploaded in this part, the checksum of the part data, and the upload ID.

4. Complete the multipart upload by calling the CompleteMultipartUpload method.

   You need to provide the upload ID, the checksum of the entire archive, the archive size (combined size of all parts you uploaded), and the vault name. S3 Glacier constructs the archive from the uploaded parts and returns an archive ID.

Example: Uploading a Large Archive in Parts Using the Amazon SDK for .NET

The following C# code example uses the AWS SDK for .NET to upload an archive to a vault (examplevault). For step-by-step instructions on how to run this example, see Running Code Examples. You need to update the code as shown with the name of a file you want to upload.

Example

```csharp
using System;
using System.Collections.Generic;
using System.IO;
using Amazon.Glacier;
using Amazon.Glacier.Model;
using Amazon.Runtime;

Uploading Large Archives in Parts Using the REST API

As described in Uploading Large Archives in Parts (Multipart Upload), multipart upload refers to a set of operations that enable you to upload an archive in parts and perform related operations. For more information about these operations, see the following API reference topics:

- Initiate Multipart Upload (POST multipart-uploads)
- Upload Part (PUT uploadID)
- Complete Multipart Upload (POST uploadID)
- Abort Multipart Upload (DELETE uploadID)
- List Parts (GET uploadID)
- List Multipart Uploads (GET multipart-uploads)

Downloading an Archive in S3 Glacier

Amazon S3 Glacier provides a management console, which you can use to create and delete vaults. However, you cannot download archives from S3 Glacier by using the management console. To download data, such as photos, videos, and other documents, you must either use the AWS Command Line Interface (AWS CLI) or write code to make requests, by using either the REST API directly or by using the AWS SDKs.

For information about using S3 Glacier with the AWS CLI, see the AWS CLI Reference for S3 Glacier. To install the AWS CLI, see AWS Command Line Interface. The following topics describe how to
download archives to S3 Glacier by using the AWS SDK for Java, the AWS SDK for .NET, and the Amazon S3 Glacier REST API.

- Retrieving S3 Glacier Archives Using AWS Console

Retrieving S3 Glacier Archives Using AWS Console

Retrieving an archive from Amazon S3 Glacier is an asynchronous operation in which you first initiate a job, and then download the output after the job is completed. To initiate an archive retrieval job, you use the Initiate Job (POST jobs) REST API operation or the equivalent in the AWS CLI, or the AWS SDKs.

Topics

- Archive Retrieval Options
- Ranged Archive Retrievals

Retrieving an archive from S3 Glacier is a two-step process.

To retrieve an archive

1. Initiate an archive retrieval job.
   a. Get the ID of the archive that you want to retrieve. You can get the archive ID from an inventory of the vault. You can get the archive ID with the REST API, AWS CLI, or AWS SDKs. For more information, see Downloading a Vault Inventory in Amazon S3 Glacier.
   b. Initiate a job that requests S3 Glacier to prepare an entire archive or a portion of the archive for subsequent download by using the Initiate Job (POST jobs) operation.

When you initiate a job, S3 Glacier returns a job ID in the response and runs the job asynchronously. (You cannot download the job output until after the job is completed, as described in Step 2.)
When required, you can restore large segments of the data stored in S3 Glacier. For more information about restoring data from the S3 Glacier storage classes, see Storage Classes for Archiving Objects in the Amazon Simple Storage Service User Guide.

2. After the job is completed, download the bytes by using the Get Job Output (GET output) operation.

You can download all bytes or specify a byte range to download only a portion of the job output. For larger output, downloading the output in chunks helps in the event of a download failure, such as a network failure. If you get job output in a single request and there is a network failure, you have to restart downloading the output from the beginning. However, if you download the output in chunks, in the event of any failure, you need only restart the download of the smaller portion and not the entire output.

S3 Glacier must complete a job before you can get its output. After completion, a job does not expire for at least 24 hours, which means that you can download the output within the 24-hour period after the job is completed. To determine if your job is complete, check its status by using one of the following options:

- **Wait for a job-completion notification** – You can specify an Amazon Simple Notification Service (Amazon SNS) topic to which S3 Glacier can post a notification after the job is completed. S3 Glacier sends a notification only after it completes the job.

You can specify an Amazon SNS topic for a job when you initiate the job. In addition to specifying an Amazon SNS topic in your job request, if your vault has notifications set for archive retrieval events, then S3 Glacier also publishes a notification to that SNS topic. For more information, see Configuring Vault Notifications in Amazon S3 Glacier.
• **Request job information explicitly** – You can also use the S3 Glacier Describe Job API operation ([Describe Job (GET JobID)])[1] to periodically poll for job information. However, we recommend using Amazon SNS notifications.

---

**Note**

The information that you get by using an Amazon SNS notification is the same as what you get by calling the Describe Job API operation.

---

**Archive Retrieval Options**

When initiating a job to retrieve an archive, you can specify one of the following retrieval options, based on your access time and cost requirements. For information about retrieval pricing, see [Amazon S3 Glacier Pricing](https://aws.amazon.com/s3glacier/pricing/).

- **Expedited** – Expedited retrievals allow you to quickly access your data that's stored in the S3 Glacier Flexible Retrieval storage class or the S3 Intelligent-Tiering Archive Access tier when occasional urgent requests for restoring archives are required. For all but the largest archives (more than 250 MB), data accessed by using Expedited retrievals is typically made available within 1–5 minutes. Provisioned capacity ensures that retrieval capacity for Expedited retrievals is available when you need it. For more information, see [Provisioned Capacity](https://aws.amazon.com/s3glacier/pricing/).

- **Standard** – Standard retrievals allow you to access any of your archives within several hours. Standard retrievals are typically completed within 3–5 hours. Standard is the default option for retrieval requests that do not specify the retrieval option.

- **Bulk** – Bulk retrievals are the lowest-cost S3 Glacier retrieval option, which you can use to retrieve large amounts, even petabytes, of data inexpensively in a day. Bulk retrievals are typically completed within 5–12 hours.

The following table summarizes the archive retrieval options. For information about pricing, see [Amazon S3 Glacier pricing](https://aws.amazon.com/s3glacier/pricing/).

To make an Expedited, Standard, or Bulk retrieval, set the `Tier` request element in the [RestoreObject](https://docs.aws.amazon.com/AmazonS3/latest/API/REST-S3-API-bucket-name getObject.html) REST API operation request to the option that you want, or the equivalent in the AWS Command Line Interface (AWS CLI) or AWS SDKs. If you purchased provisioned capacity, all Expedited retrievals are automatically served through your provisioned capacity.
Provisioned Capacity

Provisioned capacity helps ensure that your retrieval capacity for Expedited retrievals is available when you need it. Each unit of capacity provides that at least three Expedited retrievals can be performed every 5 minutes and provides up to 150 megabytes per second (MBps) of retrieval throughput.

If your workload requires highly reliable and predictable access to a subset of your data in minutes, we recommend that you purchase provisioned retrieval capacity. Without provisioned capacity, Expedited retrievals are typically accepted, except for rare situations of unusually high demand. However, if you require access to Expedited retrievals under all circumstances, you must purchase provisioned retrieval capacity.

Purchasing Provisioned Capacity

You can purchase provisioned capacity units by using the S3 Glacier console, the Purchase Provisioned Capacity (POST provisioned-capacity) REST API operation, the AWS SDKs, or the AWS CLI. For provisioned capacity pricing information, see Amazon S3 Glacier Pricing.

A provisioned capacity unit lasts for one month, starting at the date and time of purchase.

If the start date is on the 31st day of a month, the expiration date is the last day of the next month. For example, if the start date is August 31, the expiration date is September 30. If the start date is January 31, the expiration date is February 28.

To purchase provisioned capacity by using the Amazon S3 Glacier console

1. Sign in to the AWS Management Console and open the S3 Glacier console at https://console.aws.amazon.com/glacier/home.
2. In the left navigation pane, choose Data retrieval settings.
3. Under Provisioned capacity units (PCUs), choose Purchase PCU. The Purchase PCU dialog box appears.
4. If you want to purchase provisioned capacity, enter confirm in the To confirm purchase box.
5. Choose Purchase PCU.
Ranged Archive Retrievals

When you retrieve an archive from S3 Glacier, you can optionally specify a range, or portion, of the archive to retrieve. The default is to retrieve the whole archive. Specifying a range of bytes can be helpful when you want to do the following:

- **Manage your data downloads** – S3 Glacier allows retrieved data to be downloaded for 24 hours after the retrieval request is completed. Therefore, you might want to retrieve only portions of the archive so that you can manage the schedule of downloads within the given download window.

- **Retrieve a targeted part of a large archive** – For example, suppose you have previously aggregated many files and uploaded them as a single archive, and now you want to retrieve a few of the files. In this case, you can specify a range of the archive that contains the files that you are interested in by using one retrieval request. Or, you can initiate multiple retrieval requests, each with a range for one or more files.

When initiating a retrieval job using range retrievals, you must provide a range that is megabyte aligned. In other words, the byte range can start at zero (the beginning of your archive), or at any 1-MB interval thereafter (1 MB, 2 MB, 3 MB, and so on).

The end of the range can either be the end of your archive or any 1 MB interval greater than the beginning of your range. Furthermore, if you want to get checksum values when you download the data (after the retrieval job is completed), the range that you request in the job initiation must also be tree-hash aligned. You can use checksums to help ensure that your data was not corrupted during transmission. For more information about megabyte alignment and tree-hash alignment, see [Receiving Checksums When Downloading Data](#).

Downloading an Archive Using the High-Level API of the AWS SDK for Java

The ArchiveTransferManager class of the high-level API provides the download method you can use to download an archive.

⚠️ Important

The ArchiveTransferManager class creates an Amazon Simple Notification Service (Amazon SNS) topic, and an Amazon Simple Queue Service (Amazon SQS) queue that is subscribed to that topic. It then initiates the archive retrieval job and polls the queue for the archive to be available. When the archive is available, download begins. For information about retrieval times, see Archive Retrieval Options.

Example: Downloading an Archive Using the High-Level API of the AWS SDK for Java

The following Java code example downloads an archive from a vault (examplevault) in the US West (Oregon) Region (us-west-2).

For step-by-step instructions to run this sample, see Running Java Examples for Amazon S3 Glacier Using Eclipse. You need to update the code as shown with an existing archive ID and the local file path where you want to save the downloaded archive.

Example

```java
import java.io.File;
import java.io.IOException;

import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.glacier.AmazonGlacierClient;
import com.amazonaws.services.glacier.transfer.ArchiveTransferManager;
import com.amazonaws.services.sns.AmazonSNSClient;
import com.amazonaws.services.sqs.AmazonSQSClient;

public class ArchiveDownloadHighLevel {
    public static String vaultName = "examplevault";
    public static String archiveId = "*** provide archive ID ***";
    public static String downloadFilePath = "*** provide location to download archive ***";
```
Download an Archive Using the Low-Level API of the AWS SDK for Java

The following are the steps to retrieve a vault inventory using the AWS SDK for Java low-level API.

1. Create an instance of the AmazonGlacierClient class (the client).

   You need to specify an AWS Region from where you want to download the archive. All operations you perform using this client apply to that AWS Region.

2. Initiate an archive-retrieval job by executing the initiateJob method.

   You provide job information, such as the archive ID of the archive you want to download and the optional Amazon SNS topic to which you want Amazon S3 Glacier (S3 Glacier) to
post a job completion message, by creating an instance of the InitiateJobRequest class. S3 Glacier returns a job ID in response. The response is available in an instance of the InitiateJobResult class.

```java
JobParameters jobParameters = new JobParameters()
    .withArchiveId("*** provide an archive id ***")
    .withDescription("archive retrieval")
    .withRetrievalByteRange("*** provide a retrieval range***") // optional
    .withType("archive-retrieval");

InitiateJobResult initiateJobResult = client.initiateJob(new InitiateJobRequest()
    .withJobParameters(jobParameters)
    .withVaultName(vaultName));

String jobId = initiateJobResult.getJobId();
```

You can optionally specify a byte range to request S3 Glacier to prepare only a portion of the archive. For example, you can update the preceding request by adding the following statement to request S3 Glacier to prepare only the 1 MB to 2 MB portion of the archive.

```java
int ONE_MEG = 1048576;
String retrievalByteRange = String.format("%s-%s", ONE_MEG, 2*ONE_MEG -1);

JobParameters jobParameters = new JobParameters()
    .withType("archive-retrieval")
    .withArchiveId(archiveId)
    .withRetrievalByteRange(retrievalByteRange)
    .withSNSTopic(snsTopicARN);

InitiateJobResult initiateJobResult = client.initiateJob(new InitiateJobRequest()
    .withJobParameters(jobParameters)
    .withVaultName(vaultName));

String jobId = initiateJobResult.getJobId();
```

3. Wait for the job to complete.

You must wait until the job output is ready for you to download. If you have either set a notification configuration on the vault identifying an Amazon Simple Notification Service
(Amazon SNS) topic or specified an Amazon SNS topic when you initiated a job, S3 Glacier sends a message to that topic after it completes the job.

You can also poll S3 Glacier by calling the `describeJob` method to determine the job completion status. Although, using an Amazon SNS topic for notification is the recommended approach.

4. Download the job output (archive data) by executing the `getJobOutput` method.

You provide the request information such as the job ID and vault name by creating an instance of the `GetJobOutputRequest` class. The output that S3 Glacier returns is available in the `GetJobOutputResult` object.

```java
GetJobOutputRequest jobOutputRequest = new GetJobOutputRequest()
    .withJobId("*** provide a job ID ***")
    .withVaultName("*** provide a vault name ****");
GetJobOutputResult jobOutputResult = client.getJobOutput(jobOutputRequest);
// jobOutputResult.getBody() // Provides the input stream.
```

The preceding code snippet downloads the entire job output. You can optionally retrieve only a portion of the output, or download the entire output in smaller chunks by specifying the byte range in your `GetJobOutputRequest`.

```java
GetJobOutputRequest jobOutputRequest = new GetJobOutputRequest()
    .withJobId("*** provide a job ID ***")
    .withRange("bytes=0-1048575")   // Download only the first 1 MB of the output.
    .withVaultName("*** provide a vault name ****");
```

In response to your `GetJobOutput` call, S3 Glacier returns the checksum of the portion of the data you downloaded, if certain conditions are met. For more information, see [Receiving Checksums When Downloading Data](#).

To verify there are no errors in the download, you can then compute the checksum on the client-side and compare it with the checksum S3 Glacier sent in the response.

For an archive retrieval job with the optional range specified, when you get the job description, it includes the checksum of the range you are retrieving (SHA256TreeHash). You can use this value
to further verify the accuracy of the entire byte range that you later download. For example, if you initiate a job to retrieve a tree-hash aligned archive range and then download output in chunks such that each of your GetJobOutput requests return a checksum, then you can compute checksum of each portion you download on the client-side and then compute the tree hash. You can compare it with the checksum S3 Glacier returns in response to your describe job request to verify that the entire byte range you have downloaded is the same as the byte range that is stored in S3 Glacier.

For a working example, see Example 2: Retrieving an Archive Using the Low-Level API of the AWS SDK for Java—Download Output in Chunks.

Example 1: Retrieving an Archive Using the Low-Level API of the AWS SDK for Java

The following Java code example downloads an archive from the specified vault. After the job completes, the example downloads the entire output in a single getJobOutput call. For an example of downloading output in chunks, see Example 2: Retrieving an Archive Using the Low-Level API of the AWS SDK for Java—Download Output in Chunks.

The example performs the following tasks:

- Creates an Amazon Simple Notification Service (Amazon SNS) topic. S3 Glacier sends a notification to this topic after it completes the job.
- Creates an Amazon Simple Queue Service (Amazon SQS) queue. The example attaches a policy to the queue to enable the Amazon SNS topic to post messages to the queue.
- Initiates a job to download the specified archive. In the job request, the Amazon SNS topic that was created is specified so that S3 Glacier can publish a notification to the topic after it completes the job.
- Periodically checks the Amazon SQS queue for a message that contains the job ID. If there is a message, parse the JSON and check if the job completed successfully. If it did, download the archive.
- Cleans up by deleting the Amazon SNS topic and the Amazon SQS queue that it created.

### Downloading an Archive in Amazon S3 Glacier Using the AWS SDK for .NET

Both the [high-level and low-level APIs](#) provided by the Amazon SDK for .NET provide a method to download an archive.

**Topics**

### Downloading an Archive Using the High-Level API of the AWS SDK for .NET

The `ArchiveTransferManager` class of the high-level API provides the `Download` method you can use to download an archive.

⚠️ **Important**

The `ArchiveTransferManager` class creates an Amazon Simple Notification Service (Amazon SNS) topic, and an Amazon Simple Queue Service (Amazon SQS) queue that is subscribed to that topic. It then initiates the archive retrieval job and polls the queue for
the archive to be available. When the archive is available, download begins. For information about retrieval times, see Archive Retrieval Options

Example: Downloading an Archive Using the High-Level API of the AWS SDK for .NET

The following C# code example downloads an archive from a vault (examplevault) in the US West (Oregon) Region.

For step-by-step instructions on how to run this example, see Running Code Examples. You need to update the code as shown with an existing archive ID and the local file path where you want to save the downloaded archive.

```csharp
using System;
using Amazon.Glacier;
using Amazon.Glacier.Transfer;
using Amazon.Runtime;

namespace glacier.amazon.com.docsamples
{
    class ArchiveDownloadHighLevel
    {
        static string vaultName = "examplevault";
        static string archiveId = "*** Provide archive ID ***";
        static string downloadFilePath = "*** Provide the file name and path to where to store the download ***";

        public static void Main(string[] args)
        {
            try
            {
                var manager = new ArchiveTransferManager(Amazon.RegionEndpoint.USWest2);

                var options = new DownloadOptions();
                options.StreamTransferProgress += ArchiveDownloadHighLevel.progress;
                // Download an archive.
                Console.WriteLine("Intiating the archive retrieval job and then polling SQS queue for the archive to be available.");
                manager.Download(vaultName, archiveId, downloadFilePath, options);
                Console.WriteLine("Once the archive is available, downloading will begin.");
                Console.WriteLine("To continue, press Enter");
                Console.ReadKey();
            }
        }
    }
}
```
Download an Archive Using the Low-Level API of the AWS SDK for .NET

The following are the steps for downloading an Amazon S3 Glacier (S3 Glacier) archive using the low-level API of the AWS SDK for .NET.

1. Create an instance of the AmazonGlacierClient class (the client).

   You need to specify an AWS Region from where you want to download the archive. All operations you perform using this client apply to that AWS Region.

2. Initiate an archive-retrieval job by executing the InitiateJob method.

   You provide job information, such as the archive ID of the archive you want to download and the optional Amazon SNS topic to which you want S3 Glacier to post a job completion message, by creating an instance of the InitiateJobRequest class. S3 Glacier returns a job ID in response. The response is available in an instance of the InitiateJobResponse class.

```csharp
AmazonGlacierClient client;
client = new AmazonGlacierClient(Amazon.RegionEndpoint_USWest2);

InitiateJobRequest initJobRequest = new InitiateJobRequest()
{
    VaultName = vaultName,
};
```
You can optionally specify a byte range to request S3 Glacier to prepare only a portion of the archive as shown in the following request. The request specifies S3 Glacier to prepare only the 1 MB to 2 MB portion of the archive.

```csharp
AmazonGlacierClient client;
client = new AmazonGlacierClient(Amazon.RegionEndpoint.USWest2);

InitiateJobRequest initJobRequest = new InitiateJobRequest()
{
    VaultName = vaultName,
    JobParameters = new JobParameters()
    {
        Type = "archive-retrieval",
        ArchiveId = "*** Provide archive id ***",
        SNSTopic = "*** Provide Amazon SNS topic ARN ***",
    }
};

// Specify byte range.
int ONE_MEG = 1048576;
initJobRequest.JobParameters.RetrievalByteRange = string.Format("{0}-{1}", ONE_MEG, 2 * ONE_MEG -1);

InitiateJobResponse initJobResponse = client.InitiateJob(initJobRequest);
string jobId = initJobResponse.JobId;
```

3. Wait for the job to complete.

You must wait until the job output is ready for you to download. If you have either set a notification configuration on the vault identifying an Amazon Simple Notification Service (Amazon SNS) topic or specified an Amazon SNS topic when you initiated a job, S3 Glacier sends
a message to that topic after it completes the job. The code example given in the following section uses Amazon SNS for S3 Glacier to publish a message.

You can also poll S3 Glacier by calling the `DescribeJob` method to determine the job completion status. Although, using an Amazon SNS topic for notification is the recommended approach.

4. Download the job output (archive data) by executing the `GetJobOutput` method.

You provide the request information such as the job ID and vault name by creating an instance of the `GetJobOutputRequest` class. The output that S3 Glacier returns is available in the `GetJobOutputResponse` object.

```csharp
GetJobOutputRequest jobOutputRequest = new GetJobOutputRequest()
{
    JobId = jobId,
    VaultName = vaultName
};

GetJobOutputResponse jobOutputResponse = client.GetJobOutput(jobOutputRequest);
using (Stream webStream = jobOutputResponse.Body)
{
    using (Stream fileToSave = File.OpenWrite(fileName))
    {
        CopyStream(webStream, fileToSave);
    }
}
```

The preceding code snippet downloads the entire job output. You can optionally retrieve only a portion of the output, or download the entire output in smaller chunks by specifying the byte range in your `GetJobOutputRequest`.

```csharp
GetJobOutputRequest jobOutputRequest = new GetJobOutputRequest()
{
    JobId = jobId,
    VaultName = vaultName
};

jobOutputRequest.SetRange(0, 1048575); // Download only the first 1 MB chunk of the output.
```
In response to your `GetJobOutput` call, S3 Glacier returns the checksum of the portion of the data you downloaded, if certain conditions are met. For more information, see Receiving Checksums When Downloading Data.

To verify there are no errors in the download, you can then compute the checksum on the client-side and compare it with the checksum S3 Glacier sent in the response.

For an archive retrieval job with the optional range specified, when you get the job description, it includes the checksum of the range you are retrieving (SHA256TreeHash). You can use this value to further verify the accuracy of the entire byte range that you later download. For example, if you initiate a job to retrieve a tree-hash aligned archive range and then download output in chunks such that each of your `GetJobOutput` requests return a checksum, then you can compute checksum of each portion you download on the client-side and then compute the tree hash. You can compare it with the checksum S3 Glacier returns in response to your describe job request to verify that the entire byte range you have downloaded is the same as the byte range that is stored in S3 Glacier.

For a working example, see Example 2: Retrieving an Archive Using the Low-Level API of the AWS SDK for .NET—Download Output in Chunks.

**Example 1: Retrieving an Archive Using the Low-Level API of the AWS SDK for .NET**

The following C# code example downloads an archive from the specified vault. After the job completes, the example downloads the entire output in a single `GetJobOutput` call. For an example of downloading output in chunks, see Example 2: Retrieving an Archive Using the Low-Level API of the AWS SDK for .NET—Download Output in Chunks.

The example performs the following tasks:

- Sets up an Amazon Simple Notification Service (Amazon SNS) topic
  - S3 Glacier sends a notification to this topic after it completes the job.
- Sets up an Amazon Simple Queue Service (Amazon SQS) queue.
  - The example attaches a policy to the queue to enable the Amazon SNS topic to post messages.
- Initiates a job to download the specified archive.
In the job request, the example specifies the Amazon SNS topic so that S3 Glacier can send a
message after it completes the job.

- Periodically checks the Amazon SQS queue for a message.

If there is a message, parse the JSON and check if the job completed successfully. If it did,
download the archive. The code example uses the JSON.NET library (see [JSON.NET](#)) to parse the
JSON.

- Cleans up by deleting the Amazon SNS topic and the Amazon SQS queue it created.

**Downloading an Archive by Using the REST API**

To download an archive by using the REST API

Downloading an archive is a two-step process.

1. Initiate a job of the archive-retrieval type. For more information, see [Initiate Job (POST jobs)].
2. After the job is completed, download the archive data. For more information, see [Get Job Output (GET output)].
Downloading an Archive in Amazon S3 Glacier Using the AWS CLI

You can download archives in Amazon S3 Glacier (S3 Glacier) using the AWS Command Line Interface (AWS CLI).

Topics

- **(Prerequisite) Setting Up the AWS CLI**
- **Example: Download an Archive Using the AWS CLI**

**(Prerequisite) Setting Up the AWS CLI**

1. Download and configure the AWS CLI. For instructions, see the following topics in the *AWS Command Line Interface User Guide*:

   - **Installing the AWS Command Line Interface**
   - **Configuring the AWS Command Line Interface**

2. Verify your AWS CLI setup by entering the following commands at the command prompt. These commands don't provide credentials explicitly, so the credentials of the default profile are used.

   - Try using the help command.

     ```bash
     aws help
     ```

   - To get a list of S3 Glacier vaults on the configured account, use the `list-vaults` command. Replace *123456789012* with your AWS account ID.

     ```bash
     aws glacier list-vaults --account-id 123456789012
     ```

   - To see the current configuration data for the AWS CLI, use the `aws configure list` command.

     ```bash
     aws configure list
     ```
## Example: Download an Archive Using the AWS CLI

1. **Use the initiate-job command to start an inventory-retrieval job.** The inventory report will list your archive ids.

   ```
   aws glacier initiate-job --vault-name awsexamplevault --account-id 111122223333 --job-parameters="{"Type":"inventory-retrieval"}"
   ```

   **Expected output:**

   ```
   {
   "location": "/111122223333/vaults/awsexamplevault/jobs/*** jobid ***",
   "jobId": "*** jobid ***"
   }
   ```

2. **Use the describe-job command to check status of the previous job command.**

   ```
   aws glacier describe-job --vault-name awsexamplevault --account-id 111122223333 --job-id *** jobid ***
   ```

   **Expected output:**

   ```
   {
   "InventoryRetrievalParameters": {
   "Format": "JSON"
   },
   "VaultARN": "*** vault arn ***",
   "Completed": false,
   "JobId": "*** jobid ***",
   "Action": "InventoryRetrieval",
   "CreationDate": "*** job creation date ***",
   "StatusCode": "InProgress"
   }
   ```
3. Wait for the job to complete.

You must wait until the job output is ready for you to download. If you set a notification configuration on the vault or specified an Amazon Simple Notification Service (Amazon SNS) topic when you initiated the job, S3 Glacier sends a message to the topic after it completes the job.

You can set notification configuration for specific events on the vault. For more information, see Configuring Vault Notifications in Amazon S3 Glacier. S3 Glacier sends a message to the specified SNS topic anytime the specific event occurs.

4. When it's complete, use the `get-job-output` command to download the retrieval job to the file `output.json`. This file will contain your archive ids.

   ```bash
   aws glacier get-job-output --vault-name awsexamplevault --account-id 111122223333 --job-id *** jobid *** output.json
   ```

   This command produces a file with the following fields.

   ```json
   {
   "InventoryDate":"*** job completion date ***",
   "ArchiveList":[
   {"ArchiveId":"*** archiveid ***",
   "ArchiveDescription":*** archive description (if set) ***,
   "CreationDate":"*** archive creation date ***",
   "Size":"*** archive size (in bytes) ***",
   "SHA256TreeHash":"*** archive hash ***
   }
   {"ArchiveId":
   ...
   ]
   }
   ```

5. Use the `initiate-job` command to start the retrieval process each archive from a vault. You will need to specify the job parameter as `archive-retrieval` as seen below.

---

**Downloading an Archive Using the AWS CLI**

**API Version 2012-06-01 178**

---
aws glacier initiate-job --vault-name awsexamplevault --account-id 111122223333 --job-parameters='{{"Type":"archive-retrieval","ArchiveId":"*** archiveId ***"}}" |

6. Wait for the archive-retrieval job to complete. Use the describe-job command to check status of the previous command.

aws glacier describe-job --vault-name awsexamplevault --account-id 111122223333 --job-id *** jobid *** |

7. When the above job is complete use the get-job-output command to download your archive.

aws glacier get-job-output --vault-name awsexamplevault --account-id 111122223333 --job-id *** jobid *** output_file_name |

Deleting an Archive in Amazon S3 Glacier

You cannot delete an archive using the Amazon S3 Glacier (S3 Glacier) management console. To delete an archive you must use the AWS Command Line Interface (CLI) or write code to make a delete request using either the REST API directly or the AWS SDK for Java and .NET wrapper libraries. The following topics explain how to use the AWS SDK for Java and .NET wrapper libraries, the REST API, and the AWS CLI.

Topics

- Deleting an Archive in Amazon S3 Glacier Using the AWS SDK for Java
- Deleting an Archive in Amazon S3 Glacier Using the AWS SDK for .NET
- Deleting an Amazon S3 Glacier Archive Using the REST API
- Deleting an Archive in Amazon S3 Glacier Using the AWS Command Line Interface

You can delete one archive at a time from a vault. To delete the archive you must provide its archive ID in your delete request. You can get the archive ID by downloading the vault inventory for the vault that contains the archive. For more information about downloading the vault inventory, see Downloading a Vault Inventory in Amazon S3 Glacier.
After you delete an archive, you might still be able to make a successful request to initiate a job to retrieve the deleted archive, but the archive retrieval job will fail.

Archive retrievals that are in progress for an archive ID when you delete the archive might or might not succeed according to the following scenarios:

- If the archive retrieval job is actively preparing the data for download when S3 Glacier receives the delete archive request, then the archival retrieval operation might fail.
- If the archive retrieval job has successfully prepared the archive for download when S3 Glacier receives the delete archive request, then you will be able to download the output.

For more information about archive retrieval, see [Downloading an Archive in S3 Glacier](#).

This operation is idempotent. Deleting an already-deleted archive does not result in an error.

After you delete an archive, if you immediately download the vault inventory, it might include the deleted archive in the list because S3 Glacier prepares vault inventory only about once a day.

**Deleting an Archive in Amazon S3 Glacier Using the AWS SDK for Java**

The following are the steps to delete an archive using the AWS SDK for Java low-level API.

1. Create an instance of the `AmazonGlacierClient` class (the client).

   You need to specify an AWS Region where the archive you want to delete is stored. All operations you perform using this client apply to that AWS Region.

2. Provide request information by creating an instance of the `DeleteArchiveRequest` class.

   You need to provide an archive ID, a vault name, and your account ID. If you don't provide an account ID, then account ID associated with the credentials you provide to sign the request is assumed. For more information, see [Using the AWS SDK for Java with Amazon S3 Glacier](#).

3. Run the `deleteArchive` method by providing the request object as a parameter.

   The following Java code snippet illustrates the preceding steps.

```java
AmazonGlacierClient client;
```
DeleteArchiveRequest request = new DeleteArchiveRequest()
   .withVaultName("*** provide a vault name ***")
   .withArchiveId("*** provide an archive ID ***");

client.deleteArchive(request);

**Note**

For information about the underlying REST API, see [Delete Archive (DELETE archive)](https://docs.aws.amazon.com/AmazonS3/latestRESTReference/RESTReference-DeleteArchive.html).

---

**Example: Deleting an Archive Using the AWS SDK for Java**

The following Java code example uses the AWS SDK for Java to delete an archive. For step-by-step instructions on how to run this example, see [Running Java Examples for Amazon S3 Glacier Using Eclipse](https://docs.aws.amazon.com/glacier/latest/dev/running-java-examples.html). You need to update the code as shown with a vault name and the archive ID of the archive you want to delete.

**Example**

```java
import java.io.IOException;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.services.glacier.AmazonGlacierClient;
import com.amazonaws.services.glacier.model.DeleteArchiveRequest;

public class ArchiveDelete {

    public static String vaultName = "*** provide vault name ****";
    public static String archiveId = "*** provide archive ID***";
    public static AmazonGlacierClient client;

    public static void main(String[] args) throws IOException {
        ProfileCredentialsProvider credentials = new ProfileCredentialsProvider();

        client = new AmazonGlacierClient(credentials);
        client.setEndpoint("https://glacier.us-east-1.amazonaws.com/");

        try {
```

Deleting an Archive Using Java
Deleting an Archive Using the High-Level API of the AWS SDK for .NET

The ArchiveTransferManager class of the high-level API provides the DeleteArchive method you can use to delete an archive.

Example: Deleting an Archive Using the High-Level API of the AWS SDK for .NET

The following C# code example uses the high-level API of the AWS SDK for .NET to delete an archive. For step-by-step instructions on how to run this example, see Running Code Examples. You need to update the code as shown with the archive ID of the archive you want to delete.

Example

```csharp
using System;
using Amazon.Glacier;
```
using Amazon.Glacier.Transfer;
using Amazon.Runtime;

namespace glacier.amazon.com.dosamples
{
    class ArchiveDeleteHighLevel
    {
        static string vaultName = "examplevault";
        static string archiveId = "*** Provide archive ID ***";

        public static void Main(string[] args)
        {
            try
            {
                var manager = new ArchiveTransferManager(Amazon.RegionEndpoint.USWest2);
                manager.DeleteArchive(vaultName, archiveId);
                Console.ReadKey();
            }
            catch (AmazonGlacierException e) { Console.WriteLine(e.Message); }
            catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
            catch (Exception e) { Console.WriteLine(e.Message); }
            Console.WriteLine("To continue, press Enter");
            Console.ReadKey();
        }
    }
}

Deleting an Archive Using the Low-Level API AWS SDK for .NET

The following are the steps to delete an using the AWS SDK for .NET.

1. Create an instance of the AmazonGlacierClient class (the client).

   You need to specify an AWS Region where the archive you want to delete is stored. All operations you perform using this client apply to that AWS Region.

2. Provide request information by creating an instance of the DeleteArchiveRequest class.

   You need to provide an archive ID, a vault name, and your account ID. If you don't provide an account ID, then account ID associated with the credentials you provide to sign the request is assumed. For more information, see Using the AWS SDKs with Amazon S3 Glacier.

3. Run the DeleteArchive method by providing the request object as a parameter.
Example: Deleting an Archive Using the Low-Level API of the AWS SDK for .NET

The following C# example illustrates the preceding steps. The example uses the low-level API of the AWS SDK for .NET to delete an archive.

For information about the underlying REST API, see [Delete Archive (DELETE archive)](deletearchive.html).

For step-by-step instructions on how to run this example, see [Running Code Examples](runningcodeexamples.html). You need to update the code as shown with the archive ID of the archive you want to delete.

Example

```csharp
using System;
using Amazon.Glacier;
using Amazon.Glacier.Model;
using Amazon.Runtime;

namespace glacier.amazon.com.docsamples
{
    class ArchiveDeleteLowLevel
    {
        static string vaultName = "examplevault";
        static string archiveId = "*** Provide archive ID ***";

        public static void Main(string[] args)
        {
            AmazonGlacierClient client;
            try
            {
                using (client = new AmazonGlacierClient(Amazon.RegionEndpoint.USWest2))
                {
                    Console.WriteLine("Deleting the archive");
                    DeleteAnArchive(client);
                }
                Console.WriteLine("Operations successful. To continue, press Enter");
                Console.ReadKey();
            }
            catch (AmazonGlacierException e) { Console.WriteLine(e.Message); }
            catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
```
```csharp
catch (Exception e) { Console.WriteLine(e.Message); }
Console.WriteLine("To continue, press Enter");
Console.ReadKey();
}

static void DeleteAnArchive(AmazonGlacierClient client)
{
    DeleteArchiveRequest request = new DeleteArchiveRequest()
    {
        VaultName = vaultName,
        ArchiveId = archiveId
    };  
    DeleteArchiveResponse response = client.DeleteArchive(request);
}
```

### Deleting an Amazon S3 Glacier Archive Using the REST API

You can use the Delete Archive API to delete an archive.

- For information about the Delete Archive API, see [Delete Archive (DELETE archive)](Delete Archive (DELETE archive)).
- For information about using the REST API, see [API Reference for Amazon S3 Glacier](API Reference for Amazon S3 Glacier).

### Deleting an Archive in Amazon S3 Glacier Using the AWS Command Line Interface

You can delete archives in Amazon S3 Glacier (S3 Glacier) using the AWS Command Line Interface (AWS CLI).

**Topics**

- [Prerequisite] Setting Up the AWS CLI
- [Example: Deleting an Archive Using the AWS CLI](Example: Deleting an Archive Using the AWS CLI)

### (Prerequisite) Setting Up the AWS CLI

1. Download and configure the AWS CLI. For instructions, see the following topics in the AWS Command Line Interface User Guide:
Installing the AWS Command Line Interface

Configuring the AWS Command Line Interface

2. Verify your AWS CLI setup by entering the following commands at the command prompt. These commands don't provide credentials explicitly, so the credentials of the default profile are used.

- Try using the help command.

```
aws help
```

- To get a list of S3 Glacier vaults on the configured account, use the `list-vaults` command. Replace `123456789012` with your AWS account ID.

```
aws glacier list-vaults --account-id 123456789012
```

- To see the current configuration data for the AWS CLI, use the `aws configure list` command.

```
aws configure list
```

Example: Deleting an Archive Using the AWS CLI

1. Use the `initiate-job` command to start an inventory retrieval job.

```
aws glacier initiate-job --vault-name awsexamplevault --account-id 111122223333 --job-parameters="{"Type":"inventory-retrieval"}"
```

Expected output:

```
{
   "location": "/111122223333/vaults/awsexamplevault/jobs/*** jobid ***",
   "jobId": "*** jobid ***"
}
```

2. Use the `describe-job` command to check status of the previous retrieval job.
aws glacier describe-job --vault-name awsexamplevault --account-id 111122223333 --job-id *** jobid ***

Expected output:

```
{
    "InventoryRetrievalParameters": {
        "Format": "JSON"
    },
    "VaultARN": "*** vault arn ***",
    "Completed": false,
    "JobId": "*** jobid ***",
    "Action": "InventoryRetrieval",
    "CreationDate": "*** job creation date ***",
    "StatusCode": "InProgress"
}
```

3. Wait for the job to complete.

You must wait until the job output is ready for you to download. If you set a notification configuration on the vault or specified an Amazon Simple Notification Service (Amazon SNS) topic when you initiated the job, S3 Glacier sends a message to the topic after it completes the job.

You can set notification configuration for specific events on the vault. For more information, see [Configuring Vault Notifications in Amazon S3 Glacier](#). S3 Glacier sends a message to the specified SNS topic anytime the specific event occurs.

4. When it's complete, use the `get-job-output` command to download the retrieval job to the file `output.json`.

```
aws glacier get-job-output --vault-name awsexamplevault --account-id 111122223333 --job-id *** jobid *** output.json
```

This command produces a file with the following fields.
5. Use the delete-archive command to delete each archive from a vault until none remain.

```bash
aws glacier delete-archive --vault-name awsexamplevault --account-id 111122223333
--archive-id *** archiveid ***
```
Using the AWS SDKs with Amazon S3 Glacier

AWS provides SDKs for you to develop applications for Amazon S3 Glacier. The SDK libraries wrap the underlying S3 Glacier API, simplifying your programming tasks. For example, for each request sent to S3 Glacier, you must include a signature to authenticate your requests. When you use the SDK libraries, you need to provide only your AWS security credentials in your code and the libraries compute the necessary signature and include it in the request sent to S3 Glacier. The AWS SDKs provide libraries that map to the underlying REST API and provide objects that you can use to easily construct requests and process responses.

- AWS SDK Libraries for Java and .NET
- Using S3 Glacier with an AWS SDK
- Using the AWS SDK for Java with Amazon S3 Glacier
- Using the AWS SDK for .NET with Amazon S3 Glacier

The AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services, including S3 Glacier. For information about downloading the AWS CLI, see AWS Command Line Interface. For a list of the S3 Glacier CLI commands, see the AWS CLI Command Reference.

AWS SDK Libraries for Java and .NET

The AWS SDKs for Java and .NET offer high-level and low-level wrapper libraries.

You can find examples of working with Amazon S3 Glacier by using the AWS SDK for Java and the AWS SDK for .NET throughout this developer guide.

What Is the Low-Level API?

The low-level wrapper libraries map closely the underlying REST API (API Reference for Amazon S3 Glacier) supported by S3 Glacier. For each S3 Glacier REST operations, the low-level API provides a corresponding method, a request object for you to provide request information and a response object for you to process S3 Glacier response. The low-level wrapper libraries are the most complete implementation of the underlying S3 Glacier operations.

For information about these SDK libraries, see Using the AWS SDK for Java with Amazon S3 Glacier and Using the AWS SDK for .NET with Amazon S3 Glacier.
What Is the High-Level API?

To further simplify application development, these libraries offer a higher-level abstraction for some of the operations. For example:

- Uploading an archive—To upload an archive using the low-level API in addition to the file name and the vault name where you want to save the archive, you need to provide a checksum (SHA-256 tree hash) of the payload. However, the high-level API computes the checksum for you.

- Downloading an archive or vault inventory—To download an archive using the low-level API you first initiate a job, wait for the job to complete, and then get the job output. You need to write additional code to set up an Amazon Simple Notification Service (Amazon SNS) topic for S3 Glacier to notify you when the job is complete. You also need some polling mechanism to check if a job completion message was posted to the topic. The high-level API provides a method to download an archive that takes care of all these steps. You only specify an archive ID and a folder path where you want to save the downloaded data.

For information about these SDK libraries, see [Using the AWS SDK for Java with Amazon S3 Glacier](#) and [Using the AWS SDK for .NET with Amazon S3 Glacier](#).

When to Use the High-Level and Low-Level API

In general, if the high-level API provides methods you need to perform an operation, you should use the high-level API because of the simplicity it provides. However, if the high-level API does not offer the functionality, you can use the low-level API. Additionally, the low-level API allows granular control of the operation such as retry logic in the event of a failure. For example, when uploading an archive the high-level API uses the file size to determine whether to upload the archive in a single operation or use the multipart upload API. The API also has built-in retry logic in case an upload fails. However, your application might need granular control over these decisions, in which case you can use the low-level API.

Using S3 Glacier with an AWS SDK

AWS software development kits (SDKs) are available for many popular programming languages. Each SDK provides an API, code examples, and documentation that make it easier for developers to build applications in their preferred language.

Using the AWS SDK for Java with Amazon S3 Glacier

The AWS SDK for Java provides both high-level and low-level APIs for Amazon S3 Glacier (S3 Glacier) as described in Using the AWS SDKs with Amazon S3 Glacier. For information about downloading the AWS SDK for Java, see Amazon SDK for Java.

**Note**
The AWS SDK for Java provides thread-safe clients for accessing S3 Glacier. As a best practice, your applications should create one client and reuse the client between threads.

**Topics**

- Using the High-Level API
- Running Java Examples for Amazon S3 Glacier Using Eclipse
- Setting the Endpoint

**Using the Low-Level API**

The low-level AmazonGlacierClient class provides all the methods that map to the underlying REST operations of S3 Glacier (API Reference for Amazon S3 Glacier). When calling any of these methods, you must create a corresponding request object and provide a response object in which the method can return the S3 Glacier response to the operation.

For example, the AmazonGlacierClient class provides the createVault method to create a vault. This method maps to the underlying Create Vault REST operation (see Create Vault (PUT vault)). To use this method, you must create instances of the CreateVaultResult object that receives the S3 Glacier response as shown in the following Java code snippet:

```java
AmazonGlacierClient client = new AmazonGlacierClient(credentials);
client.setEndpoint("https://glacier.us-west-2.amazonaws.com/");

CreateVaultRequest request = new CreateVaultRequest()
    .withAccountId("-")
    .withVaultName(vaultName);
```
CreateVaultResult result = client.createVault(createVaultRequest);

All the low-level samples in the guide use this pattern.

**Note**

The preceding code segment specifies Account ID when creating the request. However, when using the AWS SDK for Java, the Account ID in the request is optional, and therefore all the low-level examples in this guide don't set this value. The Account ID is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can specify either the AWS account ID or optionally a '-', in which case S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your Account ID, do not include hyphens in it. When using AWS SDK for Java, if you don't provide the account ID, the library sets the account ID to '-'.

**Using the High-Level API**

To further simplify your application development, the AWS SDK for Java provides the `ArchiveTransferManager` class that implements a higher-level abstraction for some of the methods in the low-level API. It provides useful methods, such as the `upload` and `download` methods for archive operations.

For example, the following Java code snippet uses the `upload` high-level method to upload an archive.

```java
String vaultName = "examplevault";
String archiveToUpload = "c:/folder/exampleArchive.zip";

ArchiveTransferManager atm = new ArchiveTransferManager(client, credentials);
String archiveId = atm.upload(vaultName, "Tax 2012 documents", new File(archiveToUpload)).getArchiveId();
```

Note that any operations you perform apply to the AWS Region you specified when creating the `ArchiveTransferManager` object. If you don't specify any AWS Region, the AWS SDK for Java sets `us-east-1` as the default AWS Region.

All the high-level examples in this guide use this pattern.
Note
The high-level ArchiveTransferManager class can be constructed with an AmazonGlacierClient instance or an AWSCredentials instance.

Running Java Examples for Amazon S3 Glacier Using Eclipse

The easiest way to get started with the Java code examples is to install the latest AWS Toolkit for Eclipse. For information on installing or updating to the latest toolkit, go to http://aws.amazon.com/eclipse. The following tasks guide you through the creation and testing of the Java code examples provided in this section.

General Process of Creating Java Code Examples

1. Create a default credentials profile for your AWS credentials as described in the AWS SDK for Java topic Providing AWS Credentials in the Amazon SDK for Java.

2. Create a new AWS Java project in Eclipse. The project is pre-configured with the AWS SDK for Java.

3. Copy the code from the section you are reading to your project.

4. Update the code by providing any required data. For example, if uploading a file, provide the file path and the bucket name.

5. Run the code. Verify that the object is created by using the AWS Management Console. For more information about the AWS Management Console, go to http://aws.amazon.com/console/.

Setting the Endpoint

By default, the AWS SDK for Java uses the endpoint https://glacier.us-east-1.amazonaws.com. You can set the endpoint explicitly as shown in the following Java code snippets.

The following snippet shows how to set the endpoint to the US West (Oregon) Region (us-west-2) in the low-level API.
Example

```java
client = new AmazonGlacierClient(credentials);
client.setEndpoint("glacier.us-west-2.amazonaws.com");
```

The following snippet shows how to set the endpoint to the US West (Oregon) Region in the high-level API.

```java
glacierClient = new AmazonGlacierClient(credentials);
sqsClient = new AmazonSQSClient(credentials);
snsClient = new AmazonSNSClient(credentials);

glacierClient.setEndpoint("glacier.us-west-2.amazonaws.com");
sqsClient.setEndpoint("sqs.us-west-2.amazonaws.com");
snsClient.setEndpoint("sns.us-west-2.amazonaws.com");

ArchiveTransferManager atm = new ArchiveTransferManager(glacierClient, sqsClient, snsClient);
```

For a list of supported AWS Regions and endpoints, see [Accessing Amazon S3 Glacier](#).

### Using the AWS SDK for .NET with Amazon S3 Glacier

The AWS SDK for .NET API is available in `AWSSDK.dll`. For information about downloading the AWS SDK for .NET, go to [Sample Code Libraries](#). As described in [Using the AWS SDKs with Amazon S3 Glacier](#), the AWS SDK for .NET provides both the high-level and low-level APIs.

#### Note

The low-level API and high-level API provide thread-safe clients for accessing S3 Glacier. As a best practice, your applications should create one client and reuse the client between threads.

Setting the Endpoint

Using the Low-Level API

The low-level AmazonGlacierClient class provides all the methods that map to the underlying REST operations of Amazon S3 Glacier (S3 Glacier) (API Reference for Amazon S3 Glacier). When calling any of these methods, you must create a corresponding request object and provide a response object in which the method can return a S3 Glacier response to the operation.

For example, the AmazonGlacierClient class provides the CreateVault method to create a vault. This method maps to the underlying Create Vault REST operation (see Create Vault (PUT vault)). To use this method, you must create instances of the CreateVaultRequest and CreateVaultResponse classes to provide request information and receive a S3 Glacier response as shown in the following C# code snippet:

```csharp
AmazonGlacierClient client;
client = new AmazonGlacierClient(Amazon.RegionEndpoint.USEast1);

CreateVaultRequest request = new CreateVaultRequest()
{
    AccountId = "-",
    VaultName = "*** Provide vault name ***"
};

CreateVaultResponse response = client.CreateVault(request);
```

All the low-level samples in the guide use this pattern.

Note

The preceding code segment specifies AccountId when creating the request. However, when using the AWS SDK for .NET, the AccountId in the request is optional, and therefore all the low-level examples in this guide don't set this value. The AccountId is the AWS account ID. For example, the following C# code snippet uses the Upload high-level method to upload an archive.

```csharp
string vaultName = "examplevault";
string archiveToUpload = "c:\folder\exampleArchive.zip";

var manager = new ArchiveTransferManager(Amazon.RegionEndpoint.USEast1);
string archiveId = manager.Upload(vaultName, "archive description", archiveToUpload).ArchiveId;
```

Note that any operations you perform apply to the AWS Region you specified when creating the ArchiveTransferManager object. All the high-level examples in this guide use this pattern.

**Note**
The high-level ArchiveTransferManager class still needs the low-level AmazonGlacierClient client, which you can pass either explicitly or the ArchiveTransferManager creates the client.

Running Code Examples

The easiest way to get started with the .NET code examples is to install the AWS SDK for .NET. For more information, go to [Amazon SDK for .NET](https://aws.amazon.com/sdk). The following procedure outlines steps for you to test the code examples provided in this guide.
### General Process of Creating .NET Code Examples (Using Visual Studio)

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Create a credentials profile for your AWS credentials as described in the Amazon SDK for .NET topic <a href="#">Configuring AWS Credentials</a>.</td>
</tr>
<tr>
<td>2</td>
<td>Create a new Visual Studio project using the <em>AWS Empty Project</em> template.</td>
</tr>
<tr>
<td>3</td>
<td>Replace the code in the project file, <code>Program.cs</code>, with the code in the section you are reading.</td>
</tr>
<tr>
<td>4</td>
<td>Run the code. Verify that the object is created using the AWS Management Console. For more information about AWS Management Console, go to <a href="http://aws.amazon.com/console/">http://aws.amazon.com/console/</a>.</td>
</tr>
</tbody>
</table>

### Setting the Endpoint

By default, the AWS SDK for .NET sets the endpoint to the US West (Oregon) Region (https://glacier.us-west-2.amazonaws.com). You can set the endpoint to other AWS Regions as shown in the following C# snippets.

The following snippet shows how to set the endpoint to the US West (Oregon) Region (`us-west-2`) in the low-level API.

**Example**

```csharp
AmazonGlacierClient client = new AmazonGlacierClient(Amazon.RegionEndpoint.USWest2);
```

The following snippet shows how to set the endpoint to the US West (Oregon) Region in the high-level API.

```csharp
var manager = new ArchiveTransferManager(Amazon.RegionEndpoint.USWest2);
```

For a current list of supported AWS Regions and endpoints, see [Accessing Amazon S3 Glacier](#).
Code examples for S3 Glacier using AWS SDKs

The following code examples show how to use S3 Glacier with an AWS software development kit (SDK).

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

For a complete list of AWS SDK developer guides and code examples, see Using S3 Glacier with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Get started

Hello Amazon S3 Glacier

The following code example shows how to get started using Amazon S3 Glacier.

.NET

AWS SDK for .NET

```csharp
using Amazon.Glacier;
using Amazon.Glacier.Model;

namespace GlacierActions;

public static class HelloGlacier
{
    static async Task Main()
```
```csharp
var glacierService = new AmazonGlacierClient();

Console.WriteLine("Hello Amazon Glacier!");
Console.WriteLine("Let's list your Glacier vaults:");

// You can use await and any of the async methods to get a response.
// Let's get the vaults using a paginator.
var glacierVaultPaginator = glacierService.Paginators.ListVaults(new ListVaultsRequest { AccountId = "-" });

await foreach (var vault in glacierVaultPaginator.VaultList)
{
    Console.WriteLine($"{vault.CreationDate}:{vault.VaultName}, ARN: {vault.VaultARN}"");
}
```

• **Use UploadMultipartPart with an AWS SDK or CLI**

### Use AddTagsToVault with an AWS SDK or CLI

The following code examples show how to use `AddTagsToVault`.

#### .NET

**AWS SDK for .NET**

```csharp
/// <summary>
/// Add tags to the items in an Amazon S3 Glacier vault.
/// </summary>
/// <param name="vaultName">The name of the vault to add tags to.</param>
/// <param name="key">The name of the object to tag.</param>
/// <param name="value">The tag value to add.</param>
/// <returns>A Boolean value indicating the success of the action.</returns>
public async Task<bool> AddTagsToVaultAsync(string vaultName, string key, string value)
{
    var request = new AddTagsToVaultRequest
    {
        Tags = new Dictionary<string, string>
        {
            { key, value },
        },
        AccountId = "-",
        VaultName = vaultName,
    };

    var response = await _glacierService.AddTagsToVaultAsync(request);
    return response.HttpStatusCode == HttpStatusCode.NoContent;
}
```

CLI

AWS CLI

The following command adds two tags to a vault named my-vault:

```
aws glacier add-tags-to-vault --account-id - --vault-name my-vault --tags
id=1234,date=july2015
```

Amazon Glacier requires an account ID argument when performing operations, but you can use a hyphen to specify the in-use account.

• For API details, see AddTagsToVault in AWS CLI Command Reference.

CLI

AWS CLI

The following command retrieves data about a vault named my-vault:

aws glacier describe-vault --vault-name my-vault --account-id -

Amazon Glacier requires an account ID argument when performing operations, but you can use a hyphen to specify the in-use account.

Use GetJobOutput with an AWS SDK or CLI

The following code examples show how to use GetJobOutput.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get archive content and delete the archive

CLI

AWS CLI

The following command saves the output from a vault inventory job to a file in the current directory named `output.json`:

```
aws glacier get-job-output --account-id - --vault-name my-vault --job-id zbxcm3Z_3z5ukoOlO75uZKRxgGoDc3RloGduS7Eg-R047Yc6FxsdGBgf_Q2DK5Ejh18CnTS5XW4_Xq1NHS61ds04CnMW output.json
```

The `job-id` is available in the output of `aws glacier list-jobs`. Note that the output file name is a positional argument that is not prefixed by an option name. Amazon Glacier requires an account ID argument when performing operations, but you can use a hyphen to specify the in-use account.

Output:

```
{
  "status": 200,
  "acceptRanges": "bytes",
  "contentType": "application/json"
}
```

`output.json`:

```
{"VaultARN":"arn:aws:glacier:us-west-2:0123456789012:vaults/my-vault","InventoryDate":"2015-04-07T00:26:18Z","ArchiveList":null}
```

**Use GetVaultNotifications with an AWS SDK or CLI**

The following code examples show how to use GetVaultNotifications.
The following command gets a description of the notification configuration for a vault named my-vault:

```
aws glacier get-vault-notifications --account-id - --vault-name my-vault
```

Output:

```
{
    "vaultNotificationConfig": {
        "Events": [
            "InventoryRetrievalCompleted",
            "ArchiveRetrievalCompleted"
        ],
    }
}
```

If no notifications have been configured for the vault, an error is returned. Amazon Glacier requires an account ID argument when performing operations, but you can use a hyphen to specify the in-use account.

- For API details, see [GetVaultNotifications](https://docs.aws.amazon.com/cli/latest/reference/glacier/get-vault-notifications.html) in [AWS CLI Command Reference](https).

            vault.name)
            raise
    else:

**Use InitiateJob with an AWS SDK or CLI**

The following code examples show how to use `InitiateJob`.

*InitiateJob*  

API Version 2012-06-01 227
Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Archive a file, get notifications, and initiate a job

.NET

**AWS SDK for .NET**

Note

Retrieve an archive from a vault. This example uses the ArchiveTransferManager class. For API details see [ArchiveTransferManager](#).

```csharp
/// <summary>

            StreamTransferProgress = Progress!,
        };

        // Download an archive.
```
Console.WriteLine("Initiating the archive retrieval job and then polling SQS queue for the archive to be available.");
Console.WriteLine("When the archive is available, downloading will begin.");
await manager.DownloadAsync(vaultName, archiveId, localFilePath, options);

    return true;
}
catch (AmazonGlacierException ex)
{
    Console.WriteLine(ex.Message);
    return false;
}

    /// <summary>
    /// Event handler to track the progress of the Archive Transfer Manager.
    /// </summary>
    /// <param name="sender">The object that raised the event.</param>
    /// <param name="args">The argument values from the object that raised the event.</param>
    static void Progress(object sender, StreamTransferProgressArgs args)
    {
        if (args.PercentDone != _currentPercentage)
        {
            _currentPercentage = args.PercentDone;
            Console.WriteLine($"Downloaded {_currentPercentage}%");
        }
    }

- For API details, see InitiateJob in AWS SDK for .NET API Reference.

CLI

AWS CLI

The following command initiates a job to get an inventory of the vault my-vault:
aws glacier initiate-job --account-id - --vault-name my-vault --job-parameters '{"Type": "inventory-retrieval"}'

Output:

```json
{
  "location": "/0123456789012/vaults/my-vault/jobs/zbxcm3Z_3z5UkoroF7SuZKrxgGoDc3RloGduS7Eg-R047Yc6FxsdGBgf_Q2DK5Ejh18CnT55XW4_XqlNHS61ds04CnMW",
  "jobId": "zbxcm3Z_3z5UkoroF7SuZKrxgGoDc3RloGduS7Eg-R047Yc6FxsdGBgf_Q2DK5Ejh18CnT55XW4_XqlNHS61ds04CnMW"
}
```

Amazon Glacier requires an account ID argument when performing operations, but you can use a hyphen to specify the in-use account.

The following command initiates a job to retrieve an archive from the vault `my-vault`:

```bash
aws glacier initiate-job --account-id - --vault-name my-vault --job-parameters file://job-archive-retrieval.json
```

`job-archive-retrieval.json` is a JSON file in the local folder that specifies the type of job, archive ID, and some optional parameters:

```json
{
  "Type": "archive-retrieval",
  "ArchiveId": "kKB7ymWJvpsWGB6ycS0Aekp9ZYe-_--Zm_mw6K76ZFGEIWQX-ybtRDvc2VkJpS0tfKmQrj0IRQLSGnsNuDp-AJV1u2ccmDSyDumZwKfbwbpAdGATGDiB3hH00bjbGehXTcApVud_wyDw",
  "Description": "Retrieve archive on 2015-07-17",
}
```

Archive IDs are available in the output of `aws glacier upload-archive` and `aws glacier get-job-output`.

Output:

```json
{
}
```
See Initiate Job in the *Amazon Glacier API Reference* for details on the job parameters format.

- For API details, see [InitiateJob](https://docs.aws.amazon.com/cli/latest/reference/glacier/initiate-job.html) in *AWS CLI Command Reference*.

**Use ListTagsForVault with an AWS SDK or CLI**

The following code examples show how to use ListTagsForVault.

**.NET**

**AWS SDK for .NET**

```csharp
/// <summary>
/// List tags for an Amazon S3 Glacier vault.
/// </summary>
/// <param name="vaultName">The name of the vault to list tags for.</param>
/// <returns>A dictionary listing the tags attached to each object in the vault and its tags.</returns>
public async Task<Dictionary<string, string>> ListTagsForVaultAsync(string vaultName)
{
    var request = new ListTagsForVaultRequest
    {
        // Using a hyphen "-" for the Account Id will cause the SDK to use the Account Id associated with the default user.
        AccountId = "-",
        VaultName = vaultName,
    };
```

### CLI

**AWS CLI**

The following command lists the tags applied to a vault named `my-vault`:

```bash
aws glacier list-tags-for-vault --account-id - --vault-name my-vault
```

**Output:**

```json
{
  "Tags": {
    "date": "july2015",
    "id": "1234"
  }
}
```

Amazon Glacier requires an account ID argument when performing operations, but you can use a hyphen to specify the in-use account.

For API details, see `ListTagsForVault` in *AWS CLI Command Reference*.

**Use ListVaults with an AWS SDK or CLI**

The following code examples show how to use `ListVaults`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:
• Archive a file, get notifications, and initiate a job

.NET

AWS SDK for .NET

/// <summary>
/// List the Amazon S3 Glacier vaults associated with the current account.
/// </summary>
/// <returns>A list containing information about each vault.</returns>
public async Task<List<DescribeVaultOutput>> ListVaultsAsync()
{
    var glacierVaultPaginator = _glacierService.Paginators.ListVaults(
        new ListVaultsRequest { AccountId = "-" });
    var vaultList = new List<DescribeVaultOutput>();

    await foreach (var vault in glacierVaultPaginator.VaultList)
    {
        vaultList.Add(vault);
    }

    return vaultList;
}

• For API details, see ListVaults in AWS SDK for .NET API Reference.

CLI

AWS CLI

The following command lists the vaults in the default account and region:

ListVaults
```bash
aws glacier list-vaults --account-id -
```

**Output:**

```json
{
   "VaultList": [
      {
         "SizeInBytes": 3178496,
         "LastInventoryDate": "2015-04-07T00:26:19.028Z",
         "VaultName": "my-vault",
         "NumberOfArchives": 1,
         "CreationDate": "2015-04-06T21:45:708Z"
      }
   ]
}
```

Amazon Glacier requires an account ID argument when performing operations, but you can use a hyphen to specify the in-use account.

**Use UploadArchive with an AWS SDK or CLI**

The following code examples show how to use UploadArchive.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Archive a file, get notifications, and initiate a job](https://aws.amazon.com/documentation/sdk-for-python/)

UploadArchive

API Version 2012-06-01 249
/// <summary>
/// Upload an object to an Amazon S3 Glacier vault.
/// </summary>
/// <param name="vaultName">The name of the Amazon S3 Glacier vault to upload

/// the vault.</param>
/// <returns>A Boolean value indicating the success of the action.</returns>
public async Task<string> UploadArchiveWithArchiveManager(string vaultName, string archiveFilePath)
{
    try
    {
        var manager = new ArchiveTransferManager(_glacierService);

        // Upload an archive.
        var response = await manager.UploadAsync(vaultName, "upload archive test", archiveFilePath);
        return response.ArchiveId;
    }
    catch (AmazonGlacierException ex)
    {
        Console.WriteLine(ex.Message);
        return string.Empty;
    }
}
The following command uploads an archive in the current folder named archive.zip to a vault named my-vault:

```bash
aws glacier upload-archive --account-id - --vault-name my-vault --body archive.zip
```

Output:

```
{
   "archiveId": "kKB7ymWJVpPSwhGP6ycSOAekp9ZYe--zM_mw6k76ZFGEIWQX-ybtRDvc2VkJIq0IQRQSGsNuDp-AJVIU2ccmDSyDUmZwKbwbpAdGATGdiB3hH00bjbGehXTcApVud_wyDw",

PowerShell

Tools for PowerShell

Example 1: Uploads a single file to the specified vault, returning the archive ID and computed checksum.

```powershell
Write-GLCArchive -VaultName myvault -FilePath c:\temp\blue.bin
```

Output:

```
FilePath                        ArchiveId                        Checksum
--------                        ---------                          --------

Example 2: Uploads the contents of a folder hierarchy to the specified vault in the user's account. For each file uploaded the cmdlet emits the filename, corresponding archive ID and the computed checksum of the archive.

```powershell
Write-GLCArchive -VaultName myvault -FolderPath . -Recurse

Output:

Use UploadMultipartPart with an AWS SDK or CLI

The following code examples show how to use UploadMultipartPart.

CLI

AWS CLI

The following command uploads the first 1 MiB (1024 x 1024 bytes) part of an archive:

```bash
aws glacier upload-multipart-part --body part1 --range 'bytes 0-1048575/*' --account-id - --vault-name my-vault --upload-id 19gaRezEXAMPLES6RYYdqthHOC_kGRCT03L9yetr220UmPtBYKk-OssZtLqyFu7sY1_1R7vgFuJv6NtcV5zpsJ
```

Amazon Glacier requires an account ID argument when performing operations, but you can use a hyphen to specify the in-use account.

The body parameter takes a path to a part file on the local filesystem. The range parameter takes an HTTP content range indicating the bytes that the part occupies in the completed archive. The upload ID is returned by the aws glacier initiate-multipart-upload command and can also be obtained by using aws glacier list-multipart-uploads.

For more information on multipart uploads to Amazon Glacier using the AWS CLI, see Using Amazon Glacier in the AWS CLI User Guide.

• For API details, see UploadMultipartPart in AWS CLI Command Reference.
Create a multipart upload of 1 megabyte chunks of a Buffer object.

```javascript
// Create a new service object and some supporting variables
var glacier = new AWS.Glacier({ apiVersion: "2012-06-01" }),
    vaultName = "YOUR_VAULT_NAME",
    buffer = new Buffer(2.5 * 1024 * 1024), // 2.5MB buffer
    partSize = 1024 * 1024, // 1MB chunks,
    numPartsLeft = Math.ceil(buffer.length / partSize),
    startTime = new Date(),
    params = { vaultName: vaultName, partSize: partSize.toString() };

// Compute the complete SHA-256 tree hash so we can pass it
// to completeMultipartUpload request at the end
var treeHash = glacier.computeChecksums(buffer).treeHash;

// Initiate the multipart upload
console.log("Initiating upload to", vaultName);
// Call Glacier to initiate the upload.
glacier.initiateMultipartUpload(params, function (mpErr, multipart) {
    if (mpErr) {
        console.log("Error!", mpErr.stack);
        return;
    }
    console.log("Got upload ID", multipart.uploadId);

    // Grab each partSize chunk and upload it as a part
    for (var i = 0; i < buffer.length; i += partSize) {
        var end = Math.min(i + partSize, buffer.length),
            partParams = {
                vaultName: vaultName,
                uploadId: multipart.uploadId,
                range: "bytes " + i + "-" + (end - 1) + "/",
                body: buffer.slice(i, end),
            }
```

Scenarios for S3 Glacier using AWS SDKs

The following code examples show you how to implement common scenarios in S3 Glacier with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within S3 Glacier. Each scenario includes a link to GitHub, where you can find instructions on how to set up and run the code.

Examples

- Archive a file to Amazon S3 Glacier, get notifications, and initiate a job using an AWS SDK
- Get Amazon S3 Glacier archive content and delete the archive using an AWS SDK

Archive a file to Amazon S3 Glacier, get notifications, and initiate a job using an AWS SDK

The following code example shows how to:

- Create an Amazon S3 Glacier vault.
- Configure the vault to publish notifications to an Amazon SNS topic.
- Upload an archive file to the vault.
- Initiate an archive retrieval job.

Security in Amazon S3 Glacier

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. The effectiveness of our security is regularly tested and verified by third-party auditors as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon S3 Glacier (S3 Glacier), see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization’s requirements, and applicable laws and regulations.

This documentation will help you understand how to apply the shared responsibility model when using S3 Glacier. The following topics show you how to configure S3 Glacier to meet your security and compliance objectives. You'll also learn how to use other AWS services that can help you to monitor and secure your S3 Glacier resources.

**Data Protection in Amazon S3 Glacier**

Amazon S3 Glacier (S3 Glacier) provides highly durable cloud storage for data archiving and long-term backup. S3 Glacier is designed to deliver 99.999999999 percent durability and provides
comprehensive security and compliance capabilities that can help you meet stringent regulatory requirements. S3 Glacier redundantly stores data in multiple AWS Availability Zones (AZ) and on multiple devices within each AZ. To increase durability, S3 Glacier synchronously stores your data across multiple AZs before confirming a successful upload.

For more information about the AWS global cloud infrastructure, see Global Infrastructure.

For data protection purposes, we recommend that you protect AWS account credentials and give individual users, groups, or roles only the permissions necessary to fulfill their job duties.

If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

Topics
- Data Encryption
- Key Management
- Internetwork Traffic Privacy

Data Encryption

Data protection refers to protecting data while in-transit (as it travels to and from Amazon S3 Glacier) and at rest (while it is stored in AWS data centers). You can protect data in transit that is uploaded directly to S3 Glacier using Secure Sockets Layer (SSL) or client-side encryption.

You can also access S3 Glacier through Amazon S3. Amazon S3 supports lifecycle configuration on an Amazon S3 bucket, which enables you to transition objects to the S3 Glacier storage class for archival. Data in transit between Amazon S3 and S3 Glacier via lifecycle policies is encrypted using SSL.

Data at rest stored in S3 Glacier is automatically server-side encrypted using 256-bit Advanced Encryption Standard (AES-256) with keys maintained by AWS. If you prefer to manage your own keys, you can also use client-side encryption before storing data in S3 Glacier. For more information about how to setup default encryption for Amazon S3, see Amazon S3 Default Encryption in the Amazon Simple Storage Service User Guide.
Key Management

Server-side encryption addresses data encryption at rest—that is, Amazon S3 Glacier encrypts your data as it writes it to its data centers and decrypts it for you when you access it. As long as you authenticate your request and you have access permissions, there is no difference in the way you access encrypted or unencrypted data.

Data at rest stored in S3 Glacier is automatically server-side encrypted using AES-256, using keys maintained by AWS. As an additional safeguard, AWS encrypts the key itself with a root key that we regularly rotate.

Internetwork Traffic Privacy

Access to Amazon S3 Glacier via the network is through AWS published APIs. Clients must support Transport Layer Security (TLS) 1.2. We recommend TLS 1.3 or later. Clients must also support cipher suites with Perfect Forward Secrecy (PFS), such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, you must sign requests using an access key ID and a secret access key that are associated with an IAM principal, or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

VPC Endpoints

A virtual private cloud (VPC) endpoint enables you to privately connect your VPC to supported AWS services and VPC endpoint services powered by AWS PrivateLink without requiring an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Although S3 Glacier does not support VPC endpoints directly, you can take advantage of Amazon Simple Storage Service (Amazon S3) VPC endpoints if you access S3 Glacier as a storage tier integrated with Amazon S3.

For more information about Amazon S3 lifecycle configuration and transitioning objects to the S3 Glacier storage class, see Object Lifecycle Management and Transitioning Objects in the Amazon Simple Storage Service User Guide. For more information about VPC endpoints, see VPC Endpoints in the Amazon VPC User Guide.

Identity and Access Management for Amazon S3 Glacier

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in)
and *authorized* (have permissions) to use S3 Glacier resources. IAM is an AWS service that you can use with no additional charge.

**Audience**

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in S3 Glacier.

**Service user** – If you use the S3 Glacier service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more S3 Glacier features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in S3 Glacier, see **Troubleshooting Amazon S3 Glacier identity and access**.

**Service administrator** – If you're in charge of S3 Glacier resources at your company, you probably have full access to S3 Glacier. It's your job to determine which S3 Glacier features and resources your service users should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with S3 Glacier, see **How Amazon S3 Glacier works with IAM**.

**IAM administrator** – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to S3 Glacier. To view example S3 Glacier identity-based policies that you can use in IAM, see **Identity-based policy examples for Amazon S3 Glacier**.
Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be *authenticated* (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see [How to sign in to your AWS account](#) in the *AWS Sign-In User Guide*.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see [Signing AWS API requests](#) in the *IAM User Guide*.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see [Multi-factor authentication](#) in the *AWS IAM Identity Center User Guide* and [Using multi-factor authentication (MFA) in AWS](#) in the *IAM User Guide*.

**AWS account root user**

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account *root user* and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see [Tasks that require root user credentials](#) in the *IAM User Guide*.
Federated identity

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A federated identity is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center. You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For information about IAM Identity Center, see What is IAM Identity Center? in the AWS IAM Identity Center User Guide.

IAM users and groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the IAM User Guide.

An IAM group is an identity that specifies a collection of IAM users. You can’t sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

IAM roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in
the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the IAM User Guide. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the AWS IAM Identity Center User Guide.

- **Temporary IAM user permissions** – An IAM user or role can assume an IAM role to temporarily take on different permissions for a specific task.

- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.

- **Forward access sessions (FAS)** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.

- **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For
more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

• **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

• **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the IAM User Guide.

To learn whether to use IAM roles or IAM users, see When to create an IAM role (instead of a user) in the IAM User Guide.

**Managing access using policies**

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when a principal (user, root user, or role session) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.
Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

Identity-based policies can be further categorized as inline policies or managed policies. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the IAM User Guide.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

Access control lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the Amazon Simple Storage Service Developer Guide.
Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of an entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the IAM User Guide.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see How SCPs work in the AWS Organizations User Guide.

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the IAM User Guide.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the IAM User Guide.

Identity-based policies for S3 Glacier

| Supports identity-based policies                  | Yes                |

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](https://docs.aws.amazon.com/IAM/latest/userguide/creating-policies.html) in the IAM User Guide.
With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the IAM User Guide.

Resource-based policies within S3 Glacier

<table>
<thead>
<tr>
<th>Supports resource-based policies</th>
<th>Yes</th>
</tr>
</thead>
</table>

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see How IAM roles differ from resource-based policies in the IAM User Guide.

The S3 Glacier service supports only one type of resource-based policy called a vault policy, which is attached to a vault. This policy defines which principals can perform actions on the vault.

S3 Glacier vault policies manage permissions in the following ways:
• Manage user permissions in an account using a single vault policy, instead of more than one individual user policies.

• Manage cross-account permissions as an alternative to using IAM roles.

Resource-based policy examples within S3 Glacier

To view examples of S3 Glacier resource-based policies, see Resource-based policy examples for Amazon S3 Glacier.

Policy actions for S3 Glacier

| Supports policy actions | Yes |

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as permission-only actions that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called dependent actions.

Include actions in a policy to grant permissions to perform the associated operation.

To see a list of S3 Glacier actions, see Actions defined by Amazon S3 Glacier in the Service Authorization Reference.

Policy actions in S3 Glacier use the following prefix before the action:

`glacier`

To specify multiple actions in a single statement, separate them with commas.

```json
"Action": [
    "glacier:CreateVault",
    "glacier:DescribeVault",
]```
You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action:

```json
"Action": "glacier:GetVault*"
```

To view examples of S3 Glacier identity-based policies, see Identity-based policy examples for Amazon S3 Glacier.

**Policy resources for S3 Glacier**

<table>
<thead>
<tr>
<th>Supports policy resources</th>
<th>Yes</th>
</tr>
</thead>
</table>

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as resource-level permissions.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```json
"Resource": "*"
```

To see a list of S3 Glacier resource types and their ARNs, see Resources defined by Amazon S3 Glacier in the Service Authorization Reference. To learn which actions you can specify the ARN of each resource, see Actions defined by Amazon S3 Glacier.

In S3 Glacier, the primary resource is a vault. S3 Glacier supports policies only at the vault level. That is, in an IAM policy, the Resource value that you specify can be a specific vault or a set of vaults in a specific AWS Region. S3 Glacier doesn't support archive-level permissions.
For all S3 Glacier actions, Resource specifies the vault on which you want to grant the permissions. These resources have unique Amazon Resource Names (ARNs) associated with them as shown in the following table, and you can use a wildcard character (*) in the ARN to match vault names that start with the same prefix.

S3 Glacier provides a set of operations to work with the S3 Glacier resources. For information on the available operations, see API Reference for Amazon S3 Glacier.

Some S3 Glacier API actions support multiple resources. For example, glacier:AddTagsToVault accesses examplevault1 and examplevault2, so a principal must have permissions to access both resources. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [
]
```

**Policy condition keys for S3 Glacier**

<table>
<thead>
<tr>
<th>Supports service-specific policy condition keys</th>
<th>Yes</th>
</tr>
</thead>
</table>

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Condition element (or Condition block) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can create conditional expressions that use **condition operators**, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.
You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the IAM User Guide.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

To see a list of S3 Glacier condition keys, see Condition keys for Amazon S3 Glacier in the Service Authorization Reference. To learn with which actions and resources you can use a condition key, see Actions defined by Amazon S3 Glacier.

For examples of using the glacier–specific condition keys, see Vault Lock Policies.

### ACLs in S3 Glacier

<table>
<thead>
<tr>
<th>Supports ACLs</th>

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

### ABAC with S3 Glacier

<table>
<thead>
<tr>
<th>Supports ABAC (tags in policies)</th>
<th>No</th>
</tr>
</thead>
</table>

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called tags. You can attach tags to IAM entities (users or roles) and to many AWS resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.
If a service supports all three condition keys for every resource type, then the value is Yes for the service. If a service supports all three condition keys for only some resource types, then the value is Partial.

For more information about ABAC, see What is ABAC? in the IAM User Guide. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the IAM User Guide.

**Using temporary credentials with S3 Glacier**

<table>
<thead>
<tr>
<th>Supports temporary credentials</th>
<th>Yes</th>
</tr>
</thead>
</table>

Some AWS services don't work when you sign in using temporary credentials. For additional information, including which AWS services work with temporary credentials, see AWS services that work with IAM in the IAM User Guide.

You are using temporary credentials if you sign in to the AWS Management Console using any method except a user name and password. For example, when you access AWS using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see Switching to a role (console) in the IAM User Guide.

You can manually create temporary credentials using the AWS CLI or AWS API. You can then use those temporary credentials to access AWS. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM.

When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to
complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](https://docs.aws.amazon.com/AWS/latest/UserGuide/ForwardAccessSession.html).

A service role is an [IAM role](https://docs.aws.amazon.com/IAM/latest/userguide/idp-service-resource.html) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](https://docs.aws.amazon.com/IAM/latest/userguide/creating-service-role.html) in the *IAM User Guide*.

⚠️ **Warning**

Changing the permissions for a service role might break S3 Glacier functionality. Edit service roles only when S3 Glacier provides guidance to do so.

**Service-linked roles for S3 Glacier**

<table>
<thead>
<tr>
<th>Supports service-linked roles</th>
<th>No</th>
</tr>
</thead>
</table>

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about creating or managing service-linked roles, see [AWS services that work with IAM](https://docs.aws.amazon.com/IAM/latest/userguide/awsservicesservice-linked-roles.html). Find a service in the table that includes a Yes in the **Service-linked role** column. Choose the Yes link to view the service-linked role documentation for that service.

**Identity-based policy examples for Amazon S3 Glacier**

By default, users and roles don't have permission to create or modify S3 Glacier resources. They also can't perform tasks by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or AWS API. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.
To learn how to create an IAM identity-based policy by using these example JSON policy documents, see Creating IAM policies in the IAM User Guide.

For details about actions and resource types defined by S3 Glacier, including the format of the ARNs for each of the resource types, see Actions, resources, and condition keys for Amazon S3 Glacier in the Service Authorization Reference.

The following is an example policy that grants permissions for three S3 Glacier vault-related actions (glacier:CreateVault, glacier:DescribeVault and glacier:ListVaults) on a resource, using the Amazon Resource Name (ARN) that identifies all of the vaults in the us-west-2 AWS Region. ARNs uniquely identify AWS resources. For more information about ARNs used with S3 Glacier, see Policy resources for S3 Glacier.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["glacier:CreateVault",
                        "glacier:DescribeVault",
                        "glacier:ListVaults"],
        }
    ]
}
```

The policy grants permissions to create, list, and obtain descriptions of vaults in the us-west-2 Region. The wildcard character (*) at the end of the ARN means that this statement can match any vault name.

⚠️ Important

When you grant permissions to create a vault using the glacier:CreateVault operation, you must specify a wildcard character (*) because you don't know the vault name until after you create the vault.
Policy best practices

Identity-based policies determine whether someone can create, access, or delete S3 Glacier resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

• Get started with AWS managed policies and move toward least-privilege permissions – To get started granting permissions to your users and workloads, use the AWS managed policies that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the IAM User Guide.

• Apply least-privilege permissions – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as least-privilege permissions. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the IAM User Guide.

• Use conditions in IAM policies to further restrict access – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

• Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see IAM Access Analyzer policy validation in the IAM User Guide.

• Require multi-factor authentication (MFA) – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when
API operations are called, add MFA conditions to your policies. For more information, see Configuring MFA-protected API access in the IAM User Guide.

For more information about best practices in IAM, see Security best practices in IAM in the IAM User Guide.

Using the S3 Glacier console

To access the Amazon S3 Glacier console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the S3 Glacier resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that they're trying to perform.

The S3 Glacier console provides an integrated environment for you to create and manage S3 Glacier vaults. At a minimum IAM identities that you create must be granted permissions for the glacier:ListVaults action to view the S3 Glacier console as shown in the following example.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": ["glacier:ListVaults"],
            "Effect": "Allow",
            "Resource": "*"
        }
    ]
}
```

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. Managed policies grant necessary permissions for common use cases so you can avoid having to investigate what permissions are needed. For more information, see AWS Managed Policies in the IAM User Guide.
The following AWS managed policies, which you can attach to users in your account, are specific to S3 Glacier:

- **AmazonGlacierReadOnlyAccess** – Grants read only access to S3 Glacier through the AWS Management Console.
- **AmazonGlacierFullAccess** – Grants full access to S3 Glacier through the AWS Management Console.

You can also create your own custom IAM policies to allow permissions for S3 Glacier API actions and resources. You can attach these custom policies to the custom IAM roles that you create for your S3 Glacier vaults.

Both of the S3 Glacier AWS Managed policies discussed in the next section grant permissions for glacier:ListVaults.

For more information, see [Adding permissions to a user](#) in the IAM User Guide.

**Allow users to view their own permissions**

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws:iam::*:user/${aws:username}"],
        },
        {
```

Customer Managed Policy Examples

In this section, you can find example user policies that grant permissions for various S3 Glacier actions. These policies work when you are using S3 Glacier REST API, the Amazon SDKs, the AWS CLI, or, if applicable, the S3 Glacier management console.

Note

All examples use the US West (Oregon) Region (us-west-2) and contain fictitious account IDs.

Examples

- **Example 1: Allow a User to Download Archives from a Vault**
- **Example 2: Allow a User to Create a Vault and Configure Notifications**
- **Example 3: Allow a User to Upload Archives to a Specific Vault**
- **Example 4: Allow a User Full Permissions on a Specific Vault**

Example 1: Allow a User to Download Archives from a Vault

To download an archive, you first initiate a job to retrieve the archive. After the retrieval job is complete, you can download the data. The following example policy grants permissions
for the glacier:InitiateJob action to initiate a job (which allows the user to retrieve an archive or a vault inventory from the vault), and permissions for the glacier:GetJobOutput action to download the retrieved data. The policy also grants permissions to perform the glacier:DescribeJob action so that the user can get the job status. For more information, see Initiate Job (POST jobs).

The policy grants these permissions on a vault named examplevault. You can get the vault ARN from the Amazon S3 Glacier console, or programmatically by calling either the Describe Vault (GET vault) or the List Vaults (GET vaults) API actions.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["glacier:InitiateJob",
                        "glacier:GetJobOutput",
                        "glacier:DescribeJob"]
        }
    ]
}
```

**Example 2: Allow a User to Create a Vault and Configure Notifications**

The following example policy grants permissions to create a vault in the us-west-2 Region as specified in the Resource element and configure notifications. For more information about working with notifications, see Configuring Vault Notifications in Amazon S3 Glacier. The policy also grants permissions to list vaults in the AWS Region and get a specific vault description.

⚠️ **Important**

When you grant permissions to create a vault using the glacier:CreateVault operation, you must specify a wildcard character (*) in the Resource value because you don't know the vault name until after you create the vault.

```json
{
    "Version":"2012-10-17",
}
Example 3: Allow a User to Upload Archives to a Specific Vault

The following example policy grants permissions to upload archives to a specific vault in the us-west-2 Region. These permissions allow a user to upload an archive all at once using the Upload Archive (POST archive) API operation or in parts using the Initiate Multipart Upload (POST multipart-uploads) API operation.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glacier:UploadArchive",
        "glacier:InitiateMultipartUpload",
        "glacier:UploadMultipartPart",
        "glacier:ListParts",
        "glacier:ListMultipartUploads",
        "glacier:CompleteMultipartUpload"
      ]
    }
  ]
}
```

Example 4: Allow a User Full Permissions on a Specific Vault

The following example policy grants permissions for all S3 Glacier actions on a vault named examplevault.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glacier:CreateVault",
        "glacier:SetVaultNotifications",
        "glacier:GetVaultNotifications",
        "glacier:DeleteVaultNotifications",
        "glacier:DescribeVault",
        "glacier:ListVaults"
      ]
    }
  ]
}
```
Resource-based policy examples for Amazon S3 Glacier

A S3 Glacier vault can have one vault access policy and one Vault Lock policy associated with it. A Amazon S3 Glacier vault access policy is a resource-based policy that you can use to manage permissions to your vault. A Vault Lock policy is vault access policy that can be locked. After you lock a Vault Lock policy, the policy can't be changed. You can use a Vault Lock Policy to enforce compliance controls.

Vault Access Policies

An Amazon S3 Glacier vault access policy is a resource-based policy that you can use to manage permissions to your vault.

You can create one vault access policy for each vault to manage permissions. You can modify permissions in a vault access policy at any time. S3 Glacier also supports a Vault Lock policy on each vault that, after you lock it, cannot be altered. For more information about working with Vault Lock policies, see Vault Lock Policies.

Examples

• Example 1: Grant Cross-Account Permissions for Specific Amazon S3 Glacier Actions

```json
{
   "Version":"2012-10-17",
   "Statement": [ 
   {
      "Effect": "Allow",
      "Action": ["glacier:*"]
   }
   ]
}
```
Example 1: Grant Cross-Account Permissions for Specific Amazon S3 Glacier Actions

The following example policy grants cross-account permissions to two AWS accounts for a set of S3 Glacier operations on a vault named examplevault.

```json
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid":"cross-account-upload",
         "Principal": {
            "AWS": [
               "arn:aws:iam::123456789012:root",
               "arn:aws:iam::444455556666:root"
            ]
         },
         "Effect":"Allow",
         "Action": ["glacier:UploadArchive",
                     "glacier:InitiateMultipartUpload",
                     "glacier:AbortMultipartUpload",
                     "glacier:CompleteMultipartUpload"
                  ],
                      ]
      }
   ]
}
```

Resource-based policy examples

Note

The account that owns the vault is billed for all costs associated with the vault. All requests, data transfer, and retrieval costs made by allowed external accounts are billed to the account that owns the vault.
Example 2: Grant Cross-Account Permissions for MFA Delete Operations

You can use multi-factor authentication (MFA) to protect your S3 Glacier resources. To provide an extra level of security, MFA requires users to prove physical possession of an MFA device by providing a valid MFA code. For more information about configuring MFA access, see Configuring MFA-Protected API Access in the IAM User Guide.

The example policy grants an AWS account with temporary credentials permission to delete archives from a vault named examplevault, provided the request is authenticated with an MFA device. The policy uses the aws:MultiFactorAuthPresent condition key to specify this additional requirement. For more information, see Available Keys for Conditions in the IAM User Guide.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "add-mfa-delete-requirement",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::123456789012:root"
                ]
            },
            "Effect": "Allow",
            "Action": ["glacier:Delete*"],
            "Resource": [
            ],
            "Condition": {
                "Bool": {
                    "aws:MultiFactorAuthPresent": true
                }
            }
        }
    ]
}
```
Vault Lock Policies

An Amazon S3 Glacier (S3 Glacier) vault can have one resource-based vault access policy and one Vault Lock policy attached to it. A Vault Lock policy is a vault access policy that you can lock. Using a Vault Lock policy can help you enforce regulatory and compliance requirements. Amazon S3 Glacier provides a set of API operations for you to manage the Vault Lock policies, see Locking a Vault by Using the S3 Glacier API.

As an example of a Vault Lock policy, suppose that you are required to retain archives for one year before you can delete them. To implement this requirement, you can create a Vault Lock policy that denies users permissions to delete an archive until the archive has existed for one year. You can test this policy before locking it down. After you lock the policy, the policy becomes immutable. For more information about the locking process, see Vault Lock Policies. If you want to manage other user permissions that can be changed, you can use the vault access policy (see Vault Access Policies).

You can use the S3 Glacier API, Amazon SDKs, AWS CLI, or the S3 Glacier console to create and manage Vault Lock policies. For a list of S3 Glacier actions allowed for vault resource-based policies, see API Permissions Reference.

Examples

- Example 1: Deny Deletion Permissions for Archives Less Than 365 Days Old
- Example 2: Deny Deletion Permissions Based on a Tag

Example 1: Deny Deletion Permissions for Archives Less Than 365 Days Old

Suppose that you have a regulatory requirement to retain archives for up to one year before you can delete them. You can enforce that requirement by implementing the following Vault Lock policy. The policy denies the glacier:DeleteArchive action on the examplevault vault if the archive being deleted is less than one year old. The policy uses the S3 Glacier-specific condition key ArchiveAgeInDays to enforce the one-year retention requirement.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "deny-based-on-archive-age",
         "Principal": "*",
```
Example 2: Deny Deletion Permissions Based on a Tag

Suppose that you have a time-based retention rule that an archive can be deleted if it is less than a year old. At the same time, suppose that you need to place a legal hold on your archives to prevent deletion or modification for an indefinite duration during a legal investigation. In this case, the legal hold takes precedence over the time-based retention rule specified in the Vault Lock policy.

To put these two rules in place, the following example policy has two statements:

- The first statement denies deletion permissions for everyone, locking the vault. This lock is performed by using the LegalHold tag.
- The second statement grants deletion permissions when the archive is less than 365 days old. But even when archives are less than 365 days old, no one can delete them when the condition in the first statement is met.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "lock-vault",
            "Principal": "*",
            "Effect": "Deny",
            "Action": [
                "glacier:DeleteArchive"
            ],
        }
    ]
}
```
Troubleshooting Amazon S3 Glacier identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with S3 Glacier and IAM.

Topics

- I am not authorized to perform an action in S3 Glacier
- I am not authorized to perform iam:PassRole
I want to allow people outside of my AWS account to access my S3 Glacier resources

I am not authorized to perform an action in S3 Glacier

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the mateojackson IAM user tries to use the console to view details about a fictional my-example-widget resource but doesn't have the fictional glacier:GetWidget permissions.

User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform: glacier:GetWidget on resource: my-example-widget

In this case, the policy for the mateojackson user must be updated to allow access to the my-example-widget resource by using the glacier:GetWidget action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the iam:PassRole action, your policies must be updated to allow you to pass a role to S3 Glacier.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named marymajor tries to use the console to perform an action in S3 Glacier. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole

In this case, Mary's policies must be updated to allow her to perform the iam:PassRole action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.
I want to allow people outside of my AWS account to access my S3 Glacier resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether S3 Glacier supports these features, see How Amazon S3 Glacier works with IAM.
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the IAM User Guide.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the IAM User Guide.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the IAM User Guide.
- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

API Permissions Reference

When you are setting up How Amazon S3 Glacier works with IAM and writing a permissions policy that you can attach to an IAM identity (identity-based policies) or a resource (resource-based policies), you can use the following table as a reference. The list includes each S3 Glacier API operation, the corresponding actions for which you can grant permissions to perform the action, and the AWS resource for which you can grant the permissions.

You specify the actions in the policy's Action element, and you specify the resource value in the policy's Resource element. Also, you can use the IAM policy language Condition element to specify when a policy should take effect.

To specify an action, use the glacier: prefix followed by the API operation name (for example, glacier:CreateVault). For most S3 Glacier actions, Resource is the vault on which you want to grant the permissions. You specify a vault as the Resource value by using the vault ARN. To express conditions, you use predefined condition keys. For more information, see Resource-based policies within S3 Glacier.
The following table lists actions that can be used with identity-based policies and resource-based policies.

Logging and Monitoring in Amazon S3 Glacier

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon S3 Glacier (S3 Glacier) and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily identify and debug the source of a failure if one occurs. AWS provides the following tools for monitoring your S3 Glacier resources and responding to potential incidents:

Amazon CloudWatch Alarms

When using S3 Glacier via Amazon S3, you can use Amazon CloudWatch alarms to watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods. For more information, see Monitoring Metrics with Amazon CloudWatch.

AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in S3 Glacier. CloudTrail captures all API calls for S3 Glacier as events, including calls from the S3 Glacier console and from code calls to the S3 Glacier APIs. For more information, see Logging Amazon S3 Glacier API Calls with AWS CloudTrail.

AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

For more information, see AWS Trusted Advisor in the AWS Support User Guide.
Compliance Validation for Amazon S3 Glacier

The security and compliance of Amazon S3 Glacier (S3 Glacier) is assessed by third-party auditors as part of multiple AWS compliance programs, including the following:

- System and Organization Controls (SOC)
- Payment Card Industry Data Security Standard (PCI DSS)
- Federal Risk and Authorization Management Program (FedRAMP)
- Health Insurance Portability and Accountability Act (HIPAA)

AWS provides a frequently updated list of AWS services in scope of specific compliance programs at [AWS Services in Scope by Compliance Program](#).

Third-party audit reports are available for you to download using AWS Artifact. For more information, see [Downloading Reports in AWS Artifact](#) in the [AWS Artifact User Guide](#).

For more information about AWS compliance programs, see [AWS Compliance Programs](#).

Your compliance responsibility when using S3 Glacier is determined by the sensitivity of your data, your organization’s compliance objectives, and applicable laws and regulations. If your use of S3 Glacier is subject to compliance with standards like HIPAA, PCI, or FedRAMP, AWS provides resources to help:

- **S3 Glacier Vault Lock** allows you to easily deploy and enforce compliance controls for individual S3 Glacier vaults with a vault lock policy. You can specify controls such as “write once read many” (WORM) in a vault lock policy and lock the policy from future edits. After the policy is locked, it can no longer be changed. Vault lock policies can help you comply with regulatory frameworks such as SEC17a-4 and HIPAA.

- **Security and Compliance Quick Start Guides** discuss architectural considerations and steps for deploying security- and compliance-focused baseline environments on AWS.

- **Architecting for HIPAA Security and Compliance** outlines how companies use AWS to help them meet HIPAA requirements.

- **The AWS Well-Architected Tool (AWS WA Tool)** is a service in the cloud that provides a consistent process for you to review and measure your architecture using AWS best practices. The AWS WA Tool provides recommendations for making your workloads more reliable, secure, efficient, and cost-effective.
• **AWS Compliance Resources** provide several different workbooks and guides that might apply to your industry and location.

• **AWS Config** can help you assess how well your resource configurations comply with internal practices, industry guidelines, and regulations.

• **AWS Security Hub** provides you with a comprehensive view of your security state within AWS and helps you check your compliance with security industry standards and best practices.
Resilience in Amazon S3 Glacier

The AWS global infrastructure is built around Regions and Availability Zones. AWS Regions provide multiple, physically separated and isolated Availability Zones that are connected with low latency, high throughput, and highly redundant networking. These Availability Zones offer you an effective way to design and operate applications and databases. They are more highly available, fault tolerant, and scalable than traditional single data center infrastructures or multi-data center infrastructures. S3 Glacier redundantly stores data in multiple devices spanning a minimum of three Availability Zones. To increase durability, S3 Glacier synchronously stores your data across multiple AZs before confirming a successful upload.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.
Infrastructure Security in Amazon S3 Glacier

As a managed service, Amazon S3 Glacier (S3 Glacier) is protected by the AWS global network security procedures that are described in the Amazon Web Services: Overview of Security Processes.

Access to S3 Glacier via the network is through AWS published APIs. Clients must support Transport Layer Security (TLS) 1.2. We recommend TLS 1.3 or later. Clients must also support cipher suites with Perfect Forward Secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, requests must be signed using an access key ID and a secret access key that is associated with an IAM principal, or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

VPC Endpoints

A virtual private cloud (VPC) endpoint enables you to privately connect your VPC to supported AWS services and VPC endpoint services powered by AWS PrivateLink without requiring an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Although S3 Glacier does not support VPC endpoints directly, you can take advantage of Amazon S3 VPC endpoints if you access S3 Glacier as a storage tier integrated with Amazon S3.

For more information about Amazon S3 lifecycle configuration and transitioning objects to the S3 Glacier storage class, see Object Lifecycle Management and Transitioning Objects in the Amazon Simple Storage Service User Guide. For more information about VPC endpoints, see VPC Endpoints in the Amazon VPC User Guide.
S3 Glacier Data Retrieval Policies

With Amazon S3 Glacier data retrieval policies, you can easily set data retrieval quotas and manage the data retrieval activities across your AWS account in each AWS Region. For more information about S3 Glacier data retrieval charges, see [S3 Glacier pricing](#).

**Important**

A data retrieval policy applies only to Standard retrievals and manages retrieval requests made directly to S3 Glacier.

For more information about the S3 Glacier storage classes, see [Storage classes for archiving objects](#) and [Transitioning objects](#) in the *Amazon Simple Storage Service User Guide*.

Choosing an S3 Glacier Data Retrieval Policy

You can choose from three types of S3 Glacier data retrieval policies: No Retrieval Limit, Free Tier Only, and Max Retrieval Rate.

No Retrieval Limit is the default data retrieval policy that's used for retrievals. If you use the No Retrieval Limit policy, no retrieval quota is set, and all valid data retrieval requests are accepted.

By using a Free Tier Only policy, you can keep your retrievals within your daily AWS Free Tier allowance and not incur any data retrieval costs. If you want to retrieve more data than is in your AWS Free Tier allowance, you can use a Max Retrieval Rate policy to set a bytes-per-hour retrieval-rate quota. The Max Retrieval Rate policy ensures that the peak retrieval rate from all retrieval jobs across your account in an AWS Region does not exceed the bytes-per-hour quota that you set.

With both the Free Tier Only and Max Retrieval Rate policies, data retrieval requests that exceed the retrieval quotas that you specified are not accepted. If you use a Free Tier Only policy, S3 Glacier synchronously rejects retrieval requests that exceed your AWS Free Tier allowance. If you
use a Max Retrieval Rate policy, S3 Glacier rejects retrieval requests that cause the peak retrieval rate of the in-progress jobs to exceed the bytes-per-hour quota set by the policy. These policies help you simplify data retrieval cost management.

The following are some useful facts about data retrieval policies:

- Data retrieval policy settings do not change the 3- to 5-hour period that it takes to retrieve data from S3 Glacier by using Standard retrievals.
- Setting a new data retrieval policy does not affect previously accepted retrieval jobs that are already in progress.
- If a retrieval job request is rejected because of a data retrieval policy, you are not charged for the job or the request.
- You can set one data retrieval policy for each AWS Region, which will govern all data retrieval activities in the AWS Region under your account. A data retrieval policy is specific to a particular AWS Region because data retrieval costs vary across AWS Regions. For more information, see Amazon S3 Glacier pricing.

**Free Tier Only Policy**

You can set a data retrieval policy to Free Tier Only to ensure that your retrievals always stay within your AWS Free Tier allowance, so that you don't incur data retrieval charges. If a retrieval request is rejected, you receive an error message stating that the request has been denied by the current data retrieval policy.

You can set the data retrieval policy to Free Tier Only on a per-Region basis. After the policy is set, you cannot retrieve more data in a day than your prorated daily AWS Free Tier retrieval allowance for that AWS Region. You also do not incur data retrieval fees.

You can also switch to a Free Tier Only policy after you have incurred data retrieval charges within a month. In that case, the Free Tier Only policy takes effect for new retrieval requests, but does not affect past requests. You will be billed for the previously incurred charges.

**Max Retrieval Rate Policy**

You can set your data retrieval policy to Max Retrieval Rate to control the peak retrieval rate by specifying a data retrieval quota that has a bytes-per-hour maximum. When you set the data retrieval policy to Max Retrieval Rate, a new retrieval request is rejected if it would cause the peak...
retrieval rate of the in-progress jobs to exceed the bytes-per-hour quota that's specified by the policy. If a retrieval job request is rejected, you receive an error message stating that the request has been denied by the current data retrieval policy.

Setting your data retrieval policy to the Max Retrieval Rate policy can affect how much of your AWS Free Tier allowance that you can use in a day. For example, suppose you set Max Retrieval Rate to 1 MB per hour. This is less than the AWS Free Tier policy rate. To ensure that you make good use of the daily AWS Free Tier allowance, you can first set your policy to Free Tier Only, and then switch to the Max Retrieval Rate policy later if you need to. For more information about how your retrieval allowance is calculated, go to Amazon S3 Glacier FAQs.

No Retrieval Limit Policy

If your data retrieval policy is set to No Retrieval Limit, all valid data retrieval requests are accepted and your data retrieval costs will vary based on your usage.

Using the S3 Glacier Console to Set Up a Data Retrieval Policy

To create a data retrieval policy by using the Amazon S3 Glacier console

1. Sign in to the AWS Management Console and open the S3 Glacier console at https://console.aws.amazon.com/glacier/home.
2. Under Select a Region, choose an AWS Region from the dropdown menu. You can configure a data retrieval policy for each AWS Region.
3. In the left navigation pane, choose Data retrieval settings.
4. Choose Edit. The Edit data retrieval policies page appears.
5. Under Data retrieval policies, choose a policy.

You can select one of the three data retrieval policies: No retrieval limit, Free Tier only, or Specify a max retrieval rate.

- If you choose No retrieval limit, all valid data retrieval requests are accepted.
- If you choose Free Tier only, data retrieval requests that exceed the AWS Free Tier are not accepted.
- If you choose Specify a max retrieval rate, data retrieval requests are rejected if they would cause the peak retrieval rate of the in-progress jobs to exceed the max retrieval rate that you specify. You must specify a gigabytes (GB) per hour value in the GB/hour box under Max.
retrieval rate. When you enter a value for GB/hour, the console calculates an estimated cost for you.

6. Choose Save changes.

Using the Amazon S3 Glacier API to Set Up a Data Retrieval Policy

You can view and set a data retrieval policy by using the Amazon S3 Glacier REST API or by using the AWS SDKs.

Using the Amazon S3 Glacier REST API to Set Up a Data Retrieval Policy

You can view and set a data retrieval policy by using the Amazon S3 Glacier REST API. You can view an existing data retrieval policy by using the Get Data Retrieval Policy (GET policy) operation. You set a data retrieval policy by using the Set Data Retrieval Policy (PUT policy) operation.

When using the PUT policy operation, you select the data retrieval policy type by setting the JSON Strategy field value to BytesPerHour, FreeTier, or None. BytesPerHour is equivalent to choosing Specify a max retrieval rate in the console, FreeTier to choosing Free Tier only, and None to choosing No retrieval limit.

When you use the Initiate Job (POST jobs) operation to initiate a data retrieval job that will exceed the maximum retrieval rate set in your data retrieval policy, the Initiate Job operation stops and throws an exception.

Using the AWS SDKs to Set Up a Data Retrieval Policy

AWS provides SDKs for you to develop applications for Amazon S3 Glacier. These SDKs provide libraries that map to the underlying REST API and provide objects that enable you to easily construct requests and process responses. For more information, see Using the AWS SDKs with Amazon S3 Glacier.
Tagging Amazon S3 Glacier Resources

A tag is a label that you assign to an AWS resource. Each tag consists of a key and a value, both of which you define. You can assign the tags that you define to Amazon S3 Glacier (S3 Glacier) vault resources. Using tags is a simple yet powerful way to manage AWS resources and organize data, including billing data.

Tagging Basics

You use the S3 Glacier console, AWS Command Line Interface (AWS CLI), or S3 Glacier API to complete the following tasks:

• Adding tags to a vault
• Listing the tags for a vault
• Removing tags from a vault

For information about how to add, list, and remove tags, see Tagging Your S3 Glacier Vaults.

You can use tags to categorize your vaults. For example, you can categorize vaults by purpose, owner, or environment. Because you define the key and value for each tag, you can create a custom set of categories to meet your specific needs. For example, you might define a set of tags that helps you track vaults by owner and purpose for the vault. Following are a few examples of tags:

• Owner: Name
• Purpose: Video archives
• Environment: Production
Tag Restrictions

Basic tag restrictions are as follows:

- The maximum number of tags for a resource (vault) is 50.
- Tag keys and values are case-sensitive.

Tag key restrictions are as follows:

- Within a set of tags for a vault, each tag key must be unique. If you add a tag with a key that's already in use, your new tag overwrites the existing key-value pair.
- Tag keys cannot start with `aws:` because this prefix is reserved for use by AWS. AWS can create tags that begin with this prefix on your behalf, but you can't edit or delete them.
- Tag keys must be from 1 to 128 Unicode characters in length.
- Tag keys must consist of the following characters: Unicode letters, digits, spaces, and the following special characters: `_ . / = + - @`.

Tag value restrictions are as follows:

- Tag values must be from 0 to 255 Unicode characters in length.
- Tag values can be blank. Otherwise, they must consist of the following characters: Unicode letters, digits, spaces, and any of the following special characters: `_ . / = + - @`.

Tracking Costs Using Tagging

You can use tags to categorize and track your AWS costs. When you apply tags to any AWS resources, including vaults, your AWS cost allocation report includes usage and costs aggregated by tags. You can apply tags that represent business categories (such as cost centers, application names, and owners) to organize your costs across multiple services. For more information, see Use Cost Allocation Tags for Custom Billing Reports in the AWS Billing User Guide.

Managing Access Control with Tagging

You can use tags as a condition in an access policy statement. For example, you can set up a legal hold tag and include it as a condition in a data retention policy that states that “archive deletion
from everyone will be denied if the legal hold tag value is set to True.” You can deploy the data retention policy and set the legal hold tag to False under normal conditions. If your data must be put on hold to assist an investigation, you can easily turn on the legal hold by setting the tag value to True and removing the hold in a similar way later on. For more information, see Controlling Access Using Tags in the IAM User Guide.

Logging Amazon S3 Glacier API Calls with AWS CloudTrail

Amazon S3 Glacier (S3 Glacier) is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in S3 Glacier. CloudTrail captures all API calls for S3 Glacier as events, including calls from the S3 Glacier console and from code calls to the S3 Glacier APIs. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for S3 Glacier. If you don’t configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can determine the request that was made to S3 Glacier, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Amazon S3 Glacier Information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in S3 Glacier, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for S3 Glacier, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts
All S3 Glacier actions are logged by CloudTrail and are documented in the API Reference for Amazon S3 Glacier. For example, calls to the Create Vault (PUT vault), Delete Vault (DELETE vault), and List Vaults (GET vaults) actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or other credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.

Understanding Amazon S3 Glacier Log File Entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the Create Vault (PUT vault), Delete Vault (DELETE vault), List Vaults (GET vaults), and Describe Vault (GET vault) actions.

API Reference for Amazon S3 Glacier

Amazon S3 Glacier supports a set of operations—specifically, a set of RESTful API calls—that enable you to interact with the service.

You can use any programming library that can send HTTP requests to send your REST requests to S3 Glacier. When sending a REST request, S3 Glacier requires that you authenticate every request by signing the request. Additionally, when uploading an archive, you must also compute the checksum of the payload and include it in your request. For more information, see [Signing Requests](#).

If an error occurs, you need to know what S3 Glacier sends in an error response so that you can process it. This section provides all this information, in addition to documenting the REST operations, so that you can make REST API calls directly.

You can either use the REST API calls directly or use the Amazon SDKs that provide wrapper libraries. These libraries sign each request you send and compute the checksum of the payload in your request. Therefore, using the Amazon SDKs simplifies your coding task. This developer guide provides working examples of basic S3 Glacier operations using the AWS SDK for Java and .NET. For more information see, [Using the AWS SDKs with Amazon S3 Glacier](#).

# Common Request Headers

Amazon S3 Glacier (S3 Glacier) REST requests include headers that contain basic information about the request. The following table describes headers that can be used by all S3 Glacier REST requests.

<table>
<thead>
<tr>
<th>Header Name</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authorization</td>
<td>The header that is required to sign requests. S3 Glacier requires Signature Version 4. For more information, see <a href="#">Signing Requests</a>. Type: String</td>
<td>Yes</td>
</tr>
<tr>
<td>Content-Length</td>
<td>The length of the request body (without the headers).</td>
<td>Conditional</td>
</tr>
<tr>
<td>Date</td>
<td>The date that can be used to create the signature contained in the Authorization header. If the Date header is to be used for signing it must be specified in the ISO 8601 basic format. In this case, the x-amz-date header is not needed. Note that when x-amz-date is present, it always overrides the value of the Date header. If the Date header is not used for signing, it can be one of the full date formats specified by <a href="https://tools.ietf.org/html/rfc2616">RFC 2616</a>, section 3.3. For example, the following date/time Wed, 10 Feb 2017 12:00:00 GMT is a valid date/time header for use with S3 Glacier. If you are using the Date header for signing, then it must be in the ISO 8601 basic YYYYYMDD'T'HHMMSS'Z' format.</td>
<td>Conditional</td>

<tr>
<td>-------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>

</tr>
<tr>
<td>Type: String</td>
<td>Condition: If Date is specified but is not in ISO 8601 basic format, then you must also include the <code>x-amz-date</code> header. If Date is specified in ISO 8601 basic format, then this is sufficient for signing requests and you do not need the <code>x-amz-date</code> header. For more information, see <a href="https://docs.aws.amazon.com/en_us/aws/en_us/aws-glossary.html">Handling Dates in Signature Version 4</a> in the Amazon Web Services Glossary.</td>

Signing Requests

S3 Glacier requires that you authenticate every request you send by signing the request. To sign a request, you calculate a digital signature using a cryptographic hash function. A cryptographic hash is a function that returns a unique hash value based on the input. The input to the hash function includes the text of your request and your secret access key. The hash function returns a hash value
that you include in the request as your signature. The signature is part of the Authorization header of your request.

After receiving your request, S3 Glacier recalculates the signature using the same hash function and input that you used to sign the request. If the resulting signature matches the signature in the request, S3 Glacier processes the request. Otherwise, the request is rejected.

S3 Glacier supports authentication using AWS Signature Version 4. The process for calculating a signature can be broken into three tasks:

- **Task 1: Create a Canonical Request**

  Rearrange your HTTP request into a canonical format. Using a canonical form is necessary because S3 Glacier uses the same canonical form when it recalculates a signature to compare with the one you sent.

- **Task 2: Create a String to Sign**

  Create a string that you will use as one of the input values to your cryptographic hash function. The string, called the *string to sign*, is a concatenation of the name of the hash algorithm, the request date, a *credential scope* string, and the canonicalized request from the previous task. The *credential scope* string itself is a concatenation of date, AWS Region, and service information.

- **Task 3: Create a Signature**

  Create a signature for your request by using a cryptographic hash function that accepts two input strings: your *string to sign* and a *derived key*. The *derived key* is calculated by starting with your secret access key and using the *credential scope* string to create a series of hash-based message authentication codes (HMACs). Note that the hash function used in this signing step is not the tree-hash algorithm used in S3 Glacier APIs that upload data.

Example Signature Calculation

The following example walks you through the details of creating a signature for Create Vault (PUT vault). The example could be used as a reference to check your signature calculation method. For more information, see Signing AWS API requests in the IAM User Guide.

The example assumes the following:

- The time stamp of the request is Fri, 25 May 2012 00:24:53 GMT.
- The endpoint is US East (N. Virginia) Region us-east-1.

The general request syntax (including the JSON body) is:

```
PUT /-/vaults/examplevault HTTP/1.1
Host: glacier.us-east-1.amazonaws.com
Date: Fri, 25 May 2012 00:24:53 GMT
Authorization: SignatureToBeCalculated
x-amz-glacier-version: 2012-06-01
```

The canonical form of the request calculated for Task 1: Create a Canonical Request is:

```
PUT /-/vaults/examplevault

host:glacier.us-east-1.amazonaws.com
x-amz-date:20120525T002453Z
x-amz-glacier-version:2012-06-01
```

The last line of the canonical request is the hash of the request body. Also, note the empty third line in the canonical request. This is because there are no query parameters for this API.

The string to sign for Task 2: Create a String to Sign is:

```
AWS4-HMAC-SHA256
20120525T002453Z
```
The first line of the *string to sign* is the algorithm, the second line is the time stamp, the third line is the *credential scope*, and the last line is a hash of the canonical request from `Task 1: Create a Canonical Request`. The service name to use in the credential scope is `glacier`.

For `Task 3: Create a Signature`, the *derived key* can be represented as:

\[
\text{derived key} = \text{HMAC(}H\text{MAC(H}\text{MAC("AWS4" + YourSecretAccessKey,"20120525"),"us-east-1"),"glacier"),"aws4_request"})
\]

If the secret access key, `wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY`, is used, then the calculated signature is:

3ce5b2f2ffe9262b4da9256f8d086b4aaf42eba5f111c21681a65a127b7c2a

The final step is to construct the Authorization header. For the demonstration access key `AKIAIOSFODNN7EXAMPLE`, the header (with line breaks added for readability) is:

```
Authorization: AWS4-HMAC-SHA256 Credential=AKIAIOSFODNN7EXAMPLE/20120525/us-east-1/glacier/aws4_request,
SignedHeaders=host;x-amz-date;x-amz-glacier-version,
Signature=3ce5b2f2ffe9262b4da9256f8d086b4aaf42eba5f111c21681a65a127b7c2a
```

**Calculating Signatures for the Streaming Operations**

`Upload Archive (POST archive)` and `Upload Part (PUT uploadID)` are streaming operations that require you to include an additional header `x-amz-content-sha256` when signing and sending your request. The signing steps for the streaming operations are exactly the same as those for other operations, with the addition of the streaming header.

The calculation of the streaming header `x-amz-content-sha256` is based on the SHA256 hash of the entire content (payload) that is to be uploaded. Note that this calculation is different from...
the SHA256 tree hash (Computing Checksums). Besides trivial cases, the SHA 256 hash value of the payload data will be different from the SHA256 tree hash of the payload data.

If the payload data is specified as a byte array, you can use the following Java code snippet to calculate the SHA256 hash.

```java
public static byte[] computePayloadSHA256Hash2(byte[] payload) throws NoSuchAlgorithmException, IOException {
    BufferedInputStream bis =
        new BufferedInputStream(new ByteArrayInputStream(payload));
    MessageDigest messageDigest = MessageDigest.getInstance("SHA-256");
    byte[] buffer = new byte[4096];
    int bytesRead = -1;
    while ((bytesRead = bis.read(buffer, 0, buffer.length)) != -1) {
        messageDigest.update(buffer, 0, bytesRead);
    }
    return messageDigest.digest();
}
```

Similarly, in C# you can calculate the SHA256 hash of the payload data as shown in the following code snippet.

```csharp
public static byte[] CalculateSHA256Hash(byte[] payload) {
    byte[] hash = sha256.ComputeHash(payload);

    return hash;
}
```

Example Signature Calculation for Streaming API

The following example walks you through the details of creating a signature for Upload Archive (POST archive), one of the two streaming APIs in S3 Glacier. The example assumes the following:

- The time stamp of the request is Mon, 07 May 2012 00:00:00 GMT.
- The endpoint is the US East (N. Virginia) Region, us-east-1.
- The content payload is a string "Welcome to S3 Glacier."
The general request syntax (including the JSON body) is shown in the example below. Note that the `x-amz-content-sha256` header is included. In this simplified example, the `x-amz-sha256-tree-hash` and `x-amz-content-sha256` are the same value. However, for archive uploads greater than 1 MB, this is not the case.

```build
POST /-/vaults/examplevault HTTP/1.1
Host: glacier.us-east-1.amazonaws.com
Date: Mon, 07 May 2012 00:00:00 GMT
x-amz-archive-description: my archive
x-amz-sha256-tree-hash: SHA256 tree hash
x-amz-content-sha256: SHA256 payload hash
Authorization: SignatureToBeCalculated
x-amz-glacier-version: 2012-06-01
```

The canonical form of the request calculated for Task 1: Create a Canonical Request is shown below. Note that the streaming header `x-amz-content-sha256` is included with its value. This means you must read the payload and calculate the SHA256 hash first and then compute the signature.

```build
POST
/-/vaults/examplevault
host:glacier.us-east-1.amazonaws.com
x-amz-content-sha256:726e392cb4d09924dbad1cc0ba3b00c3643d03d14cb4b823e2f041cffe12a628
x-amz-date:20120507T000000Z
x-amz-glacier-version:2012-06-01
host;x-amz-content-sha256;x-amz-date;x-amz-glacier-version
726e392cb4d09924dbad1cc0ba3b00c3643d03d14cb4b823e2f041cffe12a628
```

The remainder of the signature calculation follows the steps outlined in Example Signature Calculation. The Authorization header using the secret access key wJalrXUtlnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY and the access key AKIAIOSFODNN7EXAMPLE is shown below (with line breaks added for readability):

```build
Authorization=AWS4-HMAC-SHA256
Credential=AKIAIOSFODNN7EXAMPLE/20120507/us-east-1/glacier/aws4_request,
SignedHeaders=host;x-amz-content-sha256;x-amz-date;x-amz-glacier-version,
```

Calculating Signatures for the Streaming Operations
Computing Checksums

When uploading an archive, you must include both the x-amz-sha256-tree-hash and x-amz-content-sha256 headers. The x-amz-sha256-tree-hash header is a checksum of the payload in your request body. This topic describes how to calculate the x-amz-sha256-tree-hash header. The x-amz-content-sha256 header is a hash of the entire payload and is required for authorization. For more information, see Example Signature Calculation for Streaming API.

The payload of your request can be an:

- **Entire archive**— When uploading an archive in a single request using the Upload Archive API, you send the entire archive in the request body. In this case, you must include the checksum of the entire archive.

- **Archive part**— When uploading an archive in parts using the multipart upload API, you send only a part of the archive in the request body. In this case, you include the checksum of the archive part. And after you upload all the parts, you send a Complete Multipart Upload request, which must include the checksum of the entire archive.

The checksum of the payload is a SHA-256 tree hash. It is called a tree hash because in the process of computing the checksum you compute a tree of SHA-256 hash values. The hash value at the root is the checksum for the entire archive.

**Note**

This section describes a way to compute the SHA-256 tree hash. However, you may use any procedure as long as it produces the same result.

You compute the SHA-256 tree hash as follows:

1. For each 1 MB chunk of payload data, compute the SHA-256 hash. The last chunk of data can be less than 1 MB. For example, if you are uploading a 3.2 MB archive, you compute the SHA-256
hash values for each of the first three 1 MB chunks of data, and then compute the SHA-256 hash of the remaining 0.2 MB data. These hash values form the leaf nodes of the tree.

2. Build the next level of the tree.
   a. Concatenate two consecutive child node hash values and compute the SHA-256 hash of the concatenated hash values. This concatenation and generation of the SHA-256 hash produces a parent node for the two child nodes.
   b. If only one child node remains, promote that hash value to the next level in the tree.

3. Repeat step 2 until the resulting tree has a root. The root of the tree provides a hash of the entire archive and a root of the appropriate subtree provides the hash for the part in a multipart upload.

Tree Hash Example 1: Uploading an archive in a single request

When you upload an archive in a single request using the Upload Archive API (see Upload Archive (POST archive)), the request payload includes the entire archive. Accordingly, you must include the tree hash of the entire archive in the x-amz-sha256-tree-hash request header. Suppose you want to upload a 6.5 MB archive. The following diagram illustrates the process of creating the SHA-256 hash of the archive. You read the archive and compute the SHA-256 hash for each 1 MB chunk. You also compute the hash for the remaining 0.5 MB data and then build the tree as outlined in the preceding procedure.
Tree Hash Example 2: Uploading an archive using a multipart upload

The process of computing the tree hash when uploading an archive using multipart upload is the same when uploading the archive in a single request. The only difference is that in a multipart upload you upload only a part of the archive in each request (using the `Upload Part (PUT uploadID)` API), and therefore you provide the checksum of only the part in the `x-amz-sha256-tree-hash` request header. However, after you upload all parts, you must send the Complete Multipart Upload (see `Complete Multipart Upload (POST uploadID)`) request with a tree hash of the entire archive in the `x-amz-sha256-tree-hash` request header.
Computing the Tree Hash of a File

The algorithms shown here are selected for demonstration purposes. You can optimize the code as needed for your implementation scenario. If you are using an Amazon SDK to program against Amazon S3 Glacier (S3 Glacier), the tree hash calculation is done for you and you only need to provide the file reference.

Example 1: Java Example

The following example shows how to calculate the SHA256 tree hash of a file using Java. You can run this example by either supplying a file location as an argument or you can use the TreeHashExample.computeSHA256TreeHash method directly from your code.

* This method uses a pair of arrays to iteratively compute the tree hash level by level. Each iteration takes two adjacent elements from the previous level source array, computes the SHA-256 hash on their concatenated value and places the result in the next level's destination array. At the end of an iteration, the destination array becomes the source array for the next level.

Receiving Checksums When Downloading Data

When you retrieve an archive using the Initiate Job API (see Initiate Job (POST jobs)), you can optionally specify a range to retrieve of the archive. Similarly, when you download your data using the Get Job Output API (see Get Job Output (GET output)), you can optionally specify a range of data to download. There are two characteristics of these ranges that are important to understand when you are retrieving and downloading your archive's data. The range to retrieve is required to be megabyte aligned to the archive. Both the range to retrieve and the range to download must be tree hash aligned in order to receive checksum values when you download your data. The definition of these two types of range alignments are as follows:

- Megabyte aligned - A range \([\text{StartByte}, \text{EndBytes}]\) is megabyte (1024*1024) aligned when \(\text{StartBytes}\) is divisible by 1 MB and \(\text{EndBytes} + 1\) is divisible by 1 MB or is equal to the end of the archive specified (archive byte size minus 1). A range used in the Initiate Job API, if specified, is required to be megabyte aligned.

- Tree-hash aligned - A range \([\text{StartBytes}, \text{EndBytes}]\) is tree hash aligned with respect to an archive if and only if the root of the tree hash built over the range is equivalent to a node in the tree hash of the whole archive. Both the range to retrieve and range to download must be tree hash aligned in order to receive checksum values for the data you download. For an example of ranges and their relationship to the archive tree hash, see Tree Hash Example: Retrieving an archive range that is tree-hash aligned.

Note that a range that is tree-hash aligned is also megabyte aligned. However, a megabyte aligned range is not necessarily tree-hash aligned.

The following cases describe when you receive a checksum value when you download your archive data:

- If you do not specify a range to retrieve in the Initiate Job request and you download the whole archive in the Get Job Request.

- If you do not specify a range to retrieve in the Initiate Job request and you do specify a tree-hash aligned range to download in the Get Job Request.

- If you specify a tree-hash aligned range to retrieve in the Initiate Job request and you download the whole range in the Get Job Request.
If you specify a tree-hash aligned range to retrieve in the Initiate Job request and you specify a tree-hash aligned range to download in the Get Job Request.

If you specify a range to retrieve in the Initiate Job request that is not tree hash aligned, then you can still get your archive data but no checksum values are returned when you download data in the Get Job Request.

**Tree Hash Example: Retrieving an archive range that is tree-hash aligned**

Suppose you have a 6.5 MB archive in your vault and you want to retrieve 2 MB of the archive. How you specify the 2 MB range in the Initiate Job request determines if you receive data checksum values when you download your data. The following diagram illustrates two 2 MB ranges for the 6.5 MB archive that you could download. Both ranges are megabyte aligned, but only one is tree-hash aligned.

**Tree-Hash Aligned Range Specification**

This section gives the exact specification for what constitutes a tree-hash aligned range. Tree-hash aligned ranges are important when you are downloading a portion of an archive and you specify...
the range of data to retrieve and the range to download from the retrieved data. If both of these ranges are tree-hash aligned, then you will receive checksum data when you download the data.

A range \([A, B]\) is *tree-hash aligned* with respect to an archive if and only if when a new tree hash is built over \([A, B]\), the root of the tree hash of that range is equivalent to a node in the tree hash of the whole archive. You can see this shown in the diagram in Tree Hash Example: Retrieving an archive range that is tree-hash aligned. In this section, we provide the specification for tree-hash alignment.

Consider \([P, Q]\) as the range query for an archive of \(N\) megabytes (MB) and \(P\) and \(Q\) are multiples of one MB. Note that the actual inclusive range is \([P \text{ MB}, Q \text{ MB} – 1 \text{ byte}]\), but for simplicity, we show it as \([P, Q]\). With these considerations, then

- If \(P\) is an odd number, there is only one possible tree-hash aligned range—that is \([P, P + 1 \text{ MB}]\).
- If \(P\) is an even number and \(k\) is the maximum number, where \(P\) can be written as \(2^k \times X\), then there are at most \(k\) tree-hash aligned ranges that start with \(P\). \(X\) is an integer greater than 0. The tree-hash aligned ranges fall in the following categories:
  
  - For each \(i\), where \((0 <= i <= k)\) and where \(P + 2^i < N\), then \([P, Q + 2^i]\) is a tree-hash aligned range.
  - \(P = 0\) is the special case where \(A = 2^{\lfloor \log N \rfloor} \times 0\)

Various S3 Glacier APIs return the same exception, but with different exception messages to help you troubleshoot the specific error encountered.
S3 Glacier returns error information in the response body. The following examples show some of the error responses.

**Example 1: Describe Job request with a job ID that does not exist**

Suppose you send a Describe Job (GET JobID) request for a job that does not exist. That is, you specify a job ID that does not exist.

```
GET /-/vaults/examplevault/jobs/
K3CGl6fuSm6VzW9T7esGQfco8nUXVYwS0jlb5gq1JZ55yHgt5vP54ZShjoQzQVEXAMPLEbadJobID HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
Date: 20170210T120000Z
x-amz-glacier-version: 2012-06-01
Authorization: AWS4-HMAC-SHA256 Credential=AKIAIOSFODNN7EXAMPLE/20141123/
us-west-2/glacier/aws4_request,SignedHeaders=host;x-amz-date;x-amz-glacier-
version,Signature=9257c16da6b25a715ce900a5b45b03da0447acf430195dcb540091b12966f2a2
```

In response, S3 Glacier returns the following error response.

```
HTTP/1.1 404 Not Found
x-amzn-RequestId: AAABaZ9N92Iiyv4N7sru3ABEpSQkuFtmH3NP6aAC51ixfjg
Content-Type: application/json

  "message": "The job ID was not found: HkF9p6o7yjhFx-K3CGl6fuSm6VzW9T7esGQfco8nUXVYwS0jlb5gq1JZ55yHgt5vP54ZShjoQzQVEXAMPLEbadJobID",
  "type": "Client"
}
```

Where:

**Code**

One of the general exceptions.

**Type: String**

**Message**

A generic description of the error condition specific to the API that returns the error.
**Type**: String

**Type**

The source of the error. The field can be one of the following values: Client, Server, or Unknown.

**Type**: String.

Note the following in the preceding response:

- For the error response, S3 Glacier returns status code values of 4xx and 5xx. In this example, the status code is 404 Not Found.
- The Content-Type header value application/json indicates JSON in the body
- The JSON in the body provides the error information.

In the previous request, instead of a bad job ID, suppose you specify a vault that does not exist. The response returns a different message.

```
HTTP/1.1 404 Not Found
x-amzn-RequestId: AAABBeC9Zw0rp_5D0L8VfB3FA_W1TupqTKAUehMcPhdgni0
Content-Type: application/json
Content-Length: 154
Date: Wed, 10 Feb 2017 12:00:00 GMT
{
  "code": "ResourceNotFoundException",
  "type": "Client"
}
```

**Example 2: List Jobs request with an invalid value for the request parameter**

In this example you send a List Jobs (GET jobs) request to retrieve vault jobs with a specific statuscode, and you provide an incorrect statuscode value finished, instead of the acceptable values InProgress, Succeeded, or Failed.

```
GET /-/vaults/examplevault/jobs?statuscode=finished HTTP/1.1
```
S3 Glacier returns the `InvalidParameterValueException` with an appropriate message.

```
HTTP/1.1 400 Bad Request
x-amzn-RequestId: AAABaZ9N92Iiyv4N7sru3ABEp5QkuFtmH3NP6aAC51ixfjg
Content-Type: application/json
Content-Length: 141
Date: Wed, 10 Feb 2017 12:00:00 GMT
{
  "code": "InvalidParameterValueException",
  "message": "The job status code is not valid: finished",
  "type": "Client"
}
```

**Vault Operations**

The following are the vault operations available in S3 Glacier.

**Topics**

- [Abort Vault Lock (DELETE lock-policy)](#)
- [Add Tags To Vault (POST tags add)](#)
- [Create Vault (PUT vault)](#)
- [Complete Vault Lock (POST lockId)](#)
- [Delete Vault (DELETE vault)](#)
- [Delete Vault Access Policy (DELETE access-policy)](#)
- [Delete Vault Notifications (DELETE notification-configuration)](#)
- [Describe Vault (GET vault)](#)
- [Get Vault Access Policy (GET access-policy)](#)
- [Get Vault Lock (GET lock-policy)](#)
- [Get Vault Notifications (GET notification-configuration)](#)
Abort Vault Lock (DELETE lock-policy)

Description

This operation stops the vault locking process if the vault lock is not in the Locked state. If the vault lock is in the Locked state when this operation is requested, the operation returns an AccessDeniedException error. Stopping the vault locking process removes the vault lock policy from the specified vault.

A vault lock is put into the InProgress state by calling Initiate Vault Lock (POST lock-policy). A vault lock is put into the Locked state by calling Complete Vault Lock (POST lockId). You can get the state of a vault lock by calling Get Vault Lock (GET lock-policy). For more information about the vault locking process, see S3 Glacier Vault Lock. For more information about vault lock policies, see Vault Lock Policies.

This operation is idempotent. You can successfully invoke this operation multiple times, if the vault lock is in the InProgress state or if there is no policy associated with the vault.

Requests

To delete the vault lock policy, send an HTTP DELETE request to the URI of the vault's lock-policy subresource.

Syntax

DELETE /AccountId/vaults/vaultName/lock-policy HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01
Note

The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens ('-') in the ID.

Request Parameters

This operation does not use request parameters.

Request Headers

This operation uses only request headers that are common to all operations. For information about common request headers, see Common Request Headers.

Request Body

This operation does not have a request body.

Responses

If the policy is successfully deleted, S3 Glacier returns an HTTP 204 No Content response.

Syntax

HTTP/1.1 204 No Content
x-amzn-RequestId: x-amzn-RequestId
Date: Date

Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see Common Response Headers.

Response Body

This operation does not return a response body.
Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.

Examples

The following example demonstrates how to stop the vault locking process.

Example Request

In this example, a DELETE request is sent to the lock-policy subresource of the vault named examplevault.

```
DELETE /-/vaults/examplevault/lock-policy HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z
Authorization: AWS4-HMAC-SHA256 Credential=AKIAIOSFODNN7EXAMPLE/20141123/us-west-2/glacier/aws4_request,SignedHeaders=host;x-amz-date;x-amz-glacier-version,Signature=9257c16da6b25a715ce900a5b45b03da0447acf430195dc540091b12966f2a2
x-amz-glacier-version: 2012-06-01
```

Example Response

If the policy is successfully deleted S3 Glacier returns an HTTP 204 No Content response, as shown in the following example.

```
HTTP/1.1 204 No Content
x-amzn-RequestId: AAABZpJrTyioDC_HsOmHae8EZp_uBSJr6cnGOLKp_XJCl-Q
Date: Wed, 10 Feb 2017 12:00:00 GMT
```

Add Tags To Vault (POST tags add)

This operation adds the specified tags to a vault. Each tag is composed of a key and a value. Each vault can have up to 50 tags. If your request would cause the tag limit for the vault to be exceeded, the operation throws the LimitExceededException error.

If a tag already exists on the vault under a specified key, the existing key value will be overwritten. For more information about tags, see Tagging Amazon S3 Glacier Resources.

Request Syntax

To add tags to a vault, send an HTTP POST request to the tags URI as shown in the following syntax example.

```plaintext
POST /AccountId/vaults/vaultName/tags?operation=add HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
Content-Length: Length
x-amz-glacier-version: 2012-06-01

{
   "Tags":

   }
}
```

Note

The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS...
account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens ('-') in the ID.

**Request Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation=add</td>
<td>A single query string parameter operation with a value of add to distinguish it from Remove Tags From Vault (POST tags remove)</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Request Headers**

This operation uses only request headers that are common to all operations. For information about common request headers, see [Common Request Headers](#).

**Request Body**

The request body contains the following JSON fields.

**Tags**

The tags to add to the vault. Each tag is composed of a key and a value. The value can be an empty string.

*Type: String to String map*

*Length constraints: Minimum length of 1. Maximum length 10.*

*Required: Yes*

**Responses**

If the operation request is successful, the service returns an HTTP 204 No Content response.

**Syntax**

```
HTTP/1.1 204 No Content
```
Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see Common Response Headers.

Response Body

This operation does not return a response body.

Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.

Examples

Example Request

The following example sends an HTTP POST request with the tags to add to the vault.

```http
POST /-/vaults/examplevault/tags?operation=add HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amzn-Date: 20170210T120000Z

Create Vault (PUT vault)

Description

This operation creates a new vault with the specified name. The name of the vault must be unique within an AWS Region for an AWS account. You can create up to 1,000 vaults per account. For information on creating more vaults, go to the Amazon S3 Glacier product detail page.

You must use the following guidelines when naming a vault.

- Names can be between 1 and 255 characters long.
- Allowed characters are a–z, A–Z, 0–9, '_' (underscore), '-' (hyphen), and '.' (period).

This operation is idempotent, you can send the same request multiple times and it has no further effect after the first time Amazon S3 Glacier (S3 Glacier) creates the specified vault.
Requests

Syntax

To create a vault, send an HTTP PUT request to the URI of the vault to be created.

```
PUT /AccountID/vaults/VaultName HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
Content-Length: Length
x-amz-glacier-version: 2012-06-01
```

Note

The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens ('-') in the ID.

Request Parameters

This operation does not use request parameters.

Request Headers

This operation uses only request headers that are common to all operations. For information about common request headers, see Common Request Headers.

Request Body

The request body for this operation must be empty (0 bytes).

Responses

Syntax

```

Examples

Example Request

The following example sends an HTTP PUT request to create a vault named examplevault.

```
PUT /-/vaults/examplevault HTTP/1.1

Complete Vault Lock (POST lockId)

Description

This operation completes the vault locking process by transitioning the vault lock from the InProgress state to the Locked state, which causes the vault lock policy to become unchangeable. A vault lock is put into the InProgress state by calling [Initiate Vault Lock (POST lock-policy)](#). You can obtain the state of the vault lock by calling [Get Vault Lock (GET lock-policy)](#). For more information about the vault locking process, see [S3 Glacier Vault Lock](#).

This operation is idempotent. This request is always successful if the vault lock is in the Locked state and the provided lock ID matches the lock ID originally used to lock the vault.
If an invalid lock ID is passed in the request when the vault lock is in the Locked state, the operation returns an AccessDeniedException error. If an invalid lock ID is passed in the request when the vault lock is in the InProgress state, the operation throws an InvalidParameter error.

**Requests**

To complete the vault locking process, send an HTTP POST request to the URI of the vault's lock-policy subresource with a valid lock ID.

**Syntax**

```
POST /AccountId/vaults/vaultName/lock-policy/lockId HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
Content-Length: Length
x-amz-glacier-version: 2012-06-01
```

**Note**

The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens ('-') in the ID.

The lockId value is the lock ID obtained from a [Initiate Vault Lock (POST lock-policy)](https://docs.aws.amazon.com/s3/latest/devguide/Initiate-Vault-Lock.html) request.

**Request Parameters**

**Request Headers**

This operation uses only request headers that are common to all operations. For information about common request headers, see [Common Request Headers](https://docs.aws.amazon.com/s3/latest/devguide/Common-Request-Headers.html).

**Request Body**

This operation does not have a request body.
Responses

If the operation request is successful, the service returns an HTTP 204 No Content response.

Syntax

HTTP/1.1 204 No Content

Examples

Example Request

The following example sends an HTTP POST request with the lock ID to complete the vault locking process.

```plaintext
POST /-/vaults/examplevault/lock-policy/AE863rKkWZU53SLW5be4DUcW HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z
Authorization: AWS4-HMAC-SHA256 Credential=AKIAIOSFODNN7EXAMPLE/20141123/us-west-2/glacier/aws4_request,SignedHeaders=host;x-amz-date;x-amz-glacier-version,Signature=9257c16da6b25a715ce900a5b45b03da0447acf430195dcb540091b12966f2a2
Content-Length: length
x-amz-glacier-version: 2012-06-01
```

Example Response

If the request was successful, Amazon S3 Glacier (S3 Glacier) returns an HTTP 204 No Content response, as shown in the following example.

Delete Vault (DELETE vault)

Description

This operation deletes a vault. Amazon S3 Glacier (S3 Glacier) will delete a vault only if there are no archives in the vault as per the last inventory and there have been no writes to the vault since the last inventory. If either of these conditions is not satisfied, the vault deletion fails (that is, the vault is not removed) and S3 Glacier returns an error.

You can use the [Describe Vault (GET vault)](Describe Vault (GET vault)) operation that provides vault information, including the number of archives in the vault; however, the information is based on the vault inventory S3 Glacier last generated.

This operation is idempotent.
Requests

To delete a vault, send a DELETE request to the vault resource URI.

Syntax

DELETE /AccountID/vaults/VaultName HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01

Request Parameters

Examples

Example Request

The following example deletes a vault named examplevault. The example request is a DELETE request to the URI of the resource (the vault) to delete.

DELETE /-/vaults/examplevault HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z

Delete Vault Access Policy (DELETE access-policy)

Description

This operation deletes the access policy associated with the specified vault. The operation is eventually consistent—that is, it might take some time for Amazon S3 Glacier (S3 Glacier) to completely remove the access policy, and you might still see the effect of the policy for a short time after you send the delete request.

This operation is idempotent. You can invoke delete multiple times, even if there is no policy associated with the vault. For more information about vault access policies, see Vault Access Policies.

Requests

To delete the current vault access policy, send an HTTP DELETE request to the URI of the vault's access-policy subresource.

Syntax

```
DELETE /AccountID/vaults/vaultName/access-policy HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
```
Note

The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

Request Parameters

This operation does not use request parameters.

Request Headers

This operation uses only request headers that are common to all operations. For information about common request headers, see Common Request Headers.

Request Body

This operation does not have a request body.

Responses

In response, S3 Glacier returns 204 No Content if the policy is successfully deleted.

Syntax

```
HTTP/1.1 204 No Content
x-amzn-Request-Id: x-amzn-Request-Id
Date: Date
```

Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see Common Response Headers.

Response Body

This operation does not return a response body.
Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.

Examples

The following example demonstrates how to delete a vault access policy.

Example Request

In this example, a DELETE request is sent to the access-policy subresource of the vault named examplevault.

```
DELETE /-/vaults/examplevault/access-policy HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z
Authorization: AWS4-HMAC-SHA256 Credential=AKIAIOSFODNN7EXAMPLE/20141123/

x-amz-glacier-version: 2012-06-01
```

Example Response

In response, if the policy is successfully deleted S3 Glacier returns a 204 No Content as shown in the following example.

```
HTTP/1.1 204 No Content
x-amzn-RequestId: AAABZpJrTyioDC_HsOmHae8EZp_uB5Jr6cnGOLKp_XJCl-Q
Date: Wed, 10 Feb 2017 12:00:00 GMT

Describe Vault (GET vault)

Description

This operation returns information about a vault, including the vault Amazon Resource Name (ARN), the date the vault was created, the number of archives contained within the vault, and the total size of all the archives in the vault. The number of archives and their total size are as of the last vault inventory Amazon S3 Glacier (S3 Glacier) generated (see Working with Vaults in Amazon S3 Glacier). S3 Glacier generates vault inventories approximately daily. This means that if you add or remove an archive from a vault, and then immediately send a Describe Vault request, the response might not reflect the changes.

Requests

To get information about a vault, send a GET request to the URI of the specific vault resource.

Syntax

GET /AccountId/vaults/VaultName HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01

Note

The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

Request Parameters

This operation does not use request parameters.

Request Headers

This operation uses only request headers that are common to all operations. For information about common request headers, see Common Request Headers.

Request Body

This operation does not have a request body.

Responses

Syntax

HTTP/1.1 200 OK
x-amzn-RequestId: x-amzn-RequestId
Date: Date
Content-Type: application/json
Content-Length: Length

{
   "CreationDate" : String,
   "LastInventoryDate" : String,
   "NumberOfArchives" : Number,
   "SizeInBytes" : Number,
}
"VaultARN" : String,
"VaultName" : String
}

Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see [Common Response Headers](#).

Response Body

The response body contains the following JSON fields.

**CreationDate**

The UTC date when the vault was created.

*Type:* A string representation in the ISO 8601 date format, for example 2013-03-20T17:03:43.221Z.

**LastInventoryDate**

The UTC date when S3 Glacier completed the last vault inventory. For information about initiating an inventory for a vault, see [Initiate Job (POST jobs)](#).

*Type:* A string representation in the ISO 8601 date format, for example 2013-03-20T17:03:43.221Z.

**NumberOfArchives**

The number of archives in the vault as per the last vault inventory. This field will return null if an inventory has not yet run on the vault, for example, if you just created the vault.

*Type:* Number

**SizeInBytes**

The total size in bytes of the archives in the vault including any per-archive overhead, as of the last inventory date. This field will return null if an inventory has not yet run on the vault, for example, if you just created the vault.

*Type:* Number

**VaultARN**

The Amazon Resource Name (ARN) of the vault.
Type: String

VaultName

The vault name that was specified at creation time. The vault name is also included in the vault's ARN.

Type: String

Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.

Get Vault Access Policy (GET access-policy)

Description

This operation retrieves the access-policy subresource set on the vault—for more information on setting this subresource, see Set Vault Access Policy (PUT access-policy). If there is no access policy set on the vault, the operation returns a 404 Not Found error. For more information about vault access policies, see Vault Access Policies.

Requests

To return the current vault access policy, send an HTTP GET request to the URI of the vault's access-policy subresource.

Syntax

GET /AccountID/vaults/vaultName/access-policy HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01
### Note

The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

This operation does not use request parameters.

**Request Headers**

This operation uses only request headers that are common to all operations. For information about common request headers, see [Common Request Headers](#).

**Request Body**

This operation does not have a request body.

**Responses**

In response, Amazon S3 Glacier (S3 Glacier) returns the vault access policy in JSON format in the body of the response.

**Syntax**

```
HTTP/1.1 200 OK
x-amzn-RequestId: x-amzn-RequestId
Date: Date
Content-Type: application/json
Content-Length: length

{
   "Policy": "string"
}
```

**Response Headers**

This operation uses only response headers that are common to most responses. For information about common response headers, see [Common Response Headers](#).
Response Body

The response body contains the following JSON fields.

Policy

The vault access policy as a JSON string, which uses "\" as an escape character.

Type: String

Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.

Examples

The following example demonstrates how to get a vault access policy.

Example Request

In this example, a GET request is sent to the URI of a vault's access-policy subresource.

```
GET /-/vaults/examplevault/access-policy HTTP/1.1

```

Example Response

If the request was successful, S3 Glacier returns the vault access policy as a JSON string in the body of the response. The returned JSON string uses "\" as an escape character, as shown in the Set Vault Access Policy (PUT access-policy) examples. However, the following example shows the returned JSON string without escape characters for readability.

```

- AWS Command Line Interface
Get Vault Lock (GET lock-policy)

Description

This operation retrieves the following attributes from the lock-policy subresource set on the specified vault:

- The vault lock policy set on the vault.
- The state of the vault lock, which is either InProgress or Locked.
- When the lock ID expires. The lock ID is used to complete the vault locking process.
- When the vault lock was initiated and put into the InProgress state.

A vault lock is put into the InProgress state by calling Initiate Vault Lock (POST lock-policy). A vault lock is put into the Locked state by calling Complete Vault Lock (POST lockId). You can stop the vault locking process by calling Abort Vault Lock (DELETE lock-policy). For more information about the vault locking process, see S3 Glacier Vault Lock.

If there is no vault lock policy set on the vault, the operation returns a 404 Not Found error. For more information about vault lock policies, see Vault Lock Policies.

Requests

To return the current vault lock policy and other attributes, send an HTTP GET request to the URI of the vault's lock-policy subresource as shown in the following syntax example.

Syntax

```
GET /AccountId/vaults/vaultName/lock-policy HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01
```

Note

The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case
Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

Response Body

The response body contains the following JSON fields.

Policy

The vault lock policy as a JSON string, which uses "\" as an escape character.

Type: String

State

The state of the vault lock.

Type: String

Valid values: InProgress | Locked

ExpirationDate

The UTC date and time at which the lock ID expires. This value can be null if the vault lock is in a Locked state.

Type: A string representation in the ISO 8601 date format, for example 2013-03-20T17:03:43.221Z.

CreationDate

The UTC date and time at which the vault lock was put into the InProgress state.

Type: A string representation in the ISO 8601 date format, for example 2013-03-20T17:03:43.221Z.

### Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see [Common Response Headers](#).

### Response Body

The response body contains the following JSON fields.

#### Events

A list of one or more events for which Amazon S3 Glacier (S3 Glacier) will send a notification to the specified Amazon SNS topic. For information about vault events for which you can configure a vault to publish notifications, see [Set Vault Notification Configuration (PUT notification-configuration)](#).

*Type: Array*

#### SNSTopic

The Amazon Simple Notification Service (Amazon SNS) topic Amazon Resource Name (ARN). For more information, see [Getting Started with Amazon SNS](#) in the Amazon Simple Notification Service Getting Started Guide.

*Type: String*

### Errors

For information about Amazon S3 Glacier exceptions and error messages, see [Error Responses](#).

### Examples

The following example demonstrates how to retrieve the notification configuration for a vault.
Example Request

In this example, a GET request is sent to the notification-configuration subresource of a vault.

GET /-/vaults/examplevault/notification-configuration HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z
x-amz-glacier-version: 2012-06-01
Authorization: AWS4-HMAC-SHA256 Credential=AKIAIOSFODNN7EXAMPLE/20141123/
us-west-2/glacier/aws4_request,SignedHeaders=host;x-amz-date;x-amz-glacier-
version,Signature=9257c16da6b25a715ce900a5b45b03da0447acf430195dc8540091b12966f2a2

Example Response

A successful response shows the audit logging configuration document in the body of the response in JSON format. In this example, the configuration shows that notifications for two events (ArchiveRetrievalCompleted and InventoryRetrievalCompleted) are sent to the Amazon SNS topic arn:aws:sns:us-west-2:012345678901:mytopic.

HTTP/1.1 200 OK

Initiate Vault Lock (POST lock-policy)

Description

This operation initiates the vault locking process by doing the following:

- Installing a vault lock policy on the specified vault.
- Setting the lock state of vault lock to InProgress.
- Returning a lock ID, which is used to complete the vault locking process.

You can set one vault lock policy for each vault and this policy can be up to 20 KB in size. For more information about vault lock policies, see Vault Lock Policies.

You must complete the vault locking process within 24 hours after the vault lock enters the InProgress state. After the 24 hour window ends, the lock ID expires, the vault automatically exits the InProgress state, and the vault lock policy is removed from the vault. You call Complete Vault Lock (POST lockId) to complete the vault locking process by setting the state of the vault lock to Locked.

Note

After a vault lock is in the Locked state, you cannot initiate a new vault lock for the vault.

You can stop the vault locking process by calling Abort Vault Lock (DELETE lock-policy). You can get the state of the vault lock by calling Get Vault Lock (GET lock-policy). For more information about the vault locking process, see S3 Glacier Vault Lock.

If this operation is called when the vault lock is in the InProgress state, the operation returns an AccessDeniedException error. When the vault lock is in the InProgress state you must call Abort Vault Lock (DELETE lock-policy) before you can initiate a new vault lock policy.
Requests

To initiate the vault locking process, send an HTTP POST request to the URI of the lock-policy subresource of the vault, as shown in the following syntax example.

Syntax

```
POST /AccountId/vaults/vaultName/lock-policy HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
Content-Length: Length
x-amz-glacier-version: 2012-06-01

{
    "Policy": "string"
}
```

Note

The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens ('-') in the ID.

Request Parameters

This operation does not use request parameters.

Request Headers

This operation uses only request headers that are common to all operations. For information about common request headers, see Common Request Headers.

Request Body

The request body contains the following JSON fields.
Policy

The vault lock policy as a JSON string, which uses "\" as an escape character.

Type: String

Required: Yes

Responses

Amazon S3 Glacier (S3 Glacier) returns an HTTP 201 Created response, if the policy is accepted.

Syntax

HTTP/1.1 201 Created
x-amzn-RequestId: x-amzn-RequestId
Date: Date
x-amz-lock-id: lockId

Response Headers

A successful response includes the following response headers, in addition to the response headers that are common to all operations. For more information about common response headers, see Common Response Headers.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x-amz-lock-id</td>
<td>The lock ID, which is used to complete the vault locking process.</td>
</tr>
<tr>
<td></td>
<td>Type: String</td>
</tr>
</tbody>
</table>

Response Body

This operation does not return a response body.

Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.
Examples

Example Request

The following example sends an HTTP PUT request to the URI of the vault's lock-policy subresource. The Policy JSON string uses "\" as an escape character.

```
PUT /-/vaults/examplevault/lock-policy HTTP/1.1

Example Response

If the request was successful, S3 Glacier returns an HTTP 201 Created response, as shown in the following example.

```
HTTP/1.1 201 Created
x-amzn-RequestId: AAABZpJrTyioDC_HsOmHaeBEZp_uBS5jr6cnGOLKp_XJC1-Q

List Tags For Vault (GET tags)

This operation lists all the tags attached to a vault. The operation returns an empty map if there are no tags. For more information about tags, see Tagging Amazon S3 Glacier Resources.

Request Syntax

To list the tags for a vault, send an HTTP GET request to the tags URI as shown in the following syntax example.

```
GET /AccountId/vaults/vaultName/tags HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01
```

Note

The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens ('-') in the ID.

Request Parameters

This operation does not use request parameters.
Request Headers

This operation uses only request headers that are common to all operations. For information about common request headers, see [Common Request Headers](#).

Request Body

This operation does not have a request body.

Responses

If the operation is successful, the service sends back an HTTP 200 OK response.

Response Syntax

```
HTTP/1.1 200 OK
x-amzn-RequestId: x-amzn-RequestId
Date: Date
Content-Type: application/json
Content-Length: Length
{
    "Tags":
    {

        "string" : "string"
    }
}
```

Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see [Common Response Headers](#).

Response Body

The response body contains the following JSON fields.

Tags

The tags attached to the vault. Each tag is composed of a key and a value.

*Type:* String to String map

*Required:* Yes
Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.

Examples

Example: List Tags For a Vault

The following example lists the tags for a vault.

Example Request

In this example, a GET request is sent to retrieve a list of tags from the specified vault.

```
GET /-/vaults/examplevault/tags HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z

List Vaults (GET vaults)

Description

This operation lists all vaults owned by the calling user's account. The list returned in the response is ASCII-sorted by vault name.

By default, this operation returns up to 10 items per request. If there are more vaults to list, the marker field in the response body contains the vault Amazon Resource Name (ARN) at which to continue the list with a new List Vaults request; otherwise, the marker field is null. In your next List Vaults request you set the marker parameter to the value Amazon S3 Glacier (S3 Glacier) returned in the responses to your previous List Vaults request. You can also limit the number of vaults returned in the response by specifying the limit parameter in the request.

Requests

To get a list of vaults, you send a GET request to the vaults resource.

Syntax

GET /AccountId/vaults HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01
### Note
The Account Id value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens ('-') in the ID.

### Request Parameters
This operation uses the following request parameters.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>limit</td>
<td>The maximum number of vaults to be returned. The default limit is 10. The number of vaults returned might be fewer than the specified limit, but the number of returned vaults never exceeds the limit.</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>Type: String</td>
<td></td>
</tr>
<tr>
<td>marker</td>
<td>A string used for pagination. marker specifies the vault ARN after which the listing of vaults should begin. (The vault specified by marker is not included in the returned list.) Get the marker value from a previous List Vaults response. You need to include the marker only if you are continuing the pagination of results started in a previous List Vaults request. Specifying an empty value (&quot;&quot;&quot;) for the marker returns a list of vaults starting from the first vault.</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>Type: String</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Constraints: None</td>
<td></td>
</tr>
</tbody>
</table>

      ...
   ]
}

Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see Common Response Headers.

Response Body

The response body contains the following JSON fields.
CreationDate

The date the vault was created, in Coordinated Universal Time (UTC).

_Type:_ String. A string representation in the ISO 8601 date format, for example `2013-03-20T17:03:43.221Z`.

LastInventoryDate

The date of the last vault inventory, in Coordinated Universal Time (UTC). This field can be null if an inventory has not yet run on the vault, for example, if you just created the vault. For information about initiating an inventory for a vault, see [Initiate Job (POST jobs)](https://docs.aws.amazon.com/AmazonS3/latest/API/InitiateJob.html).

_Type:_ A string representation in the ISO 8601 date format, for example `2013-03-20T17:03:43.221Z`.

Marker

The vaultARN that represents where to continue pagination of the results. You use the marker in another List Vaults request to obtain more vaults in the list. If there are no more vaults, this value is null.

_Type:_ String

NumberOfArchives

The number of archives in the vault as of the last inventory date.

_Type:_ Number

SizeInBytes

The total size, in bytes, of all the archives in the vault including any per-archive overhead, as of the last inventory date.

_Type:_ Number

VaultARN

The Amazon Resource Name (ARN) of the vault.

_Type:_ String

VaultList

An array of objects, with each object providing a description of a vault.

_Type:_ Array
VaultName

The vault name.

Type: String

Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.

Examples

Example: List All Vaults

The following example lists vaults. Because the marker and limit parameters are not specified in the request, up to 10 vaults are returned.

Example Request

GET /-/vaults HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z

Remove Tags From Vault (POST tags remove)

This operation removes one or more tags from the set of tags attached to a vault. For more information about tags, see Tagging Amazon S3 Glacier Resources.

This operation is idempotent. The operation will be successful, even if there are no tags attached to the vault.

Request Syntax

To remove tags from a vault, send an HTTP POST request to the tags URI as shown in the following syntax example.

```plaintext
POST /AccountId/vaults/vaultName/tags?operation=remove HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
Content-Length: Length
x-amz-glacier-version: 2012-06-01

}
```

Note

The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens ('-') in the ID.
Request Parameters

<table>
<thead>
<tr>

<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation=remove</td>
<td>A single query string parameter operation with a value of remove to distinguish it from Add Tags To Vault (POST tags add).</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Request Headers

This operation uses only request headers that are common to all operations. For information about common request headers, see Common Request Headers.

Request Body

The request body contains the following JSON fields.

TagKeys

A list of tag keys. Each corresponding tag is removed from the vault.

*Type:* array of Strings

*Length constraint:* Minimum of 1 item in the list. Maximum of 10 items in the list.

*Required:* Yes

Responses

If the action is successful, the service sends back an HTTP 204 No Content response with an empty HTTP body.

Syntax

```
HTTP/1.1 204 No Content
x-amzn-RequestId: x-amzn-RequestID
Date: Date
```
Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see Common Response Headers.

Response Body

```

Example Response

If the request was successful Amazon S3 Glacier (S3 Glacier) returns a HTTP 204 No Content as shown in the following example.

```plaintext
HTTP/1.1 204 No Content
x-amzn-RequestId: AAABZpJrTyioDC_HsOmHaeBEZp_uBSJr6cnGOLKp_XJCl-Q
```
Set Vault Access Policy (PUT access-policy)

Description

This operation configures an access policy for a vault and will overwrite an existing policy. To configure a vault access policy, send a PUT request to the access-policy subresource of the vault. You can set one access policy per vault and the policy can be up to 20 KB in size. For more information about vault access policies, see Vault Access Policies.

Requests

Syntax

To set a vault access policy, send an HTTP PUT request to the URI of the vault's access-policy subresource as shown in the following syntax example.

```
PUT /AccountID/vaults/vaultName/access-policy HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
Content-Length: Length
x-amz-glacier-version: 2012-06-01
```
{  "Policy": "string"}

**Note**

The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

**Request Parameters**

This operation does not use request parameters.

**Request Headers**

This operation uses only request headers that are common to all operations. For information about common request headers, see [Common Request Headers](#).

**Request Body**

The request body contains the following JSON fields.

**Policy**

The vault access policy as a JSON string, which uses "\" as an escape character.

Type: String

Required: Yes

**Responses**

In response, S3 Glacier returns 204 No Content if the policy is accepted.

**Syntax**

HTTP/1.1 204 No Content
Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see Common Response Headers.

Response Body

This operation does not return a response body.

Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.

Examples

Example Request

The following example sends an HTTP PUT request to the URI of the vault's access-policy subresource. The Policy JSON string uses "\\" as an escape character.

```
PUT /-/vaults/examplevault/access-policy HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z
Authorization: AWS4-HMAC-SHA256 Credential=AKIAIOSFODNN7EXAMPLE/20141123/us-west-2/glacier/aws4_request,SignedHeaders=host;x-amz-date;x-amz-glacier-version,Signature=9257c16da6b25a715ce900a5b45b03da0447acf430195dc8b540091b12966f2a2
Content-Length: length
x-amz-glacier-version: 2012-06-01

```

Example Response

If the request was successful, Amazon S3 Glacier (S3 Glacier) returns a HTTP 204 No Content as shown in the following example.

Set Vault Notification Configuration (PUT notification-configuration)

Description

Retrieving an archive and a vault inventory are asynchronous operations in Amazon S3 Glacier (S3 Glacier) for which you must first initiate a job and wait for the job to complete before you can download the job output. You can configure a vault to post a message to an Amazon Simple Notification Service (Amazon SNS) topic when these jobs complete. You can use this operation to set notification configuration on the vault. For more information, see Configuring Vault Notifications in Amazon S3 Glacier.

To configure vault notifications, send a PUT request to the notification-configuration subresource of the vault. A notification configuration is specific to a vault; therefore, it is also referred to as a vault subresource. The request should include a JSON document that provides an Amazon Simple Notification Service (Amazon SNS) topic and the events for which you want S3 Glacier to send notifications to the topic.

You can configure a vault to publish a notification for the following vault events:
- **ArchiveRetrievalCompleted**— This event occurs when a job that was initiated for an archive retrieval is completed ([Initiate Job (POST jobs)]). The status of the completed job can be Succeeded or Failed. The notification sent to the SNS topic is the same output as returned from [Describe Job (GET JobID)].

- **InventoryRetrievalCompleted**— This event occurs when a job that was initiated for an inventory retrieval is completed ([Initiate Job (POST jobs)]). The status of the completed job can be Succeeded or Failed. The notification sent to the SNS topic is the same output as returned from [Describe Job (GET JobID)].

Amazon SNS topics must grant permission to the vault to be allowed to publish notifications to the topic.

**Requests**

To set notification configuration on your vault, send a PUT request to the URI of the vault's notification-configuration subresource. You specify the configuration in the request body. The configuration includes the Amazon SNS topic name and an array of events that trigger notification to each topic.

**Syntax**

```plaintext
PUT /AccountId/vaults/VaultName/notification-configuration HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01

{
    "SNSTopic": String,
    "Events": [String, ...]
}
```

**Note**

The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.
Request Parameters

This operation does not use request parameters.

Request Headers

This operation uses only request headers that are common to all operations. For information about common request headers, see Common Request Headers.

Request Body

The JSON in the request body contains the following fields.

Events

An array of one or more events for which you want S3 Glacier to send notification.

Valid Values: ArchiveRetrievalCompleted | InventoryRetrievalCompleted

Required: yes

Type: Array

SNSTopic

The Amazon SNS topic ARN. For more information, go to Getting Started with Amazon SNS in the Amazon Simple Notification Service Getting Started Guide.

Required: yes

Type: String

Responses

In response, Amazon S3 Glacier (S3 Glacier) returns 204 No Content if the notification configuration is accepted.

Syntax

HTTP/1.1 204 No Content
x-amzn-RequestId: x-amzn-RequestId
Date: Date
Response Headers

This operation uses only request headers that are common to all operations. For information about common request headers, see Common Request Headers.

Response Body

This operation does not return a response body.

Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.

Examples

The following example demonstrates how to configure vault notification.

Example Request

The following request sets the examplevault notification configuration so that notifications for two events (ArchiveRetrievalCompleted and InventoryRetrievalCompleted) are sent to the Amazon SNS topic arn:aws:sns:us-west-2:012345678901:mytopic.

```plaintext
PUT /-/vaults/examplevault/notification-policy HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z
x-amz-glacier-version: 2012-06-01
Authorization: AWS4-HMAC-SHA256 Credential=AKIAIOSFODNN7EXAMPLE/20141123/us-west-2/glacier/aws4_request,SignedHeaders=host;x-amz-date;x-amz-glacier-version,Signature=9257c16da6b25a715ce900a5b45b03da0447acf430195dcb540091b12966f2a2

{
  "Events": ["ArchiveRetrievalCompleted", "InventoryRetrievalCompleted"],
}
```

Example Response

A successful response returns a 204 No Content.

```plaintext
HTTP/1.1 204 No Content
x-amzn-RequestId: AABAZpJrTyioDC_Hs0mHaeBEZp_uB5Jr6cnGOLKp_XJC1-Q
Date: Wed, 10 Feb 2017 12:00:00 GMT

Archive Operations

The following are the archive operations available for use in S3 Glacier.

Topics

- Delete Archive (DELETE archive)
- Upload Archive (POST archive)

Delete Archive (DELETE archive)

Description

This operation deletes an archive from a vault. You can delete one archive at a time from a vault. To delete the archive you must provide its archive ID in the delete request. You can get the archive ID by downloading the vault inventory for the vault that contains the archive. For more information about downloading the vault inventory, see Downloading a Vault Inventory in Amazon S3 Glacier.

After you delete an archive, you might still be able to make a successful request to initiate a job to retrieve the deleted archive, but the archive retrieval job will fail.

Archive retrievals that are in progress for an archive ID when you delete the archive might or might not succeed according to the following scenarios:
• If the archive retrieval job is actively preparing the data for download when Amazon S3 Glacier (S3 Glacier) receives the delete archive request, the archival retrieval operation might fail.

• If the archive retrieval job has successfully prepared the archive for download when S3 Glacier receives the delete archive request, you will be able to download the output.

For more information about archive retrieval, see Downloading an Archive in S3 Glacier.

This operation is idempotent. Attempting to delete an already-deleted archive does not result in an error.

Requests

To delete an archive you send a DELETE request to the archive resource URI.

Syntax

```
DELETE /AccountId/vaults/VaultName/archives/ArchiveID HTTP/1.1
Host: glacier.Region.amazonaws.com
x-amz-Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01
```

Note

The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

Upload Archive (POST archive)

Description

This operation adds an archive to a vault. For a successful upload, your data is durably persisted. In response, Amazon S3 Glacier (S3 Glacier) returns the archive ID in the x-amz-archive-id header of the response. You should save the archive ID returned so that you can access the archive later.

You must provide a SHA256 tree hash of the data you are uploading. For information about computing a SHA256 tree hash, see Computing Checksums.

Note

The SHA256 tree hash is only required for the Upload Archive (POST archive) action when using the API. It is not required when using the AWS CLI.

When uploading an archive, you can optionally specify an archive description of up to 1,024 printable ASCII characters. S3 Glacier returns the archive description when you either retrieve the archive or get the vault inventory. S3 Glacier does not interpret the description in any way. An archive description does not need to be unique. You cannot use the description to retrieve or sort the archive list.
Except for the optional archive description, S3 Glacier does not support any additional metadata for the archives. The archive ID is an opaque sequence of characters from which you cannot infer any meaning about the archive. So you might maintain metadata about the archives on the client-side. For more information, see Working with Archives in Amazon S3 Glacier.

Archives are immutable. After you upload an archive, you cannot edit the archive or its description.

Requests

To upload an archive, you use the HTTP POST method and scope the request to the archives subresource of the vault in which you want to save the archive. The request must include the archive payload size, checksum (SHA256 tree hash), and can optionally include a description of the archive.

Syntax

```
POST /AccountId/vaults/VaultName/archives
Host: glacier.Region.amazonaws.com
x-amz-glacier-version: 2012-06-01
Date: Date
Authorization: SignatureValue
x-amz-archive-description: Description
x-amz-sha256-tree-hash: SHA256 tree hash
x-amz-content-sha256: SHA256 linear hash
Content-Length: Length

<Request body.>
```

Note

The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

Multipart Upload Operations

The following are the multipart upload operations available for use in S3 Glacier.

Topics

• Abort Multipart Upload (DELETE uploadID)
Abort Multipart Upload (DELETE uploadID)

Description

This command for multipart upload operation stops a multipart upload identified by the upload ID.

After the Abort Multipart Upload request succeeds, you cannot use the upload ID to upload any more parts or perform any other operations. Stopping a completed multipart upload fails. However, stopping an already-stopped upload will succeed, for a short time.

This operation is idempotent.

For information about multipart upload, see Uploading Large Archives in Parts (Multipart Upload).

Requests

To stop a multipart upload, send an HTTP DELETE request to the URI of the multipart-uploads subresource of the vault and identify the specific multipart upload ID as part of the URI.

Syntax

```
DELETE /AccountId/vaults/VaultName/multipart-uploads/uploadID HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01
```

Note

The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case
Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

Complete Multipart Upload (POST uploadID)

Description

You call this multipart upload operation to inform Amazon S3 Glacier (S3 Glacier) that all the archive parts have been uploaded and S3 Glacier can now assemble the archive from the uploaded parts.

For information about multipart upload, see [Uploading Large Archives in Parts (Multipart Upload)](https://docs.aws.amazon.com/s3glacier/latest/dev/UploadingLargeArchivesInParts.html).
After assembling and saving the archive to the vault, S3 Glacier returns the archive ID of the newly created archive resource. After you upload an archive, you should save the archive ID returned to retrieve the archive at a later point.

In the request, you must include the computed SHA256 tree hash of the entire archive you have uploaded. For information about computing a SHA256 tree hash, see Computing Checksums. On the server side, S3 Glacier also constructs the SHA256 tree hash of the assembled archive. If the values match, S3 Glacier saves the archive to the vault; otherwise, it returns an error, and the operation fails. The List Parts (GET uploadID) operation returns list of parts uploaded for a specific multipart upload. It includes checksum information for each uploaded part that can be used to debug a bad checksum issue.

Additionally, S3 Glacier also checks for any missing content ranges. When uploading parts, you specify range values identifying where each part fits in the final assembly of the archive. When assembling the final archive S3 Glacier checks for any missing content ranges and if there are any missing content ranges, S3 Glacier returns an error and the Complete Multipart Upload operation fails.

Complete Multipart Upload is an idempotent operation. After your first successful complete multipart upload, if you call the operation again within a short period, the operation will succeed and return the same archive ID. This is useful in the event you experience a network issue or receive a 500 server error, in which case you can repeat your Complete Multipart Upload request and get the same archive ID without creating duplicate archives. Note, however, that after the multipart upload completes, you cannot call the List Parts operation and the multipart upload will not appear in List Multipart Uploads response, even if idempotent complete is possible.

Requests

To complete a multipart upload, you send an HTTP POST request to the URI of the upload ID that S3 Glacier created in response to your Initiate Multipart Upload request. This is the same URI you used when uploading parts. In addition to the common required headers, you must include the result of the SHA256 tree hash of the entire archive and the total size of the archive in bytes.

Syntax

```
POST /AccountId/vaults/VaultName/multipart-uploads/uploadID
Host: glacier.Region.amazonaws.com
Date: date
Authorization: SignatureValue
x-amz-sha256-tree-hash: SHA256 tree hash of the archive
```
x-amz-archive-size: *ArchiveSize in bytes*
x-amz-glacier-version: 2012-06-01

### Note

The Account Id value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

<td>Yes</td>
</tr>
</tbody>
</table>
### Request Elements

This operation does not use request elements.

### Responses

Amazon S3 Glacier (S3 Glacier) creates a SHA256 tree hash of the entire archive. If the value matches the SHA256 tree hash of the entire archive you specified in the request, S3 Glacier adds the archive to the vault. In response it returns the HTTP Location header with the URL path of the newly added archive resource. If the archive size or SHA256 that you sent in the request does not match, S3 Glacier will return an error and the upload remains in the incomplete state. It is possible to retry the Complete Multipart Upload operation later with correct values, at which point you can successfully create an archive. If a multipart upload does not complete, then eventually S3 Glacier will reclaim the upload ID.

### Syntax

```
HTTP/1.1 201 Created
x-amzn-RequestId: x-amzn-RequestId
Date: Date
Location: Location
x-amz-archive-id: ArchiveId
```

### Response Headers

A successful response includes the following response headers, in addition to the response headers that are common to all operations. For more information about common response headers, see [Common Response Headers](#).

<table>

</table>

**Response Fields**

This operation does not return a response body.

**Example**

**Example Request**

In this example, an HTTP POST request is sent to the URI that was returned by an Initiate Multipart Upload request. The request specifies both the SHA256 tree hash of the entire archive and the total archive size.

```

**Example Response**

The following example response shows that S3 Glacier successfully created an archive from the parts you uploaded. The response includes the archive ID with complete path.
You can now send HTTP requests to the URI of the newly added resource/archive. For example, you can send a GET request to retrieve the archive.

**Initiate Multipart Upload (POST multipart-uploads)**

**Description**

This operation initiates a multipart upload (see [Uploading Large Archives in Parts (Multipart Upload)]). Amazon S3 Glacier (S3 Glacier) creates a multipart upload resource and returns its ID in the response. You use this Upload ID in subsequent multipart upload operations.

When you initiate a multipart upload, you specify the part size in number of bytes. The part size must be a mebibyte (MiB) (1024 kibibytes [KiB]) multiplied by a power of 2—for example, 1048576 (1 MiB), 2097152 (2 MiB), 4194304 (4 MiB), 8388608 (8 MiB), and so on. The minimum allowable part size is 1 MiB, and the maximum is 4 gibibytes (GiB).
Every part you upload using this upload ID, except the last one, must have the same size. The last one can be the same size or smaller. For example, suppose you want to upload a 16.2 MiB file. If you initiate the multipart upload with a part size of 4 MiB, you will upload four parts of 4 MiB each and one part of 0.2 MiB.

Note

You don't need to know the size of the archive when you start a multipart upload because S3 Glacier does not require you to specify the overall archive size.

After you complete the multipart upload, S3 Glacier removes the multipart upload resource referenced by the ID. S3 Glacier will also remove the multipart upload resource if you cancel the multipart upload or it may be removed if there is no activity for a period of 24 hours. The ID may still be available after 24 hours, but applications should not expect this behavior.

Requests

To initiate a multipart upload, you send an HTTP POST request to the URI of the multipart-uploads subresource of the vault in which you want to save the archive. The request must include the part size and can optionally include a description of the archive.

Syntax

POST /AccountId/vaults/VaultName/multipart-uploads
Host: glacier.us-west-2.amazonaws.com
Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01
x-amz-archive-description: ArchiveDescription
x-amz-part-size: PartSize

Note

The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

**Errors**

For information about Amazon S3 Glacier exceptions and error messages, see [Error Responses](#).

**Example**

**Example Request**

The following example initiates a multipart upload by sending an HTTP POST request to the URI of the multipart-uploads subresource of a vault named examplevault. The request includes headers to specify the part size of 4 MiB (4194304 bytes) and the optional archive description.

```
POST /-/vaults/examplevault/multipart-uploads
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z
x-amz-archive-description: MyArchive-101

Authorization: AWS4-HMAC-SHA256 Credential=AKIAIOSFODNN7EXAMPLE/20141123/us-west-2/glacier/aws4_request, SignedHeaders=host;x-amz-date;x-amz-glacier-version, Signature=9257c16da6b25a715ce900a5b45b03da0447acf430195dcb540091b12966f2a2
```

**Example Response**

S3 Glacier creates a multipart upload resource and adds it to the multipart-uploads subresource of the vault. The Location response header includes the relative URI path to the multipart upload ID.
For information about uploading individual parts, see Upload Part (PUT uploadID).

List Parts (GET uploadID)

Description

This multipart upload operation lists the parts of an archive that have been uploaded in a specific multipart upload identified by an upload ID. For information about multipart upload, see Uploading Large Archives in Parts (Multipart Upload).

You can make this request at any time during an in-progress multipart upload before you complete the multipart upload. S3 Glacier returns the part list sorted by range you specified in each part upload. If you send a List Parts request after completing the multipart upload, Amazon S3 Glacier (S3 Glacier) returns an error.
The List Parts operation supports pagination. You should always check the Marker field in the response body for a marker at which to continue the list. If there are no more items the marker field is null. If the marker is not null, to fetch the next set of parts you sent another List Parts request with the marker request parameter set to the marker value S3 Glacier returned in response to your previous List Parts request.

You can also limit the number of parts returned in the response by specifying the limit parameter in the request.

Requests

Syntax

To list the parts of an in-progress multipart upload, you send a GET request to the URI of the multipart upload ID resource. The multipart upload ID is returned when you initiate a multipart upload (Initiate Multipart Upload (POST multipart-uploads)). You may optionally specify marker and limit parameters.

```
GET /AccountId/vaults/VaultName/multipart-uploads/uploadID HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01
```

Note

The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

Request Parameters

Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see Common Response Headers.

Response Body

The response body contains the following JSON fields.

ArchiveDescription

The description of the archive that was specified in the Initiate Multipart Upload request. This field is `null` if no archive description was specified in the Initiate Multipart Upload operation.

Type: String

CreationDate

The UTC time that the multipart upload was initiated.

Type: String. A string representation in the ISO 8601 date format, for example `2013-03-20T17:03:43.221Z`.

Marker

An opaque string that represents where to continue pagination of the results. You use the `marker` in a new List Parts request to obtain more jobs in the list. If there are no more parts, this value is `null`. 
Type: String

MultipartUploadId

The ID of the upload to which the parts are associated.

Type: String

PartSizeInBytes

The part size in bytes. This is the same value that you specified in the Initiate Multipart Upload request.

Type: Number

Parts

A list of the part sizes of the multipart upload. Each object in the array contains a RangeBytes and sha256-tree-hash name/value pair.

Type: Array

RangeInBytes

The byte range of a part, inclusive of the upper value of the range.

Type: String

SHA256TreeHash

The SHA256 tree hash value that S3 Glacier calculated for the part. This field is never null.

Type: String

VaultARN

The Amazon Resource Name (ARN) of the vault to which the multipart upload was initiated.

Type: String

Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.
Examples

Example: List Parts of a Multipart Upload

The following example lists all the parts of an upload. The example sends an HTTP GET request to the URI of the specific multipart upload ID of an in-progress multipart upload and returns up to 1,000 parts.

Example: List Parts of a Multipart Upload (Specify the Marker and the Limit Request Parameters)

The following example demonstrates how to use pagination to get a limited number of results. The example sends an HTTP GET request to the URI of the specific multipart upload ID of an in-progress multipart upload to return one part. A starting marker parameter specifies at which part to start the part list. You can get the marker value from the response of a previous request for a part list. Furthermore, in this example, the limit parameter is set to 1 and returns one part. Note that the Marker field is not null, indicating that there is at least one more part to obtain.

List Multipart Uploads (GET multipart-uploads)

Description

This multipart upload operation lists in-progress multipart uploads for the specified vault. An in-progress multipart upload is a multipart upload that has been initiated by an [Initiate Multipart Upload (POST multipart-uploads)] request, but has not yet been completed or stopped. The list returned in the List Multipart Upload response has no guaranteed order.

The List Multipart Uploads operation supports pagination. By default, this operation returns up to 50 multipart uploads in the response. You should always check the marker field in the response.
body for a marker at which to continue the list; if there are no more items the `marker` field is null.

If the `marker` is not null, to fetch the next set of multipart uploads you sent another List Multipart Uploads request with the `marker` request parameter set to the marker value Amazon S3 Glacier (S3 Glacier) returned in response to your previous List Multipart Uploads request.

Note the difference between this operation and the List Parts (GET uploadID) operation. The List Multipart Uploads operation lists all multipart uploads for a vault. The List Parts operation returns parts of a specific multipart upload identified by an Upload ID.

For information about multipart upload, see [Uploading Large Archives in Parts (Multipart Upload)](https://docs.aws.amazon.com/AmazonS3/latest/userguide/multipart-upload.html).

### Requests

### Syntax

To list multipart uploads, send a GET request to the URI of the multipart-uploads subresource of the vault. You may optionally specify `marker` and `limit` parameters.

```
GET /AccountId/vaults/VaultName/multipart-uploads HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01
```

#### Note

The `AccountId` value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see Common Response Headers.

Response Body

The response body contains the following JSON fields.

ArchiveDescription

The description of the archive that was specified in the Initiate Multipart Upload request. This field is null if no archive description was specified in the Initiate Multipart Upload operation.

Type: String

CreationDate

The UTC time that the multipart upload was initiated.

Type: String. A string representation in the ISO 8601 date format, for example 2013-03-20T17:03:43.221Z.

Marker

An opaque string that represents where to continue pagination of the results. You use the marker in a new List Multipart Uploads request to obtain more uploads in the list. If there are no more uploads, this value is null.
Type: String

PartSizeInBytes

The part size specified in the **Initiate Multipart Upload (POST multipart-uploads)** request. This is the size of all the parts in the upload except the last part, which may be smaller than this size.

Type: Number

MultipartUploadId

The ID of the multipart upload.

Type: String

UploadsList

A list of metadata about multipart upload objects. Each item in the list contains a set of name-value pairs for the corresponding upload, including ArchiveDescription, CreationDate, MultipartUploadId, PartSizeInBytes, and VaultARN.

Type: Array

VaultARN

The Amazon Resource Name (ARN) of the vault that contains the archive.

Type: String

Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.

Examples

Example: List All Multipart Uploads

The following example lists all the multipart uploads in progress for the vault. The example shows an HTTP GET request to the URI of the multipart-uploads subresource of a specified vault. Because the marker and limit parameters are not specified in the request, up to 1,000 in-progress multipart uploads are returned.

Example Request

```
GET /-/vaults/examplevault/multipart-uploads HTTP/1.1
```
Example Response

In the response S3 Glacier returns a list of all in-progress multipart uploads for the specified vault. The marker field is null, which indicates that there are no more uploads to list.

Upload Part (PUT uploadID)

Description

This multipart upload operation uploads a part of an archive. You can upload archive parts in any order because in your Upload Part request you specify the range of bytes in the assembled archive that will be uploaded in this part. You can also upload these parts in parallel. You can upload up to 10,000 parts for a multipart upload.

For information about multipart upload, see Uploading Large Archives in Parts (Multipart Upload).

Amazon S3 Glacier (S3 Glacier) rejects your upload part request if any of the following conditions is true:

- **SHA256 tree hash does not match**—To ensure that part data is not corrupted in transmission, you compute a SHA256 tree hash of the part and include it in your request. Upon receiving the part data, S3 Glacier also computes a SHA256 tree hash. If the two hash values don't match,
the operation fails. For information about computing a SHA256 tree hash, see Computing Checksums.

- **SHA256 linear hash does not match**—Required for authorization, you compute a SHA256 linear hash of the entire uploaded payload and include it in your request. For information about computing a SHA256 linear hash, see Computing Checksums.

- **Part size does not match**—The size of each part except the last must match the size that is specified in the corresponding Initiate Multipart Upload (POST multipart-uploads) request. The size of the last part must be the same size as, or smaller than, the specified size.

  **Note**
  
  If you upload a part whose size is smaller than the part size you specified in your initiate multipart upload request and that part is not the last part, then the upload part request will succeed. However, the subsequent Complete Multipart Upload request will fail.

- **Range does not align**—The byte range value in the request does not align with the part size specified in the corresponding initiate request. For example, if you specify a part size of 4194304 bytes (4 MB), then 0 to 4194303 bytes (4 MB —1) and 4194304 (4 MB) to 8388607 (8 MB —1) are valid part ranges. However, if you set a range value of 2 MB to 6 MB, the range does not align with the part size and the upload will fail.

This operation is idempotent. If you upload the same part multiple times, the data included in the most recent request overwrites the previously uploaded data.

**Requests**

You send this HTTP PUT request to the URI of the upload ID that was returned by your Initiate Multipart Upload request. S3 Glacier uses the upload ID to associate part uploads with a specific multipart upload. The request must include a SHA256 tree hash of the part data (x-amz-SHA256-tree-hash header), a SHA256 linear hash of the entire payload (x-amz-content-sha256 header), the byte range (Content-Range header), and the length of the part in bytes (Content-Length header).

**Syntax**

```
PUT /AccountId/vaults/VaultName/multipart-uploads/uploadID HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
```
The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

**Request Body**

The request body contains the data to upload.
Responses

Upon a successful part upload, S3 Glacier returns a 204 No Content response.

Syntax

HTTP/1.1 204 No Content
x-amzn-Request-Id: x-amzn-Request-Id
Date: Date
x-amz-sha256-tree-hash: ChecksumComputedByAmazonGlacier

Response Headers

A successful response includes the following response headers, in addition to the response headers that are common to all operations. For more information about common response headers, see Common Response Headers.

<table>

<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

Response Body

This operation does not return a response body.

Example

The following request uploads a 4 MB part. The request sets the byte range to make this the first part in the archive.

Example Request

The example sends an HTTP PUT request to upload a 4 MB part. The request is sent to the URI of the Upload ID that was returned by the Initiate Multipart Upload request. The Content-Range header identifies the part as the first 4 MB data part of the archive.
To upload the next part, the procedure is the same; however, you must calculate a new SHA256 tree hash of the part you are uploading and also specify a new byte range to indicate where the part will go in the final assembly. The following request uploads another part using the same upload ID. The request specifies the next 4 MB of the archive after the previous request and a part size of 4 MB.

Describe Job (GET JobID)

Description

This operation returns information about a job you previously initiated, including the job initiation date, the user who initiated the job, the job status code/message, and the Amazon Simple Notification Service (Amazon SNS) topic to notify after Amazon S3 Glacier (S3 Glacier) completes the job. For more information about initiating a job, see Initiate Job (POST jobs).
Note
This operation enables you to check the status of your job. However, we strongly recommend that you set up an Amazon SNS topic and specify it in your initiate job request so that S3 Glacier can notify the topic after it completes the job.

A job ID will not expire for at least 24 hours after S3 Glacier completes the job.

Requests

Syntax

To obtain information about a job, you use the HTTP GET method and scope the request to the specific job. Note that the relative URI path is the same one that S3 Glacier returned to you when you initiated the job.

GET /AccountID/vaults/VaultName/jobs/JobID HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: date
Authorization: signatureValue
x-amz-glacier-version: 2012-06-01

Note
The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

Note
In the request, if you omit the JobID, the response returns a list of all active jobs on the specified vault. For more information about listing jobs, see List Jobs (GET jobs).

Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see Common Response Headers.

Response Body

The response body contains the following JSON fields.

**Action**

The job type. It is either ArchiveRetrieval, InventoryRetrieval, or Select.

*Type:* String

**ArchiveId**

The archive ID requested for a select or archive retrieval job. Otherwise, this field is null.

*Type:* String

**ArchiveSHA256TreeHash**

The SHA256 tree hash of the entire archive for an archive retrieval job. For inventory retrieval jobs, this field is null.

*Type:* String
ArchiveSizeInBytes

For an ArchiveRetrieval job, this is the size in bytes of the archive being requested for download. For the InventoryRetrieval job, the value is null.

*Type: Number*

Completed

The job status. When an archive or inventory retrieval job is completed, you get the job's output using the [Get Job Output (GET output)](https://www.example.com).

*Type: Boolean*

CompletionDate

The Universal Coordinated Time (UTC) time that the job request completed. While the job is in progress, the value is null.

*Type: String*

CreationDate

The UTC time that the job was created.

*Type: A string representation in the ISO 8601 date format, for example 2013-03-20T17:03:43.221Z.*

InventoryRetrievalParameters

Input parameters used for a range inventory retrieval.

*Type: [InventoryRetrievalJobInput](https://www.example.com) object*

InventorySizeInBytes

For an InventoryRetrieval job, this is the size in bytes of the inventory requested for download. For the ArchiveRetrieval or Select job, the value is null.

*Type: Number*

JobDescription

The job description you provided when you initiated the job.

*Type: String*
JobId

The ID that identifies the job in S3 Glacier.

*Type:* String

JobOutputPath

Contains the job output location.

*Type:* String

OutputLocation

An object that contains information about the location where the select job results and errors are stored.

*Type:* [OutputLocation](#) object

RetrievalByteRange

The retrieved byte range for archive retrieval jobs in the form "StartByteValue-EndByteValue." If you don’t specify a range in the archive retrieval, then the whole archive is retrieved; also *StartByteValue* equals 0, and *EndByteValue* equals the size of the archive minus 1. For inventory retrieval or select jobs, this field is null.

*Type:* String

SelectParameters

An object that contains information about the parameters used for a select.

*Type:* [SelectParameters](#) object

SHA256TreeHash

The SHA256 tree hash value for the requested range of an archive. If the [Initiate Job (POST jobs)](#) request for an archive specified a tree-hash aligned range, then this field returns a value. For more information about tree-hash alignment for archive range retrievals, see [Receiving Checksums When Downloading Data](#).

For the specific case when the whole archive is retrieved, this value is the same as the ArchiveSHA256TreeHash value.

This field is null in the following situations:
• Archive retrieval jobs that specify a range that is not tree-hash aligned.
• Archival jobs that specify a range that is equal to the whole archive and the job status is InProgress.
• Inventory jobs.
• Select jobs.

*Type: String*

**SNSTopic**

An Amazon SNS topic that receives notification.

*Type: String*

**StatusCode**

The code indicating the status of the job.

*Valid Values: InProgress | Succeeded | Failed*

*Type: String*

**StatusMessage**

A friendly message that describes the job status.

*Type: String*

**Tier**

The data access tier to use for the select or archive retrieval.

*Valid Values: Bulk | Expedited | Standard*

*Type: String*

**VaultARN**

The Amazon Resource Name (ARN) of the vault of which the job is a subresource.

*Type: String*

**Errors**

For information about Amazon S3 Glacier exceptions and error messages, see [Error Responses](#).
Examples

The following example shows the request for a job that retrieves an archive.

Example Request: Get job description

```

Example Response

The response body includes JSON that describes the specified job. Note that for both the inventory retrieval and archive retrieval jobs, the JSON fields are the same. However, when a field doesn't apply to the type of job, its value is null. The following is an example response for an archive retrieval job. Note the following:

- The Action field value is ArchiveRetrieval.
- The ArchiveSizeInBytes field shows the size of the archive requested in the archive retrieval job.
- The ArchiveSHA256TreeHash field shows the SHA256 tree hash for the entire archive.
- The RetrievalByteRange field shows the range requested in the Initiate Job request. In this example, the whole archive is requested.
- The SHA256TreeHash field shows the SHA256 tree hash for the range requested in the Initiate Job request. In this example, it is the same as the ArchiveSHA256TreeHash field, which means that the whole archive was requested.
- The InventorySizeInBytes field value is null because it does not apply to an archive retrieval job.

```
HTTP/1.1 200 OK

Date: Wed, 10 Feb 2017 12:00:00 GMT
Content-Type: application/json
```
The following is an example response for an inventory retrieval job. Note the following:

- The Action field value is InventoryRetrieval.
- The ArchiveSizeInBytes, ArchiveSHA256TreeHash, and RetrievalByteRange field values are null because these fields do not apply to an inventory retrieval job.
- The InventorySizeInBytes field value is null because the job is still in progress, and has not fully prepared the inventory for download. If the job was completed before your describe job request, this field would give you the size of the output.
The following is an example response for a completed inventory retrieval job that contains a marker used to continue pagination of the vault inventory retrieval.

Get Job Output (GET output)

Description

This operation downloads the output of the job you initiated using Initiate Job (POST jobs). Depending on the job type you specified when you initiated the job, the output will be either the content of an archive or a vault inventory.

You can download all the job output or download a portion of the output by specifying a byte range. For both archive and inventory retrieval jobs, you should verify the downloaded size against the size returned in the headers from the Get Job Output response.

For archive retrieval jobs, you should also verify that the size is what you expected. If you download a portion of the output, the expected size is based on the range of bytes you specified. For example, if you specify a range of bytes=0-1048575, you should verify your download size is 1,048,576 bytes. If you download an entire archive, the expected size is the size of the archive when you uploaded it to Amazon S3 Glacier (S3 Glacier). The expected size is also returned in the headers from the Get Job Output response.

In the case of an archive retrieval job, depending on the byte range you specify, S3 Glacier returns the checksum for the portion of the data. To ensure the portion you downloaded is the correct data, compute the checksum on the client, verify that the values match, and verify that the size is what you expected.

A job ID does not expire for at least 24 hours after S3 Glacier completes the job. That is, you can download the job output within the 24-hour period after S3 Glacier completes the job.
Requests

Syntax

To retrieve a job output, you send the HTTP GET request to the URI of the output of the specific job.

```
GET /AccountId/vaults/VaultName/jobs/JobID/output HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
Range: ByteRangeToRetrieve
x-amz-glacier-version: 2012-06-01
```

Note

The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.

Request Parameters

This operation does not use request parameters.

Request Headers

This operation uses the following request headers, in addition to the request headers that are common to all operations. For more information about the common request headers, see Common Request Headers.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>The range of bytes to retrieve from the output. For example, if you want to</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>download the first 1,048,576 bytes, specify the range as bytes=0-1048575.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For more information, go to Range Header Field Definition. The range is relative to</td>
<td></td>
</tr>
</tbody>
</table>
any range specified in the Initiate Job request. By default, this operation downloads the entire output.

If the job output is large, then you can use the Range request header to retrieve a portion of the output. This allows you to download the entire output in smaller chunks of bytes. For example, suppose you have 1 GB job output you want to download and you decide to download 128 MB chunks of data at a time, a total of eight Get Job Output requests. You will use the following process to download the job output:

1. Download a 128 MB chunk of output by specifying the appropriate byte range using the Range header. Verify that all 128 MB of data was received.

2. Along with the data, the response will include a checksum of the payload. You compute the checksum of the payload on the client and compare it with the checksum you received in the response to ensure you received all the expected data.

3. Repeat steps 1 and 2 for all the eight 128 MB chunks of output data, each time specifying the appropriate byte range.

4. After downloading all the parts of the job output, you have a list of eight checksum values. Compute the tree hash of these values to find the checksum of the entire output. Using the Describe Job (GET JobID) operation, obtain job information of the job that provided you the output. The response includes the checksum of the entire archive stored in S3 Glacier. You compare this value with the checksum you computed to ensure you have downloaded the entire archive content with no errors.

#### Responses

**Syntax**

For a retrieval request that returns all of the job data, the job output response returns a 200 OK response code. When partial content is requested, for example, if you specified the Range header in the request, then the response code 206 Partial Content is returned.

Header | Description
--- | ---
x-amz-sha256-tree-hash | The checksum of the data in the response. This header is returned only when retrieving the output for an archive retrieval job. Furthermore, this header appears when the retrieved data range requested in the Initiate Job request is tree hash aligned and the range to download in the Get Job Output is also tree hash aligned. For more information about tree hash aligned ranges, see Receiving Checksums When Downloading Data.

For example, if in your Initiate Job request you specified a tree hash aligned range to retrieve (which includes the whole archive), then you will receive the checksum of the data you download under the following conditions:

- You get the entire range of the retrieved data.
- You request a byte range of the retrieved data that has a size of a megabyte (1024 KB) multiplied by a power of 2 and that starts and ends on a multiple of the size of the requested range. For example, if you have 3.1 MB of retrieved data and you specify a range to return that starts at 1 MB and ends at 2 MB, then the x-amz-sha256-tree-hash is returned as a response header.
- You request a range to return of the retrieved data that goes to the end of the data, and the start of the range is a multiple of the size of the range to retrieve rounded up to the next power of two but not smaller than one megabyte (1024 KB). For example, if you have 3.1 MB of retrieved data and you specify a range that starts at 2 MB and ends at 3.1 MB (the end of the data), then the x-amz-sha256-tree-hash is returned as a response header.

Type: String
Response Body

S3 Glacier returns the job output in the response body. Depending on the job type, the output can be the archive contents or the vault inventory. In case of a vault inventory, by default the inventory list is returned as the following JSON body.

```
{
  "VaultARN": String,
  "InventoryDate": String,
  "ArchiveList": [
    {
      "ArchiveId": String,
      "ArchiveDescription": String,
      "CreationDate": String,
      "Size": Number,
      "SHA256TreeHash": String
    },
    ...
  ]
}
```

If you requested the comma-separated values (CSV) output format when you initiated the vault inventory job, then the vault inventory is returned in CSV format in the body. The CSV format has five columns "ArchiveId", "ArchiveDescription", "CreationDate", "Size", and "SHA256TreeHash" with the same definitions as the corresponding JSON fields.

⚠️ **Note**

In the returned CSV format, fields may be returned with the whole field enclosed in double-quotes. Fields that contain a comma or double-quotes are always returned enclosed in double-quotes. For example, my archive description,1 is returned as "my archive description,1". Double-quote characters that are within returned double-quote enclosed fields are *escaped* by preceding them with a backslash character. For example, my archive description,1"2 is returned as "my archive description,1"2" and my archive description,1"2 is returned as "my archive description,1""2". The backslash character is not escaped.

The JSON response body contains the following JSON fields.
ArchiveDescription

The description of an archive.

*Type: String*

ArchiveId

The ID of an archive.

*Type: String*

ArchiveList

An array of archive metadata. Each object in the array represents metadata for one archive contained in the vault.

*Type: Array*

CreationDate

The UTC date and time the archive was created.

*Type: A string representation in the ISO 8601 date format, for example 2013-03-20T17:03:43.221Z.*

InventoryDate

The UTC date and time of the last inventory for the vault that was completed after changes to the vault. Even though S3 Glacier prepares a vault inventory once a day, the inventory date is only updated if there have been archive additions or deletions to the vault since the last inventory.

*Type: A string representation in the ISO 8601 date format, for example 2013-03-20T17:03:43.221Z.*

SHA256TreeHash

The tree hash of the archive.

*Type: String*

Size

The size in bytes of the archive.
**Type**: Number

**VaultARN**

The Amazon Resource Name (ARN) resource from which the archive retrieval was requested.

**Type**: String

**Errors**

For information about Amazon S3 Glacier exceptions and error messages, see [Error Responses](#).

**Examples**

The following example shows the request for a job that retrieves an archive.

**Example 1: Download output**

This example retrieves data prepared by S3 Glacier in response to your initiate archive retrieval job request.

**Example Request**

Initiate Job (POST jobs)

This operation initiates the following types of Amazon S3 Glacier (S3 Glacier) jobs:

- archive-retrieval—Retrieve an archive
- inventory-retrieval—Inventory a vault

Initializing an Archive or Vault Inventory Retrieval Job

Retrieving an archive or a vault inventory are asynchronous operations that require you to initiate a job. Once started, job cannot be cancelled. Retrieval is a two-step process:

1. Initiate a retrieval job by using the Initiate Job (POST jobs) operation.

   **Important**
   A data retrieval policy can cause your initiate retrieval job request to fail with a PolicyEnforcedException. For more information about data retrieval policies, see S3 Glacier Data Retrieval Policies. For more information about the PolicyEnforcedException exception, see Error Responses.

2. After the job completes, download the bytes using the Get Job Output (GET output) operation.

The retrieval request is ran asynchronously. When you initiate a retrieval job, S3 Glacier creates a job and returns a job ID in the response. When S3 Glacier completes the job, you can get the
job output (archive or inventory data). For information about getting job output, see the Get Job Output (GET output) operation.

The job must complete before you can get its output. To determine when a job is complete, you have the following options:

- **Use an Amazon SNS notification**— You can specify an Amazon SNS topic to which S3 Glacier can post a notification after the job is completed. You can specify an SNS topic per job request. The notification is sent only after S3 Glacier completes the job. In addition to specifying an SNS topic per job request, you can configure vault notifications for a vault so that job notifications are sent for all retrievals. For more information, see Set Vault Notification Configuration (PUT notification-configuration).

- **Get job details**— You can make a Describe Job (GET JobID) request to obtain job status information while a job is in progress. However, it is more efficient to use an Amazon SNS notification to determine when a job is complete.

**Note**
The information you get via notification is same that you get by calling Describe Job (GET JobID).

If for a specific event, you add both the notification configuration on the vault and also specify an SNS topic in your initiate job request, S3 Glacier sends both notifications. For more information, see Set Vault Notification Configuration (PUT notification-configuration).

**The Vault Inventory**

S3 Glacier updates a vault inventory approximately once a day, starting on the day you first upload an archive to the vault. If there have been no archive additions or deletions to the vault since the last inventory, the inventory date is not updated. When you initiate a job for a vault inventory, S3 Glacier returns the last inventory it generated, which is a point-in-time snapshot and not real-time data.

After S3 Glacier creates the first inventory for the vault, it typically takes half a day and up to a day before that inventory is available for retrieval.
You might not find it useful to retrieve a vault inventory for each archive upload. However, suppose that you maintain a database on the client-side associating metadata about the archives you upload to S3 Glacier. Then, you might find the vault inventory useful to reconcile information, as needed, in your database with the actual vault inventory. For more information about the data fields returned in an inventory job output, see Response Body.

**Range Inventory Retrieval**

You can limit the number of inventory items retrieved by filtering on the archive creation date or by setting a limit.

**Filtering by Archive Creation Date**

You can retrieve inventory items for archives created between `StartDate` and `EndDate` by specifying values for these parameters in the Initiate Job request. Archives created on or after the `StartDate` and before the `EndDate` are returned. If you provide only the `StartDate` without the `EndDate`, you retrieve the inventory for all archives created on or after the `StartDate`. If you provide only the `EndDate` without the `StartDate`, you get back the inventory for all archives created before the `EndDate`.

**Limiting Inventory Items per Retrieval**

You can limit the number of inventory items returned by setting the Limit parameter in the Initiate Job request. The inventory job output contains inventory items up to the specified Limit. If there are more inventory items available, the result is paginated. After a job is complete, you can use the Describe Job (GET JobID) operation to get a marker that you use in a subsequent Initiate Job request. The marker indicates the starting point to retrieve the next set of inventory items. You can page through your entire inventory by repeatedly making Initiate Job requests with the marker from the previous Describe Job output. You do so until you get a marker from Describe Job that returns null, indicating that there are no more inventory items available.

You can use the Limit parameter together with the date range parameters.

**Ranged Archive Retrieval**

You can initiate archive retrieval for the whole archive or a range of the archive. In the case of ranged archive retrieval, you specify a byte range to return or the whole archive. The range specified must be megabyte (MB) aligned. In other words, the range start value must be divisible by 1 MB and the range end value plus 1 must be divisible by 1 MB or equal the end of the archive. If the ranged archive retrieval is not megabyte-aligned, this operation returns a 400 response.
Furthermore, to ensure that you get checksum values for data you download using Get Job Output (Get Job Output (GET output)), the range must be tree-hash aligned. For more information about tree-hash aligned ranges, see Receiving Checksums When Downloading Data.

**Expedited, Standard, and Bulk Tiers**

When initiating an archive retrieval job, you can specify one of the following options in the Tier field of the request body:

- **Expedited** – Expedited allows you to quickly access your data when occasional urgent requests for restoring archives are required. For all but the largest archives (250 MB+), data accessed using the Expedited tier is typically made available within 1–5 minutes.

- **Standard** – Standard allows you to access any of your archives within several hours. Data accessed using the Standard tier typically made available within 3–5 hours. This option is the default one for job requests that don't specify the tier option.

- **Bulk** – Bulk is the lowest-cost tier for S3 Glacier, enabling you to retrieve large amounts, even petabytes, of data inexpensively in a day. Data accessed using the Bulk tier is typically made available within 5–12 hours.

For more information about expedited and bulk retrievals, see Retrieving S3 Glacier Archives Using AWS Console.

**Requests**

To initiate a job, you use the HTTP POST method and scope the request to the vault's jobs subresource. You specify details of the job request in the JSON document of your request. The job type is specified with the Type field. Optionally, you can specify an SNSTopic field to indicate an Amazon SNS topic to which S3 Glacier can post notification after it completes the job.

**Note**

To post a notification to Amazon SNS, you must create the topic yourself if it doesn't already exist. S3 Glacier doesn't create the topic for you. The topic must have permissions to receive publications from a S3 Glacier vault. S3 Glacier doesn't verify if the vault has permission to publish to the topic. If the permissions are not configured appropriately, you might not receive notification even after the job completes.

>Note

The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case
Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens (‘-’) in the ID.

Request Body

The request accepts the following data in JSON format in the body of the request.

jobParameters

Provides options for specifying job information.

*Type:* jobParameters object

*Required:* Yes

Responses

S3 Glacier creates the job. In the response, it returns the URI of the job.

List Jobs (GET jobs)

Description

This operation lists jobs for a vault, including jobs that are in-progress and jobs that have recently finished.

Note

Amazon S3 Glacier (S3 Glacier) retains recently completed jobs for a period before deleting them; however, it eventually removes completed jobs. The output of completed jobs can be retrieved. Retaining completed jobs for a period of time after they have completed enables you to get a job output in the event you miss the job completion notification, or your first attempt to download it fails. For example, suppose that you start an archive retrieval job to download an archive. After the job completes, you start to download the archive but encounter a network error. In this scenario, you can retry and download the archive while the job exists.
The List Jobs operation supports pagination. You should always check the response Marker field. If there are no more jobs to list, the Marker field is set to null. If there are more jobs to list, the Marker field is set to a non-null value, which you can use to continue the pagination of the list. To return a list of jobs that begins at a specific job, set the marker request parameter to the Marker value for that job that you obtained from a previous List Jobs request.

You can set a maximum limit for the number of jobs returned in the response by specifying the limit parameter in the request. The default limit is 50. The number of jobs returned might be fewer than the limit, but the number of returned jobs never exceeds the limit.

Additionally, you can filter the jobs list returned by specifying the optional statuscode parameter or completed parameter, or both. Using the statuscode parameter, you can specify to return only jobs that match either the InProgress, Succeeded, or Failed status. Using the completed parameter, you can specify to return only jobs that were completed (true) or jobs that were not completed (false).

Requests

Syntax

To return a list of jobs of all types, send a GET request to the URI of the vault's jobs subresource.

```
GET /AccountId/vaults/VaultName/jobs HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01
```

⚠️ Note

The AccountId value is the AWS account ID of the account that owns the vault. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you use an account ID, do not include any hyphens ('-') in the ID.
## Request Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>completed</td>
<td>The state of the jobs to return. You can specify <code>true</code> or <code>false</code>.</td>
<td>No</td>
</tr>
<tr>
<td>limit</td>
<td>The maximum number of jobs to be returned. The default limit is 50. The number of jobs returned might be fewer than the specified limit, but the number of returned jobs never exceeds the limit.</td>
<td>No</td>
</tr>
<tr>
<td>marker</td>
<td>An opaque string used for pagination that specifies the job at which the listing of jobs should begin. You get the <code>marker</code> value from a previous <code>List Jobs</code> response. You only need to include the <code>marker</code> if you are continuing the pagination of the results started in a previous <code>List Jobs</code> request.</td>
<td>No</td>
</tr>
<tr>
<td>statuscode</td>
<td>The type of job status to return.</td>
<td>No</td>
</tr>
</tbody>
</table>

Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see Common Response Headers.

Response Body

The response body contains the following JSON fields.

JobList

A list of job objects. Each job object contains metadata describing the job.

Type: Array of GlacierJobDescription objects

Marker

An opaque string that represents where to continue pagination of the results. You use the marker value in a new List Jobs request to obtain more jobs in the list. If there are no more jobs to list, this value is null.

Type: String
Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.

Examples

The following examples demonstrate how to return information about vault jobs. The first example returns a list of two jobs, and the second example returns a subset of jobs.

Example: Return All Jobs

Example Request

The following GET request returns the jobs for a vault.

```
GET /-/vaults/examplevault/jobs HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z
x-amz-glacier-version: 2012-06-01
Authorization: AWS4-HMAC-SHA256 Credential=AKIAIOSFODNN7EXAMPLE/20141123/us-west-2/glacier/aws4_request,SignedHeaders=host;x-amz-date;x-amz-glacier-version,Signature=9257c16da6b25a715ce900a5b45b03da0447acf430195dcb540091b12966f2a2
```

Example Response

The following response includes an archive retrieval job and an inventory retrieval job that contains a marker used to continue pagination of the vault inventory retrieval. The response also shows the Marker field set to null, which indicates there are no more jobs to list.

CSVInput

Contains information about the comma-separated values (CSV) file.

Contents

Comments

A single character used to indicate that a row should be ignored when the character is present at the start of that row.
**Type**: String

**Required**: no

**FieldDelimiter**

A single character used to separate individual fields from each other within a record. The character must be a \n, \r, or an ASCII character in the range 32–126. The default is a comma.

*Type*: String

*Default*: ,

*Required*: no

**FileHeaderInfo**

A value that describes what to do with the first line of the input.

*Type*: String

*Valid Values*: Use | Ignore | None

*Required*: no

**QuoteCharacter**

A single character used as an escape character where the field delimiter is part of the value.

*Type*: String

*Required*: no

**QuoteEscapeCharacter**

A single character used for escaping the quotation-mark character inside an already escaped value.

*Type*: String

*Required*: no

**RecordDelimiter**

A single character used to separate individual records from each other.
**Type**: String

**Required**: no

**More Info**

- [Initiate Job (POST jobs)](Initiate_Job_(POST_jobs))

**CSVOutput**

Contains information about the comma-separated values (CSV) format that the job results are stored in.

**Contents**

**FieldDelimiter**

**Type**: String

**Required**: no

**QuoteCharacter**

A single character used as an escape character where the field delimiter is part of the value.

**Type**: String

**Required**: no

**QuoteEscapeCharacter**

A single character used for escaping the quotation-mark character inside an already escaped value.

**Type**: String

**Required**: no

**QuoteFields**

A value that indicates whether all output fields should be contained within quotation marks.
Valid Values: ALWAYS | ASNEEDED

Type: String

Required: no

RecordDelimiter

A single character used to separate individual records from each other.

Type: String

Required: no

Encryption

Contains information about the encryption used to store the job results in Amazon S3.

Contents

Encryption

The server-side encryption algorithm used when storing job results in Amazon S3. The default is no encryption.

Type: String

Valid Values: aws:kms | AES256

Required: no

KMSContext

Optional. If the encryption type is aws:kms, you can use this value to specify the encryption context for the job results.

Type: String
KMSKeyld

The AWS Key Management Service (AWS KMS) key ID to use for object encryption.

Type: String

Required: no

More Info

- Initiate Job (POST jobs)

GlacierJobDescription

Contains the description of an Amazon S3 Glacier (S3 Glacier) job.

Contents

Action

The job type. It is either ArchiveRetrieval, InventoryRetrieval, or Select.

Type: String

ArchiveId

The archive ID requested for a select or archive retrieval job. Otherwise, this field is null.

Type: String

ArchiveSHA256TreeHash

The SHA256 tree hash of the entire archive for an archive retrieval. For inventory retrieval jobs, this field is null.

Type: String

ArchiveSizeInBytes

For an ArchiveRetrieval job, this is the size in bytes of the archive being requested for download. For the InventoryRetrieval job, the value is null.
Type: Number

Completed

ture if the job is completed; false otherwise.

Type: Boolean

CompletionDate

The date when the job completed.

The Universal Coordinated Time (UTC) time that the job request completed. While the job is in progress, the value is null.

Type: A string representation in the ISO 8601 date format, for example 2013-03-20T17:03:43.221Z.

CreationDate

The Universal Coordinated Time (UTC) date the job started.

Type: A string representation in the ISO 8601 date format, for example 2013-03-20T17:03:43.221Z.

InventoryRetrievalParameters

Input parameters used for a range inventory retrieval.

Type: InventoryRetrievalJobInput object

InventorySizeInBytes

For an InventoryRetrieval job, this is the size in bytes of the inventory requested for download. For the ArchiveRetrieval or Select job, the value is null.

Type: Number

JobDescription

The job description that you provided when you initiated the job.

Type: String

JobId

The ID that identifies the job in S3 Glacier.
Type: String

JobOutputPath

Contains the job output location.

Type: String

OutputLocation

An object that contains information about the location where the select job results and errors are stored.

Type: OutputLocation object

RetrievalByteRange

The retrieved byte range for archive retrieval jobs in the form "StartByteValue-EndByteValue." If no range was specified in the archive retrieval, then the whole archive is retrieved and StartByteValue equals 0 and EndByteValue equals the size of the archive minus 1. For inventory retrieval jobs, this field is null.

Type: String

SelectParameters

An object that contains information about the parameters used for a select.

Type: SelectParameters object

SHA256TreeHash

The SHA256 tree hash value for the requested range of an archive. If the Initiate Job (POST jobs) request for an archive specified a tree-hash aligned range, then this field returns a value. For more information about tree-hash alignment for archive range retrievals, see Receiving Checksums When Downloading Data.

For the specific case in which the whole archive is retrieved, this value is the same as the ArchiveSHA256TreeHash value.

This field is null in the following situations:

- Archive retrieval jobs that specify a range that is not tree-hash aligned.
- Archival jobs that specify a range that is equal to the whole archive and the job status is InProgress.
Inventory jobs.
Select jobs.

Type: String

SNSTopic

The Amazon Resource Name (ARN) that represents an Amazon SNS topic where notification of job completion or failure is sent, if notification was configured in the job initiation (*Initiate Job (POST jobs)*).

Type: String

StatusCode

The code indicating the status of the job.

*Valid Values*: InProgress | Succeeded | Failed

Type: String

StatusMessage

The job status message.

Type: String

Tier

The data access tier to use for the select or archive retrieval.

*Valid Values*: Expedited | Standard | Bulk

Type: String

VaultARN

The ARN of the vault of which the job is a subresource.

Type: String

Grantee

Contains information about a grantee.

Contents

DisplayName

The screen name of the grantee.

*Type:* String

*Required:* no
EmailAddress

The email address of the grantee.

*Type*: String

*Required*: no

ID

The canonical user ID of the grantee.

*Type*: String

*Required*: no

Type

The type of the grantee.

*Type*: String

*Valid Values*: AmazonCustomerByEmail | CanonicalUser | Group

*Required*: no

URI

The URI of the grantee group.

*Type*: String

*Required*: no

InputSerialization

Describes how the archive is serialized.
Contents

CSV

An object that describes the serialization of a CSV-encoded object.

*Type:* CSVInput object

*Required:* no

More Info

- [Initiate Job (POST jobs)](https://aws.amazon.com)

**InventoryRetrievalJobInput**

Provides options for specifying a range inventory retrieval job.

Contents

**EndDate**

The end of the date range, in UTC time, for a vault inventory retrieval that includes archives created before this date.

*Valid Values:* A string representation in the ISO 8601 date format (YYYY-MM-DDTh:mm:ssTZD) in seconds, for example `2013-03-20T17:03:43Z`.

*Type:* String. A string representation in the ISO 8601 date format (YYYY-MM-DDTh:mm:ssTZD) in seconds, for example `2013-03-20T17:03:43Z`.

*Required:* no

**Format**

The output format for the vault inventory list, which is set by the [Initiate Job (POST jobs)](https://aws.amazon.com) request when initiating a job to retrieve a vault inventory.

*Valid Values:* CSV | JSON

*Required:* no
Type: String

Limit

The maximum number of inventory items that can be returned for each vault inventory retrieval request.

Valid Values: An integer value greater than or equal to 1.

Type: String

Required: no

Marker

An opaque string that represents where to continue pagination of the vault inventory retrieval results. You use this marker in a new Initiate Job request to obtain additional inventory items. If there are no more inventory items, this value is null.

Type: String

Required: no

StartDate

The start of the date range, in UTC time, for a vault inventory retrieval that includes archives created on or after this date.

Valid Values: A string representation in the ISO 8601 date format (YYYY-MM-DDThh:mm:ssTZD) in seconds, for example 2013-03-20T17:03:43Z.

Type: String. A string representation in the ISO 8601 date format (YYYY-MM-DDThh:mm:ssTZD) in seconds, for example 2013-03-20T17:03:43Z.

Required: no

More Info

jobParameters

Provides options for defining a job.
Contents

Archiveld

The ID of the archive that you want. This field is required if the Type field is set to select or archive-retrieval. An error occurs if you specify this field for an inventory retrieval job request.

Valid Values: Must be a valid archive ID that you obtained from a previous request to Amazon S3 Glacier (S3 Glacier).

Type: String

Required: Yes when Type is set to select or archive-retrieval.

Description

The optional description for the job.

Valid Values: The description must be less than or equal to 1,024 bytes. The allowable characters are 7-bit ASCII without control codes—specifically, ASCII values 32–126 decimal or 0x20–0x7E hexadecimal.

Type: String

Required: no

Format

(Optional) The output format, when initiating a job to retrieve a vault inventory. If you are initiating an inventory job and don't specify a Format field, JSON is the default format.

Valid Values: CSV | JSON

Type: String

Required: no

InventoryRetrievalParameters

Input parameters used for a range inventory retrieval.

Type: InventoryRetrievalJobInput object
OutputLocation

An object that contains information about the location where the select job results are stored.

*Type:* OutputLocation object

*Required:* Yes, for select jobs.

RetrievalByteRange

The byte range to retrieve for an archive-retrieval, in the form "StartByteValue-EndByteValue". If this field isn't specified, the whole archive is retrieved. If this field is specified, the byte range must be megabyte (1024*1024) aligned. Megabyte-aligned means that StartByteValue must be divisible by 1 MB, and EndByteValue plus 1 must be divisible by 1 MB or be the end of the archive specified as the archive byte size value minus 1. If RetrievalByteRange is not megabyte-aligned, this operation returns a 400 response.

An error occurs if you specify this field for an inventory-retrieval or select job request.

*Type:* String

*Required:* no

SelectParameters

An object that contains information about the parameters used for a select.

*Type:* SelectParameters object

*Required:* no

SNSTopic

The Amazon Resource Name (ARN) of the Amazon SNS topic where S3 Glacier sends a notification when the job is completed and output is ready for you to download. The specified topic publishes the notification to its subscribers.

The SNS topic must exist. If it doesn't, S3 Glacier doesn't create it for you. Additionally, the SNS topic must have a policy that allows the account that created the job to publish messages to the topic. For information about SNS topic names, see CreateTopic in the Amazon Simple Notification Service API Reference.
Type: String

Required: no

Tier

The tier to use for a select or an archive retrieval job. Standard is the default value used.

Valid Values: Expedited | Standard | Bulk

Type: String

Required: no

Type

The job type. You can initiate a job to perform a select query on an archive, retrieve an archive, or get an inventory of a vault.

Valid Values: select | archive-retrieval | inventory-retrieval

Type: String

Required: yes

More Info

- [Initiate Job (POST jobs)]

OutputLocation

Contains information about the location where the job results and errors are stored.

Contents

S3

An object that describes an Amazon S3 location to receive the results of the restore request.

Type: S3Location

Required: yes
More Info

- [Initiate Job (POST jobs)](#)

OutputSerialization

Describes how the output is serialized.

Contents

CSV

An object that describes the serialization of the comma-separated values (CSV)-encoded query results.

*Type:* CSVOutput object

*Required:* no

More Info

- [Initiate Job (POST jobs)](#)

S3Location

Contains information about the location in Amazon S3 where the job results are stored.

Contents

AccessControlList

A list of grants that control access to the stored results.

*Type:* Array of Grant objects

*Required:* no

BucketName

The name of the Amazon S3 bucket where the job results are stored. The bucket must be in the same AWS Region as the vault that contains the input archive object.
Type: String

Required: yes

**CannedACL**

The canned access control list (ACL) to apply to the job results.

Type: String

Valid Values: private | public-read | public-read-write | aws-exec-read | authenticated-read | bucket-owner-read | bucket-owner-full-control

Required: no

**Encryption**

An object that contains information about the encryption used to store the job results in Amazon S3.

Type: Encryption object

Required: no

**Prefix**

The prefix that is prepended to the results for this request. The maximum length for the prefix is 512 bytes.

Type: String

Required: yes

**StorageClass**

The class of storage used to store the job results.

Type: String

Valid Values: STANDARD | REDUCED_REDUndANCY | STANDARD_IA

Required: no

**Tagging**

The tag set that is applied to the job results.
UserMetadata

A map of metadata to store with the job results in Amazon S3.

Type: String to string map

Required: no

More Info

- [Initiate Job (POST jobs)](#)

SelectParameters

Contains information about the parameters used for the select.

Contents

Expression

The expression that is used to select the object. The expression must not exceed the quota of 128,000 characters.

Type: String

Required: yes

ExpressionType

The type of the provided expression, for example SQL.

Valid Values: SQL

Type: String

Required: yes
**InputSerialization**

Describes the serialization format of the object in the select.

*Type: InputSerialization object*

*Required: no*

**OutputSerialization**

Describes how the results of the select job are serialized.

*Required: no*

*Type: OutputSerialization object*

**Data Retrieval Operations**

The following are the data retrieval–related operations available in S3 Glacier.

**Topics**

- [Get Data Retrieval Policy (GET policy)](https://aws.amazon.com)
- [List Provisioned Capacity (GET provisioned-capacity)](https://aws.amazon.com)
- [Purchase Provisioned Capacity (POST provisioned-capacity)](https://aws.amazon.com)
- [Set Data Retrieval Policy (PUT policy)](https://aws.amazon.com)

**Get Data Retrieval Policy (GET policy)**

**Description**

This operation returns the current data retrieval policy for the AWS account and AWS Region specified in the GET request. For more information about data retrieval policies, see [S3 Glacier Data Retrieval Policies](https://aws.amazon.com).
Requests

To return the current data retrieval policy, send an HTTP GET request to the data retrieval policy URI as shown in the following syntax example.

Syntax

GET /AccountID/policies/data-retrieval HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
x-amz-glacier-version: 2012-06-01

Note

The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens ('-') in the ID.

Request Parameters

This operation does not use request parameters.

Request Headers

This operation uses only request headers that are common to all operations. For information about common request headers, see Common Request Headers.

Request Body

This operation does not have a request body.

Responses

Syntax

HTTP/1.1 200 OK
Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see Common Response Headers.

Response Body

The response body contains the following JSON fields.

BytesPerHour

The maximum number of bytes that can be retrieved in an hour.

This field will be present only if the value of the Strategy field is BytesPerHour.

Type: Number

Rules

The policy rule. Although this is a list type, currently there will be only one rule, which contains a Strategy field and optionally a BytesPerHour field.

Type: Array

Strategy

The type of data retrieval policy.
Type: String

Valid values: BytesPerHour|FreeTier|None. BytesPerHour is equivalent to selecting Max Retrieval Rate in the console. FreeTier is equivalent to selecting Free Tier Only in the console. None is equivalent to selecting No Retrieval Policy in the console. For more information about selecting data retrieval policies in the console, see S3 Glacier Data Retrieval Policies.

Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.

Examples

The following example demonstrates how to get a data retrieval policy.

Example Request

In this example, a GET request is sent to the URI of a policy's location.

GET /-/policies/data-retrieval HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z
x-amz-glacier-version: 2012-06-01
Authorization: AWS4-HMAC-SHA256 Credential=AKIAIOSFODNN7EXAMPLE/20141123/us-west-2/glacier/aws4_request,SignedHeaders=host;x-amz-date;x-amz-glacier-version,Signature=9257c16da6b25a715ce900a5b45b03da0447acf430195dcb540091b12966f2a2

Example Response

A successful response shows the data retrieval policy in the body of the response in JSON format.

List Provisioned Capacity (GET provisioned-capacity)

This operation lists the provisioned capacity units for the specified AWS account. For more information about provisioned capacity, see Archive Retrieval Options.

A provisioned capacity unit lasts for one month starting at the date and time of purchase, which is the start date. The unit expires on the expiration date, which is exactly one month after the start date to the nearest second.

If the start date is on the 31st day of a month, the expiration date is the last day of the next month. For example, if the start date is August 31, the expiration date is September 30. If the start date is January 31, the expiration date is February 28. You can see this functionality in the Example Response.

Request Syntax

To list the provisioned retrieval capacity for an account, send an HTTP GET request to the provisioned-capacity URI as shown in the following syntax example.

```plaintext
GET /AccountId/provisioned-capacity HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
```
Note

The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens ('-') in the ID.

Request Parameters

This operation does not use request parameters.

Request Headers

This operation uses only request headers that are common to all operations. For information about common request headers, see Common Request Headers.

Request Body

This operation does not have a request body.

Responses

If the operation is successful, the service sends back an HTTP 200  OK response.

Response Syntax

HTTP/1.1 200 OK
x-amzn-RequestId: x-amzn-RequestId
Date: Date
Content-Type: application/json
Content-Length: Length
{
    "ProvisionedCapacityList":
        {
            "CapacityId" : "string",
            },
Response Headers

This operation uses only response headers that are common to most responses. For information about common response headers, see Common Response Headers.

Response Body

The response body contains the following JSON fields.

**CapacityId**

The ID that identifies the provisioned capacity unit.

*Type: String.*

**StartDate**

The date that the provisioned capacity unit was purchased, in Coordinated Universal Time (UTC).

*Type: String.* A string representation in the ISO 8601 date format, for example 2013-03-20T17:03:43.221Z.

**ExpirationDate**

The date that the provisioned capacity unit expires, in Coordinated Universal Time (UTC).

*Type: String.* A string representation in the ISO 8601 date format, for example 2013-03-20T17:03:43.221Z.

Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.

Examples

The following example lists the provisioned capacity units for an account.
Example Request

In this example, a GET request is sent to retrieve a list of the provisioned capacity units for the specified account.

```
GET /123456789012/priority-capacity HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z
x-amz-glacier-version: 2012-06-01
Authorization: AWS4-HMAC-SHA256 Credential=AKIAIOSFODNN7EXAMPLE/20141123/

```

Example Response

If the request was successful, Amazon S3 Glacier (S3 Glacier) returns a HTTP 200 OK with a list of provisioned capacity units for the account as shown in the following example.

The provisioned capacity unit listed first is an example of a unit with a start date of January 31, 2017 and expiration date of February 28, 2017. As stated earlier, if the start date is on the 31st day of a month, the expiration date is the last day of the next month.

- Purchase Provisioned Capacity (POST provisioned-capacity)

Purchase Provisioned Capacity (POST provisioned-capacity)

This operation purchases a provisioned capacity unit for an AWS account.

A provisioned capacity unit lasts for one month starting at the date and time of purchase, which is the start date. The unit expires on the expiration date, which is exactly one month after the start date to the nearest second.

If the start date is on the 31st day of a month, the expiration date is the last day of the next month. For example, if the start date is August 31, the expiration date is September 30. If the start date is January 31, the expiration date is February 28.

Provisioned capacity helps ensure that your retrieval capacity for expedited retrievals is available when you need it. Each unit of capacity ensures that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. For more information about provisioned capacity, see Archive Retrieval Options.

Note

There is a limit of two provisioned capacity units per AWS account.

Requests

To purchase provisioned capacity unit for an AWS account send an HTTP POST request to the provisioned-capacity URI.

Syntax

```
POST /AccountId/provisioned-capacity HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
Content-Length: Length
```
Note

The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens ('-') in the ID.

Request Parameters

Request Headers

This operation uses only request headers that are common to all operations. For information about common request headers, see Common Request Headers.

Request Body

This operation does not have a request body.

Responses

If the operation request is successful, the service returns an HTTP 201 Created response.

Syntax

HTTP/1.1 201 Created
x-amzn-RequestId: x-amzn-RequestId
Date: Date
x-amz-capacity-id: CapacityId

Response Headers

A successful response includes the following response headers, in addition to the response headers that are common to all operations. For more information about common response headers, see Common Response Headers.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x-amz-capacity-id</td>
<td>The ID that identifies the provisioned capacity unit.</td>
</tr>
<tr>

<td>Type: String</td>
</tr>
</tbody>
</table>

**Response Body**

This operation does not return a response body.

**Errors**

This operation includes the following error or errors, in addition to the possible errors common to all Amazon S3 Glacier operations. For information about Amazon S3 Glacier errors and a list of error codes, see [Error Responses](#).

<table>
<thead>
<tr>
<th>Code</th>

</tr>
</tbody>
</table>

**Examples**

The following example purchases provisioned capacity for an account.

**Example Request**

The following example sends an HTTP POST request to purchase a provisioned capacity unit.

```
POST /123456789012/provisioned-capacity HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z
Authorization: AWS4-HMAC-SHA256 Credential=AKIAI05FODNN7EXAMPLE/20141123/

Content-Length: length
x-amz-glacier-version: 2012-06-01
```
Example Response

If the request was successful, Amazon S3 Glacier (S3 Glacier) returns an HTTP 201 Created response, as shown in the following example.

```
HTTP/1.1 201 Created
x-amzn-RequestId: AAABZpJrTyioDC_HsOmHae8EZp_uBSJr6cnG0LKp_XJCl-Q
Date: Wed, 10 Feb 2017 12:02:00 GMT

Set Data Retrieval Policy (PUT policy)

Description

This operation sets and then enacts a data retrieval policy in the AWS Region specified in the PUT request. You can set one policy per AWS Region for an AWS account. The policy is enacted within a few minutes of a successful PUT operation.

The set policy operation does not affect retrieval jobs that were in progress before the policy was enacted. For more information about data retrieval policies, see [S3 Glacier Data Retrieval Policies](#).

Requests

Syntax

To set a data retrieval policy, send an HTTP PUT request to the data retrieval policy URI as shown in the following syntax example.

```
PUT /AccountId/policies/data-retrieval HTTP/1.1
Host: glacier.Region.amazonaws.com
Date: Date
Authorization: SignatureValue
Content-Length: Length
x-amz-glacier-version: 2012-06-01

{
    "Policy":
```
```json
{
   "Rules":[
      {
         "Strategy": String,
         "BytesPerHour": Number
      }
   ]
}
```

**Note**

The AccountId value is the AWS account ID. This value must match the AWS account ID associated with the credentials used to sign the request. You can either specify an AWS account ID or optionally a single '-' (hyphen), in which case Amazon S3 Glacier uses the AWS account ID associated with the credentials used to sign the request. If you specify your account ID, do not include any hyphens ('-') in the ID.

**Request Parameters**

This operation does not use request parameters.

**Request Headers**

This operation uses only request headers that are common to all operations. For information about common request headers, see [Common Request Headers](#).

**Request Body**

The request body contains the following JSON fields.

**BytesPerHour**

The maximum number of bytes that can be retrieved in an hour.

This field is required only if the value of the Strategy field is BytesPerHour. Your PUT operation will be rejected if the Strategy field is not set to BytesPerHour and you set this field.

*Type:* Number
**Required:** Yes, if the Strategy field is set to `BytesPerHour`. Otherwise, no.

**Valid Values:** Minimum integer value of 1. Maximum integer value of \(2^{63} - 1\) inclusive.

**Rules**

The policy rule. Although this is a list type, currently there must be only one rule, which contains a Strategy field and optionally a `BytesPerHour` field.

*Type:* Array

**Required:** Yes

**Strategy**

The type of data retrieval policy to set.

*Type:* String

**Required:** Yes

Valid values: `BytesPerHour`|`FreeTier`|`None`. `BytesPerHour` is equivalent to selecting Max Retrieval Rate in the console. `FreeTier` is equivalent to selecting Free Tier Only in the console. None is equivalent to selecting No Retrieval Policy in the console. For more information about selecting data retrieval policies in the console, see S3 Glacier Data Retrieval Policies.

**Responses**

**Syntax**

```
HTTP/1.1 204 No Content
x-amzn-RequestId: x-amzn-RequestId
Date: Date
```

**Response Headers**

This operation uses only response headers that are common to most responses. For information about common response headers, see Common Response Headers.

**Response Body**

This operation does not return a response body.
Errors

For information about Amazon S3 Glacier exceptions and error messages, see Error Responses.

Examples

Example Request

The following example sends an HTTP PUT request with the Strategy field set to BytesPerHour.

```
PUT /-/policies/data-retrieval HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z

            }
        ]
    }
}
```

The following example sends an HTTP PUT request with the Strategy field set to FreeTier.

```
PUT /-/policies/data-retrieval HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z
x-amz-glacier-version: 2012-06-01
Authorization: AWS4-HMAC-SHA256 Credential=AKIAIOSFODNN7EXAMPLE/20141123/
us-west-2/glacier/aws4_request,SignedHeaders=host;x-amz-date;x-amz-glacier-
version,Signature=9257c16da6b25a715ce900a5b45b03da0447acf430195dcb540091b12966f2a2

{
    "Policy":
    {
```
The following example sends an HTTP PUT request with the Strategy field set to None.

```http
PUT /-/policies/data-retrieval HTTP/1.1
Host: glacier.us-west-2.amazonaws.com
x-amz-Date: 20170210T120000Z
x-amz-glacier-version: 2012-06-01
Authorization: AWS4-HMAC-SHA256 Credential=AKIAIOSFODNN7EXAMPLE/20141123/us-west-2/glacier/aws4_request,SignedHeaders=host;x-amz-date;x-amz-glacier-version,Signature=9257c16da6b25a715ce900a5b45b03da0447acf430195dcb540091b12966f2a2

        "Rules":
        {
            "Strategy":"None"
        }
    }
}
```

**Example Response**

If the request was successful Amazon S3 Glacier (S3 Glacier) sets the policy and returns a HTTP 204 No Content as shown in the following example.

```http
HTTP/1.1 204 No Content
x-amzn-RequestId: AAABZpJrTyioDC_HsOmhae8EZp_uB5Jr6cnGOLKp_XJCl-Q
Date: Wed, 10 Feb 2017 12:02:00 GMT

<tr>
<td>Support for range retrievals</td>
<td>S3 Glacier now supports retrieval of specific ranges of your archives. You can initiate a job requesting S3 Glacier to prepare an entire archive or a portion of the archive for subsequent download. When an archive is very large, you may find it cost effective to initiate several sequential jobs to prepare your archive.</td>
