What is the AWS Command Line Interface?

The AWS Command Line Interface (AWS CLI) is an open source tool that enables you to interact with AWS services using commands in your command-line shell. With minimal configuration, the AWS CLI enables you to start running commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from the command prompt in your terminal program:

- **Linux shells** – Use common shell programs such as bash, zsh, and tcsh to run commands in Linux or macOS.
- **Windows command line** – On Windows, run commands at the Windows command prompt or in PowerShell.
- **Remotely** – Run commands on Amazon Elastic Compute Cloud (Amazon EC2) instances through a remote terminal program such as PuTTY or SSH, or with AWS Systems Manager.

All IaaS (infrastructure as a service) AWS administration, management, and access functions in the AWS Management Console are available in the AWS API and AWS CLI. New AWS IaaS features and services provide full AWS Management Console functionality through the API and CLI at launch or within 180 days of launch.

The AWS CLI provides direct access to the public APIs of AWS services. You can explore a service's capabilities with the AWS CLI, and develop shell scripts to manage your resources. In addition to the low-level, API-equivalent commands, several AWS services provide customizations for the AWS CLI. Customizations can include higher-level commands that simplify using a service with a complex API.

About AWS CLI version 2

The AWS CLI version 2 is the most recent major version of the AWS CLI and supports all of the latest features. Some features introduced in version 2 are not backported to version 1 and you must upgrade to access those features. There are some "breaking" changes from version 1 that might require you to change your scripts. For a list of breaking changes in version 2, see [Migrate from AWS CLI version 1 to version 2](#).

The AWS CLI version 2 is available to install only as a bundled installer. While you might find it in package managers, these are unsupported and unofficial packages that are not produced
or managed by AWS. We recommend that you install the AWS CLI from only the official AWS distribution points, as documented in this guide.

To install the AWS CLI version 2, see the section called “Install/Update”.

To check the currently installed version, use the following command:

```
$ aws --version
aws-cli/2.15.30 Python/3.11.6 Linux/5.10.205-195.807.amzn2.x86_64 botocore/1.18.6
```

For version history, see the AWS CLI version 2 Changelog on GitHub.

**Maintenance and support for SDK major versions**

For information about maintenance and support for SDK major versions and their underlying dependencies, see the following in the AWS SDKs and Tools Reference Guide:

- [AWS SDKs and tools maintenance policy](#)
- [AWS SDKs and tools version support matrix](#)

**About Amazon Web Services**

Amazon Web Services (AWS) is a collection of digital infrastructure services that developers can leverage when developing their applications. The services include computing, storage, database, and application synchronization (messaging and queuing). AWS uses a pay-as-you-go service model. You are charged only for the services that you—or your applications—use. Also, to make AWS more approachable as a platform for prototyping and experimentation, AWS offers a free usage tier. On this tier, services are free below a certain level of usage. For more information about AWS costs and the Free Tier, see [AWS Free Tier](#). To obtain an AWS account, open the [AWS home page](#) and then choose Create an AWS Account.

**About the AWS CLI examples**

The AWS Command Line Interface (AWS CLI) examples in this guide are formatted using the following conventions:
• **Prompt** – The command prompt uses the Linux prompt and is displayed as ($ ). For commands that are Windows specific, C: \> is used as the prompt. Do not include the prompt when you type commands.

• **Directory** – When commands must be executed from a specific directory, the directory name is shown before the prompt symbol.

• **User input** – Command text that you enter at the command line is formatted as user input.

• **Replaceable text** – Variable text, including names of resources that you choose, or IDs generated by AWS services that you must include in commands, is formatted as replaceable text. In multiple-line commands or commands where specific keyboard input is required, keyboard commands can also be shown as replaceable text.

• **Output** – Output returned by AWS services is shown under user input, and is formatted as computer output.

The following **aws configure** command example demonstrates user input, replaceable text, and output:

1. Enter **aws configure** at the command line, and then press Enter.
2. The AWS CLI outputs lines of text, prompting you to enter additional information.
3. Enter each of your access keys in turn, and then press Enter.
4. Then, enter an AWS Region name in the format shown, press Enter, and then press Enter a final time to skip the output format setting.
5. The final Enter command is shown as replaceable text because there is no user input for that line.

```bash
$ aws configure
AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
Default region name [None]: us-west-2
Default output format [None]: ENTER
```

The following example shows a simple command with output. To use this example, enter the full text of the command (the highlighted text after the prompt), and then press Enter. The name of the security group, **my-sg**, is replaceable to your desired security group name. The JSON document, including the curly braces, is output. If you configure your CLI to output in text or table format, the output will be formatted differently. **JSON** is the default output format.

Get started with the AWS CLI

This chapter provides steps to get started with version 2 of the AWS Command Line Interface (AWS CLI) and provides links to the relevant instructions.

1. **Complete all prerequisites** - To access AWS services with the AWS CLI, you need at minimum an AWS account and IAM credentials. To increase the security of your AWS account, we recommend that you do not use your root account credentials. You should create a user with least privilege to provide access credentials to the tasks you’ll be running in AWS.

2. Install or gain access to the AWS CLI using one of the following methods:
   - **(Recommended) the section called “Install/Update”**.
   - *the section called “Past releases”*. Installing a specific version is primarily used if your team aligns their tools to a specific version.
   - *the section called “Build and install from source”*. Building the AWS CLI from GitHub source is a more in-depth method that is primarily used by customers who work on platforms that we do not directly support with our pre-built installers.
   - *the section called “Amazon ECR Public/Docker”*.
   - Access the AWS CLI version 2 in the AWS console from your browser using AWS CloudShell. For more information, see the [AWS CloudShell User Guide](#).

3. **After you have access to the AWS CLI, configure your AWS CLI with your IAM credentials for first time use.**

Troubleshooting installer or configure errors

If you have issues after installing, uninstalling, or configuring the AWS CLI, see *Troubleshoot errors* for troubleshooting steps.

Topics

- Prerequisites to use the AWS CLI version 2
- Install or update to the latest version of the AWS CLI
- Install past releases of the AWS CLI version 2
- Build and install the AWS CLI from source
- Run the AWS CLI from the official Amazon ECR Public or Docker images
Prerequisites to use the AWS CLI version 2

To access AWS services with the AWS CLI, you need an AWS account and IAM credentials. When running AWS CLI commands, the AWS CLI needs to have access to those AWS credentials. To increase the security of your AWS account, we recommend that you do not use your root account credentials. You should create a user with least privilege to provide access credentials to the tasks you'll be running in AWS.

Next steps

After creating an AWS account and IAM credentials, to use the AWS CLI you can do one of the following:

- **Install the latest release** of the AWS CLI version 2 on your computer.
- **Install a past release** of the AWS CLI version 2 on your computer.
- Access the AWS CLI version 2 from your computer using a Docker image.
- Access the AWS CLI version 2 in the AWS console from your browser using AWS CloudShell. For more information see the **AWS CloudShell User Guide**.

Install or update to the latest version of the AWS CLI

This topic describes how to install or update the latest release of the AWS Command Line Interface (AWS CLI) on supported operating systems. For information on the latest releases of AWS CLI, see the **AWS CLI version 2 Changelog** on GitHub.

To install a past release of the AWS CLI, see **the section called “Past releases”**. For uninstall instructions, see **Uninstall**.
Important

AWS CLI versions 1 and 2 use the same aws command name. If you previously installed AWS CLI version 1, see Migrate from AWS CLI version 1 to version 2.

AWS CLI install and update instructions

For installation instructions, expand the section for your operating system.

Linux

Install and update requirements

- You must be able to extract or "unzip" the downloaded package. If your operating system doesn't have the built-in unzip command, use an equivalent.
- The AWS CLI uses glibc, groff, and less. These are included by default in most major distributions of Linux.
- We support the AWS CLI on 64-bit versions of recent distributions of CentOS, Fedora, Ubuntu, Amazon Linux 1, Amazon Linux 2, Amazon Linux 2023, and Linux ARM.
- Because AWS doesn't maintain third-party repositories, we can't guarantee that they contain the latest version of the AWS CLI.

Install or update the AWS CLI

Warning

If this is your first time updating on Amazon Linux, to install the latest version of the AWS CLI, you must uninstall the pre-installed yum version using the following command:

```
$ sudo yum remove awscli
```
After the yum installation of the AWS CLI is removed, follow the below Linux install instructions.

To update your current installation of AWS CLI, download a new installer each time you update to overwrite previous versions. Follow these steps from the command line to install the AWS CLI on Linux.

The following are quick installation steps in a single copy and paste group based on whether you use 64-bit Linux or Linux ARM that provide a basic installation. For guided instructions, see the steps that follow.

Linux x86 (64-bit)

**Note** *(Optional)* The following command block downloads and installs the AWS CLI without first verifying the integrity of your download. To verify the integrity of your download, use the below step by step instructions.

**To install** the AWS CLI, run the following commands.

```
$ curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip"
unzip awscliv2.zip
sudo ./aws/install
```

**To update your current installation** of the AWS CLI, add your existing symlink and installer information to construct the install command using the `--bin-dir`, `--install-dir`, and `--update` parameters. The following command block uses an example symlink of `/usr/local/bin` and example installer location of `/usr/local/aws-cli`.

```
$ curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip"
unzip awscliv2.zip
sudo ./aws/install --bin-dir /usr/local/bin --install-dir /usr/local/aws-cli --update
```
To install the AWS CLI, run the following commands.

```
$ curl "https://awscli.amazonaws.com/awscli-exe-linux-aarch64.zip" -o "awscliv2.zip"
unzip awscliv2.zip
sudo ./aws/install
```

To update your current installation of the AWS CLI, add your existing symlink and installer information to construct the install command using the `--bin-dir`, `--install-dir`, and `--update` parameters. The following command block uses an example symlink of `/usr/local/bin` and example installer location of `/usr/local/aws-cli`.

```
$ curl "https://awscli.amazonaws.com/awscli-exe-linux-aarch64.zip" -o "awscliv2.zip"
unzip awscliv2.zip
sudo ./aws/install --bin-dir /usr/local/bin --install-dir /usr/local/aws-cli --update
```

Guided installation steps

1. Download the installation file in one of the following ways:

   **Linux x86 (64-bit)**

   - **Use the curl command** – The `-o` option specifies the file name that the downloaded package is written to. The options on the following example command write the downloaded file to the current directory with the local name `awscliv2.zip`.

     ```
     $ curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip"
     ```
• **Downloading from the URL** – To download the installer with your browser, use the following URL: [https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip](https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip)

Linux ARM

• **Use the **curl** command** – The -o option specifies the file name that the downloaded package is written to. The options on the following example command write the downloaded file to the current directory with the local name `awscliv2.zip`.

*cos$ curl "https://awscli.amazonaws.com/awscli-exe-linux-aarch64.zip" -o "awscliv2.zip"

• **Downloading from the URL** – To download the installer with your browser, use the following URL: [https://awscli.amazonaws.com/awscli-exe-linux-aarch64.zip](https://awscli.amazonaws.com/awscli-exe-linux-aarch64.zip)

2. **(Optional) Verifying the integrity of your downloaded zip file**

If you chose to manually download the AWS CLI installer package `.zip` in the above steps, you can use the following steps to verify the signatures by using the GnuPG tool.

The AWS CLI installer package `.zip` files are cryptographically signed using PGP signatures. If there is any damage or alteration of the files, this verification fails and you should not proceed with installation.

a. Download and install the `gpg` command using your package manager. For more information about GnuPG, see the GnuPG website.

b. To create the public key file, create a text file and paste in the following text.

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
mQINBF2Cz7UBEADJZHcgus0J17ENSyumXh85z0TRV0xJoxM2B7L0kH0yiqQlUUGZMLhENa0bYatdrkXP+3H911vkK050pXwn07R7f8B/FSTouki4ciIx50ulnJZI5szxPqG10mxlMLnbGWOi6Lto0LYxqHN2iqz1wTVmq9733zd3XfcXi3+Lb1hAgEt5GTFNxeEK38s0PLyWmvH6HCnJZ/aIQRLTIQ05uVeEoYxSh6W0ai7ss/KevoSNBBYyzgbdzoq12Y8c7h2nbfgp3DSasaLZEdCSIsK1u05CinE7k2qZ7KgKAIIC/cR/grkC6VwsnDU00UCideXcQ8WeHuqvgZH1JgKDbznoIzeQHJDZ38GEu+eKhRHzc8/jeG94zkcgJ0z3KbZGYMiTh277Fvjz9zzZsbMBcedV1BTg3TqgvdX4bdkhf5cH+7Ntw01rFj6UwAsGukBTA0xc01/dn5SmZhJ7Z1KmElrozg9Drj0xqRQut1iqG22TaqoPGfVYN+en32zbwt97kcg2DqwbuykNt64oZWc4XKca3mpzEGC3IbJTBFaq1XmZ719ywGEUJY0l2bxSnuPWL39beWdKMKzz10jn10m6+1pTRCBfo0wa9F8YZRhHPAkwKkXNDeoGWPWj4ohx0d2GWkyV5xyN14p2tQOCdoOdmz80yUTgRpPVQUt0EhXQARAQAB
-----END PGP PUBLIC KEY BLOCK-----
```
For reference, the following are the details of the public key.

Key ID: A6310ACC4672
Type: RSA
Size: 4096/4096
Created: 2019-09-18
Expires: 2024-07-26
User ID: AWS CLI Team <aws-cli@amazon.com>
Key fingerprint: FB5D B77F D5C1 18B8 0511 ADA8 A631 0ACC 4672 475C

c. Import the AWS CLI public key with the following command, substituting public-key-file-name with the file name of the public key you created.

```
$ gpg --import public-key-file-name
```

```
gpg: /home/username/.gnupg/trustdb.gpg: trustdb created
gpg: key A6310ACC4672475C: public key "AWS CLI Team <aws-cli@amazon.com>"
imported
gpg: Total number processed: 1
gpg: imported: 1
```

d. Download the AWS CLI signature file for the package you downloaded. It has the same path and name as the .zip file it corresponds to, but has the extension .sig. In the following examples, we save it to the current directory as a file named awscliv2.sig.
Linux x86 (64-bit)

For the latest version of the AWS CLI, use the following command block:

```bash
$ curl -o awscliv2.sig https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip.sig
```

For a specific version of the AWS CLI, append a hyphen and the version number to the filename. For this example the filename for version 2.0.30 would be awscli-exe-linux-x86_64-2.0.30.zip.sig resulting in the following command:

```bash
$ curl -o awscliv2.sig https://awscli.amazonaws.com/awscli-exe-linux-x86_64-2.0.30.zip.sig
```

For a list of versions, see the AWS CLI version 2 Changelog on GitHub.

Linux ARM

For the latest version of the AWS CLI, use the following command block:

```bash
$ curl -o awscliv2.sig https://awscli.amazonaws.com/awscli-exe-linux-aarch64.zip.sig
```

For a specific version of the AWS CLI, append a hyphen and the version number to the filename. For this example the filename for version 2.0.30 would be awscli-exe-linux-aarch64-2.0.30.zip.sig resulting in the following command:

```bash
```

For a list of versions, see the AWS CLI version 2 Changelog on GitHub.

e. Verify the signature, passing both the downloaded .sig and .zip file names as parameters to the gpg command.

```bash
$ gpg --verify awscliv2.sig awscliv2.zip
```

The output should look similar to the following.
3. **Unzip the installer.** If your Linux distribution doesn't have a built-in `unzip` command, use an equivalent to unzip it. The following example command unzips the package and creates a directory named `aws` under the current directory.

   ```bash
   $ unzip awscliv2.zip
   ```

   **Note**
   When updating from a previous version, the `unzip` command prompts to overwrite existing files. To skip these prompts, such as with script automation, use the `-u` update flag for `unzip`. This flag automatically updates existing files and creates new ones as needed.

   ```bash
   $ unzip -u awscliv2.zip
   ```

4. **Run the install program.** The installation command uses a file named `install` in the newly unzipped `aws` directory. By default, the files are all installed to `/usr/local/aws-cli`, and a symbolic link is created in `/usr/local/bin`. The command includes `sudo` to grant write permissions to those directories.

   ```bash
   $ sudo ./aws/install
   ```
You can install without `sudo` if you specify directories that you already have write permissions to. Use the following instructions for the `install` command to specify the installation location:

- Ensure that the paths you provide to the `-i` and `-b` parameters contain no volume name or directory names that contain any space characters or other white space characters. If there is a space, the installation fails.
- `--install-dir` or `-i` – This option specifies the directory to copy all of the files to.

The default value is `/usr/local/aws-cli`.

- `--bin-dir` or `-b` – This option specifies that the main `aws` program in the install directory is symbolically linked to the file `aws` in the specified path. You must have write permissions to the specified directory. Creating a symlink to a directory that is already in your path eliminates the need to add the install directory to the user's `$PATH` variable.

The default value is `/usr/local/bin`.

```
$ ./aws/install -i /usr/local/aws-cli -b /usr/local/bin
```

**Note**

To update your current installation of the AWS CLI, add your existing symlink and installer information to construct the `install` command with the `--update` parameter.

```
$ sudo ./aws/install --bin-dir /usr/local/bin --install-dir /usr/local/aws-cli --update
```

To locate the existing symlink and installation directory, use the following steps:

1. Use the `which` command to find your symlink. This gives you the path to use with the `--bin-dir` parameter.

```
$ which aws
/usr/local/bin/aws
```
2. Use the `ls` command to find the directory that your symlink points to. This gives you the path to use with the `--install-dir` parameter.

```
$ ls -l /usr/local/bin/aws
lrwxrwxrwx 1 ec2-user ec2-user 49 Oct 22 09:49 /usr/local/bin/aws -> /usr/local/aws-cli/v2/current/bin/aws
```

5. Confirm the installation with the following command.

```
$ aws --version
aws-cli/2.15.30 Python/3.11.6 Linux/5.10.205-195.807.amzn2.x86_64 botocore/2.4.5
```

If the `aws` command cannot be found, you might need to restart your terminal or follow the troubleshooting in *Troubleshoot errors*.

**macOS**

**Install and update requirements**

- We support the AWS CLI on macOS versions 10.9 and later. For more information, see macOS support policy updates for the AWS CLI v2 on the AWS Developer Tools Blog.
- Because AWS doesn't maintain third-party repositories, we can't guarantee that they contain the latest version of the AWS CLI.

**Install or update the AWS CLI**

If you are updating to the latest version, use the same installation method that you used in your current version. You can install the AWS CLI on macOS in the following ways.

**GUI installer**

The following steps show how to install the latest version of the AWS CLI by using the standard macOS user interface and your browser.

1. In your browser, download the macOS pkg file: [https://awscli.amazonaws.com/AWSCLIV2.pkg](https://awscli.amazonaws.com/AWSCLIV2.pkg)
2. Run your downloaded file and follow the on-screen instructions. You can choose to install the AWS CLI in the following ways:
• **For all users on the computer (requires sudo)**
  
  • You can install to any folder, or choose the recommended default folder of /usr/local/aws-cli.
  
  • The installer automatically creates a symlink at /usr/local/bin/aws that links to the main program in the installation folder you chose.

• **For only the current user (doesn't require sudo)**
  
  • You can install to any folder to which you have write permission.
  
  • Due to standard user permissions, after the installer finishes, you must manually create a symlink file in your $PATH that points to the aws and aws_completer programs by using the following commands at the command prompt. If your $PATH includes a folder you can write to, you can run the following command without sudo if you specify that folder as the target's path. If you don't have a writable folder in your $PATH, you must use sudo in the commands to get permissions to write to the specified target folder. The default location for a symlink is /usr/local/bin/.

  ```bash
  $ sudo ln -s /folder/installed/aws-cli/aws /usr/local/bin/aws
  $ sudo ln -s /folder/installed/aws-cli/aws_completer /usr/local/bin/aws_completer
  ```

  **Note**

  You can view debug logs for the installation by pressing **Cmd+L** anywhere in the installer. This opens a log pane that enables you to filter and save the log. The log file is also automatically saved to /var/log/install.log.

3. To verify that the shell can find and run the aws command in your $PATH, use the following commands.

  ```bash
  $ which aws
  /usr/local/bin/aws
  $ aws --version
  aws-cli/2.15.30 Python/3.11.6 Darwin/23.3.0 botocore/2.4.5
  ```

  If the aws command cannot be found, you might need to restart your terminal or follow the troubleshooting in *Troubleshoot errors*. 

AWS CLI install and update instructions
Command line installer - All users

If you have `sudo` permissions, you can install the AWS CLI for all users on the computer. We provide the steps in one easy to copy and paste group. See the descriptions of each line in the following steps.

```
$ curl "https://awscli.amazonaws.com/AWSCLIV2.pkg" -o "AWSCLIV2.pkg"
$ sudo installer -pkg AWSCLIV2.pkg -target /
```

Guided installation instructions

1. Download the file using the `curl` command. The `-o` option specifies the file name that the downloaded package is written to. In this example, the file is written to `AWSCLIV2.pkg` in the current folder.

   ```
   $ curl "https://awscli.amazonaws.com/AWSCLIV2.pkg" -o "AWSCLIV2.pkg"
   ```

2. Run the standard macOS `installer` program, specifying the downloaded `.pkg` file as the source. Use the `-pkg` parameter to specify the name of the package to install, and the `-target /` parameter for which drive to install the package to. The files are installed to `/usr/local/aws-cli`, and a symlink is automatically created in `/usr/local/bin`. You must include `sudo` on the command to grant write permissions to those folders.

   ```
   $ sudo installer -pkg ./AWSCLIV2.pkg -target /
   ```

   After installation is complete, debug logs are written to `/var/log/install.log`.

3. To verify that the shell can find and run the `aws` command in your `$PATH`, use the following commands.

   ```
   $ which aws
   /usr/local/bin/aws
   $ aws --version
   aws-cli/2.15.30 Python/3.11.6 Darwin/23.3.0 botocore/2.4.5
   ```

   If the `aws` command cannot be found, you might need to restart your terminal or follow the troubleshooting in `Troubleshoot errors`. 
Command line - Current user

1. To specify which folder the AWS CLI is installed to, you must create an XML file with any file name. This file is an XML-formatted file that looks like the following example. Leave all values as shown, except you must replace the path /Users/myusername in line 9 with the path to the folder you want the AWS CLI installed to. The folder must already exist, or the command fails. The following XML example, named choices.xml, specifies the installer to install the AWS CLI in the folder /Users/myusername, where it creates a folder named aws-cli.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
  <array>
    <dict>
      <key>choiceAttribute</key>
      <string>customLocation</string>
      <key>attributeSetting</key>
      <string>/Users/myusername</string>
      <key>choiceIdentifier</key>
      <string>default</string>
    </dict>
  </array>
</plist>
```

2. Download the pkg installer using the `curl` command. The -o option specifies the file name that the downloaded package is written to. In this example, the file is written to AWSCLIV2.pkg in the current folder.

   ```bash
   $ curl "https://awscli.amazonaws.com/AWSCLIV2.pkg" -o "AWSCLIV2.pkg"
   ```

3. Run the standard macOS installer program with the following options:
   - Specify the name of the package to install by using the -pkg parameter.
   - Specify installing to a current user only by setting the -target parameter to CurrentUserHomeDirectory.
   - Specify the path (relative to the current folder) and name of the XML file that you created in the -applyChoiceChangesXML parameter.
The following example installs the AWS CLI in the folder /Users/myusername/aws-cli.

$$
installer -pkg AWSCLIV2.pkg \\
   -target CurrentUserHomeDirectory \\
   -applyChoiceChangesXML choices.xml
$$

4. Because standard user permissions typically don't allow writing to folders in your $PATH, the installer in this mode doesn't try to add the symlinks to the aws and aws_completer programs. For the AWS CLI to run correctly, you must manually create the symlinks after the installer finishes. If your $PATH includes a folder you can write to and you specify the folder as the target's path, you can run the following command without sudo. If you don't have a writable folder in your $PATH, you must use sudo for permissions to write to the specified target folder. The default location for a symlink is /usr/local/bin/. Replace folder/installed with the path to your AWS CLI installation.

$$
sudo ln -s /folder/installed/aws-cli/aws /usr/local/bin/aws
sudo ln -s /folder/installed/aws-cli/aws_completer /usr/local/bin/aws_completer
$$

After installation is complete, debug logs are written to /var/log/install.log.

5. To verify that the shell can find and run the aws command in your $PATH, use the following commands.

$$
which aws
/usr/local/bin/aws
$ aws --version
aws-cli/2.15.30 Python/3.11.6 Darwin/23.3.0 botocore/2.4.5
$$

If the aws command cannot be found, you might need to restart your terminal or follow the troubleshooting in Troubleshoot errors.

Windows

Install and update requirements

- We support the AWS CLI on Microsoft-supported versions of 64-bit Windows.
- Admin rights to install software
Install or update the AWS CLI

To update your current installation of AWS CLI on Windows, download a new installer each time you update to overwrite previous versions. AWS CLI is updated regularly. To see when the latest version was released, see the AWS CLI version 2 Changelog on GitHub.

1. Download and run the AWS CLI MSI installer for Windows (64-bit):

   https://awscli.amazonaws.com/AWSCLIV2.msi

   Alternatively, you can run the msiexec command to run the MSI installer.

   C:\> msiexec.exe /i https://awscli.amazonaws.com/AWSCLIV2.msi

   For various parameters that can be used with msiexec, see msiexec on the Microsoft Docs website. For example, you can use the /qn flag for a silent installation.

   C:\> msiexec.exe /i https://awscli.amazonaws.com/AWSCLIV2.msi /qn

2. To confirm the installation, open the Start menu, search for cmd to open a command prompt window, and at the command prompt use the aws --version command.

   C:\> aws --version
   aws-cli/2.15.30 Python/3.11.6 Windows/10 exe/AMD64 prompt/off

   If Windows is unable to find the program, you might need to close and reopen the command prompt window to refresh the path, or follow the troubleshooting in Troubleshoot errors.

Troubleshooting AWS CLI install and uninstall errors

If you come across issues after installing or uninstalling the AWS CLI, see Troubleshoot errors for troubleshooting steps. For the most relevant troubleshooting steps, see the section called “Command not found errors”, the section called “The "aws --version" command returns a different version than you installed”, and the section called “The "aws --version" command returns a version after uninstalling the AWS CLI".
Next steps

After you successfully install the AWS CLI, you can safely delete your downloaded installer files. After completing the steps in the section called “Prerequisites” and installing the AWS CLI, you should perform a the section called “Setup”.

Install past releases of the AWS CLI version 2

This topic describes how to install the past releases of the AWS Command Line Interface version 2 (AWS CLI) on supported operating systems. For information on the AWS CLI version 2 releases, see the AWS CLI version 2 Changelog on GitHub.

AWS CLI version 2 installation instructions:

Linux

Installation requirements

- You know which release of the AWS CLI version 2 you’d like to install. For a list of versions, see the AWS CLI version 2 Changelog on GitHub.
- You must be able to extract or “unzip” the downloaded package. If your operating system doesn't have the built-in unzip command, use an equivalent.
- The AWS CLI version 2 uses glibc, groff, and less. These are included by default in most major distributions of Linux.
- We support the AWS CLI version 2 on 64-bit versions of recent distributions of CentOS, Fedora, Ubuntu, Amazon Linux 1, Amazon Linux 2 and Linux ARM.
- Because AWS doesn't maintain third-party repositories, we can't guarantee that they contain the latest version of the AWS CLI.

Installation instructions

Follow these steps from the command line to install the AWS CLI on Linux.

We provide the steps in one easy to copy and paste group based on whether you use 64-bit Linux or Linux ARM. See the descriptions of each line in the steps that follow.
Linux x86 (64-bit)

**Note**

(Optional) The following command block downloads and installs the AWS CLI without first verifying the integrity of your download. To verify the integrity of your download, use the below step by step instructions.

For a list of versions, see the [AWS CLI version 2 Changelog](https://github.com/aws/aws-cli) on GitHub.

To install the AWS CLI, run the following commands.

To specify a version, append a hyphen and the version number to the filename. For this example the filename for version **2.0.30** would be `awscli-exe-linux-x86_64-2.0.30.zip` resulting in the following command:

```bash
$ curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64-2.0.30.zip" -o "awscliv2.zip"
unzip awscliv2.zip
sudo ./aws/install
```

To update your current installation of the AWS CLI, add your existing symlink and installer information to construct the `install` command using the `--bin-dir`, `--install-dir`, and `--update` parameters. The following command block uses an example symlink of `/usr/local/bin` and example installer location of `/usr/local/aws-cli`.

```bash
$ curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64-2.0.30.zip" -o "awscliv2.zip"
unzip awscliv2.zip
sudo ./aws/install --bin-dir /usr/local/bin --install-dir /usr/local/aws-cli --update
```

Linux ARM

**Note**

(Optional) The following command block downloads and installs the AWS CLI without first verifying the integrity of your download. To verify the integrity of your download, use the below step by step instructions.

Past releases
For a list of versions, see the [AWS CLI version 2 Changelog](https://github.com/aws/aws-cli/releases) on GitHub.

**To install** the AWS CLI, run the following commands.

To specify a version, append a hyphen and the version number to the filename. For this example the filename for version 2.0.30 would be `awscli-exe-linux-aarch64-2.0.30.zip` resulting in the following command:

```
$ curl "https://awscli.amazonaws.com/awscli-exe-linux-aarch64-2.0.30.zip" -o awscliv2.zip
unzip awscliv2.zip
sudo ./aws/install
```

**To update your current installation** of the AWS CLI, add your existing symlink and installer information to construct the install command using the `--bin-dir`, `--install-dir`, and `--update` parameters. The following command block uses an example symlink of `/usr/local/bin` and example installer location of `/usr/local/aws-cli`.

```
$ curl "https://awscli.amazonaws.com/awscli-exe-linux-aarch64-2.0.30.zip" -o awscliv2.zip
unzip awscliv2.zip
sudo ./aws/install --bin-dir /usr/local/bin --install-dir /usr/local/aws-cli --update
```

1. Download the installation file in one of the following ways:

   **Linux x86 (64-bit)**

   - **Use the curl command** – The `-o` option specifies the file name that the downloaded package is written to. The options on the following example command write the downloaded file to the current directory with the local name `awscliv2.zip`.

     To specify a version, append a hyphen and the version number to the filename. For this example the filename for version 2.0.30 would be `awscli-exe-linux-x86_64-2.0.30.zip` resulting in the following command:

     ```
     $ curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64-2.0.30.zip" -o awscliv2.zip
     ```
For a list of versions, see the AWS CLI version 2 Changelog on GitHub.

- **Downloading from the URL** –

  In your browser, download your specific version of the AWS CLI by appending a hyphen and the version number to the filename.

  ```
  https://awscli.amazonaws.com/awscli-exe-linux-x86_64-version.number.zip
  ```

  For this example the filename for version `2.0.30` would be `awscli-exe-linux-x86_64-2.0.30.zip` resulting in the following link: `https://awscli.amazonaws.com/awscli-exe-linux-x86_64-2.0.30.zip`

**Linux ARM**

- **Use the curl command** – The `-o` option specifies the file name that the downloaded package is written to. The options on the following example command write the downloaded file to the current directory with the local name `awscliv2.zip`.

  ```
  $ curl "https://awscli.amazonaws.com/awscli-exe-linux-aarch64-2.0.30.zip" -o "awscliv2.zip"
  unzip awscliv2.zip
  sudo ./aws/install
  ```

- **Downloading from the URL** –

  In your browser, download your specific version of the AWS CLI by appending a hyphen and the version number to the filename.

  ```
  https://awscli.amazonaws.com/awscli-exe-linux-aarch64-version.number.zip
  ```

  For this example the filename for version `2.0.30` would be `awscli-exe-linux-aarch64-2.0.30.zip` resulting in the following link: `https://awscli.amazonaws.com/awscli-exe-linux-aarch64-2.0.30.zip`
2. **(Optional) Verifying the integrity of your downloaded zip file**

If you chose to manually download the AWS CLI installer package .zip in the above steps, you can use the following steps to verify the signatures by using the GnuPG tool.

The AWS CLI installer package .zip files are cryptographically signed using PGP signatures. If there is any damage or alteration of the files, this verification fails and you should not proceed with installation.

a. Download and install the gpg command using your package manager. For more information about GnuPG, see the [GnuPG website](https://gnupg.org).

b. To create the public key file, create a text file and paste in the following text.

c. Import the AWS CLI public key with the following command, substituting `public-key-file-name` with the file name of the public key you created.

```bash
$ gpg --import public-key-file-name
```

```
gpg: /home/username/.gnupg/trustdb.gpg: trustdb created
gpg: key A6310ACC4672475C: public key "AWS CLI Team <aws-cli@amazon.com>"
    imported
gpg: Total number processed: 1
```

d. Download the AWS CLI signature file for the package you downloaded. It has the same path and name as the `.zip` file it corresponds to, but has the extension `.sig`. In the following examples, we save it to the current directory as a file named `awscliv2.sig`.

**Linux x86 (64-bit)**

For the latest version of the AWS CLI, use the following command block:

```bash
$ curl -o awscliv2.sig https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip.sig
```

For a specific version of the AWS CLI, append a hyphen and the version number to the filename. For this example the filename for version 2.0.30 would be `awscli-exe-linux-x86_64-2.0.30.zip.sig` resulting in the following command:

```bash
$ curl -o awscliv2.sig https://awscli.amazonaws.com/awscli-exe-linux-x86_64-2.0.30.zip.sig
```

For a list of versions, see the [AWS CLI version 2 Changelog](https://github.com/aws/awscli) on [GitHub](https://github.com).
Linux ARM

For the latest version of the AWS CLI, use the following command block:

```
$ curl -o awsc1iv2.sig https://awscli.amazonaws.com/awsc1i-exe-linux-aarch64.zip.sig
```

For a specific version of the AWS CLI, append a hyphen and the version number to the filename. For this example the filename for version 2.0.30 would be awsc1i-exe-linux-aarch64-2.0.30.zip.sig resulting in the following command:

```
$ curl -o awsc1iv2.sig https://awscli.amazonaws.com/awsc1i-exe-linux-aarch64-2.0.30.zip.sig
```

For a list of versions, see the [AWS CLI version 2 Changelog](https://github.com/aws/aws-cli) on GitHub.

e. Verify the signature, passing both the downloaded .sig and .zip file names as parameters to the gpg command.

```
$ gpg --verify awsc1iv2.sig awsc1iv2.zip
```

The output should look similar to the following.

```
gpg: Signature made Mon Nov  4 19:00:01 2019 PST
gpg: using RSA key FB5D B77F D5C1 18B8 0511 ADA8 A631 0ACC 4672 475C
```

```
gpg: Good signature from "AWS CLI Team <aws-cli@amazon.com>" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg: There is no indication that the signature belongs to the owner.
Primary key fingerprint: FB5D B77F D5C1 18B8 0511 ADA8 A631 0ACC 4672 475C
```

⚠ **Important**

The warning in the output is expected and doesn't indicate a problem. It occurs because there isn't a chain of trust between your personal PGP key (if you have one) and the AWS CLI PGP key. For more information, see [Web of trust](https://github.com/aws/aws-cli).
3. Unzip the installer. If your Linux distribution doesn't have a built-in unzip command, use an equivalent to unzip it. The following example command unzips the package and creates a directory named aws under the current directory.

```bash
$ unzip awscliv2.zip
```

4. Run the install program. The installation command uses a file named install in the newly unzipped aws directory. By default, the files are all installed to `/usr/local/aws-cli`, and a symbolic link is created in `/usr/local/bin`. The command includes sudo to grant write permissions to those directories.

```bash
$ sudo ./aws/install
```

You can install without sudo if you specify directories that you already have write permissions to. Use the following instructions for the `install` command to specify the installation location:

- Ensure that the paths you provide to the `-i` and `-b` parameters contain no volume name or directory names that contain any space characters or other white space characters. If there is a space, the installation fails.
- `--install-dir` or `-i` – This option specifies the directory to copy all of the files to. The default value is `/usr/local/aws-cli`.
- `--bin-dir` or `-b` – This option specifies that the main `aws` program in the install directory is symbolically linked to the file `aws` in the specified path. You must have write permissions to the specified directory. Creating a symlink to a directory that is already in your path eliminates the need to add the install directory to the user's `$PATH` variable. The default value is `/usr/local/bin`.

```bash
$ ./aws/install -i /usr/local/aws-cli -b /usr/local/bin
```

**Note**

To update your current installation of the AWS CLI version 2 to a newer version, add your existing symlink and installer information to construct the `install` command with the `--update` parameter.
$ sudo ./aws/install --bin-dir /usr/local/bin --install-dir /usr/local/aws-cli --update

To locate the existing symlink and installation directory, use the following steps:

1. Use the `which` command to find your symlink. This gives you the path to use with the `--bin-dir` parameter.

   ```bash
   $ which aws
   /usr/local/bin/aws
   ```

2. Use the `ls` command to find the directory that your symlink points to. This gives you the path to use with the `--install-dir` parameter.

   ```bash
   $ ls -l /usr/local/bin/aws
   lrwxrwxrwx 1 ec2-user ec2-user 49 Oct 22 09:49 /usr/local/bin/aws -> /usr/local/aws-cli/v2/current/bin/aws
   ```

5. Confirm the installation with the following command.

   ```bash
   $ aws --version
   aws-cli/2.15.30 Python/3.11.6 Linux/5.10.205-195.807.amzn2.x86_64 botocore/2.4.5
   ```

   If the `aws` command cannot be found, you might need to restart your terminal or follow the troubleshooting in [Troubleshoot errors](#).

(Optional) Verifying the integrity of your downloaded zip file

If you chose to manually download the AWS CLI version 2 installer package `.zip` in the above steps, you use can use the following steps to verify the signatures by using the GnuPG tool.

The AWS CLI version 2 installer package `.zip` files are cryptographically signed using PGP signatures. If there is any damage or alteration of the files, this verification fails and you should not proceed with installation.

1. Download and install the `gpg` command using your package manager. For more information about GnuPG, see the [GnuPG website](#).
2. To create the public key file, create a text file and paste in the following text.
For reference, the following are the details of the public key.

Key ID: A6310ACC4672
Type: RSA
Size: 4096/4096
Created: 2019-09-18
Expires: 2024-07-26
User ID: AWS CLI Team <aws-cli@amazon.com>
Key fingerprint: FB5D B77F D5C1 18B8 0511 ADA8 A631 0ACC 4672 475C

3. Import the AWS CLI public key with the following command, substituting \texttt{public-key-file-name} with the file name of the public key you created.
Download the AWS CLI signature file for the package you downloaded. It has the same path and name as the .zip file it corresponds to, but has the extension .sig. In the following examples, we save it to the current directory as a file named awscliv2.sig.

**Linux x86 (64-bit)**

For the latest version of the AWS CLI, use the following command block:

```
$ curl -o awscliv2.sig https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip.sig
```

For a specific version of the AWS CLI, append a hyphen and the version number to the filename. For this example the filename for version 2.0.30 would be awscli-exe-linux-x86_64-2.0.30.zip.sig resulting in the following command:

```
$ curl -o awscliv2.sig https://awscli.amazonaws.com/awscli-exe-linux-x86_64-2.0.30.zip.sig
```

For a list of versions, see the AWS CLI version 2 Changelog on GitHub.

**Linux ARM**

For the latest version of the AWS CLI, use the following command block:

```
$ curl -o awscliv2.sig https://awscli.amazonaws.com/awscli-exe-linux-aarch64.zip.sig
```

For a specific version of the AWS CLI, append a hyphen and the version number to the filename. For this example the filename for version 2.0.30 would be awscli-exe-linux-aarch64-2.0.30.zip.sig resulting in the following command:

```
```
5. Verify the signature, passing both the downloaded .sig and .zip file names as parameters to the gpg command.

```
$ gpg --verify awscliv2.sig awscliv2.zip
```

The output should look similar to the following.

```
gpg: Signature made Mon Nov  4 19:00:01 2019 PST
gpg:         using RSA key FB5D B77F D5C1 18B8 0511 ADA8 A631 0ACC 4672 475C
gpg: Good signature from "AWS CLI Team <aws-cli@amazon.com>" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg:         There is no indication that the signature belongs to the owner.
Primary key fingerprint: FB5D B77F D5C1 18B8 0511 ADA8 A631 0ACC 4672 475C
```

⚠️ Important

The warning in the output is expected and doesn't indicate a problem. It occurs because there isn't a chain of trust between your personal PGP key (if you have one) and the AWS CLI PGP key. For more information, see [Web of trust](#).

**macOS**

**Installation requirements**

- You know which release of the AWS CLI version 2 you'd like to install. For a list of versions, see the [AWS CLI version 2 Changelog](#) on GitHub.
- We support the AWS CLI version 2 on Apple-supported versions of 64-bit macOS.
- Because AWS doesn't maintain third-party repositories, we can't guarantee that they contain the latest version of the AWS CLI.

**Installation instructions**

You can install the AWS CLI version 2 on macOS in the following ways.
GUI installer

The following steps show how to install or update to the latest version of the AWS CLI version 2 by using the standard macOS user interface and your browser. If you are updating to the latest version, use the same installation method that you used for your current version.

1. In your browser, download your specific version of the AWS CLI by appending a hyphen and the version number to the filename.

   https://awscli.amazonaws.com/AWSCLIV2-version.number.pkg

   For this example, the filename for version 2.0.30 would be AWSCLIV2-2.0.30.pkg resulting in the following link: https://awscli.amazonaws.com/AWSCLIV2-2.0.30.pkg.

2. Run your downloaded file and follow the on-screen instructions. You can choose to install the AWS CLI version 2 in the following ways:

   - **For all users on the computer (requires sudo)**
     - You can install to any folder, or choose the recommended default folder of /usr/local/aws-cli.
     - The installer automatically creates a symlink at /usr/local/bin/aws that links to the main program in the installation folder you chose.

   - **For only the current user (doesn't require sudo)**
     - You can install to any folder to which you have write permission.
     - Due to standard user permissions, after the installer finishes, you must manually create a symlink file in your $PATH that points to the aws and aws_completer programs by using the following commands at the command prompt. If your $PATH includes a folder you can write to, you can run the following command without sudo if you specify that folder as the target's path. If you don't have a writable folder in your $PATH, you must use sudo in the commands to get permissions to write to the specified target folder. The default location for a symlink is /usr/local/bin/.

   ```
   $ sudo ln -s /folder-installed/aws-cli/aws /usr/local/bin/aws
   $ sudo ln -s /folder-installed/aws-cli/aws_completer /usr/local/bin/
   aws_completer
   ```
Note

You can view debug logs for the installation by pressing **Cmd+L** anywhere in the installer. This opens a log pane that enables you to filter and save the log. The log file is also automatically saved to `/var/log/install.log`.

3. To verify that the shell can find and run the `aws` command in your `$PATH`, use the following commands.

```bash
$ which aws
/usr/local/bin/aws
$ aws --version
aws-cli/2.15.30 Python/3.11.6 Darwin/23.3.0 botocore/2.4.5
```

If the `aws` command cannot be found, you might need to restart your terminal or follow the troubleshooting in *Troubleshoot errors*.

Command line installer - All users

If you have `sudo` permissions, you can install the AWS CLI version 2 for all users on the computer. We provide the steps in one easy to copy and paste group. See the descriptions of each line in the following steps.

For a specific version of the AWS CLI, append a hyphen and the version number to the filename. For this example the filename for version **2.0.30** would be `AWSCLIV2-2.0.30.pkg` resulting in the following command:

```bash
$ curl "https://awscli.amazonaws.com/AWSCLIV2-2.0.30.pkg" -o "AWSCLIV2.pkg"
$ sudo installer -pkg AWSCLIV2.pkg -target /
```

1. Download the file using the `curl` command. The `-o` option specifies the file name that the downloaded package is written to. In this example, the file is written to `AWSCLIV2.pkg` in the current folder.

   For a specific version of the AWS CLI, append a hyphen and the version number to the filename. For this example the filename for version **2.0.30** would be `AWSCLIV2-2.0.30.pkg` resulting in the following command:
$ curl "https://awscli.amazonaws.com/AWSCLIV2-2.0.30.pkg" -o "AWSCLIV2.pkg"

For a list of versions, see the AWS CLI version 2 Changelog on GitHub.

2. Run the standard macOS installer program, specifying the downloaded .pkg file as the source. Use the -pkg parameter to specify the name of the package to install, and the -target / parameter for which drive to install the package to. The files are installed to /usr/local/aws-cli, and a symlink is automatically created in /usr/local/bin. You must include sudo on the command to grant write permissions to those folders.

$ sudo installer -pkg ./AWSCLIV2.pkg -target /

After installation is complete, debug logs are written to /var/log/install.log.

3. To verify that the shell can find and run the aws command in your $PATH, use the following commands.

$ which aws
/usr/local/bin/aws
$ aws --version
aws-cli/2.15.30 Python/3.11.6 Darwin/23.3.0 botocore/2.4.5

If the aws command cannot be found, you might need to restart your terminal or follow the troubleshooting in Troubleshoot errors.

Command line - Current user

1. To specify which folder the AWS CLI is installed to, you must create an XML file. This file is an XML-formatted file that looks like the following example. Leave all values as shown, except you must replace the path /Users/myusername in line 9 with the path to the folder you want the AWS CLI version 2 installed to. The folder must already exist, or the command fails. This XML example specifies that the installer installs the AWS CLI in the folder /Users/myusername, where it creates a folder named aws-cli.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
```

Past releases
2. Download the pkg installer using the `curl` command. The `-o` option specifies the file name that the downloaded package is written to. In this example, the file is written to `AWSCLIV2.pkg` in the current folder.

For the specific version of the AWS CLI, append a hyphen and the version number to the filename. For this example the filename for version `2.0.30` would be `AWSCLIV2-2.0.30.pkg` resulting in the following command:

```
$ curl "https://awscli.amazonaws.com/AWSCLIV2-2.0.30.pkg" -o "AWSCLIV2.pkg"
```

For a list of versions, see the [AWS CLI version 2 Changelog](https://github.com/aws/aws-cli) on GitHub.

3. Run the standard macOS installer program with the following options:

   - Specify the name of the package to install by using the `-pkg` parameter.
   - Specify installing to a *current user only* by setting the `-target` parameter to `CurrentUserHomeDirectory`.
   - Specify the path (relative to the current folder) and name of the XML file that you created in the `-applyChoiceChangesXML` parameter.

The following example installs the AWS CLI in the folder `/Users/myusername/aws-cli`.

```
$ installer -pkg AWSCLIV2.pkg \
    -target CurrentUserHomeDirectory \
    -applyChoiceChangesXML choices.xml
```

4. Because standard user permissions typically don't allow writing to folders in your `$PATH`, the installer in this mode doesn't try to add the symlinks to the `aws` and `aws_completer`
programs. For the AWS CLI to run correctly, you must manually create the symlinks after the installer finishes. If your $PATH includes a folder you can write to and you specify the folder as the target's path, you can run the following command without sudo. If you don't have a writable folder in your $PATH, you must use sudo for permissions to write to the specified target folder. The default location for a symlink is /usr/local/bin/.

```
$ sudo ln -s /folder/installed/aws-cli/aws /usr/local/bin/aws
$ sudo ln -s /folder/installed/aws-cli/aws_completer /usr/local/bin/
aws_completer
```

After installation is complete, debug logs are written to /var/log/install.log.

5. To verify that the shell can find and run the aws command in your $PATH, use the following commands.

```
$ which aws
/usr/local/bin/aws
$ aws --version
aws-cli/2.15.30 Python/3.11.6 Darwin/23.3.0 botocore/2.4.5
```

If the aws command cannot be found, you might need to restart your terminal or follow the troubleshooting in *Troubleshoot errors*.

### Windows

**Installation requirements**

- You know which release of the AWS CLI version 2 you'd like to install. For a list of versions, see the [AWS CLI version 2 Changelog](https://github.com/aws/aws-cli) on GitHub.
- We support the AWS CLI on Microsoft-supported versions of 64-bit Windows.
- Admin rights to install software

**Installation instructions**

To update your current installation of AWS CLI version 2 on Windows, download a new installer each time you update to overwrite previous versions. AWS CLI is updated regularly. To see when the latest version was released, see the [AWS CLI version 2 Changelog](https://github.com/aws/aws-cli) on GitHub.
1. Download and run the AWS CLI MSI installer for Windows (64-bit) in one of the following ways:

- **Downloading and running the MSI installer:** To create your download link for a specific version of the AWS CLI, append a hyphen and the version number to the filename.

  https://awscli.amazonaws.com/AWSCLIV2-\texttt{version.number}.msi

  For this example the filename for version 2.0.30 would be AWSCLIV2-2.0.30.msi resulting in the following link: https://awscli.amazonaws.com/AWSCLIV2-2.0.30.msi.

- **Using the msiexec command:** Alternatively, you can use the MSI installer by adding the link to the msiexec command. For a specific version of the AWS CLI, append a hyphen and the version number to the filename.

  C:\> msiexec.exe /i https://awscli.amazonaws.com/AWSCLIV2-\texttt{version.number}.msi

  For this example the filename for version 2.0.30 would be AWSCLIV2-2.0.30.msi resulting in the following link https://awscli.amazonaws.com/AWSCLIV2-2.0.30.msi.

  C:\> msiexec.exe /i https://awscli.amazonaws.com/AWSCLIV2-2.0.30.msi

  For various parameters that can be used with msiexec, see msiexec on the Microsoft Docs website.

  For a list of versions, see the [AWS CLI version 2 Changelog](https://github.com/aws/aws-cli/releases) on [GitHub](https://github.com).

2. To confirm the installation, open the **Start** menu, search for cmd to open a command prompt window, and at the command prompt use the `aws --version` command.

  C:\> aws --version
  aws-cli/2.15.30 Python/3.11.6 Windows/10 exe/AMD64 prompt/off

  If Windows is unable to find the program, you might need to close and reopen the command prompt window to refresh the path, or follow the troubleshooting in *Troubleshoot errors*.
Troubleshooting AWS CLI install and uninstall errors

If you come across issues after installing or uninstalling the AWS CLI, see Troubleshoot errors for troubleshooting steps. For the most relevant troubleshooting steps, see the section called “Command not found errors”, the section called “The "aws --version" command returns a different version than you installed”, and the section called “The "aws --version" command returns a version after uninstalling the AWS CLI”.

Next steps

After completing the steps in the section called “Prerequisites” and installing the AWS CLI, you should perform a the section called “Setup”.

Build and install the AWS CLI from source

This topic describes how to install or update from source to the latest release of the AWS Command Line Interface (AWS CLI) on supported operating systems.

For information on the latest releases of AWS CLI, see the AWS CLI version 2 Changelog on GitHub.

⚠️ Important

AWS CLI versions 1 and 2 use the same aws command name. If you previously installed AWS CLI version 1, see Migrate from AWS CLI version 1 to version 2.

Why build from source?

The AWS CLI is available as pre-built installers for most platforms and environments as well as a Docker image.

Generally, these installers provide coverage for most use-cases. The instructions for installing from source are to help with the use-cases our installers do not cover. Some of these use-cases include the following:

• The pre-built installers do not support your environment. For example, ARM 32-bit is not supported by the pre-built installers.

• The pre-built installers have dependencies your environment lacks. For example, Alpine Linux uses musl, but the current installers require glibc causing the pre-built installers to not immediately work.

• The pre-built installers require resources your environment restricts access to. For example, security hardened systems might not give permissions to shared memory. This is needed for the frozen aws installer.

• The pre-built installers are often blockers for maintainers in package managers, as full control over the building process for code and packages is preferred. Building from source enables distribution maintainers a more streamlined process to keep the AWS CLI updated. Enabling maintainers provides customers more up-to-date versions of the AWS CLI when installing from a 3rd party package manager such as brew, yum, and apt.

• Customers that patch AWS CLI functionality require building and installing the AWS CLI from source. This is especially important for community members that want to test changes they've made to the source prior to contributing the change to the AWS CLI GitHub repository.

Quicksteps

Note

All code examples are assumed to run from the root of the source directory.
To build and install the AWS CLI from source, follow the steps in this section. The AWS CLI leverages GNU Autotools to install from source. In the simplest case, the AWS CLI can be installed from source by running the default example commands from the root of the AWS CLI GitHub repository.

1. **Setup all requirements for your environment.** This includes being able to run GNU Autotools generated files and Python 3.8 or later is installed.

2. In your terminal, navigate to the top level of the AWS CLI source folder and run the `.configure` command. This command checks the system for all required dependencies and generates a Makefile for building and installing the AWS CLI based on detected and specified configurations.

**Linux and macOS**

The following `.configure` command example sets the build configuration for the AWS CLI using default settings.

```
$ ./configure
```

**Windows PowerShell**

Before running any commands calling MSYS2, you must preserve your current working directory:

```
PS C:\> $env:CHERE_INVOKING = 'yes'
```

Then use the following `.configure` command example to set the build configuration for the AWS CLI using your local path to your Python executable, installing to C:\Program Files\AWSCLI, and downloading all dependencies.

```
PS C:\> C:\msys64\usr\bin\bash -lc " PYTHON='C:\path\to\python.exe' ./configure --prefix='C:\Program Files\AWSCLI' --with-download-deps "
```

For details, available configuration options, and default setting information, see the [section called “Step 2: Configuring the AWS CLI source installation”](#) section.
3. Run the `make` command. This command builds the AWS CLI according to your configuration settings.

   The following `make` command example builds with default options using your existing .`/configure` settings.

   **Linux and macOS**
   ```
   $ make
   ```

   **Windows PowerShell**
   ```
   PS C:\> C:\msys64\usr\bin\bash -lc "make"
   ```

   For details and available build options, see the [section called “Step 3: Building the AWS CLI”](#) section.

4. Run the `make install` command. This command installs your built AWS CLI to the configured location on your system.

   The following `make install` command example installs your built AWS CLI and creates symlinks in your configured locations using default command settings.

   **Linux and macOS**
   ```
   $ make install
   ```

   **Windows PowerShell**
   ```
   PS C:\> C:\msys64\usr\bin\bash -lc "make install"
   ```

   After installing, add the path to the AWS CLI using the following:

   ```
   PS C:\> $Env: PATH +=";C:\Program Files\AWSCLI\bin"
   ```

   For details and available install options, see the [section called “Step 4: Installing the AWS CLI”](#) section.
5. Confirm the AWS CLI successfully installed using the following command:

```
$ aws --version
aws-cli/2.15.30 Python/3.11.6 Windows/10 exe/AMD64 prompt/off
```

For troubleshooting steps for install errors see the section called “Troubleshooting AWS CLI install and uninstall errors” section.

**Step 1: Setup all requirements**

To build the AWS CLI from source you need the following completed beforehand:

- **Note**
  
  All code examples are assumed to run from the root of the source directory.

1. Download the AWS CLI source by either forking the AWS CLI GitHub repository or downloading the source tarball. The instructions is one of the following:

   - Fork and clone the [AWS CLI repository](https://github.com/aws/aws-cli) from GitHub. For more information, see [Fork a repo](https://help.github.com) in the [GitHub Docs](https).

   - Download the latest source tarball at [https://awscli.amazonaws.com/awscli.tar.gz](https://awscli.amazonaws.com/awscli.tar.gz) extract the contents using the following commands:

     ```
     $ curl -o awscli.tar.gz https://awscli.amazonaws.com/awscli.tar.gz
     $ tar -xzf awscli.tar.gz
     ```

   - **Note**
     
     To download a specific version, use the following link format: [https://awscli.amazonaws.com/awscli-versionnumber.tar.gz](https://awscli.amazonaws.com/awscli-versionnumber.tar.gz)

     For example, for version 2.10.0 the link is the following: [https://awscli.amazonaws.com/awscli-2.10.0.tar.gz](https://awscli.amazonaws.com/awscli-2.10.0.tar.gz)

     Source versions are available starting with version **2.10.0** of the AWS CLI.
(Optional) Verifying the integrity of your downloaded zip file by completing the following steps:

1. You can use the following steps to verify the signatures by using the GnuPG tool.

   The AWS CLI installer package .zip files are cryptographically signed using PGP signatures. If there is any damage or alteration of the files, this verification fails and you should not proceed with installation.

2. Download and install the gpg command using your package manager. For more information about GnuPG, see the [GnuPG website](https://www.gnupg.org).

3. To create the public key file, create a text file and paste in the following text.

```

4. Import the AWS CLI public key with the following command, substituting `public-key-file-name` with the file name of the public key you created.

```bash
$ gpg --import public-key-file-name
```

5. Download the AWS CLI signature file for the package you downloaded at [https://awscli.amazonaws.com/awscli.tar.gz.sig](https://awscli.amazonaws.com/awscli.tar.gz.sig). It has the same path and name as the tarball file it corresponds to, but has the extension .sig. Save it in the same path as the tarball file. Or use the following command block:

```bash
$ curl -o awscliv2.sig https://awscli.amazonaws.com/awscli.tar.gz.sig
```

6. Verify the signature, passing both the downloaded .sig and .zip file names as parameters to the gpg command.

```bash
$ gpg --verify awscliv2.sig awscli.tar.gz
```

The output should look similar to the following.

```
gpg: Signature made Mon Nov  4 19:00:01 2019 PST
gpg: using RSA key FB5D B77F D5C1 18B8 0511 ADA8 A631 0ACC 4672 475C
```
Important

The warning in the output is expected and doesn't indicate a problem. It occurs because there isn't a chain of trust between your personal PGP key (if you have one) and the AWS CLI PGP key. For more information, see Web of trust.

2. You have an environment that can run GNU Autotools generated files such as configure and Makefile. These files are widely portable across POSIX platforms.

Linux and macOS

If Autotools is not already installed in your environment or you need to update them, then follow the installation instructions found in How do I install the Autotools (as user)? or Basic Installation in the GNU documentation.

Windows PowerShell

Warning

We suggest if you are in a Windows environment, you use the pre-built installers. For install instructions on the pre-built installers, see the section called “Install/Update”

Since Windows does not come with a POSIX-compliant shell, you need to install additional software to install the AWS CLI from source. MSYS2 provides a collection of tools and libraries to help build and install Windows software, especially for the POSIX-based scripting that Autotools uses.

1. Install MSYS2. For information on installing and using MSYS2, see the install and usage instructions in the MSYS2 Documentation.

2. Open the MSYS2 terminal and install autotools using the following command.

$ pacman -S autotools
When using the configure, build, and install code examples in this guide for Windows, the default MSYS2 install path of `C:\msys64\usr\bin\bash` is assumed. When calling MSYS2 inside of PowerShell you'll be using the following format, with the bash command in quotes:

```
PS C:\> C:\msys64\usr\bin\bash -lc "command example"
```

The following command example calls the `./configure` command.

```
PS C:\> C:\msys64\usr\bin\bash -lc "./configure"
```

3. A Python 3.8 or later interpreter is installed. The minimum Python version required follows the same timelines as the official [Python support policy for AWS SDKs and Tools](https://aws.amazon.com/sdk-for-python/). An interpreter is only supported 6 months after its end-of-support date.

4. *(Optional)* Install all build and runtime Python library dependencies of the AWS CLI. The `./configure` command informs you if you are missing any dependencies and how to install them.

You can automatically install and use these dependencies through configuration, see the section called “Downloading dependencies” for more information.

**Step 2: Configuring the AWS CLI source installation**

Configuration for building and installing the AWS CLI is specified using the `configure` script. For the documentation of all configuration options, run the `configure` script with the `--help` option:

**Linux and macOS**

```
$ ./configure --help
```

**Windows PowerShell**

```
PS C:\> C:\msys64\usr\bin\bash -lc "./configure --help"
```
The most important options are the following:

- **Install location**
- **Python interpreter**
- **Downloading dependencies**
- **Install type**

**Install location**

The source installation of the AWS CLI uses two configurable directories to install the AWS CLI:

- **libdir** - Parent directory where the AWS CLI will be installed. The path to the AWS CLI installation is `<libdir-value>/aws-cli`. The default `libdir` value for Linux and macOS is `/usr/local/lib` making the default installation directory `/usr/local/lib/aws-cli`.
- **bindir** - Directory where the AWS CLI executables are installed. The default location is `/usr/local/bin`.

The following configure options control the directories used:

- **--prefix** - Sets the directory prefix to use for the installation. The default value for Linux and macOS is `/usr/local`.
- **--libdir** - Sets the `libdir` to use for installing the AWS CLI. The default value is `<prefix-value>/lib`. If both `--libdir` and `--prefix` are not specified, the default for Linux and macOS is `/usr/local/lib`.
- **--bindir** - Sets the `bindir` to use for installing the AWS CLI executables. The default value is `<prefix-value>/bin`. If both `bindir` and `--prefix` are not specified, the default for Linux and macOS is `/usr/local/bin`.

**Linux and macOS**

The following command example uses the `--prefix` option to do a local user install of the AWS CLI. This command installs the AWS CLI in `$HOME/.local/lib/aws-cli` and the executables in `$HOME/.local/bin`:

```
$ ./configure --prefix=$HOME/.local
```
The following command example uses the --libdir option to install the AWS CLI as an add-on application in the /opt directory. This command installs the AWS CLI at /opt/aws-cli and the executables at their default location of /usr/local/bin.

```
$ ./configure --libdir=/opt
```

Windows PowerShell

The following command example uses the --prefix option to do a local user install of the AWS CLI. This command installs the AWS CLI in $HOME/.local/lib/aws-cli and the executables in $HOME/.local/bin:

```
$ C:\msys64\usr\bin\bash -lc './configure --prefix='C:\Program Files\AWSCLI'"
```

The following command example uses the --libdir option to install the AWS CLI as an add-on application in the /opt directory. This command installs the AWS CLI at C:\Program Files\AWSCLI\opt\aws-cli.

**Python interpreter**

⚠️ **Note**

It is highly recommended to specify the Python interpreter when installing for Windows.

The ./configure script automatically selects an installed Python 3.8 or later interpreter to use in building and running the AWS CLI using the `AM_PATH_PYTHON` Autoconf macro.

The Python interpreter to use can be explicitly set using the PYTHON environment variable when running the configure script:

Linux and macOS

```
$ PYTHON=/path/to/python ./configure
```

Windows PowerShell

```
PS C:\> C:\msys64\usr\bin\bash -lc "PYTHON='C:\path\to\python' ./configure"
```
Downloading dependencies

By default, it is required that all build and runtime dependencies of the AWS CLI are already installed on the system. This includes any Python library dependencies. All dependencies are checked when the configure script is run, and if the system is missing any Python dependencies, the configure script errors out.

The following code example errors out when your system is missing dependencies:

Linux and macOS

```
/Users/username/.envs/env3.11/bin/python -m pip install --prefer-binary 'awscrt>=0.12.4,<0.17.0'
```

canfigure: error: "Python dependencies not met."

To automatically install the required Python dependencies, use the --with-download-deps option. When using this flag, the build process does the following:

- Skips the Python library dependencies check.
- Configures the settings to download all required Python dependencies and use only the downloaded dependencies to build the AWS CLI during the make build.

The following configure command example uses the --with-download-deps option to download and use the Python dependencies:

Linux and macOS

```
$ ./configure --with-download-deps
```

Windows PowerShell

```
PS C:\> C:\msys64\usr\bin\bash -lc "./configure --with-download-deps"
```

**Install type**

The source install process supports the following installation types:

- *system-sandbox* - (Default) Creates an isolated Python virtual environment, installs the AWS CLI into the virtual environment, and symlinks to the `aws` and `aws_completer` executable in the virtual environment. This install of the AWS CLI depends directly on the selected Python interpreter for its runtime.
This is a lightweight install mechanism to get the AWS CLI installed on a system and follows best Python practices by sandboxing the installation in a virtual environment. This installation is intended for customers that want to install the AWS CLI from source in the most frictionless way possible with the installation coupled to your installation of Python.

- **portable-exe** - Freezes the AWS CLI into a standalone executable that can be distributed to environments of similar architectures. This is the same process used to generate the official pre-built executables of the AWS CLI. The portable-exe freezes in a copy of the Python interpreter chosen in the configure step to use for the runtime of the AWS CLI. This allows it to be moved to other machines that may not have a Python interpreter.

This type of builds is useful because you can ensure your AWS CLI installation isn't coupled to the environment's installed Python version and you can distribute a build to other system that may not already have Python installed. This enables you to control the dependencies and security on the AWS CLI executables you use.

To configure the installation type, use the `--with-install-type` option and specify a value of portable-exe or system-sandbox.

The following `./configure` command example specifies a value of portable-exe:

**Linux and macOS**

```
$ ./configure --with-install-type=portable-exe
```

**Windows PowerShell**

```
PS C:\> C:\msys64\usr\bin\bash -lc "./configure --with-install-type=portable-exe"
```

### Step 3: Building the AWS CLI

Use the `make` command to build the AWS CLI using your configuration settings:

**Linux and macOS**

```
$ make
```
Note

When using the `make` command, the following steps are completed behind the scenes:

1. A virtual environment is created in the build directory using the Python `venv` module. The virtual environment is bootstrapped with a version of pip that is vendored in the Python standard library.

2. Copies Python library dependencies. Depending on if the `--with-download-deps` flag is specified in the `configure` command, this step does one of the following:
   - The `--with-download-deps` is specified. Python dependencies are pip installed. This includes wheel, setuptools, and all AWS CLI runtime dependencies. If you are building the portable-exe, pyinstaller is installed. These requirements are all specified in lock files generated from `pip-compile`.
   - The `--with-download-deps` is not specified. Python libraries from the Python interpreter's site package plus any scripts (e.g. pyinstaller) are copied into the virtual environment being used for the build.

3. Runs `pip install` directly on the AWS CLI codebase to do an offline, in-tree build and install of the AWS CLI into the build virtual environment. This install uses the pip flags `--no-build-isolation`, `--use-feature=in-tree-build`, `--no-cache-dir`, and `--no-index`.

4. (Optional) If the `--install-type` is set to portable-exe in the `configure` command, builds a standalone executable using `pyinstaller`.

Step 4: Installing the AWS CLI

The `make install` command installs your built AWS CLI to the configured location on the system.
Linux and macOS

The following command example installs the AWS CLI using your configuration and build settings:

```
$ make install
```

Windows PowerShell

The following command example installs the AWS CLI using your configuration and build settings, then adds an environment variable with the path for the AWS CLI:

```
PS C:\> C:\msys64\usr\bin\bash -lc " make install "
PS C:\> $Env: PATH +=";C:\Program Files\AWSCLI\bin";
```

The `make install` rule supports the `DESTDIR` variable. When specified, this variable prefixes the specified path to the already configured installation path when installing the AWS CLI. By default, no value is set for this variable.

Linux and macOS

The following code example uses a `--prefix=/usr/local` flag for configuring an install location, and then alters that destination using `DESTDIR=/tmp/stage` for the `make install` command. These commands result in the AWS CLI being installed at `/tmp/stage/usr/local/lib/aws-cli` and its executables located in `/tmp/stage/usr/local/bin`.

```
$ ./configure --prefix=/usr/local
$ make
$ make DESTDIR=/tmp/stage install
```

Windows PowerShell

The following code example uses a `--prefix=\awscli` flag for configuring an install location, and then alters that destination using `DESTDIR=C:\Program Files` for the `make install` command. These commands result in the AWS CLI being installed at `C:\Program Files\awscli`.

```
$ ./configure --prefix=\awscli
$ make
```
$ make DESTDIR='C:\Program Files' install

### Note

When running `make install`, the following steps are completed behind the scenes:

1. Moves one of the following to the configured install directory:
   - If the install type is `system-sandbox`, moves your built virtual environment.
   - If the install type is a `portable-exe`, moves your built standalone executable.
2. Creates symlinks for both the `aws` and `aws_completer` executables in your configured bin directory.

### Step 5: Verifying the AWS CLI installation

Confirm the AWS CLI successfully installed by using the following command:

```bash
$ aws --version
aws-cli/2.15.30 Python/3.11.6 Windows/10 exe/AMD64 prompt/off
```

If the `aws` command is not recognized, you may need to restart your terminal for new symlinks to update. If you come across additional issues after installing or uninstalling the AWS CLI, see [Troubleshoot errors](#) for common troubleshooting steps.

### Workflow examples

This section provides some basic workflow examples for installing from source.

#### Basic Linux and macOS install

The following example is a basic installation workflow where the AWS CLI is installed in the default location of `/usr/local/lib/aws-cli`.

```bash
$ cd path/to/cli/repository/
$ ./configure
$ make
$ make install
```
Automated Windows install

**Note**
You must run PowerShell as an Administrator to use this workflow.

MSYS2 can be used in an automated fashion in a CI setting, see Using MSYS2 in CI in the MSYS2 Documentation.

Downloaded Tarball

Download the `awscli.tar.gz` file, extract, and install the AWS CLI. When using the following commands, replace the following paths:

- `C:\msys64\usr\bin\bash` with the location of your MSYS2 path.
- `\awscli-2.x.x\` with the extracted `awscli.tar.gz` folder name.
- `PYTHON='C:\path\to\python.exe'` with your local Python path.

The following code example automates building and installing the AWS CLI from PowerShell using MSYS2, and specifies which local install of Python to use:

```powershell
PS C:\> curl -o awscli.tar.gz https://awscli.amazonaws.com/awscli.tar.gz  # Download the awscli.tar.gz file in the current working directory
PS C:\> tar -xvzf .\awscli.tar.gz  # Extract awscli.tar.gz file
PS C:\> cd .\awscli-2.x.x\  # Navigate to the root of the extracted files
PS C:\> $env:CHERE_INVOKING = 'yes'  # Preserve the current working directory
PS C:\> "C:\\msys64\\usr\\bin\\bash" -lc "PYTHON='C:\path\to\python.exe' ./configure --prefix='C:\Program Files\AWSCLI' --with-download-deps"
PS C:\> "C:\\msys64\\usr\\bin\\bash" -lc "make"
PS C:\> "C:\\msys64\\usr\\bin\\bash" -lc "make install"
PS C:\> $Env:PATH +=";C:\Program Files\AWSCLI\bin"
PS C:\> aws --version
aws-cli/2.15.30 Python/3.11.6 Windows/10 source-sandbox/AMD64 prompt/off
```

GitHub Repository

Download the `awscli.tar.gz` file, extract, and install the AWS CLI. When using the following commands, replace the following paths:
• `C:\msys64\usr\bin\bash` with the location of your MSYS2 path.

• `C:\path\to\cli\repository\` with the path to your cloned AWS CLI repository from GitHub. For more information, see Fork a repo in the GitHub Docs.

• `PYTHON='C:\path\to\python.exe'` with your local Python path.

The following code example automates building and installing the AWS CLI from PowerShell using MSYS2, and specifies which local install of Python to use:

```
PS C:\> cd C:\path\to\cli\repository\nPS C:\> $env:CHERE_INVOKING = 'yes' # Preserve the current working directory
PS C:\> C:\msys64\usr\bin\bash -lc " PYTHON='C:\path\to\python.exe' ./configure --prefix='C:\Program Files\AWSCLI' --with-download-deps "
PS C:\> C:\msys64\usr\bin\bash -lc "make"
PS C:\> C:\msys64\usr\bin\bash -lc "make install"
PS C:\> $Env:PATH +=";C:\Program Files\AWSCLI\bin"
PS C:\> aws --version
```

## Alpine Linux container

Below is an example Dockerfile that can be used to get a working installation of the AWS CLI in an Alpine Linux container as an alternative to pre-built binaries for Alpine. When using this example, replace `AWSCLI_VERSION` with your desired AWS CLI version number:

```
FROM python:3.8-alpine AS builder

ENV AWSCLI_VERSION=2.10.1

RUN apk add --no-cache \
    curl \
    make \
    cmake \
    gcc \
    g++ \
    libc-dev \
    libffi-dev \
    openssl-dev \
    && curl https://awscli.amazonaws.com/awscli-$AWSCLI_VERSION.tar.gz | tar -xz \
    && cd awscli-$AWSCLI_VERSION \n    && ./configure --prefix=/opt/aws-cli/ --with-download-deps \
```

Workflow examples
&& make 
&& make install

FROM python:3.8-alpine

RUN apk --no-cache add groff

COPY --from=builder /opt/aws-cli/ /opt/aws-cli/

ENTRYPOINT ["/opt/aws-cli/bin/aws"]

This image is built and the AWS CLI invoked from a container similar to the one that is built on Amazon Linux 2:

$ docker build --tag awscli-alpine .
$ docker run --rm -it awscli-alpine --version
aws-cli/2.2.1 Python/3.8.11 Linux/5.10.25-linuxkit source-sandbox/x86_64.alpine.3 prompt/off

The final size of this image is smaller than the size of the official AWS CLI Docker image. For information on the official Docker image, see the section called “Amazon ECR Public/Docker”.

Troubleshooting AWS CLI install and uninstall errors

For troubleshooting steps for install errors, see Troubleshoot errors for common troubleshooting steps. For the most relevant troubleshooting steps, see the section called “Command not found errors”, the section called “The "aws --version" command returns a different version than you installed”, and the section called “The "aws --version" command returns a version after uninstalling the AWS CLI”.

For any issues not covered in the troubleshooting guides, search the issues with the source-distribution label in the AWS CLI Repository on GitHub. If no existing issues cover your errors, create a new issue to receive help from the AWS CLI maintainers.

Next steps

After installing the AWS CLI, you should perform a the section called “Setup”.
Run the AWS CLI from the official Amazon ECR Public or Docker images

This topic describes how to run, version control, and configure the AWS CLI version 2 on Docker using either the official Amazon Elastic Container Registry Public (Amazon ECR Public) or Docker Hub image. For more information on how to use Docker, see Docker's documentation.

Official images provide isolation, portability, and security that AWS directly supports and maintains. This enables you to use the AWS CLI version 2 in a container-based environment without having to manage the installation yourself.

Topics

- Prerequisites
- Deciding between Amazon ECR Public and Docker Hub
- Run the official AWS CLI version 2 images
- Notes on interfaces and backwards compatibility of the official images
- Use specific versions and tags
- Update to the latest official image
- Share host files, credentials, environment variables, and configuration
- Shorten the docker run command

Prerequisites

You must have Docker installed. For installation instructions, see the Docker website.

To verify your installation of Docker, run the following command and confirm there is an output.

```
$ docker --version
Docker version 19.03.1
```

Deciding between Amazon ECR Public and Docker Hub

We recommend using Amazon ECR Public over Docker Hub for AWS CLI images. Docker Hub has stricter rate limiting for public consumers which can cause throttling issues. In addition, Amazon ECR Public replicates images in more than one region to provide strong availability and handle region outage issues.
For more information on Docker Hub rate limiting see Understanding Docker Hub Rate Limiting on the Docker website.

**Run the official AWS CLI version 2 images**

The first time you use the `docker run` command, the latest image is downloaded to your computer. Each subsequent use of the `docker run` command runs from your local copy.

To run the AWS CLI version 2 Docker images, use the `docker run` command.

Amazon ECR Public

The official AWS CLI version 2 Amazon ECR Public image is hosted on Amazon ECR Public in the `aws-cli/aws-cli` repository.

```
$ docker run --rm -it public.ecr.aws/aws-cli/aws-cli command
```

Docker Hub

The official AWS CLI version 2 Docker image is hosted on Docker Hub in the `amazon/aws-cli` repository.

```
$ docker run --rm -it amazon/aws-cli command
```

This is how the command functions:

- `docker run --rm -it repository/name` – The equivalent of the `aws` executable. Each time you run this command, Docker spins up a container of your downloaded image, and executes your `aws` command. By default, the image uses the latest version of the AWS CLI version 2.

For example, to call the `aws --version` command in Docker, you run the following.

Amazon ECR Public

```
$ docker run --rm -it public.ecr.aws/aws-cli/aws-cli --version
aws-cli/2.15.30 Python/3.7.3 Linux/4.9.184-linuxkit botocore/2.4.5dev10
```

Docker Hub

```
$ docker run --rm -it amazon/aws-cli --version
```
• `--rm` – Specifies to clean up the container after the command exits.

• `-it` – Specifies to open a pseudo-TTY with stdin. This enables you to provide input to the AWS CLI version 2 while it’s running in a container, for example, by using the `aws configure` and `aws help` commands. When choosing whether to omit `-it`, consider the following:

  • If you are running scripts, `-it` is not needed.
  
  • If you are experiencing errors with your scripts, omitting `-it` from your Docker call might fix the issue.

  • If you are trying to pipe output, `-it` might cause errors and omitting `-it` from your Docker call might resolve this issue. If you'd like to keep the `-it` flag, but still would like to pipe output, disabling the [client-side pager](https://docs.aws.amazon.com/cli/latest/manual/aws-configure.html) the AWS CLI uses by default should resolve the issue.

For more information about the `docker run` command, see the [Docker reference guide](https://docs.docker.com/reference/).  

**Notes on interfaces and backwards compatibility of the official images**

• The only tool supported on the image is the AWS CLI. Only the `aws` executable should ever be directly run. For example, even though `less` and `groff` are explicitly installed on the image, they should not be executed directly outside of an AWS CLI command.

• The `/aws` working directory is user controlled. The image will not write to this directory, unless instructed by the user in running an AWS CLI command.

• There are no backwards compatibility guarantees in relying on the latest tag. To guarantee backwards compatibility, you must pin to a specific `<major.minor.patch>` tag as those tags are immutable; they will only ever be pushed to once.

**Use specific versions and tags**

The official AWS CLI version 2 image has multiple versions you can use, starting with version 2.0.6. To run a specific version of the AWS CLI version 2, append the appropriate tag to your `docker run` command. The first time you use the `docker run` command with a tag, the latest image for that tag is downloaded to your computer. Each subsequent use of the `docker run` command with that tag runs from your local copy.

You can use two types of tags:
• latest – Defines the latest version of the AWS CLI version 2 for the image. We recommend you use the latest tag when you want the latest version of the AWS CLI version 2. However, there are no backward-compatibility guarantees when relying on this tag. The latest tag is used by default in the docker run command. To explicitly use the latest tag, append the tag to the container image name.

Amazon ECR Public

$ docker run --rm -it public.ecr.aws/aws-cli/aws-cli:latest command

Docker Hub

$ docker run --rm -it amazon/aws-cli:latest command

• <major.minor.patch> – Defines a specific version of the AWS CLI version 2 for the image. If you plan to use an official image in production, we recommend you use a specific version of the AWS CLI version 2 to ensure backward compatibility. For example, to run version 2.0.6, append the version to the container image name.

Amazon ECR Public

$ docker run --rm -it public.ecr.aws/aws-cli/aws-cli:2.0.6 command

Docker Hub

$ docker run --rm -it amazon/aws-cli:2.0.6 command

**Update to the latest official image**

Because the latest image is downloaded to your computer only the first time you use the docker run command, you need to manually pull an updated image. To manually update to the latest version, we recommend you pull the latest tagged image. Pulling the image downloads the latest version to your computer.

Amazon ECR Public

$ docker pull public.ecr.aws/aws-cli/aws-cli:latest
Share host files, credentials, environment variables, and configuration

Because the AWS CLI version 2 is run in a container, by default the CLI can't access the host file system, which includes configuration and credentials. To share the host file system, credentials, and configuration to the container, mount the host system's ~/.aws directory to the container at /root/.aws with the -v flag to the `docker run` command. This allows the AWS CLI version 2 running in the container to locate host file information.

### Amazon ECR Public

**Linux and macOS**

```
$ docker run --rm -it -v ~/.aws:/root/.aws public.ecr.aws/aws-cli/aws-cli command
```

**Windows Command Prompt**

```

```

### Docker Hub

**Linux and macOS**

```
$ docker run --rm -it -v ~/.aws:/root/.aws amazon/aws-cli command
```

**Windows Command Prompt**

```
$ docker run --rm -it -v %userprofile%\.aws:/root/.aws amazon/aws-cli command
```

**Windows PowerShell**

```
C:\> docker run --rm -it -v $env:userprofile\.aws:/root/.aws amazon/aws-cli command
```
C:\> docker run --rm -it -v $env:userprofile\aws:/root/.aws  amazon/aws-cli command

For more information about the -v flag and mounting, see the Docker reference guide.

⚠️ Note
For information on config and credentials files, see the section called “Configuration and credential file settings”.

Example 1: Providing credentials and configuration

In this example, we're providing host credentials and configuration when running the s3 ls command to list your buckets in Amazon Simple Storage Service (Amazon S3). The below examples use the default location for AWS CLI credentials and configuration files, to use a different location, change the file path.

Amazon ECR Public

Linux and macOS

$ docker run --rm -it -v ~/.aws:/root/.aws public.ecr.aws/aws-cli/aws-cli s3 ls
2020-03-25 00:30:48 aws-cli-docker-demo

Windows Command Prompt

$ docker run --rm -it -v %userprofile%\.aws:/root/.aws public.ecr.aws/aws-cli/aws-cli s3 ls
2020-03-25 00:30:48 aws-cli-docker-demo

Windows PowerShell

C:\> docker run --rm -it -v $env:userprofile\aws:/root/.aws public.ecr.aws/aws-cli/aws-cli s3 ls

Docker Hub

Linux and macOS
You can call specific system's environment variables using the `-e` flag. To use an environment variable, call it by name.

Amazon ECR Public

**Linux and macOS**

```
$ docker run --rm -it -v ~/.aws:/root/.aws -e ENVVAR_NAME public.ecr.aws/aws-cli/ aws-cli s3 ls
2020-03-25 00:30:48 aws-cli-docker-demo
```

**Windows Command Prompt**

```
$ docker run --rm -it -v %userprofile%\aws:/root/.aws -e ENVVAR_NAME public.ecr.aws/aws-cli/aws-cli s3 ls
2020-03-25 00:30:48 aws-cli-docker-demo
```

**Windows PowerShell**

```
C:> docker run --rm -it -v $env:userprofile\aws:/root/.aws -e ENVVAR_NAME public.ecr.aws/aws-cli/aws-cli s3 ls
```

**Docker Hub**

**Linux and macOS**

```
$ docker run --rm -it -v ~/.aws:/root/.aws -e ENVVAR_NAME amazon/aws-cli s3 ls
```

Share host files, credentials, environment variables, and configuration
Example 2: Downloading an Amazon S3 file to your host system

For some AWS CLI version 2 commands, you can read files from the host system in the container or write files from the container to the host system.

In this example, we download the S3 object s3://aws-cli-docker-demo/hello to your local file system by mounting the current working directory to the container's /aws directory. By downloading the hello object to the container's /aws directory, the file is saved to the host system's current working directory also.

Amazon ECR Public

**Linux and macOS**

```bash
download: s3://aws-cli-docker-demo/hello to ./hello
```

**Windows Command Prompt**

```bash
download: s3://aws-cli-docker-demo/hello to ./hello
```

**Windows PowerShell**

```bash
C:\> docker run --rm -it -v $env:userprofile\.aws:/root\.aws -e ENVVAR_NAME amazon/aws-cli s3 ls
```
Docker Hub

**Linux and macOS**

```bash
download: s3://aws-cli-docker-demo/hello to ./hello
```

**Windows Command Prompt**

```bash
docker run --rm -it -v %userprofile%\aws:/root/.aws -v %cd%:/aws amazon/aws-cli s3 cp s3://aws-cli-docker-demo/hello .
download: s3://aws-cli-docker-demo/hello to ./hello
```

**Windows PowerShell**

```bash
docker run --rm -it -v $env:userprofile\aws:/root/.aws -v $pwd\aws:/aws amazon/aws-cli s3 cp s3://aws-cli-docker-demo/hello .
```

To confirm the downloaded file exists in the local file system, run the following.

**Linux and macOS**

```bash
cat hello
Hello from Docker!
```

**Windows PowerShell**

```bash
type hello
Hello from Docker!
```

**Example 3: Using your AWS_PROFILE environment variable**

You can call specific system's environment variables using the `-e` flag. Call each environment variable you'd like to use. In this example, we're providing host credentials, configuration, and the
**AWS_PROFILE** environment variable when running the `s3 ls` command to list your buckets in Amazon Simple Storage Service (Amazon S3).

### Amazon ECR Public

**Linux and macOS**

```bash
$ docker run --rm -it -v ~/.aws:/root/.aws -e AWS_PROFILE public.ecr.aws/aws-cli/aws-cli s3 ls
2020-03-25 00:30:48 aws-cli-docker-demo
```

**Windows Command Prompt**

```bash
$ docker run --rm -it -v %userprofile%\.aws:/root/.aws -e AWS_PROFILE public.ecr.aws/aws-cli/aws-cli s3 ls
2020-03-25 00:30:48 aws-cli-docker-demo
```

**Windows PowerShell**

```bash
C:\> docker run --rm -it -v $env:userprofile\.aws:/root/.aws -e AWS_PROFILE public.ecr.aws/aws-cli/aws-cli s3 ls
```

### Docker Hub

**Linux and macOS**

```bash
$ docker run --rm -it -v ~/.aws:/root/.aws -e AWS_PROFILE amazon/aws-cli s3 ls
2020-03-25 00:30:48 aws-cli-docker-demo
```

**Windows Command Prompt**

```bash
$ docker run --rm -it -v %userprofile%\.aws:/root/.aws -e AWS_PROFILE amazon/aws-cli s3 ls
2020-03-25 00:30:48 aws-cli-docker-demo
```

**Windows PowerShell**

```bash
C:\> docker run --rm -it -v $env:userprofile\.aws:/root/.aws -e AWS_PROFILE amazon/aws-cli s3 ls
```
Shorten the docker run command

To shorten the `docker run` command, we suggest you use your operating system's ability to create a symbolic link (symlink) or alias in Linux and macOS, or `doskey` in Windows. To set the `aws` alias, you can run one of the following commands.

- For basic access to `aws` commands, run the following.

  **Amazon ECR Public**

  **Linux and macOS**

  ```
  $ alias aws='docker run --rm -it public.ecr.aws/aws-cli/aws-cli'
  ```

  **Windows Command Prompt**

  ```
  C:\> doskey aws=docker run --rm -it public.ecr.aws/aws-cli/aws-cli $*
  ```

  **Windows PowerShell**

  ```
  C:\> Function AWSCLI {docker run --rm -it public.ecr.aws/aws-cli/aws-cli $args}
  Set-Alias -Name aws -Value AWSCLI
  ```

  **Docker Hub**

  **Linux and macOS**

  ```
  $ alias aws='docker run --rm -it amazon/aws-cli'
  ```

  **Windows Command Prompt**

  ```
  C:\> doskey aws=docker run --rm -it amazon/aws-cli $*
  ```

  **Windows PowerShell**

  ```
  C:\> Function AWSCLI {docker run --rm -it amazon/aws-cli $args}
  Set-Alias -Name aws -Value AWSCLI
  ```
For access to the host file system and configuration settings when using aws commands, run the following.

**Amazon ECR Public**

**Linux and macOS**

```
$ alias aws='docker run --rm -it -v ~/.aws:/root/.aws -v $(pwd):/aws public.ecr.aws/aws-cli/aws-cli'
```

**Windows Command Prompt**

```
C:\> doskey aws=docker run --rm -it -v %userprofile%\.aws:/root/.aws -v %cd%:/aws public.ecr.aws/aws-cli/aws-cli $*
```

**Windows PowerShell**

```
C:\> Function AWSCLI {docker run --rm -it -v $env:userprofile\.aws:/root/.aws -v $pwd\aws:/aws public.ecr.aws/aws-cli/aws-cli $args}
Set-Alias -Name aws -Value AWSCLI
```

**Docker Hub**

**Linux and macOS**

```
$ alias aws='docker run --rm -it -v ~/.aws:/root/.aws -v $(pwd):/aws amazon/aws-cli'
```

**Windows Command Prompt**

```
C:\> doskey aws=docker run --rm -it -v %userprofile%\.aws:/root/.aws -v %cd%:/aws amazon/aws-cli $*
```

**Windows PowerShell**

```
C:\> Function AWSCLI {docker run --rm -it -v $env:userprofile\.aws:/root/.aws -v $pwd\aws:/aws amazon/aws-cli $args}
Set-Alias -Name aws -Value AWSCLI
```

To assign a specific version to use in your aws alias, append your version tag.
After setting your alias, you can run the AWS CLI version 2 from within a container as if it's installed on your host system.
Set up the AWS CLI

This topic explains how to quickly configure basic settings that the AWS Command Line Interface (AWS CLI) uses to interact with AWS. These include your security credentials, the default output format, and the default AWS Region.

Topics

- Gather your credential information for programmatic access
- Setting up new configuration and credentials
- Using existing configuration and credentials files

Gather your credential information for programmatic access

You'll need programmatic access if you want to interact with AWS outside of the AWS Management Console. For authentication and credential instructions, choose one of the following options:

<table>
<thead>
<tr>
<th>Authentication type</th>
<th>Purpose</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>IAM Identity Center workforce users short-term credentials</td>
<td>(Recommended) Use short-term credentials for an IAM Identity Center workforce user. Security best practice is to use AWS Organizations with IAM Identity Center. It combines short-term credentials with a user directory, such as the built-in IAM Identity Center directory or Active Directory.</td>
<td>the section called “IAM Identity Center authentication”</td>
</tr>
<tr>
<td>IAM user short-term credentials</td>
<td>Use IAM user short-term credentials, which are</td>
<td>the section called “Short-term credentials”</td>
</tr>
<tr>
<td>Authentication type</td>
<td>Purpose</td>
<td>Instructions</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IAM or IAM Identity Center users on an Amazon EC2 instance.</td>
<td>more secure than long-term credentials. If your credentials are compromised, there is a limited time they can be used before they expire.</td>
<td></td>
</tr>
<tr>
<td>assume roles for permissions</td>
<td>Use Amazon EC2 instance metadata to query for temporary credentials using the role assigned to the Amazon EC2 instance.</td>
<td>the section called “Use credentials for Amazon EC2 instance metadata”</td>
</tr>
<tr>
<td>IAM user long-term credentials</td>
<td>(Not recommended) Use long-term credentials, which have no expiration.</td>
<td>the section called “IAM users”</td>
</tr>
<tr>
<td>External storage of IAM or IAM Identity Center workforce users</td>
<td>(Not recommended) Pair another credential method but store credential values in a location outside of the AWS CLI. This method is only as secure as the external location the credentials are stored.</td>
<td>the section called “External credentials”</td>
</tr>
</tbody>
</table>

**Setting up new configuration and credentials**

The AWS CLI stores your configuration and credential information in a *profile* (a collection of settings) in the credentials and config files.
There are primarily two methods to quickly get setup:

- Configuring using AWS CLI commands
- Manually editing the credentials and config files

The following examples use sample values for each of the authentication methods. Replace sample values with your own.

**Configuring using AWS CLI commands**

For general use, the `aws configure` or `aws configure sso` commands in your preferred terminal are the fastest way to set up your AWS CLI installation. Based on the credential method you prefer, the AWS CLI prompts you for the relevant information. By default, the information in this profile is used when you run an AWS CLI command that doesn't explicitly specify a profile to use.

For more information on the credentials and config files, see [Configuration and credential file settings](#).

**IAM Identity Center (SSO)**

This example is for AWS IAM Identity Center using the `aws configure sso` wizard. For more information, see the section called “Configure automatic token refresh”.

```
$ aws configure sso
SSO session name (Recommended): my-sso
SSO start URL [None]: https://my-sso-portal.awsapps.com/start
SSO region [None]: us-east-1

Attempting to automatically open the SSO authorization page in your default browser.

There are 2 AWS accounts available to you.
> DeveloperAccount, developer-account-admin@example.com (111122223333)
  ProductionAccount, production-account-admin@example.com (444455556666)

Using the account ID 111122223333

There are 2 roles available to you.
> ReadOnly
  FullAccess
```
Using the role name "ReadOnly"

CLI default client Region [None]: **us-west-2**
CLI default output format [None]: **json**
CLI profile name [123456789011_ReadOnly]: **user1**

IAM Identity Center (Legacy SSO)

This example is for the legacy method of AWS IAM Identity Center using the `aws configure sso` wizard. To use the legacy SSO, leave the session name blank. For more information, see the section called “Configure legacy non-refreshable”.

```bash
$ aws configure sso
SSO session name (Recommended):
SSO start URL [None]: **https://my-sso-portal.awsapps.com/start**
SSO region [None]: **us-east-1**

SSO authorization page has automatically been opened in your default browser. Follow the instructions in the browser to complete this authorization request.

There are 2 AWS accounts available to you.
> DeveloperAccount, developer-account-admin@example.com (111122223333)
  ProductionAccount, production-account-admin@example.com (444455556666)

Using the account ID **111122223333**

There are 2 roles available to you.
> ReadOnly
  FullAccess

Using the role name "ReadOnly"

CLI default client Region [None]: **us-west-2**
CLI default output format [None]: **json**
CLI profile name [123456789011_ReadOnly]: **user1**

Short-term credentials

This example is for the short-term credentials from AWS Identity and Access Management. The `aws configure` wizard is used to set initial values and then the `aws configure set` command assigns the last value needed. For more information, see the section called “Short-term credentials”.

IAM role

This example is for assuming an IAM role. Profiles that use IAM roles pull credentials from another profile, and then apply IAM role permissions. In the following examples, default is the source profile for credentials and user1 borrows the same credentials then assumes a new role. There is no wizard for this process, therefore each value is set using the `aws configure set` command. For more information, see the section called “IAM roles”.

```bash
$ aws configure set role_arn arn:aws:iam::123456789012:role/defaultrole
$ aws configure set source_profile default
$ aws configure set role_session_name session_user1
$ aws configure set region us-west-2
$ aws configure set output json
```

Amazon EC2 instance metadata credentials

This example is for the credentials obtained from the hosting Amazon EC2 instance metadata. There is no wizard for this process, therefore each value is set using the `aws configure set` command. For more information, see the section called “Use credentials for Amazon EC2 instance metadata”.

```bash
$ aws configure set role_arn arn:aws:iam::123456789012:role/defaultrole
$ aws configure set credential_source Ec2InstanceMetadata
$ aws configure set region us-west-2
$ aws configure set output json
```
Long-term credentials

⚠️ **Warning**

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](https://aws.amazon.com/iam/).

This example is for the long-term credentials from AWS Identity and Access Management. For more information, see the section called “IAM users”.

```
$ aws configure
AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
Default region name [None]: us-west-2
Default output format [None]: json
```

For more detailed information on authentication and credential methods see [Authentication and access credentials](https://docs.aws.amazon.com/cli/latest/userguide/cli-reference-access-keys.html).

**Manually editing the credentials and config files**

When copy and pasting information, we suggest manually editing the config and credentials file. Based on the credential method you prefer, the files are setup in a different way.

The files are stored in your home directory under the `.aws` folder. Where you find your home directory location varies based on the operating system, but is referred to using the environment variables `%UserProfile%` in Windows and `$HOME` or `~` (tilde) in Unix-based systems. For more information on where these settings are stored, see the section called “Where are configuration settings stored?”.

The following examples show a default profile and a profile named `user1` and use sample values. Replace sample values with your own. For more information on the credentials and config files, see [Configuration and credential file settings](https://docs.aws.amazon.com/cli/latest/userguide/cli-configure-files.html).

**IAM Identity Center (SSO)**

This example is for AWS IAM Identity Center. For more information, see the section called “Configure automatic token refresh”.

### Using existing configuration and credentials files

If you have existing configuration and credentials files, these can be used for the AWS CLI.

To use the `config` and `credentials` files, move them to the folder named `.aws` in your home directory. Where you find your home directory location varies based on the operating system, but is referred to using the environment variables `%UserProfile%` in Windows and `$HOME` or `~` (tilde) in Unix-based systems.

You can specify a non-default location for the `config` and `credentials` files by setting the `AWS_CONFIG_FILE` and `AWS_SHARED_CREDENTIALS_FILE` environment variables to another local path. See [Environment variables to configure the AWS CLI](#) for details.

For more detailed information on configuration and credentials files, see the section called “Configuration and credential file settings”. 
Configure the AWS CLI

This section explains how to configure the settings that the AWS Command Line Interface (AWS CLI) uses to interact with AWS. These include the following:

- **Credentials** identify who is calling the API. Access credentials are used to encrypt the request to the AWS servers to confirm your identity and retrieve associated permissions policies. These permissions determine the actions you can perform. For information on setting up your credentials, see [Authentication and access credentials](#).

- **Other configuration details** to tell the AWS CLI how to process requests, such as the default output format and the default AWS Region.

**Note**

AWS requires that all incoming requests are cryptographically signed. The AWS CLI does this for you. The "signature" includes a date/time stamp. Therefore, you must ensure that your computer's date and time are set correctly. If you don't, and the date/time in the signature is too far off of the date/time recognized by the AWS service, AWS rejects the request.

Configuration and credentials precedence

Credentials and configuration settings are located in multiple places, such as the system or user environment variables, local AWS configuration files, or explicitly declared on the command line as a parameter. Certain locations take precedence over others. The AWS CLI credentials and configuration settings take precedence in the following order:

1. **Command line options** – Overrides settings in any other location, such as the `--region`, `--output`, and `--profile` parameters.

2. **Environment variables** – You can store values in your system's environment variables.

3. **Assume role** – Assume the permissions of an IAM role through configuration or the `aws sts assume-role` command.

4. **Assume role with web identity** – Assume the permissions of an IAM role using web identity through configuration or the `aws sts assume-role` command.
5. **AWS IAM Identity Center** – The IAM Identity Center configuration settings stored in the config file are updated when you run the `aws configure sso` command. Credentials are then authenticated when you run the `aws sso login` command. The config file is located at `~/.aws/config` on Linux or macOS, or at `C:\Users\USERNAME\.aws\config` on Windows.

6. **Credentials file** – The credentials and config file are updated when you run the command `aws configure`. The credentials file is located at `~/.aws/credentials` on Linux or macOS, or at `C:\Users\USERNAME\.aws\credentials` on Windows.

7. **Custom process** – Get your credentials from an external source.

8. **Configuration file** – The credentials and config file are updated when you run the command `aws configure`. The config file is located at `~/.aws/config` on Linux or macOS, or at `C:\Users\USERNAME\.aws\config` on Windows.

9. **Container credentials** – You can associate an IAM role with each of your Amazon Elastic Container Service (Amazon ECS) task definitions. Temporary credentials for that role are then available to that task’s containers. For more information, see [IAM Roles for Tasks](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/iam-roles-for-tasks.html) in the Amazon Elastic Container Service Developer Guide.

10. **Amazon EC2 instance profile credentials** – You can associate an IAM role with each of your Amazon Elastic Compute Cloud (Amazon EC2) instances. Temporary credentials for that role are then available to code running in the instance. The credentials are delivered through the Amazon EC2 metadata service. For more information, see [IAM Roles for Amazon EC2](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html) in the Amazon EC2 User Guide for Linux Instances and [Using Instance Profiles](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_for_instances.html) in the IAM User Guide.

Configuration and credential file settings

You can save your frequently used configuration settings and credentials in files that are maintained by the AWS CLI.

The files are divided into profiles. By default, the AWS CLI uses the settings found in the profile named default. To use alternate settings, you can create and reference additional profiles.

You can override an individual setting by either setting one of the supported environment variables, or by using a command line parameter. For more information on configuration setting precedence, see Configure the AWS CLI.

Note
For information on setting up your credentials, see Authentication and access credentials.

Format of the configuration and credential files

The config and credentials files are organized into sections. Sections include profiles, sso-sessions, and services. A section is a named collection of settings, and continues until another section definition line is encountered. Multiple profiles and sections can be stored in the config and credentials files.

These files are plaintext files that use the following format:

- Section names are enclosed in brackets [] such as [default], [profile user1], and [sso-session].
- All entries in a section take the general form of setting_name=value.
• Lines can be commented out by starting the line with a hash character (#).

The config and credentials files contain the following section types:

- **Section type: profile**
- **Section type: sso-session**
- **Section type: services**

**Section type: profile**

The AWS CLI stores

Depending on the file, profile section names use the following format:

- **Config file:** [default] [profile user1]
- **Credentials file:** [default] [user1]

Do _not_ use the word profile when creating an entry in the credentials file.

Each profile can specify different credentials and can also specify different AWS Regions and output formats. When naming the profile in a config file, include the prefix word "profile", but do not include it in the credentials file.

The following examples show a credentials and config file with two profiles, region, and output specified. The first [default] is used when you run a AWS CLI command with no profile specified. The second is used when you run a AWS CLI command with the --profile user1 parameter.

**IAM Identity Center (SSO)**

This example is for AWS IAM Identity Center. For more information, see the section called “Configure automatic token refresh”.

**Credentials file**

The credentials file is not used for this authentication method.

**Config file**

```

IAM Identity Center (Legacy SSO)

This example is for the legacy method of AWS IAM Identity Center. For more information, see the section called “Configure legacy non-refreshable”.

**Credentials file**

The credentials file is not used for this authentication method.

**Config file**

```ini
[default]
sso_start_url = https://my-sso-portal.awsapps.com/start
sso_region = us-east-1
sso_account_id = 111122223333
sso_role_name = readOnly
region = us-west-2
output = text

[profile user1]
sso_start_url = https://my-sso-portal.awsapps.com/start
sso_region = us-east-1
sso_account_id = 444455556666
sso_role_name = readOnly

```

IAM role

This example is for assuming an IAM role. Profiles that use IAM roles pull credentials from another profile, and then apply IAM role permissions. In the following examples, default is the source profile for credentials and user1 borrows the same credentials then assumes a new role. For more information, see the section called “IAM roles”.

Credentials file

The credentials file depends on what authentication your source profile uses. For the following example, the source profile uses short-term credentials.
[default]

⚠️ **Warning**

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](https://aws.amazon.com/iam/).

This example is for the long-term credentials from AWS Identity and Access Management. For more information, see the section called “IAM users”.

For more information and additional authorization and credential methods see, see the section called “IAM users”.

**Section type: sso-session**

The sso-session section of the config file is used to group configuration variables for acquiring SSO access tokens, which can then be used to acquire AWS credentials. The following settings are used:
• (Required) **sso_start_url**

• (Required) **sso_region**

• **sso_account_id**

• **sso_role_name**

• **sso_registration_scopes**

You define an sso-session section and associate it to a profile. sso_region and sso_start_url must be set within the sso-session section. Typically, sso_account_id and sso_role_name must be set in the profile section so that the SDK can request SSO credentials.

The following example configures the SDK to request SSO credentials and supports automated token refresh:

```ini
[profile dev]
sso_session = my-sso
sso_account_id = 111122223333
sso_role_name = SampleRole

[sso-session my-sso]
sso_region = us-east-1
sso_start_url = https://my-sso-portal.awsapps.com/start
```

This also allows sso-session configurations to be reused across multiple profiles:

```ini
[profile dev]
sso_session = my-sso
sso_account_id = 111122223333
sso_role_name = SampleRole

[profile prod]
sso_session = my-sso
sso_account_id = 111122223333
sso_role_name = SampleRole2

[sso-session my-sso]
sso_region = us-east-1
sso_start_url = https://my-sso-portal.awsapps.com/start
```
However, `sso_account_id` and `sso_role_name` aren't required for all scenarios of SSO token configuration. If your application only uses AWS services that support bearer authentication, then traditional AWS credentials are not needed. Bearer authentication is an HTTP authentication scheme that uses security tokens called bearer tokens. In this scenario, `sso_account_id` and `sso_role_name` aren't required. See the individual guide for your AWS service to determine if it supports bearer token authorization.

Additionally, registration scopes can be configured as part of a `sso-session`. Scope is a mechanism in OAuth 2.0 to limit an application's access to a user's account. An application can request one or more scopes, and the access token issued to the application will be limited to the scopes granted. These scopes define the permissions requested to be authorized for the registered OIDC client and access tokens retrieved by the client. The following example sets `sso_registration_scopes` to provide access for listing accounts/roles:

```
[sso-session my-sso]
sso_region = us-east-1
sso_start_url = https://my-sso-portal.awsapps.com/start
sso_registration_scopes = sso:account:access
```

The authentication token is cached to disk under the `~/.aws/sso/cache` directory with a filename based on the session name.

For more information on this configuration type, see the section called “Configure automatic token refresh”.

**Section type: services**

The `services` section is a group of settings that configures custom endpoints for AWS service requests. A profile then is linked to a `services` section.

```
[profile dev]
services = my-services
```

The `services` section is separated into subsections by `<SERVICE> =` lines, where `<SERVICE>` is the AWS service identifier key. The AWS service identifier is based on the API model’s `serviceId` by replacing all spaces with underscores and lowercasing all letters. For a list of all service identifier keys to use in the `services` section, see Use endpoints in the AWS CLI. The service identifier key is followed by nested settings with each on its own line and indented by two spaces.
The following example configures the endpoint to use for requests made to the Amazon DynamoDB service in the `my-services` section that is used in the `dev` profile. Any immediately following lines that are indented are included in that subsection and apply to that service.

```python
[profile dev]
services = my-services

[services my-services]
dynamodb =
  endpoint_url = http://localhost:8000
```

For more information on service-specific endpoints, see Use endpoints in the AWS CLI.

If your profile has role-based credentials configured through a `source_profile` parameter for IAM assume role functionality, the SDK only uses service configurations for the specified profile. It does not use profiles that are role chained to it. For example, using the following shared config file:

```python
[profile A]
credential_source = Ec2InstanceMetadata
endpoint_url = https://profile-a-endpoint.aws/

[profile B]
source_profile = A
role_arn = arn:aws:iam::123456789012:role/roleB
services = profileB

[services profileB]
ec2 =
  endpoint_url = https://profile-b-ec2-endpoint.aws
```

If you use profile B and make a call in your code to Amazon EC2, the endpoint resolves as `https://profile-b-ec2-endpoint.aws`. If your code makes a request to any other service, the endpoint resolution will not follow any custom logic. The endpoint does not resolve to the global endpoint defined in profile A. For a global endpoint to take effect for profile B, you would need to set `endpoint_url` directly within profile B.

**Where are configuration settings stored?**

The AWS CLI stores sensitive credential information that you specify with `aws configure` in a local file named `credentials`, in a folder named `.aws` in your home directory. The less sensitive
configuration options that you specify with `aws configure` are stored in a local file named `config`, also stored in the `.aws` folder in your home directory.

**Storing credentials in the config file**

You can keep all of your profile settings in a single file as the AWS CLI can read credentials from the `config` file. If there are credentials in both files for a profile sharing the same name, the keys in the credentials file take precedence. We suggest keeping credentials in the `credentials` files. These files are also used by the various language software development kits (SDKs). If you use one of the SDKs in addition to the AWS CLI, confirm if the credentials should be stored in their own file.

Where you find your home directory location varies based on the operating system, but is referred to using the environment variables `%UserProfile%` in Windows and `$HOME` or `~` (tilde) in Unix-based systems. You can specify a non-default location for the files by setting the `AWS_CONFIG_FILE` and `AWS_SHARED_CREDENTIALS_FILE` environment variables to another local path. See [Environment variables to configure the AWS CLI](#) for details.

When you use a shared profile that specifies an AWS Identity and Access Management (IAM) role, the AWS CLI calls the AWS STS `AssumeRole` operation to retrieve temporary credentials. These credentials are then stored in `~/.aws/cli/cache`). Subsequent AWS CLI commands use the cached temporary credentials until they expire, and at that point the AWS CLI automatically refreshes the credentials.

**Using named profiles**

If no profile is explicitly defined, the default profile is used.

To use a named profile, add the `--profile profile-name` option to your command. The following example lists all of your Amazon EC2 instances using the credentials and settings defined in the `user1` profile.

```
$ aws ec2 describe-instances --profile user1
```

To use a named profile for multiple commands, you can avoid specifying the profile in every command by setting the `AWS_PROFILE` environment variable as the default profile. You can override this setting by using the `--profile` parameter.
Linux or macOS

$ export AWS_PROFILE=user1

Windows

C:\> setx AWS_PROFILE user1

Using `set` to set an environment variable changes the value used until the end of the current command prompt session, or until you set the variable to a different value.

Using `setx` to set an environment variable changes the value in all command shells that you create after running the command. It does not affect any command shell that is already running at the time you run the command. Close and restart the command shell to see the effects of the change.

Setting the environment variable changes the default profile until the end of your shell session, or until you set the variable to a different value. You can make environment variables persistent across future sessions by putting them in your shell's startup script. For more information, see Environment variables to configure the AWS CLI.

Set and view configuration settings using commands

There are several ways to view and set your configuration settings using commands.

**aws configure**

Run this command to quickly set and view your credentials, Region, and output format. The following example shows sample values.

```
$ aws configure
AWS Access Key ID [None]: AKI AIS FODNN7EXAMPLE
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
Default region name [None]: us-west-2
Default output format [None]: json
```

**aws configure set**

You can set any credentials or configuration settings using `aws configure set`. Specify the profile that you want to view or modify with the `--profile` setting.
For example, the following command sets the `region` in the profile named `integ`.

```
$ aws configure set region us-west-2 --profile integ
```

To remove a setting, use an empty string as the value, or manually delete the setting in your `config` and `credentials` files in a text editor.

```
$ aws configure set cli_pager "" --profile integ
```

### `aws configure get`

You can retrieve any credentials or configuration settings you've set using `aws configure get`. Specify the profile that you want to view or modify with the `--profile` setting.

For example, the following command retrieves the `region` setting in the profile named `integ`.

```
$ aws configure get region --profile integ
us-west-2
```

If the output is empty, the setting is not explicitly set and uses the default value.

### `aws configure import`

Import CSV credentials generated from the IAM web console. This is not for credentials generated from IAM Identity Center; customers who use IAM Identity Center should use `aws configure sso`. A CSV file is imported with the profile name matching the username. The CSV file must contain the following headers.

- User Name
- Access key ID
- Secret access key

#### Note

During initial key pair creation, once you close the **Download .csv file** dialog box, you cannot access your secret access key after you close the dialog box. If you need a `.csv` file, you'll need to create one yourself with the required headers and your stored key pair information. If you do not have access to your key pair information, you need to create a new key pair.
aws configure list

To list configuration data, use the `aws configure list` command. This command lists the profile, access key, secret key, and region configuration information used for the specified profile. For each configuration item, it shows the value, where the configuration value was retrieved, and the configuration variable name.

For example, if you provide the AWS Region in an environment variable, this command shows you the name of the region you've configured, that this value came from an environment variable, and the name of the environment variable.

For temporary credential methods such as roles and IAM Identity Center, this command displays the temporarily cached access key and secret access key is displayed.

```
$ aws configure list

Name            Value                  Type   Location
----            -----                  ----    --------
profile         <not set>              None   None
access_key      ****************ABCD   shared-credentials-file
secret_key      ****************ABCD   shared-credentials-file
region          us-west-2             env    AWS_DEFAULT_REGION
```

aws configure list-profiles

To list all your profile names, use the `aws configure list-profiles` command.

```
$ aws configure list-profiles

default
test
```

aws configure sso

Run this command to quickly set and view your AWS IAM Identity Center credentials, Region, and output format. The following example shows sample values.

```
$ aws configure sso
SSO session name (Recommended): my-sso
SSO start URL [None]: https://my-sso-portal.awsapps.com/start
SSO region [None]: us-east-1
```
**aws configure sso-session**

Run this command to quickly set and view your AWS IAM Identity Center credentials, Region, and output format in the sso-session section of the credentials and config files. The following example shows sample values.

```
$ aws configure sso-session
SSO session name: my-sso
SSO start URL [None]: https://my-sso-portal.awsapps.com/start
SSO region [None]: us-east-1
SSO registration scopes [None]: sso:account:access
```

**Setting new configuration and credentials command examples**

The following examples show configuring a default profile with credentials, region, and output specified for different authentication methods.

**IAM Identity Center (SSO)**

This example is for AWS IAM Identity Center using the `aws configure sso` wizard. For more information, see the section called “Configure automatic token refresh”.

```
$ aws configure sso

IAM Identity Center (Legacy SSO)

This example is for the legacy method of AWS IAM Identity Center using the aws configure sso wizard. To use the legacy SSO, leave the session name blank. For more information, see the section called “Configure legacy non-refreshable”.

$ aws configure sso
SSO session name (Recommended):

Short-term credentials

This example is for the short-term credentials from AWS Identity and Access Management. The aws configure wizard is used to set initial values and then the aws configure set command assigns the last value needed. For more information, see the section called “Short-term credentials”.
IAM role

This example is for assuming an IAM role. Profiles that use IAM roles pull credentials from another profile, and then apply IAM role permissions. In the following examples, default is the source profile for credentials and user1 borrows the same credentials then assumes a new role. There is no wizard for this process, therefore each value is set using the `aws configure set` command. For more information, see the section called “IAM roles”.

```
$ aws configure set role_arn arn:aws:iam::123456789012:role/defaultrole
$ aws configure set source_profile default
$ aws configure set role_session_name session_user1
$ aws configure set region us-west-2
$ aws configure set output json
```

Amazon EC2 instance metadata credentials

This example is for the credentials obtained from the hosting Amazon EC2 instance metadata. There is no wizard for this process, therefore each value is set using the `aws configure set` command. For more information, see the section called “Use credentials for Amazon EC2 instance metadata”.

```
$ aws configure set role_arn arn:aws:iam::123456789012:role/defaultrole
$ aws configure set credential_source Ec2InstanceMetadata
$ aws configure set region us-west-2
$ aws configure set output json
```
Long-term credentials

⚠️ Warning
To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as AWS IAM Identity Center.

This example is for the long-term credentials from AWS Identity and Access Management. For more information, see the section called “IAM users”.

Supported config file settings

Topics
• Global settings
• S3 Custom command settings

The following settings are supported in the config file. The values listed in the specified (or default) profile are used unless they are overridden by the presence of an environment variable with the same name, or a command line option with the same name. For more information on what order settings take precedence, see Configure the AWS CLI

Global settings

aws_access_key_id

Specifies the AWS access key used as part of the credentials to authenticate the command request. Although this can be stored in the config file, we recommend that you store this in the credentials file.
Can be overridden by the `AWS_ACCESS_KEY_ID` environment variable. You can't specify the access key ID as a command line option.

```bash
can be overridden by the AWS_ACCESS_KEY_ID environment variable. You can’t specify the access key ID as a command line option.
``` 

**aws_secret_access_key**

Specifies the AWS secret key used as part of the credentials to authenticate the command request. Although this can be stored in the config file, we recommend that you store this in the credentials file.

Can be overridden by the `AWS_SECRET_ACCESS_KEY` environment variable. You can't specify the secret access key as a command line option.

```bash
can be overridden by the AWS_SECRET_ACCESS_KEY environment variable. You can’t specify the secret access key as a command line option.
``` 

**aws_session_token**

Specifies an AWS session token. A session token is required only if you manually specify temporary security credentials. Although this can be stored in the config file, we recommend that you store this in the credentials file.

Can be overridden by the `AWS_SESSION_TOKEN` environment variable. You can't specify the session token as a command line option.

```bash
can be overridden by the AWS_SESSION_TOKEN environment variable. You can’t specify the session token as a command line option.
``` 

**ca_bundle**

Specifies a CA certificate bundle (a file with the `.pem` extension) that is used to verify SSL certificates.

Can be overridden by the `AWS_CA_BUNDLE` environment variable or the `--ca-bundle` command line option.

```bash
can be overridden by the AWS_CA_BUNDLE environment variable or the --ca-bundle command line option.
```
**cli_auto_prompt**

Enables the auto-prompt for the AWS CLI version 2. There are two settings that can be used:

- **on** uses the full auto-prompt mode each time you attempt to run an `aws` command. This includes pressing ENTER after both a complete command or incomplete command.

  ```
  cli_auto_prompt = on
  ```

- **on-partial** uses partial auto-prompt mode. If a command is incomplete or cannot be run due to client-side validation errors, auto-prompt is used. This mode is particularly useful if you have pre-existing scripts, runbooks, or you only want to be auto-prompted for commands you are unfamiliar with rather than prompted on every command.

  ```
  cli_auto_prompt = on-partial
  ```

You can override this setting by using the `aws_cli_auto_prompt` environment variable or the `--cli-auto-prompt` and `--no-cli-auto-prompt` command line parameters.

For information on the AWS CLI version 2 auto-prompt feature, see [Have the AWS CLI prompt you for commands](#).

**cli_binary_format**

Specifies how the AWS CLI version 2 interprets binary input parameters. It can be one of the following values:

- **base64** – This is the default value. An input parameter that is typed as a binary large object (BLOB) accepts a base64-encoded string. To pass true binary content, put the content in a file and provide the file's path and name with the `fileb://` prefix as the parameter's value. To pass base64-encoded text contained in a file, provide the file's path and name with the `file://` prefix as the parameter's value.

  ```
  cli_binary_format = base64
  ```

- **raw-in-base64-out** – Default for the AWS CLI version 1. If the setting's value is `raw-in-base64-out`, files referenced using the `file://` prefix is read as text and then the AWS CLI attempts to encode it to binary.

  ```
  cli_binary_format = raw-in-base64-out
  ```

This entry does not have an equivalent environment variable. You can specify the value on a single command by using the `--cli-binary-format raw-in-base64-out` parameter.
If you reference a binary value in a file using the fileb:// prefix notation, the AWS CLI always expects the file to contain raw binary content and does not attempt to convert the value.

If you reference a binary value in a file using the file:// prefix notation, the AWS CLI handles the file according to the current cli_binary_format setting. If that setting's value is base64 (the default when not explicitly set), the AWS CLI expects the file to contain base64-encoded text. If that setting's value is raw-in-base64-out, the AWS CLI expects the file to contain raw binary content.

**cli_history**

Disabled by default. This setting enables command history for the AWS CLI. After enabling this setting, the AWS CLI records the history of aws commands.

```bash
cli_history = enabled
```

You can list your history using the `aws history list` command, and use the resulting `command_ids` in the `aws history show` command for details. For more information see `aws history` in the *AWS CLI reference guide*.

**cli_pager**

Specifies the pager program used for output. By default, AWS CLI version 2 returns all output through your operating system's default pager program.

Can be overridden by the `AWS_PAGER` environment variable.

```bash
cli_pager=less
```

To disable all use of an external paging program, set the variable to an empty string as shown in the following example.

```bash
cli_pager=
```

**cli_timestamp_format**

Specifies the format of timestamp values included in the output. You can specify either of the following values:

- **iso8601** – The default value for the AWS CLI version 2. If specified, the AWS CLI reformats all timestamps according to [ISO 8601](https://en.wikipedia.org/wiki/ISO_8601).

---

Supported config file settings
ISO 8601 formatted timestamps look like the following examples. The first example shows the time in Coordinated Universal Time (UTC) by including a Z after the time. The date and the time are separated by a T.

To specify a different time zone, instead of the Z, specify a + or - and the number of hours the desired time zone is ahead of or behind UTC, as a two-digit value. The following example shows the same time as the previous example but adjusted to Pacific Standard time, which is eight hours behind UTC.

2019-10-31T14:21:41-08

• wire – The default value for the AWS CLI version 1. If specified, the AWS CLI displays all timestamp values exactly as received in the HTTP query response.

This entry does not have an equivalent environment variable or command line option.

cli_timestamp_format = iso8601

credential_process

Specifies an external command that the AWS CLI runs to generate or retrieve authentication credentials to use for this command. The command must return the credentials in a specific format. For more information about how to use this setting, see Source credentials with an external process.

This entry does not have an equivalent environment variable or command line option.

credential_process = /opt/bin/awscreds-retriever --username susan

credential_source

Used within Amazon EC2 instances or containers to specify where the AWS CLI can find credentials to use to assume the role you specified with the role_arn parameter. You cannot specify both source_profile and credential_source in the same profile.

This parameter can have one of three values:
• **Environment** – Specifies that the AWS CLI is to retrieve source credentials from environment variables.

• **Ec2InstanceMetadata** – Specifies that the AWS CLI is to use the IAM role attached to the **EC2 instance profile** to get source credentials.

• **EcsContainer** – Specifies that the AWS CLI is to use the IAM role attached to the ECS container as source credentials.

```plaintext
credential_source = Ec2InstanceMetadata
```

**duration_seconds**

Specifies the maximum duration of the role session, in seconds. The value can range from 900 seconds (15 minutes) up to the maximum session duration setting for the role (which can be a maximum of 43200). This is an optional parameter and by default, the value is set to 3600 seconds.

**endpoint_url**

Specifies the endpoint that is used for all service requests. If this setting is used in the **services** section of the config file, then the endpoint is used only for the specified service.

The following example uses the global endpoint **http://localhost:1234** and a service-specific endpoint of **http://localhost:4567** for Amazon S3.

```plaintext
[profile dev]
endpoint_url = http://localhost:1234
services = s3-specific

[services s3-specific]
s3 =
   endpoint_url = http://localhost:4567
```

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local AWS configuration files, or explicitly declared on the command line as a parameter. The AWS CLI endpoint configuration settings take precedence in the following order:

1. The **--endpoint-url** command line option.
2. If enabled, the `AWS_IGNORE_CONFIGURED_ENDPOINT_URLS` global endpoint environment variable or profile setting `ignore_configure_endpoint_urls` to ignore custom endpoints.

3. The value provided by a service-specific environment variable `AWS_ENDPOINT_URL_<SERVICE>`, such as `AWS_ENDPOINT_URL_DYNAMODB`.

4. The values provided by the `AWS_USE_DUALSTACK_ENDPOINT`, `AWS_USE_FIPS_ENDPOINT`, and `AWS_ENDPOINT_URL` environment variables.

5. The service-specific endpoint value provided by the `endpoint_url` setting within a services section of the shared config file.

6. The value provided by the `endpoint_url` setting within a profile of the shared config file.

7. `use_dualstack_endpoint`, `use_fips_endpoint`, and `endpoint_url` settings.

8. Any default endpoint URL for the respective AWS service is used last. For a list of the standard service endpoints available in each Region, see `AWS Regions and Endpoints` in the `Amazon Web Services General Reference`.

**ignore_configure_endpoint_urls**

If enabled, the AWS CLI ignores all custom endpoint configurations specified in the config file. Valid values are `true` and `false`.

```
ignore_configure_endpoint_urls = true
```

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local AWS configuration files, or explicitly declared on the command line as a parameter. The AWS CLI endpoint configuration settings take precedence in the following order:

1. The `--endpoint-url` command line option.

2. If enabled, the `AWS_IGNORE_CONFIGURED_ENDPOINT_URLS` global endpoint environment variable or profile setting `ignore_configure_endpoint_urls` to ignore custom endpoints.

3. The value provided by a service-specific environment variable `AWS_ENDPOINT_URL_<SERVICE>`, such as `AWS_ENDPOINT_URL_DYNAMODB`.

4. The values provided by the `AWS_USE_DUALSTACK_ENDPOINT`, `AWS_USE_FIPS_ENDPOINT`, and `AWS_ENDPOINT_URL` environment variables.
5. The service-specific endpoint value provided by the `endpoint_url` setting within a services section of the shared config file.

6. The value provided by the `endpoint_url` setting within a profile of the shared config file.

7. `use_dualstack_endpoint`, `use_fips_endpoint`, and `endpoint_url` settings.

8. Any default endpoint URL for the respective AWS service is used last. For a list of the standard service endpoints available in each Region, see AWS Regions and Endpoints in the Amazon Web Services General Reference.

**external_id**

Specifies a unique identifier that is used by third parties to assume a role in their customers' accounts. This maps to the ExternalId parameter in the AssumeRole operation. This parameter is needed only if the trust policy for the role specifies a value for ExternalId. For more information, see How to use an external ID when granting access to your AWS resources to a third party in the IAM User Guide.

**max_attempts**

Specifies a value of maximum retry attempts the AWS CLI retry handler uses, where the initial call counts toward the max_attempts value that you provide.

You can override this value by using the AWS_MAX_ATTEMPTS environment variable.

```
max_attempts = 3
```

**mfa_serial**

The identification number of an MFA device to use when assuming a role. This is mandatory only if the trust policy of the role being assumed includes a condition that requires MFA authentication. The value can be either a serial number for a hardware device (such as GAHT12345678) or an Amazon Resource Name (ARN) for a virtual MFA device (such as arn:aws:iam::123456789012:mfa/user).

**output**

Specifies the default output format for commands requested using this profile. You can specify any of the following values:

- `json` – The output is formatted as a JSON string.
- `yaml` – The output is formatted as a YAML string.
• **yaml-stream** – The output is streamed and formatted as a YAML string. Streaming allows for faster handling of large data types.

• **text** – The output is formatted as multiple lines of tab-separated string values. This can be useful to pass the output to a text processor, like `grep`, `sed`, or `awk`.

• **table** – The output is formatted as a table using the characters `|` to form the cell borders. It typically presents the information in a "human-friendly" format that is much easier to read than the others, but not as programmatically useful.

Can be overridden by the AWS_DEFAULT_OUTPUT environment variable or the `--output` command line option.

```plaintext
output = table
```

**parameter_validation**

Specifies whether the AWS CLI client attempts to validate parameters before sending them to the AWS service endpoint.

• **true** – This is the default value. If specified, the AWS CLI performs local validation of command line parameters.

• **false** – If specified, the AWS CLI does not validate command line parameters before sending them to the AWS service endpoint.

This entry does not have an equivalent environment variable or command line option.

```plaintext
parameter_validation = false
```

**region**

Specifies the AWS Region to send requests to for commands requested using this profile.

• You can specify any of the Region codes available for the chosen service as listed in [AWS Regions and Endpoints](https://aws.amazon.com/about-aws/servehub/global-endpoints/) in the *Amazon Web Services General Reference*.

• `aws_global` enables you to specify the global endpoint for services that support a global endpoint in addition to Regional endpoints, such as AWS Security Token Service (AWS STS) and Amazon Simple Storage Service (Amazon S3).

You can override this value by using the AWS_REGION environment variable, AWS_DEFAULT_REGION environment variable, or the `--region` command line option.
region = us-west-2

retry_mode

Specifies which retry mode AWS CLI uses. There are three retry modes available: legacy (default), standard, and adaptive. For more information on retries, see AWS CLI retries.

You can override this value by using the AWS_RETRIEVE_MODE environment variable.

retry_mode = standard

role_arn

Specifies the Amazon Resource Name (ARN) of an IAM role that you want to use to run the AWS CLI commands. You must also specify one of the following parameters to identify the credentials that have permission to assume this role:

- source_profile
- credential_source

role_arn = arn:aws:iam::123456789012:role/role-name

The environment variable AWS_ROLE_ARN overrides this setting.

For more information on using web identities, see the section called “Assume role with web identity”.

role_session_name

Specifies the name to attach to the role session. This value is provided to the RoleSessionName parameter when the AWS CLI calls the AssumeRole operation, and becomes part of the assumed role user ARN: arn:aws:sts::123456789012:assumed-role/role_name/role_session_name. This is an optional parameter. If you do not provide this value, a session name is generated automatically. This name appears in AWS CloudTrail logs for entries associated with this session.

role_session_name = maria_garcia_role

The environment variable AWS_ROLE_SESSION_NAME overrides this setting.
For more information on using web identities, see the section called “Assume role with web identity”.

**services**

Specifies the service configuration to use for your profile.

```plaintext
[profile dev-s3-specific-and-global]
endpoint_url = http://localhost:1234
services = s3-specific

[services s3-specific]
s3 =
  endpoint_url = http://localhost:4567
```

For more information on the services section, see the section called “services”.

The environment variable AWS_ROLE_SESSION_NAME overrides this setting.

For more information on using web identities, see the section called “Assume role with web identity”.

**source_profile**

Specifies a named profile with long-term credentials that the AWS CLI can use to assume a role that you specified with the role_arn parameter. You cannot specify both source_profile and credential_source in the same profile.

```plaintext
source_profile = production-profile
```

**sso_account_id**

Specifies the AWS account ID that contains the IAM role with the permission that you want to grant to the associated IAM Identity Center user.

This setting does not have an environment variable or command line option.

```plaintext
sso_account_id = 123456789012
```

**sso_region**

Specifies the AWS Region that contains the AWS access portal host. This is separate from, and can be a different Region than the default CLI region parameter.
This setting does not have an environment variable or command line option.

\[
\text{sso\_region} = \text{us\_west-2}
\]

**sso\_registration\_scopes**

A comma-delimited list of scopes to be authorized for the `sso\_session`. Scopes authorize access to IAM Identity Center bearer token authorized endpoints. A valid scope is a string, such as `sso:account:access`. This setting isn't applicable to the legacy non-refreshable configuration.

\[
\text{sso\_registration\_scopes} = \text{sso:account:access}
\]

**sso\_role\_name**

Specifies the friendly name of the IAM role that defines the user's permissions when using this profile.

This setting does not have an environment variable or command line option.

\[
\text{sso\_role\_name} = \text{ReadAccess}
\]

**sso\_start\_url**

Specifies the URL that points to the organization's AWS access portal. The AWS CLI uses this URL to establish a session with the IAM Identity Center service to authenticate its users. To find your AWS access portal URL, use one of the following:

- Open your invitation email, the AWS access portal URL is listed.
- Open the AWS IAM Identity Center console at [https://console.aws.amazon.com/singlesignon/](https://console.aws.amazon.com/singlesignon/). The AWS access portal URL is listed in your settings.

This setting does not have an environment variable or command line option.

\[
\text{sso\_start\_url} = \text{https://my-sso-portal.awsapps.com/start}
\]
**use_dualstack_endpoint**

Enables the use of dual-stack endpoints to send AWS requests. To learn more about dual-stack endpoints, which support both IPv4 and IPv6 traffic, see [Using Amazon S3 dual-stack endpoints](#) in the *Amazon Simple Storage Service User Guide*. Dual-stack endpoints are available for some services in some regions. If a dual-stack endpoint does not exist for the service or AWS Region, the request fails. This is disabled by default.

This is mutually exclusive with the `use_accelerate_endpoint` setting.

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local AWS configuration files, or explicitly declared on the command line as a parameter. The AWS CLI endpoint configuration settings take precedence in the following order:

1. The `--endpoint-url` command line option.
2. If enabled, the `AWS_IGNORE_CONFIGURED_ENDPOINT_URLS` global endpoint environment variable or profile setting `ignore_configure_endpoint_urls` to ignore custom endpoints.
3. The value provided by a service-specific environment variable `AWS_ENDPOINT_URL_<SERVICE>`, such as `AWS_ENDPOINT_URL_DYNAMODB`.
4. The values provided by the `AWS_USE_DUALSTACK_ENDPOINT`, `AWS_USE_FIPS_ENDPOINT`, and `AWS_ENDPOINT_URL` environment variables.
5. The service-specific endpoint value provided by the `endpoint_url` setting within a services section of the shared config file.
6. The value provided by the `endpoint_url` setting within a profile of the shared config file.
7. `use_dualstack_endpoint`, `use_fips_endpoint`, and `endpoint_url` settings.
8. Any default endpoint URL for the respective AWS service is used last. For a list of the standard service endpoints available in each Region, see [AWS Regions and Endpoints](#) in the *Amazon Web Services General Reference*.

**use_fips_endpoint**

Some AWS services offer endpoints that support [Federal Information Processing Standard (FIPS) 140-2](#) in some AWS Regions. When the AWS service supports FIPS, this setting specifies what FIPS endpoint the AWS CLI should use. Unlike standard AWS endpoints, FIPS endpoints...
use a TLS software library that complies with FIPS 140-2. These endpoints might be required by enterprises that interact with the United States government.

If this setting is enabled, but a FIPS endpoint does not exist for the service in your AWS Region, the AWS command may fail. In this case, manually specify the endpoint to use in the command using the `--endpoint-url` option or use `service-specific endpoints`.

For more information on specifying FIPS endpoints by AWS Region, see [FIPS Endpoints by Service](#).

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local AWS configuration files, or explicitly declared on the command line as a parameter. The AWS CLI endpoint configuration settings take precedence in the following order:
1. The `--endpoint-url` command line option.
2. If enabled, the `AWS_IGNORE_CONFIGURED_ENDPOINT_URLS` global endpoint environment variable or profile setting `ignore_configure_endpoint_urls` to ignore custom endpoints.
3. The value provided by a service-specific environment variable `AWS_ENDPOINT_URL_<SERVICE>`, such as `AWS_ENDPOINT_URL_DYNAMODB`.
4. The values provided by the `AWS_USE_DUALSTACK_ENDPOINT`, `AWS_USE_FIPS_ENDPOINT`, and `AWS_ENDPOINT_URL` environment variables.
5. The service-specific endpoint value provided by the `endpoint_url` setting within a services section of the shared config file.
6. The value provided by the `endpoint_url` setting within a profile of the shared config file.
7. `use_dualstack_endpoint`, `use_fips_endpoint`, and `endpoint_url` settings.
8. Any default endpoint URL for the respective AWS service is used last. For a list of the standard service endpoints available in each Region, see [AWS Regions and Endpoints](#) in the Amazon Web Services General Reference.

**web_identity_token_file**

Specifies the path to a file that contains an OAuth 2.0 access token or OpenID Connect ID token that is provided by an identity provider. The AWS CLI loads the contents of this file and passes it as the WebIdentityToken argument to the AssumeRoleWithWebIdentity operation.

The environment variable `AWS_WEB_IDENTITY_TOKEN_FILE` overrides this setting.
For more information on using web identities, see the section called “Assume role with web identity”.

**tcp_keepalive**

Specifies whether the AWS CLI client uses TCP keep-alive packets.

This entry does not have an equivalent environment variable or command line option.

```
tcp_keepalive = false
```

**S3 Custom command settings**

Amazon S3 supports several settings that configure how the AWS CLI performs Amazon S3 operations. Some apply to all S3 commands in both the `s3api` and `s3` namespaces. Others are specifically for the S3 "custom" commands that abstract common operations and do more than a one-to-one mapping to an API operation. The `aws s3` transfer commands `cp`, `sync`, `mv`, and `rm` have additional settings you can use to control S3 transfers.

All of these options can be configured by specifying the `s3` nested setting in your `config` file. Each setting is then indented on its own line.

**Note**

These settings are entirely optional. You should be able to successfully use the `aws s3` transfer commands without configuring any of these settings. These settings are provided to enable you to tune for performance or to account for the specific environment where you are running these `aws s3` commands.

These settings are all set under a top-level `s3` key in the `config` file, as shown in the following example for the development profile.

```
[profile development]
s3 =
    max_concurrent_requests = 20
    max_queue_size = 10000
    multipart_threshold = 64MB
    multipart_chunksize = 16MB
```
The following settings apply to any S3 command in the s3 or s3api namespaces.

**addressing_style**

Specifies which addressing style to use. This controls whether the bucket name is in the hostname or is part of the URL. Valid values are: path, virtual, and auto. The default value is auto.

There are two styles of constructing an Amazon S3 endpoint. The first is called virtual and includes the bucket name as part of the hostname. For example: https://bucketname.s3.amazonaws.com. Alternatively, with the path style, you treat the bucket name as if it is a path in the URI; for example, https://s3.amazonaws.com/bucketname. The default value in the CLI is to use auto, which attempts to use the virtual style where it can, but will fall back to path style when required. For example, if your bucket name is not DNS compatible, the bucket name cannot be part of the hostname and must be in the path. With auto, the CLI will detect this condition and automatically switch to path style for you. If you set the addressing style to path, you must then ensure that the AWS Region you configured in the AWS CLI matches the Region of your bucket.

**payload_signing_enabled**

Specifies whether to SHA256 sign sigv4 payloads. By default, this is disabled for streaming uploads (UploadPart and PutObject) when using HTTPS. By default, this is set to false for streaming uploads (UploadPart and PutObject), but only if a ContentMD5 is present (it is generated by default) and the endpoint uses HTTPS.

If set to true, S3 requests receive additional content validation in the form of a SHA256 checksum which is calculated for you and included in the request signature. If set to false, the checksum isn't calculated. Disabling this can be useful to reduce the performance overhead created by the checksum calculation.

**use_accelerate_endpoint**

Use the Amazon S3 Accelerate endpoint for all s3 and s3api commands. The default value is false. This is mutually exclusive with the use_dualstack_endpoint setting.
If set to true, the AWS CLI directs all Amazon S3 requests to the S3 Accelerate endpoint at s3-accelerate.amazonaws.com. To use this endpoint, you must enable your bucket to use S3 Accelerate. All requests are sent using the virtual style of bucket addressing: my-bucket.s3-accelerate.amazonaws.com. Any ListBuckets, CreateBucket, and DeleteBucket requests aren't sent to the S3 Accelerate endpoint as that endpoint doesn't support those operations. This behavior can also be set if the --endpoint-url parameter is set to https://s3-accelerate.amazonaws.com or http://s3-accelerate.amazonaws.com for any s3 or s3api command.

The following settings apply only to commands in the s3 namespace command set.

**max_bandwidth**

Specifies the maximum bandwidth that can be consumed for uploading and downloading data to and from Amazon S3. The default is no limit.

This limits the maximum bandwidth that the S3 commands can use to transfer data to and from Amazon S3. This value applies to only uploads and downloads; it doesn't apply to copies or deletes. The value is expressed as bytes per second. The value can be specified as:

- An integer. For example, 1048576 sets the maximum bandwidth usage to 1 megabyte per second.
- An integer followed by a rate suffix. You can specify rate suffixes using: KB/s, MB/s, or GB/s. For example, 300KB/s, 10MB/s.

In general, we recommend that you first try to lower bandwidth consumption by lowering max_concurrent_requests. If that doesn't adequately limit bandwidth consumption to the desired rate, you can use the max_bandwidth setting to further limit bandwidth consumption. This is because max_concurrent_requests controls how many threads are currently running. If you instead first lower max_bandwidth but leave a high max_concurrent_requests setting, it can result in threads having to wait unnecessarily. This can lead to excess resource consumption and connection timeouts.

**max_concurrent_requests**

Specifies the maximum number of concurrent requests. The default value is 10.

The aws s3 transfer commands are multithreaded. At any given time, multiple Amazon S3 requests can be running. For example, when you use the command aws s3 cp localdir
s3://bucket/ --recursive to upload files to an S3 bucket, the AWS CLI can upload the files localdir/file1, localdir/file2, and localdir/file3 in parallel. The setting max_concurrent_requests specifies the maximum number of transfer operations that can run at the same time.

You might need to change this value for a few reasons:

- Decreasing this value – On some environments, the default of 10 concurrent requests can overwhelm a system. This can cause connection timeouts or slow the responsiveness of the system. Lowering this value makes the S3 transfer commands less resource intensive. The tradeoff is that S3 transfers can take longer to complete. Lowering this value might be necessary if you use a tool to limit bandwidth.

- Increasing this value – In some scenarios, you might want the Amazon S3 transfers to complete as quickly as possible, using as much network bandwidth as necessary. In this scenario, the default number of concurrent requests might not be sufficient to use all of the available network bandwidth. Increasing this value can improve the time it takes to complete an Amazon S3 transfer.

max_queue_size

Specifies the maximum number of tasks in the task queue. The default value is 1000.

The AWS CLI internally uses a model where it queues up Amazon S3 tasks that are then executed by consumers whose numbers are limited by max_concurrent_requests. A task generally maps to a single Amazon S3 operation. For example, a task could be a PutObjectTask, or a GetObjectTask, or an UploadPartTask. The rate at which tasks are added to the queue can be much faster than the rate at which consumers finish the tasks. To avoid unbounded growth, the task queue size is capped to a specific size. This setting changes the value of that maximum number.

You generally don't need to change this setting. This setting also corresponds to the number of tasks that the AWS CLI is aware of that need to be run. This means that by default the AWS CLI can only see 1000 tasks ahead. Increasing this value means that the AWS CLI can more quickly know the total number of tasks needed, assuming that the queuing rate is quicker than the rate of task completion. The tradeoff is that a larger max_queue_size requires more memory.

multipart_chunksize

Specifies the chunk size that the AWS CLI uses for multipart transfers of individual files. The default value is 8 MB, with a minimum of 5 MB.
When a file transfer exceeds the `multipart_threshold`, the AWS CLI divides the file into chunks of this size. This value can be specified using the same syntax as `multipart_threshold`, either as the number of bytes as an integer, or by using a size and a suffix.

**multipart_threshold**

Specifies the size threshold the AWS CLI uses for multipart transfers of individual files. The default value is 8 MB.

When uploading, downloading, or copying a file, the Amazon S3 commands switch to multipart operations if the file exceeds this size. You can specify this value in one of two ways:

- The file size in bytes. For example, 1048576.
- The file size with a size suffix. You can use KB, MB, GB, or TB. For example: 10MB, 1GB.

**Note**

S3 can impose constraints on valid values that can be used for multipart operations. For more information, see the [S3 Multipart Upload documentation](https://docs.aws.amazon.com/AmazonS3/latest/userguide/multipart-upload.html) in the *Amazon Simple Storage Service User Guide*.

**Environment variables to configure the AWS CLI**

Environment variables provide another way to specify configuration options and credentials, and can be useful for scripting or temporarily setting a named profile as the default.

**Precedence of options**

- If you specify an option by using one of the environment variables described in this topic, it overrides any value loaded from a profile in the configuration file.
- If you specify an option by using a parameter on the AWS CLI command line, it overrides any value from either the corresponding environment variable or a profile in the configuration file.

For more information about precedence and how the AWS CLI determines which credentials to use, see [Configure the AWS CLI](https://docs.aws.amazon.com/cli/latest/userguide/cli-configure-overview.html).

**Topics**
How to set environment variables

The following examples show how you can configure environment variables for the default user.

### Linux or macOS

```bash
$ export AWS_ACCESS_KEY_ID=AKIAIOSFODNN7EXAMPLE
$ export AWS_SECRET_ACCESS_KEY=wJalrXUtznFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
$ export AWS_DEFAULT_REGION=us-west-2
```

Setting the environment variable changes the value used until the end of your shell session, or until you set the variable to a different value. You can make the variables persistent across future sessions by setting them in your shell's startup script.

### Windows Command Prompt

**To set for all sessions**

```cmd
C:\> setx AWS_ACCESS_KEY_ID AKIAIOSFODNN7EXAMPLE
C:\> setx AWS_SECRET_ACCESS_KEY wJalrXUtznFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
C:\> setx AWS_DEFAULT_REGION us-west-2
```

Using `setx` to set an environment variable changes the value used in both the current command prompt session and all command prompt sessions that you create after running the command. It does not affect other command shells that are already running at the time you run the command. You may need to restart you terminal for settings to load.

**To set for current session only**

Using `set` to set an environment variable changes the value used until the end of the current command prompt session, or until you set the variable to a different value.

```cmd
C:\> set AWS_ACCESS_KEY_ID=AKIAIOSFODNN7EXAMPLE
C:\> set AWS_SECRET_ACCESS_KEY=wJalrXUtznFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
C:\> set AWS_DEFAULT_REGION=us-west-2
```
If you set an environment variable at the PowerShell prompt as shown in the previous examples, it saves the value for only the duration of the current session. To make the environment variable setting persistent across all PowerShell and Command Prompt sessions, store it by using the System application in Control Panel. Alternatively, you can set the variable for all future PowerShell sessions by adding it to your PowerShell profile. See the PowerShell documentation for more information about storing environment variables or persisting them across sessions.

AWS CLI supported environment variables

The AWS CLI supports the following environment variables.

AWS_ACCESS_KEY_ID

Specifies an AWS access key associated with an IAM account.

If defined, this environment variable overrides the value for the profile setting aws_access_key_id. You can't specify the access key ID by using a command line option.

AWS_CA_BUNDLE

Specifies the path to a certificate bundle to use for HTTPS certificate validation.

If defined, this environment variable overrides the value for the profile setting ca_bundle. You can override this environment variable by using the --ca-bundle command line parameter.

AWS_CLI_AUTO_PROMPT

Enables the auto-prompt for the AWS CLI version 2. There are two settings that can be used:

- **on** uses the full auto-prompt mode each time you attempt to run an aws command. This includes pressing ENTER after both a complete command or incomplete command.

- **on-partial** uses partial auto-prompt mode. If a command is incomplete or cannot be run due to client-side validation errors, auto-prompt is used. This mode is useful if you have pre-
existing scripts, runbooks, or you only want to be auto-prompted for commands you are unfamiliar with rather than prompted on every command.

If defined, this environment variable overrides the value for the `cli_auto_prompt` profile setting. You can override this environment variable by using the `--cli-auto-prompt` and `--no-cli-auto-prompt` command line parameters.

For information on the AWS CLI version 2 auto-prompt feature, see [Have the AWS CLI prompt you for commands](#).

**AWS_CLI_FILE_ENCODING**

Specifies the encoding used for text files. By default encoding matches your locale. To set encoding different from the locale, use the `aws_cli_file_encoding` environment variable. For example, if you use Windows with default encoding CP1252, setting `aws_cli_file_encoding=UTF-8` sets the CLI to open text files using UTF-8.

**AWS_CLI_S3_MV_VALIDATE_SAME_S3_PATHS**

If the source and destination buckets are the same when using custom the `s3 mv` command, the source file or object can be moved onto itself, which can result in accidental deletion of your source file or object. The `AWS_CLI_S3_MV_VALIDATE_SAME_S3_PATHS` environment variable and `--validate-same-s3-paths` option specifies whether to validate your access point ARNs or access point aliases in your Amazon S3 source or destination URIs.

[Note]

Path validation for `s3 mv` requires additional API calls.

**AWS_CONFIG_FILE**

Specifies the location of the file that the AWS CLI uses to store configuration profiles. The default path is `~/.aws/config`.

You can't specify this value in a named profile setting or by using a command line parameter.

**AWS_DATA_PATH**

A list of additional directories to check outside of the built-in search path of `~/.aws/models` when loading AWS CLI data. Setting this environment variable indicates additional directories to

AWS CLI supported environment variables
check first before falling back to the built-in search path. Multiple entries should be separated with the os.pathsep character, which is : on Linux or macOS and ; on Windows.

AWS_DEFAULT_OUTPUT

Specifies the output format to use.

If defined, this environment variable overrides the value for the profile setting output. You can override this environment variable by using the --output command line parameter.

AWS_DEFAULT_REGION

The Default region name identifies the AWS Region whose servers you want to send your requests to by default. This is typically the Region closest to you, but it can be any Region. For example, you can type us-west-2 to use US West (Oregon). This is the Region that all later requests are sent to, unless you specify otherwise in an individual command.

Note

You must specify an AWS Region when using the AWS CLI, either explicitly or by setting a default Region. For a list of the available Regions, see Regions and Endpoints. The Region designators used by the AWS CLI are the same names that you see in AWS Management Console URLs and service endpoints.

If defined, this environment variable overrides the value for the profile setting region. You can override this environment variable by using the --region command line parameter and the AWS SDK compatible AWS_REGION environment variable.

AWS_EC2_METADATA_DISABLED

Disables the use of the Amazon EC2 instance metadata service (IMDS).

If set to true, user credentials or configuration (like the Region) are not requested from IMDS.

AWS_ENDPOINT_URL

Specifies the endpoint that is used for all service requests.

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local AWS configuration files, or explicitly declared on the command line.
as a parameter. The AWS CLI endpoint configuration settings take precedence in the following order:

1. The `--endpoint-url` command line option.

2. If enabled, the `AWS_IGNORE_CONFIGURED_ENDPOINT_URLS` global endpoint environment variable or profile setting `ignore_configure_endpoint_urls` to ignore custom endpoints.

3. The value provided by a service-specific environment variable `AWS_ENDPOINT_URL_<SERVICE>`, such as `AWS_ENDPOINT_URL_DYNAMODB`.

4. The values provided by the `AWS_USE_DUALSTACK_ENDPOINT`, `AWS_USE_FIPS_ENDPOINT`, and `AWS_ENDPOINT_URL` environment variables.

5. The service-specific endpoint value provided by the `endpoint_url` setting within a services section of the shared config file.

6. The value provided by the `endpoint_url` setting within a profile of the shared config file.

7. `use_dualstack_endpoint`, `use_fips_endpoint`, and `endpoint_url` settings.

8. Any default endpoint URL for the respective AWS service is used last. For a list of the standard service endpoints available in each Region, see `AWS Regions and Endpoints` in the `Amazon Web Services General Reference`.

**AWS_ENDPOINT_URL_<SERVICE>**

Specifies a custom endpoint that is used for a specific service, where `<SERVICE>` is replaced with the AWS service identifier. For example, Amazon DynamoDB has a serviceId of `DynamoDB`. For this service, the endpoint URL environment variable is `AWS_ENDPOINT_URL_DYNAMODB`.

For a list of all service-specific environment variables, see `List of service-specific identifiers`.

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local AWS configuration files, or explicitly declared on the command line as a parameter. The AWS CLI endpoint configuration settings take precedence in the following order:

1. The `--endpoint-url` command line option.

2. If enabled, the `AWS_IGNORE_CONFIGURED_ENDPOINT_URLS` global endpoint environment variable or profile setting `ignore_configure_endpoint_urls` to ignore custom endpoints.
3. The value provided by a service-specific environment variable
   `AWS_ENDPOINT_URL_<SERVICE>`, such as `AWS_ENDPOINT_URL_DYNAMODB`.

4. The values provided by the `AWS_USE_DUALSTACK_ENDPOINT`, `AWS_USE_FIPS_ENDPOIINT`,
   and `AWS_ENDPOINT_URL` environment variables.

5. The service-specific endpoint value provided by the `endpoint_url` setting within a
   `services` section of the shared config file.

6. The value provided by the `endpoint_url` setting within a profile of the shared config
   file.

7. `use_dualstack_endpoint`, `use_fips_endpoint`, and `endpoint_url` settings.

8. Any default endpoint URL for the respective AWS service is used last. For a list of the
   standard service endpoints available in each Region, see `AWS Regions and Endpoints`
   in the `Amazon Web Services General Reference`.

**AWS_IGNORE_CONFIGURED_ENDPOINT_URLS**

If enabled, the AWS CLI ignores all custom endpoint configurations. Valid values are `true`
and `false`.

Endpoint configuration settings are located in multiple places, such as the system or user
environment variables, local AWS configuration files, or explicitly declared on the command line
as a parameter. The AWS CLI endpoint configuration settings take precedence in the following
order:

1. The `--endpoint-url` command line option.

2. If enabled, the `AWS_IGNORE_CONFIGURED_ENDPOINT_URLS` global endpoint environment
   variable or profile setting `ignore_configure_endpoint_urls` to ignore custom
   endpoints.

3. The value provided by a service-specific environment variable
   `AWS_ENDPOINT_URL_<SERVICE>`, such as `AWS_ENDPOINT_URL_DYNAMODB`.

4. The values provided by the `AWS_USE_DUALSTACK_ENDPOINT`, `AWS_USE_FIPS_ENDPOINT`,
   and `AWS_ENDPOINT_URL` environment variables.

5. The service-specific endpoint value provided by the `endpoint_url` setting within a
   `services` section of the shared config file.

6. The value provided by the `endpoint_url` setting within a profile of the shared config
   file.

7. `use_dualstack_endpoint`, `use_fips_endpoint`, and `endpoint_url` settings.
8. Any default endpoint URL for the respective AWS service is used last. For a list of the
standard service endpoints available in each Region, see AWS Regions and Endpoints in the
Amazon Web Services General Reference.

AWS_MAX_ATTEMPTS

Specifies a value of maximum retry attempts the AWS CLI retry handler uses, where the initial
call counts toward the value that you provide. For more information on retries, see AWS CLI
retries.

If defined, this environment variable overrides the value for the profiles setting max_attempts.

AWS_METADATA_SERVICE_NUM_ATTEMPTS

When attempting to retrieve credentials on an Amazon EC2 instance that has been configured
with an IAM role, the AWS CLI attempts to retrieve credentials once from the instance metadata
service before stopping. If you know your commands will run on an Amazon EC2 instance, you
can increase this value to make AWS CLI retry multiple times before giving up.

AWS_METADATA_SERVICE_TIMEOUT

The number of seconds before a connection to the instance metadata service should time out.
When attempting to retrieve credentials on an Amazon EC2 instance that is configured with an
IAM role, a connection to the instance metadata service times out after 1 second by default.
If you know you're running on an Amazon EC2 instance with an IAM role configured, you can
increase this value if needed.

AWS_PAGER

Specifies the pager program used for output. By default, AWS CLI version 2 returns all output
through your operating system's default pager program.

To disable all use of an external paging program, set the variable to an empty string.

If defined, this environment variable overrides the value for the profile setting cli_pager.

AWS_PROFILE

Specifies the name of the AWS CLI profile with the credentials and options to use. This can be
the name of a profile stored in a credentials or config file, or the value default to use the
default profile.

If defined, this environment variable overrides the behavior of using the profile named
[default] in the configuration file. You can override this environment variable by using the --
profile command line parameter.
AWS_REGION

The AWS SDK compatible environment variable that specifies the AWS Region to send the request to.

If defined, this environment variable overrides the values in the environment variable AWS_DEFAULT_REGION and the profile setting region. You can override this environment variable by using the --region command line parameter.

AWS_RETRY_MODE

Specifies which retry mode AWS CLI uses. There are three retry modes available: legacy (default), standard, and adaptive. For more information on retries, see AWS CLI retries.

If defined, this environment variable overrides the value for the profiles setting retry_mode.

AWS_ROLE_ARN

Specifies the Amazon Resource Name (ARN) of an IAM role with a web identity provider that you want to use to run the AWS CLI commands.

Used with the AWS_WEB_IDENTITY_TOKEN_FILE and AWS_ROLE_SESSION_NAME environment variables.

If defined, this environment variable overrides the value for the profile setting role_arn. You can't specify a role session name as a command line parameter.

⚠️ Note

This environment variable only applies to an assumed role with web identity provider it does not apply to the general assume role provider configuration.

For more information on using web identities, see the section called “Assume role with web identity”.

AWS_ROLE_SESSION_NAME

Specifies the name to attach to the role session. This value is provided to the RoleSessionName parameter when the AWS CLI calls the AssumeRole operation, and becomes part of the assumed role user ARN: arn:aws:sts::123456789012:assumed-role/role_name/role_session_name. This is an optional parameter. If you do not provide
this value, a session name is generated automatically. This name appears in AWS CloudTrail logs for entries associated with this session.

If defined, this environment variable overrides the value for the profile setting `role_session_name`.

Used with the `AWS_ROLE_ARN` and `AWS_WEB_IDENTITY_TOKEN_FILE` environment variables.

For more information on using web identities, see the section called “Assume role with web identity”.

**Note**

This environment variable only applies to an assumed role with web identity provider it does not apply to the general assume role provider configuration.

**AWS_SECRET_ACCESS_KEY**

Specifies the secret key associated with the access key. This is essentially the "password" for the access key.

If defined, this environment variable overrides the value for the profile setting `aws_secret_access_key`. You can't specify the secret access key ID as a command line option.

**AWS_SESSION_TOKEN**

Specifies the session token value that is required if you are using temporary security credentials that you retrieved directly from AWS STS operations. For more information, see the **Output section of the assume-role command** in the *AWS CLI Command Reference*.

If defined, this environment variable overrides the value for the profile setting `aws_session_token`.

**AWS_SHARED_CREDENTIALS_FILE**

Specifies the location of the file that the AWS CLI uses to store access keys. The default path is `~/.aws/credentials`.

You can't specify this value in a named profile setting or by using a command line parameter.
AWS Command Line Interface
User Guide for Version 2

AWS_USE_DUALSTACK_ENDPOINT

Enables the use of dual-stack endpoints to send AWS requests. To learn more about dual-stack endpoints, which support both IPv4 and IPv6 traffic, see Using Amazon S3 dual-stack endpoints in the Amazon Simple Storage Service User Guide. Dual-stack endpoints are available for some services in some regions. If a dual-stack endpoint does not exist for the service or AWS Region, the request fails. This is disabled by default.

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local AWS configuration files, or explicitly declared on the command line as a parameter. The AWS CLI endpoint configuration settings take precedence in the following order:

1. The `--endpoint-url` command line option.
2. If enabled, the AWS_IGNORE_CONFIGURED_ENDPOINT_URLS global endpoint environment variable or profile setting ignore_configure_endpoint_urls to ignore custom endpoints.
3. The value provided by a service-specific environment variable AWS_ENDPOINT_URL_<SERVICE>, such as AWS_ENDPOINT_URL_DYNAMODB.
4. The values provided by the AWS_USE_DUALSTACK_ENDPOINT, AWS_USE_FIPS_ENDPOINT, and AWS_ENDPOINT_URL environment variables.
5. The service-specific endpoint value provided by the endpoint_url setting within a services section of the shared config file.
6. The value provided by the endpoint_url setting within a profile of the shared config file.
7. use_dualstack_endpoint, use_fips_endpoint, and endpoint_url settings.
8. Any default endpoint URL for the respective AWS service is used last. For a list of the standard service endpoints available in each Region, see AWS Regions and Endpoints in the Amazon Web Services General Reference.

AWS_USE_FIPS_ENDPOINT

Some AWS services offer endpoints that support Federal Information Processing Standard (FIPS) 140-2 in some AWS Regions. When the AWS service supports FIPS, this setting specifies what FIPS endpoint the AWS CLI should use. Unlike standard AWS endpoints, FIPS endpoints use a TLS software library that complies with FIPS 140-2. These endpoints might be required by enterprises that interact with the United States government.
If this setting is enabled, but a FIPS endpoint does not exist for the service in your AWS Region, the AWS command may fail. In this case, manually specify the endpoint to use in the command using the \texttt{--endpoint-url} option or use service-specific endpoints.

For more information on specifying FIPS endpoints by AWS Region, see \texttt{FIPS Endpoints by Service}.

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local AWS configuration files, or explicitly declared on the command line as a parameter. The AWS CLI endpoint configuration settings take precedence in the following order:

1. The \texttt{--endpoint-url} command line option.
2. If enabled, the \texttt{AWS_IGNORE_CONFIGURED_ENDPOINT_URLS} global endpoint environment variable or profile setting \texttt{ignore_configure_endpoint_urls} to ignore custom endpoints.
3. The value provided by a service-specific environment variable \texttt{AWS_ENDPOINT_URL_<SERVICE>}, such as \texttt{AWS_ENDPOINT_URL_DYNAMODB}.
4. The values provided by the \texttt{AWS_USE_DUALSTACK_ENDPOINT}, \texttt{AWS_USE_FIPS_ENDPOINT}, and \texttt{AWS_ENDPOINT_URL} environment variables.
5. The service-specific endpoint value provided by the \texttt{endpoint_url} setting within a services section of the shared config file.
6. The value provided by the \texttt{endpoint_url} setting within a profile of the shared config file.
7. \texttt{use_dualstack_endpoint}, \texttt{use_fips_endpoint}, and \texttt{endpoint_url} settings.
8. Any default endpoint URL for the respective AWS service is used last. For a list of the standard service endpoints available in each Region, see \texttt{AWS Regions and Endpoints} in the \textit{Amazon Web Services General Reference}.

\textbf{AWS_WEB_IDENTITY_TOKEN_FILE}

Specifies the path to a file that contains an OAuth 2.0 access token or OpenID Connect ID token that is provided by an identity provider. The AWS CLI loads the contents of this file and passes it as the WebIdentityToken argument to the AssumeRoleWithWebIdentity operation.

Used with the \texttt{AWS_ROLE_ARN} and \texttt{AWS_ROLE_SESSION_NAME} environment variables.

If defined, this environment variable overrides the value for the profile setting \texttt{web_identity_token_file}. 

\hspace{1cm} 

AWS CLI supported environment variables
For more information on using web identities, see the section called “Assume role with web identity”.

**Note**

This environment variable only applies to an assumed role with web identity provider it does not apply to the general assume role provider configuration.

## Command line options

In the AWS CLI, command line options are global parameters you can use to override the default configuration settings, any corresponding profile setting, or environment variable setting for that single command. You can't use command line options to directly specify credentials, although you can specify which profile to use.

### Topics

- How to use command line options
- AWS CLI supported global command line options
- Common uses of command line options

### How to use command line options

Most command line options are simple strings, such as the profile name `profile1` in the following example:

```
$ aws s3 ls --profile profile1
example-bucket-1
example-bucket-2
...
```

Each option that takes an argument requires a space or equals sign (=) separating the argument from the option name. If the argument value is a string that contains a space, you must use quotation marks around the argument. For details on argument types and formatting for parameters, see Specify parameter values for the AWS CLI.
AWS CLI supported global command line options

In the AWS CLI you can use the following command line options to override the default configuration settings, any corresponding profile setting, or environment variable setting for that single command.

--ca-bundle <string>

Specifies the certificate authority (CA) certificate bundle to use when verifying SSL certificates.

If defined, this option overrides the value for the profile setting `ca_bundle` and the `AWS_CA_BUNDLE` environment variable.

--cli-auto-prompt

Enables auto-prompt mode for a single command. As the following examples show, you can specify it at any point.

```
$ aws --cli-auto-prompt
$ aws dynamodb --cli-auto-prompt
$ aws dynamodb describe-table --cli-auto-prompt
```

This option overrides the `aws_cli_auto_prompt` environment variable and the `cli_auto_prompt` profile setting.

For information on the AWS CLI version 2 auto-prompt feature, see Have the AWS CLI prompt you for commands.

--cli-binary-format

Specifies how the AWS CLI version 2 interprets binary input parameters. It can be one of the following values:

- **base64** – This is the default value. An input parameter that is typed as a binary large object (BLOB) accepts a base64-encoded string. To pass true binary content, put the content in a file and provide the file's path and name with the `fileb://` prefix as the parameter's value. To pass base64-encoded text contained in a file, provide the file's path and name with the `file://` prefix as the parameter's value.

- **raw-in-base64-out** – Default for the AWS CLI version 1. If the setting's value is `raw-in-base64-out`, files referenced using the `file://` prefix is read as text and then the AWS CLI attempts to encode it to binary.
This overrides the `cli_binary_format` file configuration setting.

```bash
$ aws lambda invoke \
   --cli-binary-format raw-in-base64-out \
   --function-name my-function \
   --invocation-type Event \
   --payload '{ "name": "Bob" }' \
   response.json
```

If you reference a binary value in a file using the `fileb://` prefix notation, the AWS CLI always expects the file to contain raw binary content and does not attempt to convert the value.

If you reference a binary value in a file using the `file://` prefix notation, the AWS CLI handles the file according to the current `cli_binary_format` setting. If that setting's value is `base64` (the default when not explicitly set), the AWS CLI expects the file to contain base64-encoded text. If that setting's value is `raw-in-base64-out`, the AWS CLI expects the file to contain raw binary content.

`--cli-connect-timeout <integer>`

Specifies the maximum socket connect time in seconds. If the value is set to zero (0), the socket connect waits indefinitely (is blocking) and doesn't timeout.

`--cli-read-timeout <integer>`

Specifies the maximum socket read time in seconds. If the value is set to zero (0) the socket read waits indefinitely (is blocking) and doesn't timeout.

`--color <string>`

Specifies support for color output. Valid values are `on`, `off`, and `auto`. The default value is `auto`.

`--debug`

A Boolean switch that enables debug logging. The AWS CLI by default provides cleaned up information regarding any successes or failures regarding command outcomes in the command output. The `--debug` option provides the full Python logs. This includes additional `stderr` diagnostic information about the operation of the command that can be useful when troubleshooting why a command provides unexpected results. To easily view debug logs, we suggest sending the logs to a file to more easily search the information. You can do this by using one of the following.
To send only the stderr diagnostic information, append `2> debug.txt` where `debug.txt` is the name you want to use for your debug file:

```
$ aws servicename commandname options --debug 2> debug.txt
```

To send both the output and stderr diagnostic information, append `&>` `debug.txt` where `debug.txt` is the name you want to use for your debug file:

```
$ aws servicename commandname options --debug &> debug.txt
```

`--endpoint-url <string>`

Specifies the URL to send the request to. For most commands, the AWS CLI automatically determines the URL based on the selected service and the specified AWS Region. However, some commands require that you specify an account-specific URL. You can also configure some AWS services to host an endpoint directly within your private VPC, which might then need to be specified.

The following command example uses a custom Amazon S3 endpoint URL.

```
$ aws s3 ls --endpoint-url http://localhost:4567
```

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local AWS configuration files, or explicitly declared on the command line as a parameter. The AWS CLI endpoint configuration settings take precedence in the following order:

1. The `--endpoint-url` command line option.
2. If enabled, the `AWS_IGNORE_CONFIGURED_ENDPOINT_URLS` global endpoint environment variable or profile setting `ignore_configure_endpoint_urls` to ignore custom endpoints.
3. The value provided by a service-specific environment variable `AWS_ENDPOINT_URL_<SERVICE>`, such as `AWS_ENDPOINT_URL_DYNAMODB`.
4. The values provided by the `AWS_USE_DUALSTACK_ENDPOINT`, `AWS_USE_FIPS_ENDPOINT`, and `AWS_ENDPOINT_URL` environment variables.
5. The service-specific endpoint value provided by the `endpoint_url` setting within a services section of the shared config file.
The value provided by the `endpoint_url` setting within a profile of the shared config file.

7. `use_dualstack_endpoint`, `use_fips_endpoint`, and `endpoint_url` settings.

8. Any default endpoint URL for the respective AWS service is used last. For a list of the standard service endpoints available in each Region, see Amazon Regions and Endpoints in the Amazon Web Services General Reference.

---

**--no-cli-auto-prompt**

Disables auto-prompt mode for a single command.

```
$ aws dynamodb describe-table --table-name Table1 --no-cli-auto-prompt
```

This option overrides the `aws_cli_auto_prompt` environment variable and the `cli_auto_prompt` profile setting.

For information on the AWS CLI version 2 auto-prompt feature, see Have the AWS CLI prompt you for commands.

---

**--no-cli-pager**

A Boolean switch that disables using a pager for the output of the command.

---

**--no-paginate**

A Boolean switch that disables the multiple calls the automatically AWS CLI makes to receive all command results that creates pagination of the output. This means only the first page of your output is displayed.

---

**--no-sign-request**

A Boolean switch that disables signing the HTTP requests to the AWS service endpoint. This prevents credentials from being loaded.

---

**--no-verify-ssl**

By default, the AWS CLI uses SSL when communicating with AWS services. For each SSL connection and call, the AWS CLI verifies the SSL certificates. Using this option overrides the default behavior of verifying SSL certificates.

---

⚠️ **Warning**

This option is **not** best practice. If you use `--no-verify-ssl`, your traffic between your client and AWS services is no longer secured. This means your traffic is a security
risk and vulnerable to man-in-the-middle exploits. If you're having issues with certificates, it's best to resolve those issues instead. For certificate troubleshooting steps, see the section called “SSL certificate errors”.

--output <string>

Specifies the output format to use for this command. You can specify any of the following values:

- **json** – The output is formatted as a JSON string.
- **yaml** – The output is formatted as a YAML string.
- **yaml-stream** – The output is streamed and formatted as a YAML string. Streaming allows for faster handling of large data types.
- **text** – The output is formatted as multiple lines of tab-separated string values. This can be useful to pass the output to a text processor, like grep, sed, or awk.
- **table** – The output is formatted as a table using the characters +|- to form the cell borders. It typically presents the information in a "human-friendly" format that is much easier to read than the others, but not as programmatically useful.

--profile <string>

Specifies the named profile to use for this command. To set up additional named profiles, you can use the `aws configure` command with the --profile option.

```
$ aws configure --profile <profilename>
```

--query <string>

Specifies a JMESPath query to use in filtering the response data. For more information, see Filter AWS CLI output.

--region <string>

Specifies which AWS Region to send this command's AWS request to. For a list of all of the Regions that you can specify, see AWS Regions and Endpoints in the Amazon Web Services General Reference.

--version

A Boolean switch that displays the current version of the AWS CLI program that is running.
Common uses of command line options

Common uses for command line options include checking your resources in multiple AWS Regions, and changing the output format for legibility or ease of use when scripting. In the following examples, we run the `describe-instances` command against each Region until we find which Region our instance is in.

```
$ aws ec2 describe-instances --output table --region us-west-1
---------------------------------
| DescribeInstances |
+-------------------+
$ aws ec2 describe-instances --output table --region us-west-2
--------------------------------------------------------------------------
|                        DescribeInstances                        |
+-------------------------------------------------------------------+
||                        Reservations                       ||
+-------------------------------------+-----------------------------+|
||  OwnerId                            |  012345678901              ||
||  ReservationId                      |  r-abcdefgh                 ||
+-------------------------------------+-----------------------------+|
|||                       Instances       |||

Command completion

The AWS Command Line Interface (AWS CLI) includes a bash-compatible command-completion feature that enables you to use the Tab key to complete a partially entered command. On most systems you need to configure this manually.

For information on the AWS CLI version 2 auto-prompt feature instead, see Have the AWS CLI prompt you for commands.

Topics

- How it works
- Configuring command completion on Linux or macOS
- Configuring command completion on Windows
How it works

When you partially enter a command, parameter, or option, the command-completion feature either automatically completes your command or displays a suggested list of commands. To prompt command completion, you partially enter in a command and press the completion key, which is typically `Tab` in most shells.

The following examples show different ways that you can use command completion:

- Partially enter a command and press `Tab` to display a suggested list of commands.

```
$ aws dynamodb dTAB
```

<table>
<thead>
<tr>
<th>delete-backup</th>
<th>describe-global-table</th>
</tr>
</thead>
<tbody>
<tr>
<td>delete-item</td>
<td>describe-global-table-settings</td>
</tr>
<tr>
<td>delete-table</td>
<td>describe-limits</td>
</tr>
<tr>
<td>describe-backup</td>
<td>describe-table</td>
</tr>
<tr>
<td>describe-continuous-backups</td>
<td>describe-table-replica-auto-scaling</td>
</tr>
<tr>
<td>describe-contributor-insights</td>
<td>describe-time-to-live</td>
</tr>
<tr>
<td>describe-endpoints</td>
<td></td>
</tr>
</tbody>
</table>

- Partially enter a parameter and press `Tab` to display a suggested list of parameters.

```
$ aws dynamodb delete-table --TAB
```

<table>
<thead>
<tr>
<th>--ca-bundle</th>
<th>--endpoint-url</th>
<th>--profile</th>
</tr>
</thead>
<tbody>
<tr>
<td>--cli-connect-timeout</td>
<td>--generate-cli-skeleton</td>
<td>--query</td>
</tr>
<tr>
<td>--cli-input-json</td>
<td>--no-paginate</td>
<td>--region</td>
</tr>
<tr>
<td>--cli-read-timeout</td>
<td>--no-sign-request</td>
<td>--table-name</td>
</tr>
<tr>
<td>--color</td>
<td>--no-verify-ssl</td>
<td>--version</td>
</tr>
<tr>
<td>--debug</td>
<td>--output</td>
<td></td>
</tr>
</tbody>
</table>

- Enter a parameter and press `Tab` to display a suggested list of resource values. This feature is available only in the AWS CLI version 2.

```
$ aws dynamodb db delete-table --table-name TAB
```

<table>
<thead>
<tr>
<th>Table 1</th>
<th>Table 2</th>
<th>Table 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table 1</td>

Configuring command completion on Linux or macOS

To configure command completion on Linux or macOS, you must know the name of the shell you're using and the location of the `aws_completer` script.
Confirm the completer's folder is in your path

For the AWS completer to work successfully, the `aws_completer` needs to be in your shell's path. The `which` command can check if the completer is in your path.

```
$ which aws_completer
/usr/local/bin/aws_completer
```

If the `which` command can't find the completer, then use the following steps to add the completer's folder to your path.

**Step 1: Locate the AWS completer**

The location of the AWS completer can vary depending on the installation method used.

- **Package Manager** - Programs such as pip, yum, brew, and `apt-get` typically install the AWS completer (or a symlink to it) to a standard path location.
  - If you used pip **without** the `--user` parameter, the default path is `/usr/local/bin/aws_completer`.
  - If you used pip **with** the `--user` parameter, the default path is `/home/username/.local/bin/aws_completer`.

- **Bundled Installer** - If you used the bundled installer, the default path is `/usr/local/bin/aws_completer`.

If all else fails, you can use the `find` command to search your file system for the AWS completer.
Step 2: Identify your shell

To identify which shell you’re using, you can use one of the following commands.

- **echo $SHELL** – Displays the shell’s program file name. This usually matches the name of the in-use shell, unless you launched a different shell after logging in.

  ```bash
  $ echo $SHELL
  /bin/bash
  ```

- **ps** – Displays the processes running for the current user. One of them is the shell.

  ```bash
  $ ps
  PID TTY          TIME CMD
  2148 pts/1    00:00:00 bash
  8756 pts/1    00:00:00 ps
  ```

Step 3: Add the completer to your path

1. Find your shell’s profile script in your user folder.

   ```bash
   $ ls -a ~/
   . .. .bash_logout .bash_profile .bashrc Desktop Documents Downloads
   ```

   - **Bash**—`.bash_profile, .profile, or .bash_login`
   - **Zsh**—`.zshrc`
   - **Tcsh**—`.tcshrc, .cshrc, or .login`

2. Add an export command at the end of your profile script that’s similar to the following example. Replace `/usr/local/bin/` with the folder that you discovered in the previous section.

   ```bash
   export PATH=/usr/local/bin/:$PATH
   ```

3. Reload the profile into the current session to put those changes into effect. Replace `.bash_profile` with the name of the shell script you discovered in the first section.
Enable command completion

After confirming the completer is in your path, enable command completion by running the appropriate command for the shell that you’re using. You can add the command to your shell’s profile to run it each time you open a new shell. In each command, replace the `/usr/local/bin/` path with the one found on your system in Confirm the completer’s folder is in your path.

- **bash** – Use the built-in command `complete`.

  ```bash
  $ complete -C '/usr/local/bin/aws_completer' aws
  ```

  Add the previous command to `~/.bashrc` to run it each time you open a new shell. Your `~/.bash_profile` should source `~/.bashrc` to ensure that the command is also run in login shells.

- **zsh** – To run command completion, you need to run `bashcompinit` by adding the following autoload line at the end of your `~/.zshrc` profile script.

  ```bash
  $ autoload bashcompinit && bashcompinit
  $ autoload -Uz compinit && compinit
  ```

  To enable command completion, use the built-in command `complete`.

  ```bash
  $ complete -C '/usr/local/bin/aws_completer' aws
  ```

  Add the previous commands to `~/.zshrc` to run it each time you open a new shell.

- **tcsh** – Complete for `tcsh` takes a word type and pattern to define the completion behavior.

  ```bash
  > complete aws 'p/*/`aws_completer`/'
  ```

  Add the previous command to `~/.tcshrc` to run it each time you open a new shell.

After you’ve enabled command completion, [Verify command completion](#) is working.
Verify command completion

After enabling command completion, reload your shell, enter a partial command, and press Tab to see the available commands.

$ aws sTAB
s3          ses             sqs             sts             swf

Configuring command completion on Windows

Note
For information on how PowerShell handles their completion, including their various completion keys, see about_Tab_Expansion in the Microsoft PowerShell Docs.

To enable command completion for PowerShell on Windows, complete the following steps in PowerShell.

1. Open your $PROFILE with the following command.

   PS C:\> Notepad $PROFILE

   If you do not have a $PROFILE, create a user profile using the following command.

   PS C:\> if (!(Test-Path -Path $PROFILE ))
   { New-Item -Type File -Path $PROFILE -Force }

   For more information on PowerShell profiles, see How to Use Profiles in Windows PowerShell ISE on the Microsoft Docs website.

2. To enable command completion, add the following code block to your profile, save, and then close the file.

   Register-ArgumentCompleter -Native -CommandName aws -ScriptBlock {
       param($commandName, $wordToComplete, $cursorPosition)
       $env:COMP_LINE=$wordToComplete
       if ($env:COMP_LINE.Length -lt $cursorPosition){
           $env:COMP_LINE=$env:COMP_LINE + " "
   }

   Configuring command completion on Windows
   144
3. After enabling command completion, reload your shell, enter a partial command, and press `Tab` to cycle through the available commands.

```
$ aws sTab
```

```
$ aws s3
```

To see all available commands available to your completion, enter a partial command and press `Ctrl + Space`.

```
$ aws sCtrl + Space
s3    ses    sqs    sts    swf

### AWS CLI retries

This topic describes how the AWS CLI might see calls to AWS services fail due to unexpected issues. These issues can occur on the server side or might fail due to rate limiting from the AWS service you’re attempting to call. These kinds of failures usually don’t require special handling and the call is automatically made again, often after a brief waiting period. The AWS CLI provides many features to assist in retrying client calls to AWS services when these kinds of errors or exceptions are experienced.

**Topics**

- [Available retry modes](#)
- [Configuring a retry mode](#)
- [Viewing logs of retry attempts](#)
Available retry modes

The AWS CLI has multiple modes to choose from depending on your version:

- Legacy retry mode
- Standard retry mode
- Adaptive retry mode

Legacy retry mode

Legacy mode uses an older retry handler that has limited functionality which includes:

- A default value of 4 for maximum retry attempts, making a total of 5 call attempts. This value can be overwritten through the `max_attempts` configuration parameter.
- DynamoDB has a default value of 9 for maximum retry attempts, making a total of 10 call attempts. This value can be overwritten through the `max_attempts` configuration parameter.
- Retry attempts for the following limited number of errors/exceptions:
  - General socket/connection errors:
    - `ConnectionError`
    - `ConnectionClosedError`
    - `ReadTimeoutError`
    - `EndpointConnectionError`
  - Service-side throttling/limit errors and exceptions:
    - `Throttling`
    - `ThrottlingException`
    - `ThrottledException`
    - `RequestThrottledException`
    - `ProvisionedThroughputExceededException`
  - Retry attempts on several HTTP status codes, including 429, 500, 502, 503, 504, and 509.
  - Any retry attempt will include an exponential backoff by a base factor of 2.
Standard retry mode

Standard mode is a standard set of retry rules across the AWS SDKs with more functionality than legacy. This mode is the default for AWS CLI version 2. Standard mode was created for the AWS CLI version 2 and is backported to AWS CLI version 1. Standard mode’s functionality includes:

- A default value of 2 for maximum retry attempts, making a total of 3 call attempts. This value can be overwritten through the `max_attempts` configuration parameter.

- Retry attempts for the following expanded list of errors/exceptions:
  - Transient errors/exceptions
    - RequestTimeout
    - RequestTimeoutException
    - PriorRequestNotComplete
    - ConnectionError
    - HTTPClientError
  - Service-side throttling/limit errors and exceptions:
    - Throttling
    - ThrottlingException
    - ThrottledException
    - RequestThrottledException
    - TooManyRequestsException
    - ProvisionedThroughputExceededException
    - TransactionInProgressException
    - RequestLimitExceeded
    - BandwidthLimitExceeded
    - LimitExceededException
    - RequestThrottled
    - SlowDown
    - EC2ThrottledException

- Retry attempts on nondescriptive, transient error codes. Specifically, these HTTP status codes: 500, 502, 503, 504.
• Any retry attempt will include an exponential backoff by a base factor of 2 for a maximum backoff time of 20 seconds.

Adaptive retry mode

⚠️ Warning
Adaptive mode is an experimental mode and is subject to change, both in features and behavior.

Adaptive retry mode is an experimental retry mode that includes all the features of standard mode. In addition to the standard mode features, adaptive mode also introduces client-side rate limiting through the use of a token bucket and rate-limit variables that are dynamically updated with each retry attempt. This mode offers flexibility in client-side retries that adapts to the error/exception state response from an AWS service.

With each new retry attempt, adaptive mode modifies the rate-limit variables based on the error, exception, or HTTP status code presented in the response from the AWS service. These rate-limit variables are then used to calculate a new call rate for the client. Each exception/error or non-success HTTP response (provided in the list above) from an AWS service updates the rate-limit variables as retries occur until success is reached, the token bucket is exhausted, or the configured maximum attempts value is reached.

Configuring a retry mode

The AWS CLI includes a variety of both retry configurations as well as configuration methods to consider when creating your client object.

Available configuration methods

In the AWS CLI, users can configure retries in the following ways:

- Environment variables
- AWS CLI configuration file

Users can customize the following retry options:
• Retry mode - Specifies which retry mode the AWS CLI uses. As described previously, there are three retry modes available: legacy, standard, and adaptive. The default value for the AWS CLI version 2 is standard.

• Max attempts - Specifies the value of maximum retry attempts the AWS CLI retry handler uses, where the initial call counts toward the value that you provide. The default value is 5.

**Defining a retry configuration in your environment variables**

To define your retry configuration for the AWS CLI, update your operating system's environment variables.

The retry environment variables are:

- AWS_RETRY_MODE
- AWS_MAX_ATTEMPTS

For more information on environment variables, see [Environment variables to configure the AWS CLI](#).

**Defining a retry configuration in your AWS configuration file**

To change your retry configuration, update your global AWS configuration file. The default location for your AWS config file is ~/.aws/config.

The following is an example of an AWS config file:

```
[default]
retry_mode = standard
max_attempts = 6
```

For more information on configuration files, see [Configuration and credential file settings](#).

**Viewing logs of retry attempts**

The AWS CLI uses Boto3’s retry methodology and logging. You can use the --debug option on any command to receive debug logs. For more information on how to use the --debug option, see [Command line options](#).
If you search for "retry" in your debug logs, you'll find the retry information you need. The client log entries for retry attempts depend on which retry mode you've enabled.

**Legacy mode:**

Retry messages are generated by botocore.retryhandler. You'll see one of three messages:

- No retry needed
- Retry needed, action of: `<action_name>`
- Reached the maximum number of retry attempts: `<attempt_number>`

**Standard or adaptive mode:**

Retry messages are generated by botocore.retries.standard. You'll see one of three messages:

- No retrying request
- Retry needed, retrying request after delay of: `<delay_value>`
- Retry needed but retry quota reached, not retrying request

For the full definition file of botocore retries, see `_retry.json` on the botocore GitHub Repository.

**Use an HTTP proxy**

To access AWS through proxy servers, you can configure the HTTP_PROXY and HTTPS_PROXY environment variables with either the DNS domain names or IP addresses and port numbers that your proxy servers use.

**Topics**

- [Using the examples](#)
- [Authenticating to a proxy](#)

Using the examples

Note

The following examples show the environment variable name in all uppercase letters. However, if you specify a variable twice using different cases, the lowercase letters take precedence. We recommend that you define each variable only once to avoid system confusion and unexpected behavior.

The following examples show how you can use either the explicit IP address of your proxy or a DNS name that resolves to the IP address of your proxy. Either can be followed by a colon and the port number to which queries should be sent.

Linux or macOS

$ export HTTP_PROXY=http://10.15.20.25:1234
$ export HTTP_PROXY=http://proxy.example.com:1234
$ export HTTPS_PROXY=http://10.15.20.25:5678
$ export HTTPS_PROXY=http://proxy.example.com:5678

Windows Command Prompt

To set for all sessions

C:\> setx HTTP_PROXY http://10.15.20.25:1234
C:\> setx HTTP_PROXY http://proxy.example.com:1234
C:\> setx HTTPS_PROXY http://10.15.20.25:5678
C:\> setx HTTPS_PROXY http://proxy.example.com:5678

Using `setx` to set an environment variable changes the value used in both the current command prompt session and all command prompt sessions that you create after running the command. It does not affect other command shells that are already running at the time you run the command.

To set for current session only

Using `set` to set an environment variable changes the value used until the end of the current command prompt session, or until you set the variable to a different value.
Authenticating to a proxy

**Note**
The AWS CLI doesn't support NTLM proxies. If you use an NTLM or Kerberos protocol proxy, you might be able to connect through an authentication proxy like Cntlm.

The AWS CLI supports HTTP Basic authentication. Specify the username and password in the proxy URL, as follows.

**Linux or macOS**

```bash
$ export HTTP_PROXY=http://username:password@proxy.example.com:1234
$ export HTTPS_PROXY=http://username:password@proxy.example.com:5678
```

**Windows Command Prompt**

**To set for all sessions**

```cmd
C:\> setx HTTP_PROXY http://username:password@proxy.example.com:1234
C:\> setx HTTPS_PROXY http://username:password@proxy.example.com:5678
```

**To set for current session only**

```cmd
C:\> set HTTP_PROXY=http://username:password@proxy.example.com:1234
C:\> set HTTPS_PROXY=http://username:password@proxy.example.com:5678
```

**Using a proxy on Amazon EC2 instances**

If you configure a proxy on an Amazon EC2 instance launched with an attached IAM role, ensure that you exempt the address used to access the instance metadata. To do this, set the NO_PROXY
environment variable to the IP address of the instance metadata service, 169.254.169.254. This address does not vary.

Linux or macOS

$$\texttt{export NO_PROXY=169.254.169.254}$$

Windows Command Prompt

To set for all sessions

```
C:\> setx NO_PROXY 169.254.169.254
```

To set for current session only

```
C:\> set NO_PROXY=169.254.169.254
```

Troubleshooting

If you come across issues with the AWS CLI, see [Troubleshoot errors](#) for troubleshooting steps. For the most relevant troubleshooting steps, see the section called “SSL certificate errors”.

Use endpoints in the AWS CLI

To connect programmatically to an AWS service, you use an endpoint. An *endpoint* is the URL of the entry point for an AWS web service. The AWS Command Line Interface (AWS CLI) automatically uses the default endpoint for each service in an AWS Region, but you can specify an alternate endpoint for your API requests.

**Endpoint topics**

- [Set endpoint for a single command](#)
- [Set global endpoint for all AWS services](#)
- [Set to use FIPs endpoints for all AWS services](#)
- [Set to use dual-stack endpoints for all AWS services](#)
- [Set service-specific endpoints](#)
  - [Service-specific endpoints: Environment variables](#)
Set endpoint for a single command

To override any endpoint settings or environment variables for a single command, use the `--endpoint-url` command line option. The following command example uses a custom Amazon S3 endpoint URL.

```
$ aws s3 ls --endpoint-url http://localhost:4567
```

Set global endpoint for all AWS services

To route requests for all services to a custom endpoint URL, use one of the following settings:

- Environment variables:
  - `AWS_IGNORE_CONFIGURED_ENDPOINT_URLS` - Ignore configured endpoint URLs.

  **Linux or macOS**
  ```
  $ export AWS_IGNORE_CONFIGURED_ENDPOINT_URLS=true
  ```

  **Windows Command Prompt**
  
  **To set for all sessions**
  ```
  C:\> setx AWS_IGNORE_CONFIGURED_ENDPOINT_URLS=true
  ```

  **To set for current session only**
  ```
  C:\> set AWS_IGNORE_CONFIGURED_ENDPOINT_URLS=true
  ```

  **PowerShell**
  ```
  PS C:\> $Env:AWS_IGNORE_CONFIGURED_ENDPOINT_URLS="true"
  ```

- `AWS_ENDPOINT_URL` - Set global endpoint URL.
Linux or macOS

```bash
$ export AWS_ENDPOINT_URL=http://localhost:4567
```

Windows Command Prompt

**To set for all sessions**

```
C:\> setx AWS_ENDPOINT_URL http://localhost:4567
```

**To set for current session only**

```
C:\> set AWS_ENDPOINT_URL=http://localhost:4567
```

PowerShell

```
PS C:\> $Env:AWS_ENDPOINT_URL="http://localhost:4567"
```

- The config file:
  - `ignore_configure_endpoint_urls` - Ignore configured endpoint URLs.
    ```
    ignore_configure_endpoint_urls = true
    ```
  - `endpoint_url` - Set global endpoint URL.
    ```
    endpoint_url = http://localhost:4567
    ```

Service-specific endpoints and the `--endpoint-url` command line option override any global endpoints.

**Set to use FIPs endpoints for all AWS services**

To route requests for all services to use FIPs endpoints, use one of the following:

- `AWS_USE_FIPS_ENDPOINT` environment variable.
Linux or macOS

```bash
$ export AWS_USE_FIPS_ENDPOINT=true
```

Windows Command Prompt

**To set for all sessions**

```cmd
C:\> setx AWS_USE_FIPS_ENDPOINT true
```

**To set for current session only**

```cmd
C:\> set AWS_USE_FIPS_ENDPOINT=true
```

PowerShell

```powershell
PS C:\> $Env:AWS_USE_FIPS_ENDPOINT="true"
```

- use_fips_endpoint file setting.

```bash
use_fips_endpoint = true
```

Some AWS services offer endpoints that support Federal Information Processing Standard (FIPS) 140-2 in some AWS Regions. When the AWS service supports FIPS, this setting specifies what FIPS endpoint the AWS CLI should use. Unlike standard AWS endpoints, FIPS endpoints use a TLS software library that complies with FIPS 140-2. These endpoints might be required by enterprises that interact with the United States government.

If this setting is enabled, but a FIPS endpoint does not exist for the service in your AWS Region, the AWS command may fail. In this case, manually specify the endpoint to use in the command using the --endpoint-url option or use service-specific endpoints.

For more information on specifying FIPS endpoints by AWS Region, see FIPS Endpoints by Service.

### Set to use dual-stack endpoints for all AWS services

To route requests for all services to use dual-stack endpoints when available, use one of the following settings:
- **AWS_USE_DUALSTACK_ENDPOINT** environment variable.

  Linux or macOS

  ```bash
  $ export AWS_USE_DUALSTACK_ENDPOINT=true
  ```

  Windows Command Prompt

  **To set for all sessions**

  ```cmd
  C:\> setx AWS_USE_DUALSTACK_ENDPOINT true
  ```

  **To set for current session only**

  ```cmd
  C:\> set AWS_USE_DUALSTACK_ENDPOINT=true
  ```

  PowerShell

  ```powershell
  PS C:\> $Env:AWS_USE_DUALSTACK_ENDPOINT="true"
  ```

- **use_dualstack_endpoint** file setting.

  ```bash
  use_dualstack_endpoint = true
  ```

Enables the use of dual-stack endpoints to send AWS requests. To learn more about dual-stack endpoints, which support both IPv4 and IPv6 traffic, see [Using Amazon S3 dual-stack endpoints](#) in the *Amazon Simple Storage Service User Guide*. Dual-stack endpoints are available for some services in some regions. If a dual-stack endpoint does not exist for the service or AWS Region, the request fails. This is disabled by default.

**Set service-specific endpoints**

Service-specific endpoint configuration provides the option to use a persistent endpoint of your choosing for AWS CLI requests. These settings provide flexibility to support local endpoints, VPC endpoints, and third-party local AWS development environments. Different endpoints can be used for testing and production environments. You can specify an endpoint URL for individual AWS services.

Service-specific endpoints can be specified in the following ways:
• The command line option `--endpoint-url` for a single command.

• Environment variables:

  • `AWS_IGNORE_CONFIGURED_ENDPOINT_URLS` - Ignore all configured endpoint URLs, unless specified on the command line.

  • `AWS_ENDPOINT_URL_<SERVICE>` - Specifies a custom endpoint that is used for a specific service, where `<SERVICE>` is replace with the AWS service identifier. For all service-specific variables, see the section called “List of service-specific identifiers”.

• config file:

  • `ignore_configure_endpoint_urls` - Ignore all configured endpoint URLs, unless specified using environment variables or on the command line.

  • The `services` section of the config file combined with the `endpoint_url` file setting.

**Service-specific endpoints topics:**

• [Service-specific endpoints: Environment variables](#)

• [Service-specific endpoints: Shared config file](#)

• [Service-specific endpoints: List of service-specific identifiers](#)

**Service-specific endpoints: Environment variables**

Environment variables override settings in your config file, but do not override options specified on the command line. Use environment variables if you want all profiles to use the same endpoints on your device.

The following are service-specific environment variables:

• `AWS_IGNORE_CONFIGURED_ENDPOINT_URLS` - Ignore all configured endpoint URLs, unless specified on the command line.

  Linux or macOS

  ```
  $ export AWS_IGNORE_CONFIGURED_ENDPOINT_URLS=true
  ```

  Windows Command Prompt

  **To set for all sessions**
To set for current session only

C:\> set AWS_IGNORE_CONFIGURED_ENDPOINT_URLS=true

PowerShell

PS C:\> $Env:AWS_IGNORE_CONFIGURED_ENDPOINT_URLS="true"

- **AWS_ENDPOINT_URL_<SERVICE>** - Specifies a custom endpoint that is used for a specific service, where `<SERVICE>` is replaced with the AWS service identifier. For all service-specific variables, see the section called “List of service-specific identifiers”.

The following environment variable examples sets an endpoint for AWS Elastic Beanstalk:

Linux or macOS

$ export AWS_ENDPOINT_URL_ELASTIC_BEANSTALK=http://localhost:4567

Windows Command Prompt

To set for all sessions

C:\> setx AWS_ENDPOINT_URL_ELASTIC_BEANSTALK http://localhost:4567

To set for current session only

C:\> set AWS_ENDPOINT_URL_ELASTIC_BEANSTALK=http://localhost:4567

PowerShell

PS C:\> $Env:AWS_ENDPOINT_URL_ELASTIC_BEANSTALK="http://localhost:4567"

For more information on setting environment variables, see the section called “Environment Variables”.

Set service-specific endpoints
Service-specific endpoints: Shared config file

In the shared config file, endpoint_url is used in multiple sections. To set a service-specific endpoint, use the endpoint_url setting nested under a service identifier key within a services section. For details on defining a services section in your shared config file, see the section called “services”.

The following example uses a services section to configure a service-specific endpoint URL for Amazon S3 and a custom global endpoint used for all other services:

```
[profile dev1]
endpoint_url = http://localhost:1234
services = s3-specific

[services testing-s3]
s3 =
  endpoint_url = http://localhost:4567
```

A single profile can configure endpoints for multiple services. The following example sets the service-specific endpoint URLs for Amazon S3 and AWS Elastic Beanstalk in the same profile.

For a list of all service identifier keys to use in the services section, see List of service-specific identifiers.

```
[profile dev1]
services = testing-s3-and-eb

[services testing-s3-and-eb]
s3 =
  endpoint_url = http://localhost:4567
elastic_beanstalk =
  endpoint_url = http://localhost:8000
```

The service configuration section can be used in multiple profiles. The following example has two profiles use the same services definition:

```
[profile dev1]
output = json
services = testing-s3

[profile dev2]
```
Service-specific endpoints: List of service-specific identifiers

The AWS service identifier is based on the API model's serviceId by replacing all spaces with underscores and lowercasing all letters.

The following service identifier example uses AWS Elastic Beanstalk. AWS Elastic Beanstalk has a serviceId of Elastic Beanstalk, therefore the service identifier key is elastic_beanstalk.

The following table lists all service-specific identifiers, config file keys, and environment variables.

Endpoint configuration and settings precedence

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local AWS configuration files, or explicitly declared on the command line as a parameter. The AWS CLI endpoint configuration settings take precedence in the following order:

1. The `--endpoint-url` command line option.
2. If enabled, the `AWS_IGNORE_CONFIGURED_ENDPOINT_URLS` global endpoint environment variable or profile setting `ignore_configure_endpoint_urls` to ignore custom endpoints.
3. The value provided by a service-specific environment variable `AWS_ENDPOINT_URL_<SERVICE>`, such as `AWS_ENDPOINT_URL_DYNAMODB`.
4. The values provided by the `AWS_USE_DUALSTACK_ENDPOINT`, `AWS_USE_FIPS_ENDPOINT`, and `AWS_ENDPOINT_URL` environment variables.
5. The service-specific endpoint value provided by the `endpoint_url` setting within a services section of the shared config file.
6. The value provided by the `endpoint_url` setting within a profile of the shared config file.
7. `use_dualstack_endpoint`, `use_fips_endpoint`, and `endpoint_url` settings.
8. Any default endpoint URL for the respective AWS service is used last. For a list of the standard service endpoints available in each Region, see [AWS Regions and Endpoints](https://aws.amazon.com/integrations/aws-regions-endpoints/) in the *Amazon Web Services General Reference*. 
# Authentication and access credentials

You must establish how the AWS CLI authenticates with AWS when you develop with AWS services. To configure credentials for programmatic access for the AWS CLI, choose one of the following options. The options are in order of recommendation.

Configuration and credential precedence

Credentials and configuration settings are located in multiple places, such as the system or user environment variables, local AWS configuration files, or explicitly declared on the command line as a parameter. Certain authentication take precedence over others. The AWS CLI authentication settings take precedence in the following order:

1. **Command line options** – Overrides settings in any other location, such as the `--region`, `--output`, and `--profile` parameters.
2. **Environment variables** – You can store values in your system’s environment variables.
3. **Assume role** – Assume the permissions of an IAM role through configuration or the `aws sts assume-role` command.
4. **Assume role with web identity** – Assume the permissions of an IAM role using web identity through configuration or the `aws sts assume-role` command.
5. **AWS IAM Identity Center** – The IAM Identity Center configuration settings stored in the config file are updated when you run the `aws configure sso` command. Credentials are then authenticated when you run the `aws sso login` command. The config file is located at `~/.aws/config` on Linux or macOS, or at `C:\Users\USERNAME\.aws\config` on Windows.
6. **Credentials file** – The credentials and config file are updated when you run the command `aws configure`. The credentials file is located at `~/.aws/credentials` on Linux or macOS, or at `C:\Users\USERNAME\.aws\credentials` on Windows.
7. **Custom process** – Get your credentials from an external source.
8. **Configuration file** – The credentials and config file are updated when you run the command `aws configure`. The config file is located at `~/.aws/config` on Linux or macOS, or at `C:\Users\USERNAME\.aws\config` on Windows.
9. **Container credentials** – You can associate an IAM role with each of your Amazon Elastic Container Service (Amazon ECS) task definitions. Temporary credentials for that role are then available to that task's containers. For more information, see [IAM Roles for Tasks](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/iam-roles.html) in the *Amazon Elastic Container Service Developer Guide*.
10. **Amazon EC2 instance profile credentials** – You can associate an IAM role with each of your Amazon Elastic Compute Cloud (Amazon EC2) instances. Temporary credentials for that role are then available to code running in the instance. The credentials are delivered through the Amazon EC2 metadata service. For more information, see [IAM Roles for Amazon EC2](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_for_amazon_resource.html) in the *Amazon EC2 User Guide for Linux Instances* and [Using Instance Profiles](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_for_amazon_resource.html) in the *IAM User Guide*.

Configure the AWS CLI to use AWS IAM Identity Center

There are primarily two ways to authenticate users with AWS IAM Identity Center (IAM Identity Center) to get credentials to run AWS Command Line Interface (AWS CLI) commands through the config file:

- **(Recommended) SSO token provider configuration.** The SSO token provider configuration, your AWS SDK or tool can automatically retrieve refreshed authentication tokens.
- **Legacy non-refreshable configuration.** When using the legacy non-refreshable configuration, you need to manually refresh the token as it periodically expires.

When using IAM Identity Center, you can login to Active Directory, a built-in IAM Identity Center directory, or another IdP connected to IAM Identity Center. You can map these credentials to an AWS Identity and Access Management (IAM) role for you to run AWS CLI commands.

Regardless of which IdP you use, IAM Identity Center abstracts those distinctions away. For example, you can connect Microsoft Azure AD as described in the blog article [The Next Evolution in IAM Identity Center](https://aws.amazon.com/blogs/aws/the-next-evolution-in-iam-identity-center/).

⚠️ **Note**

For information on using bearer auth, which uses no account ID and role, see [Setting up to use the AWS CLI with CodeCatalyst](https://docs.aws.amazon.com/codecatalyst/latest/userguide/setup.html) in the Amazon CodeCatalyst User Guide.

Configure the AWS CLI to use IAM Identity Center token provider credentials with automatic authentication refresh

This topic describes how to configure the AWS CLI to authenticate users with the AWS IAM Identity Center (IAM Identity Center) token provider configuration. Using this SSO token provider configuration, your AWS SDK or tool can automatically retrieve refreshed authentication tokens.

When using IAM Identity Center, you can login to Active Directory, a built-in IAM Identity Center directory, or another IdP connected to IAM Identity Center. You can map these credentials to an AWS Identity and Access Management (IAM) role for you to run AWS CLI commands.

Regardless of which IdP you use, IAM Identity Center abstracts those distinctions away. For example, you can connect Microsoft Azure AD as described in the blog article The Next Evolution in IAM Identity Center.

Note

For information on using bearer auth, which uses no account ID and role, see Setting up to use the AWS CLI with CodeCatalyst in the Amazon CodeCatalyst User Guide.

You can use the SSO token provider configuration to automatically refresh authentication tokens as needed for your application, and to use extended session duration options. You can configure this in the following ways:

- Automatically, using the aws configure sso and aws configure sso-session commands. The following commands are wizards that guide you through configuring your profile and sso-session information are the following:
  - Use aws configure sso to create or edit both your config profiles and sso-session sections.
  - Use aws configure sso-session to create or edit only sso-session sections.
- Manually, by editing the config file that stores the named profiles.
**Prerequisites**

- Install the AWS CLI. For more information, see the section called “Install/Update”.
- You must first have access to SSO authentication within IAM Identity Center. Choose one of the following methods to access your AWS credentials.

**I do not have established access through IAM Identity Center**

Follow the instructions in Getting started in the *AWS IAM Identity Center User Guide*. This process activates IAM Identity Center, creates an administrative user, and adds an appropriate least-privilege permission set.

⚠️ **Note**

Create a permission set that applies least-privilege permissions. We recommend using the predefined PowerUserAccess permission set, unless your employer has created a custom permission set for this purpose.

Exit the portal and sign in again to see your AWS accounts and options for Administrator or PowerUserAccess. Select PowerUserAccess when working with the SDK. This also helps you find details about programmatic access.

**I already have access to AWS through a federated identity provider managed by my employer (such as Azure AD or Okta)**

Sign in to AWS through your identity provider’s portal. If your Cloud Administrator has granted you PowerUserAccess (developer) permissions, you see the AWS accounts that you have access to and your permission set. Next to the name of your permission set, you see options to access the accounts manually or programmatically using that permission set.

Custom implementations might result in different experiences, such as different permission set names. If you’re not sure which permission set to use, contact your IT team for help.

**Configure your profile with the `aws configure sso` wizard**

**To configure both an IAM Identity Center profile and sso-session to your AWS CLI**

1. Gather your IAM Identity Center information by performing the following:

   1. In your AWS access portal, select the permission set you use for development, and select the **Access keys** link.

   2. In the **Get credentials** dialog box, choose the tab that matches your operating system.

   3. Choose the **IAM Identity Center credentials** method to get the SSO Start URL and SSO Region values that you need to run `aws configure sso`.

   4. For information on which scopes value to register, see [OAuth 2.0 Access scopes](#) in the **IAM Identity Center User Guide**.

2. In your preferred terminal, run the `aws configure sso` command and provide your IAM Identity Center start URL and the AWS Region that hosts the Identity Center directory.

   ```bash
   $ aws configure sso
   SSO session name (Recommended): my-sso
   SSO start URL [None]: https://my-sso-portal.awsapps.com/start
   SSO region [None]: us-east-1
   SSO registration scopes [None]: sso:account:access
   ```

3. The AWS CLI attempts to open your default browser and begin the login process for your IAM Identity Center account.

   Attempting to automatically open the SSO authorization page in your default browser.

   **If the AWS CLI cannot open the browser**, the following message appears with instructions on how to manually start the login process.
If the browser does not open or you wish to use a different device to authorize this request, open the following URL:

https://device.sso.us-west-2.amazonaws.com/

Then enter the code:

QCFK-N451

IAM Identity Center uses the code to associate the IAM Identity Center session with your current AWS CLI session. The IAM Identity Center browser page prompts you to log in with your IAM Identity Center credentials. This gives permissions to the AWS CLI to retrieve and display the AWS accounts and roles that you are authorized to use with IAM Identity Center.

![Note]

The sign in process may prompt you to allow the AWS CLI access to your data. Since the AWS CLI is built on top of the SDK for Python, permission messages may contain variations of the `botocore` name.

4. The AWS CLI displays the AWS accounts available for you to use. If you are authorized to use only one account, the AWS CLI selects that account for you automatically and skips the prompt. The AWS accounts that are available for you to use are determined by your user configuration in IAM Identity Center.

There are 2 AWS accounts available to you.
> DeveloperAccount, developer-account-admin@example.com (123456789011)
  ProductionAccount, production-account-admin@example.com (123456789022)

Use the arrow keys to select the account you want to use. The "->" character on the left points to the current choice. Press ENTER to make your selection.

5. The AWS CLI confirms your account choice, and displays the IAM roles that are available to you in the selected account. If the selected account lists only one role, the AWS CLI selects that role for you automatically and skips the prompt. The roles that are available for you to use are determined by your user configuration in IAM Identity Center.

Using the account ID 123456789011
There are 2 roles available to you.
Use the arrow keys to select the IAM role you want to use and press <ENTER>.

6. Specify the default output format, the default AWS Region to send commands to, and providing a name for the profile so you can reference this profile from among all those defined on the local computer. In the following example, the user enters a default Region, default output format, and the name of the profile. If you have a previously existing configuration, you can alternatively press <ENTER> to select any default values that are shown between the square brackets. The suggested profile name is the account ID number followed by an underscore followed by the role name.

CLI default client Region [None]: us-west-2<ENTER>
CLI default output format [None]: json<ENTER>
CLI profile name [123456789011_ReadOnly]: my-dev-profile<ENTER>

Note

If you specify default as the profile name, this profile becomes the one used whenever you run an AWS CLI command and do not specify a profile name.

7. A final message describes the completed profile configuration.

To use this profile, specify the profile name using --profile, as shown:

aws s3 ls --profile my-dev-profile

8. This results in creating the sso-session section and named profile in ~/.aws/config that looks like the following:

```
[profile my-dev-profile]
sso_session = my-sso
sso_account_id = 123456789011
sso_role_name = readOnly
region = us-west-2
output = json

[sso-session my-sso]
sso_region = us-east-1
```
You can now use this sso-session and profile to request refreshed credentials. Use the `aws sso login` command to request and retrieve the credentials needed to run commands. For instructions, see Use an IAM Identity Center named profile.

Configure only your sso-session section with `aws configure sso-session` wizard

The `aws configure sso-session` command only updates the sso-session sections in the `~/.aws/config` file. This command can be used to create or updates your sessions. This is useful if you already have existing configuration settings and would like to create new or edit existing sso-session configuration.

Run the `aws configure sso-session` command and provide your IAM Identity Center start URL and the AWS Region that hosts the Identity Center directory.

```
$ aws configure sso-session
SSO session name: my-sso
SSO start URL [None]: https://my-sso-portal.awsapps.com/start
SSO region [None]: us-east-1
SSO registration scopes [None]: sso:account:access
```

After entering in your information a message describes the completed profile configuration.

```
Completed configuring SSO session: my-sso
Run the following to login and refresh access token for this session:

aws sso login --sso-session my-sso
```

⚠️ Note

If you are signed in to the sso-session you are updating, refresh your token by running the `aws sso login` command.
Manual configuration using the config file

The sso-session section of the config file is used to group configuration variables for acquiring SSO access tokens, which can then be used to acquire AWS credentials. The following settings are used:

- (Required) `sso_start_url`
- (Required) `sso_region`
- `sso_account_id`
- `sso_role_name`
- `sso_registration_scopes`

You define an sso-session section and associate it to a profile. `sso_region` and `sso_start_url` must be set within the sso-session section. Typically, `sso_account_id` and `sso_role_name` must be set in the profile section so that the SDK can request SSO credentials.

The following example configures the SDK to request SSO credentials and supports automated token refresh:

```
[profile dev]
sso_session = my-sso
sso_account_id = 111122223333
sso_role_name = SampleRole

[sso-session my-sso]
sso_region = us-east-1
sso_start_url = https://my-sso-portal.awsapps.com/start
```

This also allows sso-session configurations to be reused across multiple profiles:

```
[profile dev]
sso_session = my-sso
sso_account_id = 111122223333
sso_role_name = SampleRole

[profile prod]
sso_session = my-sso
sso_account_id = 111122223333
sso_role_name = SampleRole2
```
However, `sso_account_id` and `sso_role_name` aren’t required for all scenarios of SSO token configuration. If your application only uses AWS services that support bearer authentication, then traditional AWS credentials are not needed. Bearer authentication is an HTTP authentication scheme that uses security tokens called bearer tokens. In this scenario, `sso_account_id` and `sso_role_name` aren’t required. See the individual guide for your AWS service to determine if it supports bearer token authorization.

Additionally, registration scopes can be configured as part of a `sso-session`. Scope is a mechanism in OAuth 2.0 to limit an application’s access to a user’s account. An application can request one or more scopes, and the access token issued to the application will be limited to the scopes granted. These scopes define the permissions requested to be authorized for the registered OIDC client and access tokens retrieved by the client. The following example sets `sso_registration_scopes` to provide access for listing accounts/roles:

```
[sso-session my-sso]
sso_region = us-east-1
sso_start_url = https://my-sso-portal.awsapps.com/start
sso_registration_scopes = sso:account:access
```

The authentication token is cached to disk under the `~/.aws/sso/cache` directory with a filename based on the session name.

**Legacy non-refreshable configuration for AWS IAM Identity Center**

This topic describes how to configure the AWS CLI to authenticate users with AWS IAM Identity Center (IAM Identity Center) to get credentials to run AWS CLI commands using the legacy method. When using the legacy non-refreshable configuration, you need to manually refresh the token as it periodically expires.

When using IAM Identity Center, you can login to Active Directory, a built-in IAM Identity Center directory, or another IdP connected to IAM Identity Center. You can map these credentials to an AWS Identity and Access Management (IAM) role where you can run AWS CLI commands.

Regardless of which IdP you use, IAM Identity Center abstracts those distinctions away. For example, you can connect Microsoft Azure AD as described in the blog article *The Next Evolution in IAM Identity Center.*
You can configure one or more of your AWS CLI named profiles to use a role from a legacy IAM Identity Center in the following ways:

- **Automatically**, using the `aws configure sso` command.
- **Manually**, by editing the config file that stores the named profiles.

**Prerequisites**

- Install the AWS CLI. For more information, see the section called “Install/Update”.
- You must first have access to SSO authentication within IAM Identity Center. Choose one of the following methods to access your AWS credentials.

**Automatic configuration for legacy configuration**

To configure an IAM Identity Center profile to your AWS CLI

1. Run the `aws configure sso` command and provide your IAM Identity Center start URL and the AWS Region that hosts the Identity Center directory.

   ```bash
   $ aws configure sso
   SSO session name (Recommended):
   SSO start URL [None]: https://my-sso-portal.awsapps.com/start
   SSO region [None]: us-east-1
   ```

2. The AWS CLI attempts to open your default browser and begin the login process for your IAM Identity Center account.

   ```bash
   SSO authorization page has automatically been opened in your default browser.
   Follow the instructions in the browser to complete this authorization request.
   ```
If the AWS CLI cannot open the browser, the following message appears with instructions on how to manually start the login process.

Using a browser, open the following URL:

https://device.sso.us-west-2.amazonaws.com/

and enter the following code:

QCFK-N451

IAM Identity Center uses the code to associate the IAM Identity Center session with your current AWS CLI session. The IAM Identity Center browser page prompts you to sign in with your IAM Identity Center credentials. This gives permissions to the AWS CLI to retrieve and display the AWS accounts and roles that you are authorized to use with IAM Identity Center.

3. Next, the AWS CLI displays the AWS accounts available for you to use. If you are authorized to use only one account, the AWS CLI selects that account for you automatically and skips the prompt. The AWS accounts that are available for you to use are determined by your user configuration in IAM Identity Center.

There are 2 AWS accounts available to you.
> DeveloperAccount, developer-account-admin@example.com (123456789011)
    ProductionAccount, production-account-admin@example.com (123456789022)

Use the arrow keys to select the account you want to use with this profile. The ">" character on the left points to the current choice. Press ENTER to make your selection.

4. Next, the AWS CLI confirms your account choice, and displays the IAM roles that are available to you in the selected account. If the selected account lists only one role, the AWS CLI selects that role for you automatically and skips the prompt. The roles that are available for you to use are determined by your user configuration in IAM Identity Center.

Using the account ID 123456789011
There are 2 roles available to you.
> ReadOnly
    FullAccess

Use the arrow keys to select the IAM role you want to use with this profile and press <ENTER>.

5. The AWS CLI confirms your role selection.
Using the role name "ReadOnly"

6. Finish the configuration of your profile by specifying the default output format, the default AWS Region to send commands to, and providing a name for the profile so you can reference this profile from among all those defined on the local computer. In the following example, the user enters a default Region, default output format, and the name of the profile. You can alternatively press <ENTER> to select any default values that are shown between the square brackets. The suggested profile name is the account ID number followed by an underscore followed by the role name.

   CLI default client Region [None]: us-west-2<ENTER>
   CLI default output format [None]: json<ENTER>
   CLI profile name [123456789011_ReadOnly]: my-dev-profile<ENTER>

   Note
   If you specify default as the profile name, this profile becomes the one used whenever you run an AWS CLI command and do not specify a profile name.

7. A final message describes the completed profile configuration.

   To use this profile, specify the profile name using --profile, as shown:

   aws s3 ls --profile my-dev-profile

8. The previous example entries would result in a named profile in ~/.aws/config that looks like the following example.

   [profile my-dev-profile]
   sso_start_url = https://my-sso-portal.awsapps.com/start
   sso_region = us-east-1
   sso_account_id = 123456789011
   sso_role_name = readOnly
   region = us-west-2
   output = json
At this point, you have a profile that you can use to request temporary credentials. You must use the `aws sso login` command to actually request and retrieve the temporary credentials needed to run commands. For instructions, see [Use an IAM Identity Center named profile](#).

**Manual configuration for legacy configuration**

Automated token refresh isn't supported using the legacy non-refreshable configuration. We recommend using the SSO token configuration.

To manually add IAM Identity Center support to a named profile, you must add the following keys and values to the profile definition in the file `~/.aws/config` (Linux or macOS) or `%USERPROFILE%/.aws/config` (Windows).

- `sso_start_url`
- `sso_region`
- `sso_account_id`
- `sso_role_name`

You can include any other keys and values that are valid in the `.aws/config` file, such as `region`, `output`, or `s3`. To prevent errors, don't include any credential related values, such as `role_arn` or `aws_secret_access_key`.

The following is an example IAM Identity Center profile in `.aws/config`:

```
[profile my-sso-profile]
sso_start_url = https://my-sso-portal.awsapps.com/start
sso_region = us-west-2
sso_account_id = 111122223333
sso_role_name = SSORoleReadOnly
region = us-west-2
output = json
```

Your profile for temporary credentials is complete.

To run commands, you must first use the `aws sso login` command to request and retrieve your temporary credentials. For instructions, see the next section, [Use an IAM Identity Center named profile](#). The authentication token is cached to disk under the `~/.aws/sso/cache` directory with a filename based on the `sso_start_url`. 
Use an IAM Identity Center named profile

This topic describes how to use the AWS CLI to authenticate users with AWS IAM Identity Center (IAM Identity Center) to get credentials to run AWS CLI commands.

Note
Whether your credentials are temporary or automatically refreshing depends on how you previously configured your profile.

Topics

- Prerequisites
- Signing in and getting credentials
- Running a command with your IAM Identity Center profile
- Signing out of your IAM Identity Center sessions

Prerequisites

You've configured an IAM Identity Center profile. See the section called “Configure automatic token refresh” and the section called “Configure legacy non-refreshable” for more information.

Signing in and getting credentials

Note
The sign in process may prompt you to allow the AWS CLI access to your data. Since the AWS CLI is built on top of the SDK for Python, permission messages may contain variations of the botocore name.

After you configure a named profile, you can invoke it to request credentials from AWS. Before you can run an AWS CLI service command, you must retrieve and cache a set of credentials. To get these credentials, run the following command.

```
$ aws sso login --profile my-dev-profile
```
The AWS CLI opens your default browser and verifies your IAM Identity Center log in.

SSO authorization page has automatically been opened in your default browser. Follow the instructions in the browser to complete this authorization request. Successfully logged into Start URL: https://my-sso-portal.awsapps.com/start

If you are not currently signed into IAM Identity Center, you must provide your IAM Identity Center credentials.

If the AWS CLI can't open your browser, it prompts you to open it yourself and enter the specified code.

$ aws sso login --profile my-dev-profile
Using a browser, open the following URL:

https://device.sso.us-west-2.amazonaws.com/

and enter the following code:
QCFK-N4S1

The AWS CLI opens your default browser (or you manually open the browser of your choice) to the specified page, and enter the provided code. The webpage then prompts you for your IAM Identity Center credentials.

Your IAM Identity Center session credentials are cached. If these credentials are temporary, it includes an expiration timestamp and when they expire, the AWS CLI requests you to sign in to IAM Identity Center again.

If your IAM Identity Center credentials are valid, the AWS CLI uses them to securely retrieve AWS credentials for the IAM role specified in the profile.

Welcome, you have successfully signed-in to the AWS-CLI.

You can also specify which sso-session profile to use when logging in using the --sso-session parameter of the aws sso login command.

$ aws sso login --sso-session my-dev-session
Attempting to automatically open the SSO authorization page in your default browser. If the browser does not open or you wish to use a different device to authorize this request, open the following URL:
and enter the following code:

QCFK-N451

Successfully logged into Start URL: https://cli-reinvent.awsapps.com/start

Running a command with your IAM Identity Center profile

You can use these credentials to invoke an AWS CLI command with the associated named profile. The following example shows that the command was run under an assumed role that is part of the specified account.

```bash
$ aws sts get-caller-identity --profile my-dev-profile
{
    "UserId": "AROA12345678901234567:test-user@example.com",
    "Account": "123456789011",
    "Arn": "arn:aws:sts::123456789011:assumed-role/AWS Peregrine_readOnly_12321abc454d123/test-user@example.com"
}
```

As long as you signed in to IAM Identity Center and those cached credentials are not expired, the AWS CLI automatically renews expired AWS credentials when needed. However, if your IAM Identity Center credentials expire, you must explicitly renew them by logging in to your IAM Identity Center account again.

```bash
$ aws s3 ls --profile my-sso-profile
Your short-term credentials have expired. Please sign-in to renew your credentials
SSO authorization page has automatically been opened in your default browser.
Follow the instructions in the browser to complete this authorization request.
```

Signing out of your IAM Identity Center sessions

When you are done using your IAM Identity Center profiles, you can choose to do nothing and let the AWS temporary credentials and your IAM Identity Center credentials expire. However, you can also choose to run the following command to immediately delete all cached credentials in the SSO credential cache folder and all AWS temporary credentials that were based on the IAM Identity Center credentials. This makes those credentials unavailable to be used for any future command.

```bash
$ aws sso logout
```
Successfully signed out of all SSO profiles.

If you later want to run commands with one of your IAM Identity Center profiles, you must again run the `aws sso login` command (see the previous section) and specify the profile to use.

**Authenticate with short-term credentials**

We recommend configuring your SDK or tool to use IAM Identity Center authentication with extended session duration options. However, you can copy and use temporary credentials that are available in the AWS access portal. New credentials will need to be copied when these expire. You can use the temporary credentials in a profile or use them as values for system properties and environment variables.

1. **Sign in to the AWS access portal.**
2. Follow these instructions to copy IAM role credentials from the AWS access portal.
   1. For step 2 in the linked instructions, choose the AWS account and IAM role name that grants access for your development needs. This role typically has a name like `PowerUserAccess` or `Developer`.
   2. For step 4, select the Add a profile to your AWS credentials file option and copy the contents.
   3. Create or open the shared credentials file. This file is `~/.aws/credentials` on Linux and macOS systems, and `%USERPROFILE%\aws\credentials` on Windows. For more information, see the section called “Configuration and credential file settings”.
   4. Add the following text to the shared credentials file. Replace the sample values with the credentials you copied.

```
[default]
aws_access_key_id = AKIAIOSFODNN7EXAMPLE
aws_secret_access_key = wJalrXUtntEMI/K7MDENG/bPxFiCYEXAMPLEKEY
aws_session_token = IQoJb3JpZ2luX2IqoJb3JpZ2luX2IqoJb3JpZ2luX2IqoJb3JpZVERYLONGSTRINGEXAMPLE
```

5. Add your preferred default region and format to the shared config file.

```
[default]
region=us-west-2
output=json
```
When the SDK creates a service client, it will access these temporary credentials and use them for each request. The settings for the IAM role chosen in step 2a determine how long the temporary credentials are valid. The maximum duration is twelve hours.

Repeat these steps each time your credentials expire.

**Use an IAM role in the AWS CLI**

An AWS Identity and Access Management (IAM) role is an authorization tool that lets a user gain additional (or different) permissions, or get permissions to perform actions in a different AWS account.

**Topics**

- Prerequisites
- Overview of using IAM roles
- Configuring and using a role
- Using multi-factor authentication
- Cross-account roles and external ID
- Specifying a role session name for easier auditing
- Assume role with web identity
- Clearing cached credentials

**Prerequisites**

To run the `iam` commands, you need to install and configure the AWS CLI. For more information, see the section called “Install/Update”.

**Overview of using IAM roles**

You can configure the AWS Command Line Interface (AWS CLI) to use an IAM role by defining a profile for the role in the `~/.aws/config` file.
The following example shows a role profile named `marketingadmin`. If you run commands with `--profile marketingadmin` (or specify it with the `AWS_PROFILE` environment variable), the AWS CLI uses the credentials defined in a separate profile `user1` to assume the role with the Amazon Resource Name (ARN) `arn:aws:iam::123456789012:role/marketingadminrole`. You can run any operations that are allowed by the permissions assigned to that role.

```
[profile marketingadmin]
role_arn = arn:aws:iam::123456789012:role/marketingadminrole
source_profile = user1
```

You can then specify a `source_profile` that points to a separate named profile that contains user credentials with permission to use the role. In the previous example, the `marketingadmin` profile uses the credentials in the `user1` profile. When you specify that an AWS CLI command is to use the profile `marketingadmin`, the AWS CLI automatically looks up the credentials for the linked `user1` profile and uses them to request temporary credentials for the specified IAM role. The CLI uses the `sts:AssumeRole` operation in the background to accomplish this. Those temporary credentials are then used to run the requested AWS CLI command. The specified role must have attached IAM permission policies that allow the requested AWS CLI command to run.

To run a AWS CLI command from within an Amazon Elastic Compute Cloud (Amazon EC2) instance or an Amazon Elastic Container Service (Amazon ECS) container, you can use an IAM role attached to the instance profile or the container. If you specify no profile or set no environment variables, that role is used directly. This enables you to avoid storing long-lived access keys on your instances. You can also use those instance or container roles only to get credentials for another role. To do this, you use `credential_source` (instead of `source_profile`) to specify how to find the credentials. The `credential_source` attribute supports the following values:

- **Environment** – Retrieves the source credentials from environment variables.
- **Ec2InstanceMetadata** – Uses the IAM role attached to the Amazon EC2 instance profile.
- **EcsContainer** – Uses the IAM role attached to the Amazon ECS container.

The following example shows the same `marketingadmin` role used by referencing an Amazon EC2 instance profile.

```
[profile marketingadmin]
role_arn = arn:aws:iam::123456789012:role/marketingadminrole
credential_source = Ec2InstanceMetadata
```
When you invoke a role, you have additional options that you can require, such as the use of multi-factor authentication and an External ID (used by third-party companies to access their clients' resources). You can also specify unique role session names that can be more easily audited in AWS CloudTrail logs.

**Configuring and using a role**

When you run commands using a profile that specifies an IAM role, the AWS CLI uses the source profile's credentials to call AWS Security Token Service (AWS STS) and request temporary credentials for the specified role. The user in the source profile must have permission to call `sts:assume-role` for the role in the specified profile. The role must have a trust relationship that allows the user in the source profile to use the role. The process of retrieving and then using temporary credentials for a role is often referred to as *assuming the role*.

You can create a role in IAM with the permissions that you want users to assume by following the procedure under [Creating a Role to Delegate Permissions to an IAM user](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_create_for_user.html) in the *AWS Identity and Access Management User Guide*. If the role and the source profile's user are in the same account, you can enter your own account ID when configuring the role's trust relationship.

After creating the role, modify the trust relationship to allow the user to assume it.

The following example shows a trust policy that you could attach to a role. This policy allows the role to be assumed by any user in the account 123456789012, *if* the administrator of that account explicitly grants the `sts:AssumeRole` permission to the user.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:root"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The trust policy doesn't actually grant permissions. The administrator of the account must delegate the permission to assume the role to individual users by attaching a policy with the appropriate
permissions. The following example shows a policy that you can attach to a user that allows the user to assume only the `marketingadminrole` role. For more information about granting a user access to assume a role, see [Granting a User Permission to Switch Roles](#) in the [IAM User Guide](#).

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Resource": "arn:aws:iam::123456789012:role/marketingadminrole"
    }
  ]
}
```

The user doesn't need to have additional permissions to run the AWS CLI commands using the role profile. Instead, the permissions to run the command come from those attached to the `role`. You attach permission policies to the role to specify which actions can be performed against which AWS resources. For more information about attaching permissions to a role (which works identically to a user), see [Changing Permissions for an IAM user](#) in the [IAM User Guide](#).

Now that you have the role profile, role permissions, role trust relationship, and user permissions correctly configured, you can use the role at the command line by invoking the `--profile` option. For example, the following calls the Amazon S3 `ls` command using the permissions attached to the `marketingadmin` role as defined by the example at the beginning of this topic.

```bash
$ aws s3 ls --profile marketingadmin
```

To use the role for several calls, you can set the `AWS_PROFILE` environment variable for the current session from the command line. While that environment variable is defined, you don't have to specify the `--profile` option on each command.

**Linux or macOS**

```bash
$ export AWS_PROFILE=marketingadmin
```

**Windows**

```bash
C:\> setx AWS_PROFILE marketingadmin
```
For more information about configuring users and roles, see Users and Groups and Roles in the IAM User Guide.

**Using multi-factor authentication**

For additional security, you can require that users provide a one-time key generated from a multi-factor authentication (MFA) device, a U2F device, or mobile app when they attempt to make a call using the role profile.

First, you can choose to modify the trust relationship on the IAM role to require MFA. This prevents anyone from using the role without first authenticating by using MFA. For an example, see the Condition line in the following example. This policy allows the user named anika to assume the role the policy is attached to, but only if they authenticate by using MFA.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": { "AWS": "arn:aws:iam::123456789012:user/anika" },
      "Action": "sts:AssumeRole",
      "Condition": { "Bool": { "aws:multifactorAuthPresent": true } }
    }
  ]
}
```

Next, add a line to the role profile that specifies the ARN of the user's MFA device. The following sample config file entries show two role profiles that both use the access keys for the user anika to request temporary credentials for the role cli-role. The user anika has permissions to assume the role, granted by the role's trust policy.

```bash
[profile role-without-mfa]
region = us-west-2
role_arn= arn:aws:iam::128716708097:role/cli-role
source_profile=cli-user

[profile role-with-mfa]
region = us-west-2
role_arn= arn:aws:iam::128716708097:role/cli-role
source_profile = cli-user
```

Using MFA
mfa_serial = arn:aws:iam::128716708097:mfa/cli-user

[profile cli-user]
region = us-west-2
output = json

The mfa_serial setting can take an ARN, as shown, or the serial number of a hardware MFA token.

The first profile, role-without-mfa, doesn’t require MFA. However, because the previous example trust policy attached to the role requires MFA, any attempt to run a command with this profile fails.

$ aws iam list-users --profile role-without-mfa
An error occurred (AccessDenied) when calling the AssumeRole operation: Access denied

The second profile entry, role-with-mfa, identifies an MFA device to use. When the user attempts to run a AWS CLI command with this profile, the AWS CLI prompts the user to enter the one-time password (OTP) that the MFA device provides. If the MFA authentication succeeds, the command performs the requested operation. The OTP is not displayed on the screen.

$ aws iam list-users --profile role-with-mfa
Enter MFA code for arn:aws:iam::123456789012:mfa/cli-user:
{
  "Users": [
    {
      ...

Cross-account roles and external ID

You can enable users to use roles that belong to different accounts by configuring the role as a cross-account role. During role creation, set the role type to Another AWS account, as described in Creating a Role to Delegate Permissions to an IAM user. Optionally, select Require MFA. Require MFA configures the appropriate condition in the trust relationship, as described in Using multi-factor authentication.

If you use an external ID to provide additional control over who can use a role across accounts, you must also add the external_id parameter to the role profile. You typically use this only when the other account is controlled by someone outside your company or organization.
Specifying a role session name for easier auditing

When many individuals share a role, auditing becomes more of a challenge. You want to associate each operation invoked with the individual who invoked the action. However, when the individual uses a role, the assumption of the role by the individual is a separate action from the invoking of an operation, and you must manually correlate the two.

You can simplify this by specifying unique role session names when users assume a role. You do this by adding a `role_session_name` parameter to each named profile in the config file that specifies a role. The `role_session_name` value is passed to the AssumeRole operation and becomes part of the ARN for the role session. It is also included in the AWS CloudTrail logs for all logged operations.

For example, you could create a role-based profile as follows.

```bash
[profile namedsessionrole]
role_arn = arn:aws:iam::234567890123:role/SomeRole
source_profile = default
role_session_name = Session_Maria_Garcia
```

This results in the role session having the following ARN.

```
arn:aws:iam::234567890123:assumed-role/SomeRole/Session_Maria_Garcia
```

Also, all AWS CloudTrail logs include the role session name in the information captured for each operation.

Assume role with web identity

You can configure a profile to indicate that the AWS CLI should assume a role using web identity federation and Open ID Connect (OIDC). When you specify this in a profile, the AWS CLI automatically makes the corresponding AWS STS AssumeRoleWithWebIdentity call for you.
Note

When you specify a profile that uses an IAM role, the AWS CLI makes the appropriate calls to retrieve temporary credentials. These credentials are stored in ~/.aws/cli/cache. Subsequent AWS CLI commands that specify the same profile use the cached temporary credentials until they expire. At that point, the AWS CLI automatically refreshes the credentials.

To retrieve and use temporary credentials using web identity federation, you can specify the following configuration values in a shared profile.

role_arn

Specifies the ARN of the role to assume.

web_identity_token_file

Specifies the path to a file which contains an OAuth 2.0 access token or OpenID Connect ID token that is provided by the identity provider. The AWS CLI loads this file and passes its content as the WebIdentityToken argument of the AssumeRoleWithWebIdentity operation.

role_session_name

Specifies an optional name applied to this assume-role session.

The following is an example of the minimal amount of configuration needed to configure an assume role with web identity profile.

# In ~/.aws/config

[profile web-identity]
role_arn=arn:aws:iam:123456789012:role/RoleNameToAssume
web_identity_token_file=/path/to/a/token

You can also provide this configuration by using environment variables.

AWS_ROLE_ARN

The ARN of the role to assume.
AWS Command Line Interface

AWS_WEB_IDENTITY_TOKEN_FILE

The path to the web identity token file.

AWS_ROLE_SESSION_NAME

The name applied to this assume-role session.

⚠️ Note

These environment variables currently apply only to the assume role with web identity provider. They don't apply to the general assume role provider configuration.

Clearing cached credentials

When you use a role, the AWS CLI caches the temporary credentials locally until they expire. The next time you try to use them, the AWS CLI attempts to renew them on your behalf.

If your role's temporary credentials are revoked, they are not renewed automatically, and attempts to use them fail. However, you can delete the cache to force the AWS CLI to retrieve new credentials.

Linux or macOS

$ rm -r ~/.aws/cli/cache

Windows

C:\> del /s /q %UserProfile%\aws\cli\cache

Authenticate with IAM user credentials

⚠️ Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as AWS IAM Identity Center.
This section explains how to configure basic settings with an IAM user. These include your security credentials using the config and credentials files. To instead see configuration instructions for AWS IAM Identity Center, see the section called “IAM Identity Center authentication”.

Topics

- Step 1: Create your IAM user
- Step 2: Get your access keys
- Configure the AWS CLI
  - Using aws configure
  - Importing access keys via .CSV file
  - Directly editing the config and credentials files

Step 1: Create your IAM user

Create your IAM user by following the Creating IAM users (console) procedure in the IAM User Guide.

- For Permission options, choose Attach policies directly for how you want to assign permissions to this user.
- Most "Getting Started" SDK tutorials use the Amazon S3 service as an example. To provide your application with full access to Amazon S3, select the AmazonS3FullAccess policy to attach to this user.

Step 2: Get your access keys

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, select Users and then select the User name of the user that you created previously.
3. On the user's page, select the Security credentials page. Then, under Access keys, select Create access key.
4. For Create access key Step 1, choose Command Line Interface (CLI).
5. For Create access key Step 2, enter an optional tag and select Next.
6. For Create access key Step 3, select Download .csv file to save a .csv file with your IAM user's access key and secret access key. You need this information for later.

7. Select Done.

**Configure the AWS CLI**

For general use, the AWS CLI needs the following pieces of information:

- Access key ID
- Secret access key
- AWS Region
- Output format

The AWS CLI stores this information in a profile (a collection of settings) named default in the credentials file. By default, the information in this profile is used when you run an AWS CLI command that doesn't explicitly specify a profile to use. For more information on the credentials file, see Configuration and credential file settings.

To configure the AWS CLI, use one of the following procedures:

**Topics**

- Using aws configure
- Importing access keys via .CSV file
- Directly editing the config and credentials files

**Using aws configure**

For general use, the aws configure command is the fastest way to set up your AWS CLI installation. This configure wizard prompts you for each piece of information you need to get started. Unless otherwise specified by using the --profile option, the AWS CLI stores this information in the default profile.

The following example configures a default profile using sample values. Replace them with your own values as described in the following sections.

```
$ aws configure
```
The following example configures a profile named userprod using sample values. Replace them with your own values as described in the following sections.

```
$ aws configure --profile userprod
```

**Importing access keys via .CSV file**

Instead of using `aws configure` to enter in access keys, you can import the plain text `.csv` file you downloaded after you created your access keys.

The `.csv` file must contain the following headers.

- User Name - This column must be added to your `.csv`. This is used to create the profile name used in the config and credentials files when you import.
- Access key ID
- Secret access key

**Note**

During initial access keys creation, once you close the **Download .csv file** dialog box, you cannot access your secret access key after you close the dialog box. If you need a `.csv` file, you'll need to create one yourself with the required headers and your stored access keys information. If you do not have access to your access keys information, you need to create a new access keys.

To import the `.csv` file, use the `aws configure import` command with the `--csv` option as follows:
$ aws configure import --csv file://credentials.csv

For more information, see `aws_configure_import`.

**Directly editing the config and credentials files**

To directly edit the config and credentials files, perform the following.

1. Create or open the shared AWS credentials file. This file is `~/.aws/credentials` on Linux and macOS systems, and `%USERPROFILE%\.aws\credentials` on Windows. For more information, see the section called “Configuration and credential file settings”.

2. Add the following text to the shared credentials file. Replace the sample values in the `.csv` file that you downloaded earlier and save the file.

```ini
[default]
aws_access_key_id = AKIAIOSFODNN7EXAMPLE
aws_secret_access_key = wJalrXUttnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
```

**Use credentials for Amazon EC2 instance metadata**

When you run the AWS CLI from within an Amazon Elastic Compute Cloud (Amazon EC2) instance, you can simplify providing credentials to your commands. Each Amazon EC2 instance contains metadata that the AWS CLI can directly query for temporary credentials. When an IAM role is attached to the instance, the AWS CLI automatically and securely retrieves the credentials from the instance metadata.

To disable this service, use the `AWS_EC2_METADATA_DISABLED` environment variable.

**Topics**

- [Prerequisites](#)
- [Configuring a profile for Amazon EC2 metadata](#)

**Prerequisites**

To use Amazon EC2 credentials with the AWS CLI, you need to complete the following:
• Install and configure the AWS CLI. For more information, see the section called “Install/Update” and Authentication and access credentials.

• You understand configuration files and named profiles. For more information, see Configuration and credential file settings.

• You’ve created an AWS Identity and Access Management (IAM) role that has access to the resources needed, and attached that role to the Amazon EC2 instance when you launch it. For more information, see IAM policies for Amazon EC2 in the Amazon EC2 User Guide for Linux Instances and Granting Applications That Run on Amazon EC2 Instances Access to AWS Resources in the IAM User Guide.

Configuring a profile for Amazon EC2 metadata

To specify that you want to use the credentials available in the hosting Amazon EC2 instance profile, use the following syntax in the named profile in your configuration file. See the following steps for more instructions.

```
[profile profilename]
role_arn = arn:aws:iam::123456789012:role/rolename
credential_source = Ec2InstanceMetadata
region = region
```

1. Create a profile in your configuration file.

```
[profile profilename]
```

2. Add your IAM arn role that has access to the resources needed.

```
role_arn = arn:aws:iam::123456789012:role/rolename
```

3. Specify Ec2InstanceMetadata as your credential source.

```
credential_source = Ec2InstanceMetadata
```

4. Set your Region.

```
region = region
```
Example

The following example assumes the `marketingadminrole` role and uses the `us-west-2` Region in an Amazon EC2 instance profile named `marketingadmin`.

```
[profile marketingadmin]
role_arn = arn:aws:iam::123456789012:role/marketingadminrole
credential_source = Ec2InstanceMetadata
region = us-west-2
```

Source credentials with an external process

⚠️ Warning

This topic discusses sourcing credentials from an external process. This could be a security risk if the command to generate the credentials becomes accessible by non-approved processes or users. We recommend that you use the supported, secure alternatives provided by the AWS CLI and AWS to reduce the risk of compromising your credentials. Ensure that you secure the config file and any supporting files and tools to prevent disclosure. Ensure that your custom credential tool does not write any secret information to StdErr because the SDKs and AWS CLI can capture and log such information, potentially exposing it to unauthorized users.

If you have a method to generate or look up credentials that isn't directly supported by the AWS CLI, you can configure the AWS CLI to use it by configuring the `credential_process` setting in the config file.

For example, you might include an entry similar to the following in the config file.

```
[profile developer]
credential_process = /opt/bin/awscreds-custom --username helen
```

Syntax

To create this string in a way that is compatible with any operating system, follow these rules:
• If the path or file name contains a space, surround the complete path and file name with double- quotation marks (" "). The path and file name can consist of only the characters: A-Z a-z 0-9 - _ . space

• If a parameter name or a parameter value contains a space, surround that element with double- quotation marks (" "). Surround only the name or value, not the pair.

• Do not include any environment variables in the strings. For example, you can't include $HOME or %USERPROFILE%.

• Do not specify the home folder as ~. You must specify the full path.

Example for Windows

```bash
credential_process = "C:\Path\To\credentials.cmd" parameterWithoutSpaces "parameter with spaces"
```

Example for Linux or macOS

```bash
credential_process = "/Users/Dave/path/to/credentials.sh" parameterWithoutSpaces "parameter with spaces"
```

Expected output from the Credentials program

The AWS CLI runs the command as specified in the profile and then reads data from STDOUT. The command you specify must generate JSON output on STDOUT that matches the following syntax.

```json
{
  "Version": 1,
  "AccessKeyId": "an AWS access key",
  "SecretAccessKey": "your AWS secret access key",
  "SessionToken": "the AWS session token for temporary credentials",
  "Expiration": "ISO8601 timestamp when the credentials expire"
}
```

Note

As of this writing, the Version key must be set to 1. This might increment over time as the structure evolves.
TheExpiration key is an ISO8601 formatted timestamp. If theExpiration key is not present in the tool's output, the CLI assumes that the credentials are long-term credentials that do not refresh. Otherwise the credentials are considered temporary credentials and are refreshed automatically by rerunning the credential_process command before they expire.

Note

The AWS CLI does not cache external process credentials the way it does assume-role credentials. If caching is required, you must implement it in the external process.

The external process can return a non-zero return code to indicate that an error occurred while retrieving the credentials.
Use the AWS CLI

This section provides information about general use, common features, and options available in the AWS Command Line Interface (AWS CLI), beyond what is written in the Configuration the section called “Endpoints” section. Instructions include how to write a command, basic structure, formatting, filtering, and locating the help content or documentation for a command.

For AWS service specific examples, see Code examples or the AWS CLI version 2 reference guide.

Note
By default, the AWS CLI sends requests to AWS services by using HTTPS on TCP port 443. To use the AWS CLI successfully, you must be able to make outbound connections on TCP port 443.

Get help with the AWS CLI

The built-in AWS CLI help command

You can get help with any command when using the AWS Command Line Interface (AWS CLI). To do so, simply type `help` at the end of a command name.

For example, the following command displays help for the general AWS CLI options and the available top-level commands.

```
$ aws help
```

The following command displays the available Amazon Elastic Compute Cloud (Amazon EC2) specific commands.

```
$ aws ec2 help
```

The following example displays detailed help for the Amazon EC2 DescribeInstances operation. The help includes descriptions of its input parameters, available filters, and what is included as output. It also includes examples showing how to type common variations of the command.

```
$ aws ec2 describe-instances help
```

The help for each command is divided into six sections:

**Name**

The name of the command.

```
NAME
   describe-instances -
```

**Description**

A description of the API operation that the command invokes.
**DESCRIPTION**

Describes one or more of your instances.

If you specify one or more instance IDs, Amazon EC2 returns information for those instances. If you do not specify instance IDs, Amazon EC2 returns information for all relevant instances. If you specify an instance ID that is not valid, an error is returned. If you specify an instance that you do not own, it is not included in the returned results.

**Synopsis**

The basic syntax for using the command and its options. If an option is shown in square brackets, it's optional, has a default value, or has an alternative option that you can use.

**SYNOPSIS**

describe-instances
    [--dry-run | --no-dry-run]
    [--instance-ids <value>]
    [--filters <value>]
    [--cli-input-json <value>]
    [--starting-token <value>]
    [--page-size <value>]
    [--max-items <value>]
    [--generate-cli-skeleton]

For example, describe-instances has a default behavior that describes all instances in the current account and AWS Region. You can optionally specify a list of instance-ids to describe one or more instances; dry-run is an optional Boolean flag that doesn't take a value. To use a Boolean flag, specify either shown value, in this case --dry-run or --no-dry-run. Likewise, --generate-cli-skeleton doesn't take a value. If there are conditions on an option's use, they are described in the OPTIONS section, or shown in the examples.

**Options**

A description of each of the options shown in the synopsis.

**OPTIONS**

--dry-run | --no-dry-run (boolean)
    Checks whether you have the required permissions for the action,
without actually making the request, and provides an error response. If you have the required permissions, the error response is `DryRunOperation`. Otherwise, it is `UnauthorizedOperation`.

--instance-ids (list)
One or more instance IDs.

Default: Describes all your instances.

Examples

Examples showing the usage of the command and its options. If no example is available for a command or use case that you need, request one using the feedback link on this page, or in the AWS CLI command reference on the help page for the command.

```bash
EXAMPLES
    To describe an Amazon EC2 instance
    Command:
    aws ec2 describe-instances --instance-ids i-5203422c

    To describe all instances with the instance type m1.small
    Command:
    aws ec2 describe-instances --filters "Name=instance-type,Values=m1.small"

    To describe all instances with an Owner tag
    Command:
    aws ec2 describe-instances --filters "Name=tag-key,Values=Owner"
```

Output

Descriptions of each of the fields and data types included in the response from AWS.

For `describe-instances`, the output is a list of reservation objects, each of which contains several fields and objects that contain information about the instances associated with it. This
Information comes from the API documentation for the reservation data type used by Amazon EC2.

**OUTPUT**

```
Reservations -> (list)
   One or more reservations.

(structure)
   Describes a reservation.

   ReservationId -> (string)
      The ID of the reservation.

   OwnerId -> (string)
      The ID of the AWS account that owns the reservation.

   RequesterId -> (string)
      The ID of the requester that launched the instances on your behalf (for example, AWS Management Console or Auto Scaling).

Groups -> (list)
   One or more security groups.

(structure)
   Describes a security group.

   GroupName -> (string)
      The name of the security group.

   GroupId -> (string)
      The ID of the security group.

Instances -> (list)
   One or more instances.

(structure)
   Describes an instance.

   InstanceId -> (string)
      The ID of the instance.

   ImageId -> (string)
      The ID of the AMI used to launch the instance.
```
State -> (structure)
The current state of the instance.

Code -> (integer)
The low byte represents the state. The high byte is an opaque internal value and should be ignored.

When the AWS CLI renders the output into JSON, it becomes an array of reservation objects, similar to the following example.

```
{
    "Reservations": [
    {
        "OwnerId": "012345678901",
        "ReservationId": "r-4c58f8a0",
        "Groups": [],
        "RequesterId": "012345678901",
        "Instances": [
        {
            "Monitoring": {
                "State": "disabled"
            },
            "PublicDnsName": "ec2-52-74-16-12.us-west-2.compute.amazonaws.com",
            "State": {
                "Code": 16,
                "Name": "running"
            }
        }
    ]
}
```

Each reservation object contains fields describing the reservation and an array of instance objects, each with its own fields (for example, PublicDnsName) and objects (for example, State) that describe it.

⚠️ **Windows users**

You can `pipe (|)` the output of the help command to the `more` command to view the help file one page at a time. Press the space bar or `PgDn` to view more of the document, and `q` to quit.
AWS CLI reference guide

The help files contain links that cannot be viewed or navigated to from the command line. You can view and interact with these links by using the online AWS CLI version 2 reference guide. The reference also contains the help content for all AWS CLI commands. The descriptions are presented for easy navigation and viewing on mobile, tablet, or desktop screens.

API documentation

All commands in the AWS CLI correspond to requests made to an AWS service's public API. Each service with a public API has an API reference that can be found on the service's home page on the AWS Documentation website. The content for an API reference varies based on how the API is constructed and which protocol is used. Typically, an API reference contains detailed information about the operations supported by the API, the data sent to and from the service, and any error conditions that the service can report.

API Documentation Sections

- **Actions** – Detailed information on each operation and its parameters (including constraints on length or content, and default values). It lists the errors that can occur for this operation. Each operation corresponds to a subcommand in the AWS CLI.

- **Data Types** – Detailed information about structures that a command might require as a parameter, or return in response to a request.

- **Common Parameters** – Detailed information about the parameters that are shared by all of action for the service.

- **Common Errors** – Detailed information about errors that can be returned by any of the service's operations.

The name and availability of each section can vary, depending on the service.
Service-specific CLIs

Some services have a separate CLI that dates from before a single AWS CLI was created to work with all services. These service-specific CLIs have separate documentation that is linked from the service's documentation page. Documentation for service-specific CLIs do not apply to the AWS CLI.

Command structure in the AWS CLI

This topic covers how AWS Command Line Interface (AWS CLI) command is structured, and how to use wait commands.

Topics

- Command structure
- Wait commands

Command structure

The AWS CLI uses a multipart structure on the command line that must be specified in this order:

1. The base call to the aws program.
2. The top-level command, which typically corresponds to an AWS service supported by the AWS CLI.
3. The subcommand that specifies which operation to perform.
4. General AWS CLI options or parameters required by the operation. You can specify these in any order as long as they follow the first three parts. If an exclusive parameter is specified multiple times, only the last value applies.
$ aws <command> <subcommand> [options and parameters]

Parameters can take various types of input values, such as numbers, strings, lists, maps, and JSON structures. What is supported is dependent upon the command and subcommand you specify.

Examples

Amazon S3

The following example lists all of your Amazon S3 buckets.

$ aws s3 ls
2018-12-11 17:08:50 my-bucket
2018-12-14 14:55:44 my-bucket2

For more information on the Amazon S3 commands, see `aws s3` in the AWS CLI Command Reference.

AWS CloudFormation

The following `create-change-set` command example changes the cloudformation stack name to `my-change-set`.

$ aws cloudformation create-change-set --stack-name my-stack --change-set-name my-change-set

For more information on the AWS CloudFormation commands, see `aws cloudformation` in the AWS CLI Command Reference.

Wait commands

Some AWS services have wait commands available. Any command that uses `aws wait` usually waits until a command is complete before it moves on to the next step. This is especially useful for multipart commands or scripting, as you can use a wait command to prevent moving to subsequent steps if the wait command fails.

The AWS CLI uses a multipart structure on the command line for the `wait` command that must be specified in this order:

1. The base call to the `aws` program.
2. The top-level *command*, which typically corresponds to an AWS service supported by the AWS CLI.

3. The wait command.

4. The *subcommand* that specifies which operation to perform.

5. General CLI options or parameters required by the operation. You can specify these in any order as long as they follow the first three parts. If an exclusive parameter is specified multiple times, only the *last value* applies.

$$\texttt{aws <command> wait <subcommand> [options and parameters]}$$

Parameters can take various types of input values, such as numbers, strings, lists, maps, and JSON structures. What is supported is dependent upon the command and subcommand you specify.

**Note**

Not every AWS service supports wait commands. See the [AWS CLI version 2 reference guide](#) to see if your service supports wait commands.

### Examples

**AWS CloudFormation**

The following *wait change-set-create-complete* command examples pauses and resumes only after it can confirm that the *my-change-set* change set in the *my-stack* stack is ready to run.

$ aws cloudformation wait change-set-create-complete --stack-name my-stack --change-set-name my-change-set

For more information on the AWS CloudFormation wait commands, see *wait* in the [AWS CLI Command Reference](#).

**AWS CodeDeploy**

The following *wait deployment-successful* command examples pauses until the *d-A1B2C3111* deployment completes successfully.
Specify parameter values for the AWS CLI

Many parameters used in the AWS Command Line Interface (AWS CLI) are simple string or numeric values, such as the key-pair name `my-key-pair` in the following example.

```bash
$ aws ec2 create-key-pair --key-name my-key-pair
```

Formatting between terminals can vary. For example, most terminals are case sensitive but PowerShell is case insensitive. This means the two following command examples would yield different results for case sensitive terminals as they view `MyFile*.txt` and `myfile*.txt` as different parameters.

However, PowerShell would process these requests as the same as it sees `MyFile*.txt` and `myfile*.txt` as the same parameters.

```bash
$ aws s3 cp . s3://my-bucket/path --include "MyFile*.txt"
$ aws s3 cp . s3://my-bucket/path --include "myfile*.txt"
```

For more information on PowerShell's case insensitivity, see `about_Case-Sensitivity` in the PowerShell documentation.

Sometimes you need to use quotation marks or literals around strings that include special or space characters. The rules around this formatting can also vary between terminals. For more information about using quotation marks around complex parameters, see Quotation marks with strings in the AWS CLI.

Parameter topics

- Common AWS CLI parameter types
- Quotation marks with strings in the AWS CLI

Common AWS CLI parameter types

This section describes some of the common parameter types and the typical required format.

If you are having trouble formatting a parameter for a specific command, check the help by entering `help` after the command name. The help for each subcommand includes an option's name and description. The option's parameter type is listed in parentheses. For more information on viewing help, see the section called “Get Help”.

Parameter types include:

- **String**
- **Timestamp**
- **List**
- **Boolean**
- **Integer**
- **Binary / blob (binary large object) and streaming blob**
- **Map**
- **Document**

**String**

String parameters can contain alphanumeric characters, symbols, and white spaces from the ASCII character set. Strings that contain white spaces must be surrounded by quotation marks. We recommend that you don't use symbols or white spaces other than the standard space character and to observe your terminal's **quoting rules** to prevent unexpected results.

Some string parameters can accept binary data from a file. See **Binary files** for an example.

**Timestamp**

Timestamps are formatted according to the ISO 8601 standard. These are often referred to as "DateTime" or "Date" parameters.

```
$ aws ec2 describe-spot-price-history --start-time 2014-10-13T19:00:00Z
```

Acceptable formats include:

- **YYYY-MM-DDThh:mm:ss.sssTZD (UTC)**, for example, 2014-10-01T20:30:00.000Z
• _YYYY-MM-DDThh:mm:ss.sssTZD (with offset)_ (with offset), for example, 2014-10-01T12:30:00.000-08:00

• _YYYY-MM-DD_, for example, 2014-10-01

• Unix time in seconds, for example, 1412195400. This is sometimes referred to as Unix Epoch time and represents the number of seconds since midnight, January 1, 1970 UTC.

By default, the AWS CLI version 2 translates all _response_ DateTime values to ISO 8601 format.

You can set the timestamp format by using the `cli_timestamp_format` file setting.

**List**

One or more strings separated by spaces. If any of the string items contain a space, you must put quotation marks around that item. Observe your terminal's quoting rules to prevent unexpected results.

```
$ aws ec2 describe-spot-price-history --instance-types m1.xlarge m1.medium
```

**Boolean**

Binary flag that turns an option on or off. For example, `ec2 describe-spot-price-history` has a Boolean `--dry-run` parameter that, when specified, validates the query with the service without actually running the query.

```
$ aws ec2 describe-spot-price-history --dry-run
```

The output indicates whether the command was well formed. This command also includes a `--no-dry-run` version of the parameter that you can use to explicitly indicate that the command should be run normally. Including it isn't necessary because this is the default behavior.

**Integer**

An unsigned, whole number.

```
$ aws ec2 describe-spot-price-history --max-items 5
```
**Binary / blob (binary large object) and streaming blob**

In the AWS CLI, you can pass a binary value as a string directly on the command line. There are two types of blobs:

- **Blob**
- **Streaming blob**

**Blob**

To pass a value to a parameter with type `blob`, you must specify a path to a local file that contains the binary data using the `fileb://` prefix. Files referenced using the `fileb://` prefix are always treated as raw unencoded binary. The specified path is interpreted as being relative to the current working directory. For example, the `--plaintext` parameter for `aws kms encrypt` is a blob.

```
$ aws kms encrypt \
   --key-id 1234abcd-12ab-34cd-56ef-1234567890ab \
   --plaintext fileb://ExamplePlaintextFile \
   --output text \
   --query CiphertextBlob | base64 \
   --decode > ExampleEncryptedFile
```

**Note**

For backwards compatibility, you can use the `file://` prefix. There are two formats used based on the file setting `cli_binary_format` or `--cli-binary-format` command line option:

- Default for the AWS CLI version 2. If the setting's value is `base64`, files referenced using the `file://` prefix are treated as base64-encoded text.
- Default for the AWS CLI version 1. If the setting's value is `raw-in-base64-out`, files referenced using the `file://` prefix is read as text and then the AWS CLI attempts to encode it to binary.

For more information, see the file setting `cli_binary_format` or `--cli-binary-format` command line option.
Streaming blob

Streaming blobs such as `aws cloudsearchdomain upload-documents` do not use prefixes. Instead, streaming blob parameters are formatted using the direct file path. The following example uses the direct file path `document-batch.json` for the `aws cloudsearchdomain upload-documents` command:

```
$ aws cloudsearchdomain upload-documents \\
    --endpoint-url https://doc-my-domain.us-west-1.cloudsearch.amazonaws.com \\
    --content-type application/json \\
    --documents document-batch.json
```

Map

A set of key-value pairs specified in JSON or by using the CLI's [shorthand syntax](#). The following JSON example reads an item from an Amazon DynamoDB table named `my-table` with a map parameter, `--key`. The parameter specifies the primary key named `id` with a number value of 1 in a nested JSON structure.

For more advanced JSON usage in a command line, consider using a command line JSON processor, like `jq`, to create JSON strings. For more information on `jq`, see the [jq repository](#) on [GitHub](#).

```
$ aws dynamodb get-item --table-name my-table --key '{"id": {"N":"1"}}'

{
    "Item": {
        "name": {
            "S": "John"
        },
        "id": {
            "N": "1"
        }
    }
}
```

Document

⚠️ **Note**

[Shorthand syntax](#) is not compatible with document types.
Document types are used to send data without needing to embed JSON inside strings. The document type enables services to provide arbitrary schemas for you to use more flexible data types.

This allows for sending JSON data without needing to escape values. For example, instead of using the following escaped JSON input:

```json
{"document": "\{"key\":true\}"}
```

You can use the following document type:

```json
{"document": {"key": true}}
```

### Valid values for document types

Due to the flexible nature of document types, there are multiple valid value types. Valid values include the following:

**String**

```javascript
--option "value"
```

**Number**

```javascript
--option 123
--option 123.456
```

**Boolean**

```javascript
--option true
```

**Null**

```javascript
--option null
```

**Array**

```javascript
--option ['value1', 'value2', 'value3']
```
Quotation marks with strings in the AWS CLI

There are primarily two ways single and double quotes are used in the AWS CLI.

- Using quotation marks around strings that contain white spaces
- Using quotation marks inside strings

Using quotation marks around strings that contain white spaces

Parameter names and their values are separated by spaces on the command line. If a string value contains an embedded space, then you must surround the entire string with quotation marks to prevent the AWS CLI from misinterpreting the space as a divider between the value and the next parameter name. Which type of quotation mark you use depends on the operating system you are running the AWS CLI on.

Linux and macOS

Use single quotation marks ' '

$ aws ec2 create-key-pair --key-name 'my key pair'

For more information on using quotes, see the user documentation for your preferred shell.

PowerShell

Single quotations (recommended)

Single quotation marks ' ' are called verbatim strings. The string is passed to the command exactly as you type it, which means PowerShell variables will not pass through.

PS C:\> aws ec2 create-key-pair --key-name 'my key pair'
Double quotations

Double quotation marks " " are called expandable string. Variables can be passed in expandable strings.

```
PS C:\> aws ec2 create-key-pair --key-name "my key pair"
```

For more information on using quotes, see About Quoting Rules in the Microsoft PowerShell Docs.

Windows command prompt

Use double quotation marks " ".

```
C:\> aws ec2 create-key-pair --key-name "my key pair"
```

Optionally, you can separate the parameter name from the value with an equals sign = instead of a space. This is typically necessary only if the value of the parameter starts with a hyphen.

```
$ aws ec2 delete-key-pair --key-name=-mykey
```

Using quotation marks inside strings

Strings might contain quotation marks, and your shell might require escaping quotations for them to work properly. One of the common parameter value types is a JSON string. This is complex since it includes spaces and double quotation marks " " around each element name and value in the JSON structure. The way you enter JSON-formatted parameters on the command line differs depending on your operating system.

For more advanced JSON usage in the command line, consider using a command line JSON processor, like jq, to create JSON strings. For more information on jq, see the jq repository on GitHub.

Linux and macOS

For Linux and macOS to interpret strings literally use single quotation marks ’ ’ to enclose the JSON data structure, as in the following example. You do not need to escape double quotation marks embedded in the JSON string, as they are being treated literally. Since the JSON is
enclosed in single quotation marks, any single quotation marks in the string will need to be escaped, this is usually accomplished using a backslash before the single quote \'.

```
$ aws ec2 run-instances \
   --image-id ami-12345678 \
   --block-device-mappings '[{"DeviceName": "/dev/sdb", "Ebs": 
   {"VolumeSize": 20, "DeleteOnTermination": false, "VolumeType": "standard"}}]'
```

For more information on using quotes, see the user documentation for your preferred shell.

**PowerShell**

Use single quotation marks ' ' or double quotation marks " ".

**Single quotations (recommended)**

Single quotation marks ' ' are called verbatim strings. The string is passed to the command exactly as you type it, which means PowerShell variables will not pass through.

Since JSON data structures include double quotes, we suggest single quotation marks ' ' to enclose it. If you use single quotation marks, you do not need to escape double quotation marks embedded in the JSON string. However, you need to escape each single quotation mark with a backtick ` within the JSON structure.

```
PS C:\> aws ec2 run-instances `\n   --image-id ami-12345678 `\n   --block-device-mappings `[{"DeviceName": "/dev/sdb", "Ebs": 
   {"VolumeSize": 20, "DeleteOnTermination": false, "VolumeType": "standard"}}]`
```

**Double quotations**

Double quotation marks " " are called expandable strings. Variables can be passed in expandable strings.

If you use double quotation marks, you do not need to escape single quotation marks embedded in the JSON string. However, you need to escape each double quotation mark with a backtick ` within the JSON structure, as with the following example.

```
PS C:\> aws ec2 run-instances `\n   --image-id ami-12345678 `
--block-device-mappings "[{"DeviceName":"/dev/sdb","Ebs":{"VolumeSize":20,"DeleteOnTermination":false,"VolumeType":"standard"}}]"

For more information on using quotes, see About Quoting Rules in the Microsoft PowerShell Docs.

⚠️ Warning

Before PowerShell sends a command to the AWS CLI, it determines if your command is interpreted using typical PowerShell or CommandLineToArgvW quoting rules. When PowerShell processes using CommandLineToArgvW, you must escape characters with a backslash \\. For more information on CommandLineToArgvW in PowerShell, see What's up with the strange treatment of quotation marks and backslashes by CommandLineToArgvW in the Microsoft DevBlogs, Everyone quotes command line arguments the wrong way in the Microsoft Docs Blog, and CommandLineToArgvW function in the Microsoft Docs.

Single quotations

Single quotation marks ' ' are called verbatim strings. The string is passed to the command exactly as you type it, which means PowerShell variables will not pass through. Escape characters with a backslash \

```
PS C:\> aws ec2 run-instances `    --image-id ami-12345678 `    --block-device-mappings '[["DeviceName":"/dev/sdb","Ebs":{""VolumeSize":20,"DeleteOnTermination":false,"VolumeType":"standard"}]}
```

Double quotations

Double quotation marks " " are called expandable strings. Variables can be passed in expandable strings. For double quoted strings you have to escape twice using \ for each quote instead of only using a backtick. The backtick escapes the backslash, and then the backslash is used as an escape character for the CommandLineToArgvW process.

```
PS C:\> aws ec2 run-instances `    --image-id ami-12345678 `    --block-device-mappings "[["DeviceName":"/dev/sdb","Ebs":{""VolumeSize":20,"DeleteOnTermination":false,"VolumeType":"standard"}]"
```
Blobs (recommended)

To bypass PowerShell quoting rules for JSON data input, use Blobs to pass your JSON data directly to the AWS CLI. For more information on Blobs, see Blob.

Windows command prompt

The Windows command prompt requires double quotation marks " " to enclose the JSON data structure. Also, to prevent the command processor from misinterpreting the double quotation marks embedded in the JSON, you must also escape (precede with a backslash \ character) each double quotation mark " within the JSON data structure itself, as in the following example.

```
C:\> aws ec2 run-instances ^
    --image-id ami-12345678 ^
    --block-device-mappings "[{{"DeviceName":="/dev/sdb"},"Ebs":
    {"VolumeSize":20,"DeleteOnTermination":false,"VolumeType":"
    standard"}]"
```

Only the outermost double quotation marks are not escaped.

Load AWS CLI parameters from a file

Some parameters expect file names as arguments, from which the AWS CLI loads the data. Other parameters enable you to specify the parameter value as either text typed on the command line or read from a file. Whether a file is required or optional, you must encode the file correctly so that the AWS CLI can understand it. The file's encoding must match the reading system's default locale. You can determine this by using the Python locale.getpreferredencoding() method.

⚠️ Note

By default, Windows PowerShell outputs text as UTF-16, which conflicts with the UTF-8 encoding used by JSON files and many Linux systems. We recommend that you use -Encoding ascii with your PowerShell Out-File commands to ensure the AWS CLI can read the resulting file.

How to load parameters from a file

Sometimes it's convenient to load a parameter value from a file instead of trying to type it all as a command line parameter value, such as when the parameter is a complex JSON string. To specify a file that contains the value, specify a file URL in the following format.

```
file://complete/path/to/file
```

- The first two slash '/' characters are part of the specification. If the required path begins with a '/', the result is three slash characters: `file:///folder/file`.
- The URL provides the path to the file that contains the actual parameter content.
- When using files with spaces or special characters, following the quoting and escaping rules for your terminal.

The file paths in the following examples are interpreted to be relative to the current working directory.

Linux or macOS

```
// Read from a file in the current directory
$ aws ec2 describe-instances --filters file://filter.json
```

```
// Read from a file in /tmp
$ aws ec2 describe-instances --filters file:///tmp/filter.json
```

```
// Read from a file with a filename with whitespaces
$ aws ec2 describe-instances --filters 'file://filter content.json'
```

Windows command prompt

```
// Read from a file in C:\temp
C:\> aws ec2 describe-instances --filters file://C:\temp\filter.json
```

```
// Read from a file with a filename with whitespaces
C:\> aws ec2 describe-instances --filters "file://C:\temp\filter content.json"
```
The `file://` prefix option supports Unix-style expansions, including "~/", "./", and ". ./". On Windows, the "~/" expression expands to your user directory, stored in the %USERPROFILE% environment variable. For example, on Windows 10 you would typically have a user directory under C: \Users\UserName\.

You must still escape JSON documents that are embedded as the value of another JSON document.

```bash
$ aws sqs create-queue --queue-name my-queue --attributes file://attributes.json
```

```json
attributes.json
{
}
```

**Binary files**

For commands that take binary data as a parameter, specify that the data is binary content by using the `fileb://` prefix. Commands that accept binary data include:

- **aws ec2 run-instances**: `--user-data` parameter.
- **aws s3api put-object**: `--sse-customer-key` parameter.
- **aws kms decrypt**: `--ciphertext-blob` parameter.

The following example generates a binary 256-bit AES key using a Linux command line tool, and then provides it to Amazon S3 to encrypt an uploaded file server-side.

```bash
$ dd if=/dev/urandom bs=1 count=32 > sse.key
32+0 records in
32+0 records out
32 bytes (32 B) copied, 0.000164441 s, 195 kB/s
$ aws s3api put-object \\n   --bucket my-bucket \\n   --key test.txt \\n   --body test.txt \\n   --sse-customer-key fileb://sse.key \\n   --sse-customer-algorithm AES256
```
For another example referencing a file containing JSON-formatted parameters, see Attach an IAM managed policy to a user.

AWS CLI skeletons and input files

Most of the AWS CLI commands accept all parameter inputs from a file. These templates can be generated using the `generate-cli-skeleton` option.

About AWS CLI skeletons and input files

Most of the AWS Command Line Interface (AWS CLI) commands support the ability to accept all parameter inputs from a file using the `--cli-input-json` and `--cli-input-yaml` parameters.

Those same commands helpfully provide the `--generate-cli-skeleton` parameter to generate a file in either JSON or YAML format with all of the parameters that you can edit and fill in. Then you can run the command with the relevant `--cli-input-json` or `--cli-input-yaml` parameter and point to the filled-in file.

⚠️ Important

Several AWS CLI commands don't map directly to individual AWS API operations, such as the `aws s3 commands`. Such commands don't support either the `--generate-cli-skeleton` or `--cli-input-json` and `--cli-input-yaml` parameters described in this topic. If you don't know whether a specific command supports these parameters, run the following command, replacing the `service` and `command` names with the ones you're interested in.

```
$ aws service command help
```
The output includes a Synopsis section that shows the parameters that the specified command supports.

```
$ aws iam list-users help
...
SYNOPSIS
  list-users
  ...
  [--cli-input-json | --cli-input-yaml]
  ...
  [--generate-cli-skeleton <value>]
...
```

The `--generate-cli-skeleton` parameter causes the command not to run, but instead to generate and display a parameter template that you can customize and use as input on a later command. The generated template includes all of the parameters that the command supports.

The `--generate-cli-skeleton` parameter accepts one of the following values:

- **input** – The generated template includes all input parameters formatted as JSON. This is the default value.
- **yaml-input** – The generated template includes all input parameters formatted as YAML.
- **output** – The generated template includes all output parameters formatted as JSON. You can't currently request the output parameters as YAML.

Because the AWS CLI is essentially a "wrapper" around the service's API, the skeleton file expects you to reference all parameters by their underlying API parameter names. This is likely different from the AWS CLI parameter name. For example, an AWS CLI parameter named `user-name` might map to the AWS service's API parameter named `UserName` (notice the altered capitalization and missing dash). We recommend that you use the `--generate-cli-skeleton` option to generate the template with the "correct" parameter names to avoid errors. You can also reference the API Reference Guide for the service to see the expected parameter names. You can delete any parameters from the template that are not required and for which you don't want to supply a value.
For example, if you run the following command, it generates the parameter template for the Amazon Elastic Compute Cloud (Amazon EC2) command `run-instances`.

**JSON**

The following example shows how to generate a template formatted in JSON by using the default value (input) for the `--generate-cli-skeleton` parameter.

```bash
$ aws ec2 run-instances --generate-cli-skeleton
```

Generating a command skeleton

To generate and use a parameter skeleton file

1. Run the command with the --generate-cli-skeleton parameter to produce either JSON or YAML and direct the output to a file to save it.

   **JSON**

   ```bash
   $ aws ec2 run-instances --generate-cli-skeleton input > ec2runinst.json
   ```

   **YAML**

   ```bash
   $ aws ec2 run-instances --generate-cli-skeleton yaml-input > ec2runinst.yaml
   ```

2. Open the parameter skeleton file in your text editor and remove any of the parameters that you don’t need. For example, you might strip the template down to the following. Be sure that the file is still valid JSON or YAML after you remove the elements you don't need.

   **JSON**

   ```json
   {
       "DryRun": true,
       "ImageId": "",
       "KeyName": "",
       "SecurityGroups": [
           ""
       ],
       "InstanceType": "",
       "Monitoring": {
           "Enabled": true
       }
   }
   ```
In this example, we leave the DryRun parameter set to true to use the Amazon EC2 dry run feature. This feature lets you safely test the command without actually creating or modifying any resources.

3. Fill in the remaining values with values appropriate for your scenario. In this example, we provide the instance type, key name, security group, and identifier of the Amazon Machine Image (AMI) to use. This example assumes the default AWS Region. The AMI ami-dfc39aef is a 64-bit Amazon Linux image hosted in the us-west-2 Region. If you use a different Region, you must find the correct AMI ID to use.

```json
{
    "DryRun": true,
    "ImageId": "ami-dfc39aef",
    "KeyName": "mykey",
    "SecurityGroups": [
        "my-sg"
    ],
    "InstanceType": "t2.micro",
    "Monitoring": {
        "Enabled": true
    }
}
```
4. Run the command with the completed parameters by passing the completed template file to either the `--cli-input-json` or `--cli-input-yaml` parameter by using the `file://` prefix. The AWS CLI interprets the path to be relative to your current working directory, so in the following example that displays only the file name with no path, it looks for the file directly in the current working directory.

**JSON**

```bash
$ aws ec2 run-instances --cli-input-json file://ec2runinst.json
```

A client error (DryRunOperation) occurred when calling the RunInstances operation: Request would have succeeded, but DryRun flag is set.

**YAML**

```bash
$ aws ec2 run-instances --cli-input-yaml file://ec2runinst.yaml
```

A client error (DryRunOperation) occurred when calling the RunInstances operation: Request would have succeeded, but DryRun flag is set.

The dry run error indicates that the JSON or YAML is formed correctly and that the parameter values are valid. If other issues are reported in the output, fix them and repeat the previous step until the "Request would have succeeded" message is displayed.

5. Now you can set the DryRun parameter to `false` to disable dry run.
Run the command, and `run-instances` actually launches an Amazon EC2 instance and displays the details generated by the successful launch. The format of the output is controlled by the `--output` parameter, separately from the format of your input parameter template.

**JSON**

```json
$ aws ec2 run-instances --cli-input-json file://ec2runinst.json --output json

{
    "OwnerId": "123456789012",
    "ReservationId": "r-d94a2b1",
    "Groups": [],
    "Instances": [
        ...
    ]
}
```
Use shorthand syntax with the AWS CLI

The AWS Command Line Interface (AWS CLI) can accept many of its option parameters in JSON format. However, it can be tedious to enter large JSON lists or structures on the command line. To make this easier, the AWS CLI also supports a shorthand syntax that enables a simpler representation of your option parameters than using the full JSON format.

Topics

• **Structure parameters**

• **Using shorthand syntax with the AWS Command Line Interface**

Structure parameters

The shorthand syntax in the AWS CLI makes it easier for users to input parameters that are flat (non-nested structures). The format is a comma-separated list of key-value pairs. Be sure to use the **quoting** and escaping rules appropriate for your terminal as shorthand syntax are strings.

Linux or macOS

```
--option key1=value1,key2=value2,key3=value3
```

PowerShell

```
--option "key1=value1,key2=value2,key3=value3"
```
These are both equivalent to the following example, formatted in JSON.

```
--option '{"key1":"value1","key2":"value2","key3":"value3"}'
```

There must be no white space between each comma-separated key-value pair. Here is an example of the Amazon DynamoDB update-table command with the `--provisioned-throughput` option specified in shorthand.

```
$ aws dynamodb update-table \
   --provisioned-throughput ReadCapacityUnits=15,WriteCapacityUnits=10 \
   --table-name MyDDBTable
```

This is equivalent to the following example formatted in JSON.

```
$ aws dynamodb update-table \
   --provisioned-throughput '{"ReadCapacityUnits":15,"WriteCapacityUnits":10}' \
   --table-name MyDDBTable
```

**Using shorthand syntax with the AWS Command Line Interface**

You can specify Input parameters in a list form in two ways: JSON or shorthand. The AWS CLI shorthand syntax is designed to make it easier to pass in lists with number, string, or non-nested structures.

The basic format is shown here, where values in the list are separated by a single space.

```
--option value1 value2 value3
```

This is equivalent to the following example, formatted in JSON.

```
--option '[value1,value2,value3]' 
```

As previously mentioned, you can specify a list of numbers, a list of strings, or a list of non-nested structures in shorthand. The following is an example of the stop-instances command for Amazon Elastic Compute Cloud (Amazon EC2), where the input parameter (list of strings) for the `--instance-ids` option is specified in shorthand.

```
$ aws ec2 stop-instances \
```
This is equivalent to the following example formatted in JSON.

```
$ aws ec2 stop-instances \
   --instance-ids '"i-1486157a","i-1286157c","i-ec3a7e87"'
```

The following example shows the Amazon EC2 create-tags command, which takes a list of non-nested structures for the --tags option. The --resources option specifies the ID of the instance to tag.

```
$ aws ec2 create-tags \
   --resources i-1286157c \
   --tags Key=My1stTag,Value=Value1 Key=My2ndTag,Value=Value2 \
   Key=My3rdTag,Value=Value3
```

This is equivalent to the following example, formatted in JSON. The JSON parameter is written over multiple lines for readability.

```
$ aws ec2 create-tags \
   --resources i-1286157c \
   --tags [\
            {"Key": "My1stTag", "Value": "Value1"},\
            {"Key": "My2ndTag", "Value": "Value2"},\
            {"Key": "My3rdTag", "Value": "Value3"}\
       ]
```

**Have the AWS CLI prompt you for commands**

You can have the AWS CLI version 2 prompt you commands, parameters, and resources when you run an aws command.

- [Auto-prompt modes](#)
- [Configure auto-prompt](#)
How it works

If enabled, the auto-prompt enables you to use the ENTER key to complete a partially entered command. After pressing the ENTER key, commands, parameters, and resources are suggested based on what you continue to type. The suggestions list the name of the command, parameter, or resource on the left and a description of it on the right. To select and use a suggestion, use the arrows keys to highlight a row, and then press the SPACE key. When you've finished entering in your command, press ENTER to use the command. The following example demonstrates what a suggested list from auto-prompt looks like.

```bash
$ aws
> aws a
  accessanalyzer  Access Analyzer
  acm             AWS Certificate Manager
  acm-pca         AWS Certificate Manager Private Certificate
  Authority       Alexa For Business
  amplify         AWS Amplify
```

Auto-prompt features

The auto-prompt contains the following useful features:

Documentation panel

Provides the help documentation for the current command. To open the documentation, press the F3 key.

Command completion

Suggests aws commands to use. To see a list, partially enter the command. The following example is searching for a service starting with the letter a.

```bash
$ aws
> aws a
  accessanalyzer  Access Analyzer
  acm             AWS Certificate Manager
  acm-pca         AWS Certificate Manager Private Certificate
  Authority       Alexa For Business
  amplify         AWS Amplify
```
Parameter completion

After a command is typed, auto-prompt starts to suggest parameters. The descriptions for the parameters include the value type, and a description of what the parameter is. Required parameters are listed first, and are labeled as required. The following example shows the auto-prompt list of parameters for `aws dynamodb describe-table`.

```
$ aws dynamodb describe-table
  > aws dynamodb describe-table
  --table-name (required) [string] The name of the table to describe.
  --cli-input-json [string] Reads arguments from the JSON string provided. The JSON string follows the format provide...
  --cli-input-yaml [string] Reads arguments from the YAML string provided. The YAML string follows the format provide...
  --generate-cli-skeleton [string] Prints a JSON skeleton to standard output without sending an API request. If provided wit...
```

Resource completion

The auto-prompt makes AWS API calls using available AWS resource properties to suggest resource values. This allows for auto-prompt to suggest possible resources you own when entering in parameters. In the following example auto-prompt lists your table names when filling in the `--table-name` parameter for the `aws dynamodb describe-table` command.

```
$ aws dynamodb describe-table
  > aws dynamodb describe-table --table-name
  Table1
  Table2
  Table3
```

Shorthand completion

For parameters that use shorthand syntax, auto-prompt suggests values to use. In the following example, auto-prompt lists shorthand syntax values for the `--placement` parameter in the `aws ec2 run-instances` command.

```
$ aws ec2 run-instances
  > aws ec2 run-instances --placement
  AvailabilityZone= [string] The Availability Zone of the instance. If not specified, an Availability Zone wil...
```
File completion

When filling out parameters in `aws` commands, auto-complete suggests local filenames after using the prefix `file://` or `fileb://`. In the following example, auto-prompt suggests local files after entering in `--item file://` for the `aws ec2 run-instances` command.

```
$ aws ec2 run-instances
  > aws ec2 run-instances --item file://
       item1.txt
       file1.json
       file2.json
```

Region completion

When using the global parameter `--region`, auto-prompt lists possible Regions to select from. In the following example, auto-prompt suggests Regions in alphabetical order after entering in `--region` for the `aws dynamodb list-tables` command.

```
$ aws dynamodb list-tables
  > aws dynamodb list-tables --region
       af-south-1
       ap-east-1
       ap-northeast-1
       ap-northeast-2
```

Profile completion

When using the global parameter `--profile`, auto-prompt lists your profiles. In the following example, auto-prompt suggests your profiles after entering in `--profile` for the `aws dynamodb list-tables` command.

```
$ aws dynamodb list-tables
  > aws dynamodb list-tables --profile
       profile1
```
Fuzzy searching

Complete commands and values that contain a specific set of characters. In the following example, auto-prompt suggests Regions that contain eu after entering in `--region eu` for the `aws dynamodb list-tables` command.

```bash
$ aws dynamodb list-tables
> aws dynamodb list-tables --region west
    eu-west-1
    eu-west-2
    eu-west-3
    us-west-1
```

History

To view and run previously used commands in auto-prompt mode, press `CTRL + R`. History lists previous commands that you can select by using the arrow keys. In the following example, the auto-prompt mode history is displayed.

```bash
$ aws
> aws
dynamodb list-tables
ds3 ls
```

Auto-prompt modes

Auto-prompt for the AWS CLI version 2 has 2 modes that can be configured:

- **Full mode**: Uses auto-prompt each time you attempt to run an `aws` command, whether you manually call it using the `--cli-auto-prompt` parameter or permanently enabled it. This includes pressing `ENTER` after both a complete command or incomplete command.

- **Partial mode**: Uses auto-prompt if a command is incomplete or cannot be run due to client-side validation errors. This mode is particular useful if you have pre-existing scripts, runbooks, or you only want to be auto-prompted for commands you are unfamiliar with rather than prompted on every command.
Configure auto-prompt

To configure auto-prompt you can use the following methods in order of precedence:

- **Command line options** enable or disable auto-prompt for a single command. Use `--cli-auto-prompt` to call auto-prompt and `--no-cli-auto-prompt` to disable auto-prompt.

- **Environment variables** use the `aws_cli_auto_prompt` variable.

- **Shared config files** use the `cli_auto_prompt` setting.

Control command output from the AWS CLI

This section describes the different ways to control the output from the AWS Command Line Interface (AWS CLI). Customizing the AWS CLI output in your terminal can improve readability, streamline scripting automation and provide easier navigation through larger data sets.

The AWS CLI supports multiple output formats, including json, text, yaml, and table. Some services have server-side pagination for their data and the AWS CLI provides its own client-side features for additional pagination options.

Lastly, the AWS CLI has both server-side and client-side filtering that you can use individually or together to filter your AWS CLI output. Server-side filtering is processed first and returns your output for client-side filtering. Server-side filtering is supported by the service API. Client-side filtering is supported by the AWS CLI client using the `--query` parameter.

Server-side vs client-side output options

**Server-side** output options are features directly supported by the AWS service API. Any data that is filtered or paged out is not sent to the client, which can speed up HTTP response times and improve bandwidth for larger data sets.

**Client-side** output options are features created by the AWS CLI. All data is sent to the client, then the AWS CLI filters or pages the content displayed. Client-side operations do not save on speed or bandwidth for larger datasets.

When server-side and client-side options are used together, server-side operations are completed first and then sent to the client for client-side operations. This uses the potential speed and bandwidth savings of server-side options, while using additional AWS CLI features to get your desired output.
Set the AWS CLI output format

This topic describes the different output formats for the AWS Command Line Interface (AWS CLI). The AWS CLI supports the following output formats:

- **json** – The output is formatted as a JSON string.
- **yaml** – The output is formatted as a YAML string.
- **yaml-stream** – The output is streamed and formatted as a YAML string. Streaming allows for faster handling of large data types.
- **text** – The output is formatted as multiple lines of tab-separated string values. This can be useful to pass the output to a text processor, like grep, sed, or awk.
- **table** – The output is formatted as a table using the characters +|- to form the cell borders. It typically presents the information in a "human-friendly" format that is much easier to read than the others, but not as programmatically useful.

How to select the output format

As explained in the configuration topic, you can specify the output format in three ways:

- **Using the output option in a named profile in the config file** – The following example sets the default output format to text.

  ```
  [default]
  output=text
  ```

- **Using the AWS_DEFAULT_OUTPUT environment variable** – The following output sets the format to table for the commands in this command line session until the variable is changed or the session ends. Using this environment variable overrides any value set in the config file.

  ```
  $ export AWS_DEFAULT_OUTPUT="table"
  ```
• **Using the --output option on the command line** – The following example sets the output of only this one command to json. Using this option on the command overrides any currently set environment variable or the value in the config file.

```
$ aws swf list-domains --registration-status REGISTERED --output json
```

⚠️ **Important**

The output type you specify changes how the --query option operates:

- If you specify --output text, the output is paginated before the --query filter is applied, and the AWS CLI runs the query once on each page of the output. Due to this, the query includes the first matching element on each page which can result in unexpected extra output. To additionally filter the output, you can use other command line tools such as head or tail.

- If you specify --output json, --output yaml, or --output yaml-stream the output is completely processed as a single, native structure before the --query filter is applied. The AWS CLI runs the query only once against the entire structure, producing a filtered result that is then output.

**JSON output format**

JSON is the default output format of the AWS CLI. Most programming languages can easily decode JSON strings using built-in functions or with publicly available libraries. You can combine JSON output with the --query option in powerful ways to filter and format the AWS CLI JSON-formatted output.

For more advanced filtering that you might not be able to do with --query, you can consider jq, a command line JSON processor. You can download it and find the official tutorial at [http://stedolan.github.io/jq/](http://stedolan.github.io/jq/).

The following is an example of JSON output.

```
$ aws iam list-users --output json
{
```
"Users": [
  {
    "Path": "/",
    "UserName": "Admin",
    "UserId": "AIDA1111111111EXAMPLE",
    "Arn": "arn:aws:iam::123456789012:user/Admin",
    "CreateDate": "2014-10-16T16:03:09+00:00",
    "PasswordLastUsed": "2016-06-03T18:37:29+00:00"
  },
  {
    "Path": "/backup/",
    "UserName": "backup-user",
    "UserId": "AIDA2222222222EXAMPLE",
    "Arn": "arn:aws:iam::123456789012:user/backup/backup-user",
    "CreateDate": "2019-09-17T19:30:40+00:00"
  },
  {
    "Path": "/",
    "UserName": "cli-user",
    "UserId": "AIDA3333333333EXAMPLE",
    "Arn": "arn:aws:iam::123456789012:user/cli-user",
    "CreateDate": "2019-09-17T19:11:39+00:00"
  }
]

YAML output format

YAML is a good choice for handling the output programmatically with services and tools that emit or consume YAML-formatted strings, such as AWS CloudFormation with its support for YAML-formatted templates.

For more advanced filtering that you might not be able to do with --query, you can consider yq, a command line YAML processor. You can download yq in the yq repository on GitHub.

The following is an example of YAML output.

$ aws iam list-users --output yaml

Users:
- Arn: arn:aws:iam::123456789012:user/Admin
  CreateDate: '2014-10-16T16:03:09+00:00'
PasswordLastUsed: '2016-06-03T18:37:29+00:00'
Path: /
UserId: AIDA1111111111EXAMPLE
UserName: Admin

  UserId: AIDA3333333333EXAMPLE

YAML stream output format

The yaml-stream format takes advantage of the YAML format while providing more responsive/faster viewing of large data sets by streaming the data to you. You can start viewing and using YAML data before the entire query downloads.

For more advanced filtering that you might not be able to do with --query, you can consider yq, a command line YAML processor. You can download yq in the yq repository on GitHub.

The following is an example of yaml-stream output.

```
$ aws iam list-users --output yaml-stream

**Text output format**

The text format organizes the AWS CLI output into tab-delimited lines. It works well with traditional Unix text tools such as `grep`, `sed`, and `awk`, and the text processing performed by PowerShell.

The text output format follows the basic structure shown below. The columns are sorted alphabetically by the corresponding key names of the underlying JSON object.
The following is an example of text output. Each field is tab separated from the others, with an extra tab where there is an empty field.

```bash
$ aws iam list-users --output text
```

<table>
<thead>
<tr>
<th>USERS</th>
<th>arn:aws:iam::123456789012:user/Admin</th>
<th>2014-10-16T16:03:09+00:00</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>2016-06-03T18:37:29+00:00 /</td>
<td>AIDA11111111EXAMPLE</td>
</tr>
<tr>
<td></td>
<td>/ AIDA11111111EXAMPLE Admin</td>
<td></td>
</tr>
<tr>
<td>USERS</td>
<td>arn:aws:iam::123456789012:user/backup/backup-user</td>
<td>2019-09-17T19:30:40+00:00</td>
</tr>
<tr>
<td></td>
<td>/backup/ AIDA2222222222EXAMPLE backup-user</td>
<td></td>
</tr>
<tr>
<td>USERS</td>
<td>arn:aws:iam::123456789012:user/cli-user</td>
<td>2019-09-17T19:11:39+00:00</td>
</tr>
<tr>
<td></td>
<td>/ AIDA3333333333EXAMPLE cli-user</td>
<td></td>
</tr>
</tbody>
</table>

The fourth column is the PasswordLastUsed field, and is empty for the last two entries because those users never sign in to the AWS Management Console.

**Important**

*We strongly recommend that if you specify text output, you also always use the `--query` option to ensure consistent behavior.*

This is because the text format alphabetically orders output columns by the key name of the underlying JSON object returned by the AWS service, and similar resources might not have the same key names. For example, the JSON representation of a Linux-based Amazon EC2 instance might have elements that are not present in the JSON representation of a Windows-based instance, or vice versa. Also, resources might have key-value elements added or removed in future updates, altering the column ordering. This is where `--query` augments the functionality of the text output to provide you with complete control over the output format.

In the following example, the command specifies which elements to display and defines the ordering of the columns with the list notation `[key1, key2, ...]`. This gives you full confidence that the correct key values are always displayed in the expected column. Finally, notice how the AWS CLI outputs None as the value for keys that don't exist.

```bash
$ aws iam list-users --output text --query 'Users[*].
[UserName,Arn,CreateDate,PasswordLastUsed,UserId]'```

---

**Output Format**

286
The following example shows how you can use `grep` and `awk` with the text output from the `aws ec2 describe-instances` command. The first command displays the Availability Zone, current state, and the instance ID of each instance in text output. The second command processes that output to display only the instance IDs of all running instances in the `us-west-2a` Availability Zone.

```bash
$ aws ec2 describe-instances --query 'Reservations[*].Instances[*].[Placement.AvailabilityZone, State.Name, InstanceId]' --output text
```

```bash
<table>
<thead>
<tr>
<th>Availability Zone</th>
<th>State</th>
<th>Instance ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-west-2a</td>
<td>running</td>
<td>i-4b41a37c</td>
</tr>
<tr>
<td>us-west-2a</td>
<td>stopped</td>
<td>i-a071c394</td>
</tr>
<tr>
<td>us-west-2b</td>
<td>stopped</td>
<td>i-97a217a0</td>
</tr>
<tr>
<td>us-west-2a</td>
<td>running</td>
<td>i-3045b007</td>
</tr>
<tr>
<td>us-west-2a</td>
<td>running</td>
<td>i-6fc67758</td>
</tr>
</tbody>
</table>
```

```bash
$ aws ec2 describe-instances --query 'Reservations[*].Instances[*].[State.Name, InstanceId]' --output text | grep stopped | awk '{print $2}'
```

```bash
i-4b41a37c
i-3045b007
i-6fc67758
```

The following example goes a step further and shows not only how to filter the output, but how to use that output to automate changing instance types for each stopped instance.

```bash
$ aws ec2 describe-instances --query 'Reservations[*].Instances[*][State.Name, InstanceId]' --output text | grep stopped | awk '{print $2}' |
```

```bash
i-4b41a37c
i-3045b007
i-6fc67758
```
while read line; do aws ec2 modify-instance-attribute --instance-id $line --instance-type '{"Value": "m1.medium"}'; done

The text output can also be useful in PowerShell. Because the columns in text output are tab delimited, you can easily split the output into an array by using PowerShell’s ‘`’ delimiter. The following command displays the value of the third column (InstanceId) if the first column (AvailabilityZone) matches the string us-west-2a.

```powershell
PS C:\> aws ec2 describe-instances --query 'Reservations[*].Instances[*].[Placement.AvailabilityZone, State.Name, InstanceId]' --output text | %{if ($_.split(`t`)[0] -match "us-west-2a") { $_.split(`t`)[2]; } }
```

-4b41a37c
i-a071c394
i-3045b007
i-6fc67758

Notice that although the previous example does show how to use the --query parameter to parse the underlying JSON objects and pull out the desired column, PowerShell has its own ability to handle JSON, if cross-platform compatibility isn't a concern. Instead of handling the output as text, as most command shells require, PowerShell lets you use the ConvertFrom-JSON cmdlet to produce a hierarchically structured object. You can then directly access the member you want from that object.

```powershell
(aws ec2 describe-instances --output json | ConvertFrom-Json).Reservations.Instances.InstanceId
```

**Tip**

If you output text, and filter the output to a single field using the --query parameter, the output is a single line of tab-separated values. To get each value onto a separate line, you can put the output field in brackets, as shown in the following examples.

Tab separated, single-line output:

```powershell
$ aws iam list-groups-for-user --user-name susan --output text --query "Groups[].GroupName"
```
Each value on its own line by putting `[GroupName]` in brackets:

```
$ aws iam list-groups-for-user --user-name susan --output text --query
"Groups\[\].\[GroupName\]"
```

```
HRDepartment
Developers
SpreadsheetUsers
LocalAdmins
```

### Table output format

The table format produces human-readable representations of complex AWS CLI output in a tabular form.

```
$ aws iam list-users --output table
```

```

<td>Users</td>
</tr>
<tr>
<td></td>
<td>+---------------------</td>
<td>--------------------</td>
</tr>
<tr>

You can combine the `--query` option with the `table` format to display a set of elements preselected from the raw output. Notice the output differences between dictionary and list notations: in the first example, column names are ordered alphabetically, and in the second example, unnamed columns are ordered as defined by the user. For more information about the `--query` option, see Filter AWS CLI output.

```bash
$ aws ec2 describe-volumes --query 'Volumes[*].{ID:VolumeId,InstanceId:Attachments[0].InstanceId,AZ:AvailabilityZone,Size:Size}' --output table

| us-west-2a | vol-2e410a47 | i-4b41a37c | 8 |
```

```bash
$ aws ec2 describe-volumes --query 'Volumes[*].[VolumeId,Attachments[0].InstanceId,AvailabilityZone,Size]' --output table

Use AWS CLI pagination options

This topic describes the different ways to paginate output from the AWS CLI.

There are primarily two ways to control pagination from the AWS CLI.

- **Using server-side pagination parameters.**
- **Using your default output client-side paging program.**
Server-side pagination parameters process first and any output is sent to client-side pagination.

### Server-side pagination

For commands that can return a large list of items, the AWS Command Line Interface (AWS CLI) has multiple options to control the number of items included in the output when the AWS CLI calls a service's API to populate the list.

**The options include the following:**

- How to use the `--no-paginate` parameter
- How to use the `--page-size` parameter
- How to use the `--max-items` parameter
- How to use the `--starting-token` parameter

By default, the AWS CLI uses a page size determined by the individual service and retrieves all available items. For example, Amazon S3 has a default page size of 1000. If you run `aws s3api list-objects` on an Amazon S3 bucket that contains 3,500 objects, the AWS CLI automatically makes four calls to Amazon S3, handling the service-specific pagination logic for you in the background and returning all 3,500 objects in the final output.

**How to use the `--no-paginate` parameter**

The `--no-paginate` option disables following pagination tokens on the client side. When using a command, by default the AWS CLI automatically makes multiple calls to return all possible results to create pagination. One call for each page. Disabling pagination has the AWS CLI only call once for the first page of command results.

For example, if you run `aws s3api list-objects` on an Amazon S3 bucket that contains 3,500 objects, the AWS CLI only makes the first call to Amazon S3, returning only the first 1,000 objects in the final output.

```bash
$ aws s3api list-objects
  --bucket my-bucket
  --no-paginate
{
  "Contents": [
...
```
How to use the --page-size parameter

If you see issues when running list commands on a large number of resources, the default page size might be too high. This can cause calls to AWS services to exceed the maximum allowed time and generate a "timed out" error. You can use the --page-size option to specify that the AWS CLI request a smaller number of items from each call to the AWS service. The AWS CLI still retrieves the full list, but performs a larger number of service API calls in the background and retrieves a smaller number of items with each call. This gives the individual calls a better chance of succeeding without a timeout. Changing the page size doesn't affect the output; it affects only the number of API calls that need to be made to generate the output.

```
$ aws s3api list-objects \
   --bucket my-bucket \ 
   --page-size 100
{
   "Contents": [ ...
```

How to use the --max-items parameter

To include fewer items at a time in the AWS CLI output, use the --max-items option. The AWS CLI still handles pagination with the service as described previously, but prints out only the number of items at a time that you specify.

```
$ aws s3api list-objects \
   --bucket my-bucket \ 
   --max-items 100
{
   "NextToken": "eyJNYXJrZXI0i0BuWxsLCAiYm90b190cnVuY2F0ZV9hbW91bnQ1OiAxfQ==",
   "Contents": [ ...
```

How to use the --starting-token parameter

If the number of items output (--max-items) is fewer than the total number of items returned by the underlying API calls, the output includes a NextToken that you can pass to a subsequent command to retrieve the next set of items. The following example shows how to use the NextToken value returned by the previous example, and enables you to retrieve the second 100 items.
Note

The parameter --starting-token cannot be null or empty. If the previous command does not return a NextToken value, there are no more items to return and you do not need to call the command again.

```bash
$ aws s3api list-objects
  --bucket my-bucket
  --max-items 100
  --starting-token eyJNYXJrZXIiOiBudWxsLCAiYm90b190cnVuY2F0ZW9hbnQiOiAxI==
{
  "Contents": [
...
```

The specified AWS service might not return items in the same order each time you call. If you specify different values for --page-size and --max-items, you can get unexpected results with missing or duplicated items. To prevent this, use the same number for --page-size and --max-items to sync the AWS CLI pagination with the pagination of the underlying service. You can also retrieve the whole list and perform any necessary paging operations locally.

Client-side pager

AWS CLI version 2 provides the use of a client-side pager program for output. By default, this feature returns all output through your operating system's default pager program.

In order of precedence, you can specify the output pager in the following ways:

- Using the cli_pager setting in the config file in the default or named profile.
- Using the AWS_PAGER environment variable.
- Using the PAGER environment variable.

In order of precedence, you can disable all use of an external paging program in the following ways:

- Use the --no-cli-pager command line option to disable the pager for a single command use.
- Set the cli_pager setting or AWS_PAGER variable to an empty string.
Client-side pager topics:

- How to use the cli_pager setting
- How to use the AWS_PAGER environment variable
- How to use the --no-cli-pager option
- How to use pager flags

How to use the cli_pager setting

You can save your frequently used configuration settings and credentials in files that are maintained by the AWS CLI. Settings in a name profile take precedence over settings in the default profile. For more information on configuration settings, see [Configuration and credential file settings](#).

The following example sets the default output pager to the `less` program.

```bash
[default]
cli_pager=less
```

The following example sets the default to disable the use of a pager.

```bash
[default]
cli_pager=
```

How to use the AWS_PAGER environment variable

The following example sets the default output pager to the `less` program. For more information on environment variables, see [Environment variables to configure the AWS CLI](#).

Linux and macOS

```bash
$ export AWS_PAGER="less"
```

Windows

```bash
C:\> setx AWS_PAGER "less"
```

The following example disables the use of a pager.
Linux and macOS

$ export AWS_PAGER=""

Windows

C:\> setx AWS_PAGER ""

How to use the --no-cli-pager option

To disable the use of a pager on a single command, use the --no-cli-pager option. For more information on command line options, see Command line options.

$ aws s3api list-objects \
   --bucket my-bucket \
   --no-cli-pager
{
   "Contents": [
   ...

How to use pager flags

You can specify flags to use automatically with your paging program. Flags are dependent on the paging program you use. The below examples are for the typical defaults of less and more.

Linux and macOS

If you do not specify otherwise, the pager AWS CLI version 2 uses by default is less. If you don't have the LESS environment variable set, the AWS CLI version 2 uses the FRX flags. You can combine flags by specifying them when setting the AWS CLI pager.

The following example uses the S flag. This flag then combines with the default FRX flags to create a final FRXS flag.

$ export AWS_PAGER="less -S"

If you don't want any of the FRX flags, you can negate them. The following example negates the F flag to create a final RX flag.

$ export AWS_PAGER="less -+F"
For more information on `less` flags see `less` on `manpages.org`.

Windows

If you do not specify otherwise, the pager AWS CLI version 2 uses by default is `more` with no additional flags.

The following example uses the `/c` parameter.

```
C:\> setx AWS_PAGER "more /c"
```

For more information on `more` flags see `more` on `Microsoft Docs`.

Filter AWS CLI output

The AWS Command Line Interface (AWS CLI) has both server-side and client-side filtering that you can use individually or together to filter your AWS CLI output. Server-side filtering is processed first and returns your output for client-side filtering.

- Server-side filtering is supported by the API, and you usually implement it with a `--filter` parameter. The service only returns matching results which can speed up HTTP response times for large data sets.
- Client-side filtering is supported by the AWS CLI client using the `--query` parameter. This parameter has capabilities the server-side filtering might not have.

- Client-side filtering
- Combining server-side and client-side filtering
- Additional resources

Server-side filtering

Server-side filtering in the AWS CLI is provided by the AWS service API. The AWS service only returns the records in the HTTP response that match your filter, which can speed up HTTP response times for large data sets. Since server-side filtering is defined by the service API, the parameter names and functions vary between services. Some common parameter names used for filtering are:
• **--filter** such as `ses` and `ce`.
• **--filters** such as `ec2`, `autoscaling`, and `rds`.
• Names starting with the word filter, for example **--filter-expression** for the `aws dynamodb scan` command.

For information about whether a specific command has server-side filtering and the filtering rules, see the [AWS CLI version 2 reference guide](#).

## Client-side filtering

The AWS CLI provides built-in JSON-based client-side filtering capabilities with the **--query** parameter. The **--query** parameter is a powerful tool you can use to customize the content and style of your output. The **--query** parameter takes the HTTP response that comes back from the server and filters the results before displaying them. Since the entire HTTP response is sent to the client before filtering, client-side filtering can be slower than server-side filtering for large datasets.

Querying uses [JMESPath syntax](#) to create expressions for filtering your output. To learn JMESPath syntax, see [Tutorial](#) on the [JMESPath website](#).

⚠️ **Important**

The output type you specify changes how the **--query** option operates:

- If you specify **--output text**, the output is paginated **before** the **--query** filter is applied, and the AWS CLI runs the query once on **each page** of the output. Due to this, the query includes the first matching element on each page which can result in unexpected extra output. To additionally filter the output, you can use other command line tools such as head or tail.
- If you specify **--output json**, **--output yaml**, or **--output yaml-stream** the output is completely processed as a single, native structure **before** the **--query** filter is applied. The AWS CLI runs the query only once against the entire structure, producing a filtered result that is then output.

Identifiers

Identifiers are the labels for output values. When creating filters, you use identifiers to narrow down your query results. In the following output example, all identifiers such as Volumes, AvailabilityZone, and AttachTime are highlighted.

```
$ aws ec2 describe-volumes
{
    "Volumes": [
        {
            "AvailabilityZone": "us-west-2a",
            "Attachments": [
                {
                    "AttachTime": "2013-09-17T00:55:03.000Z",
                    "InstanceId": "i-a071c394",
                    "VolumeId": "vol-e11a5288",
                    "State": "attached",
                    "DeleteOnTermination": true,
                    "Device": "/dev/sda1"
                }
            ],
            "VolumeType": "standard",
            "VolumeId": "vol-e11a5288",
            "State": "in-use",
            "SnapshotId": "snap-f23ec1c8",
            "CreateTime": "2013-09-17T00:55:03.000Z",
            "Size": 30
        },
        {
            "AvailabilityZone": "us-west-2a",
            "Attachments": [
                {
                    "AttachTime": "2013-09-18T20:26:16.000Z",
                    "InstanceId": "i-4b41a37c",
                    "VolumeId": "vol-2e410a47",

                    "DeleteOnTermination": true,
                    "Device": "/dev/sd1"
                }
            ],
            "VolumeType": "standard",
        }
    ]
}
```
For more information, see Identifiers on the JMESPath website.

Selecting from a list

A list or array is an identifier that is followed by a square bracket "[" such as Volumes and Attachments in the the section called “Before you start”.

Syntax

<listName>[ ]

To filter through all output from an array, you can use the wildcard notation. Wildcard expressions are expressions used to return elements using the * notation.

The following example queries all Volumes content.
$ aws ec2 describe-volumes \
   --query 'Volumes[*]' \
[
  {
    "AvailabilityZone": "us-west-2a",
    "Attachments": [
      {
        "AttachTime": "2013-09-17T00:55:03.000Z",
        "InstanceId": "i-a071c394",
        "VolumeId": "vol-e11a5288",
        "State": "attached",
        "DeleteOnTermination": true,
        "Device": "/dev/sda1"
      }
    ],
    "VolumeType": "standard",
    "VolumeId": "vol-e11a5288",
    "State": "in-use",
    "SnapshotId": "snap-f23ec1c8",
    "CreateTime": "2013-09-17T00:55:03.000Z",
    "Size": 30
  },
  {
    "AvailabilityZone": "us-west-2a",
    "Attachments": [
      {
        "AttachTime": "2020-11-20T19:54:06.000Z",
        "InstanceId": "i-1jd73kv8",
        "VolumeId": "vol-a1b3c7nd",
        "State": "attached",
        "DeleteOnTermination": true,
        "Device": "/dev/sda1"
      }
    ],
    "VolumeType": "standard",
    "VolumeId": "vol-a1b3c7nd",
    "State": "in-use",
    "SnapshotId": "snap-234087fb",
    "CreateTime": "2020-11-20T19:54:05.000Z",
    "Size": 15
  }
]
To view a specific volume in the array by index, you call the array index. For example, the first item in the Volumes array has an index of 0, resulting in the Volumes[0] query. For more information about array indexes, see index expressions on the JMESPath website.

```
$ aws ec2 describe-volumes \
   --query 'Volumes[0]' 
{
   "AvailabilityZone": "us-west-2a",
   "Attachments": [
    {
      "AttachTime": "2013-09-17T00:55:03.000Z",
      "InstanceId": "i-a071c394",
      "VolumeId": "vol-e11a5288",
      "State": "attached",
      "DeleteOnTermination": true,
      "Device": "/dev/sda1"
    }
  ],
  "VolumeType": "standard",
  "VolumeId": "vol-e11a5288",
  "State": "in-use",
  "SnapshotId": "snap-f23ec1c8",
  "CreateTime": "2013-09-17T00:55:03.000Z",
  "Size": 30
}
```

To view a specific range of volumes by index, use slice with the following syntax, where start is the starting array index, stop is the index where the filter stops processing, and step is the skip interval.

**Syntax**

```
<arrayName>[<start>:<stop>:<step>]
```

If any of these are omitted from the slice expression, they use the following default values:

- Start – The first index in the list, 0.
- Stop – The last index in the list.
- Step – No step skipping, where the value is 1.
To return only the first two volumes, you use a start value of 0, a stop value of 2, and a step value of 1 as shown in the following example.

```bash
$ aws ec2 describe-volumes \
   --query 'Volumes[0:2:1]' 
[ 
  
  
  ], 
  
  
  
  

Filter output
```
Since this example contains default values, you can shorten the slice from `Volumes[0:2:1]` to `Volumes[:2]`.

The following example omits default values and returns every two volumes in the entire array.

```bash
$ aws ec2 describe-volumes \
   --query 'Volumes[::2]'
```

```
[
  {
    "AvailabilityZone": "us-west-2a",
    "Attachments": [
      {
        "AttachTime": "2013-09-17T00:55:03.000Z",
        "InstanceId": "i-a071c394",
        "VolumeId": "vol-e11a5288",
        "State": "attached",
        "DeleteOnTermination": true,
        "Device": "/dev/sda1"
      }
    ],
    "VolumeType": "standard",
    "VolumeId": "vol-e11a5288",
    "State": "in-use",
    "SnapshotId": "snap-f23ec1c8",
    "CreateTime": "2013-09-17T00:55:03.000Z",
    "Size": 30
  },
  {
    "AvailabilityZone": "us-west-2a",
    "Attachments": [
      {
        "AttachTime": "2020-11-20T19:54:06.000Z",
        "InstanceId": "i-1jd73kv8",
        "VolumeId": "vol-a1b3c7nd",
        "State": "attached",
        "DeleteOnTermination": true,
        "Device": "/dev/sdal"
      }
    ],
    "VolumeType": "standard",
    "VolumeId": "vol-a1b3c7nd",
    "State": "in-use",
    "SnapshotId": "snap-8973c41b",
    "CreateTime": "2020-11-20T19:54:06.000Z",
    "Size": 30
  }
]
```
Steps can also use negative numbers to filter in the reverse order of an array as shown in the following example.

```bash
$ aws ec2 describe-volumes --query 'Volumes[::-2]'  
[
  {
    "AvailabilityZone": "us-west-2a",
    "Attachments": [
      {
        "AttachTime": "2020-11-20T19:54:06.000Z",
        "InstanceId": "i-1jd73kv8",
        "VolumeId": "vol-a1b3c7nd",
        "State": "attached",
        "DeleteOnTermination": true,
        "Device": "/dev/sda1"
      }
    ],
    "VolumeType": "standard",
    "VolumeId": "vol-a1b3c7nd",
    "State": "in-use",
    "SnapshotId": "snap-234087fb",
    "CreateTime": "2020-11-20T19:54:05.000Z",
    "Size": 15
  },
  {
    "AvailabilityZone": "us-west-2a",
    "Attachments": [
      {
        "AttachTime": "2013-09-17T00:55:03.000Z",
        "InstanceId": "i-a071c394",
        "VolumeId": "vol-e1a5288",
        "State": "attached",
        "DeleteOnTermination": true,
        "Device": "/dev/sda1"
      }
    ],
    "VolumeType": "standard",
    "VolumeId": "vol-e1a5288",

Filtering nested data

To narrow the filtering of the Volumes[*] for nested values, you use subexpressions by appending a period and your filter criteria.

Syntax

<expression>.<expression>

The following example shows all Attachments information for all volumes.

```
$ aws ec2 describe-volumes \
   --query 'Volumes[*].Attachments'
```

Filter output
To filter further into the nested values, append the expression for each nested identifier. The following example lists the State for all Volumes.

```
$ aws ec2 describe-volumes \
   --query 'Volumes[*].Attachments[*].State'

[ 
  [ 
    "attached"
  ],
  [ 
    "attached"
  ],
  [ 
    "attached"
  ]
]
```

**Flattening results**

For more information, see [SubExpressions](https://jmespath.org) on the [JMESPath website](https://jmespath.org).

You can flatten the results for `Volumes[*].Attachments[*].State` by removing the wildcard notation resulting in the `Volumes[*].Attachments[].State` query. Flattening often is useful to improve the readability of results.

```
$ aws ec2 describe-volumes \
   --query 'Volumes[*].Attachments[].State'

[ "attached", "attached", "attached" ]
```
For more information, see [Flatten](#) on the [JMESPath website](#).

### Filtering for specific values

To filter for specific values in a list, you use a filter expression as shown in the following syntax.

**Syntax**

```
? <expression> <comparator> <expression>
```

Expression comparators include `==`, `!=`, `<`, `<=`, `>`, and `>=`. The following example filters for the `VolumeIds` for all `Volumes` in an `Attached` State.

```
$ aws ec2 describe-volumes \
   --query 'Volumes[*].Attachments[?State==`attached`].VolumeId'
```

This can then be flattened resulting in the following example.

```
$ aws ec2 describe-volumes \
   --query 'Volumes[*].Attachments[?State==`attached`].VolumeId[]'
```

Filter output

```bash
"vol-e11a5288",
"vol-2e410a47",
"vol-a1b3c7nd"
```
The following example filters for the VolumeIds of all Volumes that have a size less than 20.

```bash
$ aws ec2 describe-volumes \
   --query 'Volumes[?Size < `20`].VolumeId'
[  
   "vol-2e410a47",
   "vol-a1b3c7nd"
]
```

For more information, see Filter Expressions on the JMESPath website.

Piping expressions

You can pipe results of a filter to a new list, and then filter the result with another expression using the following syntax:

**Syntax**

```
<expression> | <expression>
```

The following example takes the filter results of the `Volumes[*].Attachments[].InstanceId` expression and outputs the first result in the array.

```bash
$ aws ec2 describe-volumes \
   --query 'Volumes[*].Attachments[].InstanceId | [0]'
"i-a071c394"
```

This example does this by first creating the array from the following expression.

```bash
$ aws ec2 describe-volumes \
   --query 'Volumes[*].Attachments[].InstanceId'
"i-a071c394",
"i-4b41a37c",
"i-1jd73kv8"
```

And then returns the first element in that array.

"i-a071c394"
Filtering for multiple identifier values

To filter for multiple identifiers, you use a multiselect list by using the following syntax:

**Syntax**

```
<listName>[][<expression>, <expression>]
```

In the following example, VolumeId and VolumeType are filtered in theVolumes list resulting in the following expression.

```
$ aws ec2 describe-volumes \
   --query 'Volumes[][VolumeId, VolumeType]'
```

```
[ 
    [ 
      "vol-e11a5288",
      "standard"
    ],
    [ 
      "vol-2e410a47",
      "standard"
    ],
    [ 
      "vol-a1b3c7nd",
      "standard"
    ]
]
```

To add nested data to the list, you add another multiselect list. The following example expands on the previous example by also filtering for InstanceId and State in the nested Attachments list. This results in the following expression.

```
$ aws ec2 describe-volumes \
   --query 'Volumes[][VolumeId, VolumeType, Attachments[][InstanceId, State]]'
```

```
[ 
    [ 
      "vol-e11a5288",
      "standard",
      [ 
        [ 
          "i-a1234567",
          "running"
        ]
      ]
    ],
    [ 
      "vol-2e410a47",
      "standard",
      [ 
        [ 
          "i-b7890cde",
          "stopped"
        ]
      ]
    ],
    [ 
      "vol-a1b3c7nd",
      "standard",
      [ 
        [ 
          "i-76543210",
          "running"
        ]
      ]
    ]
]
To be more readable, flatten out the expression as shown in the following example.

$ aws ec2 describe-volumes \
   --query 'Volumes[].[VolumeId, VolumeType, Attachments[].[InstanceId, State[]][][]' 

[ 
  "vol-e11a5288",  
  "standard",  
  [  
    "i-a071c394",  
    "attached"  
  ],  
  "vol-2e410a47",  
  "standard",  
  [  
    "i-4b41a37c",  
    "attached"  
  ]
]
For more information, see Multiselect list on the JMESPath website.

Adding labels to identifier values

To make this output easier to read, use a multiselect hash with the following syntax.

**Syntax**

```
<listName>[].{<label>: <expression>, <label>: <expression>}
```

Your identifier label does not need to be the same as the name of the identifier. The following example uses the label `VolumeType` for the `VolumeType` values.

```
$ aws ec2 describe-volumes \
   --query 'Volumes[].{VolumeType: VolumeType}'
[
  {
    "VolumeType": "standard",
  },
  {
    "VolumeType": "standard",
  },
  {
    "VolumeType": "standard",
  }
]
```

For simplicity, the following example keeps the identifier names for each label and displays the `VolumeId`, `VolumeType`, `InstanceId`, and `State` for all volumes:

```
$ aws ec2 describe-volumes \
   --query 'Volumes[].{VolumeId: VolumeId, VolumeType: VolumeType, InstanceId: Attachments[0].InstanceId, State: Attachments[0].State}'
```
For more information, see [Multiselect hash](https://jmespath.org) on the [JMESPath website](https).

**Functions**

The JMESPath syntax contains many functions that you can use for your queries. For information on JMESPath functions, see [Built-in Functions](https://jmespath.org) on the [JMESPath website](https).

To demonstrate how you can incorporate a function into your queries, the following example uses the `sort_by` function. The `sort_by` function sorts an array using an expression as the sort key using the following syntax:

**Syntax**

```
sort_by(<listName>, <sort expression>)[[].<expression>
```

The following example uses the previous [multiselect hash example](https://jmespath.org) and sorts the output by `VolumeId`.

```
$ aws ec2 describe-volumes 
   --query 'sort_by(Volumes, &VolumeId)[[].{VolumeId: VolumeId, VolumeType: VolumeType, 
   InstanceId: Attachments[0].InstanceId, State: Attachments[0].State}'
```
For more information, see `sort_by` on the JMESPath website.

**Advanced --query examples**

**To extract information from a specific item**

The following example uses the `--query` parameter to find a specific item in a list and then extracts information from that item. The example lists all of the AvailabilityZones associated with the specified service endpoint. It extracts the item from the ServiceDetails list that has the specified ServiceName, then outputs the AvailabilityZones field from that selected item.

```bash
$ aws --region us-east-1 ec2 describe-vpc-endpoint-services \
   --query 'ServiceDetails[?ServiceName==`com.amazonaws.us-east-1.ecs`].AvailabilityZones'

[ 
  [ 
    "us-east-1a",
    "us-east-1b",
    "us-east-1c",
    "us-east-1d",
    "us-east-1e",
    "us-east-1f"
  ]
]```
To show snapshots after the specified creation date

The following example shows how to list all of your snapshots that were created after a specified date, including only a few of the available fields in the output.

```bash
$ aws ec2 describe-snapshots --owner self \
   --output json \
   --query 'Snapshots[?StartTime>=`2018-02-07`].\n   {Id:SnapshotId,VId:VolumeId,Size:VolumeSize}'
```

```json
[
  {
    "id": "snap-0effb42b7a1b2c3d4",
    "vid": "vol-0be9bb0bf12345678",
    "Size": 8
  }
]
```

To show the most recent AMIs

The following example lists the five most recent Amazon Machine Images (AMIs) that you created, sorted from most recent to oldest.

```bash
$ aws ec2 describe-images \
   --owners self \
   --query 'reverse(sort_by(Images,&CreationDate))[5].{id:ImageId,date:CreationDate}'
```

```json
[
  {
    "id": "ami-0a1b2c3d4e5f60001",
    "date": "2018-11-28T17:16:38.000Z"
  },
  {
    "id": "ami-0a1b2c3d4e5f60002",
    "date": "2018-09-15T13:51:22.000Z"
  },
  {
    "id": "ami-0a1b2c3d4e5f60003",
    "date": "2018-08-19T10:22:45.000Z"
  },
  {
    "id": "ami-0a1b2c3d4e5f60004",
  }
```
To show unhealthy Auto Scaling instances

The following example shows only the InstanceId for any unhealthy instances in the specified Auto Scaling group.

```
$ aws autoscaling describe-auto-scaling-groups \
   --auto-scaling-group-name My-AutoScaling-Group-Name \
   --output text \
   --query 'AutoScalingGroups[*].Instances[?HealthStatus==`Unhealthy`].InstanceId'
```

To include volumes with the specified tag

The following example describes all instances with a test tag. As long as there is another tag beside test attached to the volume, the volume is still returned in the results.

The below expression to return all tags with the test tag in an array. Any tags that are not the test tag contain a null value.

```
$ aws ec2 describe-volumes \
   --query 'Volumes.Tags[?Value == `test`]'
```

To exclude volumes with the specified tag

The following example describes all instances without a test tag. Using a simple `?Value != `test` expression does not work for excluding a volume as volumes can have multiple tags. As long as there is another tag beside test attached to the volume, the volume is still returned in the results.

To exclude all volumes with the test tag, start with the below expression to return all tags with the test tag in an array. Any tags that are not the test tag contain a null value.

```
$ aws ec2 describe-volumes \
   --query 'Volumes.Tags[?Value == `test`]'
Then filter out all the positive test results using the not_null function.

```bash
$ aws ec2 describe-volumes \
  --query 'Volumes[!not_null(Tags[?Value == `test`.Value])]'
```

Pipe the results to flatten out the results resulting in the following query.

```bash
$ aws ec2 describe-volumes \
  --query 'Volumes[!not_null(Tags[?Value == `test`.Value])] | []'
```

### Combining server-side and client-side filtering

You can use server-side and client-side filtering together. Server-side filtering is completed first, which sends the data to the client that the `--query` parameter then filters. If you're using large data sets, using server-side filtering first can lower the amount of data sent to the client for each AWS CLI call, while still keeping the powerful customization that client-side filtering provides.

The following example lists Amazon EC2 volumes using both server-side and client-side filtering. The service filters a list of all attached volumes in the `us-west-2a` Availability Zone. The `--query` parameter further limits the output to only those volumes with a `Size` value that is larger than 50, and shows only the specified fields with user-defined names.

```bash
$ aws ec2 describe-volumes \
  --filters "Name=availability-zone,Values=us-west-2a" "Name=status,Values=attached" \
  --query 'Volumes[?Size > `50`].{Id:VolumeId,Size:Size,Type:VolumeType}'
```

```json
[
  {
    "Id": "vol-0be9bb0bf12345678",
    "Size": 80,
    "VolumeType": "gp2"
  }
]
```

The following example retrieves a list of images that meet several criteria. It then uses the `--query` parameter to sort the output by `CreationDate`, selecting only the most recent. Finally, it displays the `ImageId` of that one image.

```bash
$ aws ec2 describe-images \
  --owners amazon \
  --query 'Images[?CreationDate > `2023-01-01`].{ImageId:image_id}'
```
The following example displays the number of available volumes that are more than 1000 IOPS by using `length` to count how many are in a list.

```bash
$ aws ec2 describe-volumes \
  --filters "Name=status,Values=available" \
  --query 'length(Volumes[?Iops > `1000`)']
3
```

**AWS CLI autoprompt**

When beginning to use filter expressions, you can use the auto-prompt feature in the AWS CLI version 2. The auto-prompt feature provides a preview when you press the **F5** key. For more information, see the section called “Auto-prompt”.

**JMESPath Terminal**

JMESPath Terminal is an interactive terminal command to experiment with JMESPath expressions that are used for client-side filtering. Using the `jpterm` command, the terminal shows immediate query results as you're typing. You can directly pipe AWS CLI output to the terminal, enabling advanced querying experimentation.

The following example pipes `aws ec2 describe-volumes` output directly to JMESPath Terminal.

```bash
$ aws ec2 describe-volumes | jpterm
```

For more information on JMESPath Terminal and installation instructions, see [JMESPath Terminal on GitHub](https://github.com/awslabs/jmespath).  

**jq utility**

The `jq` utility provides you a way to transform your output on the client-side to an output format you desire. For more information on `jq` and installation instructions, see [jq on GitHub](https://github.com/stevanford/jq).
Return codes from the AWS CLI

The return code is usually a hidden code sent after running a AWS Command Line Interface (AWS CLI) command which describes the status of the command. You can use the `echo` command to display the code sent from the last AWS CLI command and use these codes to determine if a command was successful or if it failed, and why a command might have an error. In addition to the return codes, you can view more details about a failure by running your commands with the `--debug` switch. This switch produces a detailed report of the steps the AWS CLI uses to process the command, and what the result of each step was.

To determine the return code of an AWS CLI command, run one of the following commands immediately after running the CLI command.

**Linux and macOS**

```bash
$ echo $?
0
```

**Windows PowerShell**

```powershell
PS> echo $lastexitcode
0
```

**Windows Command Prompt**

```cmd
C:\> echo %errorlevel%
0
```

The following are the return code values that can be returned at the end of running an AWS Command Line Interface (AWS CLI) command.

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The service responded with an HTTP response status code of 200 indicating that there were no errors generated by the AWS CLI and AWS service the request was sent to.</td>
</tr>
<tr>
<td>1</td>
<td>One or more Amazon S3 transfer operations failed. <em>Limited to S3 commands.</em></td>
</tr>
</tbody>
</table>
### Interactive commands using the AWS CLI wizards

The AWS Command Line Interface (AWS CLI) provides the ability to use a wizard for some commands. To contribute or view the full list of available AWS CLI wizards, see the [AWS CLI wizards folder](https://github.com/aws/aws-cli) on GitHub.
How it works

Similar to the AWS console, the AWS CLI has a UI wizard that guides you through managing your AWS resources. To use the wizard, you call the `wizard` subcommand and the wizard name after the service name in a command. The command structure is as follows:

**Syntax:**

```
$ aws <command> wizard <wizardName>
```

The following example is calling the wizard to create a new dynamodb table.

```
$ aws dynamodb wizard new-table
```

`aws configure` is the only wizard that does not have a wizard name. When running the wizard, run the `aws configure wizard` command as the following example demonstrates:

```
$ aws configure wizard
```

After calling a wizard, a form in the shell is displayed. For each parameter, you are either provided a list of options to select from or prompted to enter in a string. To select from a list, use your up and down arrow keys and press **ENTER**. To view details on an option, press the right arrow key. When you've finished filling out a parameter, press **ENTER**.

```
$ aws configure wizard
What would you like to configure
> Static Credentials
    Assume Role
    Process Provider
    Additional CLI configuration
Enter the name of the profile:
Enter your Access Key Id:
Enter your Secret Access Key:
```

To edit previous prompts, use **SHIFT + TAB**. For some wizards, after filling in all prompts, you can preview an AWS CloudFormation template or the AWS CLI command filled with your information. This preview mode is useful to learn the AWS CLI, service APIs, and creating templates for scripts.

Press **ENTER** after previewing or the last prompt to run the final command.
$ aws configure wizard
What would you like to configure
Enter the name of the profile: testWizard
Enter your Access Key Id: AB1C2D3EF46H5I678J90K
Enter your Secret Access Key: ab1c2def34gh5i67j8k90l1mnop2qr3s45tu678v90
<ENTER>

Create and use AWS CLI command shortcuts called aliases

Aliases are shortcuts you can create in the AWS Command Line Interface (AWS CLI) to shorten commands or scripts that you frequently use. You create aliases in the alias file located in your configuration folder.

Topics

• Prerequisites
• Step 1: Creating the alias file
• Step 2: Creating an alias
• Step 3: Calling an alias
• Alias repository examples
• Resources

Prerequisites

To use alias commands, you need to complete the following:

• Install and configure the AWS CLI. For more information, see the section called “Install/Update” and Authentication and access credentials.
• Use a minimum AWS CLI version of 1.11.24 or 2.0.0.
• (Optional) To use AWS CLI alias bash scripts, you must use a bash-compatible terminal.

Step 1: Creating the alias file

To create the alias file, you can use your file navigation and a text editor, or use your preferred terminal by using the step-by-step procedure. To quickly create your alias file, use the following command block.
Linux and macOS

```bash
$ mkdir -p ~/.aws/cli
$ echo '[toplevel]' > ~/.aws/cli/alias
```

Windows

```bash
C:\> md %USERPROFILE%\.aws\cli
C:\> echo [toplevel] > %USERPROFILE%\.aws\cli/alias
```

**To create the alias file**

1. Create a folder named `cli` in your AWS CLI configuration folder. By default the configuration folder is `~/.aws/` on Linux or macOS and `%USERPROFILE%\aws\` on Windows. You can create this through your file navigation or by using the following command.

   **Linux and macOS**

   ```bash
   $ mkdir -p ~/.aws/cli
   ```

   **Windows**

   ```bash
   C:\> md %USERPROFILE%\.aws\cli
   ```

   The resulting `cli` folder default path is `~/.aws/cli/` on Linux or macOS and `%USERPROFILE%\aws\cli` on Windows.

2. In the `cli` folder, create a text file named `alias` with no extension and add `[toplevel]` to the first line. You can create this file through your preferred text editor or use the following command.

   **Linux and macOS**

   ```bash
   $ echo '[toplevel]' > ~/.aws/cli/alias
   ```

   **Windows**

   ```bash
   C:\> echo [toplevel] > %USERPROFILE%\.aws\cli/alias
   ```
Step 2: Creating an alias

You can create an alias using basic commands or bash scripting.

Creating a basic command alias

You can create your alias by adding a command using the following syntax in the alias file you created in the previous step.

Syntax

```
aliasname = command [--options]
```

The `aliasname` is what you call your alias. The `command` is the command you want to call, which can include other aliases. You can include options or parameters in your alias, or add them when calling your alias.

The following example creates an alias named `aws whoami` using the `aws sts get-caller-identity` command. Since this alias calls an existing AWS CLI command, you can write the command without the `aws` prefix.

```
whoami = sts get-caller-identity
```

The following example takes the previous `whoami` example and adds the `Account` filter and text output options.

```
whoami2 = sts get-caller-identity --query Account --output text
```

Creating a sub-command alias

**Note**

The sub-command alias feature requires a minimum AWS CLI version of 1.11.24 or 2.0.0

You can create an alias for sub-commands by adding a command using the following syntax in the alias file you created in the previous step.

Syntax
The `commandGroup` is the command namespace, e.g. The command `aws ec2 describe-regions` is under the `ec2` command group. The `aliasname` is what you call your alias. The `command` is the command you want to call, which can include other aliases. You can include options or parameters in your alias, or add them when calling your alias.

The following example creates an alias named `aws ec2 regions` using the `aws ec2 describe-regions` command. Since this alias calls an existing AWS CLI command under the `ec2` command namespace, you can write the command without the `aws ec2` prefix.

```
[command ec2]
regions = describe-regions --query Regions[].RegionName
```

To create aliases from commands outside of the command namespace, prefix the full command with an exclamation mark. The following example creates an alias named `aws ec2 instance-profiles` using the `aws iam list-instance-profiles` command.

```
[command ec2]
instance-profiles = !aws iam list-instance-profiles
```

⚠️ **Note**

Aliases only use existing command namespaces and you cannot create new ones. e.g. You can't create an alias with the `[command johnsmith]` section as the johnsmith command namespace does not already exist.

## Creating a bash scripting alias

⚠️ **Warning**

To use AWS CLI alias bash scripts, you must use a bash-compatible terminal

You can create an alias using bash scripts for more advanced processes using the following syntax.
Syntax

```
aliasname =
  !f() {
    script content
  }; f
```

The `aliasname` is what you call your alias and `script content` is the script you want to run when you call the alias.

The following example uses opendns to output your current IP address. Since you can use aliases in other aliases, the following `myip` alias is useful to allow or revoke access for your IP address from within other aliases.

```
myip =
  !f() {
    dig +short myip.opendns.com @resolver1.opendns.com
  }; f
```

The following script example calls the previous `aws myip` alias to authorize your IP address for an Amazon EC2 security group ingress.

```
authorize-my-ip =
  !f() {
    ip=$(aws myip)
    aws ec2 authorize-security-group-ingress --group-id ${1} --cidr $ip/32 --protocol tcp --port 22
  }; f
```

When you call aliases that use bash scripting, the variables are always passed in the order that you entered them. In bash scripting, the variable names are not taken into consideration, only the order they appear. In the following `textalert` alias example, the variable for the `--message` option is first and `--phone-number` option is second.

```
textalert =
  !f() {
    aws sns publish --message "${1}" --phone-number ${2}
  }; f
```
Step 3: Calling an alias

To run the alias you created in your alias file use the following syntax. You can add additional options when you call your alias.

Syntax

```
$ aws aliasname
```

The following example uses the `aws whoami` command alias.

```
$ aws whoami
{"UserId": "A12BCD34E5FGHI6JKLM",
 "Account": "1234567890987",
 "Arn": "arn:aws:iam::1234567890987:user/username"
}
```

The following example uses the `aws whoami` alias with additional options to only return the Account number in text output.

```
$ aws whoami --query Account --output text
1234567890987
```

The following example uses the `aws ec2 regions` sub-command alias.

```
$ aws ec2 regions
["ap-south-1",
 "eu-north-1",
 "eu-west-3",
 "eu-west-2",
 ...]
```

Calling an alias using bash scripting variables

When you call aliases that use bash scripting, variables are passed in the order they are entered. In bash scripting, the name of the variables are not taken into consideration, only the order they
appear. For example, in the following `textalert` alias, the variable for the option `--message` is first and `--phone-number` is second.

```
textalert =
  !f() {
    aws sns publish --message "${1}" --phone-number ${2}
  }; f
```

When you call the `textalert` alias, you need to pass variables in the same order as they are run in the alias. In the following example we use the variables `$message` and `$phone`. The `$message` variable is passed as `${1}` for the `--message` option and the `$phone` variable is passed as `${2}` for the `--phone-number` option. This results in successfully calling the `textalert` alias to send a message.

```
$ aws textalert $message
   $phone
   {
     "MessageId": "1ab2cd3e4-fg56-7h89-i01j-2klmn34567"
   }
```

In the following example, the order is switched when calling the alias to `$phone` and `$message`. The `$phone` variable is passed as `${1}` for the `--message` option and the `$message` variable is passed as `${2}` for the `--phone-number` option. Since the variables are out of order, the alias passes the variables incorrectly. This causes an error because the contents of `$message` do not match the phone number formatting requirements for the `--phone-number` option.

```
$ aws textalert $phone
   $message
   usage: aws [options] <command> <subcommand> [<subcommand> ...] [parameters]
To see help text, you can run:

   aws help
   aws <command> help
   aws <command> <subcommand> help

Alias repository examples

The AWS CLI alias repository on GitHub contains AWS CLI alias examples created by the AWS CLI developer team and community. You can use the entire alias file example or take individual aliases for your own use.

⚠️ Warning

Running the commands in this section deletes your existing alias file. To avoid overwriting your existing alias file, change your download location.

To use aliases from the repository

1. Install Git. For installation instructions, see Getting Started - Installing Git in the Git Documentation.

2. Install the jp command. The jp command is used in the tostring alias. For installation instructions, see the JMESPath (jp) README.md on GitHub.

3. Install the jq command. The jq command is used in the tostring-with-jq alias. For installation instructions, see the JSON processor (jq) on GitHub.

4. Download the alias file by doing one of the following:

   - Run the following commands that downloads from the repository and copies the alias file to your configuration folder.

     Linux and macOS

     ```
     $ git clone https://github.com/awslabs/awscli-aliases.git
     $ mkdir -p ~/.aws/cli
     $ cp awscli-aliases/alias ~/.aws/cli/alias
     ```

     Windows

     ```
     C:\> git clone https://github.com/awslabs/awscli-aliases.git
     C:\> md %USERPROFILE%\aws\cli
     C:\> copy awscli-aliases\alias %USERPROFILE%\aws\cli
     ```
• Download directly from the repository and save to the cli folder in your AWS CLI configuration folder. By default the configuration folder is ~/.aws/ on Linux or macOS and %USERPROFILE%\aws\ on Windows.

5. To verify the aliases are working, run the following alias.

```
$ aws whoami
```

This displays the same response as the `aws sts get-caller-identity` command:

```
{
    "Account": "012345678901",
    "UserId": "AIUAINBADX2VEG2TC6HD6",
    "Arn": "arn:aws:iam::012345678901:user/myuser"
}
```

Code examples

This chapter provides a collection of examples that show you how to use the AWS Command Line Interface (AWS CLI) with AWS services.

The AWS CLI has the following types of examples in this guide:

- **Guided command examples** - Guided command examples for the AWS CLI User Guide on how to use the AWS CLI with some AWS services. These are often more detailed examples than the examples from the AWS CLI version 2 reference guide.

- **AWS CLI command examples** - Open source command examples that are also available in the AWS CLI version 2 reference guide. Command examples are hosted in the AWS CLI repository on GitHub.

- **AWS CLI using Bash scripting code examples** - Open source bash scripting examples. Bash scripting examples are hosted in the AWS Code Examples Repository on GitHub.

Use Amazon DynamoDB with the AWS CLI

An introduction to Amazon DynamoDB

What is Amazon DynamoDB?

The AWS Command Line Interface (AWS CLI) provides support for all of the AWS database services, including Amazon DynamoDB. You can use the AWS CLI for impromptu operations, such as creating a table. You can also use it to embed DynamoDB operations within utility scripts.

For more information about using the AWS CLI with DynamoDB, see `dynamodb` in the `AWS CLI Command Reference`.

To list the AWS CLI commands for DynamoDB, use the following command.

```
$ aws dynamodb help
```

Topics

- Prerequisites
- Creating and using DynamoDB tables
- Using DynamoDB Local
- Resources

Prerequisites

To run the dynamodb commands, you need to:
• Install and configure the AWS CLI. For more information, see the section called “Install/Update” and Authentication and access credentials.

Creating and using DynamoDB tables

The command line format consists of a DynamoDB command name, followed by the parameters for that command. The AWS CLI supports the CLI shorthand syntax for the parameter values, and full JSON.

The following example creates a table named MusicCollection.

```
$ aws dynamodb create-table \
   --table-name MusicCollection \
   --attribute-definitions AttributeName=Artist,AttributeType=S 
   AttributeName=SongTitle,AttributeType=S \
   --key-schema AttributeName=Artist,KeyType=HASH 
   AttributeName=SongTitle,KeyType=RANGE \
   --provisioned-throughput ReadCapacityUnits=1,WriteCapacityUnits=1
```

You can add new lines to the table with commands similar to those shown in the following example. These examples use a combination of shorthand syntax and JSON.

```
$ aws dynamodb put-item \
   --table-name MusicCollection \
   --item '{
       "Artist": {"S": "No One You Know"},
       "SongTitle": {"S": "Call Me Today"},
       "AlbumTitle": {"S": "Somewhat Famous"}
   }' \
   --return-consumed-capacity TOTAL
{
   "ConsumedCapacity": {
       "CapacityUnits": 1.0,
       "TableName": "MusicCollection"
   }
}
```

```
$ aws dynamodb put-item \
   --table-name MusicCollection \
   --item '{
```
It can be difficult to compose valid JSON in a single-line command. To make this easier, the AWS CLI can read JSON files. For example, consider the following JSON snippet, which is stored in a file named `expression-attributes.json`.

```
{
  "v1": {"S": "No One You Know"},
  "v2": {"S": "Call Me Today"}
}
```

You can use that file to issue a query request using the AWS CLI. In the following example, the content of the `expression-attributes.json` file is used as the value for the `--expression-attribute-values` parameter.

```
$ aws dynamodb query --table-name MusicCollection \
  --key-condition-expression "Artist = :v1 AND SongTitle = :v2" \
  --expression-attribute-values file://expression-attributes.json
```

```
{
  "Count": 1,
  "Items": [
    {
      "AlbumTitle": {
        "S": "Somewhat Famous"
      },
      "SongTitle": {
        "S": "Call Me Today"
      },
      "Artist": {
        "S": "No One You Know"
      }
    }
  ]
}
```
Using DynamoDB Local

In addition to DynamoDB, you can use the AWS CLI with DynamoDB Local. DynamoDB Local is a small client-side database and server that mimics the DynamoDB service. DynamoDB Local enables you to write applications that use the DynamoDB API, without manipulating any tables or data in the DynamoDB web service. Instead, all of the API actions are rerouted to a local database. This lets you save on provisioned throughput, data storage, and data transfer fees.

For more information about DynamoDB Local and how to use it with the AWS CLI, see the following sections of the Amazon DynamoDB Developer Guide:

- DynamoDB Local
- Using the AWS CLI with DynamoDB Local

Use Amazon EC2 with the AWS CLI

An introduction to Amazon Elastic Compute Cloud

Introduction to Amazon EC2 - Elastic Cloud Server and Hosting with AWS

You can access the features of Amazon Elastic Compute Cloud (Amazon EC2) using the AWS Command Line Interface (AWS CLI). To list the AWS CLI commands for Amazon EC2, use the following command.

```bash
aws ec2 help
```

Before you run any commands, set your default credentials. For more information, see Configure the AWS CLI.

This topic shows short-form examples of AWS CLI commands that perform common tasks for Amazon EC2.

For long-form examples of AWS CLI commands, see AWS CLI code examples repository on GitHub.

Topics

- Create, display, and delete Amazon EC2 key pairs
- Create, configure, and delete security groups for Amazon EC2
- Launch, list, and terminate Amazon EC2 instances
- Change an Amazon EC2 instance type with a bash script

Create, display, and delete Amazon EC2 key pairs

You can use the AWS Command Line Interface (AWS CLI) to create, display, and delete your key pairs for Amazon Elastic Compute Cloud (Amazon EC2). You use key pairs to connect to an Amazon EC2 instance.

You must provide the key pair to Amazon EC2 when you create the instance, and then use that key pair to authenticate when you connect to the instance.
Prerequisites

To run the `ec2` commands, you need to:

- Install and configure the AWS CLI. For more information, see the section called "Install/Update" and Authentication and access credentials.
- Set your IAM permissions to allow for Amazon EC2 access. For more information about IAM permissions for Amazon EC2, see IAM policies for Amazon EC2 in the Amazon EC2 User Guide for Linux Instances.

Create a key pair

To create a key pair, use the `aws ec2 create-key-pair` command with the --query option, and the --output text option to pipe your private key directly into a file.

```
$ aws ec2 create-key-pair --key-name MyKeyPair --query 'KeyMaterial' --output text
> MyKeyPair.pem
```

For PowerShell, the > file redirection defaults to UTF-8 encoding, which cannot be used with some SSH clients. So, you must convert the output by piping it to the out-file command and explicitly set the encoding to ascii.

```
PS C:\>aws ec2 create-key-pair --key-name MyKeyPair --query 'KeyMaterial' --output text
| out-file -encoding ascii -filepath MyKeyPair.pem
```
The resulting `MyKeyPair.pem` file looks similar to the following.

```
-----BEGIN RSA PRIVATE KEY-----
EXAMPLEKEYCQAEEAy7W7haDs1rW3mRlQtvhwORRX8nxgDAfRt/gx42kWXsT4rXE/b5CpSgie/vBoU7jLxXz2pNH0FbPyP+Dc21eyyy6CvjTmWA0JwFwiWi5/akH7i05dSrC7d0kW2dUV5QuUdE0QWZ/aNmxN1qG6vXAgfwlXvBw2r0rq+ZWQqeiUwmmrEeLeJFHMcYUrPumSCL0ehm4491lx9X1F5G0TCFe0zf18dqCP6GzbPaijiU19xY/azOR9V+tpU0zEL+wmxNzT3/nHPQ5xyd20JH67km6suPWopzev/D8V+x4+bhtfs5j9Y7YvDqjFbWvHxqBdztC2U/we18D/HYwIDAQABoIBAGZ1kaEvnrqu/uler7vgln57nLk4hJLAIw6tUT/fzvtcHK0skbCQXuniHm2MQyJX/0kn2nfJLV/ufGxbL1mb5qwMGUnEpjaZD6Q5ss3K1ClwWUYUiGfc0u15mJoap/GTLU0WS5fcv36PaBUNy5p53V6G7hXb2baxyWyJNfjeLe4M8y62yK3VZcmK+x/BOsShnJ36+hjxXPPWmV3N9zEmCdjjA+k15DYmhm/tJWSD9B10eGl9T0pEp7CkIfatEATyyZiVqoRgk64iuM9JkA30zdXrMqexVXJ1TLZVEH0E7bh1Y9d01ozR0qs/FIZNA2iijCwv0ipje73+kCgYEA9mZtyhkHkDpwrS1MAPla80NAbbjwey7Z5Mqf1+1ip1YkrlL0DbLx1vRAH+yHPRit2hH0jtnUJzh4Axv+cpq09bU1j+343eEy24B7G/Uh+GTfjbsXs0Qx/xp9otyWw7hsQ7A5PzB+mvkJ30BEKzet9XcKw0NBvELGhnEpe7cCgYEA06Vgov6YHe1Hu9kHwsayav0c5zixjF9nFHF3ry21R1trw2Vdpn+9q48I1Urzp2WVOEihvm+xtTmaZ1sp//lKq75XDwnUWA8ogn603QGf3Fq2y9h98BRsAKdJfJ5Rl1HoGqvTe10HLYYRpJnEkHu+un12ajL1LwUt5pBzRzKbUCgYbjo0+Ozk0scCzz29szbBjyipdDery5yR5xgV2uNwajLdp9FpN295yQ+BxMBX1YcWVQiw0bHmo7yykABY70zdzQwBq4A4sWSX4nGdtsiFxwi5sKvAAeoCbtosy1s8w8fxoJ57z1sdoxNeGsArg6Ww/G16zQuAe929yvkwkBfG+09yI/1wJbirsDz9ghWvFFPrTkJNvJzYt69Qezx1jsjrgKshyWBhd4xHztmCqBPLAYmEjr/T01bxyA1MxMnIOAWAnNXMGB4KGSyIlmz5VAcq+qFq+rC3j0dyp1ljjjb0ED/NY8f11NdxAVHE8BSksdx2F6GELvEYBkJ3Sr9snRaoGAM2TwYenYxzvTsk/S5Fyu010egLDaNWUH38v/nDCgEp1XD5H3n3AECjulIjmbwlvtW+nY2jvhv7UGd8MjwUTNGItdb6nsYqM2arinF3q5VRKAKKYYGzkUpUFvT1XWOFyjXfcrz/V+QFL50ndHAKJXjw7a4ejJLncTzmZSpYzAwPc=
-----END RSA PRIVATE KEY-----
```

Your private key isn't stored in AWS and can be retrieved only when it's created. You can't recover it later. Instead, if you lose the private key, you must create a new key pair.

If you're connecting to your instance from a Linux computer, we recommend that you use the following command to set the permissions of your private key file so that only you can read it.

```
$ chmod 400 MyKeyPair.pem
```

### Display your key pair

A "fingerprint" is generated from your key pair, and you can use it to verify that the private key that you have on your local machine matches the public key that's stored in AWS.

The fingerprint is an SHA1 hash taken from a DER-encoded copy of the private key. This value is captured when the key pair is created, and is stored in AWS with the public key. You can view the
fingerprint in the Amazon EC2 console or by running the AWS CLI command `aws ec2 describe-key-pairs`.

The following example displays the fingerprint for `MyKeyPair`.

```
$ aws ec2 describe-key-pairs --key-name MyKeyPair
{
  "KeyPairs": [
    {
      "KeyName": "MyKeyPair",
    }
  ]
}
```

For more information about keys and fingerprints, see [Amazon EC2 Key Pairs](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/EC2.keys.html) in the *Amazon EC2 User Guide for Linux Instances*.

**Delete your key pair**

To delete a key pair, run the `aws ec2 delete-key-pair` command, substituting `MyKeyPair` with the name of the pair to delete.

```
$ aws ec2 delete-key-pair --key-name MyKeyPair
```

Create, configure, and delete security groups for Amazon EC2

You can create a security group for your Amazon Elastic Compute Cloud (Amazon EC2) instances that essentially operates as a firewall, with rules that determine what network traffic can enter and leave.

Use the AWS Command Line Interface (AWS CLI) to create a security group, add rules to existing security groups, and delete security groups.

⚠️ Note
For additional command examples, see the AWS CLI reference guide.

Topics
- Prerequisites
- Create a security group
- Add rules to your security group
- Delete your security group
- References

Prerequisites

To run the ec2 commands, you need to:

- Install and configure the AWS CLI. For more information, see the section called “Install/Update” and Authentication and access credentials.
- Set your IAM permissions to allow for Amazon EC2 access. For more information about IAM permissions for Amazon EC2, see IAM policies for Amazon EC2 in the Amazon EC2 User Guide for Linux Instances.

Create a security group

You can create security groups associated with virtual private clouds (VPCs).

The following aws_ec2_create-security-group example shows how to create a security group for a specified VPC.
$ aws ec2 create-security-group --group-name my-sg --description "My security group" --vpc-id vpc-1a2b3c4d
{
    "GroupId": "sg-903004f8"
}

To view the initial information for a security group, run the `aws ec2 describe-security-groups` command. You can reference an EC2-VPC security group only by its `vpc-id`, not its name.

$ aws ec2 describe-security-groups --group-ids sg-903004f8
{
    "SecurityGroups": [
        {
            "IpPermissionsEgress": [
                {
                    "IpProtocol": ":-1",
                    "IpRanges": [
                        {
                            "CidrIp": "0.0.0.0/0"
                        }
                    ],
                    "UserIdGroupPairs": []
                }
            ],
            "Description": "My security group"
        }
    ],
    "OwnerId": "123456789012",
    "GroupId": "sg-903004f8"
}

Add rules to your security group

When you run an Amazon EC2 instance, you must enable rules in the security group to allow incoming network traffic for your means of connecting to the image.

For example, if you're launching a Windows instance, you typically add a rule to allow inbound traffic on TCP port 3389 to support Remote Desktop Protocol (RDP). If you're launching a
Linux instance, you typically add a rule to allow inbound traffic on TCP port 22 to support SSH connections.

Use the `aws ec2 authorize-security-group-ingress` command to add a rule to your security group. A required parameter of this command is the public IP address of your computer, or the network (in the form of an address range) that your computer is attached to, in CIDR notation.

Note

We provide the following service, https://checkip.amazonaws.com/, to enable you to determine your public IP address. To find other services that can help you identify your IP address, use your browser to search for "what is my IP address". If you connect through an ISP or from behind your firewall using a dynamic IP address (through a NAT gateway from a private network), your address can change periodically. In that case, you must find out the range of IP addresses used by client computers.

The following example shows how to add a rule for RDP (TCP port 3389) to an EC2-VPC security group with the ID `sg-903004f8` using your IP address.

To start, find your IP address.

```shell
$ curl https://checkip.amazonaws.com
x.x.x.x
```

You can then add the IP address to your security group by running the `aws ec2 authorize-security-group-ingress` command.

```shell
$ aws ec2 authorize-security-group-ingress --group-id sg-903004f8 --protocol tcp --port 3389 --cidr x.x.x.x/x
```

The following command adds another rule to enable SSH to instances in the same security group.

```shell
$ aws ec2 authorize-security-group-ingress --group-id sg-903004f8 --protocol tcp --port 22 --cidr x.x.x.x/x
```

To view the changes to the security group, run the `aws ec2 describe-security-groups` command.

```shell
$ aws ec2 describe-security-groups --group-ids sg-903004f8
```
Delete your security group

To delete a security group, run the `aws ec2 delete-security-group` command.

⚠️ Note

You can't delete a security group if it's currently attached to an environment.
The following command example deletes an EC2-VPC security group.

```
$ aws ec2 delete-security-group --group-id sg-903004f8
```

**Launch, list, and terminate Amazon EC2 instances**

You can use the AWS Command Line Interface (AWS CLI) to launch, list, and terminate Amazon Elastic Compute Cloud (Amazon EC2) instances. If you launch an instance that isn't within the AWS Free Tier, you are billed after you launch the instance and charged for the time that the instance is running, even if it remains idle.

⚠ **Note**

For additional command examples, see the [AWS CLI reference guide](#).

Prerequisites

To run the ec2 commands in this topic, you need to:

- Install and configure the AWS CLI. For more information, see the section called “Install/Update” and Authentication and access credentials.
- Set your IAM permissions to allow for Amazon EC2 access. For more information about IAM permissions for Amazon EC2, see IAM policies for Amazon EC2 in the Amazon EC2 User Guide for Linux Instances.
- Create a key pair and a security group.
- Select an Amazon Machine Image (AMI) and note the AMI ID. For more information, see Finding a Suitable AMI in the Amazon EC2 User Guide for Linux Instances.

Launch your instance

To launch an Amazon EC2 instance using the AMI you selected, use the aws ec2 run-instances command. You can launch the instance into a virtual private cloud (VPC).

Initially, your instance appears in the pending state, but changes to the running state after a few minutes.

The following example shows how to launch a t2.micro instance in the specified subnet of a VPC. Replace the italicized parameter values with your own.

```bash
$ aws ec2 run-instances --image-id ami-xxxxxxxx --count 1 --instance-type t2.micro --key-name MyKeyPair --security-group-ids sg-903004f8 --subnet-id subnet-6e7f829e

Add a block device to your instance

Each instance that you launch has an associated root device volume. You can use block device mapping to specify additional Amazon Elastic Block Store (Amazon EBS) volumes or instance store volumes to attach to an instance when it's launched.

To add a block device to your instance, specify the `--block-device-mappings` option when you use `run-instances`.

The following example parameter provisions a standard Amazon EBS volume that is 20 GB in size, and maps it to your instance using the identifier `/dev/sdf`.

```
--block-device-mappings "[{{"DeviceName":"/dev/sdf","Ebs":{"VolumeSize":20,"DeleteOnTermination":false}}]"
```

The following example adds an Amazon EBS volume, mapped to `/dev/sdf`, based on an existing snapshot. A snapshot represents an image that is loaded onto the volume for you. When you specify a snapshot, you don't have to specify a volume size; it will be large enough to hold your image. However, if you do specify a size, it must be greater than or equal to the size of the snapshot.

```
--block-device-mappings "[{{"DeviceName":"/dev/sdf","Ebs":{"SnapshotId":"snap-a1b2c3d4"}}]"
```

The following example adds two volumes to your instance. The number of volumes available to your instance depends on its instance type.
--block-device-mappings "[{
  "DeviceName": "/dev/sdf",
  "VirtualName": "ephemeral0"
},
  {
  "DeviceName": "/dev/sdg",
  "VirtualName": "ephemeral1"
}]

The following example creates the mapping (/dev/sdj), but doesn't provision a volume for the instance.

--block-device-mappings "[{
  "DeviceName": "/dev/sdj",
  "NoDevice": ""
}]

For more information, see Block Device Mapping in the Amazon EC2 User Guide for Linux Instances.

Add a tag to your instance

A tag is a label that you assign to an AWS resource. It enables you to add metadata to your resources that you can use for a variety of purposes. For more information, see Tagging Your Resources in the Amazon EC2 User Guide for Linux Instances.

The following example shows how to add a tag with the key name "Name" and the value "MyInstance" to the specified instance, by using the aws ec2 create-tags command.

$ aws ec2 create-tags --resources i-5203422c --tags Key=Name,Value=MyInstance

Connect to your instance

When your instance is running, you can connect to it and use it just as you'd use a computer sitting in front of you. For more information, see Connect to Your Amazon EC2 Instance in the Amazon EC2 User Guide for Linux Instances.

List your instances

You can use the AWS CLI to list your instances and view information about them. You can list all your instances, or filter the results based on the instances that you're interested in.

The following examples show how to use the aws ec2 describe-instances command.

The following command lists all your instances.

$ aws ec2 describe-instances

The following command filters the list to only your t2.micro instances and outputs only the InstanceId values for each match.
The following command lists any of your instances that have the tag Name=MyInstance.

$ aws ec2 describe-instances --filters "Name=tag:Name,Values=MyInstance"

The following command lists your instances that were launched using any of the following AMIs: ami-x0123456, ami-y0123456, and ami-z0123456.

$ aws ec2 describe-instances --filters "Name=image-id,Values=ami-x0123456,ami-y0123456,ami-z0123456"

**Terminate your instance**

Terminating an instance deletes it. You can't reconnect to an instance after you've terminated it.

As soon as the state of the instance changes to shutting-down or terminated, you stop incurring charges for that instance. If you want to reconnect to an instance later, use `stop-instances` instead of `terminate-instances`. For more information, see [Terminate Your Instance](#) in the *Amazon EC2 User Guide for Linux Instances*.

To delete an instance, you use the command `aws ec2 terminate-instances` to delete it.

$ aws ec2 terminate-instances --instance-ids i-5203422c

{ "TerminatingInstances": [ { "InstanceId": "i-5203422c", "CurrentState": { "Code": 32, "Name": "shutting-down" }, "PreviousState": { "Code": 16, "Name": "running" } } ] }

Change an Amazon EC2 instance type with a bash script

This bash scripting example for Amazon EC2 changes the instance type for an Amazon EC2 instance using the AWS Command Line Interface (AWS CLI). It stops the instance if it's running, changes the instance type, and then, if requested, restarts the instance. Shell scripts are programs designed to run in a command line interface.

ℹ️ Note

For additional command examples, see the [AWS CLI reference guide](https://docs.aws.amazon.com/cli/latest/index.html).

Before you start

Before you can run any of the below examples, the following things need to be completed.

- Install and configure the AWS CLI. For more information, see the section called “Install/Update” and Authentication and access credentials.
- The profile that you use must have permissions that allow the AWS operations performed by the examples.
- A running Amazon EC2 instance in the account for which you have permission to stop and modify. If you run the test script, it launches an instance for you, tests changing the type, and then terminates the instance.
- As an AWS best practice, grant this code least privilege, or only the permissions required to perform a task. For more information, see Grant Least Privilege in the AWS Identity and Access Management (IAM) User Guide.
- This code has not been tested in all AWS Regions. Some AWS services are available only in specific Regions. For more information, see Service Endpoints and Quotas in the AWS General Reference Guide.
- Running this code can result in charges to your AWS account. It is your responsibility to ensure that any resources created by this script are removed when you are done with them.

About this example

This example is written as a function in the shell script file change_ec2_instance_type.sh that you can source from another script or from the command line. Each script file contains comments describing each of the functions. Once the function is in memory, you can invoke it from the command line. For example, the following commands change the type of the specified instance to t2.nano:

```
$ source ./change_ec2_instance_type.sh
$ ./change_ec2_instance_type -i *instance-id* -t new-type
```

For the full example and downloadable script files, see Change Amazon EC2 Instance Type in the AWS Code Examples Repository on GitHub.
Parameters

-i - (string) Specifies the instance ID to modify.

-t - (string) Specifies the Amazon EC2 instance type to switch to.

-r - (switch) By default, this is unset. If -r is set, restarts the instance after the type switch.

-f - (switch) By default, the script prompts the user to confirm shutting down the instance before making the switch. If -f is set, the function doesn't prompt the user before shutting down the instance to make the type switch

-v - (switch) By default, the script operates silently and displays output only in the event of an error. If -v is set, the function displays status throughout its operation.

Files

cchange_ec2_instance_type.sh

The main script file contains the change_ec2_instance_type() function that performs the following tasks:

- Verifies that the specified Amazon EC2 instance exists.
- Unless -f is selected, warns the user before stopping the instance.
- Changes the instance type
- If you set -r, restarts the instance and confirms that the instance is running

View the code for change_ec2_instance_type.sh on GitHub.

test_change_ec2_instance_type.sh

The file test_change_ec2_instance_type.sh script tests the various code paths for the change_ec2_instance_type function. If all steps in the test script work correctly, the test script removes all resources that it created.

You can run the test script with the following parameters:

- -v - (switch) The each test shows a pass/failure status as they run. By default, the tests runs silently and the output includes only the final overall pass/failure status.
- -i - (switch) The script pauses after each test to enable you to browse the intermediate results of each step. Enables you to examine the current status of the instance using the Amazon EC2 console. The script proceeds to the next step after you press ENTER at the prompt.
View the code for `test_change_ec2_instance_type.sh` on GitHub.

`awsdoks_general.sh`

The script file `awsdoks_general.sh` holds general purpose functions used across advanced examples for the AWS CLI.

Use Amazon S3 Glacier with the AWS CLI

An introduction to Amazon S3 Glacier

Introduction to Amazon S3 Glacier
This topic shows examples of AWS CLI commands that perform common tasks for S3 Glacier. The examples demonstrate how to use the AWS CLI to upload a large file to S3 Glacier by splitting it into smaller parts and uploading them from the command line.

You can access Amazon S3 Glacier features using the AWS Command Line Interface (AWS CLI). To list the AWS CLI commands for S3 Glacier, use the following command.

```
aws glacier help
```

**Note**

For command reference and additional examples, see `aws glacier` in the *AWS CLI Command Reference*.

### Topics

- [Prerequisites](#)
- [Create an Amazon S3 Glacier vault](#)
- [Prepare a file for uploading](#)
- [Initiate a multipart upload and upload files](#)
- [Complete the upload](#)
- [Resources](#)

### Prerequisites

To run the `glacier` commands, you need to:

- Install and configure the AWS CLI. For more information, see the section called “Install/Update” and *Authentication and access credentials*.
- This tutorial uses several command line tools that typically come preinstalled on Unix-like operating systems, including Linux and macOS. Windows users can use the same tools by installing [Cygwin](https://cygwin.com) and running the commands from the Cygwin terminal. We note Windows native commands and utilities that perform the same functions where available.
Create an Amazon S3 Glacier vault

Create a vault with the `create-vault` command.

```bash
$ aws glacier create-vault --account-id - --vault-name myvault
{
    "location": "/123456789012/vaults/myvault"
}
```

ℹ️ Note

All S3 Glacier commands require an account ID parameter. Use the hyphen character (`--account-id -`) to use the current account.

Prepare a file for uploading

Create a file for the test upload. The following commands create a file named `largefile` that contains exactly 3 MiB of random data.

Linux or macOS

```bash
$ dd if=/dev/urandom of=largefile bs=3145728 count=1
1+0 records in
1+0 records out
3145728 bytes (3.1 MB) copied, 0.205813 s, 15.3 MB/s
```

`dd` is a utility that copies a number of bytes from an input file to an output file. The previous example uses the system device file `/dev/urandom` as a source of random data. `fsutil` performs a similar function in Windows.

Windows

```
C:\> fsutil file createnew largefile 3145728
File C:\temp\largefile is created
```

Next, split the file into 1 MiB (1,048,576 byte) chunks.

```bash
$ split -b 1048576 --verbose largefile chunk
```
creating file `chunkaa'
creating file `chunkab'
creating file `chunkac'

**Note**

HJ-Split is a free file splitter for Windows and many other platforms.

### Initiate a multipart upload and upload files

Create a multipart upload in Amazon S3 Glacier by using the `initiate-multipart-upload` command.

```
$ aws glacier initiate-multipart-upload --account-id - --archive-description "multipart upload test" --part-size 1048576 --vault-name myvault
{
  "uploadId": "19gaRezEXAMPLES6Ry5YYdqthHOC_kGRCT03L9yetr220UmPtBYKk-OssZtLqyFu7sY1_1R7vgFuJV6NtcV5zpsJ",
  "location": "/123456789012/vaults/myvault/multipart-uploads/19gaRezEXAMPLES6Ry5YYdqthHOC_kGRCT03L9yetr220UmPtBYKk-OssZtLqyFu7sY1_1R7vgFuJV6NtcV5zpsJ"
}
```

S3 Glacier requires the size of each part in bytes (1 MiB in this example), your vault name, and an account ID to configure the multipart upload. The AWS CLI outputs an upload ID when the operation is complete. Save the upload ID to a shell variable for later use.

**Linux or macOS**

```
$ UPLOADID="19gaRezEXAMPLES6Ry5YYdqthHOC_kGRCT03L9yetr220UmPtBYKk-OssZtLqyFu7sY1_1R7vgFuJV6NtcV5zpsJ"
```

**Windows**

```
C:\> set UPLOADID="19gaRezEXAMPLES6Ry5YYdqthHOC_kGRCT03L9yetr220UmPtBYKk-OssZtLqyFu7sY1_1R7vgFuJV6NtcV5zpsJ"
```

Next, use the `upload-multipart-part` command to upload each of the three parts.
You must specify the byte range of each part when you upload it so that S3 Glacier can reassemble it in the correct order. Each piece is 1,048,576 bytes, so the first piece occupies bytes 0-1048575, the second 1048576-2097151, and the third 2097152-3145727.

Complete the upload

Amazon S3 Glacier requires a tree hash of the original file to confirm that all of the uploaded pieces reached AWS intact.

To calculate a tree hash, you must split the file into 1 MiB parts and calculate a binary SHA-256 hash of each piece. Then you split the list of hashes into pairs, combine the two binary hashes in each pair, and take hashes of the results. Repeat this process until there is only one hash left. If there is an odd number of hashes at any level, promote it to the next level without modifying it.

The key to calculating a tree hash correctly when using command line utilities is to store each hash in binary format and convert to hexadecimal only at the last step. Combining or hashing the hexadecimal version of any hash in the tree will cause an incorrect result.
To calculate a tree hash

1. If you haven't already, split the original file into 1 MiB parts.

   ```
   $ split --bytes=1048576 --verbose largefile chunk
   creating file `chunkaa'
   creating file `chunkab'
   creating file `chunkac'
   ```

2. Calculate and store the binary SHA-256 hash of each chunk.

   ```
   $ openssl dgst -sha256 -binary chunkaa > hash1
   $ openssl dgst -sha256 -binary chunkab > hash2
   $ openssl dgst -sha256 -binary chunkac > hash3
   ```

3. Combine the first two hashes and take the binary hash of the result.

   ```
   $ cat hash1 hash2 > hash12
   $ openssl dgst -sha256 -binary hash12 > hash12hash
   ```

4. Combine the parent hash of chunks aa and ab with the hash of chunk ac and hash the result, this time outputting hexadecimal. Store the result in a shell variable.

   ```
   $ cat hash12hash hash3 > hash123
   $ openssl dgst -sha256 hash123
   SHA256(hash123)= 9628195fcdbcbbe76cdde932d4646fa7de5f219fb39823836d81f0cc0e18aa67
   $ TREEHASH=9628195fcdbcbbe76cdde932d4646fa7de5f219fb39823836d81f0cc0e18aa67
   ```

Finally, complete the upload with the `complete-multipart-upload` command. This command takes the original file's size in bytes, the final tree hash value in hexadecimal, and your account ID and vault name.

```
$ aws glacier complete-multipart-upload --checksum $TREEHASH --archive-size 3145728 --upload-id $UPLOADID --account-id - --vault-name myvault
```
You can also check the status of the vault using the `describe-vault` command.

```bash
$ aws glacier describe-vault --account-id - --vault-name myvault
{
    "SizeInBytes": 3178496,
    "LastInventoryDate": "2018-12-07T00:26:19.028Z",
    "NumberOfArchives": 1,
    "CreationDate": "2018-12-06T21:23:45.708Z",
    "VaultName": "myvault"
}
```

**Note**

Vault status is updated about once per day. See [Working with Vaults](#) for more information.

Now it's safe to remove the chunk and hash files that you created.

```bash
$ rm chunk* hash*
```

**Use AWS Identity and Access Management from the AWS CLI**

Using the AWS Command Line Interface (AWS CLI) to access features of AWS Identity and Access Management (IAM). To list the AWS CLI commands for IAM, use the following command.

```
aws iam help
```

This topic shows examples of AWS CLI commands that perform common tasks for IAM.

Before you run any commands, set your default credentials. For more information, see [Configure the AWS CLI](#).

For more information on the IAM service, see the [AWS Identity and Access Management User Guide](#).

**Topics**

• [Create IAM users and groups](#)
• [Attach an IAM managed policy to a user](#)
• [Set an initial password for an IAM user](#)
Create IAM users and groups

This topic describes how to use AWS Command Line Interface (AWS CLI) commands to create an AWS Identity and Access Management (IAM) group and a new user, and then add the user to the group. For more information on the IAM service, see the AWS Identity and Access Management User Guide.

Before you run any commands, set your default credentials. For more information, see Configure the AWS CLI.

To create a group and add a new user to it

1. Use the create-group command to create the group.

   ```
   $ aws iam create-group --group-name MyIamGroup
   {
     "Group": {
       "GroupName": "MyIamGroup",
       "CreateDate": "2018-12-14T03:03:52.834Z",
       "GroupId": "AGPAJNUJ2W4IJVEXAMPLE",
       "Arn": "arn:aws:iam::123456789012:group/MyIamGroup",
       "Path": "/"
     }
   }
   ```

2. Use the create-user command to create the user.

   ```
   $ aws iam create-user --user-name MyUser
   {
     "User": {
       "UserName": "MyUser",
       "Path": "/",
       "CreateDate": "2018-12-14T03:13:02.581Z",
       "UserId": "AIDAJY2PE5XUZ4EXAMPLE",
       "Arn": "arn:aws:iam::123456789012:user/MyUser"
     }
   }
   ```

3. Use the add-user-to-group command to add the user to the group.
Attach an IAM managed policy to a user

This topic describes how to use AWS Command Line Interface (AWS CLI) commands to attach an AWS Identity and Access Management (IAM) policy to a user. The policy in this example provides the user with "Power User Access". For more information on the IAM service, see the AWS Identity and Access Management User Guide.

Before you run any commands, set your default credentials. For more information, see Configure the AWS CLI.

To attach an IAM managed policy to a user

1. Determine the Amazon Resource Name (ARN) of the policy to attach. The following command uses list-policies to find the ARN of the policy with the name PowerUserAccess. It then stores that ARN in an environment variable.
2. To attach the policy, use the `attach-user-policy` command, and reference the environment variable that holds the policy ARN.

```bash
$ export POLICYARN=$(aws iam list-policies --query 'Policies[?PolicyName==`PowerUserAccess`].{ARN:Arn}' --output text)
$ echo $POLICYARN
arn:aws:iam::aws:policy/PowerUserAccess
```

```bash
$ aws iam attach-user-policy --user-name MyUser --policy-arn $POLICYARN
```

3. Verify that the policy is attached to the user by running the `list-attached-user-policies` command.

```bash
$ aws iam list-attached-user-policies --user-name MyUser
{
    "AttachedPolicies": [
        {
            "PolicyName": "PowerUserAccess",
            "PolicyArn": "arn:aws:iam::aws:policy/PowerUserAccess"
        }
    ]
}
```

For more information, see Access Management Resources. This topic provides links to an overview of permissions and policies, and links to examples of policies for accessing Amazon S3, Amazon EC2, and other services.

**Set an initial password for an IAM user**

This topic describes how to use AWS Command Line Interface (AWS CLI) commands to set an initial password for an AWS Identity and Access Management (IAM) user. For more information on the IAM service, see the AWS Identity and Access Management User Guide.

Before you run any commands, set your default credentials. For more information, see Configure the AWS CLI.

The following command uses `create-login-profile` to set an initial password on the specified user. When the user signs in for the first time, the user is required to change the password to something that only the user knows.
$ aws iam create-login-profile --user-name MyUser --password MyUser1Login8P@ssword --password-reset-required
{
    "LoginProfile": {
        "UserName": "MyUser",
        "CreateDate": "2018-12-14T17:27:18Z",
        "PasswordResetRequired": true
    }
}

You can use the update-login-profile command to change the password for a user.

$ aws iam update-login-profile --user-name MyUser --password MyUser1ADifferentP@ssword

Create an access key for an IAM user

This topic describes how to use AWS Command Line Interface (AWS CLI) commands to create a set of access keys for an AWS Identity and Access Management (IAM) user. For more information on the IAM service, see the AWS Identity and Access Management User Guide.

Before you run any commands, set your default credentials. For more information, see Configure the AWS CLI.

You can use the create-access-key command to create an access key for a user. An access key is a set of security credentials that consists of an access key ID and a secret key.

A user can create only two access keys at one time. If you try to create a third set, the command returns a LimitExceeded error.

$ aws iam create-access-key --user-name MyUser
{
    "AccessKey": {
        "UserName": "MyUser",
        "AccessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "Status": "Active",
        "SecretAccessKey": "wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY",
        "CreateDate": "2018-12-14T17:34:16Z"
    }
}
Use the `delete-access-key` command to delete an access key for a user. Specify which access key to delete by using the access key ID.

```
$ aws iam delete-access-key --user-name MyUser --access-key-id AKIAIOSFODNN7EXAMPLE
```

## Use Amazon S3 with the AWS CLI

### An introduction to Amazon Simple Storage Service (Amazon S3)

Introduction to Amazon Simple Storage Service (Amazon S3 - Cloud Storage on AWS)

You can access the features of Amazon Simple Storage Service (Amazon S3) using the AWS Command Line Interface (AWS CLI). The AWS CLI provides two tiers of commands for accessing Amazon S3:

- **s3** – High-level commands that simplify performing common tasks, such as creating, manipulating, and deleting objects and buckets.
- **s3api** – Exposes direct access to all Amazon S3 API operations which enables you to carry out advanced operations.

### Topics in this guide:

- Use high-level (s3) commands with the AWS CLI
- Use API-Level (s3api) commands with the AWS CLI
- Amazon S3 bucket lifecycle operations scripting example

### Use high-level (s3) commands with the AWS CLI

This topic describes some of the commands you can use to manage Amazon S3 buckets and objects using the `aws s3` commands in the AWS CLI. For commands not covered in this topic and additional command examples, see the `aws s3` commands in the AWS CLI Reference.

The high-level `aws s3` commands simplify managing Amazon S3 objects. These commands enable you to manage the contents of Amazon S3 within itself and with local directories.

### Topics
• **Prerequisites**

• **Before you start**

• **Create a bucket**

• **List buckets and objects**

• **Delete buckets**

• **Delete objects**

• **Move objects**

• **Copy objects**

• **Sync objects**

• **Frequently used options for s3 commands**

• **Resources**

**Prerequisites**

To run the s3 commands, you need to:

- Install and configure the AWS CLI. For more information, see the section called “Install/Update” and **Authentication and access credentials**.

- The profile that you use must have permissions that allow the AWS operations performed by the examples.

- Understand these Amazon S3 terms:
  - **Bucket** – A top-level Amazon S3 folder.
  - **Prefix** – An Amazon S3 folder in a bucket.
  - **Object** – Any item that's hosted in an Amazon S3 bucket.

**Before you start**

This section describes a few things to note before you use aws s3 commands.

**Large object uploads**

When you use aws s3 commands to upload large objects to an Amazon S3 bucket, the AWS CLI automatically performs a multipart upload. You can't resume a failed upload when using these aws s3 commands.
If the multipart upload fails due to a timeout, or if you manually canceled in the AWS CLI, the AWS CLI stops the upload and cleans up any files that were created. This process can take several minutes.

If the multipart upload or cleanup process is canceled by a kill command or system failure, the created files remain in the Amazon S3 bucket. To clean up the multipart upload, use the `s3api abort-multipart-upload` command.

**File properties and tags in multipart copies**

When you use the AWS CLI version 1 version of commands in the `aws s3` namespace to copy a file from one Amazon S3 bucket location to another Amazon S3 bucket location, and that operation uses `multipart copy`, no file properties from the source object are copied to the destination object.

By default, the AWS CLI version 2 commands in the `s3` namespace that perform multipart copies transfers all tags and the following set of properties from the source to the destination copy: `content-type`, `content-language`, `content-encoding`, `content-disposition`, `cache-control`, `expires`, and `metadata`.

This can result in additional AWS API calls to the Amazon S3 endpoint that would not have been made if you used AWS CLI version 1. These can include: `HeadObject`, `GetObjectTagging`, and `PutObjectTagging`.

If you need to change this default behavior in AWS CLI version 2 commands, use the `--copy-props` parameter to specify one of the following options:

- **default** – The default value. Specifies that the copy includes all tags attached to the source object and the properties encompassed by the `--metadata-directive` parameter used for non-multipart copies: `content-type`, `content-language`, `content-encoding`, `content-disposition`, `cache-control`, `expires`, and `metadata`.
- **metadata-directive** – Specifies that the copy includes only the properties that are encompassed by the `--metadata-directive` parameter used for non-multipart copies. It doesn't copy any tags.
- **none** – Specifies that the copy includes none of the properties from the source object.

**Create a bucket**

Use the `s3 mb` command to make a bucket. Bucket names must be `globally` unique (unique across all of Amazon S3) and should be DNS compliant.
Bucket names can contain lowercase letters, numbers, hyphens, and periods. Bucket names can start and end only with a letter or number, and cannot contain a period next to a hyphen or another period.

**Syntax**

```
$ aws s3 mb <target> [--options]
```

**s3 mb examples**

The following example creates the `s3://bucket-name` bucket.

```
$ aws s3 mb s3://bucket-name
```

**List buckets and objects**

To list your buckets, folders, or objects, use the `s3 ls` command. Using the command without a target or options lists all buckets.

**Syntax**

```
$ aws s3 ls <target> [--options]
```

For a few common options to use with this command, and examples, see [Frequently used options for s3 commands](#). For a complete list of available options, see `s3 ls` in the AWS CLI Command Reference.

**s3 ls examples**

The following example lists all of your Amazon S3 buckets.

```
$ aws s3 ls
2018-12-11 17:08:50 my-bucket
2018-12-14 14:55:44 my-bucket2
```

The following command lists all objects and prefixes in a bucket. In this example output, the prefix `example/` has one file named `MyFile1.txt`.

```
$ aws s3 ls s3://bucket-name
    PRE example/
```
You can filter the output to a specific prefix by including it in the command. The following command lists the objects in `bucket-name/example/` (that is, objects in `bucket-name` filtered by the prefix `example/`).

```
$ aws s3 ls s3://bucket-name/example/
```

Delete buckets

To delete a bucket, use the `s3 rb` command.

**Syntax**

```
$ aws s3 rb <target> [--options]
```

**s3 rb examples**

The following example removes the `s3://bucket-name` bucket.

```
$ aws s3 rb s3://bucket-name
```

By default, the bucket must be empty for the operation to succeed. To remove a bucket that's not empty, you need to include the `--force` option. If you're using a versioned bucket that contains previously deleted—but retained—objects, this command does *not* allow you to remove the bucket. You must first remove all of the content.

The following example deletes all objects and prefixes in the bucket, and then deletes the bucket.

```
$ aws s3 rb s3://bucket-name --force
```

Delete objects

To delete objects in a bucket or your local directory, use the `s3 rm` command.

**Syntax**

```
$ aws s3 rm <target> [--options]
```
For a few common options to use with this command, and examples, see Frequently used options for s3 commands. For a complete list of options, see s3 rm in the AWS CLI Command Reference.

**s3 rm examples**

The following example deletes filename.txt from s3://bucket-name/example.

```bash
$ aws s3 rm s3://bucket-name/example/filename.txt
```

The following example deletes all objects from s3://bucket-name/example using the --recursive option.

```bash
$ aws s3 rm s3://bucket-name/example --recursive
```

**Move objects**

Use the s3 mv command to move objects from a bucket or a local directory. The s3 mv command copies the source object or file to the specified destination and then deletes the source object or file.

**Syntax**

```bash
$ aws s3 mv <source> <target> [--options]
```

For a few common options to use with this command, and examples, see Frequently used options for s3 commands. For a complete list of available options, see s3 mv in the AWS CLI Command Reference.

⚠️ **Warning**

If you are using any type of access point ARNs or access point aliases in your Amazon S3 source or destination URIs, you must take extra care that your source and destination Amazon S3 URIs resolve to different underlying buckets. If the source and destination buckets are the same, the source file or object can be moved onto itself, which can result in accidental deletion of your source file or object. To verify that the source and destination buckets are not the same, use the --validate-same-s3-paths parameter, or set the environment variable AWS_CLI_S3_MV_VALIDATE_SAME_S3_PATHS to true.
**s3 mv examples**

The following example moves all objects from s3://bucket-name/example to s3://my-bucket/.

```
$ aws s3 mv s3://bucket-name/example s3://my-bucket/
```

The following example moves a local file from your current working directory to the Amazon S3 bucket with the `s3 mv` command.

```
$ aws s3 mv filename.txt s3://bucket-name
```

The following example moves a file from your Amazon S3 bucket to your current working directory, where ./ specifies your current working directory.

```
$ aws s3 mv s3://bucket-name/filename.txt ./
```

**Copy objects**

Use the `s3 cp` command to copy objects from a bucket or a local directory.

**Syntax**

```
$ aws s3 cp <source> <target> [--options]
```

You can use the dash parameter for file streaming to standard input (stdin) or standard output (stdout).

⚠️ **Warning**

If you're using PowerShell, the shell might alter the encoding of a CRLF or add a CRLF to piped input or output, or redirected output.

The `s3 cp` command uses the following syntax to upload a file stream from stdin to a specified bucket.

**Syntax**

```
$ aws s3 cp <source> <target> [--options]
```
The `s3 cp` command uses the following syntax to download an Amazon S3 file stream for stdout.

**Syntax**

```
$ aws s3 cp <target> [--options] -
```

For a few common options to use with this command, and examples, see [Frequently used options for s3 commands](#). For the complete list of options, see `s3 cp` in the AWS CLI Command Reference.

**s3 cp examples**

The following example copies all objects from `s3://bucket-name/example` to `s3://my-bucket/`.

```
$ aws s3 cp s3://bucket-name/example s3://my-bucket/
```

The following example copies a local file from your current working directory to the Amazon S3 bucket with the `s3 cp` command.

```
$ aws s3 cp filename.txt s3://bucket-name
```

The following example copies a file from your Amazon S3 bucket to your current working directory, where `./` specifies your current working directory.

```
$ aws s3 cp s3://bucket-name/filename.txt ./
```

The following example uses `echo` to stream the text "hello world" to the `s3://bucket-name/filename.txt` file.

```
$ echo "hello world" | aws s3 cp - s3://bucket-name/filename.txt
```

The following example streams the `s3://bucket-name/filename.txt` file to stdout and prints the contents to the console.

```
$ aws s3 cp s3://bucket-name/filename.txt -
hello world
```
The following example streams the contents of s3://bucket-name/pre to stdout, uses the bzip2 command to compress the files, and uploads the new compressed file named key.bz2 to s3://bucket-name.

```
$ aws s3 cp s3://bucket-name/pre - | bzip2 --best | aws s3 cp - s3://bucket-name/key.bz2
```

### Sync objects

The `s3 sync` command synchronizes the contents of a bucket and a directory, or the contents of two buckets. Typically, `s3 sync` copies missing or outdated files or objects between the source and target. However, you can also supply the `--delete` option to remove files or objects from the target that are not present in the source.

### Syntax

```
$ aws s3 sync <source> <target> [--options]
```

For a few common options to use with this command, and examples, see [Frequently used options for s3 commands](#). For a complete list of options, see `s3 sync` in the [AWS CLI Command Reference](#).

### s3 sync examples

The following example synchronizes the contents of an Amazon S3 prefix named `path` in the bucket named `my-bucket` with the current working directory.

`s3 sync` updates any files that have a size or modified time that are different from files with the same name at the destination. The output displays specific operations performed during the sync. Notice that the operation recursively synchronizes the subdirectory `MySubdirectory` and its contents with `s3://my-bucket/path/MySubdirectory`.

```
$ aws s3 sync . s3://my-bucket/path
upload: MySubdirectory\MyFile3.txt to s3://my-bucket/path/MySubdirectory/MyFile3.txt
upload: MyFile2.txt to s3://my-bucket/path/MyFile2.txt
upload: MyFile1.txt to s3://my-bucket/path/MyFile1.txt
```

The following example, which extends the previous one, shows how to use the `--delete` option.

```
// Delete local file
```
$ rm ./MyFile1.txt

// Attempt sync without --delete option - nothing happens
$ aws s3 sync . s3://my-bucket/path

// Sync with deletion - object is deleted from bucket
$ aws s3 sync . s3://my-bucket/path --delete
delete: s3://my-bucket/path/MyFile1.txt

// Delete object from bucket
$ aws s3 rm s3://my-bucket/path/MySubdirectory/MyFile3.txt
delete: s3://my-bucket/path/MySubdirectory/MyFile3.txt

// Sync with deletion - local file is deleted
$ aws s3 sync s3://my-bucket/path . --delete
delete: MySubdirectory\MyFile3.txt

// Sync with Infrequent Access storage class
$ aws s3 sync . s3://my-bucket/path --storage-class STANDARD_IA

When using the --delete option, the --exclude and --include options can filter files or objects to delete during an s3 sync operation. In this case, the parameter string must specify files to exclude from, or include for, deletion in the context of the target directory or bucket. The following shows an example.

Assume local directory and s3://my-bucket/path currently in sync and each contains 3 files:
MyFile1.txt
MyFile2.rtf
MyFile88.txt

// Sync with delete, excluding files that match a pattern. MyFile88.txt is deleted, while remote MyFile1.txt is not.
$ aws s3 sync . s3://my-bucket/path --delete --exclude "path/MyFile?.txt"
delete: s3://my-bucket/path/MyFile88.txt

// Sync with delete, excluding MyFile2.rtf - local file is NOT deleted
$ aws s3 sync s3://my-bucket/path . --delete --exclude "./MyFile2.rtf"
download: s3://my-bucket/path/MyFile1.txt to MyFile1.txt
Frequently used options for s3 commands

The following options are frequently used for the commands described in this topic. For a complete list of options you can use on a command, see the specific command in the AWS CLI version 2 reference guide.

acl

s3 sync and s3 cp can use the --acl option. This enables you to set the access permissions for files copied to Amazon S3. The --acl option accepts private, public-read, and public-read-write values. For more information, see Canned ACL in the Amazon Simple Storage Service User Guide.

```
$ aws s3 sync . s3://my-bucket/path --acl public-read
```

exclude

When you use the s3 cp, s3 mv, s3 sync, or s3 rm command, you can filter the results by using the --exclude or --include option. The --exclude option sets rules to only exclude objects from the command, and the options apply in the order specified. This is shown in the following example.

```
Local directory contains 3 files:
MyFile1.txt
MyFile2.rtf
MyFile88.txt

// Exclude all .txt files, resulting in only MyFile2.rtf being copied
$ aws s3 cp . s3://my-bucket/path --exclude "*.txt"

// Exclude all .txt files but include all files with the "MyFile*.txt" format, resulting in, MyFile1.txt, MyFile2.rtf, MyFile88.txt being copied
$ aws s3 cp . s3://my-bucket/path --exclude "*.txt" --include "MyFile*.txt"

// Exclude all .txt files, but include all files with the "MyFile*.txt" format, but exclude all files with the "MyFile?.txt" format resulting in, MyFile2.rtf and MyFile88.txt being copied
```
When you use the `s3 cp`, `s3 mv`, `s3 sync`, or `s3 rm` command, you can filter the results using the `--exclude` or `--include` option. The `--include` option sets rules to only include objects specified for the command, and the options apply in the order specified. This is shown in the following example.

Local directory contains 3 files:
- MyFile1.txt
- MyFile2.rtf
- MyFile88.txt

- Include all .txt files, resulting in MyFile1.txt and MyFile88.txt being copied
  ```
  $ aws s3 cp . s3://my-bucket/path --include "*.txt"
  ```

- Include all .txt files but exclude all files with the "MyFile*.txt" format, resulting in no files being copied
  ```
  $ aws s3 cp . s3://my-bucket/path --include "*.txt" --exclude "MyFile*.txt"
  ```

- Include all .txt files, but exclude all files with the "MyFile*.txt" format, but include all files with the "MyFile?.txt" format resulting in MyFile1.txt being copied
  ```
  $ aws s3 cp . s3://my-bucket/path --include "*.txt" --exclude "MyFile*.txt" --include "MyFile?.txt"
  ```

The `s3 cp`, `s3 mv`, and `s3 sync` commands include a `--grants` option that you can use to grant permissions on the object to specified users or groups. Set the `--grants` option to a list of permissions using the following syntax. Replace `Permission`, `Grantee_Type`, and `Grantee_ID` with your own values.

**Syntax**

```
--grants Permission=Grantee_Type=Grantee_ID
    [Permission=Grantee_Type=Grantee_ID ...]
```

Each value contains the following elements:
• **Permission** – Specifies the granted permissions. Can be set to read, readacl, writeacl, or full.

• **Grantee_Type** – Specifies how to identify the grantee. Can be set to uri, emailaddress, or id.

• **Grantee_ID** – Specifies the grantee based on Grantee_Type.
  
  • uri – The group's URI. For more information, see [Who is a grantee?](#)
  
  • emailaddress – The account's email address.
  
  • id – The account's canonical ID.

For more information about Amazon S3 access control, see [Access control](#).

The following example copies an object into a bucket. It grants read permissions on the object to everyone, and full permissions (read, readacl, and writeacl) to the account associated with user@example.com.

```
$ aws s3 cp file.txt s3://my-bucket/ --grants read=uri=http://acs.amazonaws.com/groups/global/AllUsers full=emailaddress=user@example.com
```

You can also specify a nondefault storage class (REDUCED_REDUNDANCY or STANDARD_IA) for objects that you upload to Amazon S3. To do this, use the --storage-class option.

```
$ aws s3 cp file.txt s3://my-bucket/ --storage-class REDUCED_REDUNDANCY
```

**recursive**

When you use this option, the command is performed on all files or objects under the specified directory or prefix. The following example deletes s3://my-bucket/path and all of its contents.

```
$ aws s3 rm s3://my-bucket/path --recursive
```

Use API-Level (s3api) commands with the AWS CLI

The API-level commands (contained in the `s3api` command set) provide direct access to the Amazon Simple Storage Service (Amazon S3) APIs, and enable some operations that are not exposed in the high-level `s3` commands. These commands are the equivalent of the other AWS services that provide API-level access to the services' functionality. For more information on the `s3` commands, see [Use high-level (s3) commands with the AWS CLI](https://docs.aws.amazon.com/AmazonS3/latest/user-guide/s3-api-commands.html)

This topic provides examples that demonstrate how to use the lower-level commands that map to the Amazon S3 APIs. In addition, you can find examples for each S3 API command in the `s3api` section of the *AWS CLI version 2 reference guide*.

Topics

• Prerequisites
• Apply a custom ACL
• Configure a logging policy
• Resources
Prerequisites

To run the s3api commands, you need to:

- Install and configure the AWS CLI. For more information, see the section called “Install/Update” and Authentication and access credentials.
- The profile that you use must have permissions that allow the AWS operations performed by the examples.
- Understand these Amazon S3 terms:
  - **Bucket** – A top-level Amazon S3 folder.
  - **Prefix** – An Amazon S3 folder in a bucket.
  - **Object** – Any item that's hosted in an Amazon S3 bucket.

Apply a custom ACL

With high-level commands, you can use the --acl option to apply predefined access control lists (ACLs) to Amazon S3 objects. But you can't use that command to set bucket-wide ACLs. However, you can do this by using the put-bucket-acl API-level command.

The following example shows how to grant full control to two AWS users (user1@example.com and user2@example.com) and read permission to everyone. The identifier for "everyone" comes from a special URI that you pass as a parameter.

```bash
$ aws s3api put-bucket-acl --bucket MyBucket --grant-full-control
'emailaddress="user1@example.com",emailaddress="user2@example.com"' --grant-read
'uri="http://acs.amazonaws.com/groups/global/AllUsers"
```

For details about how to construct the ACLs, see PUT Bucket acl in the Amazon Simple Storage Service API Reference. The s3api ACL commands in the CLI, such as put-bucket-acl, use the same shorthand argument notation.

Configure a logging policy

The API command put-bucket-logging configures a bucket logging policy.

In the following example, the AWS user user@example.com is granted full control over the log files, and all users have read access to them. Notice that the put-bucket-acl command is also
required to grant the Amazon S3 log delivery system (specified by a URI) the permissions needed to read and write the logs to the bucket.

```bash
$ aws s3api put-bucket-acl --bucket MyBucket --grant-read-acp 'URI="http://acs.amazonaws.com/groups/s3/LogDelivery"' --grant-write 'URI="http://acs.amazonaws.com/groups/s3/LogDelivery"'
$ aws s3api put-bucket-logging --bucket MyBucket --bucket-logging-status file://logging.json
```

The `logging.json` file in the previous command has the following content.

```json
{
  "LoggingEnabled": {
    "TargetBucket": "MyBucket",
    "TargetPrefix": "MyBucketLogs/",
    "TargetGrants": [
      {
        "Grantee": {
          "Type": "AmazonCustomerByEmail",
          "EmailAddress": "user@example.com"
        },
        "Permission": "FULL_CONTROL"
      },
      {
        "Grantee": {
          "Type": "Group",
          "URI": "http://acs.amazonaws.com/groups/global/AllUsers"
        },
        "Permission": "READ"
      }
    ]
  }
}
```

Amazon S3 bucket lifecycle operations scripting example

This topic uses a bash scripting example for Amazon S3 bucket lifecycle operations using the AWS Command Line Interface (AWS CLI). This scripting example uses the `aws s3api` set of commands. Shell scripts are programs designed to run in a command line interface.

Before you start

Before you can run any of the below examples, the following things need to be completed.

- Install and configure the AWS CLI. For more information, see the section called “Install/Update” and Authentication and access credentials.
- The profile that you use must have permissions that allow the AWS operations performed by the examples.
- As an AWS best practice, grant this code least privilege, or only the permissions required to perform a task. For more information, see Grant Least Privilege in the IAM User Guide.
- This code has not been tested in all AWS Regions. Some AWS services are available only in specific Regions. For more information, see Service Endpoints and Quotas in the AWS General Reference Guide.
• Running this code can result in charges to your AWS account. It is your responsibility to ensure that any resources created by this script are removed when you are done with them.

The Amazon S3 service uses the following terms:

• Bucket — A top level Amazon S3 folder.
• Prefix — An Amazon S3 folder in a bucket.
• Object — Any item hosted in an Amazon S3 bucket.

About this example

This example demonstrates how to interact with some of the basic Amazon S3 operations using a set of functions in shell script files. The functions are located in the shell script file named bucket-operations.sh. You can call these functions in another file. Each script file contains comments describing each of the functions.

To see the intermediate results of each step, run the script with a -i parameter. You can view the current status of the bucket or its contents using the Amazon S3 console. The script only proceeds to the next step when you press enter at the prompt.

For the full example and downloadable script files, see Amazon S3 Bucket Lifecycle Operations in the AWS Code Examples Repository on GitHub.

Files

The example contains the following files:

bucket-operations.sh

This main script file can be sourced from another file. It includes functions that perform the following tasks:

• Creating a bucket and verifying that it exists
• Copying a file from the local computer to a bucket
• Copying a file from one bucket location to a different bucket location
• Listing the contents of a bucket
• Deleting a file from a bucket
• Deleting a bucket
View the code for `bucket-operations.sh` on GitHub.

**test-bucket-operations.sh**

The shell script file `test-bucket-operations.sh` demonstrates how to call the functions by sourcing the `bucket-operations.sh` file and calling each of the functions. After calling functions, the test script removes all resources that it created.

View the code for `test-bucket-operations.sh` on GitHub.

**awsdocs-general.sh**

The script file `awsdocs-general.sh` holds general purpose functions used across advanced code examples for the AWS CLI.

View the code for `awsdocs-general.sh` on GitHub.

Use Amazon SNS with the AWS CLI

You can access the features of Amazon Simple Notification Service (Amazon SNS) using the AWS Command Line Interface (AWS CLI). To list the AWS CLI commands for Amazon SNS, use the following command.

```
aws sns help
```

Before you run any commands, set your default credentials. For more information, see Configure the AWS CLI.

This topic shows examples of AWS CLI commands that perform common tasks for Amazon SNS.

Create a topic

To create a topic, use the `sns create-topic` command and specify the name to assign to the topic.

```
$ aws sns create-topic --name my-topic
{
}
```

Make a note of the response's TopicArn, which you use later to publish a message.

Subscribe to a topic

To subscribe to a topic, use the `sns subscribe` command.

The following example specifies the email protocol and an email address for the notification-endpoint.
$ aws sns subscribe --topic-arn arn:aws:sns:us-west-2:123456789012:my-topic --protocol email --notification-endpoint saanvi@example.com

{
    "SubscriptionArn": "pending confirmation"
}

AWS immediately sends a confirmation message by email to the address you specified in the subscribe command. The email message has the following text.

You have chosen to subscribe to the topic:
To confirm this subscription, click or visit the following link (If this was in error no action is necessary):
Confirm subscription

After the recipient clicks the Confirm subscription link, the recipient's browser displays a notification message with information similar to the following.

Subscription confirmed!

You have subscribed saanvi@example.com to the topic:my-topic.

Your subscription's id is:

If it was not your intention to subscribe, click here to unsubscribe.

Publish to a topic

To send a message to all subscribers of a topic, use the sns publish command.

The following example sends the message "Hello World!" to all subscribers of the specified topic.

{
    "MessageId": "4e41661d-5ee5-5ddf-8dab-2c867EXAMPLE"
}

In this example, AWS sends an email message with the text "Hello World!" to saanvi@example.com.
Unsubscribe from a topic

To unsubscribe from a topic and stop receiving messages published to that topic, use the `sns unsubscribe` command and specify the ARN of the topic you want to unsubscribe from.

```bash
```

To verify that you successfully unsubscribed, use the `sns list-subscriptions` command to confirm that the ARN no longer appears in the list.

```bash
$ aws sns list-subscriptions
```

Delete a topic

To delete a topic, run the `sns delete-topic` command.

```bash
```

To verify that AWS successfully deleted the topic, use the `sns list-topics` command to confirm that the topic no longer appears in the list.

```bash
$ aws sns list-topics
```

ACM examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with ACM.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Actions**

**add-tags-to-certificate**

The following code example shows how to use `add-tags-to-certificate`.

**AWS CLI**

**To add tags to an existing ACM Certificate**

The following `add-tags-to-certificate` command adds two tags to the specified certificate. Use a space to separate multiple tags:

```bash
aws acm add-tags-to-certificate --certificate-arn arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012 --tags Key=Admin,Value=Alice Key=Purpose,Value=Website
```

- For API details, see [AddTagsToCertificate](aws-cli-command-reference) in *AWS CLI Command Reference*.

**delete-certificate**

The following code example shows how to use `delete-certificate`.

**AWS CLI**

**To delete an ACM certificate from your account**

The following `delete-certificate` command deletes the certificate with the specified ARN:

```bash
```

- For API details, see [DeleteCertificate](aws-cli-command-reference) in *AWS CLI Command Reference*.

**describe-certificate**

The following code example shows how to use `describe-certificate`.

**AWS CLI**

**To retrieve the fields contained in an ACM certificate**
The following `describe-certificate` command retrieves all of the fields for the certificate with the specified ARN:

```bash
aws acm describe-certificate --certificate-arn
arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012
```

Output similar to the following is displayed:

```json

For API details, see `DescribeCertificate` in *AWS CLI Command Reference*.

**export-certificate**

The following code example shows how to use `export-certificate`.

**AWS CLI**

To export a private certificate issued by a private CA.

The following `export-certificate` command exports a private certificate, certificate chain, and private key to your display:

```

To export the certificate, chain, and private key to a local file, use the following command:

```

For API details, see `ExportCertificate` in *AWS CLI Command Reference*. 

•
**get-certificate**

The following code example shows how to use `get-certificate`.

**AWS CLI**

To retrieve an ACM certificate

The following `get-certificate` command retrieves the certificate for the specified ARN and the certificate chain:

```bash
aws acm get-certificate --certificate-arn
arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012

```

Actions and scenarios
For API details, see `GetCertificate` in *AWS CLI Command Reference*.
import-certificate

The following code example shows how to use import-certificate.

**AWS CLI**

**To import a certificate into ACM.**

The following import-certificate command imports a certificate into ACM. Replace the file names with your own:

```bash
```

- For API details, see [ImportCertificate](https://awscli.amazonaws.com/v2/documentation/api/latest/reference/acm/import-certificate.html) in *AWS CLI Command Reference*.

list-certificates

The following code example shows how to use list-certificates.

**AWS CLI**

**To list the ACM certificates for an AWS account**

The following list-certificates command lists the ARNs of the certificates in your account:

```bash
aws acm list-certificates
```

The preceding command produces output similar to the following:

```json
{
   "CertificateSummaryList": [
      {
         "DomainName": "www.example.com"
      },
      {
```
You can decide how many certificates you want to display each time you call `list-certificates`. For example, if you have four certificates and you want to display no more than two at a time, set the `max-items` argument to 2 as in the following example:

```sh
aws acm list-certificates --max-items 2
```

Two certificate ARNs and a `NextToken` value will be displayed:

```
"CertificateSummaryList": [
{
  "CertificateArn": "arn:aws:acm:region:account: 
  certificate/12345678-1234-1234-1234-123456789012",
  "DomainName": "www.example.com"
},
{
  "CertificateArn": "arn:aws:acm:region:account: 
  certificate/aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeee",
  "DomainName": "www.example.net"
}
],
"NextToken": "9f4d9f69-275a-41fe-b58e-2b837bd9ba48"
```

To display the next two certificates in your account, set this `NextToken` value in your next call:

```sh
aws acm list-certificates --max-items 2 --next-token 9f4d9f69-275a-41fe-b58e-2b837bd9ba48
```

You can filter your output by using the `certificate-statuses` argument. The following command displays certificates that have a `PENDING_VALIDATION` status:

```sh
aws acm list-certificates --certificate-statuses PENDING_VALIDATION
```

You can also filter your output by using the `includes` argument. The following command displays certificates filtered on the following properties. The certificates to be displayed:
- Specify that the RSA algorithm and a 2048 bit key are used to generate key pairs.
- Contain a Key Usage extension that specifies that the certificates can be used to create digital signatures.
- Contain an Extended Key Usage extension that specifies that the certificates can be used for code signing.

```
aws acm list-certificates --max-items 10 --includes extendedKeyUsage=CODE_SIGNING,keyUsage=DIGITAL_SIGNATURE,keyTypes=rsa_2048
```

- For API details, see ListCertificates in AWS CLI Command Reference.

### list-tags-for-certificate

The following code example shows how to use list-tags-for-certificate.

#### AWS CLI

**To list the tags applied to an ACM Certificate**

The following `list-tags-for-certificate` command lists the tags applied to a certificate in your account:

```
aws acm list-tags-for-certificate --certificate-arn arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012
```

The preceding command produces output similar to the following:

```json
{
   "Tags": [
      {
         "Value": "Website",
         "Key": "Purpose"
      },
      {
         "Value": "Alice",
         "Key": "Admin"
      }
   ]
}
```

- For API details, see ListTagsForCertificate in AWS CLI Command Reference.
remove-tags-from-certificate

The following code example shows how to use remove-tags-from-certificate.

AWS CLI

To remove a tag from an ACM Certificate

The following remove-tags-from-certificate command removes two tags from the specified certificate. Use a space to separate multiple tags:

```bash
aws acm remove-tags-from-certificate --certificate-arn arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012 --tags Key=Admin,Value=Alice Key=Purpose,Value=Website
```

- For API details, see RemoveTagsFromCertificate in AWS CLI Command Reference.

request-certificate

The following code example shows how to use request-certificate.

AWS CLI

To request a new ACM certificate

The following request-certificate command requests a new certificate for the www.example.com domain using DNS validation:

```bash
aws acm request-certificate --domain-name www.example.com --validation-method DNS
```

You can enter an idempotency token to distinguish between calls to request-certificate:

```bash
aws acm request-certificate --domain-name www.example.com --validation-method DNS --idempotency-token 91adc45q
```

You can enter one or more subject alternative names to request a certificate that will protect more than one apex domain:

```bash
aws acm request-certificate --domain-name example.com --validation-method DNS --idempotency-token 91adc45q --subject-alternative-names www.example.net
```
You can enter an alternative name that can also be used to reach your website:

```bash
aws acm request-certificate --domain-name example.com --validation-method DNS --idempotency-token 91adc45q --subject-alternative-names www.example.com
```

You can use an asterisk (*) as a wildcard to create a certificate for several subdomains in the same domain:

```bash
aws acm request-certificate --domain-name example.com --validation-method DNS --idempotency-token 91adc45q --subject-alternative-names *.example.com
```

You can also enter multiple alternative names:

```bash
aws acm request-certificate --domain-name example.com --validation-method DNS --subject-alternative-names b.example.com c.example.com d.example.com
```

If you are using email for validation, you can enter domain validation options to specify the domain to which the validation email will be sent:

```bash
aws acm request-certificate --domain-name example.com --validation-method EMAIL --subject-alternative-names www.example.com --domain-validation-options DomainName=example.com,ValidationDomain=example.com
```

The following command opts out of certificate transparency logging when you request a new certificate:

```bash
aws acm request-certificate --domain-name www.example.com --validation-method DNS --options CertificateTransparencyLoggingPreference=DISABLED --idempotency-token 184627
```

- For API details, see [RequestCertificate](https://docs.aws.amazon.com/cli/latest/reference/acm/request-certificate.html) in *AWS CLI Command Reference*.

**resend-validation-email**

The following code example shows how to use `resend-validation-email`.

**AWS CLI**

To resend validation email for your ACM certificate request
The following `resend-validation-email` command tells the Amazon certificate authority to send validation email to the appropriate addresses:

```
aws acm resend-validation-email --certificate-arn
  arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012 --
  domain www.example.com --validation-domain example.com
```

- For API details, see [ResendValidationEmail](#) in *AWS CLI Command Reference*.

**update-certificate-options**

The following code example shows how to use `update-certificate-options`.

**AWS CLI**

**To update the certificate options**

The following `update-certificate-options` command opts out of certificate transparency logging:

```
aws acm update-certificate-options --certificate-arn
  arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012 --
  options CertificateTransparencyLoggingPreference=DISABLED
```

- For API details, see [UpdateCertificateOptions](#) in *AWS CLI Command Reference*.

create-network-profile

The following code example shows how to use `create-network-profile`.

**AWS CLI**

To create a network profile

The following `create-network-profile` example creates a network profile with the specified details.

```bash
aws alexaforbusiness create-network-profile \
   --network-profile-name Network123 \
   --ssid Janenetwork \
   --security-type WPA2_PSK \
   --current-password 12345
```

Output:

```json
{
   "NetworkProfileArn": "arn:aws:a4b:us-east-1:123456789012:network-profile/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111/a1b2c3d4-5678-90ab-cdef-EXAMPLE22222"
}
```

For more information, see [Managing Network Profiles](#) in the *Alexa for Business Administration Guide*.

- For API details, see [CreateNetworkProfile](#) in *AWS CLI Command Reference*.

delete-network-profile

The following code example shows how to use `delete-network-profile`.

**AWS CLI**

To delete a network profile
The following `delete-network-profile` example deletes the specified network profile.

```bash
aws alexaforbusiness delete-network-profile \
  --network-profile-arn arn:aws:a4b:us-east-1:123456789012:network-profile/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111/a1b2c3d4-5678-90ab-cdef-EXAMPLE22222
```

This command produces no output.

For more information, see [Managing Network Profiles](#) in the [Alexa for Business Administration Guide](#).

- For API details, see [DeleteNetworkProfile](#) in [AWS CLI Command Reference](#).

---

**get-network-profile**

The following code example shows how to use `get-network-profile`.

**AWS CLI**

**To get network profile details**

The following `get-network-profile` example retrieves details of the specified network profile.

```bash
aws alexaforbusiness get-network-profile \
  --network-profile-arn arn:aws:a4b:us-east-1:123456789012:network-profile/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

**Output:**

```json
{
  "NetworkProfile": {
    "NetworkProfileArn": "arn:aws:a4b:us-east-1:123456789012:network-profile/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111/a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
    "NetworkProfileName": "Networkprofile",
    "Ssid": "Janenetwork",
    "SecurityType": "WPA2_PSK",
    "CurrentPassword": "12345"
  }
}
```
For more information, see [Managing Network Profiles](#) in the *Alexa for Business Administration Guide*.

- For API details, see [GetNetworkProfile](#) in *AWS CLI Command Reference*.

search-network-profiles

The following code example shows how to use search-network-profiles.

**AWS CLI**

To search network profiles

The following `search-network-profiles` example lists network profiles that meet a set of filter and sort criteria. In this example, all profiles are listed.

```bash
aws alexaforbusiness search-network-profiles
```

Output:

```
{
   "NetworkProfiles": [
   {
      "NetworkProfileArn": "arn:aws:a4b:us-east-1:123456789111:network-profile/a1b2c3d4-5678-90ab-cdef-EXAMPLE22222/a1b2c3d4-5678-90ab-cdef-EXAMPLE33333",

      "NetworkProfileName": "Networkprofile3",
      "Ssid": "Carlosnetwork",
      "SecurityType": "WPA2_PSK"
   }
   ]
}
```
For more information, see Managing Network Profiles in the Alexa for Business Administration Guide.

- For API details, see SearchNetworkProfiles in AWS CLI Command Reference.

**update-network-profile**

The following code example shows how to use `update-network-profile`.

**AWS CLI**

**To update a network profile**

The following `update-network-profile` example updates the specified network profile by using the network profile ARN.

```
aws alexaforbusiness update-network-profile \\
  --network-profile-arn arn:aws:a4b:us-east-1:123456789012:network-profile/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \\
  --network-profile-name Networkprofile
```

This command produces no output.

For more information, see Managing Network Profiles in the Alexa for Business Administration Guide.

- For API details, see UpdateNetworkProfile in AWS CLI Command Reference.

**API Gateway examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with API Gateway.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.
Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Actions

create-api-key

The following code example shows how to use create-api-key.

AWS CLI

To create an API key that is enabled for an existing API and Stage

Command:

```bash
aws apigateway create-api-key --name 'Dev API Key' --description 'Used for development' --enabled --stage-keys restApiId='a1b2c3d4e5',stageName='dev'
```

- For API details, see CreateApiKey in AWS CLI Command Reference.

create-authorizer

The following code example shows how to use create-authorizer.

AWS CLI

Example 1: To create a token-based API Gateway Custom Authorizer for the API

The following create-authorizer example creates a token-based authorizer.

```bash
aws apigateway create-authorizer
    --rest-api-id 1234123412
    --name 'First_Token_Custom_Authorizer'
    --type TOKEN
```
--identity-source 'method.request.header.Authorization'\
--authorizer-result-ttl-in-seconds 300

Output:

```
{
    "authType": "custom",
    "name": "First_Token_Custom_Authorizer",
    "authorizerResultTtlInSeconds": 300,
    "identitySource": "method.request.header.Authorization",
    "type": "TOKEN",
    "id": "z40xj0"
}
```

**Example 2: To create a Cognito User Pools based API Gateway Custom Authorizer for the API**

The following `create-authorizer` example creates a Cognito User Pools based API Gateway Custom Authorizer.

```bash
aws apigateway create-authorizer \ 
    --rest-api-id 1234123412 \ 
    --name 'First_Cognito_Custom_Authorizer' \ 
    --type COGNITO_USER_POOLS \

Example 3: To create a request-based API Gateway Custom Authorizer for the API

The following `create-authorizer` example creates a request-based authorizer.

```
aws apigateway create-authorizer \
   --rest-api-id 1234123412 \
   --name 'First_Request_Custom_Authorizer' \
   --type REQUEST \
   --identity-source 'method.request.header.Authorization,context.accountId' \
   --authorizer-result-ttl-in-seconds 300
```

Output:

```
{
   "id": "z40xj0",
   "name": "First_Request_Custom_Authorizer",
   "type": "REQUEST",
   "authType": "custom",
   "identitySource": "method.request.header.Authorization,context.accountId",
   "authorizerResultTtlInSeconds": 300
}
```

- For API details, see [CreateAuthorizer](https://docs.aws.amazon.com/cli/latest/reference/apigateway/create-authorizer.html) in *AWS CLI Command Reference*.

**create-base-path-mapping**

The following code example shows how to use `create-base-path-mapping`.

**AWS CLI**

To create the base path mapping for a custom domain name

Command:

```
aws apigateway create-base-path-mapping --domain-name subdomain.domain.tld --rest-api-id 1234123412 --stage prod --base-path v1
```

- For API details, see [CreateBasePathMapping](https://docs.aws.amazon.com/cli/latest/reference/apigateway/create-base-path-mapping.html) in *AWS CLI Command Reference*.
create-deployment

The following code example shows how to use create-deployment.

AWS CLI

To deploy the configured resources for an API to a new Stage

Command:

```bash
aws apigateway create-deployment --rest-api-id 1234123412 --stage-name dev --stage-description 'Development Stage' --description 'First deployment to the dev stage'
```

To deploy the configured resources for an API to an existing stage

Command:

```bash
aws apigateway create-deployment --rest-api-id 1234123412 --stage-name dev --description 'Second deployment to the dev stage'
```

To deploy the configured resources for an API to an existing stage with Stage Variables

```bash
aws apigateway create-deployment --rest-api-id 1234123412 --stage-name dev --description 'Third deployment to the dev stage' --variables key='value',otherKey='otherValue'
```

- For API details, see [CreateDeployment](https://docs.aws.amazon.com/cli/latest/reference/apigateway/create-deployment.html) in *AWS CLI Command Reference*.

create-domain-name

The following code example shows how to use create-domain-name.

AWS CLI

To create the custom domain name

Command:

```bash
aws apigateway create-domain-name --domain-name 'my.domain.tld' --certificate-name 'my.domain.tld cert' --certificate-arn 'arn:aws:acm:us-east-1:012345678910:certificate/fb1b9770-a305-495d-aefb-27e5e101ff3'
```
create-model

The following code example shows how to use `create-model`.

**AWS CLI**

**To create a model for an API**

**Command:**

```bash
aws apigateway create-model --rest-api-id 1234123412 --name 'firstModel' --description 'The First Model' --content-type 'application/json' --schema '{ "$schema": "http://json-schema.org/draft-04/schema#", "title": "firstModel", "type": "object", "properties": { "firstProperty": { "type": "object", "properties": { "key": { "type": "string" } } } } }'
```

**Output:**

```json
{
    "contentType": "application/json",
    "description": "The First Model",
    "name": "firstModel",
    "id": "2rzg0l",
    "schema": '{ "$schema": "http://json-schema.org/draft-04/schema#", "title": "firstModel", "type": "object", "properties": { "firstProperty": { "type": "object", "properties": { "key": { "type": "string" } } } } }'
}
```

- For API details, see [CreateDomainName](#) in *AWS CLI Command Reference*.

create-resource

The following code example shows how to use `create-resource`.

**AWS CLI**

**To create a resource in an API**

**Command:**

```bash
aws apigateway create-model --rest-api-id 1234123412 --name 'firstModel' --description 'The First Model' --content-type 'application/json' --schema '{ "$schema": "http://json-schema.org/draft-04/schema#", "title": "firstModel", "type": "object", "properties": { "firstProperty": { "type": "object", "properties": { "key": { "type": "string" } } } } }'
```

**Output:**

```json
{
    "contentType": "application/json",
    "description": "The First Model",
    "name": "firstModel",
    "id": "2rzg0l",
    "schema": '{ "$schema": "http://json-schema.org/draft-04/schema#", "title": "firstModel", "type": "object", "properties": { "firstProperty": { "type": "object", "properties": { "key": { "type": "string" } } } } }'
}
```

- For API details, see [CreateModel](#) in *AWS CLI Command Reference*. 
aws apigateway create-resource --rest-api-id 1234123412 --parent-id a1b2c3 --path-part 'new-resource'

- For API details, see CreateResource in AWS CLI Command Reference.

create-rest-api

The following code example shows how to use create-rest-api.

AWS CLI

To create an API

Command:

aws apigateway create-rest-api --name 'My First API' --description 'This is my first API'

To create a duplicate API from an existing API

Command:

aws apigateway create-rest-api --name 'Copy of My First API' --description 'This is a copy of my first API' --clone-from 1234123412

- For API details, see CreateRestApi in AWS CLI Command Reference.

create-stage

The following code example shows how to use create-stage.

AWS CLI

To create a stage in an API which will contain an existing deployment

Command:

aws apigateway create-stage --rest-api-id 1234123412 --stage-name 'dev' --description 'Development stage' --deployment-id a1b2c3
To create a stage in an API which will contain an existing deployment and custom Stage Variables

Command:

```
aws apigateway create-stage --rest-api-id 1234123412 --stage-name 'dev'
   --description 'Development stage' --deployment-id a1b2c3 --variables
   key='value',otherKey='otherValue'
```

- For API details, see CreateStage in AWS CLI Command Reference.

create-usage-plan-key

The following code example shows how to use create-usage-plan-key.

AWS CLI

**Associate an existing API key with a Usage Plan**

Command:

```
aws apigateway create-usage-plan-key --usage-plan-id a1b2c3 --key-type "API_KEY" --key-id 4vq3yryqm5
```

- For API details, see CreateUsagePlanKey in AWS CLI Command Reference.

create-usage-plan

The following code example shows how to use create-usage-plan.

AWS CLI

**To create a usage plan with throttle and quota limits that resets at the beginning of the month**

Command:

```
aws apigateway create-usage-plan --name "New Usage Plan" --description "A new usage plan" --throttle burstLimit=10,rateLimit=5 --quota limit=500,offset=0,period=MONTH
```

- For API details, see CreateUsagePlan in AWS CLI Command Reference.
delete-api-key

The following code example shows how to use delete-api-key.

**AWS CLI**

**To delete an API key**

Command:

```
aws apigateway delete-api-key --api-key 8bk1k8bl1k3sB38D9B3l0enyWT8c09B30lkq0bk
```

- For API details, see [DeleteApiKey](#) in *AWS CLI Command Reference*.

delete-authorizer

The following code example shows how to use delete-authorizer.

**AWS CLI**

**To delete a Custom Authorizer in an API**

Command:

```
aws apigateway delete-authorizer --rest-api-id 1234123412 --authorizer-id 7gkfbo
```

- For API details, see [DeleteAuthorizer](#) in *AWS CLI Command Reference*.

delete-base-path-mapping

The following code example shows how to use delete-base-path-mapping.

**AWS CLI**

**To delete a base path mapping for a custom domain name**

Command:

```
aws apigateway delete-base-path-mapping --domain-name 'api.domain.tld' --base-path 'dev'
```

- For API details, see [DeleteBasePathMapping](#) in *AWS CLI Command Reference*.  

---

Actions and scenarios 418
delete-client-certificate

The following code example shows how to use delete-client-certificate.

AWS CLI

To delete a client certificate

Command:

```
aws apigateway delete-client-certificate --client-certificate-id a1b2c3
```

delete-deployment

The following code example shows how to use delete-deployment.

AWS CLI

To delete a deployment in an API

Command:

```
aws apigateway delete-deployment --rest-api-id 1234123412 --deployment-id a1b2c3
```

- For API details, see [DeleteDeployment](https://awscli.amazonaws.com/v2/documentation/api/latest/reference/apigateway/delete-deployment.html) in *AWS CLI Command Reference*.

delete-domain-name

The following code example shows how to use delete-domain-name.

AWS CLI

To delete a custom domain name

Command:

```
aws apigateway delete-domain-name --domain-name 'api.domain.tld'
```

- For API details, see [DeleteDomainName](https://awscli.amazonaws.com/v2/documentation/api/latest/reference/apigateway/delete-domain-name.html) in *AWS CLI Command Reference*. 
delete-integration-response

The following code example shows how to use delete-integration-response.

AWS CLI

To delete an integration response for a given resource, method, and status code in an API

Command:

```
aws apigateway delete-integration-response --rest-api-id 1234123412 --resource-id a1b2c3 --http-method GET --status-code 200
```

- For API details, see DeleteIntegrationResponse in AWS CLI Command Reference.

delete-integration

The following code example shows how to use delete-integration.

AWS CLI

To delete an integration for a given resource and method in an API

Command:

```
aws apigateway delete-integration --rest-api-id 1234123412 --resource-id a1b2c3 --http-method GET
```

- For API details, see DeleteIntegration in AWS CLI Command Reference.

delete-method-response

The following code example shows how to use delete-method-response.

AWS CLI

To delete a method response for the given resource, method, and status code in an API

Command:

```
aws apigateway delete-method-response --rest-api-id 1234123412 --resource-id a1b2c3 --http-method GET --status-code 200
```
• For API details, see DeleteMethodResponse in AWS CLI Command Reference.

delete-method

The following code example shows how to use delete-method.

AWS CLI

To delete a method for the given resource in an API

Command:

```
aws apigateway delete-method --rest-api-id 1234123412 --resource-id a1b2c3 --http-method GET
```

• For API details, see DeleteMethod in AWS CLI Command Reference.

delete-model

The following code example shows how to use delete-model.

AWS CLI

To delete a model in the given API

Command:

```
aws apigateway delete-model --rest-api-id 1234123412 --model-name 'customModel'
```

• For API details, see DeleteModel in AWS CLI Command Reference.

delete-resource

The following code example shows how to use delete-resource.

AWS CLI

To delete a resource in an API

Command:
aws apigateway delete-resource --rest-api-id 1234123412 --resource-id a1b2c3

- For API details, see DeleteResource in AWS CLI Command Reference.

deliste-rest-api

The following code example shows how to use delete-rest-api.

AWS CLI

To delete an API

Command:

aws apigateway delete-rest-api --rest-api-id 1234123412

- For API details, see DeleteRestApi in AWS CLI Command Reference.

delete-stage

The following code example shows how to use delete-stage.

AWS CLI

To delete a stage in an API

Command:

aws apigateway delete-stage --rest-api-id 1234123412 --stage-name 'dev'

- For API details, see DeleteStage in AWS CLI Command Reference.

deliste-usage-plan-key

The following code example shows how to use delete-usage-plan-key.

AWS CLI

To remove an API key from a Usage Plan

Command:
aws apigateway delete-usage-plan-key --usage-plan-id a1b2c3 --key-id 1NbjQzMReAkeEQPNAW8r3dXsU2rDD7fc7f2Sipnu

• For API details, see DeleteUsagePlanKey in AWS CLI Command Reference.

dele-usage-plan

The following code example shows how to use delete-usage-plan.

AWS CLI

To delete a Usage Plan

Command:

aws apigateway delete-usage-plan --usage-plan-id a1b2c3

• For API details, see DeleteUsagePlan in AWS CLI Command Reference.

flush-stage-authorizers-cache

The following code example shows how to use flush-stage-authorizers-cache.

AWS CLI

To flush all authorizer cache entries on a stage

Command:

aws apigateway flush-stage-authorizers-cache --rest-api-id 1234123412 --stage-name dev

• For API details, see FlushStageAuthorizersCache in AWS CLI Command Reference.

flush-stage-cache

The following code example shows how to use flush-stage-cache.

AWS CLI

To flush the cache for an API's stage
Command:

```bash
aws apigateway flush-stage-cache --rest-api-id 12341234122 --stage-name dev
```

- For API details, see [FlushStageCache](https://docs.aws.amazon.com/cli/latest/reference/apigateway/flush-stage-cache.html) in *AWS CLI Command Reference*.

### generate-client-certificate

The following code example shows how to use `generate-client-certificate`.

**AWS CLI**

**To create a Client-Side SSL Certificate**

Command:

```bash
aws apigateway generate-client-certificate --description 'My First Client Certificate'
```

### get-account

The following code example shows how to use `get-account`.

**AWS CLI**

**To get API Gateway account settings**

Command:

```bash
aws apigateway get-account
```

Output:

```
{
   "cloudwatchRoleArn": "arn:aws:iam::123412341234:role/APIGatewayToCloudWatchLogsRole",
   "throttleSettings": {
      "rateLimit": 500.0,
      "burstLimit": 1000
   }
}
```
get-api-key

The following code example shows how to use get-api-key.

**AWS CLI**

To get the information about a specific API key

**Command:**

```bash
aws apigateway get-api-key --api-key 8bklk8b1l1k3sB38D9B3l0enyWT8c09B30lkq0blk
```

**Output:**

```json
{
   "description": "My first key",
   "enabled": true,

   "name": "My key"
}
```

**get-api-keys**

The following code example shows how to use get-api-keys.

**AWS CLI**

To get the list of API keys

• For API details, see [GetAccount](#) in *AWS CLI Command Reference*.

• For API details, see [GetApiKey](#) in *AWS CLI Command Reference*. 
Command:

aws apigateway get-api-keys

Output:

```json
{
  "items": [
    {
      "description": "My first key",
      "enabled": true,
      "stageKeys": [
        "a1b2c3d4e5/dev",
        "e5d4c3b2a1/dev"
      ],

      "name": "My key"
    }
  ]
}
```

- For API details, see [GetApiKeys](#) in *AWS CLI Command Reference*.

**get-authorizer**

The following code example shows how to use `get-authorizer`.

**AWS CLI**

To get the API Gateway per-API Authorizer settings

Command:

```
aws apigateway get-authorizer --rest-api-id 1234123412 --authorizer-id gfi4n3
```

Output:

```json
{
```

```
"authorizerResultTtlInSeconds": 300,
"name": "MyAuthorizer",
"type": "TOKEN",
"identitySource": "method.request.header.Authorization",
"id": "gfi4n3"
}

- For API details, see [GetAuthorizer](https://aws.amazon.com/documentation/cli/reference/generic/get-authorizer) in *AWS CLI Command Reference*.

**get-authorizers**

The following code example shows how to use get-authorizers.

**AWS CLI**

To get the list of authorizers for a REST API

Command:

```bash
aws apigateway get-authorizers --rest-api-id 1234123412
```

Output:

```json
{
   "items": [
      {
         "name": "MyAuthorizer",
         "authorizerResultTtlInSeconds": 300,
         "identitySource": "method.request.header.Authorization",
         "type": "TOKEN",
         "id": "gfi4n3"
      }
   ]
}
```

- For API details, see [GetAuthorizers](https://aws.amazon.com/documentation/cli/reference/generic/get-authorizers) in *AWS CLI Command Reference*. 
get-base-path-mapping

The following code example shows how to use get-base-path-mapping.

AWS CLI

To get the base path mapping for a custom domain name

Command:

```
aws apigateway get-base-path-mapping --domain-name subdomain.domain.tld --base-path v1
```

Output:

```
{
    "basePath": "v1",
    "restApiId": "1234w4321e",
    "stage": "api"
}
```

get-base-path-mappings

The following code example shows how to use get-base-path-mappings.

AWS CLI

To get the base path mappings for a custom domain name

Command:

```
aws apigateway get-base-path-mappings --domain-name subdomain.domain.tld
```

Output:

```
{
    "items": [
        {
```
**get-client-certificate**

The following code example shows how to use `get-client-certificate`.

**AWS CLI**

**To get a client certificate**

Command:

```
aws apigateway get-client-certificate --client-certificate-id a1b2c3
```

For API details, see [GetClientCertificate](#) in *AWS CLI Command Reference*.

**get-client-certificates**

The following code example shows how to use `get-client-certificates`.

**AWS CLI**

**To get a list of client certificates**

Command:

```
aws apigateway get-client-certificates
```

Output:

For API details, see [GetClientCertificate](#) in *AWS CLI Command Reference*. 
For API details, see [GetClientCertificates](#) in *AWS CLI Command Reference*.

**get-deployment**

The following code example shows how to use `get-deployment`.

**AWS CLI**

**To get information about a deployment**

Command:

```sh
aws apigateway get-deployment --rest-api-id 1234123412 --deployment-id ztt4m2
```

Output:

```json
{
   "description": "myDeployment",
   "id": "ztt4m2",
   "createdDate": 1455218022
}
```

For API details, see [GetDeployment](#) in *AWS CLI Command Reference*.

**get-deployments**

The following code example shows how to use `get-deployments`.

```json
{
   "items": [
      {
         "pemEncodedCertificate": "-----BEGIN CERTIFICATE----- <certificate content> -----END CERTIFICATE-----",
         "clientCertificateId": "a1b2c3",

```

- For API details, see [GetDeployments](https://aws.amazon.com) in *AWS CLI Command Reference*.

**get-domain-name**

The following code example shows how to use `get-domain-name`.

AWS CLI

**To get information about a custom domain name**

Command:

```
aws apigateway get-domain-name --domain-name api.domain.tld
```

Output:

```json
{
   "domainName": "api.domain.tld",
   "distributionDomainName": "d1a2f3a4c5o6d.cloudfront.net",
   "certificateName": "uploadedCertificate"
}
```
For API details, see GetDomainName in AWS CLI Command Reference.

get-domain-names

The following code example shows how to use get-domain-names.

AWS CLI

To get a list of custom domain names

Command:

```
aws apigateway get-domain-names
```

Output:

```
{
  "items": [
    {
      "distributionDomainName": "d9511k3l09bkd.cloudfront.net",

    }
  ]
}
```

For API details, see GetDomainNames in AWS CLI Command Reference.

get-export

The following code example shows how to use get-export.

AWS CLI

To get the JSON Swagger template for a stage

Command:
aws apigateway get-export --rest-api-id a1b2c3d4e5 --stage-name dev --export-type swagger /path/to/filename.json

**To get the JSON Swagger template + API Gateway Extentions for a stage**

Command:

aws apigateway get-export --parameters extensions='integrations' --rest-api-id a1b2c3d4e5 --stage-name dev --export-type swagger /path/to/filename.json

**To get the JSON Swagger template + Postman Extensions for a stage**

Command:

aws apigateway get-export --parameters extensions='postman' --rest-api-id a1b2c3d4e5 --stage-name dev --export-type swagger /path/to/filename.json

- For API details, see GetExport in AWS CLI Command Reference.

get-integration-response

The following code example shows how to use get-integration-response.

**AWS CLI**

**To get the integration response configuration for a HTTP method defined under a REST API's resource**

Command:

aws apigateway get-integration-response --rest-api-id 1234123412 --resource-id y9h6rt --http-method GET --status-code 200

Output:

{
  "statusCode": "200",
  "responseTemplates": {
    "application/json": null
  }
}
get-integration

The following code example shows how to use get-integration.

AWS CLI

To get the integration configuration for a HTTP method defined under a REST API's resource

Command:

```bash
aws apigateway get-integration --rest-api-id 1234123412 --resource-id y9h6rt --http-method GET
```

Output:

```json

**get-model-template**

The following code example shows how to use `get-model-template`.

**AWS CLI**

To get the mapping template for a model defined under a REST API

**Command:**

```bash
aws apigateway get-model-template --rest-api-id 1234123412 --model-name Empty
```

**Output:**

```json
{

}
```
get-model

The following code example shows how to use get-model.

AWS CLI

To get the configuration for a model defined under a REST API

Command:

```bash
aws apigateway get-model --rest-api-id 1234123412 --model-name Empty
```

Output:

```json
{
    "contentType": "application/json",
    "description": "This is a default empty schema model",
    "name": "Empty",
    "id": "etd5w5",
    "schema": "{
      "$schema": "http://json-schema.org/draft-04/schema#",
      "title": "Empty Schema",
      "type": "object"
    }"
}
```

For API details, see `GetModelTemplate` in AWS CLI Command Reference.

get-models

The following code example shows how to use get-models.

AWS CLI

To get a list of models for a REST API

Command:

```bash
aws apigateway get-models --rest-api-id 1234123412
```
Output:

```json
{
   "items": [
       {
           "description": "This is a default error schema model",
           "schema": "{
                         "$schema": "http://json-schema.org/draft-04/schema#",
                         "title": "Error Schema",
                         "type": "object",
                         "properties": {
                            "message": { "type": "string" }
                         }
                      }",
           "contentType": "application/json",
           "id": "7tpbze",
           "name": "Error"
       },
       {
           "description": "This is a default empty schema model",
           "schema": "{
                         "$schema": "http://json-schema.org/draft-04/schema#",
                         "title": "Empty Schema",
                         "type": "object"
                      }",
           "contentType": "application/json",
           "id": "etd5w5",
           "name": "Empty"
       }
   ]
}
```

- For API details, see [GetModels](awscli://GetModels) in *AWS CLI Command Reference*.

**get-resource**

The following code example shows how to use `get-resource`.

**AWS CLI**

To get information about a resource

Command:

```
aws apigateway get-resource --rest-api-id 1234123412 --resource-id zwo0y3
```

Output:

```json
{

```
get-resources

The following code example shows how to use get-resources.

AWS CLI

To get a list of resources for a REST API

Command:

```bash
grep apigateway get-resources --rest-api-id 1234123412
```

Output:

```json
{
  "items": [
    {
      "path": "/resource/subresource",
      "resourceMethods": {
        "POST": {}
      },
      "id": "024ace",
      "pathPart": "subresource",
      "parentId": "ai5b02"
    }
  ]
}
```

get-rest-api

The following code example shows how to use get-rest-api.

• For API details, see GetResource in AWS CLI Command Reference.

• For API details, see GetResources in AWS CLI Command Reference.
AWS CLI

To get information about an API

Command:

```bash
aws apigateway get-rest-api --rest-api-id 1234123412
```

Output:

```json
{
   "name": "myAPI",
   "id": "o1y243m4f5",
   "createdDate": 1453416433
}
```

• For API details, see [GetRestApi](awscli/command-reference/aws-apigateway-get-rest-api) in AWS CLI Command Reference.

get-rest-apis

The following code example shows how to use get-rest-apis.

AWS CLI

To get a list of REST APIs

Command:

```bash
aws apigateway get-rest-apis
```

Output:

```json
{
   "items": [
      {
         "createdDate": 1438884790,
         "id": "12s44z21rb",
         "name": "My First API"
      }
   ]
}
```
• For API details, see GetRestApis in AWS CLI Command Reference.

get-sdk

The following code example shows how to use get-sdk.

AWS CLI

To get the Android SDK for a REST API stage

Command:

```bash
aws apigateway get-sdk --rest-api-id 1234123412 --stage-name dev --sdk-type android --parameters
  groupId='com.mycompany',invokerPackage='com.mycompany.clientsdk',artifactId='Mycompany-client',artifactVersion='1.0.0' /path/to/android_sdk.zip
```

Output:

```json
{
  "contentType": "application/octet-stream",
  "contentDisposition": "attachment; filename=\"android_2016-02-22_23-52Z.zip\"
}
```

To get the IOS SDK for a REST API stage

Command:

```bash
aws apigateway get-sdk --rest-api-id 1234123412 --stage-name dev --sdk-type objectivec --parameters classPrefix='myprefix' /path/to/iOS_sdk.zip
```

Output:

```json
{
  "contentType": "application/octet-stream",
  "contentDisposition": "attachment; filename=\"objectivec_2016-02-22_23-52Z.zip\"
}
```
To get the Javascript SDK for a REST API stage

Command:

```
aws apigateway get-sdk --rest-api-id 1234123412 --stage-name dev --sdk-type javascript /path/to/javascript_sdk.zip
```

Output:

```
{
    "contentType": "application/octet-stream",
    "contentDisposition": "attachment; filename="javascript_2016-02-22_23-52Z.zip"
}
```

- For API details, see [GetSdk](aws-cli-command-reference) in *AWS CLI Command Reference*.

**get-stage**

The following code example shows how to use `get-stage`.

**AWS CLI**

To get information about an API's stage

Command:

```
aws apigateway get-stage --rest-api-id 1234123412 --stage-name dev
```

Output:

```
{
    "stageName": "dev",
    "cacheClusterSize": "0.5",
    "cacheClusterEnabled": false,
    "cacheClusterStatus": "NOT_AVAILABLE",
    "deploymentId": "rbh1fj",

}

- For API details, see `GetStage` in AWS CLI Command Reference.

**get-stages**

The following code example shows how to use `get-stages`.

**AWS CLI**

**To get the list of stages for a REST API**

Command:

```
aws apigateway get-stages --rest-api-id 1234123412
```
Output:

```json
{
    "item": [
        {
            "stageName": "dev",

            }
        }
    ]
}
```

For API details, see [GetStages](https://docs.aws.amazon.com/cli/latest/reference/apigateway/get-stages) in *AWS CLI Command Reference*.

### get-usage-plan-key

The following code example shows how to use `get-usage-plan-key`.

**AWS CLI**

To get the details of an API key associated with a Usage Plan

**Command:**

```bash
aws apigateway get-usage-plan-key --usage-plan-id a1b2c3 --key-id 1NbjQzMReAkeEQPNAW8r3dXsU2rDD7fc7f2Sipnu
```
get-usage-plan-keys

The following code example shows how to use get-usage-plan-keys.

**AWS CLI**

To get the list of API keys associated with a Usage Plan

Command:

```bash
aws apigateway get-usage-plan-keys --usage-plan-id a1b2c3
```

For API details, see [GetUsagePlanKeys](aws_cli/command_reference) in *AWS CLI Command Reference*.

get-usage-plan

The following code example shows how to use get-usage-plan.

**AWS CLI**

To get the details of a Usage Plan

Command:

```bash
aws apigateway get-usage-plan --usage-plan-id a1b2c3
```

For API details, see [GetUsagePlan](aws_cli/command_reference) in *AWS CLI Command Reference*.

get-usage-plans

The following code example shows how to use get-usage-plans.

**AWS CLI**

To get the details of all Usage Plans

Command:
aws apigateway get-usage-plans

- For API details, see `GetUsagePlans` in *AWS CLI Command Reference*.

**get-usage**

The following code example shows how to use `get-usage`.

**AWS CLI**

**To get the usage details for a Usage Plan**

Command:

```
aws apigateway get-usage --usage-plan-id a1b2c3 --start-date "2016-08-16" --end-date "2016-08-17"
```

- For API details, see `GetUsage` in *AWS CLI Command Reference*.

**import-rest-api**

The following code example shows how to use `import-rest-api`.

**AWS CLI**

**To import a Swagger template and create an API**

Command:

```
aws apigateway import-rest-api --body 'file:///path/to/API_Swagger_template.json'
```

- For API details, see `ImportRestApi` in *AWS CLI Command Reference*.

**put-integration-response**

The following code example shows how to use `put-integration-response`.

**AWS CLI**

**To create an integration response as the default response with a mapping template defined**
Command:

```
aws apigateway put-integration-response --rest-api-id 1234123412 --resource-id a1b2c3 --http-method GET --status-code 200 --selection-pattern "" --response-templates '{"application/json": "{\"json\": \"template\"}\"'}
```

To create an integration response with a regex of 400 and a statically defined header value

Command:

```
aws apigateway put-integration-response --rest-api-id 1234123412 --resource-id a1b2c3 --http-method GET --status-code 400 --selection-pattern 400 --response-parameters '{"method.response.header.custom-header": "custom-value"'}
```

- For API details, see **PutIntegrationResponse** in *AWS CLI Command Reference*.

**put-integration**

The following code example shows how to use `put-integration`.

**AWS CLI**

To create a MOCK integration request

Command:

```
aws apigateway put-integration --rest-api-id 1234123412 --resource-id a1b2c3 --http-method GET --type MOCK --request-templates '{ "application/json": "{\"statusCode\": 200}\"'}
```

To create a HTTP integration request

Command:

```
aws apigateway put-integration --rest-api-id 1234123412 --resource-id a1b2c3 --http-method GET --type HTTP --integration-http-method GET --uri 'https://domain.tld/path'
```

To create an AWS integration request with a Lambda Function endpoint

Command:

- For API details, see PutIntegration in AWS CLI Command Reference.

**put-method-response**

The following code example shows how to use put-method-response.

**AWS CLI**

*To create a method response under the specified status code with a custom method response header*

Command:

```
aws apigateway put-method-response --rest-api-id 1234123412 --resource-id a1b2c3 --http-method GET --status-code 400 --response-parameters "method.response.header.custom-header=false"
```

- For API details, see PutMethodResponse in AWS CLI Command Reference.

**put-method**

The following code example shows how to use put-method.

**AWS CLI**

*To create a method for a resource in an API with no authorization, no API key, and a custom method request header*

Command:

```
aws apigateway put-method --rest-api-id 1234123412 --resource-id a1b2c3 --http-method PUT --authorization-type "NONE" --no-api-key-required --request-parameters "method.request.header.custom-header=false"
```

- For API details, see PutMethod in AWS CLI Command Reference.
put-rest-api

The following code example shows how to use put-rest-api.

AWS CLI

To overwrite an existing API using a Swagger template

Command:

```
aws apigateway put-rest-api --rest-api-id 1234123412 --mode overwrite --body 'fileb:///path/to/API_Swagger_template.json'
```

To merge a Swagger template into an existing API

Command:

```
aws apigateway put-rest-api --rest-api-id 1234123412 --mode merge --body 'fileb:///path/to/API_Swagger_template.json'
```

• For API details, see PutRestApi in AWS CLI Command Reference.

test-invoker-authorizer

The following code example shows how to use test-invoke-authorizer.

AWS CLI

To test invoke a request to a Custom Authorizer including the required header and value

Command:

```
aws apigateway test-invoker-authorizer --rest-api-id 1234123412 --authorizer-id 5yid1t --headers Authorization='Value'
```

• For API details, see TestInvokeAuthorizer in AWS CLI Command Reference.

test-invoker-method

The following code example shows how to use test-invoker-method.
AWS CLI

To test invoke the root resource in an API by making a GET request

Command:

```
aws apigateway test-invoke-method --rest-api-id 1234123412 --resource-id avl5sg8fw8 --http-method GET --path-with-query-string '='/
```

To test invoke a sub-resource in an API by making a GET request with a path parameter value specified

Command:

```
aws apigateway test-invoke-method --rest-api-id 1234123412 --resource-id 3gapai --http-method GET --path-with-query-string '/pets/1'
```

- For API details, see [TestInvokeMethod](#) in *AWS CLI Command Reference*.

update-account

The following code example shows how to use `update-account`.

AWS CLI

To change the IAM Role ARN for logging to CloudWatch Logs

Command:

```
aws apigateway update-account --patch-operations op='replace',path='/cloudwatchRoleArn',value='arn:aws:iam::123412341234:role/APIGatewayToCloudWatchLogs'
```

Output:

```json
{
  "cloudwatchRoleArn": "arn:aws:iam::123412341234:role/APIGatewayToCloudWatchLogs",
  "throttleSettings": {
    "rateLimit": 1000.0,
    "burstLimit": 2000
  }
}
```
update-api-key

The following code example shows how to use update-api-key.

AWS CLI

To change the name for an API Key

Command:

```bash
aws apigateway update-api-key --api-key sNvjQDMReA1eEQPNAW8r37XsU2tDD7fc7m2SiMnu --patch-operations op='replace',path='/name',value='newName'
```

Output:

```json
{
   "description": "currentDescription",
   "enabled": true,
   "stageKeys": [
      "41t2j324r5/dev"
   ],
   "lastUpdatedDate": 1470086052,
   "createdDate": 1445460347,
   "id": "sNvjQDMReA1vEQPNzW8r3dXsU2rrD7fcjm2SiMnu",
   "name": "newName"
}
```

To disable the API Key

Command:

```bash
aws apigateway update-api-key --api-key sNvjQDMReA1eEQPNAW8r37XsU2tDD7fc7m2SiMnu --patch-operations op='replace',path='/enabled',value='false'
```

Output:

```json
{ 
}
```
For API details, see UpdateApiKey in AWS CLI Command Reference.

**update-authorizer**

The following code example shows how to use update-authorizer.

**AWS CLI**

To change the name of the Custom Authorizer

Command:

```bash
aws apigateway update-authorizer --rest-api-id 1234123412 --authorizer-id gfi4n3 --patch-operations op='replace',path='/name',value='testAuthorizer'
```

Output:

```json
{
   "authType": "custom",
   "name": "testAuthorizer",
   "authorizerResultTtlInSeconds": 300,
   "identitySource": "method.request.header.Authorization",
   "type": "TOKEN",
   "id": "gfi4n3"
}
```

To change the Lambda Function that is invoked by the Custom Authorizer
Command:

```bash
```

Output:

```
{
    "authType": "custom",
    "name": "testAuthorizer",
    "authorizerResultTtlInSeconds": 300,
    "identitySource": "method.request.header.Authorization",
    "type": "TOKEN",
    "id": "gfi4n3"
}
```

- For API details, see [UpdateAuthorizer](https://docs.aws.amazon.com/cli/latest/reference/apigateway/update-authorizer.html) in *AWS CLI Command Reference*.

**update-base-path-mapping**

The following code example shows how to use `update-base-path-mapping`.

**AWS CLI**

**To change the base path for a custom domain name**

Command:

```bash
aws apigateway update-base-path-mapping --domain-name api.domain.tld --base-path prod --patch-operations op='replace',path='/basePath',value='v1'
```

Output:

```
{
    "basePath": "v1",
    "restApiId": "1234123412",
    "stage": "api"
}
```
update-client-certificate

The following code example shows how to use update-client-certificate.

AWS CLI

**To update the description of a client certificate**

Command:

```
aws apigateway update-client-certificate --client-certificate-id a1b2c3 --patch-operations op='replace',path='/description',value='My new description'
```

For API details, see [UpdateClientCertificate](#) in AWS CLI Command Reference.

update-deployment

The following code example shows how to use update-deployment.

AWS CLI

**To change the description of a deployment**

Command:

```
aws apigateway update-deployment --rest-api-id 1234123412 --deployment-id ztt4m2 --patch-operations op='replace',path='/description',value='newDescription'
```

Output:

```
{
    "description": "newDescription",
    "id": "ztt4m2",
    "createdDate": 1455218022
}
```

For API details, see [UpdateDeployment](#) in AWS CLI Command Reference.
update-domain-name

The following code example shows how to use update-domain-name.

AWS CLI

To change the certificate name for a custom domain name

The following update-domain-name example changes the certificate name for a custom domain.

```bash
aws apigateway update-domain-name \
   --domain-name api.domain.tld \
   --patch-operations op='replace',path='/certificateArn',value='arn:aws:acm:us-west-2:111122223333:certificate/CERTEXAMPLE123EXAMPLE'
```

Output:

```json
{
   "domainName": "api.domain.tld",
   "distributionDomainName": "d123456789012.cloudfront.net",
   "certificateUploadDate": 1462565487
}
```

For more information, see [Set up Custom Domain Name for an API in API Gateway](https://docs.aws.amazon.com/apigateway/latest/developerguide/set-up-custom-domain.html) in the [Amazon API Gateway Developer Guide](https://docs.aws.amazon.com/apigateway/latest/developerguide/)

update-integration-response

The following code example shows how to use update-integration-response.

AWS CLI

To change an integration response header to have a static mapping of '*'

Command:

```bash
aws apigateway update-integration-response --rest-api-id 1234123412 --resource-id 3gapai --http-method GET --status-code 200 --patch-operations
```
The following code example shows how to use `update-integration`.

**AWS CLI**

**To add the 'Content-Type: application/json' Mapping Template configured with Input Passthrough**

Command:

```bash
aws apigateway update-integration \ 
   --rest-api-id a1b2c3d4e5 \ 
   --resource-id a1b2c3 \ 
   --http-method POST \ 
   --patch-operations "op='add',path='/requestTemplates/application~1json'"
```

**To update (replace) the 'Content-Type: application/json' Mapping Template configured with a custom template**

Command:

```bash
aws apigateway update-integration \ 
   --rest-api-id a1b2c3d4e5 \ 
   --resource-id a1b2c3 \ 
   --http-method POST \ 
```

Output:

```json
{
   "statusCode": "200",
   "responseParameters": {
      "method.response.header.Access-Control-Allow-Origin": "*"
   }
}
```

**To remove an integration response header**

Command:

```bash
```

The following code example shows how to use `update-integration`.

**AWS CLI**

**To add the 'Content-Type: application/json' Mapping Template configured with Input Passthrough**

Command:

```bash
aws apigateway update-integration \ 
   --rest-api-id a1b2c3d4e5 \ 
   --resource-id a1b2c3 \ 
   --http-method POST \ 
   --patch-operations "op='add',path='/requestTemplates/application~1json'"
```

**To update (replace) the 'Content-Type: application/json' Mapping Template configured with a custom template**

Command:

```bash
aws apigateway update-integration \ 
   --rest-api-id a1b2c3d4e5 \ 
   --resource-id a1b2c3 \ 
   --http-method POST \ 
```
Command:

```bash
aws apigateway update-integration \
   --rest-api-id a1b2c3d4e5 \
   --resource-id a1b2c3 \
   --http-method POST \
   --patch-operations "op='replace',path='/requestTemplates/application~1json',value='{"example": "json"}'''
```

**To update (replace) a custom template associated with 'Content-Type: application/json' with Input Passthrough**

Command:

```bash
aws apigateway update-integration \
   --rest-api-id a1b2c3d4e5 \
   --resource-id a1b2c3 \
   --http-method POST \
   --patch-operations "op='replace',path='requestTemplates/application~1json'''
```

**To remove the 'Content-Type: application/json' Mapping Template**

Command:

```bash
aws apigateway update-integration \
   --rest-api-id a1b2c3d4e5 \
   --resource-id a1b2c3 \
   --http-method POST \
   --patch-operations "op='remove',path='/requestTemplates/application~1json'''
```

- For API details, see [UpdateIntegration](#) in [AWS CLI Command Reference](#).

**update-method-response**

The following code example shows how to use update-method-response.

**AWS CLI**

To create a new method response header for the 200 response in a method and define it as not required (default)
To delete a response model for the 200 response in a method

Command:

```
aws apigateway update-method-response --rest-api-id 1234123412 --resource-id a1b2c3 --http-method GET --status-code 200 --patch-operations op="remove",path="/responseModels/application~1json"
```

- For API details, see UpdateMethodResponse in AWS CLI Command Reference.

update-method

The following code example shows how to use update-method.

AWS CLI

**Example 1: To modify a method to require an API key**

The following update-method example modifies the method to require an API key.

```
aws apigateway update-method \\
    --rest-api-id 1234123412 \\
    --resource-id a1b2c3 \\
    --http-method GET \\
    --patch-operations op="replace",path="/apiKeyRequired",value="true"
```

Output:

```json
{
    "httpMethod": "GET",
    "authorizationType": "NONE",
    "apiKeyRequired": true,
    "methodResponses": {
        "200": {
            "statusCode": "200",
```
Example 2: To modify a method to require IAM authorization

The following update-method example modifies the method to require IAM authorization.

```bash
aws apigateway update-method \
  --rest-api-id 1234123412 \
  --resource-id a1b2c3 \
  --http-method GET \
  --patch-operations op="replace",path="/authorizationType",value="AWS_IAM"
```

Output:

```json
{
  "httpMethod": "GET",
  "authorizationType": "AWS_IAM",
  "apiKeyRequired": false,
  "methodResponses": {
    "200": {
      "statusCode": "200",
      "responseModels": {}
    }
  }
}
```
Example 3: To modify a method to require Lambda authorization

The following update-method example modifies the method to required Lambda authorization.

```
aws apigateway update-method --rest-api-id 1234123412 \ 
  --resource-id a1b2c3 \ 
  --http-method GET \ 
  --patch-operations op="replace",path="/authorizationType",value="CUSTOM" \ 
  op="replace",path="/authorizerId",value="e4f5g6"
```

Output:

```
{
  "httpMethod": "GET",
  "authorizationType": "CUSTOM",
  "authorizerId": "e4f5g6",
  "apiKeyRequired": false,
  "methodResponses": {
    "200": {
      "statusCode": "200",
      "responseModels": {}
    }
  }
}```

### update-model

The following code example shows how to use `update-model`.

**AWS CLI**

**To change the description of a model in an API**

**Command:**

```bash
aws apigateway update-model --rest-api-id 1234123412 --model-name 'Empty' --patch-operations op=replace,path=/description,value='New Description'
```

**To change the schema of a model in an API**

**Command:**
For API details, see UpdateModel in AWS CLI Command Reference.

**update-resource**

The following code example shows how to use update-resource.

**AWS CLI**

**To move a resource and place it under a different parent resource in an API**

Command:

```bash
aws apigateway update-resource --rest-api-id 1234123412 --resource-id 1a2b3c --patch-operations op=replace,path=/parentId,value='3c2b1a'
```

Output:

```json
{
    "path": "/resource",
    "pathPart": "resource",
    "id": "1a2b3c",
    "parentId": "3c2b1a"
}
```

**To rename a resource (pathPart) in an API**

Command:

```bash
aws apigateway update-resource --rest-api-id 1234123412 --resource-id 1a2b3c --patch-operations op=replace,path=/pathPart,value=newresourcename
```

Output:

```json
{
    "path": "/newresourcename",
    "pathPart": "newresourcename",
```
• For API details, see UpdateResource in AWS CLI Command Reference.

update-rest-api

The following code example shows how to use update-rest-api.

**AWS CLI**

To change the name of an API

Command:

```bash
aws apigateway update-rest-api --rest-api-id 1234123412 --patch-operations
op=replace,path=/name,value='New Name'
```

To change the description of an API

Command:

```bash
aws apigateway update-rest-api --rest-api-id 1234123412 --patch-operations
op=replace,path=/description,value='New Description'
```

• For API details, see UpdateRestApi in AWS CLI Command Reference.

update-stage

The following code example shows how to use update-stage.

**AWS CLI**

**Example 1: To override the stage settings for a resource and method**

The following update-stage example overrides the stage settings and turns off full request/response logging for a specific resource and method.

```bash
aws apigateway update-stage \n```
Example 2: To update the stage settings for all resources and methods of an API stage

The following update-stage example turns on full request/response logging for all resources and methods of an API stage.

```bash
aws apigateway update-stage \
  --rest-api-id 1234123412 \
  --stage-name 'dev' \
  --patch-operations 'op=replace,path=/resourceName/GET/logging/dataTrace,value=true'
```
Output:

```json
{
    "deploymentId": "5ubd17",
    "stageName": "dev",
    "cacheClusterEnabled": false,
    "cacheClusterStatus": "NOT_AVAILABLE",
    "methodSettings": {
        "*/*": {
            "metricsEnabled": false,
            "dataTraceEnabled": true,
            "throttlingBurstLimit": 5000,
            "throttlingRateLimit": 10000.0,
            "cachingEnabled": false,
            "cacheTtlInSeconds": 300,
            "cacheDataEncrypted": false,
            "requireAuthorizationForCacheControl": true,
            "unauthorizedCacheControlHeaderStrategy": "SUCCEED_WITH_RESPONSE_HEADER"
        }
    },
    "tracingEnabled": false,
    "createdDate": "2022-07-18T10:11:18-07:00",
    "lastUpdatedDate": "2022-07-18T10:31:04-07:00"
}
```

For more information, see [Setting up a stage for a REST API](#) in the [Amazon API Gateway Developer Guide](#).

- For API details, see [UpdateStage](#) in [AWS CLI Command Reference](#).

### update-usage-plan

The following code example shows how to use `update-usage-plan`.

**AWS CLI**

To change the period defined in a Usage Plan

Command:

```
aws apigateway update-usage-plan --usage-plan-id a1b2c3 --patch-operations
op="replace",path="/quota/period",value="MONTH"
```
To change the quota limit defined in a Usage Plan

Command:

```
aws apigateway update-usage-plan --usage-plan-id a1b2c3 --patch-operations
op="replace",path="/quota/limit",value="500"
```

To change the throttle rate limit defined in a Usage Plan

Command:

```
aws apigateway update-usage-plan --usage-plan-id a1b2c3 --patch-operations
op="replace",path="/throttle/rateLimit",value="10"
```

To change the throttle burst limit defined in a Usage Plan

Command:

```
aws apigateway update-usage-plan --usage-plan-id a1b2c3 --patch-operations
op="replace",path="/throttle/burstLimit",value="20"
```

- For API details, see [UpdateUsagePlan](#) in [AWS CLI Command Reference](#).

update-usage

The following code example shows how to use update-usage.

AWS CLI

To temporarily modify the quota on an API key for the current period defined in the Usage Plan

Command:

```
aws apigateway update-usage --usage-plan-id a1b2c3 --key-id
1NbjQzMReAkeEQPNAW8z3dXsU2rDD7fc7f2Sipnu --patch-operations op="replace",path="/remaining",value="50"
```

- For API details, see [UpdateUsage](#) in [AWS CLI Command Reference](#).
API Gateway HTTP and WebSocket API examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with API Gateway HTTP and WebSocket API.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

create-api-mapping

The following code example shows how to use create-api-mapping.

AWS CLI

To create an API mapping for an API

The following create-api-mapping example maps the test stage of an API to the /myApi path of the regional.example.com custom domain name.

```bash
aws apigatewayv2 create-api-mapping \   --domain-name regional.example.com \   --api-mapping-key myApi \   --api-id a1b2c3d4 \   --stage test
```

Output:

```json
{
   "ApiId": "a1b2c3d4",
```
For more information, see Setting up a regional custom domain name in API Gateway in the Amazon API Gateway Developer Guide.

- For API details, see CreateApiMapping in AWS CLI Command Reference.

**create-api**

The following code example shows how to use create-api.

**AWS CLI**

**To create an HTTP API**

The following create-api example creates an HTTP API by using quick create. You can use quick create to create an API with an AWS Lambda or HTTP integration, a default catch-all route, and a default stage that is configured to automatically deploy changes. The following command uses quick create to create an HTTP API that integrates with a Lambda function.

```bash
aws apigatewayv2 create-api \
    --name my-http-api \
    --protocol-type HTTP \
```

**Output:**

```
{
    "ApiEndpoint": "https://a1b2c3d4.execute-api.us-west-2.amazonaws.com",
    "ApiId": "a1b2c3d4",
    "ApiKeySelectionExpression": "$request.header.x-api-key",
    "CreatedDate": "2020-04-08T19:05:45+00:00",
    "Name": "my-http-api",
    "ProtocolType": "HTTP",
    "RouteSelectionExpression": "$request.method $request.path"
}
```

For more information, see Developing an HTTP API in API Gateway in the Amazon API Gateway Developer Guide.
To create a WebSockets API

The following `create-api` example creates a WebSockets API with the specified name.

```
aws apigatewayv2 create-api \
  --name "myWebSocketApi" \
  --protocol-type WEBSOCKET \
  --route-selection-expression '$request.body.action'
```

Output:

```
{
    "ApiKeySelectionExpression": "$request.header.x-api-key",
    "Name": "myWebSocketApi",
    "CreatedDate": "2018-11-15T06:23:51Z",
    "ProtocolType": "WEBSOCKET",
    "RouteSelectionExpression": "'$request.body.action'",
    "ApiId": "aabbccddee"
}
```

For more information, see [Create a WebSockets API in API Gateway](https://docs.aws.amazon.com/apigateway/latest/developerguide/how-to-create-api.html) in the *Amazon API Gateway Developer Guide*.

- For API details, see [CreateApi](https://docs.aws.amazon.com/cli/latest/reference/apigatewayv2/create-api.html) in *AWS CLI Command Reference*.

create-authorizer

The following code example shows how to use `create-authorizer`.

**AWS CLI**

To create a JWT authorizer for an HTTP API

The following `create-authorizer` example creates a JWT authorizer that uses Amazon Cognito as an identity provider.

```
aws apigatewayv2 create-authorizer \
  --name my-jwt-authorizer \
  --api-id a1b2c3d4 \
  --authorizer-type JWT \
  --identity-source '$request.header.Authorization' \
```
Output:

```
{
    "AuthorizerId": "a1b2c3",
    "AuthorizerType": "JWT",
    "IdentitySource": ["$request.header.Authorization"],
    "JwtConfiguration": {
        "Audience": ["123456abc"],
        "Name": "my-jwt-authorizer"
    }
}
```

For more information, see Controlling access to HTTP APIs with JWT authorizers in the Amazon API Gateway Developer Guide.

- For API details, see CreateAuthorizer in AWS CLI Command Reference.

create-deployment

The following code example shows how to use create-deployment.

**AWS CLI**

To create a deployment for an API

The following create-deployment example creates a deployment for an API and associates that deployment with the dev stage of the API.

```bash
aws apigatewayv2 create-deployment \
    --api-id a1b2c3d4 \
    --stage-name dev
```

Output:
For more information, see API deployment in the Amazon API Gateway Developer Guide.

- For API details, see CreateDeployment in AWS CLI Command Reference.

create-domain-name

The following code example shows how to use create-domain-name.

AWS CLI

To create a custom domain name

The following create-domain-name example creates a regional custom domain name for an API.

```bash
aws apigatewayv2 create-domain-name \ 
   --domain-name regional.example.com \ 
```

Output:

```json
{
   "ApiMappingSelectionExpression": "$request.basepath",
   "DomainName": "regional.example.com",
   "DomainNameConfigurations": [
      {
         "ApiGatewayDomainName": "d-id.execute-api.us-west-2.amazonaws.com",
         "EndpointType": "REGIONAL",
         "HostedZoneId": "123456789111",
         "SecurityPolicy": "TLS_1_2",
         "DomainNameStatus": "AVAILABLE"
      }
   ]
}
```
For more information, see Setting up a regional custom domain name in API Gateway in the Amazon API Gateway Developer Guide.

- For API details, see CreateDomainName in AWS CLI Command Reference.

create-integration

The following code example shows how to use create-integration.

AWS CLI

To create a WebSocket API integration

The following create-integration example creates a mock integration for a WebSocket API.

```
aws apigatewayv2 create-integration \
   --api-id aabbccddeee \
   --passthrough-behavior WHEN_NO.MATCH \
   --timeout-in-millis 29000 \
   --connection-type INTERNET \
   --integration-type MOCK
```

Output:

```
{
    "ConnectionId": "INTERNET",
    "IntegrationId": "0abcdef",
    "IntegrationResponseSelectionExpression": "${integration.response.statuscode}",
    "IntegrationType": "MOCK",
    "PassthroughBehavior": "WHEN_NO_MATCH",
    "PayloadFormatVersion": "1.0",
    "TimeoutInMillis": 29000
}
```

For more information, see Set up a WebSocket API integration request in API Gateway in the Amazon API Gateway Developer Guide.

To create an HTTP API integration
The following create-integration example creates an AWS Lambda integration for an HTTP API.

```
aws apigatewayv2 create-integration \
--api-id a1b2c3d4 \
--integration-type AWS_PROXY \
--integration-uri arn:aws:lambda:us-west-2:123456789012:function:my-function \
--payload-format-version 2.0
```

Output:

```
{
    "ConnectionType": "INTERNET",
    "IntegrationId": "0abcdef",
    "IntegrationMethod": "POST",
    "IntegrationType": "AWS_PROXY",
    "PayloadFormatVersion": "2.0",
    "TimeoutInMillis": 30000
}
```

For more information, see Configuring integrations for HTTP APIs in the Amazon API Gateway Developer Guide.

- For API details, see CreateIntegration in AWS CLI Command Reference.

create-route

The following code example shows how to use create-route.

AWS CLI

To create a $default route for a WebSocket or HTTP API

The following create-route example creates a $default route for a WebSocket or HTTP API.

```
aws apigatewayv2 create-route \
--api-id aabbccddeee \
--route-key '$default'
```
Output:

```
{
    "ApiKeyRequired": false,
    "AuthorizationType": "NONE",
    "RouteKey": "POST /signup",
    "RouteId": "1122334"
}
```

For more information, see [Working with routes for WebSocket APIs](#) in the *Amazon API Gateway Developer Guide*

**To create a route for an HTTP API**

The following `create-route` example creates a route named signup that accepts POST requests.

```
aws apigatewayv2 create-route \
    --api-id aabbccddeee \
    --route-key 'POST /signup'
```

Output:

```
{
    "ApiKeyRequired": false,
    "AuthorizationType": "NONE",
    "RouteKey": "POST /signup",
    "RouteId": "1122334"
}
```

For more information, see [Working with routes for HTTP APIs](#) in the *Amazon API Gateway Developer Guide*

- For API details, see [CreateRoute](#) in *AWS CLI Command Reference*.

**create-stage**

The following code example shows how to use `create-stage`.

**AWS CLI**

To create a stage
The following create-stage example creates a stage named dev for an API.

```bash
aws apigatewayv2 create-stage \
  --api-id a1b2c3d4 \
  --stage-name dev
```

Output:

```json
{
  "CreatedDate": "2020-04-06T23:23:46Z",
  "DefaultRouteSettings": {
    "DetailedMetricsEnabled": false
  },
  "LastUpdatedDate": "2020-04-06T23:23:46Z",
  "RouteSettings": {},
  "StageName": "dev",
  "StageVariables": {},
  "Tags": {}
}
```

For more information, see Working with stages for HTTP APIs in the Amazon API Gateway Developer Guide.

- For API details, see **CreateStage** in AWS CLI Command Reference.

**create-vpc-link**

The following code example shows how to use create-vpc-link.

**AWS CLI**

To create a VPC link for an HTTP API

The following create-vpc-link example creates a VPC link for HTTP APIs.

```bash
aws apigatewayv2 create-vpc-link \
  --name MyVpcLink \
  --subnet-ids subnet-aaaa subnet-bbbb \
  --security-group-ids sg1234 sg5678
```

Output:
For more information, see [Working with VPC links for HTTP APIs](#) in the Amazon API Gateway Developer Guide.

- For API details, see [CreateVpcLink](#) in AWS CLI Command Reference.

**delete-access-log-settings**

The following code example shows how to use `delete-access-log-settings`.

### AWS CLI

**To disable access logging for an API**

The following `delete-access-log-settings` example deletes the access log settings for the `$default` stage of an API. To disable access logging for a stage, delete its access log settings.

```bash
aws apigatewayv2 delete-access-log-settings \
   --api-id a1b2c3d4 \
   --stage-name '$default'
```

This command produces no output.

For more information, see [Configuring logging for an HTTP API](#) in the Amazon API Gateway Developer Guide.
delete-api-mapping

The following code example shows how to use delete-api-mapping.

AWS CLI

To delete an API mapping

The following delete-api-mapping example deletes an API mapping for the api.example.com custom domain name.

```
aws apigatewayv2 delete-api-mapping \
  --api-mapping-id a1b2c3 \
  --domain-name api.example.com
```

This command produces no output.

For more information, see Setting up a regional custom domain name in API Gateway in the Amazon API Gateway Developer Guide.

delete-api

The following code example shows how to use delete-api.

AWS CLI

To delete an API

The following delete-api example deletes an API.

```
aws apigatewayv2 delete-api \
  --api-id a1b2c3d4
```

This command produces no output.

For more information, see Working with HTTP APIs and Working with WebSocket APIs in the Amazon API Gateway Developer Guide.
For API details, see `DeleteApi` in *AWS CLI Command Reference*.

**delete-authorizer**

The following code example shows how to use delete-authorizer.

**AWS CLI**

**To delete an authorizer**

The following `delete-authorizer` example deletes an authorizer.

```
aws apigatewayv2 delete-authorizer \
  --api-id a1b2c3d4 \
  --authorizer-id a1b2c3
```

This command produces no output.

For more information, see [Controlling access to HTTP APIs with JWT authorizers](https://docs.aws.amazon.com/apigatewayv2/latest/userguide/cors.html) in the *Amazon API Gateway Developer Guide*.

For API details, see `DeleteAuthorizer` in *AWS CLI Command Reference*.

**delete-cors-configuration**

The following code example shows how to use delete-cors-configuration.

**AWS CLI**

**To delete the CORS configuration for an HTTP API**

The following `delete-cors-configuration` example disables CORS for an HTTP API by deleting its CORS configuration.

```
aws apigatewayv2 delete-cors-configuration \
  --api-id a1b2c3d4
```

This command produces no output.

For more information, see [Configuring CORS for an HTTP API](https://docs.aws.amazon.com/apigatewayv2/latest/userguide/cors.html) in the *Amazon API Gateway Developer Guide*. 
For API details, see `DeleteCorsConfiguration` in *AWS CLI Command Reference*.

**delete-deployment**

The following code example shows how to use delete-deployment.

**AWS CLI**

**To delete a deployment**

The following `delete-deployment` example deletes a deployment of an API.

```bash
aws apigatewayv2 delete-deployment \
    --api-id a1b2c3d4 \
    --deployment-id a1b2c3
```

This command produces no output.

For more information, see *API deployment* in the *Amazon API Gateway Developer Guide*.

• For API details, see `DeleteDeployment` in *AWS CLI Command Reference*.

**delete-domain-name**

The following code example shows how to use delete-domain-name.

**AWS CLI**

**To delete a custom domain name**

The following `delete-domain-name` example deletes a custom domain name.

```bash
aws apigatewayv2 delete-domain-name \
    --domain-name api.example.com
```

This command produces no output.

For more information, see *Setting up a regional custom domain name in API Gateway* in the *Amazon API Gateway Developer Guide*.

• For API details, see `DeleteDomainName` in *AWS CLI Command Reference*. 

Actions and scenarios
delete-integration

The following code example shows how to use delete-integration.

**AWS CLI**

**To delete an integration**

The following delete-integration example deletes an API integration.

```bash
aws apigatewayv2 delete-integration \
   --api-id a1b2c3d4 \
   --integration-id a1b2c3
```

This command produces no output.

For more information, see Configuring integrations for HTTP APIs and Setting up WebSocket API integrations in the Amazon API Gateway Developer Guide.

- For API details, see DeleteIntegration in AWS CLI Command Reference.

delete-route-settings

The following code example shows how to use delete-route-settings.

**AWS CLI**

**To delete route settings**

The following delete-route-settings example deletes the route settings for the specified route.

```bash
aws apigatewayv2 delete-route-settings \
   --api-id a1b2c3d4 \
   --stage-name dev \
   --route-key 'GET /pets'
```

This command produces no output.

For more information, see Working with routes for HTTP APIs in the Amazon API Gateway Developer Guide.
• For API details, see DeleteRouteSettings in AWS CLI Command Reference.

delete-route

The following code example shows how to use delete-route.

AWS CLI

To delete a route

The following delete-route example deletes an API route.

```
aws apigatewayv2 delete-route \\
   --api-id a1b2c3d4 \\
   --route-id a1b2c3
```

This command produces no output.

For more information, see Working with routes for HTTP APIs in the Amazon API Gateway Developer Guide.

• For API details, see DeleteRoute in AWS CLI Command Reference.

delete-stage

The following code example shows how to use delete-stage.

AWS CLI

To delete a stage

The following delete-stage example deletes the test stage of an API.

```
aws apigatewayv2 delete-stage \\
   --api-id a1b2c3d4 \\
   --stage-name test
```

This command produces no output.

For more information, see Working with stages for HTTP APIs in the Amazon API Gateway Developer Guide.
• For API details, see `DeleteStage` in *AWS CLI Command Reference*.

**delete-vpc-link**

The following code example shows how to use `delete-vpc-link`.

**AWS CLI**

**To delete a VPC link for an HTTP API**

The following `delete-vpc-link` example deletes a VPC link.

```
aws apigatewayv2 delete-vpc-link \
   --vpc-link-id abcd123
```

This command produces no output.

For more information, see Working with VPC links for HTTP APIs in the *Amazon API Gateway Developer Guide*.

• For API details, see `DeleteVpcLink` in *AWS CLI Command Reference*.

**export-api**

The following code example shows how to use `export-api`.

**AWS CLI**

**To export an OpenAPI definition of an HTTP API**

The following `export-api` example exports an OpenAPI 3.0 definition of an API stage named prod to a YAML file named `stage-definition.yaml`. The exported definition file includes API Gateway extensions by default.

```
aws apigatewayv2 export-api \
   --api-id a1b2c3d4 \
   --output-type YAML \
   --specification OAS30 \
   --stage-name prod \
   stage-definition.yaml
```

This command produces no output.
For more information, see Exporting an HTTP API from API Gateway in the Amazon API Gateway Developer Guide.

- For API details, see ExportApi in AWS CLI Command Reference.

get-api-mapping

The following code example shows how to use get-api-mapping.

AWS CLI

To get information about an API mapping for a custom domain name

The following get-api-mapping example displays information about an API mapping for the api.example.com custom domain name.

```bash
aws apigatewayv2 get-api-mapping \
   --api-mapping-id a1b2c3 \
   --domain-name api.example.com
```

Output:

```
{
   "ApiId": "a1b2c3d4",
   "ApiMappingId": "a1b2c3d5",
   "ApiMappingKey": "myTestApi"
   "Stage": "test"
}
```

For more information, see Setting up a regional custom domain name in API Gateway in the Amazon API Gateway Developer Guide.

- For API details, see GetApiMapping in AWS CLI Command Reference.

get-api-mappings

The following code example shows how to use get-api-mappings.

AWS CLI

To get API mappings for a custom domain name
The following `get-api-mappings` example displays a list of all of the API mappings for the `api.example.com` custom domain name.

```
aws apigatewayv2 get-api-mappings \
   --domain-name api.example.com
```

Output:

```
{
   "Items": [
      {

get-api

The following code example shows how to use `get-api`.

**AWS CLI**

**To retrieve information about an API**

The following `get-api` example displays information about an API.

```
aws apigatewayv2 get-api \
```
Output:

```json
{
   "ApiEndpoint": "https://a1b2c3d4.execute-api.us-west-2.amazonaws.com",
   "ApiId": "a1b2c3d4",
   "ApiKeySelectionExpression": "$request.header.x-api-key",
   "CreatedDate": "2020-03-28T00:32:37Z",
   "Name": "my-api",
   "ProtocolType": "HTTP",
   "RouteSelectionExpression": "$request.method $request.path",
   "Tags": {
      "department": "finance"
   }
}
```

- For API details, see [GetApi](#) in [AWS CLI Command Reference](#).

**get-apis**

The following code example shows how to use `get-apis`.

**AWS CLI**

To retrieve a list of APIs

The following `get-apis` example lists all of the APIs for the current user.

```
aws apigatewayv2 get-apis
```

Output:

```json
{
   "Items": [
      {
         "ApiEndpoint": "wss://a1b2c3d4.execute-api.us-west-2.amazonaws.com",

- For API details, see GetApis in AWS CLI Command Reference.

get-authorizer

The following code example shows how to use get-authorizer.

AWS CLI

To retrieve information about an authorizer

The following get-authorizer example displays information about an authorizer.

```bash
aws apigatewayv2 get-authorizer \
--api-id a1b2c3d4 \
--authorizer-id a1b2c3
```

Output:

```json
{
   "AuthorizerId": "a1b2c3",
   "AuthorizerType": "JWT",
   "IdentitySource": [
```
For more information, see [Controlling access to HTTP APIs with JWT authorizers](https://docs.aws.amazon.com/apigateway/latest/developerguide/authorizers-http-api-jwt.html) in the [Amazon API Gateway Developer Guide](https://docs.aws.amazon.com/apigateway/latest/developerguide/authorizers-http-api-jwt.html).

### get-authorizers

The following code example shows how to use `get-authorizers`.

**AWS CLI**

**To retrieve a list of authorizers for an API**

The following `get-authorizers` example displays a list of all of the authorizers for an API.

```
aws apigatewayv2 get-authorizers \
  --api-id a1b2c3d4
```

**Output:**

```
{
  "Items": [
    {
      "AuthorizerId": "a1b2c3",
      "AuthorizerType": "JWT",
      "IdentitySource": [

      },
      "Name": "my-jwt-authorizer"
    }
  ]
}
```
For more information, see Controlling access to HTTP APIs with JWT authorizers in the Amazon API Gateway Developer Guide.

- For API details, see GetAuthorizers in AWS CLI Command Reference.

get-deployment

The following code example shows how to use get-deployment.

AWS CLI

To retrieve information about a deployment

The following get-deployment example displays information about a deployment.

```
aws apigatewayv2 get-deployment
   --api-id alb2c3d4
   --deployment-id abcdef
```
Output:

```json
{
   "AutoDeployed": true,
   "CreatedDate": "2020-04-07T23:58:40Z",
   "DeploymentId": "abcdef",
   "DeploymentStatus": "DEPLOYED",
   "Description": "Automatic deployment triggered by changes to the Api configuration"
}
```

- For API details, see [GetDeployment](https://docs.aws.amazon.com/cli/latest/reference/apigatewayv2/get-deployment.html) in *AWS CLI Command Reference*.

### get-deployments

The following code example shows how to use `get-deployments`.

#### AWS CLI

To retrieve a list of deployments

The following `get-deployments` example displays a list of all of an API's deployments.

```bash
aws apigatewayv2 get-deployments \\ --api-id a1b2c3d4
```

Output:

```json
{
   "Items": [
   {
      "AutoDeployed": true,
      "CreatedDate": "2020-04-07T23:58:40Z",
      "DeploymentId": "abcdef",
      "DeploymentStatus": "DEPLOYED",
      "Description": "Automatic deployment triggered by changes to the Api configuration"
   },
   {
      "AutoDeployed": true,
```
For more information, see [API deployment](https://docs.aws.amazon.com/apigateway/latest/developerguide/api-deployment.html) in the Amazon API Gateway Developer Guide.

**get-domain-name**

The following code example shows how to use get-domain-name.

**AWS CLI**

To retrieve information about a custom domain name

The following get-domain-name example displays information about a custom domain name.

```bash
aws apigatewayv2 get-domain-name \
   --domain-name api.example.com
```

**Output:**

```json
{
    "ApiMappingSelectionExpression": "$request.basepath",
    "DomainName": "api.example.com",
    "DomainNameConfigurations": [
        {
            "ApiGatewayDomainName": "d-1234.execute-api.us-west-2.amazonaws.com",
            "EndpointType": "REGIONAL",
            "HostedZoneId": "123456789111",
            "SecurityPolicy": "TLS_1_2",
            "DomainNameStatus": "AVAILABLE"
        }
    ],
    "Tags": {}
}
```
For more information, see Setting up a regional custom domain name in API Gateway in the Amazon API Gateway Developer Guide.

- For API details, see GetDomainName in AWS CLI Command Reference.

get-domain-names

The following code example shows how to use get-domain-names.

AWS CLI

To retrieve a list of custom domain names

The following get-domain-names example displays a list of all of the custom domain names for the current user.

```bash
aws apigatewayv2 get-domain-names
```

Output:

```json
{
   "Items": [
       {
           "ApiMappingSelectionExpression": "$request.basepath",
           "DomainName": "api.example.com",
           "DomainNameConfigurations": [
               {
                   "ApiGatewayDomainName": "d-1234.execute-api.us-west-2.amazonaws.com",
                   "EndpointType": "REGIONAL",
                   "HostedZoneId": "123456789111",
                   "SecurityPolicy": "TLS_1_2",
                   "DomainNameStatus": "AVAILABLE"
               }
           ]
       },
       {
           "ApiMappingSelectionExpression": "$request.basepath",
```
For more information, see Setting up a regional custom domain name in API Gateway in the Amazon API Gateway Developer Guide.

- For API details, see GetDomainNames in AWS CLI Command Reference.

get-integration

The following code example shows how to use get-integration.

**AWS CLI**

To retrieve information about an integration

The following get-integration example displays information about an integration.

```
aws apigatewayv2 get-integration \
  --api-id a1b2c3d4 \
  --integration-id a1b2c3
```

Output:

```
{
  "ApiGatewayManaged": true,
  "ConnectionType": "INTERNET",
  "IntegrationId": "a1b2c3",
  "ApiGatewayDomainName": "d-5678.execute-api.us-west-2.amazonaws.com",

  "DomainNameStatus": "AVAILABLE"
}
```
"IntegrationMethod": "POST",
"IntegrationType": "AWS_PROXY",
"PayloadFormatVersion": "2.0",
"TimeoutInMillis": 30000
}

For more information, see Configuring integrations for HTTP APIs and Setting up WebSocket API integrations in the Amazon API Gateway Developer Guide.

- For API details, see GetIntegration in AWS CLI Command Reference.

get-integrations

The following code example shows how to use get-integrations.

AWS CLI

To retrieve a list of integrations

The following get-integrations example displays a list of all of an API's integrations.

aws apigatewayv2 get-integrations \
   --api-id a1b2c3d4

Output:

{
    "Items": [
        {
            "ApiGatewayManaged": true,

- For API details, see GetIntegrations in AWS CLI Command Reference.

get-route

The following code example shows how to use get-route.

AWS CLI

To retrieve information about a route

The following get-route example displays information about a route.

```
aws apigatewayv2 get-route \
  --api-id a1b2c3d4 \
  --route-id 72jz1wk
```

Output:

```
{
    "ApiKeyRequired": false,
    "AuthorizationType": "NONE",
    "RouteId": "72jz1wk",
    "RouteKey": "ANY /pets",
    "Target": "integrations/a1b2c3"
}
```

For more information, see Working with routes for HTTP APIs in the Amazon API Gateway Developer Guide

- For API details, see GetRoute in AWS CLI Command Reference.
get-routes

The following code example shows how to use get-routes.

AWS CLI

To retrieve a list of routes

The following get-routes example displays a list of all of an API's routes.

```bash
aws apigatewayv2 get-routes \
   --api-id a1b2c3d4
```

Output:

```json
{
   "Items": [
      {

      }
   ]
}
```

For more information, see Working with routes for HTTP APIs in the Amazon API Gateway Developer Guide.

- For API details, see GetRoutes in AWS CLI Command Reference.

get-stage

The following code example shows how to use get-stage.
AWS CLI

To retrieve information about a stage

The following get-stage example displays information about the prod stage of an API.

```bash
aws apigatewayv2 get-stage \
   --api-id a1b2c3d4 \
   --stage-name prod
```

Output:

```json
{
   "CreatedDate": "2020-04-08T00:36:05Z",

get-stages

The following code example shows how to use get-stages.

AWS CLI

To retrieve a list of stages

The following get-stages example lists all of an API's stages.
aws apigatewayv2 get-stages \
   --api-id a1b2c3d4

Output:

get-tags

The following code example shows how to use get-tags.

AWS CLI

To retrieve a list of tags for a resource

The following get-tags example lists all of an API's tags.

```bash
aws apigatewayv2 get-tags \
   --resource-arn arn:aws:apigateway:us-west-2::/apis/a1b2c3d4
```

Output:

```json

      "environment": "prod"
   }
}
```

For more information, see Tagging your API Gateway resources in the Amazon API Gateway Developer Guide.

- For API details, see GetTags in AWS CLI Command Reference.
get-vpc-link

The following code example shows how to use get-vpc-link.

**AWS CLI**

To retrieve information about a VPC link

The following get-vpc-link example displays information about a VPC link.

```bash
aws apigatewayv2 get-vpc-link \
   --vpc-link-id abcd123
```

Output:

```json
{
   "CreatedDate": "2020-04-07T00:27:47Z",

For more information, see Working with VPC links for HTTP APIs in the Amazon API Gateway Developer Guide.

- For API details, see GetVpcLink in AWS CLI Command Reference.

get-vpc-links

The following code example shows how to use get-vpc-links.
AWS CLI

To retrieve a list of VPC links

The following `get-vpc-links` example displays a list of all of the VPC links for the current user.

```
aws apigatewayv2 get-vpc-links

**import-api**

The following code example shows how to use `import-api`.

**AWS CLI**

To import an HTTP API

The following `import-api` example creates an HTTP API from an OpenAPI 3.0 definition file named `api-definition.yaml`.

```bash
aws apigatewayv2 import-api \
  --body file://api-definition.yaml
```

Contents of `api-definition.yaml`:

```yaml
openapi: 3.0.1
info:
  title: My Lambda API
  version: v1.0
paths:
  /hello:
    x-amazon-apigateway-any-method:
    x-amazon-apigateway-integration:
      payloadFormatVersion: 2.0
      type: aws_proxy
      httpMethod: POST
      connectionType: INTERNET
```

}
```

For more information, see Working with OpenAPI definitions for HTTP APIs in the Amazon API Gateway Developer Guide.

- For API details, see ImportApi in AWS CLI Command Reference.

**reimport-api**

The following code example shows how to use reimport-api.

**AWS CLI**

**To reimport an HTTP API**

The following reimport-api example updates an existing HTTP API to use the OpenAPI 3.0 definition specified in api-definition.yaml.

```
aws apigatewayv2 reimport-api \
    --body file://api-definition.yaml \
    --api-id a1b2c3d4
```

Contents of api-definition.yaml:

```yaml
openapi: 3.0.1
info:
    title: My Lambda API
    version: v1.0
paths:
```
AWS Command Line Interface

The following code example shows how to use `tag-resource`.

**AWS CLI**

**To tag a resource**

The following `tag-resource` example adds a tag with the key name `Department` and a value of `Accounting` to the specified API.

```
aws apigatewayv2 tag-resource
   --resource-arn arn:aws:apigateway:us-west-2::/apis/a1b2c3d4
```
This command produces no output.

For more information, see Tagging your API Gateway resources in the Amazon API Gateway Developer Guide.

- For API details, see TagResource in AWS CLI Command Reference.

**untag-resource**

The following code example shows how to use untag-resource.

**AWS CLI**

**To remove tags from a resource**

The following untag-resource example removes tags with the key names Project and Owner from the specified API.

```bash
aws apigatewayv2 untag-resource \
    --resource-arn arn:aws:apigateway:us-west-2::/apis/a1b2c3d4 \
    --tag-keys Project Owner
```

This command produces no output.

For more information, see Tagging your API Gateway resources in the Amazon API Gateway Developer Guide.

- For API details, see UntagResource in AWS CLI Command Reference.

**update-api-mapping**

The following code example shows how to use update-api-mapping.

**AWS CLI**

**To update an API mapping**

The following update-api-mapping example changes an API mapping for a custom domain name. As a result, the base URL using the custom domain name for the specified API and stage becomes https://api.example.com/dev.
aws apigatewayv2 update-api-mapping \
   --api-id a1b2c3d4 \ 
   --stage dev \ 
   --domain-name api.example.com \ 
   --api-mapping-id 0qzs2sy7bh \ 
   --api-mapping-key dev

Output:

```
{
    "ApiId": "a1b2c3d4",
    "ApiMappingId": "0qzs2sy7bh",
    "ApiMappingKey": "dev",
    "Stage": "dev"
}
```

For more information, see Setting up a regional custom domain name in API Gateway in the Amazon API Gateway Developer Guide.

- For API details, see UpdateApiMapping in AWS CLI Command Reference.

**update-api**

The following code example shows how to use update-api.

**AWS CLI**

To enable CORS for an HTTP API

The following update-api example updates the specified API's CORS configuration to allow requests from https://www.example.com.

```
aws apigatewayv2 update-api \
   --api-id a1b2c3d4 \ 
   --cors-configuration AllowOrigins=https://www.example.com
```

Output:

```
{
    "ApiEndpoint": "https://a1b2c3d4.execute-api.us-west-2.amazonaws.com",
```
"ApiId": "a1b2c3d4",
"ApiKeySelectionExpression": "$request.header.x-api-key",
"CorsConfiguration": {
    "AllowCredentials": false,

update-authorizer

The following code example shows how to use update-authorizer.

AWS CLI

To update an authorizer

The following update-authorizer example changes a JWT authorizer's identity source to a header named Authorization.

```
aws apigatewayv2 update-authorizer \
    --api-id a1b2c3d4 \
    --authorizer-id a1b2c3 \
```
--identity-source '$request.header.Authorization'

Output:

```json
{
    "AuthorizerId": "a1b2c3",
    "AuthorizerType": "JWT",
    "IdentitySource": ["$request.header.Authorization"],
    "JwtConfiguration": {
        "Audience": ["123456abc"],
        "Issuer": "https://cognito-idp.us-west-2.amazonaws.com/us-west-2_abc123"
    },
    "Name": "my-jwt-authorizer"
}
```

**update-deployment**

The following code example shows how to use `update-deployment`.

**AWS CLI**

**To change a deployment's description**

The following update-deployment example updates a deployment's description.

```bash
aws apigatewayv2 update-deployment \
    --api-id a1b2c3d4 \
    --deployment-id abcdef \
    --description 'Manual deployment to fix integration test failures.'
```

Output:

```json
{
```
update-domain-name

The following code example shows how to use update-domain-name.

AWS CLI

To update a custom domain name

The following update-domain-name example specifies a new ACM certificate for the api.example.com custom domain name.

```
aws apigatewayv2 update-domain-name \
  --domain-name api.example.com \
```

Output:

```json
{
  "ApiMappingSelectionExpression": "$request.basepath",
  "DomainName": "regional.example.com",
  "DomainNameConfigurations": [
    {
      "ApiGatewayDomainName": "d-id.execute-api.us-west-2.amazonaws.com",
      "EndpointType": "REGIONAL",
      "HostedZoneId": "123456789111",
      "SecurityPolicy": "TLS_1_2",
      "DomainNameStatus": "AVAILABLE"
    }
  ]
}
```

**update-integration**

The following code example shows how to use `update-integration`.

**AWS CLI**

**To update a Lambda integration**

The following `update-integration` example updates an existing AWS Lambda integration to use the specified Lambda function.

```
aws apigatewayv2 update-integration \
  --api-id a1b2c3d4 \
  --integration-id a1b2c3 \
```

**Output:**

```
{
  "ConnectionType": "INTERNET",
  "IntegrationId": "a1b2c3",
  "IntegrationMethod": "POST",
  "IntegrationType": "AWS_PROXY",
  "PayloadFormatVersion": "2.0",
  "TimeoutInMillis": 5000
}
```

For API details, see UpdateIntegration in AWS CLI Command Reference.

**update-route**

The following code example shows how to use update-route.

### AWS CLI

**Example 1: To update the integration of a route**

The following update-route example updates the integration of a specified route.

```
aws apigatewayv2 update-route \
  --api-id a1b2c3d4 \
  --route-id a1b2c3 \
  --target integrations/a1b2c6
```

Output:

```
{
    "ApiKeyRequired": false,
    "AuthorizationType": "NONE",
    "RouteId": "a1b2c3",
    "RouteKey": "ANY /pets",
    "Target": "integrations/a1b2c6"
}
```

**Example 2: To add an authorizer to a route**

The following update-route example updates the specified route to use a JWT authorizer.

```
aws apigatewayv2 update-route \
  --api-id a1b2c3d4  \
  --route-id a1b2c3  \
  --authorization-type JWT \
  --authorizer-id a1b2c5  \
  --authorization-scopes user.id user.email
```

Output:

```
{
```
For more information, see [Controlling access to HTTP APIs with JWT authorizers](https://docs.aws.amazon.com/apigateway/latest/developerguide/using-authorizers-jwt.html) in the *Amazon API Gateway Developer Guide*.

**update-stage**

The following code example shows how to use `update-stage`.

**AWS CLI**

**To configure custom throttling**

The following `update-stage` example configures custom throttling for the specified stage and route of an API.

```
aws apigatewayv2 update-stage \
  --api-id a1b2c3d4 \
  --stage-name dev \
  --route-settings '{"GET /pets": \n    {"ThrottlingBurstLimit":100,"ThrottlingRateLimit":2000}}'
```

**Output:**

```
{
  "CreatedDate": "2020-04-05T16:21:16+00:00",
  "DefaultRouteSettings": {
    "DetailedMetricsEnabled": false
  }
}
```
For more information, see Protecting your HTTP API in the Amazon API Gateway Developer Guide.

- For API details, see UpdateStage in AWS CLI Command Reference.

update-vpc-link

The following code example shows how to use update-vpc-link.

AWS CLI

To update a VPC link

The following update-vpc-link example updates the name of a VPC link. After you've created a VPC link, you can't change its security groups or subnets.

```
aws apigatewayv2 update-vpc-link \
  --vpc-link-id abcd123 \
  --name MyUpdatedVpcLink
```

Output:

```
{
  "CreatedDate": "2020-04-07T00:27:47Z",
  "Name": "MyUpdatedVpcLink",
  "SecurityGroupId": [
    "sg1234",
    "sg5678"
  ]
}
For more information, see Working with VPC links for HTTP APIs in the Amazon API Gateway Developer Guide.

API Gateway Management API examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with API Gateway Management API.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Actions

delete-connection

The following code example shows how to use delete-connection.
AWS CLI

To delete a WebSocket connection

The following delete-connection example disconnects a client from the specified WebSocket API.

```
aws apigatewaymanagementapi delete-connection \
  --connection-id L0SM9cOFvHcCIhw= \
  --endpoint-url https://aabbccddee.execute-api.us-west-2.amazonaws.com/prod
```

This command produces no output.

For more information, see Use @connections commands in your backend service in the Amazon API Gateway Developer Guide.

- For API details, see DeleteConnection in AWS CLI Command Reference.

get-connection

The following code example shows how to use get-connection.

AWS CLI

To get information about a WebSocket connection

The following get-connection example describes a connection to the specified WebSocket API.

```
aws apigatewaymanagementapi get-connection \
  --connection-id L0SM9cOFvHcCIhw= \
  --endpoint-url https://aabbccddee.execute-api.us-west-2.amazonaws.com/prod
```

Output:

```
{
  "ConnectedAt": "2020-04-30T20:10:33.236Z",
  "Identity": {
    "SourceIp": "192.0.2.1"

}
```
For more information, see Use @connections commands in your backend service in the Amazon API Gateway Developer Guide.

- For API details, see GetConnection in AWS CLI Command Reference.

**post-to-connection**

The following code example shows how to use post-to-connection.

**AWS CLI**

**To send data to a WebSocket connection**

The following post-to-connection example sends a message to a client that's connected to the specified WebSocket API.

```
aws apigatewaymanagementapi post-to-connection \
  --connection-id LO5M9cOFvHcCIhw= \
  --data "Hello from API Gateway!" \
  --endpoint-url https://aabbccddeee.execute-api.us-west-2.amazonaws.com/prod
```

This command produces no output.

For more information, see Use @connections commands in your backend service in the Amazon API Gateway Developer Guide.

- For API details, see PostToConnection in AWS CLI Command Reference.

**App Mesh examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with App Mesh.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

**create-mesh**

The following code example shows how to use `create-mesh`.

**AWS CLI**

**Example 1: To create a new service mesh**

The following create-mesh example creates a service mesh.

```
aws appmesh create-mesh \
  --mesh-name app1
```

Output:

```

**Example 2: To create a new service mesh with multiple tags**
The following `create-mesh` example creates a service mesh with multiple tags.

```bash
aws appmesh create-mesh \
    --mesh-name app2 \
    --tags key=key1,value=value1 key=key2,value=value2 key=key3,value=value3

### create-route

The following code example shows how to use `create-route`.

**AWS CLI**

**To create a new gRPC route**

The following `create-route` example uses a JSON input file to create a gRPC route. GRPC traffic that has metadata that starts with 123 is routed to a virtual node named `serviceBgrpc`. If there are specific gRPC, HTTP, or TCP failures when attempting to communicate with the target of the route, the route is retried three times. There is a 15 second delay between each retry attempt.
aws appmesh create-route \
   --cli-input-json file://create-route-grpc.json

Contents of create-route-grpc.json:

```json
{
    "meshName" : "apps",
    "routeName" : "grpcRoute",

To create a new HTTP or HTTP/2 route

The following `create-route` example uses a JSON input file to create an HTTP/2 route. To create an HTTP route, replace `http2Route` with `httpRoute` under `spec`. All HTTP/2 traffic addressed to any URL prefix that has a header value that starts with 123 is routed to a virtual node named `serviceBhttp2`. If there are specific HTTP or TCP failures when attempting to communicate with the target of the route, the route is retried three times. There is a 15 second delay between each retry attempt.

```
aws appmesh create-route \
    --cli-input-json file://create-route-http2.json
```

Contents of `create-route-http2.json`:

To create a new TCP route

The following create-route example uses a JSON input file to create a TCP route. 75 percent of traffic is routed to a virtual node named serviceBtcp, and 25 percent of traffic is routed to a virtual node named serviceBv2tcp. Specifying different weightings for different targets is an effective way to do a deployment of a new version of an application. You can adjust the weights so that eventually, 100 percent of all traffic is routed to a target that has the new version of an application.

```bash
aws appmesh create-route \
   --cli-input-json file://create-route-tcp.json
```

Contents of create-route-tcp.json:

```json
{
   "meshName": "apps",
   "routeName": "tcpRoute",
   "spec": {
      "priority": 300,
      "tcpRoute": {

                "virtualNode": "serviceBtcp",
                "weight": 75
             },
             {
                "virtualNode": "serviceBv2tcp",
                "weight": 25
             }
            ]
         }
      }
   }
}
```
"weight": 75,
  
  {  
    "virtualNode": "serviceBv2tcp",
    "weight": 25
  }
}

Output:

**create-virtual-gateway**

The following code example shows how to use create-virtual-gateway.

**AWS CLI**

To create a new virtual gateway

The following create-virtual-gateway example uses a JSON input file to create a virtual gateway with a listener for HTTP using port 9080.

```
aws appmesh create-virtual-gateway \
    --mesh-name meshName \
    --virtual-gateway-name virtualGatewayName \
    --cli-input-json file://create-virtual-gateway.json
```

Contents of create-virtual-gateway.json:

```json
{
    "spec": {
        "listeners": [
            {
                "portMapping": {
                    "port": 9080,
                    "protocol": "http"
                }
            }
        ]
    }
}

**create-virtual-node**

The following code example shows how to use `create-virtual-node`.

**AWS CLI**

**Example 1: To create a new virtual node that uses DNS for discovery**
The following `create-virtual-node` example uses a JSON input file to create a virtual node that uses DNS for service discovery.

```bash
aws appmesh create-virtual-node \
  --cli-input-json file://create-virtual-node-dns.json
```

Contents of `create-virtual-node-dns.json`:

```json
{
  "meshName": "app1",
  "spec": {

### describe-mesh

The following code example shows how to use describe-mesh.

#### AWS CLI

To describe a service mesh

The following describe-mesh example returns details about the specified service mesh.

```
aws appmesh describe-mesh \
   --mesh-name app1
```

Output:

```
{
   "mesh": {
      "meshName": "app1",
      "metadata": {
         "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1",
```

### describe-route

The following code example shows how to use `describe-route`.

#### AWS CLI

**To describe a route**

The following `describe-route` example returns details about the specified route.

```bash
aws appmesh describe-route \
  --mesh-name app1 \
  --virtual-router-name vrServiceB \
  --route-name toVnServiceB-weighted
```

**Output:**

```json

### describe-virtual-node

The following code example shows how to use `describe-virtual-node`.

**AWS CLI**

*To describe a virtual node*

The following `describe-virtual-node` example returns details about the specified virtual node.
aws appmesh describe-virtual-node \
 --mesh-name app1 \
 --virtual-node-name vnServiceBv1

Output:

```json
{
  "virtualNode": {
    "meshName": "app1",

**describe-virtual-router**

The following code example shows how to use **describe-virtual-router**.

**AWS CLI**

**To describe a virtual router**

The following `describe-virtual-router` example returns details about the specified virtual router.

```
aws appmesh describe-virtual-router \
  --mesh-name app1 \
  --virtual-router-name vrServiceB
```

**Output:**

```json

describe-virtual-service

The following code example shows how to use describe-virtual-service.

AWS CLI

To describe a virtual service

The following describe-virtual-service example returns details about the specified virtual service.

```
aws appmesh describe-virtual-service
   --mesh-name app1
   --virtual-service-name serviceB.svc.cluster.local
```

Output:

```
{
   "virtualService": {

### list-meshes

The following code example shows how to use `list-meshes`.

**AWS CLI**

**To list service meshes**

The following `list-meshes` example lists all of the service meshes in the current AWS Region.

```bash
aws appmesh list-meshes
```

**Output:**

```json
{
  "meshes": [
    {
      "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1",
      "meshName": "app1"
    }
  ]
}
```

For more information, see [Service Meshes](#) in the *AWS App Mesh User Guide*.
- For API details, see [ListMeshes](#) in *AWS CLI Command Reference*.

### list-routes

The following code example shows how to use `list-routes`.

**AWS CLI**

**To list routes**
The following list-routes example lists all of the routes for the specified virtual router.

```
aws appmesh list-routes \
    --mesh-name app1 \
    --virtual-router-name vrServiceB
```

Output:

```
{
    "routes": [
        {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualRouter/vrServiceB/route/toVnServiceB",

            "routeName": "toVnServiceB-weighted",
            "virtualRouterName": "vrServiceB"
        }
    ]
}
```

For more information, see [Routes](#) in the [AWS App Mesh User Guide](#).

- For API details, see [ListRoutes](#) in [AWS CLI Command Reference](#).

### list-tags-for-resource

The following code example shows how to use list-tags-for-resource.

**AWS CLI**

**To list tags for a resource**

The following list-tags-for-resource example lists all of the tags assigned to the specified resource.

```
aws appmesh list-tags-for-resource \
    --resource-arn arn:aws:appmesh:us-east-1:123456789012:mesh/app1
```

Output:

```
{
    
}
```
For API details, see ListTagsForResource in AWS CLI Command Reference.

list-virtual-nodes

The following code example shows how to use list-virtual-nodes.

AWS CLI

To list virtual nodes

The following list-virtual-nodes example lists all of the virtual nodes in the specified service mesh.

```bash
aws appmesh list-virtual-nodes \
  --mesh-name app1
```

Output:

```json
{
  "virtualNodes": [
    {
      "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualNode/vnServiceBv1",
      "meshName": "app1",
      "virtualNodeName": "vnServiceBv1"
    },
    {
      "key": "key1",
      "value": "value1"
    },
    {
      "key": "key2",
      "value": "value2"
    },
    {

      "value": "value3"
    }
  ]
}
```
For more information, see Virtual Nodes in the AWS App Mesh User Guide.

- For API details, see ListVirtualNodes in AWS CLI Command Reference.

list-virtual-routers

The following code example shows how to use list-virtual-routers.

AWS CLI

To list virtual routers

The following list-virtual-routers example lists all of the virtual routers in the specified service mesh.

```
aws appmesh list-virtual-routers \
    --mesh-name app1
```

Output:

```
{
    "virtualRouters": [
        {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualRouter/vrServiceB",
            "meshName": "app1",
            "virtualRouterName": "vrServiceB"
        }
    ]
}
```

For more information, see Virtual Routers in the AWS App Mesh User Guide.
For API details, see ListVirtualRouters in AWS CLI Command Reference.

**list-virtual-services**

The following code example shows how to use list-virtual-services.

**AWS CLI**

**To list virtual services**

The following list-virtual-services example lists all of the virtual services in the specified service mesh.

```bash
aws appmesh list-virtual-services \
    --mesh-name app1
```

Output:

```
{
    "virtualServices": [
        {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualService/serviceA.svc.cluster.local",

            "virtualServiceName": "serviceA.svc.cluster.local"
        },
        {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualService/serviceB.svc.cluster.local",
            "meshName": "app1",
            "virtualServiceName": "serviceB.svc.cluster.local"
        }
    ]
}
```

For more information, see Virtual Services in the AWS App Mesh User Guide.

- For API details, see ListVirtualServices in AWS CLI Command Reference.

**tag-resource**

The following code example shows how to use tag-resource.
To tag a resource

The following `tag-resource` example adds the tag `key1` with the value `value1` to the specified resource.

```
aws appmesh tag-resource \
  --resource-arn arn:aws:appmesh:us-east-1:123456789012:mesh/app1 \
  --tags key=key1,value=value1
```

This command produces no output.

- For API details, see `TagResource` in *AWS CLI Command Reference*.

untag-resource

The following code example shows how to use `untag-resource`.

AWS CLI

To untag a resource

The following `untag-resource` example removes a tag with the key `key1` from the specified resource.

```
aws appmesh untag-resource \
  --resource-arn arn:aws:appmesh:us-east-1:123456789012:mesh/app1 \
  --tag-keys key1
```

This command produces no output.

- For API details, see `UntagResource` in *AWS CLI Command Reference*.

update-mesh

The following code example shows how to use `update-mesh`.

AWS CLI

To update a service mesh
The following `update-mesh` example uses a JSON input file to update a service mesh to allow all external egress traffic to be forwarded through the Envoy proxy untouched.

```bash
aws appmesh update-mesh \
   --cli-input-json file://update-mesh.json
```

Contents of `update-mesh.json`:

```json
{
   "meshName": "app1",
   "spec": {
      "egressFilter": {
         "type": "ALLOW_ALL"
      }
   }
}
```

Output:

```json

```

For more information, see [Service Meshes](#) in the AWS App Mesh User Guide.
update-route

The following code example shows how to use update-route.

AWS CLI

To update a route

The following update-route example uses a JSON input file to update the weights for a route.

```
aws appmesh update-route \
  --cli-input-json file://update-route-weighted.json
```

Contents of update-route-weighted.json:

```json
{
  "meshName": "app1",
  "routeName": "toVnServiceB-weighted",
  "spec": {
    "httpRoute": {

update-virtual-router

The following code example shows how to use update-virtual-router.

AWS CLI

To update a virtual router

The following update-virtual-router example uses a JSON input file to update a virtual router listener port.

```plaintext
aws appmesh update-virtual-router \
   --cli-input-json file://update-virtual-router.json
```

Contents of update-virtual-router.json:

```json
{
   "meshName": "app1",
   "spec": {
      "listeners": [
         {
            "portMapping": {

            }
         }
      
   },
   "virtualRouterName": "vrServiceB"
}
```

Output:

```json
{
```
"virtualRouter": {

update-virtual-service

The following code example shows how to use update-virtual-service.

AWS CLI

To update a virtual service

The following update-virtual-service example uses a JSON input file to update a virtual service to use a virtual router provider.

```
aws appmesh update-virtual-service \
```
--cli-input-json file://update-virtual-service.json

Contents of update-virtual-service.json:

```
{
    "meshName": "app1",
    "spec": {
        "provider": {
            "virtualRouter": {
                "virtualRouterName": "vrServiceA"
            }
        },
    },
    "virtualServiceName": "serviceA.svc.cluster.local"
}
```

Output:

```
{
    "virtualService": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualService/serviceA.svc.cluster.local",

App Runner examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with App Runner.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

associate-custom-domain

The following code example shows how to use associate-custom-domain.

AWS CLI

To associate a domain name and the www subdomain with a service

The following associate-custom-domain example associates a custom domain name that you control with an App Runner service. The domain name is the root domain example.com, including the special-case subdomain www.example.com.

```
aws apprunner associate-custom-domain \
  --cli-input-json file://input.json
```

Contents of input.json:

```json
{
   "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-app/8fe1e10304f84fd2b0df550fe98a71fa",

### create-auto-scaling-configuration

The following code example shows how to use `create-auto-scaling-configuration`.

```bash
create-auto-scaling-configuration
```

The following code example shows how to use `create-auto-scaling-configuration`.
AWS CLI

To create a high availability auto scaling configuration

The following `create-auto-scaling-configuration` example creates an auto scaling configuration optimized for high availability by setting `MinSize` to 5. With this configuration, App Runner attempts to spread your service instances over the most Availability Zones possible, up to five, depending on the AWS Region.

The call returns an `AutoScalingConfiguration` object with the other settings set to their defaults. In the example, this is the first call to create a configuration named `high-availability`. The revision is set to 1, and it's the latest revision.

```bash
aws apprunner create-auto-scaling-configuration \\
--cli-input-json file://input.json
```

Contents of `input.json`:

```json
{
    "AutoScalingConfigurationName": "high-availability",
    "MinSize": 5
}
```

Output:

```json
{
    "AutoScalingConfiguration": {
        "AutoScalingConfigurationArn": "arn:aws:apprunner:us-east-1:123456789012:autoscalingconfiguration/high-availability/1/2f50e7656d7819fde0f59672e68042e",

        "Latest": true,
        "Status": "ACTIVE",
        "MaxConcurrency": 100,
        "MaxSize": 50,
        "MinSize": 5
    }
}
```
create-connection

The following code example shows how to use create-connection.

AWS CLI

To create a GitHub connection

The following create-connection example creates a connection to a private GitHub code repository. The connection status after a successful call is PENDING_HANDSHAKE. This is because an authentication handshake with the provider still hasn't happened. Complete the handshake using the App Runner console.

```
aws apprunner create-connection \
   --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
   "ConnectionName": "my-github-connection",
   "ProviderType": "GITHUB"
}
```

Output:

```
{
   "Connection": {
      "ConnectionName": "my-github-connection",
      "Status": "PENDING_HANDSHAKE",
      "CreatedAt": "2020-11-03T00:32:51Z",
      "ProviderType": "GITHUB"
   }
}
```

For more information, see Managing App Runner connections in the AWS App Runner Developer Guide.
create-service

The following code example shows how to use create-service.

AWS CLI

Example 1: To create a source code repository service

The following create-service example creates an App Runner service based on a Python source code repository.

```
aws apprunner create-service \
  --cli-input-json file://input.json

delete-auto-scaling-configuration

The following code example shows how to use delete-auto-scaling-configuration.

AWS CLI

Example 1: To delete the latest active revision of an auto scaling configuration

The following delete-auto-scaling-configuration example deletes the latest active revision of an App Runner auto scaling configuration. To delete the latest active revision, specify an Amazon Resource Name (ARN) that ends with the configuration name, without the revision component.

In the example, two revisions exist before this action. Therefore, revision 2 (the latest) is deleted. However, it now shows "Latest": false, because, after being deleted, it isn't the latest active revision anymore.

```bash
aws apprunner delete-auto-scaling-configuration \
--cli-input-json file://input.json
```

Contents of input.json:

```json
{
    "RuntimeEnvironmentVariables": [
        {
            "NAME": "Jane"
        }
    ],
    "ImageRepositoryType": "ECR"
}
```

"Status": "OPERATION_IN_PROGRESS",
"InstanceConfiguration": {
    "CPU": "1 vCPU",
    "Memory": "3 GB"
}
}
"AutoScalingConfigurationArn": "arn:aws:apprunner:us-east-1:123456789012:autoscalingconfiguration/high-availability"
}

Output:

{
    "AutoScalingConfiguration": {
        "AutoScalingConfigurationArn": "arn:aws:apprunner:us-east-1:123456789012:autoscalingconfiguration/high-availability/2/e76562f50d78042e819fead0f59672e6",
        "AutoScalingConfigurationName": "high-availability",
        "AutoScalingConfigurationRevision": 2,
        "CreatedAt": "2021-02-25T17:42:59Z",
        "DeletedAt": "2021-03-02T08:07:06Z",
        "Latest": false,
        "Status": "INACTIVE",
        "MaxConcurrency": 30,
        "MaxSize": 90,
        "MinSize": 5
    }
}

**Example 2: To delete a specific revision of an auto scaling configuration**

The following delete-auto-scaling-configuration example deletes a specific revision of an App Runner auto scaling configuration. To delete a specific revision, specify an ARN that includes the revision number.

In the example, several revisions exist before this action. The action deletes revision 1.

```
aws apprunner delete-auto-scaling-configuration \
    --cli-input-json file://input.json
```

**Contents of input.json:**

```json
{
    "AutoScalingConfigurationArn": "arn:aws:apprunner:us-east-1:123456789012:autoscalingconfiguration/high-availability/1"
}
```

**Output:**

```
{
    "AutoScalingConfiguration": {
        "AutoScalingConfigurationArn": "arn:aws:apprunner:us-east-1:123456789012:autoscalingconfiguration/high-availability/1/2f50e7656d7819f8e60f59672e68042e",
        "AutoScalingConfigurationName": "high-availability",
        "AutoScalingConfigurationRevision": 1,
        "CreatedAt": "2020-11-03T00:29:17Z",
        "DeletedAt": "2021-03-02T08:07:06Z",
        "Latest": false,
        "Status": "INACTIVE",
        "MaxConcurrency": 100,
        "MaxSize": 50,
        "MinSize": 5
    }
}
```

**delete-connection**

The following code example shows how to use `delete-connection`.

**AWS CLI**

**To delete a connection**

The following `delete-connection` example deletes an App Runner connection. The connection status after a successful call is `DELETED`. This is because the connection is no longer available.

```
aws apprunner delete-connection \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ConnectionArn": "arn:aws:apprunner:us-east-1:123456789012:connection/my-github-connection"
}
```
Output:

```
{
    "Connection": {
        "ConnectionName": "my-github-connection",
        "Status": "DELETED",
        "CreatedAt": "2020-11-03T00:32:51Z",
        "ProviderType": "GITHUB"
    }
}
```

- For API details, see [DeleteConnection](#) in *AWS CLI Command Reference*.

### delete-service

The following code example shows how to use `delete-service`.

**AWS CLI**

**To delete a service**

The following `delete-service` example deletes an App Runner service.

```
aws apprunner delete-service \\

describe-auto-scaling-configuration

The following code example shows how to use describe-auto-scaling-configuration.

AWS CLI

Example 1: To describe the latest active revision of an auto scaling configuration

The following describe-auto-scaling-configuration example gets a description of the latest active revision of an App Runner auto scaling configuration. To describe the latest active revision, specify an ARN that ends with the configuration name, without the revision component.

In the example, two revisions exist. Therefore, revision 2 (the latest) is described. The resulting object shows "Latest": true.

```
aws apprunner describe-auto-scaling-configuration
   --cli-input-json file://input.json
```

Contents of input.json:

```
{
   "AutoScalingConfigurationArn": "arn:aws:apprunner:us-east-1:123456789012:autoscalingconfiguration/high-availability"
}
```

Output:

```
{
   "AutoScalingConfiguration": {
      "AutoScalingConfigurationArn": "arn:aws:apprunner:us-east-1:123456789012:autoscalingconfiguration/high-availability/2/e76562f50d78042e819fead0f59672e6",
      "AutoScalingConfigurationName": "high-availability",
      "AutoScalingConfigurationRevision": 2,
      "CreatedAt": "2021-02-25T17:42:59Z",
      "Latest": true,
      "Status": "ACTIVE",
      "MaxConcurrency": 30,
      "MaxSize": 90,
      "MinSize": 5
   }
}
```
Example 2: To describe a specific revision of an auto scaling configuration

The following describe-auto-scaling-configuration example get a description of a specific revision of an App Runner auto scaling configuration. To describe a specific revision, specify an ARN that includes the revision number.

In the example, several revisions exist and revision 1 is queried. The resulting object shows "Latest": false.

```
aws apprunner describe-auto-scaling-configuration \
   --cli-input-json file://input.json
```

Contents of input.json:

```
{
   "AutoScalingConfigurationArn": "arn:aws:apprunner:us-east-1:123456789012:autoscalingconfiguration/high-availability/1"
}
```

Output:

```
{
   "AutoScalingConfiguration": {
      "AutoScalingConfigurationArn": "arn:aws:apprunner:us-east-1:123456789012:autoscalingconfiguration/high-availability/1/2f50e7656d7819f6ead0f59672e68042e",
      "AutoScalingConfigurationName": "high-availability",
      "AutoScalingConfigurationRevision": 1,
      "CreatedAt": "2020-11-03T00:29:17Z",
      "Latest": false,
      "Status": "ACTIVE",
      "MaxConcurrency": 100,
      "MaxSize": 50,
      "MinSize": 5
   }
}
```

**describe-custom-domains**

The following code example shows how to use `describe-custom-domains`.

**AWS CLI**

**To get descriptions of custom domain names associated with a service**

The following `describe-custom-domains` example gets descriptions and status of the custom domain names associated with an App Runner service.

```bash
aws apprunner describe-custom-domains \
--cli-input-json file://input.json
```

Contents of `input.json`:

```json
{
    "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-app/8fe1e10304f84f2b0df550fe98a71fa",
    "DomainName": "example.com",
    "EnableWWWSubdomain": true
}
```

Output:

```json

**disassociate-custom-domain**

The following code example shows how to use `disassociate-custom-domain`.

**AWS CLI**

**To disassociate a domain name from a service**

The following `disassociate-custom-domain` example disassociates the domain `example.com` from an App Runner service. The call also disassociates the subdomain `www.example.com` that was associated together with the root domain.

```
aws apprunner disassociate-custom-domain \
  --cli-input-json file://input.json
```

**Contents of `input.json`:**

```json
{
    "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-app/8fe1e10304f84fd2b0df550fe98a71fa",
    "DomainName": "example.com"
}
```

**Output:**

```json
{
    "CustomDomain": {
        "CertificateValidationRecords": [
            {
```
For API details, see `DisassociateCustomDomain` in *AWS CLI Command Reference*.

**list-auto-scaling-configurations**

The following code example shows how to use `list-auto-scaling-configurations`.

**AWS CLI**

**To get a paginated listing of App Runner auto scaling configurations**

The following `list-auto-scaling-configurations` example lists all App Runner auto scaling configurations in your AWS account. Up to five auto scaling configurations are listed in each response. `AutoScalingConfigurationName` and `LatestOnly` aren't specified. Their defaults cause the latest revision of all active configurations to be listed.

In this example, the response includes two results and there aren't additional ones, so no `NextToken` is returned.

```bash
aws apprunner list-auto-scaling-configurations \
```
Contents of input.json:

```json
{
    "MaxResults": 5
}
```

Output:

```json
{
    "AutoScalingConfigurationSummaryList": [
        {
            "AutoScalingConfigurationArn": "arn:aws:apprunner:us-east-1:123456789012:autoscalingconfiguration/high-availability/2/e76562f50d78042e819f6ead0f59672e6",
            "AutoScalingConfigurationName": "high-availability",

            "AutoScalingConfigurationName": "low-cost",
            "AutoScalingConfigurationRevision": 1
        }
    ]
}
```

- For API details, see [ListAutoScalingConfigurations](https://docs.aws.amazon.com/cli/latest/reference/apprunner/list-autoscaling-configurations.html) in AWS CLI Command Reference.

**list-connections**

The following code example shows how to use `list-connections`.

**AWS CLI**

**Example 1: To list all connections**

The following `list-connections` example lists all App Runner connections in the AWS account.
aws apprunner list-connections

Output:

```json
{
    "ConnectionSummaryList": [
    {
        "ConnectionName": "my-github-connection",
        "Status": "AVAILABLE",
        "CreatedAt": "2020-11-03T00:32:51Z",
        "ProviderType": "GITHUB"
    },
    {
        "ConnectionName": "my-github-org-connection",
        "Status": "AVAILABLE",
        "CreatedAt": "2020-11-03T02:54:17Z",
        "ProviderType": "GITHUB"
    }
    ]
}
```

Example 2: To list a connection by name

The following list-connections example lists a connection by its name.

```bash
aws apprunner list-connections \
  --cli-input-json file://input.json
```

Contents of input.json:

```json
{
    "ConnectionName": "my-github-org-connection"
}
```

Output:

```json
{
}
```
"ConnectionSummaryList": [
  {
    "ConnectionName": "my-github-org-connection",
    "Status": "AVAILABLE",
    "CreatedAt": "2020-11-03T02:54:17Z",
    "ProviderType": "GITHUB"
  }
]

- For API details, see [ListConnections](#) in *AWS CLI Command Reference*.

**list-operations**

The following code example shows how to use `list-operations`.

**AWS CLI**

To list operations that occurred on a service

The following `list-operations` example lists all operations that occurred on an App Runner service so far. In this example, the service is new and only a single operation of type `CREATE_SERVICE` has occurred.

```
aws apprunner list-operations \
  --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
  "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-app/8fe1e10304f84fd2b0df550fe98a71fa"
}
```

Output:

```
{
  "OperationSummaryList": [
    {
      "EndedAt": 1606156217,
```

list-services

The following code example shows how to use list-services.

AWS CLI

To get a paginated listing of App Runner services

The following list-services example lists all App Runner services in the AWS account. Up to two services are listed in each response. This example shows the first request. The response includes two results and a token that can be used in the next request. When a subsequent response doesn't include a token, all services have been listed.

```bash
aws apprunner list-services \ 
--cli-input-json file://input.json
```

Contents of input.json:

```json
{
   "MaxResults": 2
}
```

Output:

**list-tags-for-resource**

The following code example shows how to use `list-tags-for-resource`.

**AWS CLI**

To list tags associated with an App Runner service

The following `list-tags-for-resource` example lists all the tags that are associated with an App Runner service.

```
aws apprunner list-tags-for-resource \
  --cli-input-json file://input.json
```

Contents of `input.json`:

}
```

- For API details, see [StartDeployment](https://docs.aws.amazon.com/cli/latest/reference/apprunner/start-deployment.html) in AWS CLI Command Reference.

**tag-resource**

The following code example shows how to use `tag-resource`.

AWS CLI

To add tags to an App Runner service

The following `tag-resource` example adds two tags to an App Runner service.

```bash
aws apprunner tag-resource \
--cli-input-json file://input.json
```

Contents of `input.json`:
This command produces no output.

- For API details, see TagResource in AWS CLI Command Reference.

untag-resource

The following code example shows how to use untag-resource.

AWS CLI

To remove tags from an App Runner service

The following untag-resource example removes two tags from an App Runner service.

```bash
aws apprunner untag-resource \
    --cli-input-json file://input.json
```

Contents of input.json:

```json
{
    "ResourceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-app/8fe1e10304f84fd2b0df550fe98a71fa",
    "TagKeys": [
        "Department",
        "CustomerId"
    ]
}
```
This command produces no output.

- For API details, see UntagResource in AWS CLI Command Reference.

**update-service**

The following code example shows how to use update-service.

**AWS CLI**

**To update memory size**

The following update-service example updates the memory size of instances (scaling units) of an App Runner service to 2048 MiB.

When the call succeeds, App Runner starts an asynchronous update process. The Service structure that's returned by the call reflects the new memory value that's being applied by this call.

```bash
aws apprunner update-service \
   --cli-input-json file://input.json
```

**Contents of input.json:**

```json
{
   "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-app/8fe1e10304f84fd2b0df550fe98a71fa",
   "InstanceConfiguration": {
       "Memory": "4 GB"
   }
}
```

**Output:**

```json
{
   "OperationId": "17fe9f55-7e91-4097-b243-fcabb69a4cf",
   "Service": {
       "CreatedAt": "2020-11-20T19:05:25Z",
   }
}
```
For API details, see UpdateService in AWS CLI Command Reference.
AWS AppConfig examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with AWS AppConfig.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Topics**
- **Actions**

**Actions**

**create-application**

The following code example shows how to use `create-application`.

**AWS CLI**

**To create an application**

The following `create-application` example creates an application in AWS AppConfig.

```bash
aws appconfig create-application \
    --name "example-application" \
    --description "An application used for creating an example."
```

**Output:**

```json
{
    "Description": "An application used for creating an example.",
    "Id": "339ohji",
    "Name": "example-application"
}
```
For more information, see Step 1: Creating an AWS AppConfig application in the AWS AppConfig User Guide.

- For API details, see CreateApplication in AWS CLI Command Reference.

create-configuration-profile

The following code example shows how to use create-configuration-profile.

AWS CLI

To create a configuration profile

The following create-configuration-profile example creates a configuration profile using a configuration stored in Parameter Store, a capability of Systems Manager.

```bash
aws appconfig create-configuration-profile \
--application-id "339ohji" \
--name "Example-Configuration-Profile" \
--location-uri "ssm-parameter://Example-Parameter" \
--retrieval-role-arn "arn:aws:iam::111122223333:role/Example-App-Config-Role"
```

Output:

```
{
  "ApplicationId": "339ohji",
  "Description": null,
  "Id": "ur8hx2f",
  "LocationUri": "ssm-parameter://Example-Parameter",
  "Name": "Example-Configuration-Profile",
  "RetrievalRoleArn": "arn:aws:iam::111122223333:role/Example-App-Config-Role",
  "Type": null,
  "Validators": null
}
```

For more information, see Step 3: Creating a configuration and a configuration profile in the AWS AppConfig User Guide.

- For API details, see CreateConfigurationProfile in AWS CLI Command Reference.
create-environment

The following code example shows how to use create-environment.

AWS CLI

To create an environment

The following create-environment example creates an AWS AppConfig environment named Example-Environment using the application you created using create-application.

```
aws appconfig create-environment \
   --application-id "339ohji" \
   --name "Example-Environment"
```

Output:

```
{
   "ApplicationId": "339ohji",
   "Description": null,
   "Id": "54j1r29",
   "Monitors": null,
   "Name": "Example-Environment",
   "State": "ReadyForDeployment"
}
```

For more information, see Step 2: Creating an environment in the AWS AppConfig User Guide.

- For API details, see CreateEnvironment in AWS CLI Command Reference.

create-extension-association

The following code example shows how to use create-extension-association.

AWS CLI

To create an extension association

The following create-extension-association example creates a new extension association in AWS AppConfig.

```
aws appconfig create-extension-association \
```
The following code example shows how to use create-extension.

**AWS CLI**

To create an extension

The following create-extension example creates a new extension in AWS AppConfig.

```
aws appconfig create-extension \\   --region us-west-2 \\   --name S3-backup-extension \\   --actions PRE_CREATE_HOSTED_CONFIGURATION_VERSION=[\{Name=S3backup,Uri=arn:aws:lambda:us-west-2:123456789012:function:s3backupfunction,RoleArn=arn:aws:iam::123456789012:role/appconfigextensionrole\} ] \\   --parameters S3bucket={Required=true}
```
Output:

```json
{
  "Id": "1A2B3C4D",
  "Name": "S3-backup-extension",
  "VersionNumber": 1,
  "Arn": "arn:aws:appconfig:us-west-2:123456789012:extension/1A2B3C4D/1",
  "Actions": {
    "PRE_CREATE_HOSTED_CONFIGURATION_VERSION": [
      {
        "Name": "S3backup",
        "RoleArn": "arn:aws:iam::123456789012:role/appconfigextensionrole"
      }
    ]
  },
  "Parameters": {
    "S3bucket": {
      "Required": true
    }
  }
}
```

For more information, see [Working with AWS AppConfig extensions](http://aws.amazon.com/documentation/appconfig/userguide/) in the *AWS AppConfig User Guide*.

- For API details, see [CreateExtension](http://aws.amazon.com/documentation/awscli/reference/) in *AWS CLI Command Reference*.

**create-hosted-configuration-version**

The following code example shows how to use `create-hosted-configuration-version`.

**AWS CLI**

**To create a hosted configuration version**

The following `create-hosted-configuration-version` example creates a new configuration in the AWS AppConfig hosted configuration store. The configuration content must first be converted to base64.

```bash
aws appconfig create-hosted-configuration-version \
```
--application-id "339ohji" \
--configuration-profile-id "ur8hx2f" \
--content
eyAiTmFtZSI6ICJFeGFtcGxlQXBwbGljYXRpb24iLCAiSWQiOiBFeGFtcGxlSUQsICJSYW5rIjogNyB9 \
--content-type "application/json" \
configuration_version_output_file

Contents of configuration_version_output_file:

{ "Name": "ExampleApplication", "Id": ExampleID, "Rank": 7 }

Output:

{
    "ApplicationId": "339ohji",
    "ConfigurationProfileId": "ur8hx2f",
    "VersionNumber": "1",
    "ContentType": "application/json"
}

For more information, see [About the AWS AppConfig hosted configuration store](https://docs.aws.amazon.com/appconfig/latest/userguide/about-hosted-configuration-store.html) in the [AWS AppConfig User Guide](https://docs.aws.amazon.com/appconfig/latest/userguide/).

**delete-application**

The following code example shows how to use delete-application.

AWS CLI

**To delete an application**

The following delete-application example deletes the specified application.

```
aws appconfig delete-application \
  --application-id 339ohji
```

This command produces no output.

For more information, see [Step 1: Creating an AWS AppConfig application](https://docs.aws.amazon.com/appconfig/latest/userguide/step1-creating-aws-appconfig-application.html) in the [AWS AppConfig User Guide](https://docs.aws.amazon.com/appconfig/latest/userguide/).
delete-configuration-profile

The following code example shows how to use delete-configuration-profile.

**AWS CLI**

To delete a configuration profile

The following delete-configuration-profile example deletes the specified configuration profile.

```plaintext
aws appconfig delete-configuration-profile \
   --application-id 339ohji \
   --configuration-profile-id ur8hx2f
```

This command produces no output.

For more information, see Step 3: Creating a configuration and a configuration profile in the AWS AppConfig User Guide.

- For API details, see [DeleteApplication](#) in AWS CLI Command Reference.

delete-deployment-strategy

The following code example shows how to use delete-deployment-strategy.

**AWS CLI**

To delete a deployment strategy

The following delete-deployment-strategy example deletes the specified deployment strategy.

```plaintext
aws appconfig delete-deployment-strategy \
   --deployment-strategy-id 1225qzk
```

This command produces no output.

For more information, see Step 4: Creating a deployment strategy in the AWS AppConfig User Guide.

- For API details, see [DeleteConfigurationProfile](#) in AWS CLI Command Reference.
• For API details, see `DeleteDeploymentStrategy` in *AWS CLI Command Reference*.

**delete-environment**

The following code example shows how to use `delete-environment`.

**AWS CLI**

**To delete an environment**

The following `delete-environment` example deletes the specified application environment.

```bash
aws appconfig delete-environment \
   --application-id 339ohji \
   --environment-id 54j1r29
```

This command produces no output.

For more information, see *Step 2: Creating an environment* in the *AWS AppConfig User Guide*.

• For API details, see `DeleteEnvironment` in *AWS CLI Command Reference*.

**delete-extension-association**

The following code example shows how to use `delete-extension-association`.

**AWS CLI**

**To delete an extension association**

The following `delete-extension-association` example deletes an extension association from AWS AppConfig.

```bash
aws appconfig delete-extension-association \
   --region us-west-2 \
   --extension-association-id a1b2c3d4
```

This command produces no output.

For more information, see *Working with AWS AppConfig extensions* in the *AWS AppConfig User Guide*. 
delete-extension

The following code example shows how to use delete-extension.

AWS CLI

To delete an extension

The following delete-extension example deletes an extension from AWS AppConfig.

```
aws appconfig delete-extension \
   --region us-west-2 \
   --extension-identifier S3-backup-extension
```

This command produces no output.

For more information, see Working with AWS AppConfig extensions in the AWS AppConfig User Guide.

• For API details, see DeleteExtension in AWS CLI Command Reference.

delete-hosted-configuration-version

The following code example shows how to use delete-hosted-configuration-version.

AWS CLI

To delete a hosted configuration version

The following delete-hosted-configuration-version example deletes a configuration version hosted in the AWS AppConfig hosted configuration store.

```
aws appconfig delete-hosted-configuration-version \
   --application-id 339ohji \
   --configuration-profile-id ur8hx2f \
   --version-number 1
```

Output:: This command produces no output.
For more information, see [Step 3: Creating a configuration and a configuration profile](#) in the [AWS AppConfig User Guide](#).

- For API details, see [DeleteHostedConfigurationVersion](#) in [AWS CLI Command Reference](#).

### get-application

The following code example shows how to use get-application.

**AWS CLI**

**To list details of an application**

The following get-application example lists the details of the specified application.

```
aws appconfig get-application \
  --application-id 339ohji
```

**Output:**

```
{
  "Description": "An application used for creating an example.",
  "Id": "339ohji",
  "Name": "example-application"
}
```

For more information, see [How AWS AppConfig works](#) in the [AWS AppConfig User Guide](#).

- For API details, see [GetApplication](#) in [AWS CLI Command Reference](#).

### get-configuration-profile

The following code example shows how to use get-configuration-profile.

**AWS CLI**

**To retrieve configuration profile details**

The following get-configuration-profile example returns the details of the specified configuration profile.

```
aws appconfig get-configuration-profile \
```

...
--application-id 339ohji \ 
--configuration-profile-id ur8hx2f

Output:

```
{
    "ApplicationId": "339ohji",
    "Id": "ur8hx2f",
    "Name": "Example-Configuration-Profile",
    "LocationUri": "ssm-parameter://Example-Parameter",
    "RetrievalRoleArn": "arn:aws:iam::111122223333:role/Example-App-Config-Role"
}
```

For more information, see Step 3: Creating a configuration and a configuration profile in the AWS AppConfig User Guide.

- For API details, see GetConfigurationProfile in AWS CLI Command Reference.

**get-configuration**

The following code example shows how to use get-configuration.

**AWS CLI**

**To retrieve configuration details**

The following get-configuration example returns the configuration details of the example application. On subsequent calls to get-configuration use the client-configuration-version parameter to only update the configuration of your application if the version has changed. Only updating the configuration when the version has changed avoids excess charges incurred by calling get-configuration.

```
aws appconfig get-configuration \ 
    --application "example-application" \ 
    --environment "Example-Environment" \ 
    --configuration "Example-Configuration-Profile" \ 
    --client-id "test-id" \ 
    configuration-output-file
```

Contents of configuration-output-file:
Output:

```
{
    "ConfigurationVersion": "1",
    "ContentType": "application/json"
}
```

For more information, see [Step 6: Receiving the configuration](https://aws.amazon.com/documentation/appconfig/) in the *AWS AppConfig User Guide*.

- For API details, see [GetConfiguration](https://aws.amazon.com/documentation/appconfig/) in *AWS CLI Command Reference*.

**get-deployment-strategy**

The following code example shows how to use `get-deployment-strategy`.

**AWS CLI**

**To retrieve details of a deployment strategy**

The following `get-deployment-strategy` example lists the details of the specified deployment strategy.

```
aws appconfig get-deployment-strategy
   --deployment-strategy-id 1225qzk
```

Output:

```
{
    "Id": "1225qzk",
    "Name": "Example-Deployment",
    "DeploymentDurationInMinutes": 15,
    "GrowthType": "LINEAR",
    "GrowthFactor": 25.0,
    "FinalBakeTimeInMinutes": 0,
    "ReplicateTo": "SSM_DOCUMENT"
}
```

For more information, see [Step 4: Creating a deployment strategy](https://aws.amazon.com/documentation/appconfig/) in the *AWS AppConfig User Guide*.
• For API details, see GetDeploymentStrategy in AWS CLI Command Reference.

get-deployment

The following code example shows how to use get-deployment.

AWS CLI

To retrieve deployment details

The following get-deployment example lists details of the deployment to the application in the specified environment and deployment.

```
aws appconfig get-deployment \
  --application-id 339ohji \
  --environment-id 54j1r29 \
  --deployment-number 1
```

Output:

```
{
    "ApplicationId": "339ohji",
    "EnvironmentId": "54j1r29",
    "DeploymentStrategyId": "1225qzk",
    "ConfigurationProfileId": "ur8hx2f",
    "DeploymentNumber": 1,
    "ConfigurationName": "Example-Configuration-Profile",
    "ConfigurationLocationUri": "ssm-parameter://Example-Parameter",
    "ConfigurationVersion": "1",
    "DeploymentDurationInMinutes": 15,
    "GrowthType": "LINEAR",
    "GrowthFactor": 25.0,
    "FinalBakeTimeInMinutes": 0,
    "State": "COMPLETE",
    "EventLog": [
        {
            "EventType": "DEPLOYMENT_COMPLETED",
            "TriggeredBy": "APPCONFIG",

            "OccurredAt": "2021-09-17T21:59:03.888000+00:00"
        },
        {
        }
    ]
}
```
For more information, see Step 5: Deploying a configuration in the AWS AppConfig User Guide.

- For API details, see GetDeployment in AWS CLI Command Reference.
get-environment

The following code example shows how to use `get-environment`.

**AWS CLI**

**To retrieve environment details**

The following `get-environment` example returns the details and state of the specified environment.

```bash
aws appconfig get-environment \
    --application-id 339ohji \
    --environment-id 54j1r29
```

Output:

```
{
    "ApplicationId": "339ohji",
    "Id": "54j1r29",
    "Name": "Example-Environment",
    "State": "ReadyForDeployment"
}
```

For more information, see [Step 2: Creating an environment](https://docs.aws.amazon.com/appconfig/latest/userguide/step-2-creating-an-environment.html) in the *AWS AppConfig User Guide*.

- For API details, see [GetEnvironment](https://docs.aws.amazon.com/cli/latest/reference/appconfig/get-environment.html) in *AWS CLI Command Reference*.

get-extension-association

The following code example shows how to use `get-extension-association`.

**AWS CLI**

**To get extension association details**

The following `get-extension-association` example displays information about an extension association.

```bash
aws appconfig get-extension-association \
    --region us-west-2
```
```bash
aws appconfig get-extension
--region us-west-2
--extension-identifier S3-backup-extension
```

Output:

```json
{
    "Id": "1A2B3C4D",
    "Name": "S3-backup-extension",
    "VersionNumber": 1,
}
```

### get-extension

The following code example shows how to use `get-extension`.

**AWS CLI**

**To get extension details**

The following `get-extension` example displays information about an extension.

```bash
aws appconfig get-extension
--extension-association-id a1b2c3d4
```

Output:

```json
{
    "Id": "a1b2c3d4",
    "Parameters": {
        "S3bucket": "FinanceConfigurationBackup"
    },
    "ExtensionVersionNumber": 1

        }
    ],
    "Parameters": {
        "S3bucket": {
            "Required": true
        }
    }
}

For more information, see [Working with AWS AppConfig extensions](#) in the [AWS AppConfig User Guide](#).

- For API details, see [GetExtension](#) in [AWS CLI Command Reference](#).

get-hosted-configuration-version

The following code example shows how to use get-hosted-configuration-version.

AWS CLI

To retrieve hosted configuration details

The following get-hosted-configuration-version example retrieves the configuration details of the AWS AppConfig hosted configuration.

```
aws appconfig get-hosted-configuration-version \
    --application-id 339ohji \
    --configuration-profile-id ur8hx2f \
    --version-number 1 \
    hosted-configuration-version-output
```

Contents of hosted-configuration-version-output:

```
{ "Name": "ExampleApplication", "Id": ExampleID, "Rank": 7 }
```
Output:

```
{
   "ApplicationId": "339ohji",
   "ConfigurationProfileId": "ur8hx2f",
   "VersionNumber": "1",
   "ContentType": "application/json"
}
```

For more information, see [About the AWS AppConfig hosted configuration store](#) in the *AWS AppConfig User Guide*.

- For API details, see [GetHostedConfigurationVersion](#) in *AWS CLI Command Reference*.

### list-applications

The following code example shows how to use `list-applications`.

**AWS CLI**

**To list the available applications**

The following `list-applications` example lists the available applications in your AWS account.

```
aws appconfig list-applications
```

Output:

```
{
   "Items": [ 
   {
      "Id": "339ohji",
      "Name": "test-application",
      "Description": "An application used for creating an example."
   },
   {
      "Id": "rwalwu7",
      "Name": "Test-Application"
   }
   ]
}
```
For more information, see Step 1: Creating an AWS AppConfig application in the AWS AppConfig User Guide.

- For API details, see ListApplications in AWS CLI Command Reference.

list-configuration-profiles

The following code example shows how to use list-configuration-profiles.

AWS CLI

To list the available configuration profiles

The following list-configuration-profiles example lists the available configuration profiles for the specified application.

```
aws appconfig list-configuration-profiles \\
   --application-id 339ohji
```

Output:

```
{
   "Items": [
      {
         "ApplicationId": "339ohji",
         "Id": "ur8hx2f",
         "Name": "Example-Configuration-Profile",
         "LocationUri": "ssm-parameter://Example-Parameter"
      }
   ]
}
```

For more information, see Step 3: Creating a configuration and a configuration profile in the AWS AppConfig User Guide.

- For API details, see ListConfigurationProfiles in AWS CLI Command Reference.

list-deployment-strategies

The following code example shows how to use list-deployment-strategies.
AWS CLI

To list the available deployment strategies

The following list-deployment-strategies example lists the available deployment strategies in your AWS account.

```
aws appconfig list-deployment-strategies
```

Output:

```
{
    "Items": [
        {
            "Id": "1225qzk",

### list-deployments

The following code example shows how to use `list-deployments`.

**AWS CLI**

**To list the available deployments**

The following `list-deployments` example lists the available deployments in your AWS account for the specified application and environment.

```
aws appconfig list-deployments \
  --application-id 339ohji \
  --environment-id 54j1r29
```

**Output:**

```
{
  "Items": [
    {
      "DeploymentNumber": 1,
      "ConfigurationName": "Example-Configuration-Profile",
      "ConfigurationVersion": "1",
      "DeploymentDurationInMinutes": 15,
      "GrowthType": "LINEAR",
      "GrowthFactor": 10.0,
      "FinalBakeTimeInMinutes": 10,
      "ReplicateTo": "NONE"
    }
  ]
}
```
For more information, see [Step 5: Deploying a configuration](#) in the [AWS AppConfig User Guide](#).

- For API details, see [ListDeployments](#) in [AWS CLI Command Reference](#).

**list-environments**

The following code example shows how to use `list-environments`.

**AWS CLI**

**To list the available environments**

The following `list-environments` example lists the available environments in your AWS account for the specified application.

```bash
aws appconfig list-environments \
    --application-id 339ohji
```

**Output:**

```json
{
   "Items": [
   {
     "ApplicationId": "339ohji",
     "Id": "54j1r29",
     "Name": "Example-Environment",
     "State": "ReadyForDeployment"
   }
   ]
}
```

For more information, see [Step 2: Creating an environment](#) in the [AWS AppConfig User Guide](#).
list-extension-associations

The following code example shows how to use list-extension-associations.

**AWS CLI**

To list all AWS AppConfig extension associations in your AWS account for an AWS Region

The following list-extension-associations example lists all AWS AppConfig extension associations for the current AWS account in a specific AWS Region.

```bash
aws appconfig list-extension-associations \
--region us-west-2
```

Output:

```json
{
  "Items": [
    {
      "Id": "a1b2c3d4",
    }
  ]
}
```

list-extensions

The following code example shows how to use list-extensions.

**AWS CLI**

To list all AWS AppConfig extensions in your AWS account for an AWS Region

The following `list-extensions` example lists all AWS AppConfig extensions for the current AWS account in a specific AWS Region. The command returns custom and AWS authored extensions.

```
aws appconfig list-extensions \\
--region us-west-2
```

Output:

```json
{
    "Items": [ 
        {
            "Id": "1A2B3C4D",
            "Name": "S3-backup-extension",

For more information, see Working with AWS AppConfig extensions in the AWS AppConfig User Guide.

- For API details, see ListExtensions in AWS CLI Command Reference.

### list-hosted-configuration-versions

The following code example shows how to use list-hosted-configuration-versions.

**AWS CLI**

To list the available hosted configuration versions
The following list-hosted-configuration-versions example lists the configurations versions hosted in the AWS AppConfig hosted configuration store for the specified application and configuration profile.

```
aws appconfig list-hosted-configuration-versions \
   --application-id 339ohji \ 
   --configuration-profile-id ur8hx2f
```

Output:

```
{
   "Items": [
      {
         "ApplicationId": "339ohji",
         "ConfigurationProfileId": "ur8hx2f",
         "VersionNumber": 1,
         "ContentType": "application/json"
      }
   ]
}
```

For more information, see About the AWS AppConfig hosted configuration store in the AWS AppConfig User Guide.

- For API details, see ListHostedConfigurationVersions in AWS CLI Command Reference.

**list-tags-for-resource**

The following code example shows how to use list-tags-for-resource.

**AWS CLI**

To list the tags of an application

The following list-tags-for-resource example lists the tags of a specified application.

```
aws appconfig list-tags-for-resource \
```

Output:
For more information, see [Step 1: Creating an AWS AppConfig application](#) in the *AWS AppConfig User Guide*.

- For API details, see [ListTagsForResource](#) in *AWS CLI Command Reference*.

**start-deployment**

The following code example shows how to use `start-deployment`.

**AWS CLI**

**To start a configuration deployment**

The following `start-deployment` example starts a deployment to the application using the specified environment, deployment strategy, and configuration profile.

```shell
aws appconfig start-deployment \
  --application-id 339ohji \
  --environment-id 54j1r29 \
  --deployment-strategy-id 1225qzk \
  --configuration-profile-id ur8hx2f \
  --configuration-version 1
```

**Output:**

```json
{
  "ApplicationId": "339ohji",
  "EnvironmentId": "54j1r29",
  "DeploymentStrategyId": "1225qzk",
  "ConfigurationProfileId": "ur8hx2f",

  }
],
"PercentageComplete": 0.0,
"StartedAt": "2021-09-17T21:43:54.205000+00:00"
}

For more information, see Step 5: Deploying a configuration in the AWS AppConfig User Guide.

- For API details, see StartDeployment in AWS CLI Command Reference.

**stop-deployment**

The following code example shows how to use stop-deployment.

**AWS CLI**

**To stop configuration deployment**

The following stop-deployment example stops the deployment of an application configuration to the specified environment.

```
aws appconfig stop-deployment \\
  --application-id 339ohji \\
  --environment-id 54j1r29 \\
  --deployment-number 2
```

**Output:**

```
{
  "DeploymentNumber": 0,
  "DeploymentDurationInMinutes": 0,
  "GrowthFactor": 0.0,
  "GrowthType": "LINEAR",
  "GrowthFactor": 25.0,

  ],
  "PercentageComplete": 0.0,
  "StartedAt": "2021-09-17T21:43:54.205000+00:00"
}
```
For more information, see Step 5: Deploying a configuration in the AWS AppConfig User Guide.

- For API details, see StopDeployment in AWS CLI Command Reference.

**tag-resource**

The following code example shows how to use tag-resource.

**AWS CLI**

**To tag an application**

The following tag-resource example tags an application resource.

```
aws appconfig tag-resource \
--resource-arn arn:aws:appconfig:us-east-1:682428703967:application/339ohji \
--tags '{"group1" : "1"}'
```

This command produces no output.

For more information, see Step 1: Creating an AWS AppConfig application in the AWS AppConfig User Guide.

- For API details, see TagResource in AWS CLI Command Reference.

**untag-resource**

The following code example shows how to use untag-resource.

**AWS CLI**

**To remove a tag from an application**

The following untag-resource example removes the group1 tag from the specified application.

```
aws appconfig untag-resource \
```
This command produces no output.

For more information, see Step 1: Creating an AWS AppConfig application in the AWS AppConfig User Guide.

- For API details, see UntagResource in AWS CLI Command Reference.

**update-application**

The following code example shows how to use update-application.

**AWS CLI**

**To update an application**

The following update-application example updates the name of the specified application.

```bash
aws appconfig update-application \
  --application-id 339ohji \
  --name "Example-Application"
```

Output:

```
{
  "Id": "339ohji",
  "Name": "Example-Application",
  "Description": "An application used for creating an example."
}
```

For more information, see Step 1: Creating an AWS AppConfig application in the AWS AppConfig User Guide.

- For API details, see UpdateApplication in AWS CLI Command Reference.

**update-configuration-profile**

The following code example shows how to use update-configuration-profile.
AWS CLI

To update a configuration profile

The following update-configuration-profile example updates the description of the specified configuration profile.

```
aws appconfig update-configuration-profile \
  --application-id 339ohji \
  --configuration-profile-id ur8hx2f \
  --description "Configuration profile used for examples."
```

Output:

```
{
  "ApplicationId": "339ohji",
  "Id": "ur8hx2f",
  "Name": "Example-Configuration-Profile",
  "Description": "Configuration profile used for examples.",
  "LocationUri": "ssm-parameter://Example-Parameter",
  "RetrievalRoleArn": "arn:aws:iam::111122223333:role/Example-App-Config-Role"
}
```

update-deployment-strategy

The following code example shows how to use update-deployment-strategy.

AWS CLI

To update a deployment strategy

The following update-deployment-strategy example updates final bake time to 20 minutes in the specified deployment strategy.

```
aws appconfig update-deployment-strategy \
```

Actions and scenarios 625
UpdateDeploymentStrategy in AWS CLI Command Reference.

update-environment

The following code example shows how to use update-environment.

AWS CLI

To update an environment

The following update-environment example updates an environment's description.

```
aws appconfig update-environment \ 
    --application-id 339ohji \ 
    --environment-id 54j1r29 \ 
    --description "An environment for examples."
```

Output:

```
{
    "ApplicationId": "339ohji",
    "Id": "54j1r29",
    "Name": "Example-Environment",
    ...}
```
"Description": "An environment for examples.",
"State": "RolledBack"
}

For more information, see Step 2: Creating an environment in the AWS AppConfig User Guide.

- For API details, see UpdateEnvironment in AWS CLI Command Reference.

**update-extension-association**

The following code example shows how to use `update-extension-association`.

**AWS CLI**

**To update an AWS AppConfig extension association**

The following update-extension-association example adds a new parameter value to an extension association in AWS AppConfig.

```
aws appconfig update-extension-association
  --region us-west-2
  --extension-association-id a1b2c3d4
  --parameters S3bucket=FinanceMobileApp
```

**Output:**

```
{
  "Id": "a1b2c3d4",
  "Parameters": {
    "S3bucket": "FinanceMobileApp"
  },
  "ExtensionVersionNumber": 1
}
```

For more information, see Working with AWS AppConfig extensions in the AWS AppConfig User Guide.

- For API details, see UpdateExtensionAssociation in AWS CLI Command Reference.
**update-extension**

The following code example shows how to use `update-extension`.

**AWS CLI**

**To update an AWS AppConfig extension**

The following `update-extension` example adds an additional parameter `Key` to an extension in AWS AppConfig.

```
aws appconfig update-extension \
 --region us-west-2 \
 --extension-identifier S3-backup-extension \
 --parameters S3bucket={Required=true},CampaignID={Required=false}
```

**Output:**

```
{
    "Id": "1A2B3C4D",
    "Name": "S3-backup-extension",
    "VersionNumber": 1,
    "Arn": "arn:aws:appconfig:us-west-2:123456789012:extension/1A2B3C4D/1",
    "Actions": {
        "PRE_CREATE_HOSTED_CONFIGURATION_VERSION": [
            {
                "Name": "S3backup",
                "RoleArn": "arn:aws:iam::123456789012:role/appconfigextensionrole"
            }
        ]
    },
    "Parameters": {
        "CampaignID": {
            "Required": false
        },
        "S3bucket": {
            "Required": true
        }
    }
}
```
For more information, see Working with AWS AppConfig extensions in the AWS AppConfig User Guide.

- For API details, see UpdateExtension in AWS CLI Command Reference.

validate-configuration

The following code example shows how to use validate-configuration.

AWS CLI

To validate a configuration

The following validate-configuration example uses the validators in a configuration profile to validate a configuration.

```
aws appconfig validate-configuration \
  --application-id abc1234 \
  --configuration-profile-id ur8hx2f \
  --configuration-version 1
```

The command produces no output.

For more information, see Step 3: Creating a configuration and a configuration profile in the AWS AppConfig User Guide.

- For API details, see ValidateConfiguration in AWS CLI Command Reference.

Application Auto Scaling examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Application Auto Scaling.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Actions

delete-scaling-policy

The following code example shows how to use delete-scaling-policy.

AWS CLI

To delete a scaling policy

This example deletes a scaling policy for the Amazon ECS service web-app running in the default cluster.

Command:

```bash
aws application-autoscaling delete-scaling-policy --policy-name web-app-cpu-lt-25 --scalable-dimension ecs:service:DesiredCount --resource-id service/default/web-app --service-namespace ecs
```

- For API details, see DeleteScalingPolicy in AWS CLI Command Reference.

delete-scheduled-action

The following code example shows how to use delete-scheduled-action.

AWS CLI

To delete a scheduled action

The following delete-scheduled-action example deletes the specified scheduled action from the specified Amazon AppStream 2.0 fleet:

```bash
aws application-autoscaling delete-scheduled-action \\
    --service-namespace appstream \\
    --scalable-dimension appstream:fleet:DesiredCapacity \\
    --resource-id fleet/sample-fleet \\
```
This command produces no output.

For more information, see Scheduled Scaling in the Application Auto Scaling User Guide.

- For API details, see DeleteScheduledAction in AWS CLI Command Reference.

**deregister-scalable-target**

The following code example shows how to use `deregister-scalable-target`.

**AWS CLI**

**To deregister a scalable target**

This example deregisters a scalable target for an Amazon ECS service called `web-app` that is running in the default cluster.

Command:

```
aws application-autoscaling deregister-scalable-target --service-namespace ecs --scalable-dimension ecs:service:DesiredCount --resource-id service/default/web-app
```

This example deregisters a scalable target for a custom resource. The custom-resource-id.txt file contains a string that identifies the Resource ID, which, for a custom resource, is the path to the custom resource through your Amazon API Gateway endpoint.

Command:

```
```

Contents of custom-resource-id.txt file:

```
https://example.execute-api.us-west-2.amazonaws.com/prod/scalableTargetDimensions/1-23456789
```

- For API details, see DeregisterScalableTarget in AWS CLI Command Reference.
describe-scalable-targets

The following code example shows how to use describe-scalable-targets.

AWS CLI

To describe scalable targets

The following describe-scalable-targets example describes the scalable targets for the ecs service namespace.

```
aws application-autoscaling describe-scalability-targets \\
--service-namespace ecs
```

Output:

```
{
   "ScalableTargets": [
   {
      "ServiceNamespace": "ecs",
      "ScalableDimension": "ecs:service:DesiredCount",
      "ResourceId": "service/default/web-app",

   }
   ]
}
```

For more information, see AWS services that you can use with Application Auto Scaling in the Application Auto Scaling User Guide.

- For API details, see DescribeScalableTargets in AWS CLI Command Reference.
describe-scaling-activities

The following code example shows how to use describe-scaling-activities.

AWS CLI

Example 1: To describe scaling activities for the specified Amazon ECS service

The following describe-scaling-activities example describes the scaling activities for an Amazon ECS service called web-app that is running in the default cluster. The output shows a scaling activity initiated by a scaling policy.

```bash
aws application-autoscaling describe-scaling-activities \
   --service-namespace ecs \ 
   --resource-id service/default/web-app
```

Output:

```
{
   "ScalingActivities": [
   {
      "ScalableDimension": "ecs:service:DesiredCount",
      "Description": "Setting desired count to 1.",
      "ResourceId": "service/default/web-app",

      "StatusCode": "Successful"
   }

   ]
}
```

For more information, see Scaling activities for Application Auto Scaling in the Application Auto Scaling User Guide.

Example 2: To describe scaling activities for the specified DynamoDB table
The following describe-scaling-activities example describes the scaling activities for a DynamoDB table called TestTable. The output shows scaling activities initiated by two different scheduled actions.

```
aws application-autoscaling describe-scaling-activities \
   --service-namespace dynamodb \
   --resource-id table/TestTable
```

Output:

```
{
   "ScalingActivities": [
   {
      "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
      "Description": "Setting write capacity units to 10.",

For more information, see Scaling activities for Application Auto Scaling in the Application Auto Scaling User Guide.

- For API details, see DescribeScalingActivities in AWS CLI Command Reference.

describe-scaling-policies

The following code example shows how to use describe-scaling-policies.

AWS CLI

To describe scaling policies

This example command describes the scaling policies for the ecs service namespace.

Command:

```
aws application-autoscaling describe-scaling-policies --service-namespace ecs
```
Output:

```json
{
   "ScalingPolicies": [
      {
         "PolicyName": "web-app-cpu-gt-75",

         }
      }
   ]
}```
• For API details, see DescribeScalingPolicies in AWS CLI Command Reference.

**describe-scheduled-actions**

The following code example shows how to use describe-scheduled-actions.

**AWS CLI**

**To describe scheduled actions**

The following describe-scheduled-actions example displays details for the scheduled actions for the specified service namespace:

```
aws application-autoscaling describe-scheduled-actions \
    --service-namespace dynamodb
```

**Output:**

```json
{
    "ScheduledActions": [
    {
        "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
```

```json
```
For more information, see Scheduled Scaling in the Application Auto Scaling User Guide.

- For API details, see DescribeScheduledActions in AWS CLI Command Reference.

**list-tags-for-resource**

The following code example shows how to use list-tags-for-resource.

**AWS CLI**

To list the tags for a scalable target
The following `list-tags-for-resource` example lists the tag key names and values that are attached to the scalable target specified by its ARN.

```
aws application-autoscaling list-tags-for-resource \
   --resource-arn arn:aws:application-autoscaling:us-west-2:123456789012:scalable-target/1234abcd56ab78cd901ef1234567890ab123
```

Output:

```
{
   "Tags": {
       "environment": "production"
   }
}
```

**put-scaling-policy**

The following code example shows how to use `put-scaling-policy`.

**AWS CLI**

**Example 1: To apply a target tracking scaling policy with a predefined metric specification**

The following `put-scaling-policy` example applies a target tracking scaling policy with a predefined metric specification to an Amazon ECS service called web-app in the default cluster. The policy keeps the average CPU utilization of the service at 75 percent, with scale-out and scale-in cooldown periods of 60 seconds. The output contains the ARNs and names of the two CloudWatch alarms created on your behalf.

```
aws application-autoscaling put-scaling-policy --service-namespace ecs \
   --scalable-dimension ecs:service:DesiredCount \
   --resource-id service/default/web-app \
   --policy-name cpu75-target-tracking-scaling-policy --policy-type TargetTrackingScaling \
   --target-tracking-scaling-policy-configuration file://config.json
```
This example assumes that you have a config.json file in the current directory with the following contents:

```json
{
    "TargetValue": 75.0,
    "PredefinedMetricSpecification": {
        "PredefinedMetricType": "ECSServiceAverageCPUUtilization"
    },
    "ScaleOutCooldown": 60,
    "ScaleInCooldown": 60
}
```

Output:

```json
{
    "Alarms": [
        {
            "AlarmName": "TargetTracking-service/default/web-app:AlarmHigh-64087653feca"
        },
        {
            "AlarmName": "TargetTracking-service/default/web-app:AlarmLow-64087653feca"
        }
    ]
}
```

**Example 2: To apply a target tracking scaling policy with a customized metric specification**

The following `put-scaling-policy` example applies a target tracking scaling policy with a customized metric specification to an Amazon ECS service called `web-app` in the default cluster. The policy keeps the average utilization of the service at 75 percent, with scale-out and...
scale-in cooldown periods of 60 seconds. The output contains the ARNs and names of the two CloudWatch alarms created on your behalf.

```sh
```

This example assumes that you have a `config.json` file in the current directory with the following contents:

```json
{
    "TargetValue": 75.0,
    "CustomizedMetricSpecification": {
        "MetricName": "MyUtilizationMetric",
        "Namespace": "MyNamespace",
        "Dimensions": [
            {
                "Name": "MyOptionalMetricDimensionName",
                "Value": "MyOptionalMetricDimensionValue"
            }
        ],
        "Statistic": "Average",
        "Unit": "Percent"
    },
    "ScaleOutCooldown": 60,
    "ScaleInCooldown": 60
}
```

Output:

```json
{
    "Alarms": [
        {
            "AlarmARN": "arn:aws:cloudwatch:us-west-2:012345678910:alarm:TargetTracking-service/default/web-app-AlarmHigh-9bc77b56-0571-4276-ba0f-d4178882e0a0",
```
Example 3: To apply a target tracking scaling policy for scale out only

The following `put-scaling-policy` example applies a target tracking scaling policy to an Amazon ECS service called `web-app` in the default cluster. The policy is used to scale out the ECS service when the `RequestCountPerTarget` metric from the Application Load Balancer exceeds the threshold. The output contains the ARN and name of the CloudWatch alarm created on your behalf.

```
aws application-autoscaling put-scaling-policy
  --service-namespace ecs
  --scalable-dimension ecs:service:DesiredCount
  --resource-id service/default/web-app
  --policy-name alb-scale-out-target-tracking-scaling-policy
  --policy-type TargetTrackingScaling
  --target-tracking-scaling-policy-configuration file://config.json
```

Contents of `config.json`:

```
{
  "TargetValue": 1000.0,
  "PredefinedMetricSpecification": {
    "PredefinedMetricType": "ALBRequestCountPerTarget",
    "ResourceLabel": "app/EC2Co-EcsEl-1TKLTM7MN00E0/f37c06a68c1748aa/
targetgroup/EC2Co-Defau-LDNM7Q3ZH1ZN/6d4ea56ca2d6a18d"
  },
  "ScaleOutCooldown": 60,
  "ScaleInCooldown": 60,
  "DisableScaleIn": true
}
```
Output:

```json
{
  "Alarms": [
    {
      "AlarmName": "TargetTracking-service/default/web-app-AlarmHigh-d4f0770c-b46e-434a-a60f-3b36d653feca",
      "AlarmARN": "arn:aws:cloudwatch:us-west-2:123456789012:alarm:TargetTracking-service/default/web-app-AlarmHigh-d4f0770c-b46e-434a-a60f-3b36d653feca"
    }
  ]
}
```

- For API details, see PutScalingPolicy in AWS CLI Command Reference.

**put-scheduled-action**

The following code example shows how to use put-scheduled-action.

**AWS CLI**

**To add a scheduled action to a DynamoDB table**

This example adds a scheduled action to a DynamoDB table called TestTable to scale out on a recurring schedule. On the specified schedule (every day at 12:15pm UTC), if the current capacity is below the value specified for MinCapacity, Application Auto Scaling scales out to the value specified by MinCapacity.

**Command:**

```bash
aws application-autoscaling put-scheduled-action --service-namespace dynamodb --scheduled-action-name my-recurring-action --schedule "cron(15 12 * * ? *)" --resource-id table/TestTable --scalable-dimension dynamodb:table:WriteCapacityUnits --scalable-target-action MinCapacity=6
```
For more information, see Scheduled Scaling in the *Application Auto Scaling User Guide*.  
• For API details, see [PutScheduledAction](https://awscli.amazonaws.com/v2/documentation/api/current/reference/services/application-autoscaling.html#PutScheduledAction) in *AWS CLI Command Reference*.

**register-scalable-target**

The following code example shows how to use `register-scalable-target`.

**AWS CLI**

**Example 1: To register an ECS service as a scalable target**

The following `register-scalable-target` example registers an Amazon ECS service with Application Auto Scaling. It also adds a tag with the key name `environment` and the value `production` to the scalable target.

```bash
aws application-autoscaling register-scalable-target
  --service-namespace ecs
  --scalable-dimension ecs:service:DesiredCount
  --resource-id service/default/web-app
  --min-capacity 1 --max-capacity 10
  --tags environment=production
```

**Output:**

```json
{
  "ScalableTargetARN": "arn:aws:application-autoscaling:us-west-2:123456789012:scalable-target/1234abcd56ab78cd901ef1234567890ab123"
}
```

For examples for other AWS services and custom resources, see the topics in *AWS services that you can use with Application Auto Scaling* in the *Application Auto Scaling User Guide*.

**Example 2: To suspend scaling activities for a scalable target**

The following `register-scalable-target` example suspends scaling activities for an existing scalable target.

```bash
aws application-autoscaling register-scalable-target
  --service-namespace dynamodb
  --scalable-dimension dynamodb:table:ReadCapacityUnits
```
--resource-id table/my-table \
--suspended-state
DynamicScalingInSuspended=true,DynamicScalingOutSuspended=true,ScheduledScalingSuspended=true

Output:

{
   "ScalableTargetARN": "arn:aws:application-autoscaling:us-west-2:123456789012:scalable-target/1234abcd56ab78cd901ef1234567890ab123"
}

For more information, see Suspending and resuming scaling for Application Auto Scaling in the Application Auto Scaling User Guide.

Example 3: To resume scaling activities for a scalable target

The following register-scalable-target example resumes scaling activities for an existing scalable target.

aws application-autoscaling register-scalable-target \
   --service-namespace dynamodb \
   --scalable-dimension dynamodb:table:ReadCapacityUnits \
   --resource-id table/my-table \
   --suspended-state
DynamicScalingInSuspended=false,DynamicScalingOutSuspended=false,ScheduledScalingSuspended=false

Output:

{
   "ScalableTargetARN": "arn:aws:application-autoscaling:us-west-2:123456789012:scalable-target/1234abcd56ab78cd901ef1234567890ab123"
}

For more information, see Suspending and resuming scaling for Application Auto Scaling in the Application Auto Scaling User Guide.

- For API details, see RegisterScalableTarget in AWS CLI Command Reference.

**tag-resource**

The following code example shows how to use tag-resource.
AWS CLI

To add a tag to a scalable target

The following tag-resource example adds a tag with the key name environment and the value production to the scalable target specified by its ARN.

```bash
aws application-autoscaling tag-resource \
   --resource-arn arn:aws:application-autoscaling:us-west-2:123456789012:scalable-target/1234abcd56ab78cd901ef1234567890ab123 \
   --tags environment=production
```

This command produces no output.

For more information, see Tagging support for Application Auto Scaling in the Application Auto Scaling User Guide.

- For API details, see TagResource in AWS CLI Command Reference.

untag-resource

The following code example shows how to use untag-resource.

AWS CLI

To remove a tag from a scalable target

The following untag-resource example removes the tag pair with the key name environment from the scalable target specified by its ARN.

```bash
aws application-autoscaling untag-resource \
   --resource-arn arn:aws:application-autoscaling:us-west-2:123456789012:scalable-target/1234abcd56ab78cd901ef1234567890ab123 \
   --tag-keys "environment"
```

This command produces no output.

For more information, see Tagging support for Application Auto Scaling in the Application Auto Scaling User Guide.

- For API details, see UntagResource in AWS CLI Command Reference.
Application Discovery Service examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Application Discovery Service.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

#### describe-agents

The following code example shows how to use `describe-agents`.

### AWS CLI

**Describe agents with specified collectionStatus states**

This example command describes collection agents with collection status of "STARTED" or "STOPPED".

**Command:**

```bash
aws discovery describe-agents --filters
    name="collectionStatus",values="STARTED","STOPPED",condition="EQUALS" --max-results 3
```

**Output:**

```json
{
    "Snapshots": [
    {
```
• For API details, see DescribeAgents in AWS CLI Command Reference.

describe-configurations

The following code example shows how to use describe-configurations.

AWS CLI

Describe selected asset configurations
This example command describes the configurations of two specified servers. The action detects the type of asset from the configuration ID. Only one type of asset is allowed per command.

Command:

`aws discovery describe-configurations --configuration-ids "d-server-099385097ef9fbcfb" "d-server-0c4f2dd1fee22c6c1"`

Output:

list-configurations

The following code example shows how to use list-configurations.

AWS CLI

To list all of the discovered servers meeting a set of filter conditions

This example command lists discovered servers matching either of two hostname patterns and not running Ubuntu.

Command:

```
aws discovery list-configurations --configuration-type SERVER --filters
name="server.hostName",values="172-31-35","172-31-42",condition="CONTAINS"
name="server.osName",values="Ubuntu",condition="NOT_CONTAINS"

associate-attribute-group

The following code example shows how to use associate-attribute-group.

AWS CLI

To associate an attribute group
The following `associate-attribute-group` example associates a specific attribute group in your AWS account to a specific application in your AWS account.

```bash
aws servicecatalog-appregistry associate-attribute-group \
   --application "ExampleApplication" \
   --attribute-group "ExampleAttributeGroup"
```

Output:

### get-application

The following code example shows how to use get-application.

**AWS CLI**

**To get an application**

The following get-application example retrieves metadata information about a specific application in your AWS account.

```bash
aws servicecatalog-appregistry get-application \
   --application "ExampleApplication"
```

Output:

```json
{
   "id": "0ars38r6btoohvpvd9gqrptt91",
```
For more information, see Using Application details in the AWS Service Catalog AppRegistry Administrator Guide.

- For API details, see GetApplication in AWS CLI Command Reference.

get-attribute-group

The following code example shows how to use get-attribute-group.

AWS CLI

To get an attribute group

The following get-attribute-group example retrieves a specific attribute group in your AWS account.

```bash
aws servicecatalog-appregistry get-attribute-group \
  --attribute-group "ExampleAttributeGroup"
```

Output:

```json
{
  "id": "01sj5xdwhbw54kejwnt09fnpcl",
  "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/attribute-groups/01sj5xdwhbw54kejwnt09fnpcl",

"tags": {
    "aws:servicecatalog:attributeGroupName": "ExampleAttributeGroup"
}
}

For more information, see Managing metadata for attribute groups in the AWS Service Catalog AppRegistry Administrator Guide.

- For API details, see GetAttributeGroup in AWS CLI Command Reference.

**list-applications**

The following code example shows how to use list-applications.

**AWS CLI**

**To list applications**

The following list-applications example retrieves a list of all the applications in your AWS account.

```
aws servicecatalog-appregistry list-applications
```

**Output:**

```
{
    "applications": [ 
        {
            "id": "03axw94pjfj3uan00tcgbrxnkw",
            "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/applications/03axw94pjfj3uan00tcgbrxnkw",

### list-associated-attribute-groups

The following code example shows how to use list-associated-attribute-groups.

#### AWS CLI

**To list associated attribute groups**

The following list-associated-attribute-groups example retrieves a list of all attribute groups in your AWS account that are associated with a specific application in your AWS account.

```
aws servicecatalog-appregistry list-associated-attribute-groups \
  --application "ExampleApplication"
```

**Output:**

```
{
  "attributeGroups": [
    "01sj5xdwhbw54kejwnt09fnpcl"
  ]
}
```
For more information, see [Associating and disassociating attribute groups](https://docs.aws.amazon.com/servicecatalog/latest/adminguide/app-registry-associate-disassociate-attribute-groups.html) in the *AWS Service Catalog AppRegistry Administrator Guide*.

### list-attribute-groups-for-application

The following code example shows how to use `list-attribute-groups-for-application`.

**AWS CLI**

#### To list attribute groups for an application

The following `list-attribute-groups-for-application` example lists the details of all attribute groups in your AWS account that are associated with a specific application in your AWS account.

```
aws servicecatalog-appregistry list-attribute-groups-for-application \
  --application "ExampleApplication"
```

**Output:**

```
{
  "attributeGroupsDetails": [

**update-application**

The following code example shows how to use `update-application`.

**AWS CLI**

To update an application

The following `update-application` example updates a specific application in your AWS account to include a description.

```bash
aws servicecatalog-appregistry update-application \
   --application "ExampleApplication" \
   --description "This is an example application"
```

**Output:**

```json
{
   "application": {
      "id": "0ars38r6btoohvpvd9gqrptt91",
      "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/applications/0ars38r6btoohvpvd9gqrptt91",

}
```

For more information, see Editing applications in the *AWS Service Catalog AppRegistry Administrator Guide*.

• For API details, see `UpdateApplication` in *AWS CLI Command Reference*.

**update-attribute-group**

The following code example shows how to use `update-attribute-group`.
AWS CLI

To update an attribute group

The following update-attribute-group example updates a specific attribute group in your AWS account to include a description.

```
aws servicecatalog-appregistry update-attribute-group \
   --attribute-group "ExampleAttributeGroup" \
   --description "This is an example attribute group"
```

Output:

```
{
   "attributeGroup": {
      "id": "01sj5xdwhbw54kejwnt09fnpcl",

Athena examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Athena.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.
Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

batch-get-named-query

The following code example shows how to use batch-get-named-query.

AWS CLI

To return information about more than one query

The following batch-get-named-query example returns information about the named queries that have the specified IDs.

```bash
aws athena batch-get-named-query \
   --named-query-ids a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 a1b2c3d4-5678-90ab-cdef-EXAMPLE22222 a1b2c3d4-5678-90ab-cdef-EXAMPLE33333

**batch-get-query-execution**

The following code example shows how to use `batch-get-query-execution`.

**AWS CLI**

**To return information about one or more query executions**

The following `batch-get-query-execution` example returns query execution information for the queries that have the specified query IDs.

```bash
aws athena batch-get-query-execution \
    --query-execution-ids a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 a1b2c3d4-5678-90ab-cdef-EXAMPLE22222

### create-data-catalog

The following code example shows how to use `create-data-catalog`.

#### AWS CLI

**To create a data catalog**

The following `create-data-catalog` example creates the `dynamo_db_catalog` data catalog.

```bash
aws athena create-data-catalog \
  --name dynamo_db_catalog \
  --type LAMBDA \
  --description "DynamoDB Catalog" \
```

This command produces no output. To see the result, use `aws athena get-data-catalog --name dynamo_db_catalog`.
For more information, see Registering a Catalog: create-data-catalog in the Amazon Athena User Guide.

- For API details, see CreateDataCatalog in AWS CLI Command Reference.

create-named-query

The following code example shows how to use create-named-query.

AWS CLI

To create a named query

The following create-named-query example creates a saved query in the AthenaAdmin workgroup that queries the flights_parquet table for flights from Seattle to New York in January, 2016 whose departure and arrival were both delayed by more than ten minutes. Because the airport code values in the table are strings that include double quotes (for example, "SEA"), they are escaped by backslashes and surrounded by single quotes.

```bash
aws athena create-named-query
   --name "SEA to JFK delayed flights Jan 2016"
   --description "Both arrival and departure delayed more than 10 minutes."
   --database sampledb
   --query-string "SELECT flightdate, carrier, flightnum, origin, dest, depdelayminutes, arrdelayminutes FROM sampledb.flights_parquet WHERE yr = 2016 AND month = 1 AND origin = '"SEA"' AND dest = '"JFK"' AND depdelayminutes > 10 AND arrdelayminutes > 10"
   --work-group AthenaAdmin
```

Output:

```json
{
   "NamedQueryId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
}
```

For more information, see Running SQL Queries Using Amazon Athena in the Amazon Athena User Guide.

- For API details, see CreateNamedQuery in AWS CLI Command Reference.
create-work-group

The following code example shows how to use create-work-group.

AWS CLI

To create a workgroup

The following create-work-group example creates a workgroup called Data_Analyst_Group that has the query results output location s3://awsdoc-example-bucket. The command creates a workgroup that overrides client configuration settings, which includes the query results output location. The command also enables CloudWatch metrics and adds three key-value tag pairs to the workgroup to distinguish it from other workgroups. Note that the --configuration argument has no spaces before the commas that separate its options.

```bash
aws athena create-work-group \
  --name Data_Analyst_Group \
  --configuration ResultConfiguration={OutputLocation="s3://awsdoc-example-bucket"},EnforceWorkGroupConfiguration="true",PublishCloudWatchMetricsEnabled="true" \
  --description "Workgroup for data analysts" \
  --tags Key=Division,Value=West Key=Location,Value=Seattle Key=Team,Value="Big Data"
```

This command produces no output. To see the results, use aws athena get-work-group --work-group Data_Analyst_Group.

For more information, see Managing Workgroups in the Amazon Athena User Guide.

- For API details, see CreateWorkGroup in AWS CLI Command Reference.

delete-data-catalog

The following code example shows how to use delete-data-catalog.

AWS CLI

To delete a data catalog

The following delete-data-catalog example deletes the UnusedDataCatalog data catalog.
aws athena delete-data-catalog \
   --name UnusedDataCatalog

This command produces no output.

For more information, see Deleting a Catalog: delete-data-catalog in the Amazon Athena User Guide.

• For API details, see DeleteDataCatalog in AWS CLI Command Reference.

delete-named-query

The following code example shows how to use delete-named-query.

AWS CLI

To delete a named query

The following delete-named-query example deletes the named query that has the specified ID.

aws athena delete-named-query \
   --named-query-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111

This command produces no output.

For more information, see Running SQL Queries Using Amazon Athena in the Amazon Athena User Guide.

• For API details, see DeleteNamedQuery in AWS CLI Command Reference.

delete-work-group

The following code example shows how to use delete-work-group.

AWS CLI

To delete a workgroup

The following delete-work-group example deletes the TeamB workgroup.

aws athena delete-work-group \

This command produces no output. To confirm the deletion, use `aws athena list-workgroups`.

For more information, see Managing Workgroups in the Amazon Athena User Guide.

- For API details, see DeleteWorkGroup in AWS CLI Command Reference.

get-data-catalog

The following code example shows how to use get-data-catalog.

AWS CLI

To return information about a data catalog

The following get-data-catalog example returns information about the dynamo_db_catalog data catalog.

```bash
aws athena get-data-catalog \
   --name dynamo_db_catalog
```

Output:

```
{
   "DataCatalog": {
      "Name": "dynamo_db_catalog",
      "Description": "DynamoDB Catalog",
      "Type": "LAMBDA",
      "Parameters": {
         "catalog": "dynamo_db_catalog",
      }
   }
}
```

For more information, see Showing Catalog Details: get-data-catalog in the Amazon Athena User Guide.
• For API details, see [GetDataCatalog](#) in *AWS CLI Command Reference*.

**get-database**

The following code example shows how to use `get-database`.

**AWS CLI**

To return information about a database in a data catalog

The following `get-database` example returns information about the `sampledb` database in the `AwsDataCatalog` data catalog.

```
aws athena get-database \\
    --catalog-name AwsDataCatalog \\
    --database-name sampledb
```

Output:

```
{
    "Database": {
        "Name": "sampledb",
        "Description": "Sample database",
        "Parameters": {
            "CreatedBy": "Athena",
            "EXTERNAL": "TRUE"
        }
    }
}
```

For more information, see [Showing Database Details: get-database](#) in the *Amazon Athena User Guide*.

• For API details, see [GetDatabase](#) in *AWS CLI Command Reference*.

**get-named-query**

The following code example shows how to use `get-named-query`.

**AWS CLI**

To return a named query
The following `get-named-query` example returns information about the query that has the specified ID.

```bash/aws athena get-named-query \
   --named-query-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:

```json
{
   "NamedQuery": {
      "Name": "CloudFront Logs - SFO",
      "Description": "Shows successful GET request data for SFO",
      "Database": "default",
      "QueryString": "select date, location, browser, uri, status from cloudfront_logs where method = 'GET' and status = 200 and location like 'SFO%' limit 10",
      "NamedQueryId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
      "WorkGroup": "AthenaAdmin"
   }
}
```

For more information, see [Running SQL Queries Using Amazon Athena](#) in the *Amazon Athena User Guide*.

- For API details, see [GetNamedQuery](#) in *AWS CLI Command Reference*.

---

**get-query-execution**

The following code example shows how to use `get-query-execution`.

**AWS CLI**

To return information about a query execution

The following `get-query-execution` example returns information about the query that has the specified query ID.

```bash
/aws athena get-query-execution \\
   --query-execution-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:
For more information, see [Running SQL Queries Using Amazon Athena](https://docs.aws.amazon.com/athena/latest/ug/query-result-sets.html) in the [Amazon Athena User Guide](https://docs.aws.amazon.com/athena/latest/ug/)

**get-query-results**

The following code example shows how to use get-query-results.

**AWS CLI**

To return the results of a query
The following `get-query-results` example returns the results of the query that has the specified query ID.

```
aws athena get-query-results \
   --query-execution-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

**Output:**

```json
{
    "ResultSet": {
    "Rows": [
        {
            "Data": [  
                {

get-table-metadata

The following code example shows how to use get-table-metadata.

AWS CLI

To return metadata information about a table
The following `get-table-metadata` example returns metadata information about the `counties` table, including column names and their datatypes, from the `sampledb` database of the `AwsDataCatalog` data catalog.

```
aws athena get-table-metadata \
   --catalog-name AwsDataCatalog \
   --database-name sampledb \
   --table-name counties
```

Output:

```json
{
   "TableMetadata": {
      "Name": "counties",
      "CreateTime": 1593559968.0,
      "LastAccessTime": 0.0,
      "TableType": "EXTERNAL_TABLE",
      "Columns": [  
          {  
              "Name": "name",
              "Type": "string",
              "Comment": "from deserializer"
          },  
          {
              "Name": "boundaryshape",
              "Type": "binary",
              "Comment": "from deserializer"
          },  
          {

      "Parameters": {
          "EXTERNAL": "TRUE",
          "inputformat": "com.esri.json.hadoop.EnclosedJsonInputFormat",
```
The following code example shows how to use get-work-group.

**AWS CLI**

To return information about a workgroup

The following get-work-group example returns information about the AthenaAdmin workgroup.

```
aws athena get-work-group 
   --work-group AthenaAdmin
```

Output:

```json
{
   "WorkGroup": {
      "Name": "AthenaAdmin",
      "State": "ENABLED",
      "Configuration": {
         "ResultConfiguration": {

For API details, see GetWorkGroup in AWS CLI Command Reference.

### list-data-catalogs

The following code example shows how to use list-data-catalogs.

**AWS CLI**

To list the data catalogs registered with Athena

The following list-data-catalogs example lists the data catalogs registered with Athena.

```bash
aws athena list-data-catalogs
```

Output:

```json
{
    "DataCatalogsSummary": [
        {
            "CatalogName": "AwsDataCatalog",
            "Type": "GLUE"
        },
        {
            "CatalogName": "cw_logs_catalog",
            "Type": "LAMBDA"
        },
        {
            "CatalogName": "cw_metrics_catalog",
            "Type": "LAMBDA"
        }
    ]
}
```

For more information, see Listing Registered Catalogs: list-data-catalogs in the Amazon Athena User Guide.
list-databases

The following code example shows how to use list-databases.

AWS CLI

To list the databases in a data catalog

The following list-databases example lists the databases in the AwsDataCatalog data catalog.

```
aws athena list-databases \
  --catalog-name AwsDataCatalog
```

Output:

```
{
  "DatabaseList": [
    {
      "Name": "default"
    },
    {
      "Name": "mydatabase"
    },
    {

### list-named-queries

The following code example shows how to use `list-named-queries`.

**AWS CLI**

**To list the named queries for a workgroup**

The following `list-named-queries` example lists the named queries for the AthenaAdmin workgroup.

```plaintext
aws athena list-named-queries \
   --work-group AthenaAdmin
```

Output:

```
{
   "NamedQueryIds": [
       "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
       "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
       "a1b2c3d4-5678-90ab-cdef-EXAMPLE33333"
   ]
}
```

For more information, see [Running SQL Queries Using Amazon Athena](#) in the *Amazon Athena User Guide*.

- For API details, see [ListNamedQueries](#) in *AWS CLI Command Reference*.

### list-query-executions

The following code example shows how to use `list-query-executions`.

**AWS CLI**

**To list the query IDs of the queries in a specified workgroup**
The following list-query-executions example lists a maximum of ten of the query IDs in the AthenaAdmin workgroup.

```
aws athena list-query-executions \
   --work-group AthenaAdmin \ 
   --max-items 10
```

Output:

```
{
   "QueryExecutionIds": [
      "a1b2c3d4-5678-90ab-cdef-EXAMPLE11110",
      "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",

- For API details, see ListQueryExecutions in AWS CLI Command Reference.

list-table-metadata

The following code example shows how to use list-table-metadata.

AWS CLI

To list the metadata for tables in the specified database of a data catalog

The following list-table-metadata example returns metadata information for a maximum of two tables in the geography database of the AwsDataCatalog data catalog.

```
aws athena list-table-metadata \
```
--catalog-name AwsDataCatalog \
--database-name geography \
--max-items 2

Output:

```json
{
    "TableMetadataList": [
        {
            "Name": "country_codes",
            "CreateTime": 1586553454.0,

**list-tags-for-resource**

The following code example shows how to use list-tags-for-resource.

**AWS CLI**

**Example 1: To list the tags for a workgroup**

The following list-tags-for-resource example lists the tags for the Data_Analyst_Group workgroup.
aws athena list-tags-for-resource

Output:

{
   "Tags": [
   {
      "Key": "Division",
      "Value": "West"
   },
   {
      "Key": "Team",
      "Value": "Big Data"
   },
   {
      "Key": "Location",
      "Value": "Seattle"
   }
   ]
}

Example 2: To list the tags for a data catalog

The following list-tags-for-resource example lists the tags for the dynamo_db_catalog data catalog.

aws athena list-tags-for-resource

Output:

{
   "Tags": [
   {
      "Key": "Division",
      "Value": "Mountain"
   },
   {

   }

### list-work-groups

The following code example shows how to use `list-work-groups`.

**AWS CLI**

**To list workgroups**

The following `list-work-groups` example lists the workgroups in the current account.

```
aws athena list-work-groups
```

**Output:**

```
{
   "WorkGroups": [
       {
           "Name": "Data_Analyst_Group",
           "State": "ENABLED",
           "Description": ":",
           "CreationTime": 1578006683.016
       },
       {
           
       }
   ]
}
```
For more information, see Managing Workgroups in the Amazon Athena User Guide.

- For API details, see ListWorkGroups in AWS CLI Command Reference.

**start-query-execution**

The following code example shows how to use start-query-execution.

**AWS CLI**

**Example 1: To run a query in a workgroup on the specified table in the specified database and data catalog**

The following start-query-execution example uses the AthenaAdmin workgroup to run a query on the cloudfront_logs table in the cflogsdatabase in the AwsDataCatalog data catalog.

```
aws athena start-query-execution \
   --query-string "select date, location, browser, uri, status from cloudfront_logs \n   where method = 'GET' and status = 200 and location like 'SFO%' limit 10" \
   --work-group "AthenaAdmin" \
   --query-execution-context Database=cflogsdatabase,Catalog=AwsDataCatalog
```

Output:

```
{
   "QueryExecutionId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
}
```
Example 2: To run a query that uses a specified workgroup to create a database in the specified data catalog

The following `start-query-execution` example uses the `AthenaAdmin` workgroup to create the database `newdb` in the default data catalog `AwsDataCatalog`.

```bash
aws athena start-query-execution
   --query-string "create database if not exists newdb"
   --work-group "AthenaAdmin"
```

Output:

```json
{
   "QueryExecutionId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11112"
}
```

Example 3: To run a query that creates a view on a table in the specified database and data catalog

The following `start-query-execution` example uses a `SELECT` statement on the `cloudfront_logs` table in the `cflogsdatabase` to create the view `cf10`.

```bash
aws athena start-query-execution
   --query-string  "CREATE OR REPLACE VIEW cf10 AS SELECT * FROM cloudfront_logs limit 10"
   --query-execution-context Database=cflogsdatabase
```

Output:

```json
{
   "QueryExecutionId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11113"
}
```
For more information, see [Running SQL Queries Using Amazon Athena](https://docs.aws.amazon.com/athena/latest/ug/) in the *Amazon Athena User Guide*.

- For API details, see [StartQueryExecution](https://docs.aws.amazon.com/cli/latest/reference/athena/start-query-execution.html) in *AWS CLI Command Reference*.

**stop-query-execution**

The following code example shows how to use `stop-query-execution`.

**AWS CLI**

To stop a running query

The following `stop-query-execution` example stops the query that has the specified query ID.

```bash
aws athena stop-query-execution \
    --query-execution-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

This command produces no output.

For more information, see [Running SQL Queries Using Amazon Athena](https://docs.aws.amazon.com/athena/latest/ug/) in the *Amazon Athena User Guide*.

- For API details, see [StopQueryExecution](https://docs.aws.amazon.com/cli/latest/reference/athena/stop-query-execution.html) in *AWS CLI Command Reference*.

**tag-resource**

The following code example shows how to use `tag-resource`.

**AWS CLI**

To add a tag to a resource

The following `tag-resource` example adds three tags to the `dynamo_db_catalog` data catalog.

```bash
aws athena tag-resource \
```

Actions and scenarios
This command produces no output. To see the result, use `aws athena list-tags-for-resource --resource-arn arn:aws:athena:us-west-2:111122223333:datacatalog/dynamo_db_catalog`.

For more information, see Adding tags to a resource: tag-resource in the Amazon Athena User Guide.

- For API details, see TagResource in AWS CLI Command Reference.

**untag-resource**

The following code example shows how to use untag-resource.

**AWS CLI**

To remove a tag from a resource

The following untag-resource example removes the Specialization and Focus keys and their associated values from the dynamo_db_catalog data catalog resource.

```
aws athena untag-resource \
   --tag-keys Specialization Focus
```

This command produces no output. To see the results, use the list-tags-for-resource command.

For more information, see Removing tags from a resource: untag-resource in the Amazon Athena User Guide.

- For API details, see UntagResource in AWS CLI Command Reference.

**update-data-catalog**

The following code example shows how to use update-data-catalog.
AWS CLI

To update a data catalog

The following update-data-catalog example updates the Lambda function and description of the cw_logs_catalog data catalog.

```bash
aws athena update-data-catalog \
  --name cw_logs_catalog \
  --type LAMBDA \
  --description "New CloudWatch Logs Catalog" \
```

This command produces no output. To see the result, use `aws athena get-data-catalog --name cw_logs_catalog`.

For more information, see Updating a Catalog: update-data-catalog in the Amazon Athena User Guide.

- For API details, see UpdateDataCatalog in AWS CLI Command Reference.

update-work-group

The following code example shows how to use update-work-group.

AWS CLI

To update a workgroup

The following update-work-group example disables the Data_Analyst_Group workgroup. Users cannot run or create queries in the disabled workgroup, but can still view metrics, data usage limit controls, workgroup settings, query history, and saved queries.

```bash
aws athena update-work-group \
  --work-group Data_Analyst_Group \
  --state DISABLED
```

This command produces no output. To verify the change in state, use `aws athena get-work-group --work-group Data_Analyst_Group` and check the State property in the output.

For more information, see Managing Workgroups in the Amazon Athena User Guide.

- For API details, see UpdateWorkGroup in AWS CLI Command Reference.
Auto Scaling examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Auto Scaling.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

This example attaches the specified Classic Load Balancer to the specified Auto Scaling group.

```bash
aws autoscaling attach-load-balancers \
  --load-balancer-names my-load-balancer \
  --auto-scaling-group-name my-asg
```

This command produces no output.

For more information, see Elastic Load Balancing and Amazon EC2 Auto Scaling in the Amazon EC2 Auto Scaling User Guide.

- For API details, see AttachLoadBalancers in AWS CLI Command Reference.

cancel-instance-refresh

The following code example shows how to use cancel-instance-refresh.
AWS CLI

To cancel an instance refresh

The following cancel-instance-refresh example cancels an in-progress instance refresh for the specified Auto Scaling group.

```bash
aws autoscaling cancel-instance-refresh \
   --auto-scaling-group-name my-asg
```

Output:

```json
{
   "InstanceRefreshId": "08b91cf7-8fa6-48af-b6a6-d227f40f1b9b"
}
```

For more information, see Cancel an instance refresh in the Amazon EC2 Auto Scaling User Guide.

- For API details, see CancelInstanceRefresh in AWS CLI Command Reference.

complete-lifecycle-action

The following code example shows how to use complete-lifecycle-action.

AWS CLI

To complete the lifecycle action

This example notifies Amazon EC2 Auto Scaling that the specified lifecycle action is complete so that it can finish launching or terminating the instance.

```bash
aws autoscaling complete-lifecycle-action \
   --lifecycle-hook-name my-launch-hook \
   --auto-scaling-group-name my-asg \
   --lifecycle-action-result CONTINUE \
   --lifecycle-action-token bcd2f1b8-9a78-44d3-8a7a-4dd07d7cf635
```

This command produces no output.

For more information, see Amazon EC2 Auto Scaling lifecycle hooks in the Amazon EC2 Auto Scaling User Guide.
create-auto-scaling-group

The following code example shows how to use `create-auto-scaling-group`.

AWS CLI

Example 1: To create an Auto Scaling group

The following `create-auto-scaling-group` example creates an Auto Scaling group in subnets in multiple Availability Zones within a Region. The instances launch with the default version of the specified launch template. Note that defaults are used for most other settings, such as the termination policies and health check configuration.

```bash
aws autoscaling create-auto-scaling-group \
  --auto-scaling-group-name my-asg \
  --launch-template LaunchTemplateId=lt-1234567890abcde12 \
  --min-size 1 \
  --max-size 5 \
  --vpc-zone-identifier "subnet-5ea0c127,subnet-6194ea3b,subnet-c934b782"
```

This command produces no output.

For more information, see [Auto Scaling groups](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/AutoScaling.html) in the *Amazon EC2 Auto Scaling User Guide*.

Example 2: To attach an Application Load Balancer, Network Load Balancer, or Gateway Load Balancer

This example specifies the ARN of a target group for a load balancer that supports the expected traffic. The health check type specifies ELB so that when Elastic Load Balancing reports an instance as unhealthy, the Auto Scaling group replaces it. The command also defines a health check grace period of 600 seconds. The grace period helps prevent premature termination of newly launched instances.

```bash
aws autoscaling create-auto-scaling-group \
  --auto-scaling-group-name my-asg \
  --launch-template LaunchTemplateId=lt-1234567890abcde12 \
  --target-group-arns arn:aws:elasticloadbalancing:us-west-2:123456789012:targetgroup/my-targets/943f017f100becff \
  --health-check-type ELB \
```

For API details, see [CompleteLifecycleAction](https://docs.aws.amazon.com/cli/latest/reference/completelifecycleaction/) in *AWS CLI Command Reference*.
Example 3: To specify a placement group and use the latest version of the launch template

This example launches instances into a placement group within a single Availability Zone. This can be useful for low-latency groups with HPC workloads. This example also specifies the minimum size, maximum size, and desired capacity of the group.

```
aws autoscaling create-auto-scaling-group \
   --auto-scaling-group-name my-asg \
   --launch-template LaunchTemplateId=lt-1234567890abcde12,Version='$Latest' \
   --min-size 1 \
   --max-size 5 \
   --desired-capacity 3 \
   --placement-group my-placement-group \
   --vpc-zone-identifier "subnet-6194ea3b"
```

This command produces no output.

For more information, see Placement groups in the Amazon EC2 User Guide for Linux Instances.

Example 4: To specify a single instance Auto Scaling group and use a specific version of the launch template

This example creates an Auto Scaling group with minimum and maximum capacity set to 1 to enforce that one instance will be running. The command also specifies v1 of a launch template in which the ID of an existing ENI is specified. When you use a launch template that specifies an existing ENI for eth0, you must specify an Availability Zone for the Auto Scaling group that matches the network interface, without also specifying a subnet ID in the request.

```
aws autoscaling create-auto-scaling-group \
   --auto-scaling-group-name my-asg-single-instance \
   --launch-template LaunchTemplateName=my-template-for-auto-scaling,Version='1' \
```

This command produces no output.

For more information, see Elastic Load Balancing and Amazon EC2 Auto Scaling in the Amazon EC2 Auto Scaling User Guide.
--min-size 1
--max-size 1
--availability-zones us-west-2a

This command produces no output.

For more information, see Auto Scaling groups in the Amazon EC2 Auto Scaling User Guide.

Example 5: To specify a different termination policy

This example creates an Auto Scaling group using a launch configuration and sets the termination policy to terminate the oldest instances first. The command also applies a tag to the group and its instances, with a key of Role and a value of WebServer.

```bash
aws autoscaling create-auto-scaling-group
   --auto-scaling-group-name my-asg
   --launch-configuration-name my-lc
   --min-size 1
   --max-size 5
   --termination-policies "OldestInstance"
   --tags "ResourceId=my-asg,ResourceType=auto-scaling-group,Key=Role,Value=WebServer,PropagateAtLaunch=true"
   --vpc-zone-identifier "subnet-5ea0c127,subnet-6194ea3b,subnet-c934b782"
```

This command produces no output.

For more information, see Working with Amazon EC2 Auto Scaling termination policies in the Amazon EC2 Auto Scaling User Guide.

Example 6: To specify a launch lifecycle hook

This example creates an Auto Scaling group with a lifecycle hook that supports a custom action at instance launch.

```bash
aws autoscaling create-auto-scaling-group
   --cli-input-json file://~/config.json
```

Contents of config.json file:

```json
{
   "AutoScalingGroupName": "my-asg",
```

        "PropagateAtLaunch": true,
        "Value": "test",
        "Key": "environment"
    }
]
}

This command produces no output.

For more information, see Amazon EC2 Auto Scaling lifecycle hooks in the Amazon EC2 Auto Scaling User Guide.

**Example 7: To specify a termination lifecycle hook**

This example creates an Auto Scaling group with a lifecycle hook that supports a custom action at instance termination.

```bash
aws autoscaling create-auto-scaling-group \
    --cli-input-json file://~/config.json
```

Contents of config.json:

```json
{
    "AutoScalingGroupName": "my-asg",
    "LaunchTemplate": {
```
"LaunchTemplateId": "lt-1234567890abcde12"
},

"VPCZoneIdentifier": "subnet-5ea0c127,subnet-6194ea3b,subnet-c934b782"
}

This command produces no output.

For more information, see Amazon EC2 Auto Scaling lifecycle hooks in the Amazon EC2 Auto Scaling User Guide.

**Example 8: To specify a custom termination policy**

This example creates an Auto Scaling group that specifies a custom Lambda function termination policy that tells Amazon EC2 Auto Scaling which instances are safe to terminate on scale in.

```bash
aws autoscaling create-auto-scaling-group \
   --auto-scaling-group-name my-asg-single-instance \
   --launch-template LaunchTemplateName=my-template-for-auto-scaling \
   --min-size 1 \
   --max-size 5 \
   --vpc-zone-identifier "subnet-5ea0c127,subnet-6194ea3b,subnet-c934b782"
```

This command produces no output.

For more information, see Creating a custom termination policy with Lambda in the Amazon EC2 Auto Scaling User Guide.

- For API details, see CreateAutoScalingGroup in AWS CLI Command Reference.
create-launch-configuration

The following code example shows how to use create-launch-configuration.

AWS CLI

**Example 1: To create a launch configuration**

This example creates a simple launch configuration.

```
aws autoscaling create-launch-configuration \\
  --launch-configuration-name my-lc \\
  --image-id ami-04d5cc9b88example \\
  --instance-type m5.large
```

This command produces no output.

For more information, see [Creating a launch configuration](https://docs.aws.amazon.com/AutoScaling/latest/UserGuide/create-launch-configuration.html) in the Amazon EC2 Auto Scaling User Guide.

**Example 2: To create a launch configuration with a security group, key pair, and bootrapping script**

This example creates a launch configuration with a security group, a key pair, and a bootrapping script contained in the user data.

```
aws autoscaling create-launch-configuration \\
  --launch-configuration-name my-lc \\
  --image-id ami-04d5cc9b88example \\
  --instance-type m5.large \\
  --security-groups sg-eb2af88example \\
  --key-name my-key-pair \\
  --user-data file://myuserdata.txt
```

This command produces no output.

For more information, see [Creating a launch configuration](https://docs.aws.amazon.com/AutoScaling/latest/UserGuide/create-launch-configuration.html) in the Amazon EC2 Auto Scaling User Guide.

**Example 3: To create a launch configuration with an IAM role**

This example creates a launch configuration with the instance profile name of an IAM role.
aws autoscaling create-launch-configuration \
  --launch-configuration-name my-lc \ 
  --image-id ami-04d5cc9b88example \ 
  --instance-type m5.large \ 
  --iam-instance-profile my-autoscaling-role

This command produces no output.

For more information, see IAM role for applications that run on Amazon EC2 instances in the Amazon EC2 Auto Scaling User Guide.

**Example 4: To create a launch configuration with detailed monitoring enabled**

This example creates a launch configuration with EC2 detailed monitoring enabled, which sends EC2 metrics to CloudWatch in 1-minute periods.

aws autoscaling create-launch-configuration \
  --launch-configuration-name my-lc \ 
  --image-id ami-04d5cc9b88example \ 
  --instance-type m5.large \ 
  --instance-monitoring Enabled=true

This command produces no output.

For more information, see Configuring monitoring for Auto Scaling instances in the Amazon EC2 Auto Scaling User Guide.

**Example 5: To create a launch configuration that launches Spot Instances**

This example creates a launch configuration that uses Spot Instances as the only purchase option.

aws autoscaling create-launch-configuration \
  --launch-configuration-name my-lc \ 
  --image-id ami-04d5cc9b88example \ 
  --instance-type m5.large \ 
  --spot-price "0.50"

This command produces no output.

For more information, see Requesting Spot Instances in the Amazon EC2 Auto Scaling User Guide.
Example 6: To create a launch configuration using an EC2 instance

This example creates a launch configuration based on the attributes of an existing instance. It overrides the placement tenancy and whether a public IP address is set by including the --placement-tenancy and --no-associate-public-ip-address options.

```
aws autoscaling create-launch-configuration \
   --launch-configuration-name my-lc-from-instance \ 
   --instance-id i-0123a456700123456 \ 
   --instance-type m5.large \ 
   --no-associate-public-ip-address \ 
   --placement-tenancy dedicated
```

This command produces no output.

For more information, see Creating a launch configuration using an EC2 instance in the Amazon EC2 Auto Scaling User Guide.

Example 7: To create a launch configuration with a block device mapping for an Amazon EBS volume

This example creates a launch configuration with a block device mapping for an Amazon EBS gp3 volume with the device name /dev/sdh and a volume size of 20.

```
aws autoscaling create-launch-configuration \
   --launch-configuration-name my-lc \ 
   --image-id ami-04d5cc9b88example \ 
   --instance-type m5.large \ 
   --block-device-mappings '[{"DeviceName":"/dev/sdh","Ebs": \ 
   {"VolumeSize":20,"VolumeType":"gp3"}]}]
```

This command produces no output.

For more information, see EBS in the Amazon EC2 Auto Scaling API Reference.

For information about the syntax for quoting JSON-formatted parameter values, see Using quotation marks with strings in the AWS CLI in the AWS Command Line Interface User Guide.

Example 8: To create a launch configuration with a block device mapping for an instance store volume
This example creates a launch configuration with ephemeral1 as an instance store volume with the device name /dev/sdc.

```bash
aws autoscaling create-launch-configuration \
   --launch-configuration-name my-lc \
   --image-id ami-04d5cc9b88example \
   --instance-type m5.large \
   --block-device-mappings '[["DeviceName":"/dev/sdc","VirtualName":"ephemeral1"]]'
```

This command produces no output.

For more information, see `BlockDeviceMapping` in the Amazon EC2 Auto Scaling API Reference.

For information about the syntax for quoting JSON-formatted parameter values, see Using quotation marks with strings in the AWS CLI in the AWS Command Line Interface User Guide.

**Example 9: To create a launch configuration and suppress a block device from attaching at launch time**

This example creates a launch configuration that suppresses a block device specified by the block device mapping of the AMI (for example, /dev/sdf).

```bash
aws autoscaling create-launch-configuration \
   --launch-configuration-name my-lc \
   --image-id ami-04d5cc9b88example \
   --instance-type m5.large \
   --block-device-mappings '[["DeviceName":"/dev/sdf","NoDevice":""]]'
```

This command produces no output.

For more information, see `BlockDeviceMapping` in the Amazon EC2 Auto Scaling API Reference.

For information about the syntax for quoting JSON-formatted parameter values, see Using quotation marks with strings in the AWS CLI in the AWS Command Line Interface User Guide.

- For API details, see `CreateLaunchConfiguration` in AWS CLI Command Reference.

**create-or-update-tags**

The following code example shows how to use `create-or-update-tags`.
**AWS CLI**

**To create or update tags for an Auto Scaling group**

This example adds two tags to the specified Auto Scaling group.

```
aws autoscaling create-or-update-tags \\
  --tags ResourceId=my-asg,ResourceType=auto-scaling-group,Key=Role,Value=WebServer,PropagateAtLaunch=true ResourceId=my-asg,ResourceType=auto-scaling-group,Key=Dept,Value=Research,PropagateAtLaunch=true
```

This command produces no output.

For more information, see [Tagging Auto Scaling groups and instances](#) in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see [CreateOrUpdateTags](#) in *AWS CLI Command Reference*.

**delete-auto-scaling-group**

The following code example shows how to use delete-auto-scaling-group.

**AWS CLI**

**Example 1: To delete the specified Auto Scaling group**

This example deletes the specified Auto Scaling group.

```
aws autoscaling delete-auto-scaling-group \\
  --auto-scaling-group-name my-asg
```

This command produces no output.

For more information, see [Deleting your Auto Scaling infrastructure](#) in the *Amazon EC2 Auto Scaling User Guide*.

**Example 2: To force delete the specified Auto Scaling group**

To delete the Auto Scaling group without waiting for the instances in the group to terminate, use the --force-delete option.

```
aws autoscaling delete-auto-scaling-group \\
```

**delete-launch-configuration**

The following code example shows how to use `delete-launch-configuration`.

**AWS CLI**

**To delete a launch configuration**

This example deletes the specified launch configuration.

```bash
aws autoscaling delete-launch-configuration \  
   --launch-configuration-name my-launch-config
```

This command produces no output.

For more information, see [Deleting your Auto Scaling infrastructure](https://docs.aws.amazon.com/autoscaling/ec2/latest/userguide/autoscaling-delete-launch-configuration.html) in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see [DeleteLaunchConfiguration](https://docs.aws.amazon.com/cli/latest/reference/autoscaling/delete-launch-configuration.html) in *AWS CLI Command Reference*.

**delete-lifecycle-hook**

The following code example shows how to use `delete-lifecycle-hook`.

**AWS CLI**

**To delete a lifecycle hook**

This example deletes the specified lifecycle hook.

```bash
aws autoscaling delete-lifecycle-hook \  
```

This command produces no output.

For more information, see [Deleting your Auto Scaling infrastructure](https://docs.aws.amazon.com/autoscaling/ec2/latest/userguide/autoscaling-delete-lifecycle-hook.html) in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see [DeleteLifecycleHook](https://docs.aws.amazon.com/cli/latest/reference/autoscaling/delete-lifecycle-hook.html) in *AWS CLI Command Reference*.
This command produces no output.

- For API details, see `DeleteLifecycleHook` in `AWS CLI Command Reference`.

**delete-notification-configuration**

The following code example shows how to use `delete-notification-configuration`.

**AWS CLI**

**To delete an Auto Scaling notification**

This example deletes the specified notification from the specified Auto Scaling group.

```bash
aws autoscaling delete-notification-configuration \
  --auto-scaling-group-name my-asg \
```

This command produces no output.

For more information, see `Delete the notification configuration` in the `Amazon EC2 Auto Scaling User Guide`.

- For API details, see `DeleteNotificationConfiguration` in `AWS CLI Command Reference`.

**delete-policy**

The following code example shows how to use `delete-policy`.

**AWS CLI**

**To delete a scaling policy**

This example deletes the specified scaling policy.

```bash
aws autoscaling delete-policy \
  --auto-scaling-group-name my-asg \
  --policy-name alb1000-target-tracking-scaling-policy
```
This command produces no output.

- For API details, see DeletePolicy in AWS CLI Command Reference.

**delete-scheduled-action**

The following code example shows how to use delete-scheduled-action.

**AWS CLI**

To delete a scheduled action from an Auto Scaling group

This example deletes the specified scheduled action from the specified Auto Scaling group.

```bash
aws autoscaling delete-scheduled-action \
    --auto-scaling-group-name my-asg \
    --scheduled-action-name my-scheduled-action
```

This command produces no output.

- For API details, see DeleteScheduledAction in AWS CLI Command Reference.

**delete-tags**

The following code example shows how to use delete-tags.

**AWS CLI**

To delete a tag from an Auto Scaling group

This example deletes the specified tag from the specified Auto Scaling group.

```bash
aws autoscaling delete-tags \
    --tags ResourceId=my-asg,ResourceType=auto-scaling-group,Key=Dept,Value=Research
```

This command produces no output.

For more information, see Tagging Auto Scaling groups and instances in the Amazon EC2 Auto Scaling User Guide.

- For API details, see DeleteTags in AWS CLI Command Reference.
**delete-warm-pool**

The following code example shows how to use delete-warm-pool.

**AWS CLI**

**Example 1: To delete a warm pool**

The following example deletes the warm pool for the specified Auto Scaling group.

```
aws autoscaling delete-warm-pool \
  --auto-scaling-group-name my-asg
```

This command produces no output.

For more information, see [Warm pools for Amazon EC2 Auto Scaling](https://docs.aws.amazon.com/autoscaling/userguide/) in the *Amazon EC2 Auto Scaling User Guide*.

**Example 2: To force delete a warm pool**

To delete the warm pool without waiting for its instances to terminate, use the `--force-delete` option.

```
aws autoscaling delete-warm-pool \
  --auto-scaling-group-name my-asg \
  --force-delete
```

This command produces no output.

For more information, see [Warm pools for Amazon EC2 Auto Scaling](https://docs.aws.amazon.com/autoscaling/userguide/) in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see [DeleteWarmPool](https://docs.aws.amazon.com/cli/latest/reference/autoscaling/delete-warm-pool.html) in *AWS CLI Command Reference*.

**describe-account-limits**

The following code example shows how to use describe-account-limits.

**AWS CLI**

To describe your Amazon EC2 Auto Scaling account limits
This example describes the Amazon EC2 Auto Scaling limits for your AWS account.

```
aws autoscaling describe-account-limits
```

Output:

```
{
   "NumberOfLaunchConfigurations": 5,
   "MaxNumberOfLaunchConfigurations": 100,
   "NumberOfAutoScalingGroups": 3,
   "MaxNumberOfAutoScalingGroups": 20
}
```

For more information, see Amazon EC2 Auto Scaling service quotas in the Amazon EC2 Auto Scaling User Guide.

- For API details, see DescribeAccountLimits in AWS CLI Command Reference.

**describe-adjustment-types**

The following code example shows how to use describe-adjustment-types.

**AWS CLI**

To describe the available scaling adjustment types

This example describes the available adjustment types.

```
aws autoscaling describe-adjustment-types
```

Output:

```
{
   "AdjustmentTypes": [
   {
      "AdjustmentType": "ChangeInCapacity"
   },
   {
      "AdjustmentType": "ExactCapacity"
   },
   {
   
```
"AdjustmentType": "PercentChangeInCapacity"
}
]}

For more information, see Scaling adjustment types in the Amazon EC2 Auto Scaling User Guide.

- For API details, see DescribeAdjustmentTypes in AWS CLI Command Reference.

**describe-auto-scaling-groups**

The following code example shows how to use describe-auto-scaling-groups.

**AWS CLI**

**Example 1: To describe the specified Auto Scaling group**

This example describes the specified Auto Scaling group.

```bash
aws autoscaling describe-auto-scaling-groups \
  --auto-scaling-group-name my-asg
```

**Output:**

```json
{
  "AutoScalingGroups": [
    {
      "AutoScalingGroupName": "my-asg",
      "LaunchTemplate": {
        "LaunchTemplateName": "my-launch-template",

```
Example 2: To describe the first 100 specified Auto Scaling group

This example describes the specified Auto Scaling groups. It allows you to specify up to 100 group names.

```bash
aws autoscaling describe-auto-scaling-groups
```
See example 1 for sample output.

**Example 3: To describe an Auto Scaling group in the specified region**

This example describes the Auto Scaling groups in the specified region, up to a maximum of 75 groups.

```
aws autoscaling describe-auto-scaling-groups \
  --max-items 75 \
  --region us-east-1
```

See example 1 for sample output.

**Example 4: To describe the specified number of Auto Scaling group**

To return a specific number of Auto Scaling groups, use the `--max-items` option.

```
aws autoscaling describe-auto-scaling-groups \
  --max-items 1
```

See example 1 for sample output.

If the output includes a `NextToken` field, there are more groups. To get the additional groups, use the value of this field with the `--starting-token` option in a subsequent call as follows.

```
aws autoscaling describe-auto-scaling-groups \
  --starting-token Z3M3LMPEXAMPLE
```

See example 1 for sample output.

**Example 5: To describe Auto Scaling groups that use launch configurations**

This example uses the `--query` option to describe Auto Scaling groups that use launch configurations.

```
aws autoscaling describe-auto-scaling-groups \
  --query 'AutoScalingGroups[?LaunchConfigurationName!=`null`]'
```
Output:

```json

### describe-auto-scaling-instances

The following code example shows how to use `describe-auto-scaling-instances`.

#### AWS CLI

**Example 1: To describe one or more instances**

This example describes the specified instance.

```bash
aws autoscaling describe-auto-scaling-instances \
--instance-ids i-06905f55584de02da
```

Output:

```
{
   "AutoScalingInstances": [
      {
         "InstanceId": "i-06905f55584de02da",
         "InstanceType": "t2.micro",

            "Version": "1"
         }
      }
   ]
}
```

**Example 2: To describe one or more instances**
This example uses the `--max-items` option to specify how many instances to return with this call.

```
aws autoscaling describe-auto-scaling-instances \
--max-items 1
```

If the output includes a `NextToken` field, there are more instances. To get the additional instances, use the value of this field with the `--starting-token` option in a subsequent call as follows.

```
aws autoscaling describe-auto-scaling-instances \
--starting-token Z3M3LMPEXAMPLE
```

See example 1 for sample output.

**Example 3: To describe instances that use launch configurations**

This example uses the `--query` option to describe instances that use launch configurations.

```
aws autoscaling describe-auto-scaling-instances \
--query 'AutoScalingInstances[?LaunchConfigurationName!=`null`]'
```

Output:

```
[  
  
  {  
    "InstanceId": "i-088c57934a6449037",  
    "InstanceType": "t2.micro",

**describe-launch-configurations**

The following code example shows how to use describe-launch-configurations.

**AWS CLI**

**Example 1: To describe the specified launch configuration**

This example describes the specified launch configuration.

```
aws autoscaling describe-launch-configurations \\  
   --launch-configuration-names my-launch-config

Example 2: To describe a specified number of launch configurations

To return a specific number of launch configurations, use the `--max-items` option.

```
aws autoscaling describe-launch-configurations \
  --max-items 1
```

If the output includes a NextToken field, there are more launch configurations. To get the additional launch configurations, use the value of this field with the `--starting-token` option in a subsequent call as follows.

```
aws autoscaling describe-launch-configurations \

describe-load-balancer-target-groups

The following code example shows how to use describe-load-balancer-target-groups.

AWS CLI

To describe the load balancer target groups for an Auto Scaling group

This example describes the load balancer target groups attached to the specified Auto Scaling group.

aws autoscaling describe-load-balancer-target-groups \
  --auto-scaling-group-name my-asg

Output:

describe-load-balancers

The following code example shows how to use describe-load-balancers.

AWS CLI

To describe the Classic Load Balancers for an Auto Scaling group

This example describes the Classic Load Balancers for the specified Auto Scaling group.

```
aws autoscaling describe-load-balancers \
   --auto-scaling-group-name my-asg
```

Output:

```

describe-metric-collection-types

The following code example shows how to use describe-metric-collection-types.

AWS CLI

To describe the available metric collection types

This example describes the available metric collection types.
aws autoscaling describe-metric-collection-types

Output:

describe-notification-configurations

The following code example shows how to use describe-notification-configurations.

AWS CLI

Example 1: To describe the notification configurations of a specified group

This example describes the notification configurations for the specified Auto Scaling group.

```
aws autoscaling describe-notification-configurations \
  --auto-scaling-group-name my-asg
```

Output:

```json
{
  "NotificationConfigurations": [
  {
    "AutoScalingGroupName": "my-asg",
    "NotificationType": "autoscaling:TEST_NOTIFICATION",
  },
  {
    "AutoScalingGroupName": "my-asg",
    "NotificationType": "autoscaling:TEST_NOTIFICATION",
  }
  ]
}
```
For more information, see Getting Amazon SNS notifications when your Auto Scaling group scales in the Amazon EC2 Auto Scaling User Guide.

**Example 1: To describe a specified number of notification configurations**

To return a specific number of notification configurations, use the `max-items` parameter.

```bash
aws autoscaling describe-notification-configurations \
    --auto-scaling-group-name my-auto-scaling-group \
    --max-items 1
```

Output:

```json
{
    "NotificationConfigurations": [
        {
            "AutoScalingGroupName": "my-asg",
            "NotificationType": "autoscaling:TEST_NOTIFICATION",
        },
        {
            "AutoScalingGroupName": "my-asg",
            "NotificationType": "autoscaling:TEST_NOTIFICATION",
        }
    ]
}
```

If the output includes a `NextToken` field, there are more notification configurations. To get the additional notification configurations, use the value of this field with the `starting-token` parameter in a subsequent call as follows.

```bash
aws autoscaling describe-notification-configurations \
    --auto-scaling-group-name my-asg \
    --starting-token Z3M3LMPEXAMPLE
```

For more information, see Getting Amazon SNS notifications when your Auto Scaling group scales in the Amazon EC2 Auto Scaling User Guide.

- For API details, see `DescribeNotificationConfigurations` in AWS CLI Command Reference.
**describe-policies**

The following code example shows how to use `describe-policies`.

**AWS CLI**

**Example 1: To describe the scaling policies of a specified group**

This example describes the scaling policies for the specified Auto Scaling group.

```bash
aws autoscaling describe-policies \
  --auto-scaling-group-name my-asg

For more information, see Dynamic scaling in the Amazon EC2 Auto Scaling User Guide.

**Example 2: To describe the scaling policies of a specified name**

To return specific scaling policies, use the `--policy-names` option.

```bash
aws autoscaling describe-policies \
    --auto-scaling-group-name my-asg \
    --policy-names cpu40-target-tracking-scaling-policy
```

See example 1 for sample output.

For more information, see Dynamic scaling in the Amazon EC2 Auto Scaling User Guide.

**Example 3: To describe a number of scaling policies**

To return a specific number of policies, use the `--max-items` option.

```bash
aws autoscaling describe-policies \
    --auto-scaling-group-name my-asg \
    --max-items 1
```

See example 1 for sample output.

If the output includes a `NextToken` field, use the value of this field with the `--starting-token` option in a subsequent call to get the additional policies.

```bash
aws autoscaling describe-policies --auto-scaling-group-name my-asg --starting-token Z3M3LMPEXAMPLE
```

For more information, see Dynamic scaling in the Amazon EC2 Auto Scaling User Guide.

- For API details, see DescribePolicies in AWS CLI Command Reference.

**describe-scaling-activities**

The following code example shows how to use describe-scaling-activities.
Example 1: To describe scaling activities for the specified group

This example describes the scaling activities for the specified Auto Scaling group.

```
aws autoscaling describe-scaling-activities \\

Example 2: To describe the scaling activities for a deleted group

To describe scaling activities after the Auto Scaling group has been deleted, add the --include-deleted-groups option.

```
aws autoscaling describe-scaling-activities \\
  --auto-scaling-group-name my-asg \\
  --include-deleted-groups

```

For more information, see [Troubleshoot Amazon EC2 Auto Scaling](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/troubleshooting.html) in the *Amazon EC2 Auto Scaling User Guide*.

**Example 3: To describe a specified number of scaling activities**

To return a specific number of activities, use the `--max-items` option.

```
aws autoscaling describe-scaling-activities \

For more information, see Suspending and resuming scaling processes in the Amazon EC2 Auto
Scaling User Guide.

- For API details, see DescribeScalingProcessTypes in AWS CLI Command Reference.

describe-scheduled-actions

The following code example shows how to use describe-scheduled-actions.

AWS CLI

Example 1: To describe all scheduled actions

This example describes all your scheduled actions.

```
aws autoscaling describe-scheduled-actions
```

Output:

```
{
    "ScheduledUpdateGroupActions": [
        {
            "AutoScalingGroupName": "my-asg",
            "ScheduledActionName": "my-recurring-action",
            "Recurrence": "30 0 1 1,6,12 *",
            "StartTime": "2023-12-01T04:00:00Z",
            "Time": "2023-12-01T04:00:00Z",
            "MinSize": 1,
            "MaxSize": 6,
            "DesiredCapacity": 4,
            "TimeZone": "America/New_York"
        }
    ]
}
```

For more information, see Scheduled scaling in the Amazon EC2 Auto Scaling User Guide.

Example 2: To describe scheduled actions for the specified group
To describe the scheduled actions for a specific Auto Scaling group, use the `--auto-scaling-group-name` option.

```bash
aws autoscaling describe-scheduled-actions \
  --auto-scaling-group-name my-asg
```

Output:

```
{
  "ScheduledUpdateGroupActions": [
    {
      "AutoScalingGroupName": "my-asg",
      "ScheduledActionName": "my-recurring-action",
      "Recurrence": "30 0 1 1,6,12 *",
      "StartTime": "2023-12-01T04:00:00Z",
      "Time": "2023-12-01T04:00:00Z",
      "MinSize": 1,
      "MaxSize": 6,
      "DesiredCapacity": 4,
      "TimeZone": "America/New_York"
    }
  ]
}
```

For more information, see [Scheduled scaling](https://docs.aws.amazon.com/autoscaling/userguide/autoscaling-scheduled-actions.html) in the Amazon EC2 Auto Scaling User Guide.

**Example 3: To describe the specified scheduled action**

To describe a specific scheduled action, use the `--scheduled-action-names` option.

```bash
aws autoscaling describe-scheduled-actions \
  --scheduled-action-names my-recurring-action
```

Output:

```
{
  "ScheduledUpdateGroupActions": [
    {
      "AutoScalingGroupName": "my-asg",
      "ScheduledActionName": "my-recurring-action",
      "Recurrence": "30 0 1 1,6,12 *",
      "StartTime": "2023-12-01T04:00:00Z",
      "Time": "2023-12-01T04:00:00Z",
      "MinSize": 1,
      "MaxSize": 6,
      "DesiredCapacity": 4,
      "TimeZone": "America/New_York"
    }
  ]
}
```
For more information, see Scheduled scaling in the Amazon EC2 Auto Scaling User Guide.

Example 4: To describe scheduled actions with a specified start time

To describe the scheduled actions that start at a specific time, use the --start-time option.

aws autoscaling describe-scheduled-actions
   --start-time "2023-12-01T04:00:00Z"

Output:

```json
{
   "ScheduledUpdateGroupActions": [
      {
         "AutoScalingGroupName": "my-asg",
         "ScheduledActionName": "my-recurring-action",
         "Recurrence": "30 0 1 1,6,12 *",
         "StartTime": "2023-12-01T04:00:00Z",
         "Time": "2023-12-01T04:00:00Z",
         "MinSize": 1,
         "MaxSize": 6,
         "DesiredCapacity": 4,
         "TimeZone": "America/New_York"
      }
   ]
}
```
Example 5: To describe scheduled actions that end at a specified time

To describe the scheduled actions that end at a specific time, use the --end-time option.

```
aws autoscaling describe-scheduled-actions \
  --end-time "2023-12-01T04:00:00Z"
```

Output:

```
{
  "ScheduledUpdateGroupActions": [ 
    
    

For more information, see Scheduled scaling in the Amazon EC2 Auto Scaling User Guide.

Example 6: To describe a specified number of scheduled actions

To return a specific number of scheduled actions, use the --max-items option.

```
aws autoscaling describe-scheduled-actions \
  --max-items 5 \
  --auto-scaling-group-name my-asg
```

For more information, see Scheduled scaling in the Amazon EC2 Auto Scaling User Guide.
Output:

```json
{
    "ScheduledUpdateGroupActions": [
        {
            "AutoScalingGroupName": "my-asg",
            "ScheduledActionName": "my-recurring-action",
            "Recurrence": "30 0 1 1,6,12 *",
            "StartTime": "2023-12-01T04:00:00Z",
            "Time": "2023-12-01T04:00:00Z",
            "MinSize": 1,
            "MaxSize": 6,
            "DesiredCapacity": 4,
            "TimeZone": "America/New_York"
        }
    ]
}
```

If the output includes a `NextToken` field, there are more scheduled actions. To get the additional scheduled actions, use the value of this field with the `--starting-token` option in a subsequent call as follows.

```bash
aws autoscaling describe-scheduled-actions \
    --auto-scaling-group-name my-asg \
    --starting-token Z3M3LMPEXAMPLE
```

For more information, see [Scheduled scaling](https://docs.aws.amazon.com/autoscaling/ec2/userguide/scheduled-actions.html) in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see [DescribeScheduledActions](https://docs.aws.amazon.com/cli/latest/reference/autoscaling/describe-scheduled-actions.html) in *AWS CLI Command Reference*.

**describe-tags**

The following code example shows how to use `describe-tags`.

**AWS CLI**

To describe all tags
This example describes all your tags.

```bash
aws autoscaling describe-tags
```

Output:

```json
{
   "Tags": [
   {
      "ResourceType": "auto-scaling-group",
      "ResourceId": "my-asg",
      "PropagateAtLaunch": true,
      "Value": "Research",
      "Key": "Dept"
   },
   {
      "ResourceType": "auto-scaling-group",
      "ResourceId": "my-asg",
      "PropagateAtLaunch": true,
      "Value": "WebServer",
      "Key": "Role"
   }
   ]
}
```

For more information, see [Tagging Auto Scaling groups and instances](#) in the *Amazon EC2 Auto Scaling User Guide*.

**Example 2: To describe tags for a specified group**

To describe tags for a specific Auto Scaling group, use the `--filters` option.

```bash
aws autoscaling describe-tags --filters Name=auto-scaling-group,Values=my-asg
```

For more information, see [Tagging Auto Scaling groups and instances](#) in the *Amazon EC2 Auto Scaling User Guide*.

**Example 3: To describe the specified number of tags**

To return a specific number of tags, use the `--max-items` option.
aws autoscaling describe-tags \
  --max-items 1

If the output includes a NextToken field, there are more tags. To get the additional tags, use the value of this field with the --starting-token option in a subsequent call as follows.

aws autoscaling describe-tags \
  --filters Name=auto-scaling-group,Values=my-asg \
  --starting-token Z3M3LMPEXAMPLE

For more information, see Tagging Auto Scaling groups and instances in the Amazon EC2 Auto Scaling User Guide.

- For API details, see DescribeTags in AWS CLI Command Reference.

describe-termination-policy-types

The following code example shows how to use describe-termination-policy-types.

AWS CLI

To describe available termination policy types

This example describes the available termination policy types.

aws autoscaling describe-termination-policy-types

Output:

```json
{
   "TerminationPolicyTypes": [
      "AllocationStrategy",
      "ClosestToNextInstanceHour",
      "Default",
      "NewestInstance",
      "OldestInstance",
      "OldestLaunchConfiguration",
      "OldestLaunchTemplate"
   ]
}
```
For more information, see Controlling which Auto Scaling instances terminate during scale in in the Amazon EC2 Auto Scaling User Guide.

- For API details, see DescribeTerminationPolicyTypes in AWS CLI Command Reference.

**describe-warm-pool**

The following code example shows how to use describe-warm-pool.

**AWS CLI**

**To describe a warm pool**

This example describes the warm pool for the specified Auto Scaling group.

```
aws autoscaling describe-warm-pool \
  --auto-scaling-group-name my-asg
```

**Output:**

```json
{
  "WarmPoolConfiguration": {
    "MinSize": 2,
    "PoolState": "Stopped"
  },
  "Instances": [
    {
      "InstanceId": "i-070a5bbc7e7f40dc5",
      "InstanceType": "t2.micro",
      "AvailabilityZone": "us-west-2c",
      "LifecycleState": "Warmed:Pending",
      "HealthStatus": "Healthy",
      "LaunchTemplate": {
        "LaunchTemplateId": "lt-00a731f6e9fa48610",
        "LaunchTemplateName": "my-template-for-auto-scaling",
        "Version": "6"
      }
    },
    {
      "InstanceId": "i-0b52f061814d3bd2d",
      "InstanceType": "t2.micro",
      "AvailabilityZone": "us-west-2b",
      "LifecycleState": "Warmed:Pending",
      "HealthStatus": "Healthy",
      "LaunchTemplate": {
        "LaunchTemplateId": "lt-00a731f6e9fa48610",
        "LaunchTemplateName": "my-template-for-auto-scaling",
        "Version": "6"
      }
    }
  ]
}
```
For more information, see [Warm pools for Amazon EC2 Auto Scaling](https://docs.aws.amazon.com/autoscaling/ec2/userguide/warm-pools.html) in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see [DescribeWarmPool](https://docs.aws.amazon.com/cli/latest/reference/autoscaling/describe-warm-pool.html) in *AWS CLI Command Reference*.

### detach-instances

The following code example shows how to use `detach-instances`.

**AWS CLI**

**To detach an instance from an Auto Scaling group**

This example detaches the specified instance from the specified Auto Scaling group.

```bash
aws autoscaling detach-instances \\
   --instance-ids i-030017cfa84b20135 \\
   --auto-scaling-group-name my-asg \\
   --should-decrement-desired-capacity
```

Output:

```json
{
   "Activities": [
      {
         "ActivityId": "5091cb52-547a-47ce-a236-c9ccbc2cb2c9",
         "AutoScalingGroupName": "my-asg",
         "Description": "Detaching EC2 instance: i-030017cfa84b20135",
         "Cause": "At 2020-10-31T17:35:04Z instance i-030017cfa84b20135 was detached in response to a user request, shrinking the capacity from 2 to 1.",
         "StartTime": "2020-04-12T15:02:16.179Z",
         "StatusCode": "InProgress",
      }
   ]
}
```
"Progress": 50,
"Details": "{"Subnet ID":"subnet-6194ea3b","Availability Zone":"us-west-2c"}"
]
}

- For API details, see DetachInstances in AWS CLI Command Reference.

**detach-load-balancer-target-groups**

The following code example shows how to use detach-load-balancer-target-groups.

**AWS CLI**

**To detach a load balancer target group from an Auto Scaling group**

This example detaches the specified load balancer target group from the specified Auto Scaling group.

```
aws autoscaling detach-load-balancer-target-groups \
   --auto-scaling-group-name my-asg \
   --target-group-arns arn:aws:elasticloadbalancing:us-west-2:123456789012:targetgroup/my-targets/73e2d6bc24d8a067
```

This command produces no output

For more information, see Attaching a load balancer to your Auto Scaling group in the Amazon EC2 Auto Scaling User Guide.
- For API details, see DetachLoadBalancerTargetGroups in AWS CLI Command Reference.

**detach-load-balancers**

The following code example shows how to use detach-load-balancers.

**AWS CLI**

**To detach a Classic Load Balancer from an Auto Scaling group**

This example detaches the specified Classic Load Balancer from the specified Auto Scaling group.
aws autoscaling detach-load-balancers \
--load-balancer-names my-load-balancer \
--auto-scaling-group-name my-asg

This command produces no output.

For more information, see Attaching a load balancer to your Auto Scaling group in the Amazon EC2 Auto Scaling User Guide.

- For API details, see DetachLoadBalancers in AWS CLI Command Reference.

disable-metrics-collection

The following code example shows how to use disable-metrics-collection.

AWS CLI

To disable metrics collection for an Auto Scaling group

This example disables collection of the GroupDesiredCapacity metric for the specified Auto Scaling group.

aws autoscaling disable-metrics-collection \
--auto-scaling-group-name my-asg \
--metrics GroupDesiredCapacity

This command produces no output.

For more information, see Monitoring CloudWatch metrics for your Auto Scaling groups and instances in the Amazon EC2 Auto Scaling User Guide.

- For API details, see DisableMetricsCollection in AWS CLI Command Reference.

enable-metrics-collection

The following code example shows how to use enable-metrics-collection.

AWS CLI

Example 1: To enable metrics collection for an Auto Scaling group
This example enables data collection for the specified Auto Scaling group.

```
aws autoscaling enable-metrics-collection \
    --auto-scaling-group-name my-asg \
    --granularity "1Minute"
```

This command produces no output.

For more information, see [Monitoring CloudWatch metrics for your Auto Scaling groups and instances](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/monitoring-cloudwatch-metrics.html) in the *Amazon EC2 Auto Scaling User Guide*.

**Example 2: To collect data for the specified metric for an Auto Scaling group**

To collect data for a specific metric, use the `--metrics` option.

```
aws autoscaling enable-metrics-collection \
    --auto-scaling-group-name my-asg \
    --metrics GroupDesiredCapacity --granularity "1Minute"
```

This command produces no output.

For more information, see [Monitoring CloudWatch metrics for your Auto Scaling groups and instances](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/monitoring-cloudwatch-metrics.html) in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see [EnableMetricsCollection](https://docs.aws.amazon.com/cli/latest/reference/autoscaling/enable-metrics-collection.html) in *AWS CLI Command Reference*.

**enter-standby**

The following code example shows how to use `enter-standby`.

**AWS CLI**

**To move instances into standby mode**

This example puts the specified instance into standby mode. This is useful for updating or troubleshooting an instance that is currently in service.

```
aws autoscaling enter-standby \
    --instance-ids i-061c63c5eb45f0416 \
    --auto-scaling-group-name my-asg
```
Output:

```json
{
   "Activities": [
      {
         "ActivityId": "ffa056b4-6ed3-41ba-ae7c-249dfae6eba1",
         "AutoScalingGroupName": "my-asg",
         "Description": "Moving EC2 instance to Standby: i-061c63c5eb45f0416",
         "Cause": "At 2020-10-31T20:31:00Z instance i-061c63c5eb45f0416 was moved to standby in response to a user request, shrinking the capacity from 1 to 0.",
         "StartTime": "2020-10-31T20:31:00.949Z",
         "StatusCode": "InProgress",
         "Progress": 50,
         "Details": "{"Subnet ID":"subnet-6194ea3b","Availability Zone":"us-west-2c"}"
      }
   ]
}
```

For more information, see Amazon EC2 Auto Scaling instance lifecycle in the Amazon EC2 Auto Scaling User Guide.

- For API details, see EnterStandby in AWS CLI Command Reference.

### execute-policy

The following code example shows how to use execute-policy.

**AWS CLI**

To execute a scaling policy

This example executes the scaling policy named my-step-scale-out-policy for the specified Auto Scaling group.

```bash
aws autoscaling execute-policy \
   --auto-scaling-group-name my-asg \
   --policy-name my-step-scale-out-policy \
   --metric-value 95
```
This command produces no output.

For more information, see [Step and simple scaling policies](https://docs.aws.amazon.com/autoscaling/ec2/userguide/step-and-simple-scaling-policies.html) in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see [ExecutePolicy](https://docs.aws.amazon.com/cli/latest/reference/autoscaling/execute-policy.html) in *AWS CLI Command Reference*.

### exit-standby

The following code example shows how to use `exit-standby`.

**AWS CLI**

**To move instances out of standby mode**

This example moves the specified instance out of standby mode.

```bash
aws autoscaling exit-standby
  --instance-ids i-061c63c5eb45f0416
  --auto-scaling-group-name my-asg
```

**Output:**

```json
{
    "Activities": [
    {
        "ActivityId": "142928e1-a2dc-453a-9b24-b85ad6735928",
        "AutoScalingGroupName": "my-asg",
        "Description": "Moving EC2 instance out of Standby: i-061c63c5eb45f0416",
        "Cause": "At 2020-10-31T20:32:50Z instance i-061c63c5eb45f0416 was moved out of standby in response to a user request, increasing the capacity from 0 to 1."
        "StartTime": "2020-10-31T20:32:50.222Z",
        "StatusCode": "PreInService",
        "Progress": 30,
        "Details": ":\"Subnet ID\":\"subnet-6194ea3b\",\"Availability Zone\":\"us-west-2c\""
    }
    ]
}
```
put-lifecycle-hook

The following code example shows how to use put-lifecycle-hook.

AWS CLI

Example 1: To create a lifecycle hook

This example creates a lifecycle hook that will invoke on any newly launched instances, with a timeout of 4800 seconds. This is useful for keeping the instances in a wait state until the user data scripts have finished, or for invoking an AWS Lambda function using EventBridge.

```bash
aws autoscaling put-lifecycle-hook
--auto-scaling-group-name my-asg
--lifecycle-hook-name my-launch-hook
--lifecycle-transition autoscaling:EC2_INSTANCE_LAUNCHING
--heartbeat-timeout 4800
```

This command produces no output. If a lifecycle hook with the same name already exists, it will be overwritten by the new lifecycle hook.

For more information, see Amazon EC2 Auto Scaling lifecycle hooks in the Amazon EC2 Auto Scaling User Guide.

Example 2: To send an Amazon SNS email message to notify you of instance state transitions

This example creates a lifecycle hook with the Amazon SNS topic and IAM role to use to receive notification at instance launch.

```bash
aws autoscaling put-lifecycle-hook
--auto-scaling-group-name my-asg
--lifecycle-hook-name my-launch-hook
```
This command produces no output.

For more information, see Amazon EC2 Auto Scaling lifecycle hooks in the Amazon EC2 Auto Scaling User Guide.

Example 3: To publish a message to an Amazon SQS queue

This example creates a lifecycle hook that publishes a message with metadata to the specified Amazon SQS queue.

```bash
code example
aws autoscaling put-lifecycle-hook
   --auto-scaling-group-name my-asg
   --lifecycle-hook-name my-launch-hook
   --lifecycle-transition autoscaling:EC2_INSTANCE_LAUNCHING
   --role-arn arn:aws:iam::123456789012:role/my-notification-role
   --notification-metadata "SQS message metadata"
```

This command produces no output.

For more information, see Amazon EC2 Auto Scaling lifecycle hooks in the Amazon EC2 Auto Scaling User Guide.

- For API details, see PutLifecycleHook in AWS CLI Command Reference.

put-notification-configuration

The following code example shows how to use put-notification-configuration.

AWS CLI

To add a notification

This example adds the specified notification to the specified Auto Scaling group.

```bash
code example
aws autoscaling put-notification-configuration
   --auto-scaling-group-name my-asg
```
This command produces no output.

For more information, see Getting Amazon SNS notifications when your Auto Scaling group scales in the Amazon EC2 Auto Scaling User Guide.

- For API details, see PutNotificationConfiguration in AWS CLI Command Reference.

**put-scaling-policy**

The following code example shows how to use put-scaling-policy.

**AWS CLI**

**To add a target tracking scaling policy to an Auto Scaling group**

The following put-scaling-policy example applies a target tracking scaling policy to the specified Auto Scaling group. The output contains the ARNs and names of the two CloudWatch alarms created on your behalf. If a scaling policy with the same name already exists, it will be overwritten by the new scaling policy.

```bash
aws autoscaling put-scaling-policy --auto-scaling-group-name my-asg \  --policy-name alb1000-target-tracking-scaling-policy \  --policy-type TargetTrackingScaling \  --target-tracking-configuration file://config.json
```

Contents of `config.json`:

```json
{
    "TargetValue": 1000.0,
    "PredefinedMetricSpecification": {
        "PredefinedMetricType": "ALBRequestCountPerTarget",
        "ResourceLabel": "app/my-alb/778d41231b141a0f/targetgroup/my-alb-target-group/943f017f100becff"
    }
}
```

Output:
The following code example shows how to use `put-scheduled-update-group-action`.

**AWS CLI**

**Example 1: To add a scheduled action to an Auto Scaling group**

This example adds the specified scheduled action to the specified Auto Scaling group.

```
aws autoscaling put-scheduled-update-group-action \
   --auto-scaling-group-name my-asg \
   --scheduled-action-name my-scheduled-action \
   --start-time "2023-05-12T08:00:00Z" \
   --min-size 2 \
   --max-size 6 \
   --desired-capacity 4
```
This command produces no output. If a scheduled action with the same name already exists, it will be overwritten by the new scheduled action.

For more examples, see Scheduled scaling in the Amazon EC2 Auto Scaling User Guide.

**Example 2: To specify a recurring schedule**

This example creates a scheduled action to scale on a recurring schedule that is scheduled to execute at 00:30 hours on the first of January, June, and December every year.

```bash
aws autoscaling put-scheduled-update-group-action \
  --auto-scaling-group-name my-asg \
  --scheduled-action-name my-recurring-action \
  --recurrence "30 0 1,6,12 *" \
  --min-size 2 \
  --max-size 6 \
  --desired-capacity 4
```

This command produces no output. If a scheduled action with the same name already exists, it will be overwritten by the new scheduled action.

For more examples, see Scheduled scaling in the Amazon EC2 Auto Scaling User Guide.

- For API details, see PutScheduledUpdateGroupAction in AWS CLI Command Reference.

**put-warm-pool**

The following code example shows how to use put-warm-pool.

**AWS CLI**

**To create a warm pool**

The following example creates a warm pool for the specified Auto Scaling group.

```bash
aws autoscaling put-warm-pool \
  --auto-scaling-group-name my-asg \
  --min-size 2
```

This command produces no output. If a warm pool already exists, it will be updated.

For more information, see Warm pools for Amazon EC2 Auto Scaling in the Amazon EC2 Auto Scaling User Guide.
**record-lifecycle-action-heartbeat**

The following code example shows how to use `record-lifecycle-action-heartbeat`.

**AWS CLI**

**To record a lifecycle action heartbeat**

This example records a lifecycle action heartbeat to keep the instance in a pending state.

```
aws autoscaling record-lifecycle-action-heartbeat \
    --lifecycle-hook-name my-launch-hook \
    --auto-scaling-group-name my-asg \
    --lifecycle-action-token bcd2f1b8-9a78-44d3-8a7a-4dd07d7cf635
```

This command produces no output.

For more information, see [Amazon EC2 Auto Scaling lifecycle hooks](https://docs.aws.amazon.com/autoscaling/latest/userguide/lifecycle-hooks.html) in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see [RecordLifecycleActionHeartbeat](https://docs.aws.amazon.com/cli/latest/reference/autoscaling/record-lifecycle-action-heartbeat.html) in *AWS CLI Command Reference*.

**resume-processes**

The following code example shows how to use `resume-processes`.

**AWS CLI**

**To resume suspended processes**

This example resumes the specified suspended scaling process for the specified Auto Scaling group.

```
aws autoscaling resume-processes \
    --auto-scaling-group-name my-asg \
    --scaling-processes AlarmNotification
```

This command produces no output.

- For API details, see [ResumeProcesses](https://docs.aws.amazon.com/cli/latest/reference/autoscaling/resume-processes.html) in *AWS CLI Command Reference*.

## rollback-instance-refresh

The following code example shows how to use `rollback-instance-refresh`.

### AWS CLI

**To roll back an instance refresh**

The following `rollback-instance-refresh` example rolls back an in-progress instance refresh for the specified Auto Scaling group.

```bash
aws autoscaling rollback-instance-refresh \
   --auto-scaling-group-name my-asg
```

Output:

```json
{
   "InstanceRefreshId": "08b91cf7-8fa6-48af-b6a6-d227f40f1b9b"
}
```

For more information, see [Undo changes with a rollback](https://docs.aws.amazon.com/AutoScaling/latest/UserGuide/undo-changes-with-a-rollback.html) in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see [RollbackInstanceRefresh](https://docs.aws.amazon.com/AWSCommandReference/aws-autoscaling-rollback-instance-refresh.html) in *AWS CLI Command Reference*.

## set-desired-capacity

The following code example shows how to use `set-desired-capacity`.

### AWS CLI

**To set the desired capacity for an Auto Scaling group**

This example sets the desired capacity for the specified Auto Scaling group.

```bash
aws autoscaling set-desired-capacity \
   --auto-scaling-group-name my-asg
```
---desired-capacity 2 \
--honor-cooldown

This command returns to the prompt if successful.

- For API details, see `SetDesiredCapacity` in *AWS CLI Command Reference*.

**set-instance-health**

The following code example shows how to use `set-instance-health`.

**AWS CLI**

**To set the health status of an instance**

This example sets the health status of the specified instance to Unhealthy.

```
aws autoscaling set-instance-health \
    --instance-id i-061c63c5eb45f0416 \
    --health-status Unhealthy
```

This command produces no output.

- For API details, see `SetInstanceHealth` in *AWS CLI Command Reference*.

**set-instance-protection**

The following code example shows how to use `set-instance-protection`.

**AWS CLI**

**Example 1: To enable the instance protection setting for an instance**

This example enables instance protection for the specified instance.

```
aws autoscaling set-instance-protection \
    --instance-ids i-061c63c5eb45f0416 \
    --auto-scaling-group-name my-asg --protected-from-scale-in
```

This command produces no output.

**Example 2: To disable the instance protection setting for an instance**
This example disables instance protection for the specified instance.

```
aws autoscaling set-instance-protection \
  --instance-ids i-061c63c5eb45f0416 \
  --auto-scaling-group-name my-asg \
  --no-protected-from-scale-in
```

This command produces no output.

- For API details, see [SetInstanceProtection](#) in [AWS CLI Command Reference](#).

## start-instance-refresh

The following code example shows how to use `start-instance-refresh`.

### AWS CLI

*Example 1: To start an instance refresh using command line parameters*

The following `start-instance-refresh` example starts an instance refresh using command line arguments. The optional `preferences` parameter specifies an `InstanceWarmup` of 60 seconds and a `MinHealthyPercentage` of 50 percent.

```
aws autoscaling start-instance-refresh \
  --auto-scaling-group-name my-asg \
  --preferences '{"InstanceWarmup": 60, "MinHealthyPercentage": 50}'
```

Output:

```
{
  "InstanceRefreshId": "08b91cf7-8fa6-48af-b6a6-d227f40f1b9b"
}
```

For more information, see [Start an instance refresh](#) in the *Amazon EC2 Auto Scaling User Guide*.

*Example 2: To start an instance refresh using a JSON file*

The following `start-instance-refresh` example starts an instance refresh using a JSON file. You can specify the Auto Scaling group and define your desired configuration and preferences in a JSON file, as shown in the following example.
aws autoscaling start-instance-refresh \
   --cli-input-json file://config.json

Contents of config.json:

```json
{
    "AutoScalingGroupName": "my-asg",
    "DesiredConfiguration": {
        "LaunchTemplate": {
            "LaunchTemplateId": "lt-068f72b729example",
            "Version": "$Default"
        }
    },
    "Preferences": {
        "InstanceWarmup": 60,
        "MinHealthyPercentage": 50,
        "AutoRollback": true,
        "ScaleInProtectedInstances": Ignore,
        "StandbyInstances": Terminate
    }
}
```

Output:

```json
{
    "InstanceRefreshId": "08b91cf7-8fa6-48af-b6a6-d227f40f1b9b"
}
```

For more information, see [Start an instance refresh](#) in the Amazon EC2 Auto Scaling User Guide.

- For API details, see [StartInstanceRefresh](#) in AWS CLI Command Reference.

**suspend-processes**

The following code example shows how to use `suspend-processes`.

**AWS CLI**

To suspend Auto Scaling processes

This example suspends the specified scaling process for the specified Auto Scaling group.
aws autoscaling suspend-processes \
   --auto-scaling-group-name my-asg \
   --scaling-processes AlarmNotification

This command produces no output.

For more information, see Suspending and resuming scaling processes in the Amazon EC2 Auto Scaling User Guide.

- For API details, see SuspendProcesses in AWS CLI Command Reference.

terminate-instance-in-auto-scaling-group

The following code example shows how to use terminate-instance-in-auto-scaling-group.

AWS CLI

To terminate an instance in an Auto Scaling group

This example terminates the specified instance from the specified Auto Scaling group without updating the size of the group. Amazon EC2 Auto Scaling launches a replacement instance after the specified instance terminates.

aws autoscaling terminate-instance-in-auto-scaling-group \
   --instance-id i-061c63c5eb45f0416 \
   --no-should-decrement-desired-capacity

Output:

```json
{
   "Activities": [
      {
         "ActivityId": "8c35d601-793c-400c-fcd0-f64a27530df7",
         "AutoScalingGroupName": "my-asg",
         "Description": "Terminating EC2 instance: i-061c63c5eb45f0416",
         "Cause": "",
         "StartTime": "2020-10-31T20:34:25.680Z",
         "StatusCode": "InProgress",
         "Progress": 0,
         "Details": "{\"Subnet ID\":\"subnet-6194ea3b\",\"Availability Zone\":\"us-west-2c\"}"
      }
   ]
}```
update-auto-scaling-group

The following code example shows how to use update-auto-scaling-group.

AWS CLI

Example 1: To update the size limits of an Auto Scaling group

This example updates the specified Auto Scaling group with a minimum size of 2 and a maximum size of 10.

```
aws autoscaling update-auto-scaling-group \
  --auto-scaling-group-name my-asg \
  --min-size 2 \
  --max-size 10
```

This command produces no output.

For more information, see Setting capacity limits for your Auto Scaling group in the Amazon EC2 Auto Scaling User Guide.

Example 2: To add Elastic Load Balancing health checks and specify which Availability Zones and subnets to use

This example updates the specified Auto Scaling group to add Elastic Load Balancing health checks. This command also updates the value of --vpc-zone-identifier with a list of subnet IDs in multiple Availability Zones.

```
aws autoscaling update-auto-scaling-group \
  --auto-scaling-group-name my-asg \
  --health-check-type ELB \
  --health-check-grace-period 600 \
  --vpc-zone-identifier "subnet-5ea0c127,subnet-6194ea3b,subnet-c934b782"
```

This command produces no output.
Example 3: To update the placement group and termination policy

This example updates the placement group and termination policy to use.

```bash
aws autoscaling update-auto-scaling-group \
  --auto-scaling-group-name my-asg \
  --placement-group my-placement-group \
  --termination-policies "OldestInstance"
```

This command produces no output.

Example 4: To use the latest version of the launch template

This example updates the specified Auto Scaling group to use the latest version of the specified launch template.

```bash
aws autoscaling update-auto-scaling-group \
  --auto-scaling-group-name my-asg \
  --launch-template LaunchTemplateId=lt-1234567890abcde12,Version='$Latest'
```

This command produces no output.

Example 5: To use a specific version of the launch template

This example updates the specified Auto Scaling group to use a specific version of a launch template instead of the latest or default version.

```bash
aws autoscaling update-auto-scaling-group \
  --auto-scaling-group-name my-asg \
  --launch-template LaunchTemplateName=my-template-for-auto-scaling,Version='2'
```

This command produces no output.

Example 6: To define a mixed instances policy and enable capacity rebalancing
This example updates the specified Auto Scaling group to use a mixed instances policy and enables capacity rebalancing. This structure lets you specify groups with Spot and On-Demand capacities and use different launch templates for different architectures.

```
aws autoscaling update-auto-scaling-group \
    --cli-input-json file://~/config.json
```

Contents of `config.json`:

```json
{
    "AutoScalingGroupName": "my-asg",
    "CapacityRebalance": true,
    "MixedInstancesPolicy": {
        "LaunchTemplate": {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "my-launch-template-for-x86",
                "Version": "$Latest"
            },
            "Overrides": [
                {
                    "InstanceType": "c6g.large",
                    "LaunchTemplateSpecification": {
                        "LaunchTemplateName": "my-launch-template-for-arm",
                        "Version": "$Latest"
                    }
                },
                {
                    "InstanceType": "c5.large"
                },
                {
                    "InstanceType": "c5a.large"
                }
            ],
            "InstancesDistribution": {
                "OnDemandPercentageAboveBaseCapacity": 50,
                "SpotAllocationStrategy": "capacity-optimized"
            }
        }
    }
}
```

This command produces no output.
For more information, see Auto Scaling groups with multiple instance types and purchase options in the Amazon EC2 Auto Scaling User Guide.

### Auto Scaling Plans examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Auto Scaling Plans.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**create-scaling-plan**

The following code example shows how to use create-scaling-plan.

**AWS CLI**

**To create a scaling plan**

The following create-scaling-plan example creates a scaling plan named *my-scaling-plan* using an already-created JSON file (named config.json). The structure of the scaling plan includes a scaling instruction for an Auto Scaling group named *my-asg*. It specifies the TagFilters property as the application source and enables predictive scaling and dynamic scaling.

```
aws autoscaling-plans create-scaling-plan
    --scaling-plan-name my-scaling-plan
```
Contents of config.json file:

```
{
   "ApplicationSource": {
      "TagFilters": [
      {
         "Key": "purpose",
         "Values": [

For more information, see the AWS Auto Scaling User Guide.

- For API details, see `CreateScalingPlan` in AWS CLI Command Reference.

### delete-scaling-plan

The following code example shows how to use `delete-scaling-plan`.

**AWS CLI**

**To delete a scaling plan**

The following `delete-scaling-plan` example deletes the specified scaling plan.

```
aws autoscaling-plans delete-scaling-plan \
  --scaling-plan-name my-scaling-plan \
  --scaling-plan-version 1
```

This command produces no output.

For more information, see the AWS Auto Scaling User Guide.

- For API details, see `DeleteScalingPlan` in AWS CLI Command Reference.

### describe-scaling-plan-resources

The following code example shows how to use `describe-scaling-plan-resources`.

**AWS CLI**

**To describe the scalable resources for a scaling plan**

The following `describe-scaling-plan-resources` example displays details about the single scalable resource (an Auto Scaling group) that is associated with the specified scaling plan.

```
aws autoscaling-plans describe-scaling-plan-resources \
```
--scaling-plan-name my-scaling-plan \n--scaling-plan-version 1

Output:

### get-scaling-plan-resource-forecast-data

The following code example shows how to use `get-scaling-plan-resource-forecast-data`.

**AWS CLI**

**To retrieve load forecast data**

This example retrieves load forecast data for a scalable resource (an Auto Scaling group) that is associated with the specified scaling plan.

```
aws autoscaling-plans get-scaling-plan-resource-forecast-data \
  --scaling-plan-name my-scaling-plan \
  --scaling-plan-version 1 \
  --service-namespace "autoscaling" \
  --resource-id autoScalingGroup/my-asg \
  --scalable-dimension "autoscaling:autoScalingGroup:DesiredCapacity" \
  --forecast-data-type "LoadForecast" \
  --start-time "2019-08-30T00:00:00Z" \
  --end-time "2019-09-06T00:00:00Z"
```

**Output:**

```
{
```
"Datapoints": [...]
}

For more information, see What Is AWS Auto Scaling in the AWS Auto Scaling User Guide.

- For API details, see GetScalingPlanResourceForecastData in AWS CLI Command Reference.

**update-scaling-plan**

The following code example shows how to use update-scaling-plan.

**AWS CLI**

To update a scaling plan

The following update-scaling-plan example modifies the scaling metric for an Auto Scaling group in the specified scaling plan.

```
aws autoscaling-plans update-scaling-plan \
  --scaling-plan-name my-scaling-plan \
  --scaling-plan-version 1 \
  --scaling-instructions '{"ScalableDimension":"autoscaling:autoScalingGroup:DesiredCapacity","ResourceId":"autoScalingGroup/my-asg","ServiceNamespace":"autoscaling","TargetTrackingConfigurations": [{"PredefinedScalingMetricSpecification": {"PredefinedScalingMetricType":"ALBRequestCountPerTarget","ResourceLabel":"app/my-alb/f37c06a68c1748aa/targetgroup/my-target-group/6d4ea56ca2d6a18d"},"TargetValue":40.0}],"MinCapacity": 1,"MaxCapacity": 10}"
```

This command produces no output.

For more information, see What Is AWS Auto Scaling? in the AWS Auto Scaling User Guide.

- For API details, see UpdateScalingPlan in AWS CLI Command Reference.

**create-backup-plan**

The following code example shows how to use `create-backup-plan`.

**AWS CLI**

**To create a backup plan**

The following `create-backup-plan` example creates the specified backup plan with a 35 day retention.

```bash
aws backup create-backup-plan \
    --backup-plan "{"BackupPlanName":"Example-Backup-Plan","Rules":[{"RuleName":"DailyBackups","ScheduleExpression":"cron(0 5 ? * * *)","StartWindowMinutes":480,"TargetBackupVaultName":"Default","Lifecycle":{"DeleteAfterDays":35}}]"
```

**Output:**

create-backup-vault

The following code example shows how to use create-backup-vault.

AWS CLI

To create a backup vault

The following create-backup-vault example creates a backup vault with the specified name.

```bash
aws backup create-backup-vault
   --backup-vault-name sample-vault
```

This command produces no output. Output:

```json
{
   "BackupVaultName": "sample-vault",
   "CreationDate": 1568928338.385
}
```

For more information, see Creating a Backup Vault in the AWS Backup Developer Guide.

- For API details, see CreateBackupVault in AWS CLI Command Reference.

get-backup-plan-from-template

The following code example shows how to use get-backup-plan-from-template.

AWS CLI

To get an existing backup plan from a template

The following get-backup-plan-from-template example gets an existing backup plan from a template that specifies a daily backup with a 35 day retention.
aws backup get-backup-plan-from-template \
   --backup-plan-template-id "87c0c1ef-254d-4180-8fef-2e76a2c38aaa"

Output:

get-backup-plan

The following code example shows how to use get-backup-plan.

AWS CLI

**To get the details of a backup plan**

The following get-backup-plan example displays the details of the specified backup plan.

```
aws backup get-backup-plan \
   --backup-plan-id "fcbf5d8f-bd77-4f3a-9c97-f24fb3d373a5"

### list-backup-jobs

The following code example shows how to use list-backup-jobs.

**AWS CLI**

**Example 1: To list all backup jobs**

The following list-backup-jobs example returns metadata about your backup jobs in your AWS account.

```bash
aws backup list-backup-jobs

**AWS Batch examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with AWS Batch.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.
Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Actions

cancel-job

The following code example shows how to use cancel-job.

AWS CLI

To cancel a job

This example cancels a job with the specified job ID.

Command:

```
aws batch cancel-job --job-id bcf0b186-a532-4122-842e-2ccab8d54efb --reason "Cancelling job."
```

- For API details, see CancelJob in AWS CLI Command Reference.

create-compute-environment

The following code example shows how to use create-compute-environment.

AWS CLI

To create a managed compute environment with On-Demand instances

This example creates a managed compute environment with specific C4 instance types that are launched on demand. The compute environment is called C4OnDemand.

Command:
aws batch create-compute-environment --cli-input-json file://<path_to_json_file>/C4OnDemand.json

JSON file format:

```json
{
  "computeEnvironmentName": "C4OnDemand",
  "type": "MANAGED",
  "state": "ENABLED",
  "computeResources": {
    "type": "EC2",

}
```

Output:

```json
{
  "computeEnvironmentName": "C4OnDemand",
```
To create a managed compute environment with Spot Instances

This example creates a managed compute environment with the M4 instance type that is launched when the Spot bid price is at or below 20% of the On-Demand price for the instance type. The compute environment is called M4Spot.

Command:

```
aws batch create-compute-environment --cli-input-json file://<path_to_json_file>/M4Spot.json
```

JSON file format:

```json
{
    "computeEnvironmentName": "M4Spot",
    "type": "MANAGED",

### create-job-queue

The following code example shows how to use `create-job-queue`.

**AWS CLI**

**To create a low priority job queue with a single compute environment**

This example creates a job queue called `LowPriority` that uses the M4Spot compute environment.

Command:

```bash
aws batch create-job-queue --cli-input-json file://<path_to_json_file>/LowPriority.json
```

**JSON file format:**

```json
{
  "jobQueueName": "LowPriority",
  "state": "ENABLED",
  "priority": 10,
  "computeEnvironmentOrder": [
    ...
  ]
}
```
To create a high priority job queue with two compute environments

This example creates a job queue called HighPriority that uses the C4OnDemand compute environment with an order of 1 and the M4Spot compute environment with an order of 2. The scheduler will attempt to place jobs on the C4OnDemand compute environment first.

Command:

    aws batch create-job-queue --cli-input-json file://<path_to_json_file>/HighPriority.json

JSON file format:

```json
{
    "jobQueueName": "HighPriority",
    "state": "ENABLED",
    "priority": 1,
    "computeEnvironmentOrder": [
        {
            "order": 1,
            "computeEnvironment": "C4OnDemand"
        },
        {
            "order": 2,
            "computeEnvironment": "M4Spot"
        }
    ]
}
```
Output:

```
{
    "jobQueueName": "HighPriority"
}
```

- For API details, see CreateJobQueue in AWS CLI Command Reference.

**delete-compute-environment**

The following code example shows how to use delete-compute-environment.

**AWS CLI**

**To delete a compute environment**

This example deletes the P2OnDemand compute environment.

Command:

```
aws batch delete-compute-environment --compute-environment P2OnDemand
```

- For API details, see DeleteComputeEnvironment in AWS CLI Command Reference.

**delete-job-queue**

The following code example shows how to use delete-job-queue.

**AWS CLI**

**To delete a job queue**

This example deletes the GPGPU job queue.

Command:

```
aws batch delete-job-queue --job-queue GPGPU
```

- For API details, see DeleteJobQueue in AWS CLI Command Reference.
deregister-job-definition

The following code example shows how to use deregister-job-definition.

AWS CLI

To deregister a job definition

This example deregisters a job definition called sleep10.

Command:

```bash
aws batch deregister-job-definition --job-definition sleep10
```

- For API details, see [DeregisterJobDefinition](https://docs.aws.amazon.com/cli/latest/reference/batch/deregister-job-definition.html) in *AWS CLI Command Reference*.

describe-compute-environments

The following code example shows how to use describe-compute-environments.

AWS CLI

To describe a compute environment

This example describes the P2OnDemand compute environment.

Command:

```bash
aws batch describe-compute-environments --compute-environments P2OnDemand
```

Output:

```json
{
   "computeEnvironments": [
      {
         "status": "VALID",
         "serviceRole": "arn:aws:iam::012345678910:role/AWSBatchServiceRole",
         "computeEnvironmentArn": "arn:aws:batch:us-east-1:012345678910:compute-environment/P2OnDemand",
         "computeResources": {
            "subnets": [
               "subnet-220c0e0a",
               "subnet-1a95556d",
```
For API details, see DescribeComputeEnvironments in AWS CLI Command Reference.

describe-job-definitions

The following code example shows how to use describe-job-definitions.

AWS CLI

To describe active job definitions

This example describes all of your active job definitions.

Command:

```bash
aws batch describe-job-definitions --status ACTIVE
```
Output:

```json
{
    "jobDefinitions": [
        {
            "status": "ACTIVE",
            "jobDefinitionArn": "arn:aws:batch:us-east-1:012345678910:job-definition/sleep60:1",

            "type": "container",
            "jobDefinitionName": "sleep60",
            "revision": 1
        }
    ]
}
```

- For API details, see [DescribeJobDefinitions](https://docs.aws.amazon.com/cli/latest/reference/batch/describe-job-definitions.html) in *AWS CLI Command Reference*.

**describe-job-queues**

The following code example shows how to use `describe-job-queues`.

**AWS CLI**

**To describe a job queue**

This example describes the HighPriority job queue.

**Command:**
aws batch describe-job-queues --job-queues HighPriority

Output:

```json
{
    "jobQueues": [
        {
            "status": "VALID",
            "computeEnvironmentOrder": [
                {
                    "order": 1
                }
            ],
            "statusReason": "JobQueue Healthy",
            "priority": 1,
            "state": "ENABLED",
            "jobQueueName": "HighPriority"
        }
    ]
}
```

- For API details, see [DescribeJobQueues](https://docs.aws.amazon.com/cli/latest/reference/batch/describe-job-queues.html) in *AWS CLI Command Reference*.

**describe-jobs**

The following code example shows how to use **describe-jobs**.

**AWS CLI**

**To describe a job**

The following **describe-jobs** example describes a job with the specified job ID.

```
aws batch describe-jobs \
    --jobs bcf0b186-a532-4122-842e-2ccab8d54efb
```

Output:
For API details, see [DescribeJobs](awscli/documentation/commands/batch/describe-jobs) in *AWS CLI Command Reference*.

**list-jobs**

The following code example shows how to use `list-jobs`.

**AWS CLI**

To list running jobs

This example lists the running jobs in the HighPriority job queue.

**Command:**
aws batch list-jobs --job-queue HighPriority

Output:

```
{
    "jobSummaryList": [
    {
        "jobName": "example",
        "jobId": "e66ff5fd-a1ff-4640-b1a2-0b0a142f49bb"
    }
    ]
}
```

To list submitted jobs

This example lists jobs in the HighPriority job queue that are in the SUBMITTED job status.

Command:

aws batch list-jobs --job-queue HighPriority --job-status SUBMITTED

Output:

```
{
    "jobSummaryList": [
    {
        "jobName": "example",
        "jobId": "68f0c163-fbd4-44e6-9fd1-25b14a434786"
    }
    ]
}
```

For API details, see [ListJobs](https://aws.amazon.com/cli/command-reference/list-jobs) in *AWS CLI Command Reference*.

### register-job-definition

The following code example shows how to use `register-job-definition`.

**AWS CLI**

To register a job definition
This example registers a job definition for a simple container job.

Command:

```bash
aws batch register-job-definition --job-definition-name sleep30 --type container --container-properties '{ "image": "busybox", "vcpus": 1, "memory": 128, "command": [ "sleep", "30"]}'
```

Output:

```json
{
    "jobDefinitionArn": "arn:aws:batch:us-east-1:012345678910:job-definition/sleep30:1",
    "jobDefinitionName": "sleep30",
    "revision": 1
}
```

- For API details, see [RegisterJobDefinition](https://docs.aws.amazon.com/cli/latest/reference/batch/register-job-definition.html) in [AWS CLI Command Reference](https://docs.aws.amazon.com/cli/latest/index.html).

**submit-job**

The following code example shows how to use submit-job.

**AWS CLI**

**To submit a job**

This example submits a simple container job called example to the HighPriority job queue.

Command:

```bash
aws batch submit-job --job-name example --job-queue HighPriority --job-definition sleep60
```

Output:

```json
{
    "jobName": "example",
    "jobId": "876da822-4198-45f2-a252-6cea32512ea8"
}
```
**terminate-job**

The following code example shows how to use `terminate-job`.

**AWS CLI**

**To terminate a job**

This example terminates a job with the specified job ID.

Command:

```
aws batch terminate-job --job-id 61e743ed-35e4-48da-b2de-5c833821c84 --reason "Terminating job."
```

For API details, see `TerminateJob` in *AWS CLI Command Reference*.

**update-compute-environment**

The following code example shows how to use `update-compute-environment`.

**AWS CLI**

**To update a compute environment**

This example disables the P2OnDemand compute environment so it can be deleted.

Command:

```
aws batch update-compute-environment --compute-environment P2OnDemand --state DISABLED
```

Output:

```
{
   "computeEnvironmentName": "P2OnDemand",
   "computeEnvironmentArn": "arn:aws:batch:us-east-1:012345678910:compute-environment/P2OnDemand"
}
```
update-job-queue

The following code example shows how to use update-job-queue.

AWS CLI

To update a job queue

This example disables a job queue so that it can be deleted.

Command:

```
aws batch update-job-queue --job-queue GPGPU --state DISABLED
```

Output:

```
{
    "jobQueueName": "GPGPU"
}
```

- For API details, see [CreateBudget](#) in *AWS CLI Command Reference*.

**create-notification**

The following code example shows how to use `create-notification`.

**AWS CLI**

**To create a notification for the specified Cost and Usage budget**

This example creates a notification for the specified Cost and Usage budget.

Command:
aws budgets create-notification --account-id 111122223333 --budget-name "Example Budget" --notification NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=80,ThresholdType=PERCENTAGE --subscriber SubscriptionType=EMAIL,Address=example@example.com

- For API details, see CreateNotification in AWS CLI Command Reference.

create-subscriber

The following code example shows how to use create-subscriber.

AWS CLI

To create a subscriber for a notification associated with a Cost and Usage budget

This example creates a subscriber for the specified notification.

Command:

aws budgets create-subscriber --account-id 111122223333 --budget-name "Example Budget" --notification NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=80,ThresholdType=PERCENTAGE --subscriber SubscriptionType=EMAIL,Address=example@example.com

- For API details, see CreateSubscriber in AWS CLI Command Reference.

delete-budget

The following code example shows how to use delete-budget.

AWS CLI

To delete a Cost and Usage budget

This example deletes the specified Cost and Usage budget.

Command:

aws budgets delete-budget --account-id 111122223333 --budget-name "Example Budget"

- For API details, see DeleteBudget in AWS CLI Command Reference.
delete-notification

The following code example shows how to use delete-notification.

AWS CLI

To delete a notification from a budget

This example deletes the specified notification from the specified budget.

Command:

```bash
aws budgets delete-notification --account-id 111122223333 --budget-name "Example Budget" --notification NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=80,ThresholdType=PERCENTAGE
```

- For API details, see [DeleteNotification](#) in AWS CLI Command Reference.

delete-subscriber

The following code example shows how to use delete-subscriber.

AWS CLI

To delete a subscriber from a notification

This example deletes the specified subscriber from the specified notification.

Command:

```bash
aws budgets delete-subscriber --account-id 111122223333 --budget-name "Example Budget" --notification NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=80,ThresholdType=PERCENTAGE --subscriber SubscriptionType=EMAIL,Address=example@example.com
```

- For API details, see [DeleteSubscriber](#) in AWS CLI Command Reference.

describe-budget

The following code example shows how to use describe-budget.
AWS CLI

To retrieve a budget associated with an account

This example retrieves the specified Cost and Usage budget.

Command:

```bash
aws budgets describe-budget --account-id 111122223333 --budget-name "Example Budget"
```

Output:

**describe-notifications-for-budget**

The following code example shows how to use describe-notifications-for-budget.

**AWS CLI**

To retrieve the notifications for a budget
This example retrieves the notifications for a Cost and Usage budget.

Command:

```bash
aws budgets describe-notifications-for-budget --account-id 111122223333 --budget-name "Example Budget" --max-results 5
```

Output:

```json
{
   "Notifications": [
   {
      "Threshold": 80.0,
      "ComparisonOperator": "GREATER_THAN",
      "NotificationType": "ACTUAL"
   }
   ]
}
```

For API details, see [DescribeNotificationsForBudget](https://docs.aws.amazon.com/cli/latest/reference/budgets/describe-notifications-for-budget.html) in *AWS CLI Command Reference*.

### describe-subscribers-for-notification

The following code example shows how to use `describe-subscribers-for-notification`.

#### AWS CLI

**To retrieve the subscribers for a budget notification**

This example retrieves the subscribers for a Cost and Usage budget notification.

Command:

```bash
aws budgets describe-subscribers-for-notification --account-id 111122223333 --budget-name "Example Budget" --notification NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=80,ThresholdType=PERCENTAGE --max-results 5
```

Output:

```json
{
   "Subscribers": [

```

Actions and scenarios
For API details, see `DescribeSubscribersForNotification` in *AWS CLI Command Reference*.

**update-budget**

The following code example shows how to use `update-budget`.

**AWS CLI**

**To replace a budget for a Cost and Usage budget**

This example replaces a Cost and Usage budget with a new budget.

**Command:**

```
aws budgets update-budget --account-id 111122223333 --new-budget file://new-budget.json
```

**new-budget.json:**

```json
{
    "BudgetLimit": {
        "Amount": "100",
        "Unit": "USD"
    },

        "IncludeCredit": false,
        "IncludeDiscount": true,
```
For API details, see `UpdateBudget` in *AWS CLI Command Reference.*

**update-notification**

The following code example shows how to use `update-notification`.

**AWS CLI**

To replace a notification for a Cost and Usage budget

This example replaces an 80% notification for a Cost and Usage budget with a 90% notification.

Command:

```bash
aws budgets update-notification --account-id 111122223333 --budget-name "Example Budget" --old-notification
NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=80,ThresholdType=PERCENTAGE
--new-notification
NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=90,ThresholdType=PERCENTAGE
```

For API details, see `UpdateNotification` in *AWS CLI Command Reference.*

**update-subscriber**

The following code example shows how to use `update-subscriber`.

```json
"IncludeOtherSubscription": true,
"IncludeRecurring": true,
"IncludeRefund": true,
"IncludeSubscription": true,
"IncludeSupport": true,
"IncludeTax": true,

Amazon Chime examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Amazon Chime.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

```

- For API details, see [BatchSuspendUser](https://docs.aws.amazon.com/cli/latest/reference/chime/batch-suspend-user.html) in *AWS CLI Command Reference*.

batch-unsuspend-user

The following code example shows how to use `batch-unsuspend-user`.

**AWS CLI**

**To unsuspend multiple users**

The following `batch-unsuspend-user` example removes any previous suspension for the listed users on the specified Amazon Chime account.

```
aws chime batch-unsuspend-user \
--account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \
--user-id-list "a1b2c3d4-5678-90ab-cdef-22222EXAMPLE" "a1b2c3d4-5678-90ab-cdef-33333EXAMPLE" "a1b2c3d4-5678-90ab-cdef-44444EXAMPLE"
```

Output:
For API details, see `BatchUnsuspendUser` in *AWS CLI Command Reference*.

**batch-update-phone-number**

The following code example shows how to use `batch-update-phone-number`.

**AWS CLI**

To update several phone number product types at the same time

The following `batch-update-phone-number` example updates the product types for all of the specified phone numbers.

```
aws chime batch-update-phone-number \
    --update-phone-number-request-items PhoneNumberId= %2B12065550100,ProductType=BusinessCalling PhoneNumberId= %2B12065550101,ProductType=BusinessCalling
```

Output:

```json
{
    "PhoneNumberErrors": []
}
```

To update several phone number calling names at the same time

The following `batch-update-phone-number` example updates the calling names for all of the specified phone numbers.

```
aws chime batch-update-phone-number \
    --update-phone-number-request-items PhoneNumberId= %2B14013143874,CallingName=phonenumber1 PhoneNumberId= %2B14013144061,CallingName=phonenumber2
```

Output:

```json
{

### batch-update-user

The following code example shows how to use `batch-update-user`.

**AWS CLI**

**To update multiple users in a single command**

The following batch-update-user example updates the `LicenseType` for each of the listed users in the specified Amazon Chime account.

```bash
aws chime batch-update-user \\
   --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \\
   --update-user-request-items "UserId=a1b2c3d4-5678-90ab-cdef-22222EXAMPLE,LicenseType=Basic" "UserId=a1b2c3d4-5678-90ab-cdef-33333EXAMPLE,LicenseType=Basic"
```

**Output:**

```json
{
   "UserErrors": []
}
```

- For API details, see [BatchUpdateUser](#) in *AWS CLI Command Reference*.

### create-account

The following code example shows how to use `create-account`.

**AWS CLI**

**To create an account**
The following `create-account` example creates an Amazon Chime account under the administrator's AWS account.

```
aws chime create-account \
--name MyChimeAccount
```

Output:

```
{
   "Account": {
      "AwsAccountId": "111122223333",

**list-voice-connector-termination-credentials**

The following code example shows how to use list-voice-connector-termination-credentials.

**AWS CLI**

**To retrieve a list of termination credentials**

The following list-voice-connector-termination-credentials example retrieves a list of the termination credentials for the specified Amazon Chime Voice Connector.

```bash
aws chime list-voice-connector-termination-credentials \
  --voice-connector-id abcdef1ghij2klmno3pqr4
```

This command produces no output. Output:

```json
{
  "Usernames": [
    "jdoe"
  ]
}
```
For more information, see Working with Amazon Chime Voice Connectors in the Amazon Chime Administration Guide.

- For API details, see ListVoiceConnectorTerminationCredentials in AWS CLI Command Reference.

**list-voice-connectors**

The following code example shows how to use list-voice-connectors.

**AWS CLI**

To list Amazon Chime Voice Connectors for an account

The following list-voice-connectors example lists the Amazon Chime Voice Connectors associated with the caller's account.

```bash
aws chime list-voice-connectors
```

Output:

```json
{
   "VoiceConnectors": [
      {
         "VoiceConnectorId": "abcdef1ghij2klmno3pqr4",

### logout-user

The following code example shows how to use `logout-user`.

**AWS CLI**

**To log out a user**

The following `logout-user` example logs out the specified user.

```bash
aws chime logout-user
   --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE
   --user-id a1b2c3d4-5678-90ab-cdef-22222EXAMPLE
```

This command produces no output.

- For API details, see [LogoutUser](#) in AWS CLI Command Reference.

### put-voice-connector-logging-configuration

The following code example shows how to use `put-voice-connector-logging-configuration`.

**AWS CLI**

**To add a logging configuration for an Amazon Chime Voice Connector**

The following `put-voice-connector-logging-configuration` example turns on the SIP logging configuration for the specified Amazon Chime Voice Connector.

```bash
aws chime put-voice-connector-logging-configuration
   --voice-connector-id abcdef1ghij2klmno3pqr4
   --logging-configuration EnableSIPLogs=true
```
Output:

```json
{
   "LoggingConfiguration": {
      "EnableSIPLogs": true
   }
}
```

### put-voice-connector-origination

The following code example shows how to use `put-voice-connector-origination`.

**AWS CLI**

**To set up origination settings**

The following `put-voice-connector-origination` example sets up the origination host, port, protocol, priority, and weight for the specified Amazon Chime Voice Connector.

```bash
aws chime put-voice-connector-origination \
   --voice-connector-id abcdefghijklmnopqrstuvwxyz1234567890 \
   --origination \
   Routes=([{Host=10.24.34.0,Port=1234,Protocol="TCP",Priority=1,Weight=5}],Disabled=false)
```

Output:

```json
{
   "Origination": {
      "Routes": [
         {
            "Host": "10.24.34.0",
            "Port": 1234,
            "Protocol": "TCP",
            "Priority": 1,
            "Weight": 5
         }
      ]
   }
}
```
For more information, see Working with Amazon Chime Voice Connectors in the Amazon Chime Administration Guide.

- For API details, see PutVoiceConnectorOrigination in AWS CLI Command Reference.

**put-voice-connector-proxy**

The following code example shows how to use put-voice-connector-proxy.

**AWS CLI**

To put a proxy configuration

The following put-voice-connector-proxy example sets a proxy configuration to your Amazon Chime Voice Connector.

```bash
aws chime put-voice-connector-proxy \
   --voice-connector-id abcdef1ghij2klmno3pqr4 \
   --default-session-expiry-minutes 60 \
   --phone-number-pool-countries "US"
```

Output:

```json
{
   "Proxy": {
      "DefaultSessionExpiryMinutes": 60,
      "Disabled": false,
      "PhoneNumberCountries": ["US"
   ]
}
}
```

For more information, see Proxy Phone Sessions in the Amazon Chime Developer Guide.

- For API details, see PutVoiceConnectorProxy in AWS CLI Command Reference.
**put-voice-connector-streaming-configuration**

The following code example shows how to use `put-voice-connector-streaming-configuration`.

**AWS CLI**

**To create a streaming configuration**

The following `put-voice-connector-streaming-configuration` example creates a streaming configuration for the specified Amazon Chime Voice Connector. It enables media streaming from the Amazon Chime Voice Connector to Amazon Kinesis, and sets the data retention period to 24 hours.

```
aws chime put-voice-connector-streaming-configuration \
  --voice-connector-id abedef1ghij2klmno3pqr4 \
  --streaming-configuration DataRetentionInHours=24,Disabled=false
```

Output:

```
{
  "StreamingConfiguration": {
    "DataRetentionInHours": 24,
    "Disabled": false
  }
}
```

For more information, see [Streaming Amazon Chime Voice Connector Data to Kinesis](https://docs.aws.amazon.com/chime/latest/admin-guide/stream-voice-data-to-kinesis.html) in the Amazon Chime Administration Guide.

**put-voice-connector-termination-credentials**

The following code example shows how to use `put-voice-connector-termination-credentials`.

**AWS CLI**

**To set up termination credentials**
The following `put-voice-connector-termination-credentials` example sets termination credentials for the specified Amazon Chime Voice Connector.

```bash
aws chime put-voice-connector-termination-credentials \
    --voice-connector-id abcdef1ghij2klmno3pqr4 \
    --credentials Username="jdoe",Password="XXXXXXXX"
```

This command produces no output.

For more information, see Working with Amazon Chime Voice Connectors in the Amazon Chime Administration Guide.

- For API details, see `PutVoiceConnectorTerminationCredentials` in AWS CLI Command Reference.

**put-voice-connector-termination**

The following code example shows how to use `put-voice-connector-termination`.

**AWS CLI**

**To set up termination settings**

The following `put-voice-connector-termination` example sets the calling regions and allowed IP host termination settings for the specified Amazon Chime Voice Connector.

```bash
aws chime put-voice-connector-termination \
    --voice-connector-id abcdef1ghij2klmno3pqr4 \
    --termination CallingRegions="US",CidrAllowedList="10.24.34.0/23",Disabled=false
```

Output:

```
{
    "Termination": {
        "CpsLimit": 0,
        "CallingRegions": ["US"],
        "CidrAllowedList": ["10.24.34.0/23"],
        "Disabled": false
    }
}
```
The following code example shows how to use `regenerate-security-token`.

**AWS CLI**

To regenerate a security token

The following `regenerate-security-token` example regenerates the security token for the specified bot.

```
aws chime regenerate-security-token \\n   --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \\n   --bot-id 123abcd4-5ef6-789g-0h12-34j56789012k
```

Output:

```
{
   "Bot": {
      "BotId": "123abcd4-5ef6-789g-0h12-34j56789012k",
      "UserId": "123abcd4-5ef6-789g-0h12-34j56789012k",

**reset-personal-pin**

The following code example shows how to use `reset-personal-pin`.

**AWS CLI**

**To reset a user's personal meeting PIN**

The following `reset-personal-pin` example resets the specified user's personal meeting PIN.

```bash
aws chime reset-personal-pin \
   --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \
   --user-id a1b2c3d4-5678-90ab-cdef-22222EXAMPLE

search-available-phone-numbers

The following code example shows how to use `search-available-phone-numbers`.
AWS CLI

To search available phone numbers

The following search-available-phone-numbers example searches available phone numbers by area code.

```bash
aws chime search-available-phone-numbers \\
  --area-code "206"
```

Output:

```json
{
  "E164PhoneNumbers": [
    "+12065550100",

update-account-settings

The following code example shows how to use update-account-settings.

AWS CLI

To update the settings for your account

The following update-account-settings example disables the remote control of shared screens for the specified Amazon Chime account.
aws chime update-account-settings \ 
   --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \ 
   --account-settings DisableRemoteControl=true

This command produces no output.

- For API details, see UpdateAccountSettings in AWS CLI Command Reference.

update-account

The following code example shows how to use update-account.

AWS CLI

To update an account

The following update-account example updates the specified account name.

aws chime update-account \ 
   --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \ 
   --name MyAccountName

Output:

update-global-settings

The following code example shows how to use update-global-settings.

AWS CLI

To update global settings

The following update-global-settings example updates the S3 bucket used to store call detail records for Amazon Chime Business Calling and Amazon Chime Voice Connectors associated with the administrator's AWS account.

```
aws chime update-global-settings \
    --business-calling CdrBucket="s3bucket" \
    --voice-connector CdrBucket="s3bucket"
```

This command produces no output.

For more information, see Managing Global Settings in the Amazon Chime Administration Guide.
• For API details, see UpdateGlobalSettings in AWS CLI Command Reference.

update-phone-number-settings

The following code example shows how to use update-phone-number-settings.

AWS CLI

To update an outbound calling name

The following update-phone-number-settings example updates the default outbound calling name for the administrator's AWS account.

```
aws chime update-phone-number-settings \
    --calling-name "myName"
```

This command produces no output.

For more information, see Working with Phone Numbers in the Amazon Chime Administration Guide.
• For API details, see UpdatePhoneNumberSettings in AWS CLI Command Reference.
**update-phone-number**

The following code example shows how to use `update-phone-number`.

**AWS CLI**

**Example 1: To update the product type for a phone number**

The following `update-phone-number` example updates the specified phone number's product type.

```bash
aws chime update-phone-number \\

**update-room**

The following code example shows how to use update-room.

**AWS CLI**

**To update a chat room**

The following update-room example modifies the name of the specified chat room.

```bash
aws chime update-room \
```
--account-id 12a3456b-7c89-012d-3456-78901e23fg45 \  
--room-id abcd1e2d-3e45-6789-01f2-3g45h67i890j \  
--name teamRoom

Output:

```
{
   "Room": {
      "RoomId": "abcd1e2d-3e45-6789-01f2-3g45h67i890j",
      "Name": "teamRoom",
      "AccountId": "12a3456b-7c89-012d-3456-78901e23fg45",

   }
}
```

For more information, see Creating a Chat Room in the Amazon Chime User Guide.

- For API details, see UpdateRoom in AWS CLI Command Reference.

update-user-settings

The following code example shows how to use update-user-settings.

AWS CLI

To update user settings

The following update-user-settings example enables the specified user to make inbound and outbound calls and send and receive SMS messages.

```
aws chime update-user-settings \  
   --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \  
   --user-id 1ab2345c-67de-8901-f23g-45h678901j2k \  
   --user-settings "Telephony={InboundCalling=true,OutboundCalling=true,SMS=true}"
```

This command produces no output.

For more information, see Managing User Phone Numbers in the Amazon Chime Administration Guide.

- For API details, see UpdateUserSettings in AWS CLI Command Reference.
**update-user**

The following code example shows how to use `update-user`.

**AWS CLI**

**To update user details**

This example updates the specified details for the specified user.

**Command:**

```bash
cmd
aws chime update-user \
   --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \
   --user-id a1b2c3d4-5678-90ab-cdef-22222EXAMPLE \
   --license-type "Basic"
```

**Output:**

```json

**update-voice-connector-group**

The following code example shows how to use `update-voice-connector-group`.

**AWS CLI**

**To update the details for an Amazon Chime Voice Connector group**

The following `update-voice-connector-group` example updates the details of the specified Amazon Chime Voice Connector group.

```bash
cmd
aws chime update-voice-connector-group \
   --voice-connector-group-id 123a456b-c7d8-90e1-fg23-4h567jkl8901 \
   --name "newGroupName" \
   --voice-connector-items VoiceConnectorId=abcdef1ghij2klmno3pqr4,Priority=1
```
For more information, see Working with Amazon Chime Voice Connector Groups in the Amazon Chime Administration Guide.

update-voice-connector

The following code example shows how to use update-voice-connector.

AWS CLI

To update the details for an Amazon Chime Voice Connector

The following update-voice-connector example updates the name of the specified Amazon Chime Voice Connector.

```
aws chime update-voice-connector \
    --voice-connector-id abcdef1ghij2klmno3pqr4 \
    --name newName \
    --require-encryption
```

Output:

```
{
    "VoiceConnector": {

### Actions

**create-resource**

The following code example shows how to use `create-resource`.

**AWS CLI**

To create a resource
The following create-resource example creates an AWS::Kinesis::Stream resource, named ResourceExample, with a retention period of 168 hours and a shard count of three.

```
aws cloudcontrol create-resource \
   --type-name AWS::Kinesis::Stream \
   --desired-state "{"Name": "ResourceExample"","RetentionPolicyHours":168, ","ShardCount":3}"
```

Output:

```
{
   "ProgressEvent": {
      "EventTime": 1632506656.706,
      "TypeName": "AWS::Kinesis::Stream",
      "OperationStatus": "IN_PROGRESS",
      "Operation": "CREATE",
      "Identifier": "ResourceExample",
      "RequestToken": "20999d87-e304-4725-ad84-832dcbfd7fc5"
   }
}
```

For more information, see Creating a resource in the Cloud Control API User Guide.

- For API details, see CreateResource in AWS CLI Command Reference.

delete-resource

The following code example shows how to use delete-resource.

**AWS CLI**

**To delete a resource**

The following delete-resource example deletes a AWS::Kinesis::Stream resource with the identifier ResourceExample from your AWS account.

```
aws cloudcontrol delete-resource \
   --type-name AWS::Kinesis::Stream \
   --identifier ResourceExample
```

Output:
The following code example shows how to use `get-resource-request-status`.

AWS CLI

To get the status information of a resource request

The following `get-resource-request-status` example returns status information about the specified resource request.

```
aws cloudcontrol get-resource-request-status \
   --request-token "e1a6b86e-46bd-41ac-bfba-001234567890"
```

Output:

```json
{
   "ProgressEvent": {
      "TypeName": "AWS::Kinesis::Stream",
      "Identifier": "Demo",
      "RequestToken": "e1a6b86e-46bd-41ac-bfba-001234567890",
      "Operation": "CREATE",
      "OperationStatus": "FAILED",
      "EventTime": 1632950268.481,
      "StatusMessage": "Resource of type 'AWS::Kinesis::Stream' with identifier 'Demo' already exists.",
      "ErrorCode": "AlreadyExists"
   }
}
```
For more information, see [Managing resource operation requests](https://docs.aws.amazon.com/cloudcontrol/latest/userguide/managing-resource-requests.html) in the *Cloud Control API User Guide*.

**get-resource**

The following code example shows how to use `get-resource`.

**AWS CLI**

**To get the current state of a resource**

The following `get-resource` example returns the current state of the AWS::Kinesis::Stream resource named ResourceExample.

```bash
aws cloudcontrol get-resource \
   --type-name AWS::Kinesis::Stream \
   --identifier ResourceExample
```

**Output:**

```json
{
   "TypeName": "AWS::Kinesis::Stream",
   "ResourceDescription": {
      "Identifier": "ResourceExample",
}
```

For more information, see [Reading a resource's current state](https://docs.aws.amazon.com/cloudcontrol/latest/userguide/reading-resource-state.html) in the *Cloud Control API User Guide*.

**list-resource-requests**

The following code example shows how to use `list-resource-requests`.

```bash
```
AWS CLI

To list the active resource operation requests

The following `list-resource-requests` example lists the resource requests for CREATE and UPDATE operations that have failed in your AWS account.

```
aws cloudcontrol list-resource-requests \
   --resource-request-status-filter Operations=CREATE,OperationStatuses=FAILED
```

Output:

```json
{
   "ResourceRequestStatusSummaries": [
      {
         "TypeName": "AWS::Kinesis::Stream",
         "Identifier": "Demo",

**list-resources**

The following code example shows how to use `list-resources`.

**AWS CLI**

To list the resources of a given type

The following `list-resources` example lists the AWS::Kinesis::Stream resources provisioned in your AWS account.
aws cloudcontrol list-resources \
   --type-name AWS::Kinesis::Stream

Output:

```
{
   "TypeName": "AWS::Kinesis::Stream",
   "ResourceDescriptions": [
      {
         "Identifier": "MyKinesisStream",
         "Properties": "{"Name":"MyKinesisStream"}"
      },
      {
         "Identifier": "AnotherStream",
         "Properties": "{"Name":"AnotherStream"}"
      }
   ]
}
```

For more information, see Discovering resources in the Cloud Control API User Guide.

- For API details, see ListResources in AWS CLI Command Reference.

**update-resource**

The following code example shows how to use update-resource.

**AWS CLI**

**To update the properties of an existing resource**

The following update-resource example updates the retention policy of an AWS::Logs::LogGroup resource named ExampleLogGroup to 90 days.

```
aws cloudcontrol update-resource \
   --type-name AWS::Logs::LogGroup \
   --identifier ExampleLogGroup \
   --patch-document "[{{"op":"replace","path":"/RetentionInDays","value":90}}]
```

Output:
For more information, see Updating a resource in the Cloud Control API User Guide.

- For API details, see UpdateResource in AWS CLI Command Reference.

Actions

create-private-dns-namespace

The following code example shows how to use create-private-dns-namespace.
AWS CLI

To create a private DNS namespace

The following `create-private-dns-namespace` example creates a private DNS namespace.

```bash
aws servicediscovery create-private-dns-namespace \
    --name example.com \
    --vpc vpc-1c56417b
```

Output:

```json
{
    "OperationId": "gv4g5meo7ndmeh4fqskygvk23d2fijwa-k9302yzd"
}
```

To confirm that the operation succeeded, you can run `get-operation`. For more information, see `get-operation`.

For more information, see Creating namespaces in the AWS Cloud Map Developer Guide.

- For API details, see `CreatePrivateDnsNamespace` in AWS CLI Command Reference.

create-service

The following code example shows how to use `create-service`.

AWS CLI

To create a service

The following `create-service` example creates a service.

```bash
aws servicediscovery create-service \
    --name myservice \
    --namespace-id ns-ylexjili4cdxy3xm \
    --dns-config "NamespaceId=ns-ylexjili4cdxy3xm,RoutingPolicy=MULTIVALUE,DnsRecords=[[Type=A,TTL=60]]"
```

Output:
For more information, see Creating services in the AWS Cloud Map Developer Guide.

- For API details, see CreateService in AWS CLI Command Reference.

**delete-namespace**

The following code example shows how to use delete-namespace.

**AWS CLI**

To delete a namespace

The following delete-namespace example deletes a namespace.

```
aws servicediscovery delete-namespace \\
    --id ns-ylexjili4cdxy3xm
```

Output:

```
{}
```
"OperationId": "gv4g5meo7ndmeh4fqsksygkv23d2fijwa-k98y6drk"

To confirm that the operation succeeded, you can run get-operation. For more information, see [get-operation](#).

For more information, see [Deleting namespaces](#) in the *AWS Cloud Map Developer Guide*.

• For API details, see [DeleteNamespace](#) in *AWS CLI Command Reference*.

delete-service

The following code example shows how to use delete-service.

**AWS CLI**

**To delete a service**

The following delete-service example deletes a service.

```
aws servicediscovery delete-service \
--id srv-p5zdwlg5uvvzjita
```

This command produces no output.

For more information, see [Deleting services](#) in the *AWS Cloud Map Developer Guide*.

• For API details, see [DeleteService](#) in *AWS CLI Command Reference*.

deregister-instance

The following code example shows how to use deregister-instance.

**AWS CLI**

**To deregister a service instance**

The following deregister-instance example deregisters a service instance.

```
aws servicediscovery deregister-instance \
```
To discover registered instances

The following discover-instances example discovers registered instances.

```bash
aws servicediscovery discover-instances \
   --namespace-name example.com \
   --service-name myservice \
   --max-results 10 \
   --health-status ALL
```

Output:

```json
{
   "Instances": [
   {
      "InstanceId": "myservice-53",
      "NamespaceName": "example.com",
```
• For API details, see DiscoverInstances in AWS CLI Command Reference.

get-operation

The following code example shows how to use get-operation.

AWS CLI

To get the result of an operation

The following get-operation example gets the result of an operation.

```
aws servicediscovery get-operation \
    --operation-id gv4g5meo7ndmeh4fqskygvk23d2fijwa-k9302yzd
```

Output:

```
{
    "Operation": {
        "Id": "gv4g5meo7ndmeh4fqskygvk23d2fijwa-k9302yzd",

    }
}
```

• For API details, see GetOperation in AWS CLI Command Reference.
list-instances

The following code example shows how to use `list-instances`.

**AWS CLI**

**To list service instances**

The following `list-instances` example lists service instances.

```bash
aws servicediscovery list-instances
   --service-id srv-qzpwt2tfqcegapy
```

Output:

```
{
   "Instances": [

list-namespaces

The following code example shows how to use `list-namespaces`.

**AWS CLI**

**To list namespaces**

The following `list-namespaces` example lists namespaces.

```bash
aws servicediscovery list-namespaces
```
Output:

```
{
    "Namespaces": [

**list-services**

The following code example shows how to use `list-services`.

**AWS CLI**

**To list services**

The following `list-services` example lists services.

```
aws servicediscovery list-services
```

Output:

```json
{
  "Services": [

**register-instance**

The following code example shows how to use register-instance.

**AWS CLI**

**To register a service instance**

The following register-instance example registers a service instance.

```
aws servicediscovery register-instance \
  --service-id srv-p5zdwl5g5uvvzjita \
  --instance-id myservice-53 \
  --attributes=AWS_INSTANCE_IPV4=172.2.1.3,AWS_INSTANCE_PORT=808
```

Output:

```
{
  "OperationId": "4yejorelbukcjpznz6tlmrghsjwpngf4-k95yg2u7"
}
```

To confirm that the operation succeeded, you can run get-operation. For more information, see get-operation.

**Actions**

**create-environment-ec2**

The following code example shows how to use `create-environment-ec2`.

**AWS CLI**

**To create an AWS Cloud9 EC2 development environment**

This following `create-environment-ec2` example creates an AWS Cloud9 development environment with the specified settings, launches an Amazon Elastic Compute Cloud (Amazon EC2) instance, and then connects from the instance to the environment.

```bash
aws cloud9 create-environment-ec2 \
    --name my-demo-env \
    --description "My demonstration development environment." \
    --instance-type t2.micro --image-id amazonlinux-2023-x86_64 \
    --subnet-id subnet-1fab8aEX \
    --automatic-stop-time-minutes 60 \
    --owner-arn arn:aws:iam::123456789012:user/MyDemoUser
```

**Output:**

```json
{
    "environmentId": "8a34f51ce1e04a08882f1e811bd706EX"
}
```
For more information, see Creating an EC2 Environment in the AWS Cloud9 User Guide.

- For API details, see CreateEnvironmentEc2 in AWS CLI Command Reference.

create-environment-membership

The following code example shows how to use create-environment-membership.

AWS CLI

To add an environment member to an AWS Cloud9 development environment

This example adds the specified environment member to the specified AWS Cloud9 development environment.

Command:

```
aws cloud9 create-environment-membership --environment-id 8a34f51ce1e04a08882f1e811bd706EX --user-arn arn:aws:iam::123456789012:user/AnotherDemoUser --permissions read-write
```

Output:

```
{
   "membership": {
       "environmentId": "8a34f51ce1e04a08882f1e811bd706EX",
       "userId": "AIDAJ3LOROMOUXTBSU6EX",
       "userArn": "arn:aws:iam::123456789012:user/AnotherDemoUser",
       "permissions": "read-write"
   }
}
```

- For API details, see CreateEnvironmentMembership in AWS CLI Command Reference.

delete-environment-membership

The following code example shows how to use delete-environment-membership.

AWS CLI

To delete an environment member from an AWS Cloud9 development environment
This example deletes the specified environment member from the specified AWS Cloud9 development environment.

Command:

```
aws cloud9 delete-environment-membership --environment-id 8a34f51ce1e04a08882f1e811bd706EX --user-arn arn:aws:iam::123456789012:user/AnotherDemoUser
```

Output:

None.

- For API details, see `DeleteEnvironmentMembership` in *AWS CLI Command Reference*.

delete-environment

The following code example shows how to use delete-environment.

**AWS CLI**

**To delete an AWS Cloud9 development environment**

This example deletes the specified AWS Cloud9 development environment. If an Amazon EC2 instance is connected to the environment, also terminates the instance.

Command:

```
aws cloud9 delete-environment --environment-id 8a34f51ce1e04a08882f1e811bd706EX
```

Output:

None.

- For API details, see `DeleteEnvironment` in *AWS CLI Command Reference*.

describe-environment-memberships

The following code example shows how to use describe-environment-memberships.
AWS CLI

To get information about environment members for an AWS Cloud9 development environment

This example gets information about environment members for the specified AWS Cloud9 development environment.

Command:

```
aws cloud9 describe-environment-memberships --environment-id 8a34f51ce1e04a08882f1e811bd706EX
```

Output:

```
{
  "memberships": [
    {
      "environmentId": "8a34f51ce1e04a08882f1e811bd706EX",
      "userId": "AIDAJ3LOROMOUXTBSU6EX",
      "userArn": "arn:aws:iam::123456789012:user/AnotherDemoUser",

      "userArn": "arn:aws:iam::123456789012:user/MyDemoUser",
      "permissions": "owner"
    }
  ]
}
```

To get information about the owner of an AWS Cloud9 development environment

This example gets information about the owner of the specified AWS Cloud9 development environment.

Command:

```
aws cloud9 describe-environment-memberships --environment-id 8a34f51ce1e04a08882f1e811bd706EX --permissions owner
```
To get information about an environment member for multiple AWS Cloud9 development environments

This example gets information about the specified environment member for multiple AWS Cloud9 development environments.

Command:

```
aws cloud9 describe-environment-memberships --user-arn arn:aws:iam::123456789012:user/MyDemoUser
```

Output:

```
{
   "memberships": [
   {
      "environmentId": "10a75714bd494714929e7f5ec4125aEX",

      "permissions": "owner"
   }
   ]
}
```
describe-environment-status

The following code example shows how to use describe-environment-status.

AWS CLI

To get status information for an AWS Cloud9 development environment

This example gets status information for the specified AWS Cloud9 development environment.

Command:

```
aws cloud9 describe-environment-status --environment-id 685f892f431b45c2b28cb69eadc0bEX
```

Output:

```
{
   "status": "ready",
   "message": "Environment is ready to use"
}
```

For API details, see DescribeEnvironmentStatus in AWS CLI Command Reference.

describe-environments

The following code example shows how to use describe-environments.

AWS CLI

To get information about AWS Cloud9 development environments

This example gets information about the specified AWS Cloud9 development environments.

Command:

```
aws cloud9 describe-environments --environment-ids 685f892f431b45c2b28cb69eadc0bEX 349c86d4579e4e7298d500ff57a6b2EX
```
Output:

```
{
  "environments": [
    {

      }
    }
  ]
}
```

• For API details, see [DescribeEnvironments](#) in [AWS CLI Command Reference](#).

**list-environments**

The following code example shows how to use list-environments.

**AWS CLI**

To get a list of available AWS Cloud9 development environment identifiers

This example gets a list of available AWS Cloud9 development environment identifiers.
Command:

```bash
aws cloud9 list-environments
```

Output:

```json
{
    "environmentIds": [
        "685f892f431b45c2b28cb69eadc6b0EX",
        "1980b80e5f584920801c0908667f0EX"
    ]
}
```

- For API details, see [ListEnvironments](https://docs.aws.amazon.com/cli/latest/reference/cloud9/list-environments.html) in *AWS CLI Command Reference*.

**update-environment-membership**

The following code example shows how to use `update-environment-membership`.

**AWS CLI**

To change the settings of an existing environment member for an AWS Cloud9 development environment

This example changes the settings of the specified existing environment member for the specified AWS Cloud9 development environment.

Command:

```bash
aws cloud9 update-environment-membership --environment-id 8a34f51ce1e04a08882f1e811bd706EX --user-arn arn:aws:iam::123456789012:user/AnotherDemoUser --permissions read-only
```

Output:

```json
{
    "membership": {
        "environmentId": "8a34f51ce1e04a08882f1e811bd706EX",
        "userId": "AIDAJ3LOROMOUXTBSU6EX",
        "userArn": "arn:aws:iam::123456789012:user/AnotherDemoUser",
        "permissions": "read-only"
    }
}
```
"permissions": "read-only"
}
}

- For API details, see UpdateEnvironmentMembership in AWS CLI Command Reference.

**update-environment**

The following code example shows how to use update-environment.

**AWS CLI**

**To change the settings of an existing AWS Cloud9 development environment**

This example changes the specified settings of the specified existing AWS Cloud9 development environment.

Command:

```
aws cloud9 update-environment --environment-id 8a34f51ce1e04a08882f1e811bd706EX
--name my-changed-demo-env --description "My changed demonstration development environment."
```

Output:

```
None.
```

- For API details, see UpdateEnvironment in AWS CLI Command Reference.

**AWS CloudFormation examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with AWS CloudFormation.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.
Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Topics**
- Actions

**Actions**

**activate-type**

The following code example shows how to use `activate-type`.

**AWS CLI**

**To activate a type**

The following `activate-type` example activates a public third-party extension, making it available for use in stack templates.

```bash
aws cloudformation activate-type \
    --region us-west-2 \
    --type RESOURCE \
    --type-name Example::Test::1234567890abcdef0 \
    --type-name-alias Example::Test::Alias
```

Output:

```
{
}
```

- For API details, see [ActivateType](https://docs.aws.amazon.com/cli/latest/reference/cloudformation/activate-type.html) in [AWS CLI Command Reference](https://docs.aws.amazon.com/cli/latest/reference/cloudformation/activate-type.html).

**batch-describe-type-configurations**

The following code example shows how to use `batch-describe-type-configurations`.
AWS CLI

To batch describe a type configuration

The following batch-describe-type-configurations example configures the data for the type.

```bash
aws cloudformation batch-describe-type-configurations \
   --region us-west-2 \
   --type-configuration-identifiers TypeArn="arn:aws:cloudformation:us-west-2:123456789012:type/resource/Example-Test-Type,TypeConfigurationAlias=MyConfiguration"
```

Output:

```json
{
    "Errors": [],
    "UnprocessedTypeConfigurations": [],
    "TypeConfigurations": [
        {
            "Alias": "MyConfiguration",
            "Configuration": "{\n            "Example": {\n                "ApiKey": "examplekey",
                "ApplicationKey": "examplekey1",
                "ApiURL": "exampleurl"
            }\n            },
            "LastUpdated": "2021-10-01T15:25:46.210000+00:00",
            "TypeArn": "arn:aws:cloudformation:us-east-1:123456789012:type/resource/Example-Test-Type"
        }
    ]
}
```

For more information, see Using the AWS CloudFormation registry in the AWS CloudFormation User Guide.

- For API details, see BatchDescribeTypeConfigurations in AWS CLI Command Reference.

cancel-update-stack

The following code example shows how to use cancel-update-stack.
AWS CLI

To cancel a stack update that is in progress

The following `cancel-update-stack` command cancels a stack update on the `myteststack` stack:

```
aws cloudformation cancel-update-stack --stack-name myteststack
```

- For API details, see [CancelUpdateStack](#) in *AWS CLI Command Reference*.

continue-update-rollback

The following code example shows how to use `continue-update-rollback`.

AWS CLI

To retry an update rollback

The following `continue-update-rollback` example resumes a rollback operation from a previously failed stack update.

```
aws cloudformation continue-update-rollback \\
--stack-name my-stack
```

This command produces no output.

- For API details, see [ContinueUpdateRollback](#) in *AWS CLI Command Reference*.

create-change-set

The following code example shows how to use `create-change-set`.

AWS CLI

To create a change set

The following `create-change-set` example creates a change set with the `CAPABILITY_IAM` capability. The file `template.yaml` is an AWS CloudFormation template in the current folder that defines a stack that includes IAM resources.
aws cloudformation create-change-set \
    --stack-name my-application \
    --change-set-name my-change-set \
    --template-body file://template.yaml \
    --capabilities CAPABILITY_IAM

Output:

```json
{
    "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/my-application/d0a825a0-e4cd-xmpl-b9fb-061c69e99204"
}
```

- For API details, see CreateChangeSet in AWS CLI Command Reference.

create-stack-instances

The following code example shows how to use create-stack-instances.

AWS CLI

To create stack instances

The following create-stack-instances example creates instances of a stack set in two accounts and in four regions. The fault tolerance setting ensures that the update is attempted in all accounts and regions, even if some stacks cannot be created.

aws cloudformation create-stack-instances \
    --stack-set-name my-stack-set \
    --accounts 123456789012 223456789012 \
    --regions us-east-1 us-east-2 us-west-1 us-west-2 \
    --operation-preferences FailureToleranceCount=7

Output:

```json
{
    "OperationId": "d7995c31-83c2-xmpl-a3d4-e9ca2811563f"
}
```
To create a stack set, use the `create-stack-set` command.

- For API details, see [CreateStackInstances](#) in *AWS CLI Command Reference*.

### create-stack-set

The following code example shows how to use `create-stack-set`.

**AWS CLI**

**To create a stack set**

The following `create-stack-set` example creates a stack set using the specified YAML file template. `template.yaml` is an AWS CloudFormation template in the current folder that defines a stack.

```bash
aws cloudformation create-stack-set
  --stack-set-name my-stack-set
  --template-body file://template.yaml
  --description "SNS topic"
```

Output:

```json
{
   "StackSetId": "my-stack-set:8d0f160b-d157-xmpl-a8e6-c0ce8e5d8cc1"
}
```

To add stack instances to the stack set, use the `create-stack-instances` command.

- For API details, see [CreateStackSet](#) in *AWS CLI Command Reference*.

### create-stack

The following code example shows how to use `create-stack`.

**AWS CLI**

**To create an AWS CloudFormation stack**

The following `create-stacks` command creates a stack with the name `myteststack` using the `sampletemplate.json` template:
aws cloudformation create-stack --stack-name myteststack --template-body file://sampletemplate.json --parameters ParameterKey=KeyPairName,ParameterValue=TestKey ParameterKey=SubnetIDs,ParameterValue=SubnetID1,SubnetID2

Output:

{
   "StackId": "arn:aws:cloudformation:us-east-1:123456789012:stack/myteststack/466df9e0-0dff-08e3-8e2f-5088487c4896"
}

For more information, see Stacks in the AWS CloudFormation User Guide.

- For API details, see CreateStack in AWS CLI Command Reference.

**deactivate-type**

The following code example shows how to use deactivate-type.

**AWS CLI**

**To deactivate a type**

The following deactivate-type example deactivates a public extension that was previously activated in this account and Region.

```
aws cloudformation deactivate-type \
   --region us-west-2 \
   --type MODULE \
   --type-name Example::Test::Type::MODULE
```

This command produces no output.

For more information, see Using the AWS CloudFormation registry in the AWS CloudFormation User Guide.

- For API details, see DeactivateType in AWS CLI Command Reference.

**delete-change-set**

The following code example shows how to use delete-change-set.
AWS CLI

**To delete a change set**

The following `delete-change-set` example deletes a change set by specifying the change set name and stack name.

```bash
aws cloudformation delete-change-set \
    --stack-name my-stack \
    --change-set-name my-change-set
```

This command produces no output.

The following `delete-change-set` example deletes a change set by specifying the full ARN of the change set.

```bash
aws cloudformation delete-change-set \
```

This command produces no output.

- For API details, see [DeleteChangeSet](https://docs.aws.amazon.com/cli/latest/reference/cloudformation/delete-change-set.html) in *AWS CLI Command Reference*.

**delete-stack-instances**

The following code example shows how to use `delete-stack-instances`.

**AWS CLI**

**To delete stack instances**

The following `delete-stack-instances` example deletes instances of a stack set in two accounts in two regions and terminates the stacks.

```bash
aws cloudformation delete-stack-instances \
    --stack-set-name my-stack-set \
    --accounts 123456789012 567890123456 \
    --regions us-east-1 us-west-1 \
    --no-retain-stacks
```
Output:

```
{
    "OperationId": "ad49f10c-fd1d-413f-a20a-8de6e2fa8f27"
}
```

To delete an empty stack set, use the delete-stack-set command.

- For API details, see `DeleteStackInstances` in *AWS CLI Command Reference*.

**delete-stack-set**

The following code example shows how to use `delete-stack-set`.

**AWS CLI**

**To delete a stack set**

The following command deletes the specified empty stack set. The stack set must be empty.

```
aws cloudformation delete-stack-set \
    --stack-set-name my-stack-set
```

This command produces no output.

To delete instances from the stack set, use the `delete-stack-instances` command.

- For API details, see `DeleteStackSet` in *AWS CLI Command Reference*.

**delete-stack**

The following code example shows how to use `delete-stack`.

**AWS CLI**

**To delete a stack**

The following `delete-stack` example deletes the specified stack.

```
aws cloudformation delete-stack \
```

**deploy**

The following code example shows how to use `deploy`.

**AWS CLI**

Following command deploys template named `template.json` to a stack named `my-new-stack`:

```bash
aws cloudformation deploy --template-file /path_to_template/template.json --stack-name my-new-stack --parameter-overrides Key1=Value1 Key2=Value2 --tags Key1=Value1 Key2=Value2
```

• For API details, see [Deploy](https://awscli.amazonaws.com/v2/documentation/api/latest/reference/cloudformation/deploy.html) in *AWS CLI Command Reference*.

**deregister-type**

The following code example shows how to use `deregister-type`.

**AWS CLI**

**To deregister a type version**

The following `deregister-type` example removes the specified type version from active use in the CloudFormation registry, so that it can no longer be used in CloudFormation operations.

```bash
aws cloudformation deregister-type \
   --type RESOURCE \
   --type-name My::Logs::LogGroup \
   --version-id 00000002
```

This command produces no output.

For more information, see [Using the CloudFormation Registry](https://docs.aws.amazon.com/AmazonCloudFormation/latest/UserGuide/what-is-cloudformation-registry.html) in the *AWS CloudFormation Users Guide*.
• For API details, see DeregisterType in AWS CLI Command Reference.

describe-account-limits

The following code example shows how to use describe-account-limits.

AWS CLI

To get information about your account limits

The following command retrieves a list of regional limits for the current account.

aws cloudformation describe-account-limits

Output:

```json
{
    "AccountLimits": [
        {
            "Name": "StackLimit",
            "Value": 200
        },
        {
            "Name": "StackOutputsLimit",
            "Value": 60
        },
        {
            "Name": "ConcurrentResourcesLimit",
            "Value": 2500
        }
    ]
}
```

• For API details, see DescribeAccountLimits in AWS CLI Command Reference.

describe-change-set

The following code example shows how to use describe-change-set.

AWS CLI

To get information about a change set
The following `describe-change-set` example displays the details of the change set specified by change set name and stack name.

```
aws cloudformation describe-change-set \
 --change-set-name my-change-set \
 --stack-name my-stack
```

The following `describe-change-set` example displays the details of the change set specified by the full ARN of the change set:

```
aws cloudformation describe-change-set \
```

Output:

```
{
   "Changes": [
       {
           "Type": "Resource",
           "ResourceChange": {
               "Action": "Modify",

                   }
               ]
           }
       }
   ]
}
```
For API details, see DescribeChangeSet in AWS CLI Command Reference.

describe-publisher

The following code example shows how to use describe-publisher.

AWS CLI

To describe a publisher

The following describe-publisher example configures the information for a publisher.

```
aws cloudformation describe-publisher \
    --region us-west-2 \
    --publisher-id 000q6TfuovXsEMmgKowxDZL1wqr2QUsh
```

Output:

```json
{
    "PublisherId": "000q6TfuovXsEMmgKowxDZL1wqr2QUshd2e75c8c",
    "PublisherStatus": "VERIFIED",
}
```
describe-stack-drift-detection-status

The following code example shows how to use describe-stack-drift-detection-status.

AWS CLI

To check a drift detection operation's status

The following describe-stack-drift-detection-status example displays the status of a drift detection operation. Get the by ID running the detect-stack-drift command.

```bash
aws cloudformation describe-stack-drift-detection-status \
  --stack-drift-detection-id 1a229160-e4d9-xmpl-ab67-0a4f93df83d4
```

Output:

```json

For API details, see DescribeStackDriftDetectionStatus in AWS CLI Command Reference.

describe-stack-events

The following code example shows how to use describe-stack-events.

For more information, see Using the AWS CloudFormation registry in the AWS CloudFormation User Guide.

- For API details, see DescribePublisher in AWS CLI Command Reference.
To describe stack events

The following describe-stack-events example displays the 2 most recent events for the specified stack.

```bash
aws cloudformation describe-stack-events \
  --stack-name my-stack \
  --max-items 2
```

```
{
  "StackEvents": [

describe-stack-instance

The following code example shows how to use describe-stack-instance.

AWS CLI

To describe a stack instance

The following command describes an instance of the specified stack set in the specified account and Region. The stack set is in the current region and account, and the instance is in the us-west-2 region in account 123456789012:

```bash
aws cloudformation describe-stack-instance \
  --stack-set-name my-stack-set \
  --stack-instance-account 123456789012 \
  --stack-instance-region us-west-2
```

Output:

```

describe-stack-resource-drifts

The following code example shows how to use describe-stack-resource-drifts.
AWS CLI

To get information about resources that drifted from the stack definition

The following command displays information about drifted resources for the specified stack. To initiate drift detection, use the `detect-stack-drift` command:

```
aws cloudformation describe-stack-resource-drifts \
   --stack-name my-stack
```

The output shows an AWS Lambda function that was modified out-of-band:

```json
{
   "StackResourceDrifts": [

describe-stack-resource

The following code example shows how to use `describe-stack-resource`.

**AWS CLI**

**To get information about a stack resource**

The following `describe-stack-resource` example displays details for the resource named `MyFunction` in the specified stack.

```
aws cloudformation describe-stack-resource \
  --stack-name MyStack \
  --logical-resource-id MyFunction
```

**Output:**

```

describe-stack-resources

The following code example shows how to use describe-stack-resources.

AWS CLI

To get information about a stack resource

The following describe-stack-resources example displays details for the resources in the specified stack.

```bash
aws cloudformation describe-stack-resources \
   --stack-name my-stack
```

Output:

```json
{
   "StackResources": [

For API details, see DescribeStackResources in AWS CLI Command Reference.

describe-stack-set-operation

The following code example shows how to use describe-stack-set-operation.

AWS CLI

To get information about a stack set operation

The following describe-stack-set-operation example displays details for an update operation on the specified stack set.

```
aws cloudformation describe-stack-set-operation
    --stack-set-name enable-config
    --operation-id 35d45ebc-ed88-xmpl-ab59-0197a1fc83a0
```

Output:
For API details, see DescribeStackSetOperation in AWS CLI Command Reference.

describe-stack-set

The following code example shows how to use describe-stack-set.

AWS CLI

To get information about a stack set

The following describe-stack-set ` example displays details about the specified stack set.

```bash
aws cloudformation describe-stack-set
   --stack-set-name my-stack-set
```

Output:

```json
{
```
For API details, see DescribeStackSet in AWS CLI Command Reference.

**describe-stacks**

The following code example shows how to use describe-stacks.

**AWS CLI**

To describe AWS CloudFormation stacks

The following describe-stacks command shows summary information for the myteststack stack:

```
aws cloudformation describe-stacks --stack-name myteststack
```

Output:

```

describe-type-registration

The following code example shows how to use describe-type-registration.

AWS CLI

To display type registration information

The following describe-type-registration example displays information about the specified type registration, including the type's current status, type, and version.

```
aws cloudformation describe-type-registration \\n--registration-token a1b2c3d4-5678-90ab-cdef-EXAMPLE111111
```

Output:

```
{
  "ProgressStatus": "COMPLETE",

**describe-type**

The following code example shows how to use `describe-type`.

**AWS CLI**

**To display type information**

The following `describe-type` example displays information for the specified type.

```
aws cloudformation describe-type 
  --type-name My::Logs::LogGroup 
  --type RESOURCE
```

**Output:**

```
{
  "Description": "Customized resource derived from AWS::Logs::LogGroup",

detect-stack-drift

The following code example shows how to use `detect-stack-drift`.

AWS CLI

To detect drifted resources

The following `detect-stack-drift` example initiates drift detection for the specified stack.

```
aws cloudformation detect-stack-drift \
  --stack-name my-stack
```

Output:

```
{
    "StackDriftDetectionId": "1a229160-e4d9-xmpl-ab67-0a4f93df83d4"
}
```

You can then use this ID with the `describe-stack-resource-drifts` command to describe drifted resources.

- For API details, see `DetectStackDrift` in AWS CLI Command Reference.

detect-stack-resource-drift

The following code example shows how to use `detect-stack-resource-drift`.

AWS CLI

To detect drift for a resource

The following `detect-stack-resource-drift` example checks a resource named MyFunction in a stack named MyStack for drift:
aws cloudformation detect-stack-resource-drift \
--stack-name MyStack \
--logical-resource-id MyFunction

The output shows an AWS Lambda function that was modified out-of-band:

detect-stack-set-drift

The following code example shows how to use detect-stack-set-drift.

AWS CLI

To detect drift on a stack set and all associated stack instances

The following detect-stack-set-drift example initiates drift detection operations on the specified stack set, including all the stack instances associated with that stack set, and returns an operation ID that can be used to track the status of the drift operation.

```bash
aws cloudformation detect-stack-set-drift \\
--stack-set-name stack-set-drift-example
```

Output:

```json
{
   "OperationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
}
```

For more information, see Detecting Unmanaged Configuration Changes in Stack Sets in the AWS CloudFormation Users Guide.

For API details, see DetectStackSetDrift in AWS CLI Command Reference.

estimate-template-cost

The following code example shows how to use estimate-template-cost.

AWS CLI

To estimate template cost

The following estimate-template-cost example generates a cost estimate for a template named template.yaml in the current folder.

Actions and scenarios
aws cloudformation estimate-template-cost \
   --template-body file://template.yaml

Output:

{
   "Url": "http://calculator.s3.amazonaws.com/calc5.html?\n   key=cloudformation/7870825a-xmpl-4def-92e7-c4f8dd360cca"
}

• For API details, see EstimateTemplateCost in AWS CLI Command Reference.

**execute-change-set**

The following code example shows how to use execute-change-set.

**AWS CLI**

To execute a change set

The following execute-change-set example executes a change set specified by change set name and stack name.

aws cloudformation execute-change-set \
   --change-set-name my-change-set \
   --stack-name my-stack

The following execute-change-set example executes a change set specified by the full ARN of the change set.

aws cloudformation execute-change-set \

• For API details, see ExecuteChangeSet in AWS CLI Command Reference.

**get-stack-policy**

The following code example shows how to use get-stack-policy.
### AWS CLI

**To view a stack policy**

The following `get-stack-policy` example displays the stack policy for the specified stack. To attach a policy to a stack, use the `set-stack-policy` command.

```bash
aws cloudformation get-stack-policy \
   --stack-name my-stack
```

**Output:**

```json
{
   "StackPolicyBody": "{
      "Statement": [
         {
            "Effect": "Allow",
            "Action": "Update:*",

}
```

- For API details, see [GetStackPolicy](https://docs.aws.amazon.com/cli/latest/reference/cloudformation/get-stack-policy.html) in *AWS CLI Command Reference*.

### get-template-summary

The following code example shows how to use `get-template-summary`.

**AWS CLI**

**To display a template summary**

The following command displays summary information about the resources and metadata for the specified template file.

```bash
aws cloudformation get-template-summary \
   --template-body file://template.yaml
```

**Output:**

```json
{
   "Parameters": [],
   "Description": "A VPC and subnets."
}
```
For API details, see **GetTemplateSummary** in *AWS CLI Command Reference*.

**get-template**

The following code example shows how to use `get-template`.

**AWS CLI**

To view the template body for an AWS CloudFormation stack

The following `get-template` command shows the template for the `myteststack` stack:

```
aws cloudformation get-template --stack-name myteststack
```

Output:

```
{
   "TemplateBody": {
      "AWSTemplateFormatVersion": "2010-09-09",
      "Outputs": {
         "BucketName": {

### list-change-sets

The following code example shows how to use `list-change-sets`.

#### AWS CLI

**To list change sets**

The following `list-change-sets` example displays a list of the pending change sets for the specified stack.

```
aws cloudformation list-change-sets \
   --stack-name my-stack
```

Output:

```
{
    "Summaries": [
        {
            "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/my-stack/d0a825a0-e4cd-xmpl-b9fb-061c69e99204",

            "Status": "CREATE_COMPLETE",
        }
    ]
}
- For API details, see `ListChangeSets` in *AWS CLI Command Reference*.

**list-exports**

The following code example shows how to use `list-exports`.

**AWS CLI**

**To list exports**

The following `list-exports` example displays a list of the exports from stacks in the current region.

```
aws cloudformation list-exports
```

Output:

```
{
   "Exports": [
   {
      "ExportingStackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/private-vpc/99764070-b56c-xmpl-bee8-062a88d1d800",

```
list-imports

The following code example shows how to use `list-imports`.

AWS CLI

**To list imports**

The following `list-imports` example lists the stacks that import the specified export. To get the list of available exports, use the `list-exports` command.

```
aws cloudformation list-imports \\
   --export-name private-vpc-vpcid
```

Output:

```
{
   "Imports": [
     "my-database-stack"

}
```

**For API details, see** [ListExports](#) in **AWS CLI Command Reference.**

list-stack-instances

The following code example shows how to use `list-stack-instances`.

AWS CLI

**To list instances for a stack**

The following `list-stack-instances` example lists the instances created from the specified stack set.

```
aws cloudformation list-stack-instances \\
```

**For API details, see** [ListImports](#) in **AWS CLI Command Reference.**
The example output includes details about a stack that failed to update due to an error:

**list-stack-resources**

The following code example shows how to use `list-stack-resources`.

**AWS CLI**

To list resources in a stack
The following command displays the list of resources in the specified stack.

```bash
aws cloudformation list-stack-resources \

**list-stack-set-operation-results**

The following code example shows how to use `list-stack-set-operation-results`.

**AWS CLI**

**To list stack set operation results**

The following command displays the results of an update operation on instances in the specified stack set.

```bash
aws cloudformation list-stack-set-operation-results \
   --stack-set-name enable-config \
   --operation-id 35d45ebc-ed88-xmpl-ab59-0197a1fc83a0
```

**Output:**

```json
{
   "Summaries": [
      {
         "Account": "223456789012",
         "Region": "us-west-2",
         "Status": "SUCCEEDED",
         "AccountGateResult": {
            "Status": "SKIPPED",

         "Status": "CANCELLED",
         "StatusReason": "Cancelled since failure tolerance has exceeded"
      }
   ]
}
```

**Note:** The SKIPPED status for AccountGateResult is expected for successful operations unless you create an account gate function.

- For API details, see [ListStackSetOperationResults](#) in *AWS CLI Command Reference*.
list-stack-set-operations

The following code example shows how to use list-stack-set-operations.

AWS CLI

To list stack set operations

The following list-stack-set-operations example displays the list of the most recent operations on the specified stack set.

```
aws cloudformation list-stack-set-operations \
   --stack-set-name my-stack-set
```

Output:

```
{
    "Summaries": [{
        "OperationId": "35d45ebc-ed88-xmpl-ab59-0197a1fc83a0",
        "Action": "UPDATE",

        "EndTimestamp": "2019-10-03T16:45:58.925Z"
    }]
}
```

- For API details, see ListStackSetOperations in AWS CLI Command Reference.

list-stack-sets

The following code example shows how to use list-stack-sets.
AWS CLI

To list stack sets

The following `list-stack-sets` example displays the list of stack sets in the current region and account.

```bash
aws cloudformation list-stack-sets
```

Output:
```
{
   "Summaries": [
      {
         "StackSetName": "enable-config",
         "StackSetId": "enable-config:296a3360-xmpl-40af-be78-9341e95bf743",
         "Description": "Enable AWS Config",
         "Status": "ACTIVE"
      }
   ]
}
```

- For API details, see [ListStackSets](#) in AWS CLI Command Reference.

list-stacks

The following code example shows how to use `list-stacks`.

AWS CLI

To list AWS CloudFormation stacks

The following `list-stacks` command shows a summary of all stacks that have a status of `CREATE_COMPLETE`:

```bash
aws cloudformation list-stacks --stack-status-filter CREATE_COMPLETE
```

Output:
```
[
```
• For API details, see ListStacks in AWS CLI Command Reference.

list-type-registrations

The following code example shows how to use list-type-registrations.

AWS CLI

To list the completed registrations of a type

The following list-type-registrations example displays a list of the completed type registrations for the specified type.

```bash
aws cloudformation list-type-registrations \
    --type RESOURCE \
    --type-name My::Logs::LogGroup \
    --registration-status-filter COMPLETE
```

Output:

```json
{
    "RegistrationTokenList": [
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE33333"
    ]
}
```
For more information, see Using the CloudFormation Registry in the AWS CloudFormation Users Guide.

- For API details, see ListTypeRegistrations in AWS CLI Command Reference.

### list-type-versions

The following code example shows how to use `list-type-versions`.

**AWS CLI**

**To list an extension's version**

The following `list-type-versions` example returns summary information about the versions of an extension.

```bash
aws cloudformation list-type-versions \
--endpoint https://example.com \
--region us-west-2 \
--type RESOURCE \
--type-name My::Resource::Example \
--publisher-id 123456789012
```

This command produces no output.

For more information, see Using the AWS CloudFormation registry in the AWS CloudFormation User Guide.

- For API details, see ListTypeVersions in AWS CLI Command Reference.

### list-types

The following code example shows how to use `list-types`.

**AWS CLI**

**To list the private resource types in an account**

The following `list-types` example displays a list of the private resource types currently registered in the current AWS account.

```bash
aws cloudformation list-types
```
Output:

```json
{
    "TypeSummaries": [
        {
            "Description": "WordPress blog resource for internal use",
            "LastUpdated": "2019-12-04T18:28:15.059Z",
            "TypeName": "My::WordPress::BlogExample",
            "DefaultVersionId": "00000005",
            "Type": "RESOURCE"
        },
        {
            "Description": "Customized resource derived from AWS::Logs::LogGroup",
            "LastUpdated": "2019-12-04T18:28:15.059Z",
            "TypeName": "My::Logs::LogGroup",
            "DefaultVersionId": "00000003",
            "Type": "RESOURCE"
        }
    ]
}
```

For more information, see [Using the CloudFormation Registry](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/using-registry.html) in the *AWS CloudFormation Users Guide*.

- For API details, see [ListTypes](https://docs.aws.amazon.com/cli/latest/reference/cloudformation/list-types.html) in *AWS CLI Command Reference*.

**package**

The following code example shows how to use `package`.

**AWS CLI**

Following command exports a template named `template.json` by uploading local artifacts to S3 bucket `bucket-name` and writes the exported template to `packaged-template.json`:

```
aws cloudformation package --template-file /path_to_template/template.json --s3-bucket bucket-name --output-template-file packaged-template.json --use-json
```
For API details, see Package in AWS CLI Command Reference.

**publish-type**

The following code example shows how to use publish-type.

**AWS CLI**

*To publish an extension*

The following publish-type example publishes the specified extension to the CloudFormation registry as a public extension in this Region.

```bash
aws cloudformation publish-type \
  --region us-west-2 \
  --type RESOURCE \
  --type-name Example::Test::1234567890abcdef0
```

**Output:**

```json
{
   "PublicTypeArn":"arn:aws:cloudformation:us-west-2::type/resource/000q6TfUovXsEMmgKowxDZLlwqr2QUshd2e75c8c/Example-Test-1234567890abcdef0/1.0.0"
}
```

For more information, see Using the AWS CloudFormation registry in the AWS CloudFormation User Guide.

- For API details, see PublishType in AWS CLI Command Reference.

**register-publisher**

The following code example shows how to use register-publisher.

**AWS CLI**

*To register a publisher*

The following register-publisher example registers a publisher and accepts the terms and condition parameter.
aws cloudformation register-publisher \
  --region us-west-2 \
  --accept-terms-and-conditions

Output:

{
   "PublisherId": "000q6TfUovXsEMmgKowxDZLlwqr2QUshd2e75c8c"
}

For more information, see Using the AWS CloudFormation registry in the AWS CloudFormation User Guide.

- For API details, see RegisterPublisher in AWS CLI Command Reference.

 register-type

The following code example shows how to use register-type.

AWS CLI

To register a resource type

The following register-type example registers the specified resource type as a private resource type in the user's account.

aws cloudformation register-type \
   --type-name My::Organization::ResourceName \
   --schema-handler-package s3://bucket_name/my-organization-resource_name.zip \
   --type RESOURCE

Output:

{
   "RegistrationToken": "f5525280-104e-4d35-bef5-8f1f1example"
}

For more information, see Registering Resource Providers in the CloudFormation Command Line Interface User Guide for Type Development.

- For API details, see RegisterType in AWS CLI Command Reference.
set-stack-policy

The following code example shows how to use set-stack-policy.

**AWS CLI**

**To apply a stack policy**

The following set-stack-policy example disables updates for the specified resource in the specified stack. *stack-policy.json* is a JSON document that defines the operations allowed on resources in the stack.

```
aws cloudformation set-stack-policy \
   --stack-name my-stack \
   --stack-policy-body file://stack-policy.json
```

Output:

```
{
   "Statement" : [
   {
      "Effect" : "Allow",
      "Action" : "Update:*",
      "Principal": "*",
      "Resource" : "*
   },
   {
      "Effect" : "Deny",
      "Action" : "Update:*",
      "Principal": "*",
      "Resource" : "LogicalResourceId/bucket"
   }
   ]
}
```

- For API details, see [SetStackPolicy](https://docs.aws.amazon.com/cli/latest/reference/cloudformation/set-stack-policy.html) in *AWS CLI Command Reference*.

set-type-configuration

The following code example shows how to use set-type-configuration.
AWS CLI

To configure data

The following set-type-configuration example specifies the configuration data for a registered CloudFormation extension, in the given account and Region.

```bash
aws cloudformation set-type-configuration \
   --region us-west-2 \
   --type RESOURCE \
   --type-name Example::Test::Type \
   --configuration-alias default \
   --configuration "{"CredentialKey": "testUserCredential"}"
```

Output:

```
{
}
```

For more information, see [Using the AWS CloudFormation registry](#) in the AWS CloudFormation User Guide.

- For API details, see [SetTypeConfiguration](#) in AWS CLI Command Reference.

set-type-default-version

The following code example shows how to use set-type-default-version.

AWS CLI

To set a type's default version

The following set-type-default-version example sets the specified type version to be used as the default for this type.

```bash
aws cloudformation set-type-default-version \
   --type RESOURCE \
   --type-name My::Logs::LogGroup \
   --version-id 00000003
```
This command produces no output.

For more information, see Using the CloudFormation Registry in the AWS CloudFormation Users Guide.

- For API details, see SetTypeDefaultVersion in AWS CLI Command Reference in AWS CLI Command Reference.

**signal-resource**

The following code example shows how to use signal-resource.

**AWS CLI**

**To signal a resource**

The following signal-resource example signals success to fulfill the wait condition named MyWaitCondition in the stack named my-stack.

```
aws cloudformation signal-resource \
   --stack-name my-stack \
   --logical-resource-id MyWaitCondition \
   --unique-id 1234 \
   --status SUCCESS
```

This command produces no output.

- For API details, see SignalResource in AWS CLI Command Reference.

**stop-stack-set-operation**

The following code example shows how to use stop-stack-set-operation.

**AWS CLI**

**To stop a stack set operation**

The following stop-stack-set-operation example stops an in-progress update operation on the specified stack set.

```
aws cloudformation stop-stack-set-operation \
   --stack-set-name my-stack-set \
   --operation-id 1261cd27-490b-xmpl-ab42-793a896c69e6
```
This command produces no output.

- For API details, see `StopStackSetOperation` in *AWS CLI Command Reference*.

**test-type**

The following code example shows how to use test-type.

**AWS CLI**

**To test an extension**

The following test-type example tests a registered extension to make sure it meets all necessary requirements for being published in the CloudFormation registry.

```
aws cloudformation test-type 
```

Output:

```
{
}
```

For more information, see [Using the AWS CloudFormation registry](https://docs.aws.amazon.com/cloudformation/latest/UserGuide/) in the *AWS CloudFormation User Guide*.

- For API details, see `TestType` in *AWS CLI Command Reference*.

**update-stack-instances**

The following code example shows how to use update-stack-instances.

**AWS CLI**

**To update stack instances**

The following update-stack-instances example retries an update on stack instances in two accounts in two regions with the most recent settings. The specified fault tolerance setting
ensures that the update is attempted in all accounts and regions, even if some stacks cannot be updated.

```bash
aws cloudformation update-stack-instances \
  --stack-set-name my-stack-set \
  --accounts 123456789012 567890123456 \
  --regions us-east-1 us-west-2 \
  --operation-preferences FailureToleranceCount=3
```

Output:

```json
{
  "OperationId": "103ebdf2-21ea-xmpl-8892-de5e30733132"
}
```

- For API details, see `UpdateStackInstances` in *AWS CLI Command Reference*.

**update-stack-set**

The following code example shows how to use `update-stack-set`.

**AWS CLI**

**To update a stack set**

The following `update-stack-set` example adds a tag with the key name `Owner` and a value of `IT` to the stack instances in the specified stack set.

```bash
aws cloudformation update-stack-set \
  --stack-set-name my-stack-set \
  --use-previous-template \
  --tags Key=Owner,Value=IT
```

Output:

```json
{
  "OperationId": "e2b60321-6cab-xmpl-bde7-530c6f47950e"
}
```

- For API details, see `UpdateStackSet` in *AWS CLI Command Reference*. 
update-stack

The following code example shows how to use update-stack.

AWS CLI

To update AWS CloudFormation stacks

The following update-stack command updates the template and input parameters for the mystack stack:

```bash
aws cloudformation update-stack --stack-name mystack --template-url https://s3.amazonaws.com/sample/updated.template --parameters ParameterKey=KeyPairName,ParameterValue=SampleKeyPair ParameterKey=SubnetIDs,ParameterValue=SampleSubnetID1,SampleSubnetID2
```

The following update-stack command updates just the SubnetIDs parameter value for the mystack stack. If you don't specify a parameter value, the default value that is specified in the template is used:

```bash
aws cloudformation update-stack --stack-name mystack --template-url https://s3.amazonaws.com/sample/updated.template --parameters ParameterKey=KeyPairName,UsePreviousValue=true ParameterKey=SubnetIDs,ParameterValue=SampleSubnetID1,SampleSubnetID2
```

The following update-stack command adds two stack notification topics to the mystack stack:

```bash
```

For more information, see AWS CloudFormation stack updates in the AWS CloudFormation User Guide.

- For API details, see UpdateStack in AWS CLI Command Reference.

update-termination-protection

The following code example shows how to use update-termination-protection.
AWS CLI

To enable termination protection

The following update-termination-protection example enables termination protection on the specified stack.

```bash
aws cloudformation update-termination-protection \
    --stack-name my-stack \
    --enable-termination-protection
```

Output:

```json
{
    "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/my-stack/d0a825a0-e4cd-xmpl-b9fb-061c69e99204"
}
```

- For API details, see [UpdateTerminationProtection](#) in *AWS CLI Command Reference*.

validate-template

The following code example shows how to use validate-template.

AWS CLI

To validate an AWS CloudFormation template

The following validate-template command validates the sampletemplate.json template:

```bash
aws cloudformation validate-template --template-body file://sampletemplate.json
```

Output:

```json
{
    "Description": "AWS CloudFormation Sample Template S3_Bucket: Sample template showing how to create a publicly accessible S3 bucket. **WARNING** This template creates an S3 bucket. You will be billed for the AWS resources used if you create a stack from this template.",
    "Parameters": []
}
```
CloudFront examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with CloudFront.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

create-cloud-front-origin-access-identity

The following code example shows how to use create-cloud-front-origin-access-identity.

AWS CLI

To create a CloudFront origin access identity

The following example creates a CloudFront origin access identity (OAI) by providing the OAI configuration as a command line argument:

```bash
aws cloudfront create-cloud-front-origin-access-identity
```
You can accomplish the same thing by providing the OAI configuration in a JSON file, as shown in the following example:

```bash
aws cloudfront create-cloud-front-origin-access-identity \
--cloud-front-origin-access-identity-config file://OAI-config.json
```

The file `OAI-config.json` is a JSON document in the current directory that contains the following:

```json
{
    "CallerReference": "cli-example",
    "Comment": "Example OAI"
}
```

Whether you provide the OAI configuration with a command line argument or a JSON file, the output is the same:

```json
{
    "Location": "https://cloudfront.amazonaws.com/2019-03-26/origin-access-identity/cloudfront/E74FTE3AEXAMPLE",
    "ETag": "E2QWRUHEXAMPLE",
    "CloudFrontOriginAccessIdentity": {
        "Id": "E74FTE3AEXAMPLE",

        "CloudFrontOriginAccessIdentityConfig": {
            "CallerReference": "cli-example",
            "Comment": "Example OAI"
        }
    }
}
```

- For API details, see [CreateCloudFrontOriginAccessIdentity](https://docs.aws.amazon.com/cli/latest/reference/cloudfront/create-cloud-front-origin-access-identity.html) in *AWS CLI Command Reference*.

**create-distribution-with-tags**

The following code example shows how to use `create-distribution-with-tags`.

```bash
create-distribution-with-tags
```
To create a CloudFront distribution with tags

The following example creates a distribution with two tags by providing the distribution configuration and tags in a JSON file named dist-config-with-tags.json:

```
aws cloudfront create-distribution-with-tags \
    --distribution-config-with-tags file://dist-config-with-tags.json
```

The file dist-config-with-tags.json is a JSON document in the current folder that contains the following. Note the Tags object at the top of the file, which contains two tags:

Name = ExampleDistribution
Project = ExampleProject

```json
{
   "Tags": {
      "Items": [
      {
         "Key": "Name",
         "Value": "ExampleDistribution"

create-distribution

The following code example shows how to use create-distribution.

AWS CLI

To create a CloudFront distribution

The following example creates a distribution for an S3 bucket named awsexamplebucket, and also specifies index.html as the default root object, using command line arguments:

```bash
aws cloudfront create-distribution
```
Instead of using command line arguments, you can provide the distribution configuration in a JSON file, as shown in the following example:

```
aws cloudfront create-distribution \
   --distribution-config file://dist-config.json
```

The file `dist-config.json` is a JSON document in the current folder that contains the following:

```json
{
    "CallerReference": "cli-example",
    "Aliases": {
        "Quantity": 0
    },
    "DefaultRootObject": "index.html",

create-field-level-encryption-config

The following code example shows how to use `create-field-level-encryption-config`.

AWS CLI

To create a CloudFront field-level encryption configuration

The following example creates a field-level encryption configuration by providing the configuration parameters in a JSON file named `fle-config.json`. Before you can create a field-level encryption configuration, you must have a field-level encryption profile. To create a profile, see the `create-field-level-encryption-profile` command.

For more information about CloudFront field-level encryption, see Using Field-Level Encryption to Help Protect Sensitive Data in the Amazon CloudFront Developer Guide.

```
aws cloudfront create-field-level-encryption-config \ 
--field-level-encryption-config file://fle-config.json
```

The file `fle-config.json` is a JSON document in the current folder that contains the following:

```
{
  "CallerReference": "cli-example",
  "Comment": "Example FLE configuration",
  "QueryArgProfileConfig": {
```
"ForwardWhenQueryArgProfileIsUnknown": true,
"QueryArgProfiles": {

`create-field-level-encryption-profile`

The following code example shows how to use `create-field-level-encryption-profile`.

**AWS CLI**

**To create a CloudFront field-level encryption profile**

The following example creates a field-level encryption profile by providing the parameters in a JSON file named `fle-profile-config.json`. Before you can create a field-level encryption profile, you must have a CloudFront public key. To create a CloudFront public key, see the `create-public-key` command.

```bash
aws cloudfront create-field-level-encryption-profile \
  --field-level-encryption-profile-config file://fle-profile-config.json
```

The file `fle-profile-config.json` is a JSON document in the current folder that contains the following:

```json
{
  "Name": "ExampleFLEProfile",
  "CallerReference": "cli-example",
  "Comment": "FLE profile for AWS CLI example",

                        }
                    }
                ]
            }
        }
    }
}
create-invalidation

The following code example shows how to use `create-invalidation`.

**AWS CLI**

To create an invalidation for a CloudFront distribution

The following `create-invalidation` example creates an invalidation for the specified files in the specified CloudFront distribution:

```bash
aws cloudfront create-invalidation \
    --distribution-id EDFDVBD6EXAMPLE \
    --paths "/example-path/example-file.jpg" "/example-path/example-file2.png"
```

**Output:**

```json
{
    "Location": "https://cloudfront.amazonaws.com/2019-03-26/distribution/EDFDVBD6EXAMPLE/invalidation/I1JLWSDAP8FU89",
    "Invalidation": {
        "Id": "I1JLWSDAP8FU89",
        "Status": "InProgress",
        "CreateTime": "2019-12-05T18:24:51.407Z",
        "InvalidationBatch": {
            "Paths": {
                "Quantity": 2,
                "Items": [
                    "/example-path/example-file2.png",
                    "/example-path/example-file.jpg"
                ],
            },
            "CallerReference": "cli-1575570291-670203"
        }
    }
}
```
In the previous example, the AWS CLI automatically generated a random CallerReference. To specify your own CallerReference, or to avoid passing the invalidation parameters as command line arguments, you can use a JSON file. The following example creates an invalidation for two files, by providing the invalidation parameters in a JSON file named `inv-batch.json`:

```bash
aws cloudfront create-invalidation \
    --distribution-id EDFDVBD6EXAMPLE \
    --invalidation-batch file://inv-batch.json
```

Contents of `inv-batch.json`:

```json
{
    "Paths": {
        "Quantity": 2,
        "Items": [
            "/example-path/example-file.jpg",
            "/example-path/example-file2.png"
        ]
    },
    "CallerReference": "cli-example"
}
```

Output:

```json
{
    "Location": "https://cloudfront.amazonaws.com/2019-03-26/distribution/EDFDVBD6EXAMPLE/invalidation/I2J0I21PCUYOIK",
    "Invalidation": {
        "Id": "I2J0I21PCUYOIK",
        "Status": "InProgress",
        "CreateTime": "2019-12-05T18:40:49.413Z",
        "InvalidationBatch": {
            "Paths": {
                "Quantity": 2,
                "Items": [
                    "/example-path/example-file.jpg",
                    "/example-path/example-file2.png"
                ]
            }
        }
    }
}
```
For API details, see `CreateInvalidation` in AWS CLI Command Reference.

create-public-key

The following code example shows how to use `create-public-key`.

AWS CLI

To create a CloudFront public key

The following example creates a CloudFront public key by providing the parameters in a JSON file named `pub-key-config.json`. Before you can use this command, you must have a PEM-encoded public key. For more information, see [Create an RSA Key Pair](#) in the Amazon CloudFront Developer Guide.

```bash
aws cloudfront create-public-key
  --public-key-config file://pub-key-config.json
```

The file `pub-key-config.json` is a JSON document in the current folder that contains the following. Note that the public key is encoded in PEM format.

```json

**delete-cloud-front-origin-access-identity**

The following code example shows how to use `delete-cloud-front-origin-access-identity`.

**AWS CLI**

To delete a CloudFront origin access identity

The following example deletes the origin access identity (OAI) with the ID E74FTE3AEXAMPLE. To delete an OAI, you must have the OAI's ID and ETag. The OAI ID is returned in the output of the `create-cloud-front-origin-access-identity` and `list-cloud-front-origin-access-identities` commands. To get the ETag, use the `get-cloud-front-origin-access-identity` or `get-cloud-front-origin-access-identity-config` command. Use the `--if-match` option to provide the OAI's ETag.
aws cloudfront delete-cloud-front-origin-access-identity \\   --id E74FTE3AEXAMPLE \\   --if-match E2QWRUHEXAMPLE

When successful, this command has no output.

- For API details, see [DeleteCloudFrontOriginAccessIdentity](https://docs.aws.amazon.com/cli/latest/reference/cloudfront/delete-cloud-front-origin-access-identity.html) in *AWS CLI Command Reference*.

### delete-distribution

The following code example shows how to use `delete-distribution`.

**AWS CLI**

**To delete a CloudFront distribution**

The following example deletes the CloudFront distribution with the ID EDFDVBD6EXAMPLE. Before you can delete a distribution, you must disable it. To disable a distribution, use the `update-distribution` command. For more information, see the `update-distribution` examples.

When a distribution is disabled, you can delete it. To delete a distribution, you must use the `--if-match` option to provide the distribution's ETag. To get the ETag, use the `get-distribution` or `get-distribution-config` command.

```
aws cloudfront delete-distribution \\   --id EDFDVBD6EXAMPLE \\   --if-match E2QWRUHEXAMPLE
```

When successful, this command has no output.

- For API details, see [DeleteDistribution](https://docs.aws.amazon.com/cli/latest/reference/cloudfront/delete-distribution.html) in *AWS CLI Command Reference*.

### delete-field-level-encryption-config

The following code example shows how to use `delete-field-level-encryption-config`.

**AWS CLI**

**To delete a CloudFront field-level encryption configuration**

The following example deletes the CloudFront field-level encryption configuration with the ID C3KM2WVD605UAY. To delete a field-level encryption configuration, you must have its ID...
and ETag. The ID is returned in the output of the create-field-level-encryption-config and list-field-level-encryption-configs commands. To get the ETag, use the get-field-level-encryption or get-field-level-encryption-config command. Use the --if-match option to provide the configuration's ETag.

```
aws cloudfront delete-field-level-encryption-config \
  --id C3KM2WVD605UAY \
  --if-match E26M4BIAV81ZF6
```

When successful, this command has no output.

- For API details, see `DeleteFieldLevelEncryptionConfig` in *AWS CLI Command Reference*.

**delete-field-level-encryption-profile**

The following code example shows how to use `delete-field-level-encryption-profile`.

**AWS CLI**

**To delete a CloudFront field-level encryption profile**

The following example deletes the CloudFront field-level encryption profile with the ID PPK0UOSIF5WSV. To delete a field-level encryption profile, you must have its ID and ETag. The ID is returned in the output of the create-field-level-encryption-profile and list-field-level-encryption-profiles commands. To get the ETag, use the get-field-level-encryption-profile or get-field-level-encryption-profile-config command. Use the --if-match option to provide the profile's ETag.

```
aws cloudfront delete-field-level-encryption-profile \
  --id PPK0UOSIF5WSV \
  --if-match EJETYFJ9CL66D
```

When successful, this command has no output.

- For API details, see `DeleteFieldLevelEncryptionProfile` in *AWS CLI Command Reference*.

**delete-public-key**

The following code example shows how to use `delete-public-key`.
AWS CLI

To delete a CloudFront public key

The following example deletes the CloudFront public key with the ID KDFB19YGCR002. To delete a public key, you must have its ID and ETag. The ID is returned in the output of the create-public-key and list-public-keys commands. To get the ETag, use the get-public-key or get-public-key-config command. Use the --if-match option to provide the public key's ETag.

```
aws cloudfront delete-public-key
   --id KDFB19YGCR002
   --if-match E2QWRUHEXAMPLE
```

When successful, this command has no output.

- For API details, see [DeletePublicKey](https://docs.aws.amazon.com/cli/latest/reference/cloudfront/delete-public-key.html) in *AWS CLI Command Reference*.

get-cloud-front-origin-access-identity-config

The following code example shows how to use get-cloud-front-origin-access-identity-config.

AWS CLI

To get a CloudFront origin access identity configuration

The following example gets metadata about the CloudFront origin access identity (OAI) with the ID E74FTE3AEXAMPLE, including its ETag. The OAI ID is returned in the output of the create-cloud-front-origin-access-identity and list-cloud-front-origin-access-identities commands.

```
aws cloudfront get-cloud-front-origin-access-identity-config --id E74FTE3AEXAMPLE
```

Output:

```
{
   "ETag": "E2QWRUHEXAMPLE",
   "CloudFrontOriginAccessIdentityConfig": {
      "CallerReference": "cli-example",
      "Comment": "Example OAI"
   }
}
```
get-cloud-front-origin-access-identity

The following code example shows how to use get-cloud-front-origin-access-identity.

**AWS CLI**

**To get a CloudFront origin access identity**

The following example gets the CloudFront origin access identity (OAI) with the ID E74FTE3AEXAMPLE, including its ETag and the associated S3 canonical ID. The OAI ID is returned in the output of the create-cloud-front-origin-access-identity and list-cloud-front-origin-access-identities commands.

```bash
aws cloudfront get-cloud-front-origin-access-identity --id E74FTE3AEXAMPLE
```

Output:

```
{
    "ETag": "E2QWRUHEXAMPLE",
    "CloudFrontOriginAccessIdentity": {
        "Id": "E74FTE3AEXAMPLE",
        "S3CanonicalUserId": "cd1386f797c227fbea2830611a26fe0a21ba1b826ab4bed9b7771c9aEXAMPLE",

            "CallerReference": "cli-example",
            "Comment": "Example OAI"
        }
    }
}
```

• For API details, see [GetCloudFrontOriginAccessIdentityConfig](#) in *AWS CLI Command Reference*.

get-distribution-config

The following code example shows how to use get-distribution-config.

**AWS CLI**

**To get a CloudFront distribution configuration**
The following example gets metadata about the CloudFront distribution with the ID EDFDVBD6EXAMPLE, including its ETag. The distribution ID is returned in the create-distribution and list-distributions commands.

```
aws cloudfront get-distribution-config --id EDFDVBD6EXAMPLE
```

Output:

get-public-key-config

The following code example shows how to use get-public-key-config.

AWS CLI

To get a CloudFront public key configuration
The following example gets metadata about the CloudFront public key with the ID KDFB19YGCR002, including its ETag. The public key ID is returned in the create-public-key and list-public-keys commands.

```bash
aws cloudfront get-public-key-config --id KDFB19YGCR002

Output:
For API details, see [GetPublicKey](#) in *AWS CLI Command Reference*.

**list-cloud-front-origin-access-identities**

The following code example shows how to use `list-cloud-front-origin-access-identities`.

**AWS CLI**

To list CloudFront origin access identities

The following example gets a list of the CloudFront origin access identities (OAI) in your AWS account:

```
aws cloudfront list-cloud-front-origin-access-identities
```

Output:

```json
{
    "CloudFrontOriginAccessIdentityList": {
        "Items": [
```
list-distributions

The following code example shows how to use list-distributions.

AWS CLI

To list CloudFront distributions

The following example gets a list of the CloudFront distributions in your AWS account:

```
aws cloudfront list-distributions

### list-tags-for-resource

The following code example shows how to use `list-tags-for-resource`.

#### AWS CLI

**To list tags for a CloudFront distribution**

The following example gets a list of the tags for a CloudFront distribution:

```bash
aws cloudfront list-tags-for-resource \   
  --resource arn:aws:cloudfront::123456789012:distribution/EDFDVBD6EXAMPLE
```

**Output:**

```json
{
    "Tags": {
        "Items": [
            {
                "Key": "DateCreated",
                "Value": "2019-12-04"
            },
            {
                "Key": "Name",
                "Value": "Example name"
            },
            {
                "Key": "Project",
                "Value": "Example project"
            }
        ]
    }
}
```
For API details, see ListTagsForResource in AWS CLI Command Reference.

**sign**

The following code example shows how to use `sign`.

**AWS CLI**

**To sign a CloudFront URL**

The following example signs a CloudFront URL. To sign a URL, you need the key pair ID (called the **Access Key ID** in the AWS Management Console) and the private key of the trusted signer's CloudFront key pair. For more information about signed URLs, see Serving Private Content with Signed URLs and Signed Cookies in the Amazon CloudFront Developer Guide.

```
aws cloudfront sign \
    --url https://d111111abcdef8.cloudfront.net/private-content/private-file.html \
    --key-pair-id APKAEIBAERJR2EXAMPLE \
    --private-key file://cf-signer-priv-key.pem \
    --date-less-than 2020-01-01
```

Output:

https://d111111abcdef8.cloudfront.net/private-content/private-file.html?Expires=1577836800&Signature=nEXK7Kby47XKeZQKVC6pwkif6oZc-JWsPdh0UH7EBGqgvurkecCbgL5YfUAXyLQuJxFwRQWscz-owc9KpmewCXrXQbPaJZni9XSNwf4YKurPDQYaRQawKoeenH0GFteRf9ELK-Bs3n1jTLjtbg2Ut7QJNKXcWr8AuUYikzGdJ4-qzx6WnxXfH~fxg4- GG1612kgCpXUB6Jx6K~Y3kpV0dzUP0IqFLHAnJojbhxqRvejomZZ2XrquDvNUCCIbePgN3d24UPaLXG4FK0qNEaWDIBGnvJRJxqWf93uMobeMOiVYahb-e0K1tiQewGcm0eLZQ__&Key-Pair-Id=APKAEIBAERJR2EXAMPLE

For API details, see **Sign** in AWS CLI Command Reference.

**tag-resource**

The following code example shows how to use `tag-resource`.

**Actions and scenarios**
**AWS CLI**

**To tag a CloudFront distribution**

The following `tag-resource` example adds two tags to the specified CloudFront distribution.

```bash
aws cloudfront tag-resource
   --resource arn:aws:cloudfront::123456789012:distribution/EDFDVBD6EXAMPLE
   --tags 'Items=[["Key=Name,Value="Example name"],"Key=Project,Value="Example project"]'
```

Instead of using command line arguments, you can provide the tags in a JSON file, as shown in the following example:

```bash
aws cloudfront tag-resource
   --resource arn:aws:cloudfront::123456789012:distribution/EDFDVBD6EXAMPLE
   --tags file://tags.json
```

**Contents of tags.json:**

```json
{
   "Items": [
   {
      "Key": "Name",
      "Value": "Example name"
   },
   {
      "Key": "Project",
      "Value": "Example project"
   }
   ]
}
```

This command produces no output.

- For API details, see [TagResource](#) in *AWS CLI Command Reference*.

**untag-resource**

The following code example shows how to use `untag-resource`. 
AWS CLI

To remove tags from a CloudFront distribution

The following example removes two tags from a CloudFront distribution by using command line arguments:

```bash
aws cloudfront untag-resource \
   --resource arn:aws:cloudfront::123456789012:distribution/EDFDVBD6EXAMPLE \
   --tag-keys Items=Name,Project
```

Instead of using command line arguments, you can provide the tag keys in a JSON file, as shown in the following example:

```bash
aws cloudfront untag-resource \
   --resource arn:aws:cloudfront::123456789012:distribution/EDFDVBD6EXAMPLE \
   --tag-keys file://tag-keys.json
```

The file `tag-keys.json` is a JSON document in the current folder that contains the following:

```json
{
   "Items": [
      "Name",
      "Project"
   ]
}
```

When successful, this command has no output.

- For API details, see [UntagResource](#) in *AWS CLI Command Reference*.

update-cloud-front-origin-access-identity

The following code example shows how to use `update-cloud-front-origin-access-identity`.

AWS CLI

To update a CloudFront origin access identity

The following example updates the origin access identity (OAI) with the ID E74FTE3AEXAMPLE. The only field that you can update is the OAI's Comment.
To update an OAI, you must have the OAI's ID and ETag. The OAI ID is returned in the output of the create-cloud-front-origin-access-identity and list-cloud-front-origin-access-identities commands. To get the ETag, use the get-cloud-front-origin-access-identity or get-cloud-front-origin-access-identity-config command. Use the --if-match option to provide the OAI's ETag.

```
aws cloudfront update-cloud-front-origin-access-identity \
  --id E74FTE3AEXAMPLE \
  --if-match E2QWRUHEXAMPLE \
  --cloud-front-origin-access-identity-config \
    CallerReference=cli-example,Comment="Example OAI Updated"
```

You can accomplish the same thing by providing the OAI configuration in a JSON file, as shown in the following example:

```
aws cloudfront update-cloud-front-origin-access-identity \
  --id E74FTE3AEXAMPLE \
  --if-match E2QWRUHEXAMPLE \
  --cloud-front-origin-access-identity-config file:///OAI-config.json
```

The file OAI-config.json is a JSON document in the current directory that contains the following:

```
{
  "CallerReference": "cli-example",
  "Comment": "Example OAI Updated"
}
```

Whether you provide the OAI configuration with a command line argument or a JSON file, the output is the same:

```
{
  "ETag": "E9LHASXEXAMPLE",
  "CloudFrontOriginAccessIdentity": {
    "Id": "E74FTE3AEXAMPLE",
    "S3CanonicalUserId": "cd13868f797c227fbeb2830611a26fe0a21ba1b826ab4bed9b7771c9aEXAMPLE",
    "CloudFrontOriginAccessIdentityConfig": {
      "CallerReference": "cli-example",
      "Comment": "Example OAI Updated"
    }
  }
}
```
update-distribution

The following code example shows how to use update-distribution.

AWS CLI

To update a CloudFront distribution's default root object

The following example updates the default root object to index.html for the CloudFront distribution with the ID EDFDVBD6EXAMPLE:

```bash
aws cloudfront update-distribution --id EDFDVBD6EXAMPLE \   --default-root-object index.html
```

Output:

```json

To update a CloudFront distribution

The following example disables the CloudFront distribution with the ID EMLARXS9EXAMPLE by providing the distribution configuration in a JSON file named dist-config-disable.json. To update a distribution, you must use the --if-match option to provide the distribution's ETag. To get the ETag, use the get-distribution or get-distribution-config command.

After you use the following example to disable a distribution, you can use the delete-distribution command to delete it.

```sh
aws cloudfront update-distribution \
  --id EMLARXS9EXAMPLE \ 
  --if-match E2QWRUHEXAMPLE \ 
  --distribution-config file://dist-config-disable.json

The file dist-config-disable.json is a JSON document in the current folder that contains the following. Note that the Enabled field is set to false:

**update-field-level-encryption-config**

The following code example shows how to use update-field-level-encryption-config.
AWS CLI

To update a CloudFront field-level encryption configuration

The following example updates the Comment field of the field-level encryption configuration with the ID C3KM2WVD605UAY by providing the parameters in a JSON file.

To update a field-level encryption configuration, you must have the configuration's ID and ETag. The ID is returned in the output of the create-field-level-encryption-config and list-field-level-encryption-configs commands. To get the ETag, use the get-field-level-encryption or get-field-level-encryption-config command. Use the --if-match option to provide the configuration's ETag.

```
aws cloudfront update-field-level-encryption-config \
  --id C3KM2WVD605UAY \
  --if-match E2P4Z4VU7TY5SG \
  --field-level-encryption-config file://fle-config.json
```

The file fle-config.json is a JSON document in the current directory that contains the following:

```json
{
  "CallerReference": "cli-example",
  "Comment": "Updated example FLE configuration",
  "QueryArgProfileConfig": {
    "ForwardWhenQueryArgProfileIsUnknown": true,
    "QueryArgProfiles": {
      "Quantity": 0
    }
  },
  "ContentTypeProfileConfig": {
    "ForwardWhenContentTypeIsUnknown": true,
    "ContentTypeProfiles": {
      "Quantity": 1,
      "Items": [
        {

          "ProfileId": "P280MFCLSYS0CVU",
          "ContentType": "application/x-www-form-urlencoded"
        }
      ]
    }
  }
}
```
Output:

```json
{
    "ETag": "E26M4BIAV81ZF6",
    "FieldLevelEncryption": {
        "Id": "C3KM2WVD605UAY",

            "QueryArgProfileConfig": {
                "ForwardWhenQueryArgProfileIsUnknown": true,
                "QueryArgProfiles": {
                    "Quantity": 0,
                    "Items": []
                }
            },
            "ContentTypeProfileConfig": {
                "ForwardWhenContentTypeIsUnknown": true,
                "ContentTypeProfiles": {
                    "Quantity": 1,

            }
        }
    }
}
```

**update-field-level-encryption-profile**

The following code example shows how to use `update-field-level-encryption-profile`.
To update a CloudFront field-level encryption profile

The following example updates the field-level encryption profile with the ID PPK0UOSIF5WSV. This example updates the profile's Name and Comment, and adds a second FieldPatterns item, by providing the parameters in a JSON file.

To update a field-level encryption profile, you must have the profile's ID and ETag. The ID is returned in the output of the create-field-level-encryption-profile and list-field-level-encryption-profiles commands. To get the ETag, use the get-field-level-encryption-profile or get-field-level-encryption-profile-config command. Use the --if-match option to provide the profile's ETag.

```
aws cloudfront update-field-level-encryption-profile \
  --id PPK0UOSIF5WSV \
  --if-match E1QQG65FS2L2GC \
  --field-level-encryption-profile-config file://fle-profile-config.json

**Amazon CloudSearch examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Amazon CloudSearch.
Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

create-trail

The following code example shows how to use `create-trail`.

Actions and scenarios
AWS CLI

To create a trail

The following create-trail command creates a multi-region trail named Trail1 and specifies an S3 bucket:

```bash
aws cloudtrail create-trail --name Trail1 --s3-bucket-name my-bucket --is-multi-region-trail
```

Output:

```json
{
   "IncludeGlobalServiceEvents": true,
   "Name": "Trail1",
   "LogFileValidationEnabled": false,
   "IsMultiRegionTrail": true,
   "S3BucketName": "my-bucket"
}
```

- For API details, see CreateTrail in AWS CLI Command Reference.

delete-trail

The following code example shows how to use delete-trail.

**AWS CLI**

To delete a trail

The following delete-trail command deletes a trail named Trail1:

```bash
aws cloudtrail delete-trail --name Trail1
```

- For API details, see DeleteTrail in AWS CLI Command Reference.

describe-trails

The following code example shows how to use describe-trails.
To describe a trail

The following describe-trails command returns the settings for Trail1 and Trail2:

```
aws cloudtrail describe-trails --trail-name-list Trail1 Trail2
```

Output:

```json
{
  "trailList": [
    {
      "IncludeGlobalServiceEvents": true,
      "Name": "Trail1",
      "TrailARN": "arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail1",
      "LogFileValidationEnabled": false,
      "IsMultiRegionTrail": false,
      "S3BucketName": "my-bucket",
      "CloudWatchLogsRoleArn": "arn:aws:iam::123456789012:role/CloudTrail_CloudWatchLogs_Role",
      "SnsTopicName": "my-topic",
      "HomeRegion": "us-east-1"
    },
    {
      "IncludeGlobalServiceEvents": true,
      "Name": "Trail2",
      "S3KeyPrefix": "my-prefix",
      "LogFileValidationEnabled": false,
      "IsMultiRegionTrail": false,
      "S3BucketName": "my-bucket",
      "KmsKeyId": "arn:aws:kms:us-east-1:123456789012:key/4c5ae5ac-3c13-421e-8335-c7868ef6a769",
      "HomeRegion": "us-east-1"
    }
  ]
}
```

- For API details, see `DescribeTrails` in AWS CLI Command Reference.
**get-event-selectors**

The following code example shows how to use `get-event-selectors`.

**AWS CLI**

**To view the event selector settings for a trail**

The following `get-event-selectors` command returns the settings for `Trail1`:

```bash
aws cloudtrail get-event-selectors --trail-name Trail1
```

Output:

```json
{
    "EventSelectors": [
        {
            "IncludeManagementEvents": true,
            "DataResources": [],
            "ReadWriteType": "All"
        }
    ],
    "TrailARN": "arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail1"
}
```

- For API details, see [GetEventSelectors](https://docs.aws.amazon.com/cli/latest/reference/cloudtrail/get-event-selectors.html) in *AWS CLI Command Reference*.

**get-trail-status**

The following code example shows how to use `get-trail-status`.

**AWS CLI**

**To get the status of a trail**

The following `get-trail-status` command returns the delivery and logging details for `Trail1`:

```bash
aws cloudtrail get-trail-status --name Trail1
```

Output:
For API details, see [GetTrailStatus](#) in AWS CLI Command Reference.

**list-public-keys**

The following code example shows how to use `list-public-keys`.

**AWS CLI**

To list all public keys for a trail

The following `list-public-keys` command returns all public keys whose private keys were used to sign the digest files within the specified time range:

```bash
aws cloudtrail list-public-keys --start-time 2016-01-01T20:30:00.000Z
```

Output:

```
{
   "PublicKeyList": [
   {
      "ValidityStartTime": 1453076702.0,
      "ValidityEndTime": 1455668702.0,

```
list-tags

The following code example shows how to use list-tags.

AWS CLI

To list the tags for a trail

The following list-tags command lists the tags for Trail1 and Trail2:

```

Output:

```json
{
   "ResourceTagList": [
   {
      "ResourceId": "arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail1",
      "TagsList": [
      {
         "Value": "Alice",
         "Key": "name"
      },
      {
         "Value": "us",
         "Key": "location"
      }
      ]
   },
   {
      "ResourceId": "arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail2",
      "TagsList": [
      ]
   }
   ]
}
```
• For API details, see ListTags in AWS CLI Command Reference.

lookup-events

The following code example shows how to use lookup-events.

AWS CLI

To look up events for a trail

The following lookup-events command looks up API activity events by the attribute EventName:

```
aws cloudtrail lookup-events --lookup-attributes
   AttributeKey=EventName,AttributeValue=ConsoleLogin
```

Output:

```json
{
   "Events": [
      {
        "EventId": "654ccbc0-ba0d-486a-9076-db1f727a677a7",

      }
   ]
}
For API details, see LookupEvents in AWS CLI Command Reference.

put-event-selectors

The following code example shows how to use put-event-selectors.

AWS CLI

To configure event selectors for a trail

To create an event selector, run the "put-event-selectors" command. When an event occurs in your account, CloudTrail evaluates the configuration for your trails. If the event matches any event selector for a trail, the trail processes and logs the event. You can configure up to 5 event selectors for a trail and up to 250 data resources for a trail.

The following example creates an event selector for a trail named "TrailName" to include read-only and write-only management events, data events for two Amazon S3 bucket/prefix combinations, and data events for a single AWS Lambda function named "hello-world-python-function":

```bash
aws cloudtrail put-event-selectors --trail-name TrailName --event-selectors '[["ReadWriteType": "All","IncludeManagementEvents": true,"DataResources": [["Type":"AWS::S3::Object", "Values": ["arn:aws:s3:::mybucket/prefix","arn:aws:s3:::mybucket2/prefix2"],
{"Type": "AWS::Lambda::Function","Values": ["arn:aws:lambda:us-west-2:999999999999:function:hello-world-python-function"]]]]]'
```

Output:

```json
{

```
The following example creates an event selector for a trail named "TrailName2" that includes all events, including read-only and write-only management events, and all data events for all Amazon S3 buckets and AWS Lambda functions in the AWS account:

```bash
aws cloudtrail put-event-selectors --trail-name TrailName2 --event-selectors 
'[
{{"ReadWriteType": "All","IncludeManagementEvents": true,"DataResources":
[{{"Type":"AWS::S3::Object","Values": ["arn:aws:s3:::"],
{{"Type":"AWS::Lambda::Function","Values": ["arn:aws:lambda: 
python-function"],
{{"Type": "AWS::Lambda::Function"},
},
{{"ReadWriteType": "All"}

},
"TrailARN": "arn:aws:cloudtrail:us-east-2:123456789012:trail/TrailName"
}]

Output:

```json```
{
 "EventSelectors": [ 
 {
   "IncludeManagementEvents": true,
   "DataResources": [ 
    
```
"Values": [
    "arn:aws:s3:::",
  "Type": "AWS::S3::Object"
],
[{
    "Values": [
      "arn:aws:lambda"
    ],
    "Type": "AWS::Lambda::Function"
  },
  "ReadWriteType": "All"
],
"TrailARN": "arn:aws:cloudtrail:us-east-2:123456789012:trail/TrailName2"
}

- For API details, see [PutEventSelectors](#) in *AWS CLI Command Reference*.

**remove-tags**

The following code example shows how to use remove-tags.

**AWS CLI**

**To remove tags for a trail**

The following `remove-tags` command removes the specified tags for Trail1:

```
aws cloudtrail remove-tags --resource-id arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail1 --tags-list Key=name Key=location
```

- For API details, see [RemoveTags](#) in *AWS CLI Command Reference*.

**start-logging**

The following code example shows how to use start-logging.

**AWS CLI**

**To start logging for a trail**
The following `start-logging` command turns on logging for Trail1:

```
aws cloudtrail start-logging --name Trail1
```

- For API details, see `StartLogging` in *AWS CLI Command Reference*.

`stop-logging`

The following code example shows how to use `stop-logging`.

**AWS CLI**

**To stop logging a trail**

The following `stop-logging` command turns off logging for Trail1:

```
aws cloudtrail stop-logging --name Trail1
```

- For API details, see `StopLogging` in *AWS CLI Command Reference*.

`update-subscription`

The following code example shows how to use `update-subscription`.

**AWS CLI**

**To update the configuration settings for a trail**

The following `update-subscription` command updates the trail to specify a new S3 bucket and SNS topic:

```
aws cloudtrail update-subscription --name Trail1 --s3-new-bucket my-bucket-new --sns-new-topic my-topic-new
```

Output:

```
Setting up new S3 bucket my-bucket-new...
Setting up new SNS topic my-topic-new...
Creating/updating CloudTrail configuration...
CloudTrail configuration:
```
The following code example shows how to use `update-trail`.

**AWS CLI**

**To update a trail**

The following `update-trail` command updates a trail to use an existing bucket for log delivery:

```
aws cloudtrail update-trail --name Trail1 --s3-bucket-name my-bucket
```

**Output:**

```json
{
  "IncludeGlobalServiceEvents": true,
  "Name": "Trail1",
  "LogFileValidationEnabled": false,
  "IsMultiRegionTrail": true,
  "S3BucketName": "my-bucket",
  "SnsTopicName": "my-topic",
  "HomeRegion": "us-west-2"
}
```

- For API details, see [UpdateSubscription](#) in *AWS CLI Command Reference*.
The following code example shows how to use validate-logs.

**AWS CLI**

**To validate a log file**

The following validate-logs command validates the logs for Trail1:

```bash
aws cloudtrail validate-logs --trail-arn arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail1 --start-time 20160129T19:00:00Z
```

Output:

```
Validating log files for trail arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail1 between 2016-01-29T19:00:00Z and 2016-01-29T22:15:43Z

**CloudWatch examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with CloudWatch.

**Actions** are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

**Scenarios** are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.
Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**delete-alarms**

The following code example shows how to use `delete-alarms`.

**AWS CLI**

**To delete an alarm**

The following example uses the `delete-alarms` command to delete the Amazon CloudWatch alarm named "myalarm":

```
aws cloudwatch delete-alarms --alarm-names myalarm
```

**Output:**

```
This command returns to the prompt if successful.
```

**describe-alarm-history**

The following code example shows how to use `describe-alarm-history`.

**AWS CLI**

**To retrieve history for an alarm**

The following example uses the `describe-alarm-history` command to retrieve history for the Amazon CloudWatch alarm named "myalarm":

```
aws cloudwatch describe-alarm-history --alarm-name "myalarm" --history-item-type StateUpdate
```
Output:

```json

**describe-alarms-for-metric**

The following code example shows how to use describe-alarms-for-metric.

**AWS CLI**

To display information about alarms associated with a metric
The following example uses the `describe-alarms-for-metric` command to display information about any alarms associated with the Amazon EC2 CPUUtilization metric and the instance with the ID i-0c986c72:

```bash
aws cloudwatch describe-alarms-for-metric --metric-name CPUUtilization --namespace AWS/EC2 --dimensions Name=InstanceId,Value=i-0c986c72

disable-alarm-actions

The following code example shows how to use disable-alarm-actions.

AWS CLI

To disable actions for an alarm

The following example uses the disable-alarm-actions command to disable all actions for the alarm named myalarm.:

aws cloudwatch disable-alarm-actions --alarm-names myalarm

This command returns to the prompt if successful.

• For API details, see DisableAlarmActions in AWS CLI Command Reference.

enable-alarm-actions

The following code example shows how to use enable-alarm-actions.

AWS CLI

To enable all actions for an alarm

The following example uses the enable-alarm-actions command to enable all actions for the alarm named myalarm.:

aws cloudwatch enable-alarm-actions --alarm-names myalarm
This command returns to the prompt if successful.

- For API details, see EnableAlarmActions in AWS CLI Command Reference.

**get-metric-statistics**

The following code example shows how to use get-metric-statistics.

**AWS CLI**

**To get the CPU utilization per EC2 instance**

The following example uses the get-metric-statistics command to get the CPU utilization for an EC2 instance with the ID i-abcdef.

```
aws cloudwatch get-metric-statistics --metric-name CPUUtilization --start-time 2014-04-08T23:18:00Z --end-time 2014-04-09T23:18:00Z --period 3600 --namespace AWS/EC2 --statistics Maximum --dimensions Name=InstanceId,Value=i-abcdef
```

**Output:**

```
{
  "Datapoints": [

Specifying multiple dimensions

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name/Value pair, with a comma between the name and the value. Multiple dimensions are separated by a space. If a single metric includes multiple dimensions, you must specify a value for every defined dimension.

For more examples using the `get-metric-statistics` command, see Get Statistics for a Metric in the Amazon CloudWatch Developer Guide.

```
aws cloudwatch get-metric-statistics --metric-name Buffers --namespace MyNameSpace --dimensions Name=InstanceID,Value=i-abcdef Name=InstanceType,Value=m1.small --start-time 2016-10-15T04:00:00Z --end-time 2016-10-19T07:00:00Z --statistics Average --period 60
```

list-metrics

The following code example shows how to use `list-metrics`.

AWS CLI

To list the metrics for Amazon SNS

The following `list-metrics` example displays the metrics for Amazon SNS.

```
aws cloudwatch list-metrics \
   --namespace "AWS/SNS"
```
Output:

```json
{
    "Metrics": [
    {
        "Namespace": "AWS/SNS",
        "Dimensions": [
        {
            "Name": "TopicName",
            "Value": "NotifyMe"
        }
    ],
        "MetricName": "PublishSize"
    },
    {
        "Namespace": "AWS/SNS",
        "Dimensions": [
        {
            "Name": "TopicName",
            "Value": "CFO"
        }
    ],
        "MetricName": "PublishSize"
    },
    {
        "Namespace": "AWS/SNS",
        "Dimensions": [
        {
            "Name": "TopicName",
            "Value": "NotifyMe"
        }
    ],
        "MetricName": "NumberOfNotificationsFailed"
    },
    {
        "Namespace": "AWS/SNS",
        "Dimensions": [
        {
            "Name": "TopicName",
            "Value": "NotifyMe"
        }
    ],
        "MetricName": "NumberOfNotificationsDelivered"
    }
}
```
For API details, see [ListMetrics](https://awscli.amazonaws.com/v2/documentation/api/current/reference/command/aws/sns/list-metrics.html) in *AWS CLI Command Reference*. 
**put-metric-alarm**

The following code example shows how to use `put-metric-alarm`.

### AWS CLI

**To send an Amazon Simple Notification Service email message when CPU utilization exceeds 70 percent**

The following example uses the `put-metric-alarm` command to send an Amazon Simple Notification Service email message when CPU utilization exceeds 70 percent:

```shell
aws cloudwatch put-metric-alarm --alarm-name cpu-mon --alarm-description "Alarm when CPU exceeds 70 percent" --metric-name CPUUtilization --namespace AWS/EC2 --statistic Average --period 300 --threshold 70 --comparison-operator GreaterThanThreshold --dimensions "Name=InstanceId,Value=i-12345678" --evaluation-periods 2 --alarm-actions arn:aws:sns:us-east-1:111122223333:MyTopic --unit Percent
```

This command returns to the prompt if successful. If an alarm with the same name already exists, it will be overwritten by the new alarm.

**To specify multiple dimensions**

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name/Value pair, with a comma between the name and the value. Multiple dimensions are separated by a space:

```shell
aws cloudwatch put-metric-alarm --alarm-name "Default_Test_Alarm3" --alarm-description "The default example alarm" --namespace "CW EXAMPLE METRICS" --metric-name Default_Test --statistic Average --period 60 --evaluation-periods 3 --threshold 50 --comparison-operator GreaterThanOrEqualToThreshold --dimensions Name=key1,Value=value1 Name=key2,Value=value2
```

- For API details, see [PutMetricAlarm](awscli/command_reference/api_reference#put-metric-alarm) in *AWS CLI Command Reference*.

**put-metric-data**

The following code example shows how to use `put-metric-data`.

### AWS CLI

**To publish a custom metric to Amazon CloudWatch**
The following example uses the `put-metric-data` command to publish a custom metric to Amazon CloudWatch:

```bash
aws cloudwatch put-metric-data --namespace "Usage Metrics" --metric-data file://metric.json
```

The values for the metric itself are stored in the JSON file, `metric.json`.

Here are the contents of that file:

```json
[
    {
        "MetricName": "New Posts",
        "Timestamp": "Wednesday, June 12, 2013 8:28:20 PM",
        "Value": 0.50,
        "Unit": "Count"
    }
]
```

For more information, see Publishing Custom Metrics in the *Amazon CloudWatch Developer Guide*.

**To specify multiple dimensions**

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name=Value pair. Multiple dimensions are separated by a comma:

```bash
aws cloudwatch put-metric-data --metric-name Buffers --namespace MyNameSpace --unit Bytes --value 231434333 --dimensions InstanceID=1-23456789,InstanceType=m1.small
```

- For API details, see [PutMetricData](https://docs.aws.amazon.com/cli/latest/reference/cloudwatch/put-metric-data.html) in *AWS CLI Command Reference*.

**set-alarm-state**

The following code example shows how to use `set-alarm-state`.

**AWS CLI**

**To temporarily change the state of an alarm**
The following example uses the `set-alarm-state` command to temporarily change the state of an Amazon CloudWatch alarm named "myalarm" and set it to the ALARM state for testing purposes:

```bash
aws cloudwatch set-alarm-state --alarm-name "myalarm" --state-value ALARM --state-reason "testing purposes"
```

This command returns to the prompt if successful.

**CloudWatch Logs examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with CloudWatch Logs.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

*create-log-group*

The following code example shows how to use `create-log-group`.

**AWS CLI**

The following command creates a log group named `my-logs`:

```bash
aws logs create-log-group --log-group-name my-logs
```
• For API details, see `CreateLogGroup` in *AWS CLI Command Reference*.

**create-log-stream**

The following code example shows how to use `create-log-stream`.

**AWS CLI**

The following command creates a log stream named 20150601 in the log group `my-logs`:

```bash
aws logs create-log-stream --log-group-name my-logs --log-stream-name 20150601
```

• For API details, see `CreateLogStream` in *AWS CLI Command Reference*.

**delete-log-group**

The following code example shows how to use `delete-log-group`.

**AWS CLI**

The following command deletes a log group named `my-logs`:

```bash
aws logs delete-log-group --log-group-name my-logs
```

• For API details, see `DeleteLogGroup` in *AWS CLI Command Reference*.

**delete-log-stream**

The following code example shows how to use `delete-log-stream`.

**AWS CLI**

The following command deletes a log stream named 20150531 from a log group named `my-logs`:

```bash
aws logs delete-log-stream --log-group-name my-logs --log-stream-name 20150531
```

• For API details, see `DeleteLogStream` in *AWS CLI Command Reference*. 
**delete-retention-policy**

The following code example shows how to use delete-retention-policy.

**AWS CLI**

The following command removes the retention policy that has previously been applied to a log group named my-logs:

```
aws logs delete-retention-policy --log-group-name my-logs
```

- For API details, see [DeleteRetentionPolicy](https://docs.aws.amazon.com/cli/latest/reference/logs/delete-retention-policy.html) in *AWS CLI Command Reference*.

**describe-log-groups**

The following code example shows how to use describe-log-groups.

**AWS CLI**

The following command describes a log group named my-logs:

```
aws logs describe-log-groups --log-group-name-prefix my-logs
```

Output:

```
{
   "logGroups": [
      {
        "storedBytes": 0,
        "metricFilterCount": 0,
        "creationTime": 1433189500783,
        "logGroupName": "my-logs",
        "retentionInDays": 5,
      }
   ]
}
```

- For API details, see [DescribeLogGroups](https://docs.aws.amazon.com/cli/latest/reference/logs/describe-log-groups.html) in *AWS CLI Command Reference*.
describe-log-streams

The following code example shows how to use describe-log-streams.

AWS CLI

The following command shows all log streams starting with the prefix 2015 in the log group my-logs:

```bash
aws logs describe-log-streams --log-group-name my-logs --log-stream-name-prefix 2015
```

Output:

```json
{
  "logStreams": [
    {
      "creationTime": 1433189871774,
      "logStreamName": "20150531",
      "storedBytes": 0
    },
    {
      "creationTime": 1433189873898,
      "logStreamName": "20150601",
      "storedBytes": 0
    }
  ]
}
```

- For API details, see DescribeLogStreams in AWS CLI Command Reference.

get-log-events

The following code example shows how to use get-log-events.

AWS CLI

The following command retrieves log events from a log stream named 20150601 in the log group my-logs:
aws logs get-log-events --log-group-name my-logs --log-stream-name 20150601

Output:

```
{
    "nextForwardToken": "f/3196120912244748858305587946474234673512116569214640130",
    "events": [
        {
            "ingestionTime": 1433190494190,
            "timestamp": 1433190184356,
            "message": "Example Event 1"
        },
        {
            "ingestionTime": 1433190516679,
            "timestamp": 1433190184356,
            "message": "Example Event 1"
        },
        {
            "ingestionTime": 1433190494190,
            "timestamp": 1433190184358,
            "message": "Example Event 2"
        }
    ],
    "nextBackwardToken": "b/31961209122358285602261756944988674324553373268216709120"
}
```

- For API details, see [GetLogEvents](#) in [AWS CLI Command Reference](#).

**put-log-events**

The following code example shows how to use `put-log-events`.

**AWS CLI**

The following command puts log events to a log stream named `20150601` in the log group `my-logs`:

```
aws logs put-log-events --log-group-name my-logs --log-stream-name 20150601 --log-events file://events
```
Output:

```
{
   "nextSequenceToken": "49542672486831074009579604567656788214806863282469607346"
}
```

The above example reads a JSON array of events from a file named `events` in the current directory:

```
[{
   "timestamp": 1433190184356,
   "message": "Example Event 1"
},
{
   "timestamp": 1433190184358,
   "message": "Example Event 2"
},
{
   "timestamp": 1433190184360,
   "message": "Example Event 3"
}
]
```

Each subsequent call requires the next sequence token provided by the previous call to be specified with the sequence token option:

```
aws logs put-log-events --log-group-name my-logs --log-stream-name 20150601 --log-events file://events2 --sequence-token "49542672486831074009579604567656788214806863282469607346"
```

Output:

```
{
   "nextSequenceToken": "49542672486831074009579604567900991230369019956308219826"
}
```

- For API details, see [PutLogEvents](https://docs.aws.amazon.com/cli/latest/reference/logs/put-log-events.html) in *AWS CLI Command Reference*. 
put-retention-policy

The following code example shows how to use put-retention-policy.

AWS CLI

The following command adds a 5 day retention policy to a log group named my-logs:

```bash
aws logs put-retention-policy --log-group-name my-logs --retention-in-days 5
```

- For API details, see [PutRetentionPolicy](#) in *AWS CLI Command Reference*.

associate-external-connection

The following code example shows how to use associate-external-connection.

AWS CLI

To add an external connection to a repository
The following `associate-external-connection` example adds an external connection to npmjs.com to a repository named test-repo.

```bash
aws codeartifact associate-external-connection \
   --repository test-repo \
   --domain test-domain \
   --external-connection public:npmjs
```

Output:

```json
{
   "repository": {
      "name": "test-repo",
      "administratorAccount": "111122223333",

- For API details, see AssociateExternalConnection in AWS CLI Command Reference.

**copy-package-versions**

The following code example shows how to use `copy-package-versions`.

**AWS CLI**

To copy package versions from one repository to another
The following copy-package-versions moves versions 4.0.0 and 5.0.0 of a package named test-package from my-repo to test-repo.

```bash
aws codeartifact copy-package-versions \
--domain test-domain \
--source-repository my-repo \
--destination-repository test-repo \
--format npm \
--package test-package \
--versions '"4.0.0", "5.0.0"]'
```

Output:

```json
{
    "format": "npm",
    "package": "test-package",

**create-domain**

The following code example shows how to use create-domain.

**AWS CLI**

To create a domain
The following `create-domain` example creates a domain named `test-domain`.

```plaintext
aws codeartifact create-domain \

    "upstreams": [],
    "externalConnections": []
  }
}
```

For more information, see `Delete a repository` in the **AWS CodeArtifact User Guide**.

For API details, see `DeleteRepository` in **AWS CLI Command Reference**.

describe-domain

The following code example shows how to use `describe-domain`.

1065
AWS CLI

To get information about a domain

The following describe-domain example returns a DomainDescription object for a domain named test-domain.

```bash
aws codeartifact describe-domain \
   --domain test-domain
```

Output:

```json
{
   "domain": {
      "name": "test-domain",
      "owner": "111122223333",
      "status": "Active",

      "s3BucketArn": "arn:aws:s3:::assets-111122223333-us-west-2"
   }
}
```

For more information, see Domain overview in the AWS CodeArtifact User Guide.

- For API details, see DescribeDomain in AWS CLI Command Reference.

describe-repository

The following code example shows how to use describe-repository.

AWS CLI

To get information about a repository

The following describe-repository example returns a RepositoryDescription object for a repository named test-repo.
/aws codeartifact describe-repository \
   --domain test-domain \
   --repository test-repo

Output:

```
{
   "repository": {
      "name": "test-repo",
      "administratorAccount": "111122223333",
      "domainName": "test-domain",
      "domainOwner": "111122223333",
      "description": "This is a test repository.",
      "upstreams": [],
      "externalConnections": []
   }
}
```

- For API details, see [DescribeRepository](https://docs.aws.amazon.com/cli/latest/reference/codeartifact/describe-repository.html) in *AWS CLI Command Reference*.

### disassociate-external-connection

The following code example shows how to use disassociate-external-connection.

**AWS CLI**

**To remove an external connection from a repository**

The following disassociate-external-connection example removes an external connection to npmjs.com from a repository named test-repo.

/aws codeartifact disassociate-external-connection \
   --repository test-repo \
   --domain test-domain \
   --external-connection public:npmjs

Output:
For more information, see Remove an external connection in the AWS CodeArtifact User Guide.

- For API details, see DisassociateExternalConnection in AWS CLI Command Reference.

dispose-package-versions

The following code example shows how to use dispose-package-versions.

AWS CLI

To delete a package version's assets and set its status to Disposed

The following dispose-package-versions example deletes the assets of test-package version 4.0.0 and sets its status to Disposed.

```
aws codeartifact dispose-package-versions \
    --domain test-domain \
    --repo test-repo \
    --format npm \
    --package test-package \
    --versions 4.0.0
```

Output:

```
{
    "successfulVersions": {
        "4.0.0": {
            "revision": "Ciqe5/9yicvkJT13b5/LdLpCyE6fqA7poa9qp+FilPs=",
```
For more information, see Working with packages in CodeArtifact in the AWS CodeArtifact User Guide.

- For API details, see DisposePackageVersions in AWS CLI Command Reference.

get-authorization-token

The following code example shows how to use get-authorization-token.

AWS CLI

To get an authorization token

The following get-authorization-token example retrieves a CodeArtifact authorization token.

```
aws codeartifact get-authorization-token \
   --domain test-domain \n   --query authorizationToken \n   --output text
```

Output:

This command will return the authorization token. You can store the output in an environment variable when calling the command.

For more information, see Configure pip without the login command in the AWS CodeArtifact User Guide.

- For API details, see GetAuthorizationToken in AWS CLI Command Reference.

get-domain-permissions-policy

The following code example shows how to use get-domain-permissions-policy.
AWS CLI

To get the permissions policy document for a domain

The following get-domain-permissions-policy example gets the permission policy attached to a domain named test-domain.

```
aws codeartifact get-domain-permissions-policy \
  --domain test-domain
```

Output:

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "BasicDomainPolicy",
         "Action": [

         }
      }
   ]
}
```

For more information, see Read a domain policy in the AWS CodeArtifact User Guide.

- For API details, see GetDomainPermissionsPolicy in AWS CLI Command Reference.

get-package-version-asset

The following code example shows how to use get-package-version-asset.

AWS CLI

To get an asset from a package version
The following get-package-version-asset example retrieves the package.tgz asset for version 4.0.0 of an npm package named test-package.

```bash
aws codeartifact get-package-version-asset \
  --domain test-domain \
  --repository test-repo \
  --format npm \
  --package test-package \
  --package-version 4.0.0 \
  --asset 'package.tgz' \
  outfileName
```

Output:

```
The output for this command will also store the raw asset in the file provided in place of outfileName.

```
{ 
  "assetName": "package.tgz",
  "packageVersion": "4.0.0",
  "packageVersionRevision": "Cique5/9yicvkJT13b5/LdlpCyE6fqa7poa9qp+FilPs="

```

For more information, see List package version assets in the AWS CodeArtifact User Guide.

- For API details, see GetPackageVersionAsset in AWS CLI Command Reference.

get-package-version-readme

The following code example shows how to use get-package-version-readme.

AWS CLI

To get a package version's readme file

The following get-package-version-readme example retrieves the readme file for version 4.0.0 of an npm package named test-package.

```bash
aws codeartifact get-package-version-readme \
  --domain test-domain \
  --repo test-repo \
```

Actions and scenarios 1071
--format npm \
--package test-package \
--package-version 4.0.0

Output:

{
   "format": "npm",
   "package": "test-package",
   "version": "4.0.0",
   "readme": "<div align="center">
   <a href=https://github.com/test-package/testpack>

}

For more information, see View package version readme file in the AWS CodeArtifact User Guide.
- For API details, see GetPackageVersionReadme in AWS CLI Command Reference.

get-repository-endpoint

The following code example shows how to use get-repository-endpoint.

AWS CLI

To get a repository's URL endpoint

The following get-repository-endpoint example returns the npm endpoint for the test-repo repository.

aws codeartifact get-repository-endpoint \
   --domain test-domain \
   --repository test-repo \
   --format npm

Output:

{
   "repositoryEndpoint": "https://test-domain-111122223333.d.codeartifact.us-west-2.amazonaws.com/npm/test-repo/
}
For more information, see Connect to a repository in the AWS CodeArtifact User Guide.

- For API details, see GetRepositoryEndpoint in AWS CLI Command Reference.

get-repository-permissions-policy

The following code example shows how to use get-repository-permissions-policy.

AWS CLI

To get the permissions policy document for a repository

The following get-repository-permissions-policy example gets the permission policy attached to a repository named test-repo.

```
aws codeartifact get-repository-permissions-policy \
   --domain test-domain \
   --repository test-repo
```

Output:

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",

list-domains

The following code example shows how to use list-domains.

AWS CLI

To list domains

The following `list-domains` example returns a summary of all domains owned by the AWS account that makes the call.

```bash
aws codeartifact list-domains
```

Output:

```json
{
  "domains": [
    {
      "name": "my-domain",
      "owner": "111122223333",
      "status": "Active",

list-package-version-assets

The following code example shows how to use list-package-version-assets.

AWS CLI

To view a package version's assets

The following list-package-version-assets example retrieves the assets for version 4.0.0 of an npm package named test-package.

```
aws codeartifact list-package-version-assets \\
   --domain test-domain \\
   --repo test-repo \\
   --format npm \\
   --package test-package \\
   --package-version 4.0.0

list-package-version-dependencies

The following code example shows how to use list-package-version-dependencies.

AWS CLI

To view a package version's dependencies

The following list-package-version-dependencies example retrieves the dependencies for version 4.0.0 of an npm package named test-package.

```
aws codeartifact list-package-version-dependencies \
   --domain test-domain \
   --repo test-repo \
   --format npm \
   --package test-package \
   --package-version 4.0.0
```

Output:

list-package-versions

The following code example shows how to use list-package-versions.

AWS CLI

To list package versions for a package

The following list-package-versions example returns a list of package versions for a package named kind-of.

aws codeartifact list-package-versions \
   --package kind-of \
   --domain test-domain \
   --repository test-repo \
   --format npm

Output:

```json
{
   "defaultDisplayVersion": "1.0.1",
   "format": "npm",
   "package": "kind-of",
   "versions": [
      {
         "version": "1.0.1",

- For API details, see ListPackageVersions in AWS CLI Command Reference.

**list-packages**

The following code example shows how to use list-packages.

**AWS CLI**

**To list packages in a repository**

The following list-packages example list packages in a repository named test-repo in a domain named test-domain.

```
aws codeartifact list-packages \
   --domain test-domain \
   --repository test-repo
```

Output:

```
{
   "packages": [
```
For more information, see List package names in the AWS CodeArtifact User Guide.

- For API details, see ListPackages in AWS CLI Command Reference.

**list-repositories-in-domain**

The following code example shows how to use list-repositories-in-domain.

**AWS CLI**

**To list repositories in a domain**

The following list-repositories-in-domain example returns a summary of all repositories in the test-domain domain.

```
aws codeartifact list-repositories-in-domain \
  --domain test-domain
```

Output:

```
{
  "repositories": [
  
  
  ]
}
```
The following code example shows how to use `list-repositories`.

**AWS CLI**

To list repositories

The following `list-repositories` example returns a summary of all repositories in domain owned by the AWS account that makes the call.

```
aws codeartifact list-repositories
```

Output:

```
{
    "repositories": [
        {

### login

The following code example shows how to use `login`.

#### AWS CLI

**To configure authentication to your repository with the login command**

The following `login` example configures the npm package manager with a repository named `test-repo` in a domain named `test-domain`.

```
aws codeartifact login \
    --domain test-domain \
    --repository test-repo \
    --tool npm
```

**Output:**
Login expires in 12 hours at 2020-11-12 01:53:16-05:00

For more information, see Getting started with the AWS CLI in the AWS CodeArtifact User Guide.

- For API details, see Login in AWS CLI Command Reference.

**put-domain-permissions-policy**

The following code example shows how to use put-domain-permissions-policy.

**AWS CLI**

**To attach a permissions policy to a domain**

The following put-domain-permissions-policy example attaches a permission policy that is defined in the policy.json file to a domain named test-domain.

```
aws codeartifact put-domain-permissions-policy \
--domain test-domain \ 
--policy-document file://PATH/TO/policy.json
```

Output:

```
{
   "policy": {
      "document": "...policy document content...",
      "revision": "MQlyyTQRASRU3HB58gBtSDHXG7Q3hvxxxxxx="
   }
}
```

For more information, see Set a domain policy in the AWS CodeArtifact User Guide.

- For API details, see PutDomainPermissionsPolicy in AWS CLI Command Reference.

**put-repository-permissions-policy**

The following code example shows how to use put-repository-permissions-policy.

Actions and scenarios
AWS CLI

To attach a permissions policy to a repository

The following `put-repository-permissions-policy` example attaches a permission policy that is defined in the `policy.json` file to a repository named `test-repo`.

```
aws codeartifact put-repository-permissions-policy \
    --domain test-domain \
    --repository test-repo \
    --policy-document file://PATH/TO/policy.json
```

Output:

```
{
   "policy": {
      "document": "...policy document content...",
      "revision": "MQlyyTQRASRU3HB58gBtSDHXG7Q3hvxxxxxxxxx="

update-package-versions-status

The following code example shows how to use `update-package-versions-status`.

AWS CLI

To update package version status

The following `update-package-versions-status` example updates the status of version 4.0.0 of the `test-package` package to Archived.

```
aws codeartifact update-package-versions-status \
    --domain test-domain \
    --repo test-repo \
```

Actions and scenarios
Output:

```json
{
    "successfulVersions": {
        "4.0.0": {
            "revision": "Ciqe5/9yicvkJT13b5/LdLpCyE6fqA7poa9qp+FilPs=",
            "status": "Archived"
        }
    },
    "failedVersions": {}
}
```

- For API details, see [UpdatePackageVersionsStatus](https://docs.aws.amazon.com/cli/latest/reference/codeartifact/update-package-versions-status.html) in *AWS CLI Command Reference*.

**update-repository**

The following code example shows how to use `update-repository`.

**AWS CLI**

**To update a repository**

The following `update-repository` example updates the description of a repo named `test-repo` in a domain named `test-domain` to "this is an updated description".

```
aws codeartifact update-repository \
    --domain test-domain \
    --repository test-repo \
    --description "this is an updated description"
```

Output:

```json
{
    "repository": {
```
"name": "test-repo",
"administratorAccount": "111122223333",
"domainName": "test-domain",

**CodeBuild examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with CodeBuild.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**batch-get-builds**

The following code example shows how to use `batch-get-builds`.

**AWS CLI**

To view details of builds in AWS CodeBuild.

The following `batch-get-builds` example gets information about builds in CodeBuild with the specified IDs.

```bash
aws codebuild batch-get-builds --ids codebuild-demo-project:e9c4f4df-3f43-41d2-ab3a-60fe2EXAMPLE codebuild-demo-project:815e755f-bade-4a7e-80f0-efe51EXAMPLE

**batch-get-projects**

The following code example shows how to use batch-get-projects.

**AWS CLI**

To get a list of AWS CodeBuild build project names.

The following batch-get-projects example gets a list of CodeBuild build projects specified by name.

```
aws codebuild batch-get-projects --names codebuild-demo-project codebuild-demo-project2 my-other-demo-project
```

In the following output, the `projectsNotFound` array lists any build project names that were specified, but not found. The `projects` array lists details for each build project where information was found.

}
Example 2: To create an AWS CodeBuild build project using a JSON input file for the parameters

The following `create-project` example creates a CodeBuild build project by passing all of the required parameters in a JSON input file. Create the input file template by running the command with only the `--generate-cli-skeleton` parameter.

```
aws codebuild create-project --cli-input-json file://create-project.json
```

The input JSON file `create-project.json` contains the following content:

```
{
    "name": "codebuild-demo-project",
    "source": {
        "type": "S3",
        "location": "codebuild-region-ID-account-ID-input-bucket/MessageUtil.zip"
    },
    "artifacts": {
        "type": "S3",
        "location": "codebuild-region-ID-account-ID-output-bucket"
    },
    "environment": {
        "type": "LINUX_CONTAINER",
        "image": "aws/codebuild/standard:1.0",
        "computeType": "BUILD_GENERAL1_SMALL"
    },
    "serviceRole": "serviceIAMRole"
}
```

Output:

```
{
    "project": {
        "name": "codebuild-demo-project",
        "serviceRole": "serviceIAMRole",
        "tags": [],
        "artifacts": {
            "packaging": "NONE",
            "type": "S3",
            "location": "codebuild-region-ID-account-ID-output-bucket",
            "name": "message-util.zip"
        }
    }
}
```

- For API details, see [CreateProject](https://awscli.amazonaws.com/v2/documentation/api/latest/reference/codebuild/create-project.html) in [AWS CLI Command Reference](https://docs.aws.amazon.com/cli/latest/reference/codebuild/create-project.html).

**create-report-group**

The following code example shows how to use `create-report-group`.

**AWS CLI**

To create a report group in AWS CodeBuild.

The following `create-report-group` example creates a new report group.

```bash
aws codebuild create-report-group \
  --cli-input-json file://create-report-group-source.json
```

Contents of `create-report-group-source.json`:

```json
{
  "name": "cli-created-report-group",
  "type": "TEST",
  "exportConfig": {
```

### Actions and scenarios

The following code example shows how to use `create-report-group`.
"exportConfigType": "S3",
"s3Destination": {
   "bucket": "my-s3-bucket",
   "path": ",",
   "packaging": "ZIP",
   "encryptionDisabled": true
}
}
}

Output:

{
   "reportGroup": {
      "name": "cli-created-report-group",
      "type": "TEST",
      "exportConfig": {
         "exportConfigType": "S3",
         "s3Destination": {
            "bucket": "my-s3-bucket",
            "path": ",",
            "packaging": "ZIP",
            "encryptionDisabled": true
         }
      },

- For API details, see [CreateReportGroup](https://aws.amazon.com/cli/command-reference) in AWS CLI Command Reference.

create-webhook

The following code example shows how to use create-webhook.

AWS CLI

To create webhook filters for an AWS CodeBuild project
The following `create-webhook` example creates a webhook for a CodeBuild project named `my-project` that has two filter groups. The first filter group specifies pull requests that are created, updated, or reopened on branches with Git reference names that match the regular expression `^refs/heads/master$` and head references that match `^refs/heads/myBranch$`. The second filter group specifies push requests on branches with Git reference names that do not match the regular expression `^refs/heads/myBranch$`.

```bash
aws codebuild create-webhook
   --project-name my-project
   --filter-groups "[{{"type":"EVENT","pattern":"PULL_REQUEST_CREATED, PULL_REQUEST_UPDATED, PULL_REQUEST_REOPENED"},{"type":"HEAD_REF","pattern":"^refs/heads/myBranch$","excludeMatchedPattern":true},{"type":"BASE_REF","pattern":"^refs/heads/master$","excludeMatchedPattern":true}],[{"type":"EVENT","pattern":"PUSH"},{"type":"HEAD_REF","pattern":"^refs/heads/myBranch$","excludeMatchedPattern":true}]]"
```

Output:

```json
{
   "webhook": {
      "payloadUrl": "https://codebuild.us-west-2.amazonaws.com/webhooks?t=eyJlbmNyeXB0ZWREYXRhIjoivV15MGtoeGRwSzZFRXl2Whh4bld1Z0tKZ291TVpQNEtFamQ3RD1DYWpRaGIreVFrdfm5ZQ2UxMDMxZGM5Y2MzYmU4ZTQ3NzBiN2Y1ZDZiYmYyMmUzOTQ4YzkwZjcxN2I1ZWIzNjYwYTYzY2M5YjAwMzE2MmM3NDU0ZjM3Zjg1OTBkNWUxYmQxNjI1YmRiOGYwNzUzOTBjYjQ5OTczZTc5ZmNhYzliZjU4NDU0ZjEzYmI4YTJlN2UxYmY1NjI1N2U0NQ%3D%3D&v=1",

      "filterGroups": [
         {
            "type": "EVENT",
            "pattern": "PULL_REQUEST_CREATED, PULL_REQUEST_UPDATED, PULL_REQUEST_REOPENED",
            "excludeMatchedPattern": false
         },
         {
            "type": "HEAD_REF",
            "pattern": "^refs/heads/myBranch$",
            "excludeMatchedPattern": true
         },
         {
            "type": "BASE_REF",
            "pattern": "^refs/heads/master$",
            "excludeMatchedPattern": true
         }
      ]
   }
}
```
For more information, see Filter GitHub Webhook Events (SDK) in the AWS CodeBuild User Guide.

- For API details, see CreateWebhook in AWS CLI Command Reference.

**delete-build-batch**

The following code example shows how to use `delete-build-batch`.

**AWS CLI**

To delete a batch build in AWS CodeBuild.

The following `delete-build-batch` example deletes the specified batch build.

```bash
aws codebuild delete-build-batch \ 
--id <project-name>::<batch-ID>
```

Output:

```json
{
   "statusCode": "BATCH_DELETED",
   "buildsDeleted": [
      "arn:aws:codebuild:<region-ID>::<account-ID>::build/<project-name>::<build-ID>"
   ]
}
```
],
"buildsNotDeleted": []
}

For more information, see Batch builds in AWS CodeBuild in the AWS CodeBuild User Guide.

- For API details, see DeleteBuildBatch in AWS CLI Command Reference.

delete-project

The following code example shows how to use delete-project.

AWS CLI

To delete an AWS CodeBuild build project

The following delete-project example deletes the specified CodeBuild build project.

aws codebuild delete-project --name my-project

This command produces no output.

For more information, see Delete a Build Project (AWS CLI) in the AWS CodeBuild User Guide.

- For API details, see DeleteProject in AWS CLI Command Reference.

delete-report-group

The following code example shows how to use delete-report-group.

AWS CLI

To delete a report groups in AWS CodeBuild.

The following delete-report-group example deletes the report group with the specified ARN.
aws codebuild delete-report-group
   --arn arn:aws:codebuild:<region-ID>::user-ID::report-group/<report-group-name>

This command produces no output.

For more information, see Working with report groups in the AWS CodeBuild User Guide.

• For API details, see DeleteReportGroup in AWS CLI Command Reference.

delete-report

The following code example shows how to use delete-report.

AWS CLI

To delete a report in AWS CodeBuild.

The following delete-report example deletes the specified report.

aws codebuild delete-report
   --arn arn:aws:codebuild:<region-ID>::account-ID::report/<report-group-name>::<report-ID>

This command produces no output.

For more information, see Working with reports in the AWS CodeBuild User Guide.

• For API details, see DeleteReport in AWS CLI Command Reference.

delete-source-credentials

The following code example shows how to use delete-source-credentials.

AWS CLI

To disconnect from a source provider and remove its access tokens.

The following delete-source-credentials example disconnects from a source provider and removes its tokens. The ARN of source credentials used to connect to the source provider determines which source credentials.
aws codebuild delete-source-credentials --arn arn-of-your-credentials

Output:

```
{
  "arn": "arn:aws:codebuild:your-region:your-account-id:token/your-server-type"
}
```

For more information, see Connect Source Providers with Access Tokens (CLI) in the AWS CodeBuild User Guide.

- For API details, see DeleteSourceCredentials in AWS CLI Command Reference.

**delete-webhook**

The following code example shows how to use delete-webhook.

**AWS CLI**

To delete a webhook filter from an AWS CodeBuild project

The following delete-webhook example deletes a webhook from the specified CodeBuild project.

```
aws codebuild delete-webhook --project-name my-project
```

This command produces no output.

For more information, see Stop Running Builds Automatically (AWS CLI) in the AWS CodeBuild User Guide.

- For API details, see DeleteWebhook in AWS CLI Command Reference.

**describe-code-coverages**

The following code example shows how to use describe-code-coverages.

**AWS CLI**

To get detailed information about code coverage test results in AWS CodeBuild.
The following `describe-code-coverages` example gets information about the code coverage test results in the specified report.

```
aws codebuild describe-code-coverages \\
```

Output:

```
{
  "codeCoverages": [
    {
      "id": "20a0adcc-db13-4b66-804b-ecaf9f852855",

- For API details, see [DescribeCodeCoverages](https://docs.aws.amazon.com/cli/latest/reference/codebuild/describe-code-coverages.html) in AWS CLI Command Reference.
**describe-test-cases**

The following code example shows how to use `describe-test-cases`.

**AWS CLI**

To get detailed information about test cases in AWS CodeBuild.

The following `describe-test-cases` example gets information about the test cases in the specified report.

```bash
aws codebuild describe-test-cases \
```

Output:

```json
{
    "testCases": [ 
        {
            "testRawDataPath": "<test-report-path>",
            "prefix": "NUnit.Tests.Assemblies.MockTestFixture",

        }
    ]
}
```
import-source-credentials

The following code example shows how to use import-source-credentials.

AWS CLI

Connect an AWS CodeBuild user to a source provider by importing credentials for the source provider.

The following import-source-credentials example imports a token for a Bitbucket repository that uses BASIC_AUTH for its authentication type.

```
aws codebuild import-source-credentials --server-type BITBUCKET --auth-type BASIC_AUTH --token my-Bitbucket-password --username my-Bitbucket-username
```

Output:

```json
{
   "arn": "arn:aws:codebuild:us-west-2:123456789012:token/bitbucket"
}
```

For more information, see Connect Source Providers with Access Tokens (CLI) in the AWS CodeBuild User Guide.

- For API details, see ImportSourceCredentials in AWS CLI Command Reference.

invalidate-project-cache

The following code example shows how to use invalidate-project-cache.

AWS CLI

To reset the cache for an AWS CodeBuild build project.
The following invalidate-project-cache example resets the cache for the specified CodeBuild project.

```
aws codebuild invalidate-project-cache --project-name my-project
```

This command produces no output.

For more information, see Build Caching in CodeBuild in the AWS CodeBuild User Guide.

- For API details, see InvalidateProjectCache in AWS CLI Command Reference.

**list-build-batches-for-project**

The following code example shows how to use list-build-batches-for-project.

**AWS CLI**

**To list batch builds for a specific build project in AWS CodeBuild.**

The following list-build-batches-for-project example lists the CodeBuild batch builds for the specified project.

```
aws codebuild list-build-batches-for-project \
    --project-name "<project-name>"
```

Output:

```
{
    "ids": [
        "<project-name>:<batch-ID>",
        "<project-name>:<batch-ID>"
    ]
}
```

For more information, see Batch builds in AWS CodeBuild in the AWS CodeBuild User Guide.

- For API details, see ListBuildBatchesForProject in AWS CLI Command Reference.

**list-build-batches**

The following code example shows how to use list-build-batches.
AWS CLI

To list batch builds in AWS CodeBuild.

The following list-build-batches example lists the CodeBuild batch builds for the current account.

```
aws codebuild list-build-batches
```

Output:

```json
{
   "ids": [
       "<project-name>:<batch-ID>",
       "<project-name>:<batch-ID>"
   ]
}
```

list-builds-for-project

The following code example shows how to use list-builds-for-project.

AWS CLI

To view a list of builds for an AWS CodeBuild build project.

The following list-builds-for-project example lists the build IDs in descending order for the specified CodeBuild build project.

```
aws codebuild list-builds-for-project --project-name codebuild-demo-project --sort-order DESCENDING
```

Output:

```json
{
   "ids": [

```

Actions and scenarios

]
}

For more information, see View a List of Build IDs for a Build Project (AWS CLI) in the AWS CodeBuild User Guide

- For API details, see ListBuildsForProject in AWS CLI Command Reference.

**list-builds**

The following code example shows how to use list-builds.

**AWS CLI**

To get a list of AWS CodeBuild builds IDs.

The following list-builds example gets a list of CodeBuild IDs sorted in ascending order.

```bash
aws codebuild list-builds --sort-order ASCENDING
```

The output includes a `nextToken` value which indicates that there is more output available.

```json
{
    "nextToken": "4AEA6u7J...The full token has been omitted for brevity...MzY2OA==",
    "ids": [
        "codebuild-demo-project:815e755f-bade-4a7e-80f0-efe51EXAMPLE"
        "codebuild-demo-project:84a7f3d1-d40e-4956-b4cf-7a9d4EXAMPLE"
        ... The full list of build IDs has been omitted for brevity ...
        "codebuild-demo-project:931d0b72-bf6f-4040-a472-5c707EXAMPLE"
    ]
}
```

Run this command again and provide the `nextToken` value in the previous response as a parameter to get the next part of the output. Repeat until you don't receive a `nextToken` value in the response.
aws codebuild list-builds --sort-order ASCENDING --next-token 4AEA6u7J...The full
token has been omitted for brevity...MzY2OA==

Next part of the output:

```
{
  "ids": [
    "codebuild-demo-project:49015049-21cf-4b50-9708-df115EXAMPLE",
    "codebuild-demo-project:543e7206-68a3-46d6-a4da-759abEXAMPLE",

  ]
}
```

### list-curated-environment-images

The following code example shows how to use list-curated-environment-images.

**AWS CLI**

To get a list of Docker images managed by AWS CodeBuild that you can use for your builds.

The following list-curated-environment-images example lists the Docker images managed by CodeBuild that can be used for builds:

```
aws codebuild list-curated-environment-images
```

Output:

```
{
  "platforms": [
    {
      "platform": "AMAZON_LINUX",
      "languages": [
        {
          "language": "JAVA",
          "images": [

```
For more information, see [Docker Images Provided by CodeBuild](https://docs.aws.amazon.com/codebuild/latest/userguide/) in the *AWS CodeBuild User Guide*.

- For API details, see [ListCuratedEnvironmentImages](https://docs.aws.amazon.com/cli/latest/reference/codebuild/list-curated-environment-images.html) in *AWS CLI Command Reference*.

### list-projects

The following code example shows how to use `list-projects`.

#### AWS CLI

**To get a list of AWS CodeBuild build project names.**

The following `list-projects` example gets a list of CodeBuild build projects sorted by name in ascending order.

```
aws codebuild list-projects --sort-by NAME --sort-order ASCENDING
```

The output includes a `nextToken` value which indicates that there is more output available.
Run this command again and provide the `nextToken` value from the previous response as a parameter to get the next part of the output. Repeat until you don't receive a `nextToken` value in the response.

aws codebuild list-projects --sort-by NAME --sort-order ASCENDING --next-token Ci33ACF6...The full token has been omitted for brevity...U+AkMx8=

```
{
   "nextToken": "Ci33ACF6...The full token has been omitted for brevity...U+AkMx8=",
   "projects": [
      "codebuild-demo-project",
      "codebuild-demo-project2",
      "codebuild-demo-project99"
   ]
}
```

For more information, see View a List of Build Project Names (AWS CLI) in the AWS CodeBuild User Guide.

- For API details, see ListProjects in AWS CLI Command Reference.

**list-report-groups**

The following code example shows how to use `list-report-groups`.

**AWS CLI**

To get a list of the report group ARNs in AWS CodeBuild.
The following `list-report-groups` example retrieves the report group ARNs for the account in the region.

```bash
aws codebuild list-report-groups
```

Output:

```json
{
    "reportGroups": [
    ]
}
```

For more information, see [Working with report groups](https://docs.aws.amazon.com/codebuild/latest/userguide/working-with-report-groups.html) in the *AWS CodeBuild User Guide*.

- For API details, see [ListReportGroups](https://docs.aws.amazon.com/cli/latest/reference/codebuild/list-report-groups.html) in *AWS CLI Command Reference*.

### list-reports-for-report-group

The following code example shows how to use `list-reports-for-report-group`.

**AWS CLI**

**To get a list of the reports in a report group in AWS CodeBuild.**

The following `list-report-for-report-groups` example retrieves the reports in the specified report group for the account in the region.

```bash
aws codebuild list-reports-for-report-group \
```

Output:

```json
{
    "reports": [
    ]
}
```
For more information, see Working with report groups in the AWS CodeBuild User Guide.

- For API details, see ListReportsForReportGroup in AWS CLI Command Reference.

**list-reports**

The following code example shows how to use list-reports.

**AWS CLI**

To get a list of the reports for the current account in AWS CodeBuild.

The following list-reports example retrieves the ARNs of the reports for the current account.

```
aws codebuild list-reports
```

Output:

```
{
   "reports": [
   ]
}
```

For more information, see Working with reports in the AWS CodeBuild User Guide.

- For API details, see ListReports in AWS CLI Command Reference.

**list-shared-projects**

The following code example shows how to use list-shared-projects.

**AWS CLI**

To list the shared project in AWS CodeBuild.
The following `list-shared-projects` example lists the CodeBuild shared projects that are available to the current account.

```bash
aws codebuild list-shared-projects
```

Output:

```
{
    "projects": [
    "arn:aws:codebuild:<region-ID>:<account-ID>:project/<shared-project-name-1>",
    "arn:aws:codebuild:<region-ID>:<account-ID>:project/<shared-project-name-2>"]
}
```

For more information, see Working with shared projects in the AWS CodeBuild User Guide.

- For API details, see ListSharedProjects in AWS CLI Command Reference.

### list-shared-report-groups

The following code example shows how to use `list-shared-report-groups`.

#### AWS CLI

To get a list of the shared report group ARNs in AWS CodeBuild.

The following `list-shared-report-groups` example retrieves the report group ARNs for the account in the region.

```bash
aws codebuild list-shared-report-groups
```

Output:

```
{
    "reportGroups": [
    ]
}
```
For more information, see Working with report groups in the AWS CodeBuild User Guide.

- For API details, see ListSharedReportGroups in AWS CLI Command Reference.

**list-source-credentials**

The following code example shows how to use list-source-credentials.

**AWS CLI**

**To view a list of sourceCredentialsObjects**

The following list-source-credentials example lists tokens for an AWS account connected to one Bitbucket account and one GitHub account. Each sourceCredentialsInfos object in the response contains connected source credentials information.

```bash
aws codebuild list-source-credentials
```

**Output:**

```
{
   "sourceCredentialsInfos": [
   {
      "serverType": "BITBUCKET",
      "authType": "BASIC_AUTH"
   },
   {
      "serverType": "GITHUB",
      "authType": "OAUTH"
   }
   ]
}
```

For more information, see Connect Source Providers with Access Tokens (CLI) in the AWS CodeBuild User Guide.

- For API details, see ListSourceCredentials in AWS CLI Command Reference.
retry-build-batch

The following code example shows how to use retry-build-batch.

AWS CLI

To retry a failed batch build in AWS CodeBuild.

The following retry-build-batch example restarts the specified batch build.

```
aws codebuild retry-build-batch \
   --id <project-name>::<batch-ID>
```

Output:

```
{
   "buildBatch": {
      "id": "<project-name>::<batch-ID>",
      "arn": "arn:aws:codebuild:<region-ID>:<account-ID>:build-batch/<project-name>::<batch-ID>",

### start-build-batch

The following code example shows how to use start-build-batch.

**AWS CLI**

**To start a batch build in AWS CodeBuild.**

The following start-build-batch example starts a batch build of the specified project.

```bash
aws codebuild start-build-batch \
  --project-name <project-name>
```

Output:

```
{
  "buildBatch": {

The following code example shows how to use `start-build`.

**AWS CLI**

To start running a build of an AWS CodeBuild build project.

The following `start-build` example starts a build for the specified CodeBuild project. The build overrides both the project's setting for the number of minutes the build is allowed to be queued before it times out and the project's artifact settings.

```bash
aws codebuild start-build \
  --project-name "my-demo-project" \
  --queued-timeout-in-minutes-override 5 \

update-project

The following code example shows how to use update-project.

AWS CLI

To change an AWS CodeBuild build project's settings.

The following update-project example changes the settings of the specified CodeBuild build project named my-demo-project.

```bash
aws codebuild update-project --name "my-demo-project" \
    --description "This project is updated" \
    --source "{"type": "S3","location": "codebuild-us-west-2-123456789012-input-bucket/my-source-2.zip"}" \

    --environment "{"type": "LINUX_CONTAINER","image": "aws/codebuild/standard:1.0","computeType": "BUILD_GENERAL1_MEDIUM"}" \
    --service-role "arn:aws:iam::123456789012:role/service-role/my-codebuild-service-role"
```

The output displays the updated settings.

            "namespaceType": "NONE",
            "encryptionDisabled": false,
```
The following code example shows how to use `update-report-group`.

**AWS CLI**

To update a report group in AWS CodeBuild.

The following `update-report-group` example changes the export type of the report group to "NO_EXPORT".
The following code example shows how to use `update-webhook`.

**AWS CLI**

**To update the webhook for an AWS CodeBuild project**

The following update-webhook example updates a webhook for the specified CodeBuild project with two filter groups. The `--rotate-secret` parameter specifies that GitHub rotate the project's secret key every time a code change triggers a build. The first filter group specifies pull requests that are created, updated, or reopened on branches with Git reference names that match the regular expression `^refs/heads/master$` and head references that match `^refs/heads/myBranch$`. The second filter group specifies push requests on branches with Git reference names that do not match the regular expression `^refs/heads/myBranch$`.

```bash
aws codebuild update-webhook \
  --export-config="exportConfigType=NO_EXPORT"
```

Output:

```json
{
  "reportGroup": {
    "name": "cli-created-report-group",
    "type": "TEST",
    "exportConfig": {

**update-webhook**

The following code example shows how to use update-webhook.
--project-name Project2
--rotate-secret
--filter-groups "[{{"type":"EVENT","pattern":"PULL_REQUEST.Created,\nPULL_REQUEST.Updated, PULL_REQUEST.Reopened"},{"type":"HEAD_REF","pattern":"^refs/heads/myBranch$","excludeMatchedPattern":true},{"type":"BASE_REF","pattern":"^refs/heads/master$","excludeMatchedPattern":true}],[{{"type":"EVENT","pattern":"PUSH"},{"excludeMatchedPattern": true,"pattern":"refs/heads/myBranch$","excludeMatchedPattern":true}]]"

Output:

```json

**CodeCommit examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with CodeCommit.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

associate-approval-rule-template-with-repository

The following code example shows how to use associate-approval-rule-template-with-repository.

**AWS CLI**

To associate an approval rule template with a repository

The following associate-approval-rule-template-with-repository example associates the specified approval rule template with a repository named MyDemoRepo.
aws codecommit associate-approval-rule-template-with-repository \
   --repository-name MyDemoRepo \
   --approval-rule-template-name 2 approver-rule-for-main

This command produces no output.

For more information, see Associating an Approval Rule Template with a Repository in the AWS CodeCommit User Guide.

- For API details, see AssociateApprovalRuleTemplateWithRepository in AWS CLI Command Reference.

batch-associate-approval-rule-template-with-repositories

The following code example shows how to use batch-associate-approval-rule-template-with-repositories.

AWS CLI

To associate an approval rule template with multiple repositories in a single operation

The following batch-associate-approval-rule-template-with-repositories example associates the specified approval rule template with repositories named MyDemoRepo and MyOtherDemoRepo.

Note: Approval rule templates are specific to the AWS Region where they are created. They can only be associated with repositories in that AWS Region.

aws codecommit batch-associate-approval-rule-template-with-repositories \
   --repository-names MyDemoRepo, MyOtherDemoRepo \
   --approval-rule-template-name 2 approver-rule-for-main

Output:

```json

### batch-describe-merge-conflicts

The following code example shows how to use `batch-describe-merge-conflicts`.

**AWS CLI**

To get information about merge conflicts in all files or a subset of files in a merge between two commit specifiers:

The following `batch-describe-merge-conflicts` example determines the merge conflicts for merging a source branch named `feature-randomizationfeature` with a destination branch named `main` using the `THREE_WAY_MERGE` strategy in a repository named `MyDemoRepo`.

```bash
aws codecommit batch-describe-merge-conflicts \
    --source-commit-specifier feature-randomizationfeature \
    --destination-commit-specifier main \
    --merge-option THREE_WAY_MERGE \
    --repository-name MyDemoRepo
```

**Output:**

**batch-disassociate-approval-rule-template-from-repositories**

The following code example shows how to use `batch-disassociate-approval-rule-template-from-repositories`.

**AWS CLI**

**To disassociate an approval rule template from multiple repositories in a single operation**

The following `batch-disassociate-approval-rule-template-from-repositories` example disassociates the specified approval rule template from repositories named MyDemoRepo and MyOtherDemoRepo.

```bash
aws codecommit batch-disassociate-approval-rule-template-from-repositories \
  --repository-names MyDemoRepo, MyOtherDemoRepo \
  --approval-rule-template-name 1-approval-rule-for-all pull requests
```

Output:

```json
{
  "disassociatedRepositoryNames": [
    "MyDemoRepo",
    "MyOtherDemoRepo"

**batch-get-commits**

The following code example shows how to use `batch-get-commits`.
AWS CLI

To view information about multiple commits

The following `batch-get-commits` example displays details about the specified commits.

```
aws codecommit batch-get-commits  \
  --repository-name MyDemoRepo  \
  --commit-ids 317f8570EXAMPLE 4c925148EXAMPLE

}
```
For more information, see View Commit Details in the AWS CodeCommit User Guide.

- For API details, see BatchGetCommits in AWS CLI Command Reference.

**batch-get-repositories**

The following code example shows how to use batch-get-repositories.

**AWS CLI**

To view details about multiple repositories

This example shows details about multiple AWS CodeCommit repositories.

```shell
aws codecommit batch-get-repositories \
  --repository-names MyDemoRepo MyOtherDemoRepo
```

Output:

```json
{
  "repositoriesNotFound": [],
  "repositories": [

### create-approval-rule-template

The following code example shows how to use `create-approval-rule-template`.

**AWS CLI**

**To create an approval rule template**

The following `create-approval-rule-template` example creates an approval rule template named `2-approver-rule-for-main`. The template requires two users who assume the role of `CodeCommitReview` to approve any pull request before it can be merged to the main branch.

```bash
aws codecommit create-approval-rule-template
   --approval-rule-template-name 2-approver-rule-for-main
   --approval-rule-template-description "Requires two developers from the team to approve the pull request if the destination branch is main"
```
create-branch

The following code example shows how to use create-branch.

AWS CLI

To create a branch

This example creates a branch in an AWS CodeCommit repository. This command produces output only if there are errors.

Command:
aws codecommit create-branch --repository-name MyDemoRepo --branch-name MyNewBranch --commit-id 317f8570EXAMPLE

Output:
None.

- For API details, see [CreateBranch](#) in **AWS CLI Command Reference**.

### create-commit

The following code example shows how to use `create-commit`.

**AWS CLI**

**To create a commit**

The following `create-commit` example demonstrates how to create an initial commit for a repository that adds a `readme.md` file to a repository named `MyDemoRepo` in the main branch.

```
aws codecommit create-commit \
    --repository-name MyDemoRepo \
    --branch-name main \
    --put-files "filePath=readme.md,fileContent='Welcome to our team repository.'"
```

Output:

```
{
    "filesAdded": [
        {
            "blobId": "5e1c309d-EXAMPLE",
            "absolutePath": "readme.md",
            "fileMode": "NORMAL"
        }
    ],
    "commitId": "4df8b524-EXAMPLE",
    "treeId": "55b57003-EXAMPLE",
    "filesDeleted": [],
    "filesUpdated": []
}
```
For more information, see Create a Commit in AWS CodeCommit in the AWS CodeCommit User Guide.

- For API details, see CreateCommit in AWS CLI Command Reference.

create-pull-request-approval-rule

The following code example shows how to use create-pull-request-approval-rule.

AWS CLI

To create an approval rule for a pull request

The following create-pull-request-approval-rule example creates an approval rule named Require two approved approvers for the specified pull request. The rule specifies that two approvals are required from an approval pool. The pool includes all users who access CodeCommit by assuming the role of CodeCommitReview in the 123456789012 AWS account. It also includes either an IAM user or federated user named Nikhil_Jayashankar from the same AWS account.

```
aws codecommit create-pull-request-approval-rule  \
   --approval-rule-name "Require two approved approvers"  \
   --approval-rule-content "{"Version": "2018-11-08","Statements": 
   [{"Type": "Approvers","NumberOfApprovalsNeeded": 2,"ApprovalPoolMembers ": 
   ["CodeCommitApprovers:123456789012:Nikhil_Jayashankar", 
   "arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*"]}]}
```

Output:

```
{
   "approvalRule": {
   "approvalRuleName": "Require two approved approvers",
   "lastModifiedDate": 1570752871.932,
   "ruleContentSha256": "7c44e6ebEXAMPLE",
   "creationDate": 1570752871.932,
   "approvalRuleId": "aac33506-EXAMPLE",
   "approvalRuleContent": "{"Version": "2018-11-08","Statements": 
   [{"Type": "Approvers","NumberOfApprovalsNeeded": 2,"ApprovalPoolMembers ":

   "arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*"]}]}
   "lastModifiedUser": "arn:aws:iam::123456789012:user/Mary_Major"
   }
```
For more information, see Create an Approval Rule in the AWS CodeCommit User Guide.
- For API details, see CreatePullRequestApprovalRule in AWS CLI Command Reference.

**create-pull-request**

The following code example shows how to use `create-pull-request`.

**AWS CLI**

**To create a pull request**

The following `create-pull-request` example creates a pull request named 'Pronunciation difficulty analyzer' with a description of 'Please review these changes by Tuesday' that targets the 'jane-branch' source branch and is to be merged to the default branch 'main' in an AWS CodeCommit repository named 'MyDemoRepo'.

```
aws codecommit create-pull-request \
    --title "My Pull Request" \
    --description "Please review these changes by Tuesday" \
    --client-request-token 123Example \
    --targets repositoryName=MyDemoRepo,sourceReference=MyNewBranch
```

**Output:**

```
{
    "pullRequest": {
        "approvalRules": [
            {
                "approvalRuleContent": "{"\"Version\": \"2018-11-08\",\n\"DestinationReferences\": [\"refs/heads/main\"],\"Statements\": [{\"Type \": \"Approvers\",\"NumberOfApprovalsNeeded\": 2,\"ApprovalPoolMembers\": [\"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*/\"]}],\n                "approvalRuleId": "dd8b17fe-EXAMPLE",
                "approvalRuleName": "2-approver-rule-for-main",
                "creationDate": 1571356106.936,
                "lastModifiedDate": 571356106.936,
                "lastModifiedUser": \"arn:aws:iam::123456789012:user/Mary_Major\",
                "originApprovalRuleTemplate": {
                    "approvalRuleTemplateId": "dd3d22fe-EXAMPLE",
                    "approvalRuleTemplateName": "2-approver-rule-for-main"
            }
        ]
    }
}
```
For API details, see CreatePullRequest in AWS CLI Command Reference.

create-repository

The following code example shows how to use create-repository.

AWS CLI

To create a repository

This example creates a repository and associates it with the user's AWS account.

Command:

```bash
aws codecommit create-repository --repository-name MyDemoRepo --repository-description "My demonstration repository"
```
create-unreferenced-merge-commit

The following code example shows how to use create-unreferenced-merge-commit.

AWS CLI

To create an unreferenced commit that represents the result of merging two commit specifiers

The following create-unreferenced-merge-commit example creates a commit that represents the results of a merge between a source branch named bugfix-1234 with a destination branch named main using the THREE_WAY_MERGE strategy in a repository named MyDemoRepo.

```bash
aws codecommit create-unreferenced-merge-commit \
  --source-commit-specifier bugfix-1234 \
  --destination-commit-specifier main \
  --merge-option THREE_WAY_MERGE \
  --repository-name MyDemoRepo \
  --name "Maria Garcia" \
  --email "maria_garcia@example.com"
```
Output:

```
{
    "commitId": "4f178133EXAMPLE",
    "treeId": "389765daEXAMPLE"
}
```

For more information, see `Resolve Conflicts in a Pull Request` in the `AWS CodeCommit User Guide`.  
- For API details, see `CreateUnreferencedMergeCommit` in `AWS CLI Command Reference`.  

**credential-helper**

The following code example shows how to use `credential-helper`.  

**AWS CLI**

**To set up the credential helper included in the AWS CLI with AWS CodeCommit**

The `credential-helper` utility is not designed to be called directly from the AWS CLI. Instead it is intended to be used as a parameter with the `git config` command to set up your local computer. It enables Git to use HTTPS and a cryptographically signed version of your IAM user credentials or Amazon EC2 instance role whenever Git needs to authenticate with AWS to interact with CodeCommit repositories.

```
git config --global credential.helper '!aws codecommit credential-helper $@'
git config --global credential.UseHttpPath true
```

Output:

```
[credential]
  helper = !aws codecommit credential-helper $@
  UseHttpPath = true
```

For more information, see Setting up for AWS CodeCommit Using Other Methods in the `AWS CodeCommit User Guide`. Review the content carefully, and then follow the procedures in one of the following topics: For HTTPS Connections on Linux, macOS, or Unix or For HTTPS Connections on Windows in the `AWS CodeCommit User Guide`.  

**Actions and scenarios**
For API details, see CredentialHelper in AWS CLI Command Reference.

**delete-approval-rule-template**

The following code example shows how to use delete-approval-rule-template.

**AWS CLI**

**To delete an approval rule template**

The following delete-approval-rule-template example deletes the specified approval rule template.

```
aws codecommit delete-approval-rule-template  
   --approval-rule-template-name 1approver-for-all-pull-requests
```

Output:

```
{
   "approvalRuleTemplateId": "41de97b7-EXAMPLE"
}
```

For more information, see Delete an Approval Rule Template in the AWS CodeCommit User Guide.

For API details, see DeleteApprovalRuleTemplate in AWS CLI Command Reference.

**delete-branch**

The following code example shows how to use delete-branch.

**AWS CLI**

**To delete a branch**

This example shows how to delete a branch in an AWS CodeCommit repository.

Command:

```
aws codecommit delete-branch --repository-name MyDemoRepo --branch-name MyNewBranch
```
The following code example shows how to use `delete-comment-content`.

**AWS CLI**

**To delete the content of a comment**

You can only delete the content of a comment if you created the comment. This example demonstrates how to delete the content of a comment with the system-generated ID of ff30b348EXAMPLEb9aa670f.

```bash
aws codecommit delete-comment-content \
   --comment-id ff30b348EXAMPLEb9aa670f
```

**Output:**

```json
{
   "comment": {
      "creationDate": 1508369768.142,
      "deleted": true,
      "lastModifiedDate": 1508369842.278,
      "clientRequestToken": "123Example",
      "commentId": "ff30b348EXAMPLEb9aa670f",

      "callerReactions": [],
      "reactionCounts": {
         "CLAP": 1
      }
   }
}
```
For API details, see `DeleteCommentContent` in *AWS CLI Command Reference*.

**delete-file**

The following code example shows how to use `delete-file`.

**AWS CLI**

To delete a file

The following `delete-file` example demonstrates how to delete a file named `README.md` from a branch named `main` with a most recent commit ID of `c5709475EXAMPLE` in a repository named `MyDemoRepo`.

```
aws codecommit delete-file \
  --repository-name MyDemoRepo \
  --branch-name main \
  --file-path README.md \
  --parent-commit-id c5709475EXAMPLE
```

Output:

```
{
   "blobId":"559b44fEXAMPLE",
   "commitId":"353cf655EXAMPLE",
   "filePath":"README.md",
   "treeId":"6bc824cEXAMPLE"
}
```

For more information, see *Edit or Delete a File in AWS CodeCommit* in the *AWS CodeCommit API Reference* guide.

For API details, see `DeleteFile` in *AWS CLI Command Reference*.

**delete-pull-request-approval-rule**

The following code example shows how to use `delete-pull-request-approval-rule`.

Actions and scenarios
AWS CLI

To delete an approval rule for a pull request

The following delete-pull-request-approval-rule example deletes the approval rule named My Approval Rule for the specified pull request.

```
aws codecommit delete-pull-request-approval-rule  \
  --approval-rule-name "My Approval Rule"  \
  --pull-request-id 15
```

Output:

```
{
  "approvalRuleId": "077d8e8a8-EXAMPLE"
}
```

For more information, see Edit or Delete an Approval Rule in the AWS CodeCommit User Guide.
- For API details, see DeletePullRequestApprovalRule in AWS CLI Command Reference.

delete-repository

The following code example shows how to use delete-repository.

AWS CLI

To delete a repository

This example shows how to delete an AWS CodeCommit repository.

Command:

```
aws codecommit delete-repository --repository-name MyDemoRepo
```

Output:

```
{
  "repositoryId": "f7579e13-b83e-4027-aaef-650c0EXAMPLE"
}
```

- For API details, see DeleteRepository in AWS CLI Command Reference.
describe-merge-conflicts

The following code example shows how to use describe-merge-conflicts.

AWS CLI

To get detailed information about merge conflicts

The following describe-merge-conflicts example determines the merge conflicts for a file named readme.md in the specified source branch and destination branch using the THREE_WAY_MERGE strategy.

```bash
aws codecommit describe-merge-conflicts \
  --source-commit-specifier feature-randomizationfeature \
  --destination-commit-specifier main \
  --merge-option THREE_WAY_MERGE \
  --file-path readme.md \
  --repository-name MyDemoRepo
```

Output:

```json
{
  "conflictMetadata": {
    "filePath": "readme.md",
    "fileSizes": {
      "source": 139,
      "destination": 230,
      "base": 85
    },

- For API details, see DescribeMergeConflicts in AWS CLI Command Reference.

describe-pull-request-events

The following code example shows how to use describe-pull-request-events.

AWS CLI

To view events in a pull request
The following `describe-pull-request-events` example retrieves the events for a pull request with the ID of '8'.

```bash
aws codecommit describe-pull-request-events --pull-request-id 8
```

Output:

```json
{
   "pullRequestEvents": [
      {
         "pullRequestId": "8",
         "pullRequestEventType": "PULL_REQUEST_CREATED",
         "eventDate": 1510341779.53,
         "actor": "arn:aws:iam::111111111111:user/Zhang_Wei"
      },
      {
         "pullRequestId": "8",

            "pullRequestStatus": "CLOSED"
         },
         "pullRequestId": "8",
         "pullRequestEventType": "PULL_REQUEST_STATUS_CHANGED",
         "eventDate": 1510341930.72,
         "actor": "arn:aws:iam::111111111111:user/Jane_Doe"
      }
   ]
}
```

**disassociate-approval-rule-template-from-repository**

The following code example shows how to use `disassociate-approval-rule-template-from-repository`.

**AWS CLI**

To disassociate an approval rule template from a repository

The following `disassociate-approval-rule-template-from-repository` example disassociates the specified approval rule template from a repository named `MyDemoRepo`.

```bash
aws codecommit disassociate-approval-rule-template-from-repository \
```
This command produces no output.

For more information, see Disassociate an Approval Rule Template in the AWS CodeCommit User Guide.

- For API details, see DisassociateApprovalRuleTemplateFromRepository in AWS CLI Command Reference.

evaluate-pull-request-approval-rules

The following code example shows how to use evaluate-pull-request-approval-rules.

AWS CLI

To evaluate whether a pull request has all of its approval rules satisfied

The following evaluate-pull-request-approval-rules example evaluates the state of approval rules on the specified pull request. In this example, an approval rule has not been satisfied for the pull request, so the output of the command shows an approved value of false.

```bash
aws codecommit evaluate-pull-request-approval-rules \
   --pull-request-id 27 \
   --revision-id 9f29d167EXAMPLE
```

Output:

```
{
   "evaluation": {
       "approved": false,
       "approvalRulesNotSatisfied": [
           "Require two approved approvers"
       ],
       "overridden": false,
       "approvalRulesSatisfied": []
   }
}
```

For more information, see Merge a Pull Request in the AWS CodeCommit User Guide.
• For API details, see EvaluatePullRequestApprovalRules in AWS CLI Command Reference.

get-approval-rule-template

The following code example shows how to use get-approval-rule-template.

AWS CLI

To get the content of an approval rule template

The following get-approval-rule-template example gets the content of an approval rule template named 1-approver-rule-for-all-pull-requests.

```
aws codecommit get-approval-rule-template \
  --approval-rule-template-name 1-approver-rule-for-all-pull-requests
```

Output:

```
{
  "approvalRuleTemplate": {
    "approvalRuleTemplateContent": "{"Version": "2018-11-08"},{"Statements": [{"Type": "Approvers","NumberOfApprovalsNeeded": 1,"ApprovalPoolMembers": [{"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*"]}]}],

    "approvalRuleTemplateId": "a29abb15-EXAMPLE",
    "approvalRuleTemplateDescription": "All pull requests must be approved by one developer on the team."
  }
}
```

For more information, see Manage Approval Rule Templates in the AWS CodeCommit User Guide.

• For API details, see GetApprovalRuleTemplate in AWS CLI Command Reference.

get-blob

The following code example shows how to use get-blob.

```
```
AWS CLI

To view information about a Git blob object

The following `get-blob` example retrieves information about a Git blob with the ID of '2eb4af3bEXAMPLE' in an AWS CodeCommit repository named 'MyDemoRepo'.

```bash
aws codecommit get-blob --repository-name MyDemoRepo --blob-id 2eb4af3bEXAMPLE
```

Output:

```json
{
  "content": "QSBCaW5hcnkgTGFyToEXAMPLE=
}
```

- For API details, see `GetBlob` in AWS CLI Command Reference.

get-branch

The following code example shows how to use `get-branch`.

AWS CLI

To get information about a branch

This example gets information about a branch in an AWS CodeCommit repository.

Command:

```bash
aws codecommit get-branch --repository-name MyDemoRepo --branch-name MyNewBranch
```

Output:

```json
{
  "BranchInfo": {
    "commitID": "317f8570EXAMPLE",
    "branchName": "MyNewBranch"
  }
}
```

- For API details, see `GetBranch` in AWS CLI Command Reference.
get-comment-reactions

The following code example shows how to use get-comment-reactions.

AWS CLI

To view emoji reactions to a comment

The following get-comment-reactions example lists all emoji reactions to a comment with the ID of abcd1234EXAMPLEb5678efgh. If the font for your shell supports displaying Emoji Version 1.0, then in the output for emoji the emoji is displayed.

```bash
aws codecommit get-comment-reactions \
  --comment-id abcd1234EXAMPLEb5678efgh
```

Output:

```json
{
    "reactionsForComment": [
        {
            "reaction": {
                "emoji": "??",
                "shortCode": "thumbsup",
                "unicode": "U+1F44D"
            },
            "users": [

                "arn:aws:iam::123456789012:user/Jorge_Souza"
            ]
        },
        {
            "reaction": {
                "emoji": "??",
                "shortCode": "thumbsdown",
                "unicode": "U+1F44E"
            },
            "users": [
                "arn:aws:iam::123456789012:user/Nikhil_Jayashankar"
            ]
        }
    ]
}
```
For more information, see Comment on a commit in AWS CodeCommit in the AWS CodeCommit User Guide.

- For API details, see GetCommentReactions in AWS CLI Command Reference.

get-comment

The following code example shows how to use get-comment.

AWS CLI

To view details of a comment

This example demonstrates how to view details of a comment with the system-generated comment ID of ff30b348EXAMPLEb9aa670f.

```bash
aws codecommit get-comment \ 
   --comment-id ff30b348EXAMPLEb9aa670f
```

Output:

```json
{
   "comment": {
      "authorArn": "arn:aws:iam::111111111111:user/Li_Juan",
      "clientRequestToken": "123Example",

      "content": "Whoops - I meant to add this comment to the line, but I don't see how to delete it."
   }
}
```
• For API details, see GetComment in AWS CLI Command Reference.

get-comments-for-compared-commit

The following code example shows how to use get-comments-for-compared-commit.

AWS CLI

To view comments on a commit

This example demonstrates how to view comments made on the comparison between two commits in a repository named MyDemoRepo.

```
aws codecommit get-comments-for-compared-commit \
  --repository-name MyDemoRepo \
  --before-commit-ID 6e147360EXAMPLE \
  --after-commit-id 317f8570EXAMPLE

get-comments-for-pull-request

The following code example shows how to use get-comments-for-pull-request.

AWS CLI

To view comments for a pull request

This example demonstrates how to view comments for a pull request in a repository named MyDemoRepo.

```bash
aws codecommit get-comments-for-pull-request \
  --repository-name MyDemoRepo \
  --before-commit-ID 317f8570EXAMPLE \

• For API details, see GetCommentsForPullRequest in AWS CLI Command Reference.

get-commit

The following code example shows how to use get-commit.

AWS CLI

To view information about a commit in a repository

This example shows details about a commit with the system-generated ID of '7e9fd3091thisisanexamplethisisanexample1' in an AWS CodeCommit repository named 'MyDemoRepo'.

Command:
aws codecommit get-commit --repository-name MyDemoRepo --commit-id 7e9fd3091thisisanexamplethisisanexample1

Output:

```json
{
    "commit": {
        "additionalData": "",

- For API details, see [GetCommit](https://docs.aws.amazon.com/cli/latest/reference/codecommit/get-commit.html) in *AWS CLI Command Reference*.

**get-differences**

The following code example shows how to use `get-differences`.

**AWS CLI**

**To get information about differences for a commit specifier in a repository**

This example shows view metadata information about changes between two commit specifiers (branch, tag, HEAD, or other fully qualified references, such as commit IDs) in a renamed folder in AWS CodeCommit repository named MyDemoRepo. The example includes several options that are not required, including `--before-commit-specifier`, `--before-path`, and `--after-path`, in
order to more fully illustrate how you can use these options to limit the results. The response includes file mode permissions.

Command:

```bash
aws codecommit get-differences --repository-name MyDemoRepo --before-commit-specifier 955bba12thisisanexamplethisisanexample --after-commit-specifier 14a95463thisisanexamplethisisanexample --before-path tmp/example-folder --after-path tmp/renamed-folder
```

Output:

```json
{
  "differences": [
    {
      "afterBlob": {
        "path": "blob.txt",
        "blobId": "2eb4af3b1thisisanexamplethisisanexample1",

        "mode": "100644"
      }
    }
  ]
}
```

**get-file**

The following code example shows how to use get-file.

**AWS CLI**

**To get the base-64 encoded contents of a file in an AWS CodeCommit repository**

The following `get-file` example demonstrates how to get the base-64 encoded contents of a file named README.md from a branch named main in a repository named MyDemoRepo.
aws codecommit get-file
   --repository-name MyDemoRepo
   --commit-specifier main
   --file-path README.md

Output:

```json
{
   "blobId":"559b44fEXAMPLE",
   "commitId":"c5709475EXAMPLE",
   "fileContent":"IyBQaHVzEXAMPLE",
   "filePath":"README.md",

   "fileSize":1563
}
```

For more information, see GetFile in the AWS CodeCommit API Reference guide.

- For API details, see GetFile in AWS CLI Command Reference.

get-folder

The following code example shows how to use get-folder.

AWS CLI

To get the contents of a folder in an AWS CodeCommit repository

The following get-folder example demonstrates how to get the contents of a top-level folder from a repository named MyDemoRepo.

aws codecommit get-folder --repository-name MyDemoRepo --folder-path ""

Output:

```json
{
   "commitId":"c5709475EXAMPLE",

get-merge-commit

The following code example shows how to use `get-merge-commit`.

**AWS CLI**

To get detailed information about a merge commit

The following `get-merge-commit` example displays details about a merge commit for the source branch named `bugfix-bug1234` with a destination branch named `main` using the THREE_WAY_MERGE strategy in a repository named `MyDemoRepo`.

```bash
aws codecommit get-merge-commit \
--source-commit-specifier bugfix-bug1234 \
--destination-commit-specifier main \
--merge-option THREE_WAY_MERGE \
--repository-name MyDemoRepo
```

Output:

```
{
    "sourceCommitId": "c5709475EXAMPLE",
    "destinationCommitId": "317f8570EXAMPLE",
    "baseCommitId": "fb12a539EXAMPLE",
    "mergeCommitId": "ffc4d608eEXAMPLE"
}
```

For more information, see View Commit Details in the AWS CodeCommit User Guide.

- For API details, see `GetMergeCommit` in AWS CLI Command Reference.

get-merge-conflicts

The following code example shows how to use `get-merge-conflicts`.
AWS CLI

To view whether there are any merge conflicts for a pull request

The following `get-merge-conflicts` example displays whether there are any merge conflicts between the tip of a source branch named `feature-randomizationfeature` and a destination branch named 'main' in a repository named `MyDemoRepo`.

```
aws codecommit get-merge-conflicts \\
  --repository-name MyDemoRepo \\
  --source-commit-specifier feature-randomizationfeature \\
  --destination-commit-specifier main \\
  --merge-option THREE_WAY_MERGE
```

Output:

```
{
    "mergeable": false,
    "destinationCommitId": "86958e0aEXAMPLE",
    "sourceCommitId": "6ccd57fdEXAMPLE",
    "baseCommitId": "767b6958EXAMPLE",

```
• For API details, see [GetMergeConflicts](https://docs.aws.amazon.com/cli/latest/reference/codecommit/get-merge-conflicts.html) in *AWS CLI Command Reference*.

**get-merge-options**

The following code example shows how to use `get-merge-options`.

**AWS CLI**

To get information about the merge options available for merging two specified branches

The following `get-merge-options` example determines the merge options available for merging a source branch named `bugfix-bug1234` with a destination branch named `main` in a repository named `MyDemoRepo`.

```
aws codecommit get-merge-options \
   --source-commit-specifier bugfix-bug1234 \
   --destination-commit-specifier main \
   --repository-name MyDemoRepo
```

Output:

```json
{
   "mergeOptions": [
      "FAST_FORWARD_MERGE",
      "SQUASH_MERGE",
      "THREE_WAY_MERGE"
   ],
   "sourceCommitId": "18059494EXAMPLE",
   "destinationCommitId": "ffd3311dEXAMPLE",
}
```
get-pull-request-approval-states

The following code example shows how to use get-pull-request-approval-states.

AWS CLI

To view approvals on a pull request

The following get-pull-request-approval-states example returns approvals for the specified pull request.

```
aws codecommit get-pull-request-approval-states \
  --pull-request-id 8 \
  --revision-id 9f29d167EXAMPLE
```

Output:

```
{
  "approvals": [
    {
      "userArn": "arn:aws:iam::123456789012:user/Mary_Major",
      "approvalState": "APPROVE"
    }
  ]
}
```

For more information, see View Pull Requests in the AWS CodeCommit User Guide.

- For API details, see GetPullRequestApprovalStates in AWS CLI Command Reference.

get-pull-request-override-state

The following code example shows how to use get-pull-request-override-state.
AWS CLI

To get information about the override status of a pull request

The following get-pull-request-override-state example returns the override state for the specified pull request. In this example, the approval rules for the pull request were overridden by a user named Mary Major, so the output returns a value of true:

```bash
aws codecommit get-pull-request-override-state \
--pull-request-id 34 \
--revision-id 9f29d167EXAMPLE
```

Output:

```
{
    "overridden": true,
    "overrider": "arn:aws:iam::123456789012:user/Mary_Major"
}
```

For more information, see Override Approval Rules on a Pull Request in the AWS CodeCommit User Guide.

- For API details, see GetPullRequestOverrideState in AWS CLI Command Reference.

get-pull-request

The following code example shows how to use get-pull-request.

AWS CLI

To view details of a pull request

This example demonstrates how to view information about a pull request with the ID of 27.

```bash
aws codecommit get-pull-request \
--pull-request-id 27
```

Output:

```
{
}
```
For API details, see [GetPullRequest](#) in AWS CLI Command Reference.

**get-repository-triggers**

The following code example shows how to use `get-repository-triggers`.
AWS CLI

To get information about triggers in a repository

This example shows details about triggers configured for an AWS CodeCommit repository named MyDemoRepo.

```bash
aws codecommit get-repository-triggers \
   --repository-name MyDemoRepo
```

Output:

```json
{
   "configurationId": "f7579e13-b83e-4027-aaef-650c0EXAMPLE",
   "triggers": [
      {
         "branches": [
            "main",
            "preprod"
         ],
         "name": "MyFirstTrigger",
         "customData": "",
         "events": [
            "all"
         ]
      },
      {
         "branches": [],
         "name": "MySecondTrigger",
         "customData": "EXAMPLE",
         "events": [
            "all"
         ]
      }
   ]
}
```

- For API details, see [GetRepositoryTriggers](#) in [AWS CLI Command Reference](#).
**get-repository**

The following code example shows how to use get-repository.

**AWS CLI**

**To get information about a repository**

This example shows details about an AWS CodeCommit repository.

```bash
aws codecommit get-repository 
   --repository-name MyDemoRepo
```

**Output:**

```json
{
   "repositoryMetadata": {
      "creationDate": 1429203623.625,
      "defaultBranch": "main",
      "repositoryName": "MyDemoRepo",
      "cloneUrlSsh": "ssh://git-codecommit.us-east-1.amazonaws.com/v1/repos/v1/repos/MyDemoRepo",
      "lastModifiedDate": 1430783812.0869999,
      "repositoryDescription": "My demonstration repository",
      "cloneUrlHttp": "https://codecommit.us-east-1.amazonaws.com/v1/repos/MyDemoRepo",

      "Arn": "arn:aws:codecommit:us-east-1:80398EXAMPLE:MyDemoRepo",
      "accountId": "111111111111"
   }
}
```

- For API details, see [GetRepository](#) in *AWS CLI Command Reference*.

**list-approval-rule-templates**

The following code example shows how to use list-approval-rule-templates.

**AWS CLI**

**To list all approval rule templates in an AWS Region**
The following **list-approval-rule-templates** example lists all approval rule templates in the specified Region. If no AWS Region is specified as a parameter, the command returns approval rule templates for the region specified in the AWS CLI profile used to run the command.

```bash
aws codecommit list-approval-rule-templates \
   --region us-east-2
```

Output:

```json
{
   "approvalRuleTemplateNames": [
      "2 approver rule for main",
      "1 approver rule for all pull requests"
   ]
}
```

For more information, see [Manage Approval Rule Templates](https://aws.amazon.com/documentation/autorendering) in the *AWS CodeCommit User Guide*.

- For API details, see [ListApprovalRuleTemplates](https://aws.amazon.com/documentation/autorendering) in *AWS CLI Command Reference*.

**list-associated-approval-rule-templates-for-repository**

The following code example shows how to use **list-associated-approval-rule-templates-for-repository**.

**AWS CLI**

**To list all templates associated with a repository**

The following **list-associated-approval-rule-templates-for-repository** example lists all approval rule templates associated with a repository named MyDemoRepo.

```bash
aws codecommit list-associated-approval-rule-templates-for-repository \
   --repository-name MyDemoRepo
```

Output:

```json
{
   "approvalRuleTemplateNames": [
```

Actions and scenarios
"2 approver rule for main",
"1 approver rule for all pull requests"
]
}

For more information, see Manage Approval Rule Templates in the AWS CodeCommit User Guide.

- For API details, see ListAssociatedApprovalRuleTemplatesForRepository in AWS CLI Command Reference.

list-branches

The following code example shows how to use list-branches.

AWS CLI

To view a list of branch names

This example lists all branch names in an AWS CodeCommit repository.

```bash
aws codecommit list-branches \\
   --repository-name MyDemoRepo
```

Output:

```json
{
   "branches": [
      "MyNewBranch",
      "main"
   ]
}
```

- For API details, see ListBranches in AWS CLI Command Reference.

list-pull-requests

The following code example shows how to use list-pull-requests.

AWS CLI

To view a list of pull requests in a repository
This example demonstrates how to list pull requests created by an IAM user with the ARN 'arn:aws:iam::111111111111:user/Li_Juan' and the status of 'CLOSED' in an AWS CodeCommit repository named 'MyDemoRepo':

```bash
aws codecommit list-pull-requests --author-arn arn:aws:iam::111111111111:user/Li_Juan --pull-request-status CLOSED --repository-name MyDemoRepo
```

Output:

```json
{
    "nextToken": "",
    "pullRequestIds": ["2","12","16","22","23","35","30","39","47"]
}
```

- For API details, see [ListPullRequests](https://docs.aws.amazon.com/cli/latest/reference/codecommit/list-pull-requests.html) in *AWS CLI Command Reference*.

### list-repositories-for-approval-rule-template

The following code example shows how to use `list-repositories-for-approval-rule-template`.

**AWS CLI**

**To list all repositories associated with a template**

The following `list-repositories-for-approval-rule-template` example lists all repositories associated with the specified approval rule template.

```bash
aws codecommit list-repositories-for-approval-rule-template \  --approval-rule-template-name 2-approver-rule-for-main
```

Output:

```json
{
    "repositoryNames": [
        "MyDemoRepo",
        "MyClonedRepo"
    ]
}
```
For more information, see Manage Approval Rule Templates in the AWS CodeCommit User Guide.

- For API details, see ListRepositoriesForApprovalRuleTemplate in AWS CLI Command Reference.

list-repositories

The following code example shows how to use list-repositories.

AWS CLI

To view a list of repositories

This example lists all AWS CodeCommit repositories associated with the user's AWS account.

Command:

```
aws codecommit list-repositories
```

Output:

```
{
   "repositories": [
   
   
   { "repositoryName": "MyDemoRepo"  
   "repositoryId": "f7579e13-b83e-4027-aaef-650c0EXAMPLE", 
   
   },
   
   { "repositoryName": "MyOtherDemoRepo"  
   "repositoryId": "cfc29ac4-b0cb-44dc-9990-f6f51EXAMPLE"
   
   ]

   }

```

- For API details, see ListRepositories in AWS CLI Command Reference.

list-tags-for-resource

The following code example shows how to use list-tags-for-resource.
AWS CLI

To view the AWS tags for a repository

The following list-tags-for-resource example lists tag keys and tag values for the specified repository.

```bash
aws codecommit list-tags-for-resource \
```

Output:

```
{
   "tags": {
      "Status": "Secret",
      "Team": "Saanvi"
   }
}
```

For more information, see View Tags for a Repository in the AWS CodeCommit User Guide.

- For API details, see ListTagsForResource in AWS CLI Command Reference.

merge-branches-by-fast-forward

The following code example shows how to use merge-branches-by-fast-forward.

AWS CLI

To merge two branches using the fast-forward merge strategy

The following merge-branches-by-fast-forward example merges the specified source branch with the specified destination branch in a repository named MyDemoRepo.

```bash
aws codecommit merge-branches-by-fast-forward \
   --source-commit-specifier bugfix-bug1234 \
   --destination-commit-specifier bugfix-bug1233 \
   --repository-name MyDemoRepo
```

Output:

```
{
```

Actions and scenarios
"commitId": "4f178133EXAMPLE",
"treeId": "389765daEXAMPLE"
}

For more information, see Compare and Merge Branches in the AWS CodeCommit User Guide.

• For API details, see MergeBranchesByFastForward in AWS CLI Command Reference.

merge-branches-by-squash

The following code example shows how to use merge-branches-by-squash.

AWS CLI

To merge two branches using the squash merge strategy

The following merge-branches-by-squash example merges the specified source branch with the specified destination branch in a repository named MyDemoRepo.

```
aws codecommit merge-branches-by-squash \
   --source-commit-specifier bugfix-bug1234 \
   --destination-commit-specifier bugfix-bug1233 \
   --author-name "Maria Garcia" \
   --email "maria_garcia@example.com" \
   --commit-message "Merging two fix branches to prepare for a general patch." \
   --repository-name MyDemoRepo
```

Output:

```
{
   "commitId": "4f178133EXAMPLE",
   "treeId": "389765daEXAMPLE"
}
```

For more information, see Compare and Merge Branches in the AWS CodeCommit User Guide.

• For API details, see MergeBranchesBySquash in AWS CLI Command Reference.

merge-branches-by-three-way

The following code example shows how to use merge-branches-by-three-way.
AWS CLI

To merge two branches using the three-way merge strategy

The following `merge-branches-by-three-way` example merges the specified source branch with the specified destination branch in a repository named `MyDemoRepo`.

```bash
aws codecommit merge-branches-by-three-way \
  --source-commit-specifier main \
  --destination-commit-specifier bugfix-bug1234 \
  --author-name "Jorge Souza" --email "jorge_souza@example.com" \
  --commit-message "Merging changes from main to bugfix branch before additional testing." \
  --repository-name MyDemoRepo
```

Output:

```
{
  "commitId": "4f178133EXAMPLE",
  "treeId": "389765daEXAMPLE"
}
```

For more information, see Compare and Merge Branches in the AWS CodeCommit User Guide.
- For API details, see MergeBranchesByThreeWay in AWS CLI Command Reference.

merge-pull-request-by-fast-forward

The following code example shows how to use `merge-pull-request-by-fast-forward`.

AWS CLI

To merge and close a pull request

This example demonstrates how to merge and close a pull request with the ID of '47' and a source commit ID of '99132ab0EXAMPLE' in a repository named `MyDemoRepo`.

```bash
aws codecommit merge-pull-request-by-fast-forward \
  --pull-request-id 47 \
  --source-commit-id 99132ab0EXAMPLE \
  --repository-name MyDemoRepo
```
Output:

**merge-pull-request-by-squash**

The following code example shows how to use `merge-pull-request-by-squash`.

**AWS CLI**

To merge a pull request using the squash merge strategy

The following `merge-pull-request-by-squash` example merges and closes the specified pull request using the conflict resolution strategy of ACCEPT_SOURCE in a repository named MyDemoRepo.

```
aws codecommit merge-pull-request-by-squash \
   --pull-request-id 47 \ 
   --source-commit-id 99132ab0EXAMPLE \ 
   --repository-name MyDemoRepo \ 
   --conflict-detail-level LINE_LEVEL \ 
   --conflict-resolution-strategy ACCEPT_SOURCE \ 
   --name "Jorge Souza" --email "jorge_souza@example.com" \ 
   --commit-message "Merging pull request 47 by squash and accepting source in merge conflicts"
```

Output:

**merge-pull-request-by-three-way**

The following code example shows how to use merge-pull-request-by-three-way.

**AWS CLI**

To merge a pull request using the three-way merge strategy
The following `merge-pull-request-by-three-way` example merges and closes the specified pull request using the default options for conflict detail and conflict resolution strategy in a repository named `MyDemoRepo`.

```bash
codecommit merge-pull-request-by-three-way \
   --pull-request-id 47 \
   --source-commit-id 99132ab0EXAMPLE \
   --repository-name MyDemoRepo \

**override-pull-request-approval-rules**

The following code example shows how to use `override-pull-request-approval-rules`.

**AWS CLI**

**To override approval rule requirements on a pull request**

The following `override-pull-request-approval-rules` example overrides approval rules on the specified pull request. To revoke an override instead, set the `--override-status` parameter value to `REVOKE`.

```bash
aws codecommit override-pull-request-approval-rules \
  --pull-request-id 34 \
  --revision-id 927df8d8EXAMPLE \
  --override-status OVERRIDE
```

This command produces no output.

- For API details, see [OverridePullRequestApprovalRules](https://docs.aws.amazon.com/AWSCLI/latest/userguide/codecommit-commands.html) in *AWS CLI Command Reference*. 

Actions and scenarios
post-comment-for-compared-commit

The following code example shows how to use post-comment-for-compared-commit.

AWS CLI

To create a comment on a commit

This example demonstrates how to add the comment "Can you add a test case for this?" on the change to the cl_sample.js file in the comparison between two commits in a repository named MyDemoRepo.

```bash
aws codecommit post-comment-for-compared-commit \
   --repository-name MyDemoRepo \
   --before-commit-id 317f8570EXAMPLE \
   --after-commit-id 5d036259EXAMPLE \
   --client-request-token 123Example \
   --content "Can you add a test case for this?" \
   --location filePath=cl_sample.js,filePosition=1232,relativeFileVersion=AFTER
```

Output:

```json
{
   "afterBlobId": "1f330709EXAMPLE",
   "afterCommitId": "317f8570EXAMPLE",
   "beforeBlobId": "80906a4cEXAMPLE",
   "beforeCommitId": "6e147360EXAMPLE",
   "comment": {

      "relativeFileVersion": "AFTER"
   }
}
```
For API details, see PostCommentForComparedCommit in AWS CLI Command Reference.

**post-comment-for-pull-request**

The following code example shows how to use post-comment-for-pull-request.

**AWS CLI**

**To add a comment to a pull request**

The following post-comment-for-pull-request example adds the comment "These don't appear to be used anywhere. Can we remove them?" on the change to the `ahs_count.py` file in a pull request with the ID of 47 in a repository named MyDemoRepo.

```
aws codecommit post-comment-for-pull-request \
    --pull-request-id "47" \ 
    --repository-name MyDemoRepo \ 
    --before-commit-id 317f8570EXAMPLE \ 
    --after-commit-id 5d036259EXAMPLE \ 
    --client-request-token 123Example \ 
    --content "These don't appear to be used anywhere. Can we remove them?" \ 
    --location filePath=ahs_count.py,filePosition=367,relativeFileVersion=AFTER
```

**Output:**

```
{
    "afterBlobId": "1f330709EXAMPLE",
    "afterCommitId": "5d036259EXAMPLE",
    "beforeBlobId": "80906a4cEXAMPLE",
    "beforeCommitId": "317f8570EXAMPLE",
    "comment": {
        "authorArn": "arn:aws:iam::111111111111:user/Saanvi_Sarkar",

        "commentId": "abcd1234EXAMPLEb5678efgh",
        "content": "These don't appear to be used anywhere. Can we remove them?"
    }
}
```
For API details, see PostCommentForPullRequest in AWS CLI Command Reference.

post-comment-reply

The following code example shows how to use post-comment-reply.

AWS CLI

To reply to a comment on a commit or in a pull request

This example demonstrates how to add the reply "Good catch. I'll remove them." to the comment with the system-generated ID of abcd1234EXAMPLEb5678efgh.

```
aws codecommit post-comment-reply \
  --in-reply-to abcd1234EXAMPLEb5678efgh \
  --content "Good catch. I'll remove them." \
  --client-request-token 123Example
```

Output:

```
{
  "comment": {
    "authorArn": "arn:aws:iam::111111111111:user/Li_Juan",
    "clientRequestToken": "123Example",

**put-comment-reaction**

The following code example shows how to use put-comment-reaction.

**AWS CLI**

To reply to a comment on a commit with an emoji

The following put-comment-reaction example replies to a comment with the ID of abcd1234EXAMPLEb5678efgh with an emoji reaction value of :thumbsup:.

```bash
aws codecommit put-comment-reaction \ 
--comment-id abcd1234EXAMPLEb5678efgh \ 
--reaction-value :thumbsup:
```

This command produces no output.

For more information, see Comment on a commit in AWS CodeCommit in the AWS CodeCommit User Guide.

• For API details, see PutCommentReaction in AWS CLI Command Reference.

**put-file**

The following code example shows how to use put-file.

**AWS CLI**

To add a file to a repository
The following put-file example adds a file named 'ExampleSolution.py' to a repository named 'MyDemoRepo' to a branch named 'feature-randomizationfeature' whose most recent commit has an ID of '4c925148EXAMPLE'.

```
aws codecommit put-file \
   --repository-name MyDemoRepo \
   --branch-name feature-randomizationfeature \
   --file-content file://MyDirectory/ExampleSolution.py \
   --file-path /solutions/ExampleSolution.py \
   --parent-commit-id 4c925148EXAMPLE \
   --name "Maria Garcia" \
   --email "maria_garcia@example.com" \
   --commit-message "I added a third randomization routine."
```

Output:

```json
{
   "blobId": "2eb4af3bEXAMPLE",
   "commitId": "317f8570EXAMPLE",
   "treeId": "347a3408EXAMPLE"
}
```

- For API details, see PutFile in AWS CLI Command Reference.

### put-repository-triggers

The following code example shows how to use put-repository-triggers.

**AWS CLI**

**To add or update a trigger in a repository**

This example demonstrates how to update triggers named 'MyFirstTrigger' and 'MySecondTrigger' using an already-created JSON file (here named MyTriggers.json) that contains the structure of all the triggers for a repository named MyDemoRepo. To learn how to get the JSON for existing triggers, see the get-repository-triggers command.

```
aws codecommit put-repository-triggers \
   --repository-name MyDemoRepo file://MyTriggers.json
```
Contents of MyTriggers.json:

```json
{
    "repositoryName": "MyDemoRepo",
    "triggers": [
        {
            "branches": [
                "main",
                "preprod"
            ],
            "name": "MyFirstTrigger",
            "customData": "",
            "events": [
                "all"
            ]
        },
        {
            "branches": [],
            "name": "MySecondTrigger",
            "customData": "EXAMPLE",
            "events": [
                "all"
            ]
        }
    ]
}
```

Output:

```json
{
    "configurationId": "6fa51cd8-35c1-EXAMPLE"
}
```

**tag-resource**

The following code example shows how to use `tag-resource`.

Actions and scenarios
AWS CLI

**To add AWS tags to an existing repository**

The following `tag-resource` example tags the specified repository with two tags.

```
aws codecommit tag-resource \
  --tags Status=Secret,Team=Saanvi
```

This command produces no output.

For more information, see [Add a Tag to a Repository](#) in the *AWS CodeCommit User Guide*.

- For API details, see [TagResource](#) in *AWS CLI Command Reference*.

**test-repository-triggers**

The following code example shows how to use `test-repository-triggers`.

AWS CLI

**To test triggers in a repository**

This example demonstrates how to test a trigger named 'MyFirstTrigger' in an AWS CodeCommit repository named MyDemoRepo. In this example, events in the repository trigger notifications from an Amazon Simple Notification Service (Amazon SNS) topic.

Command:

```
aws codecommit test-repository-triggers --repository-name MyDemoRepo  
  --triggers name=MyFirstTrigger,destinationArn=arn:aws:sns:us-east-1:111111111111:MyCodeCommitTopic,branches=mainline,preprod,events=all
```

Output:

```
{
  "successfulExecutions": [
    "MyFirstTrigger"
  ],
  "failedExecutions": []
}
```
untag-resource

The following code example shows how to use untag-resource.

AWS CLI

To remove AWS tags from a repository

The following untag-resource example removes the tag with the specified key from the repository named MyDemoRepo.

```
aws codecommit untag-resource \
   --tag-keys Status
```

This command produces no output.

For more information, see Remove a Tag from a Repository in the AWS CodeCommit User Guide.

update-approval-rule-template-content

The following code example shows how to use update-approval-rule-template-content.

AWS CLI

To update the content of an approval rule template

The following update-approval-rule-template-content example changes the content of the specified approval rule template to redefine the approval pool to users who assume the role of CodeCommitReview.

```
aws codecommit update-approval-rule-template-content \
   --approval-rule-template-name 1-approver-rule \
   --new-rule-content "{"Version": "2018-11-08","DestinationReferences": ["refs/heads/main"],"Statements": [{"Type": "Approvers"]}
```
For more information, see Manage Approval Rule Templates in the AWS CodeCommit User Guide.

- For API details, see UpdateApprovalRuleTemplateContent in AWS CLI Command Reference.

update-approval-rule-template-description

The following code example shows how to use update-approval-rule-template-description.

AWS CLI

To update the description of an approval rule template

The following update-approval-rule-template-description example changes the description of the specified approval rule template to Requires 1 approval for all pull requests from the CodeCommitReview pool:

```
aws codecommit update-approval-rule-template-description \
  --approval-rule-template-name 1-approver-rule-for-all-pull-requests \
```
Output:

```json
{
   "approvalRuleTemplate": {
      "creationDate": 1571352720.773,
      "approvalRuleTemplateDescription": "Requires 1 approval for all pull requests from the CodeCommitReview pool",
      "lastModifiedDate": 1571358728.41,
      "approvalRuleTemplateId": "41de97b7-EXAMPLE",
      "approvalRuleTemplateContent": "{"Version": "2018-11-08","Statements": [{"Type": "Approvers","NumberOfApprovalsNeeded": 1,"ApprovalPoolMembers": ["arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*"]}], "approvalRuleTemplateName": "1-approver-rule-for-all-pull-requests",
      "ruleContentSha256": "2f6c21a5EXAMPLE",
      "lastModifiedUser": "arn:aws:iam::123456789012:user/Li_Juan"
   }
}
```

For more information, see [Manage Approval Rule Templates](https://docs.aws.amazon.com/codecommit/latest/userguide) in the *AWS CodeCommit User Guide*.

- For API details, see [UpdateApprovalRuleTemplateDescription](https://docs.aws.amazon.com/codecommit/latest/APIReference/API_UpdateApprovalRuleTemplateDescription.html) in *AWS CLI Command Reference*.

**update-approval-rule-template-name**

The following code example shows how to use `update-approval-rule-template-name`.

**AWS CLI**

To update the name of an approval rule template

The following `update-approval-rule-template-name` example changes the name of an approval rule template from `1-approver-rule` to `1-approver-rule-for-all-pull-requests`.

```bash
aws codecommit update-approval-rule-template-name \
   --old-approval-rule-template-name 1-approver-rule \
   --new-approval-rule-template-name 1-approver-rule-for-all-pull-requests
```

Output:
For more information, see Manage Approval Rule Templates in the AWS CodeCommit User Guide.

- For API details, see UpdateApprovalRuleTemplateName in AWS CLI Command Reference.

## update-comment

The following code example shows how to use update-comment.

### AWS CLI

**To update a comment on a commit**

This example demonstrates how to add the content "Fixed as requested. I'll update the pull request." to a comment with an ID of 442b498bEXAMPLE5756813.

```
aws codecommit update-comment
  --comment-id 442b498bEXAMPLE5756813
  --content "Fixed as requested. I'll update the pull request."
```

**Output:**

```
{
  "comment": {
    "authorArn": "arn:aws:iam::111111111111:user/Li_Juan",
    "clientRequestToken": "",
    "message": "Fixed as requested. I'll update the pull request."
  }
}
```
• For API details, see [UpdateComment](#) in *AWS CLI Command Reference*.

**update-default-branch**

The following code example shows how to use `update-default-branch`.

**AWS CLI**

**To change the default branch for a repository**

This example changes the default branch for an AWS CodeCommit repository. This command produces output only if there are errors.

Command:

```bash
aws codecommit update-default-branch --repository-name MyDemoRepo --default-branch-name MyNewBranch
```

Output:

None.

• For API details, see [UpdateDefaultBranch](#) in *AWS CLI Command Reference*.

**update-pull-request-approval-rule-content**

The following code example shows how to use `update-pull-request-approval-rule-content`.

Actions and scenarios
AWS CLI

To edit an approval rule for a pull request

The following update-pull-request-approval-rule-content example updates she specified approval rule to require one user approval from an approval pool that includes any IAM user in the 123456789012 AWS account.

```bash
aws codecommit update-pull-request-approval-rule-content \
    --pull-request-id 27 \ 
    --approval-rule-name "Require two approved approvers" \ 
    --approval-rule-content "{Version: 2018-11-08, Statements: 
    [{Type: "Approvers", NumberOfApprovalsNeeded: 1, ApprovalPoolMembers: 
    ["CodeCommitApprovers:123456789012:user/*"]}]"
```

Output:

```json
{
   "approvalRule": {
    "approvalRuleContent": "{Version: 2018-11-08, Statements: 
    [{Type: "Approvers", NumberOfApprovalsNeeded: 1, ApprovalPoolMembers:

update-pull-request-approval-state

The following code example shows how to use update-pull-request-approval-state.

AWS CLI

To approve or revoke approval for a pull request
The following `update-pull-request-approval-state` example approves a pull request with the ID of 27 and a revision ID of 9f29d167EXAMPLE. If you wanted to revoke approval instead, then set the `--approval-state` parameter value to `REVOKE`.

```bash
aws codecommit update-pull-request-approval-state \
   --pull-request-id 27 \
   --revision-id 9f29d167EXAMPLE \
   --approval-state "APPROVE"
```

This command produces no output.

For more information, see [Review a Pull Request](https://docs.aws.amazon.com/codecommit/latest/userguide/pull-requests.html) in the AWS CodeCommit User Guide.

### update-pull-request-description

The following code example shows how to use `update-pull-request-description`.

**AWS CLI**

**To change the description of a pull request**

This example demonstrates how to change the description of a pull request with the ID of 47.

```bash
aws codecommit update-pull-request-description \
   --pull-request-id 47 \
   --description "Updated the pull request to remove unused global variable."
```

Output:

```json
{
   "pullRequest": {
       "authorArn": "arn:aws:iam::111111111111:user/Li_Juan",
       "clientRequestToken": "",

"sourceReference": "refs/heads/variables-branch"
},
"title": "Consolidation of global variables"
}

- For API details, see [UpdatePullRequestDescription](#) in *AWS CLI Command Reference*.

### update-pull-request-status

The following code example shows how to use `update-pull-request-status`.

**AWS CLI**

**To change the status of a pull request**

This example demonstrates how to change the status of a pull request with the ID of 42 to a status of CLOSED in an AWS CodeCommit repository named MyDemoRepo.

```bash
aws codecommit update-pull-request-status \
   --pull-request-id 42 \
   --pull-request-status CLOSED
```

**Output:**

```
{
   "pullRequest": {
      "approvalRules": [
      {
         "approvalRuleContent": "{"Version": "2018-11-08"},"Statements": [{"Type": "Approvers","NumberOfApprovalsNeeded": 2,"ApprovalPoolMembers": ["arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*"]}],"approvalRuleId": "dd8b17fe-EXAMPLE",
         "approvalRuleName": "2-approvers-needed-for-this-change",
         "creationDate": 1571356106.936,
```
For API details, see UpdatePullRequestStatus in AWS CLI Command Reference.

update-pull-request-title

The following code example shows how to use update-pull-request-title.

AWS CLI

To change the title of a pull request

This example demonstrates how to change the title of a pull request with the ID of 47.

```bash
aws codecommit update-pull-request-title \
--pull-request-id 47 \
--title "Consolidation of global variables - updated review"
```
Output:

```json
{
    "pullRequest": {
        "approvalRules": [
            {
                "approvalRuleContent": "{"Version": "2018-11-08",

        "title": "Consolidation of global variables - updated review"
    }
}
```
update-repository-description

The following code example shows how to use update-repository-description.

AWS CLI

To change the description for a repository

This example changes the description for an AWS CodeCommit repository. This command produces output only if there are errors.

Command:

```bash
aws codecommit update-repository-description --repository-name MyDemoRepo --repository-description "This description was changed"
```

Output:

None.

For API details, see UpdateRepositoryDescription in AWS CLI Command Reference.

update-repository-name

The following code example shows how to use update-repository-name.

AWS CLI

To change the name of a repository

This example changes the name of an AWS CodeCommit repository. This command produces output only if there are errors. Changing the name of the AWS CodeCommit repository will change the SSH and HTTPS URLs that users need to connect to the repository. Users will not be able to connect to this repository until they update their connection settings. Also, because the repository's ARN will change, changing the repository name will invalidate any IAM user policies that rely on this repository's ARN.
Command:

```bash
aws codecommit update-repository-name --old-name MyDemoRepo --new-name MyRenamedDemoRepo
```

Output:

```
None.
```

- For API details, see [UpdateRepositoryName](#) in *AWS CLI Command Reference*.

## CodeDeploy examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with CodeDeploy.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**add-tags-to-on-premises-instances**

The following code example shows how to use `add-tags-to-on-premises-instances`.

### AWS CLI

**To add tags to on-premises instances**
The following `add-tags-to-on-premises-instances` example associates in AWS CodeDeploy the same on-premises instance tag to two on-premises instances. It does not register the on-premises instances with AWS CodeDeploy.

```bash
aws deploy add-tags-to-on-premises-instances \
    --instance-names AssetTag12010298EX AssetTag23121309EX \
    --tags Key=Name,Value=CodeDeployDemo-OnPrem
```

This command produces no output.

- For API details, see [AddToOnPremisesInstances](https://docs.aws.amazon.com/cli/latest/reference/deploy/add-tags-to-on-premises-instances.html) in *AWS CLI Command Reference*.

**batch-get-application-revisions**

The following code example shows how to use `batch-get-application-revisions`.

**AWS CLI**

To retrieve information about application revisions

The following `batch-get-application-revisions` example retrieves information about the specified revision stored in a GitHub repository.

```bash
aws deploy batch-get-application-revisions \
    --application-name my-codedeploy-application \
    --revisions "[{"gitHubLocation": {"commitId": "fa85936EXAMPLEa31736c051f10d77297EXAMPLE","repository": "my-github-token/my-repository"},"revisionType": "GitHub"}]
```

Output:

```

}
```
For more information, see BatchGetApplicationRevisions in the AWS CodeDeploy API Reference.

- For API details, see BatchGetApplicationRevisions in AWS CLI Command Reference.

**batch-get-applications**

The following code example shows how to use batch-get-applications.

**AWS CLI**

**To get information about multiple applications**

The following batch-get-applications example displays information about multiple applications that are associated with the user's AWS account.

```bash
aws deploy batch-get-applications --application-names WordPress_App MyOther_App
```

**Output:**

```json
{

**batch-get-deployment-groups**

The following code example shows how to use `batch-get-deployment-groups`.

**AWS CLI**

To retrieve information about one or more deployment groups

The following `batch-get-deployment-groups` example retrieves information about two of the deployment groups that are associated with the specified CodeDeploy application.

```bash

**batch-get-deployment-targets**

The following code example shows how to use `batch-get-deployment-targets`.

**AWS CLI**

**To retrieve the targets associated with a deployment**

The following `batch-get-deployment-targets` example returns information about one of the targets associated with the specified deployment.

```bash
aws deploy batch-get-deployment-targets \
  --deployment-id "d-1A2B3C4D5" \
  --target-ids "i-01a2b3c4d5e6f1111"

**batch-get-on-premises-instances**

The following code example shows how to use `batch-get-on-premises-instances`.

**AWS CLI**

**To get information about one or more on-premises instances**

The following `batch-get-on-premises-instances` example gets information about two on-premises instances.

```
aws deploy batch-get-on-premises-instances --instance-names AssetTag12010298EX
                                          AssetTag23121309EX
```

**Output:**

         ],
         "instanceName": "AssetTag23121309EX",
         "registerTime": 1425595585.988,
```

```
For API details, see BatchGetOnPremisesInstances in AWS CLI Command Reference.

**continue-deployment**

The following code example shows how to use continue-deployment.

**AWS CLI**

To start rerouting traffic without waiting for a specified wait time to elapse.

The following continue-deployment example starts rerouting traffic from instances in the original environment that are ready to start shifting traffic to instances in the replacement environment.

```bash
aws deploy continue-deployment \
    --deployment-id "d-A1B2C3111" \
    --deployment-wait-type "READY_WAIT"
```

This command produces no output.

For more information, see ContinueDeployment in the AWS CodeDeploy API Reference.

For API details, see ContinueDeployment in AWS CLI Command Reference.

**create-application**

The following code example shows how to use create-application.

**AWS CLI**

To create an application

The following create-application example creates an application and associates it with the user's AWS account.

```bash
aws deploy create-application --application-name MyOther_App
```
create-deployment-config

The following code example shows how to use create-deployment-config.

AWS CLI

To create a custom deployment configuration

The following create-deployment-config example creates a custom deployment configuration and associates it with the user's AWS account.

```
aws deploy create-deployment-config \
   --deployment-config-name ThreeQuartersHealthy \
   --minimum-healthy-hosts type=FLEET_PERCENT,value=75
```

Output:

```
{
   "deploymentConfigId": "a1b2c3d4-5678-90ab-cdef-1111EXAMPLE"
}
```

For API details, see CreateDeploymentConfig in AWS CLI Command Reference.

create-deployment-group

The following code example shows how to use create-deployment-group.

AWS CLI

To create a deployment group

The following create-deployment-group example creates a deployment group and associates it with the specified application and the user's AWS account.
aws deploy create-deployment-group \
  --application-name WordPress_App \
  --auto-scaling-groups CodeDeployDemo-ASG \
  --deployment-config-name CodeDeployDefault.OneAtATime \
  --deployment-group-name WordPress_DG \
  --ec2-tag-filters Key=Name,Value=CodeDeployDemo,Type=KEY_AND_VALUE \
  --service-role-arn arn:aws:iam::123456789012:role/CodeDeployDemoRole

Output:

{  
  "deploymentGroupId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE"
}

- For API details, see CreateDeploymentGroup in AWS CLI Command Reference.

create-deployment

The following code example shows how to use create-deployment.

AWS CLI

Example 1: To create a CodeDeploy deployment using the EC2/On-premises compute platform

The following create-deployment example creates a deployment and associates it with the user's AWS account.

aws deploy create-deployment \
  --application-name WordPress_App \
  --deployment-config-name CodeDeployDefault.OneAtATime \
  --deployment-group-name WordPress_DG \
  --description "My demo deployment" \
  --s3-location bucket=CodeDeployDemoBucket,bundleType=zip,eTag=dd56cfdEXAMPLE8e768f9d77fEXAMPLE,key=WordPressApp.zip

Output:

{  
  "deploymentId": "d-A1B2C3111"  
}
Example 2: To create a CodeDeploy deployment using the Amazon ECS compute platform

The following create-deployment example uses the following two files to deploy an Amazon ECS service.

Contents of create-deployment.json file:

```
{
    "applicationName": "ecs-deployment",
    "deploymentGroupName": "ecs-deployment-dg",
    "revision": {
        "revisionType": "S3",
        "s3Location": {
            "bucket": "ecs-deployment-bucket",
            "key": "appspec.yaml",
            "bundleType": "YAML"
        }
    }
}
```

That file, in turn, retrieves the following file appspec.yaml from an S3 bucket called ecs-deployment-bucket.

```
version: 0.0
Resources:
- TargetService:
  Type: AWS::ECS::Service
  Properties:
    LoadBalancerInfo:
      ContainerName: "sample-app"
      ContainerPort: 80
      PlatformVersion: "LATEST"
```

Command:

```
aws deploy create-deployment \
  --cli-input-json file://create-deployment.json \
```
Output:

```
{
   "deploymentId": "d-1234ABCDE"
}
```

For more information, see `CreateDeployment` in the *AWS CodeDeploy API Reference*.

- For API details, see `CreateDeployment` in *AWS CLI Command Reference*.

`delete-application`

The following code example shows how to use `delete-application`.

**AWS CLI**

**To delete an application**

The following `delete-application` example deletes the specified application that is associated with the user's AWS account.

```
aws deploy delete-application --application-name WordPress_App
```

This command produces no output.

- For API details, see `DeleteApplication` in *AWS CLI Command Reference*.

`delete-deployment-config`

The following code example shows how to use `delete-deployment-config`.

**AWS CLI**

**To delete a deployment configuration**

The following `delete-deployment-config` example deletes a custom deployment configuration that is associated with the user's AWS account.

```
aws deploy delete-deployment-config --deployment-config-name ThreeQuartersHealthy
```
This command produces no output.

• For API details, see DeleteDeploymentConfig in AWS CLI Command Reference.

delete-deployment-group

The following code example shows how to use delete-deployment-group.

AWS CLI

To delete a deployment group

The following delete-deployment-group example deletes a deployment group that is associated with the specified application.

```
aws deploy delete-deployment-group \
   --application-name WordPress_App \
   --deployment-group-name WordPress_DG
```

Output:

```
{
   "hooksNotCleanedUp": []
}
```

• For API details, see DeleteDeploymentGroup in AWS CLI Command Reference.

delete-git-hub-account-token

The following code example shows how to use delete-git-hub-account-token.

AWS CLI

To delete a GitHub account connection

The following delete-git-hub-account-token example deletes the connection of the specified GitHub account.

```
aws deploy delete-git-hub-account-token --token-name my-github-account
```

Output:
For more information, see [DeleteGitHubAccountToken](#) in the *AWS CodeDeploy API Reference*.  
- For API details, see [DeleteGitHubAccountToken](#) in *AWS CLI Command Reference*.

**deregister-on-premises-instance**

The following code example shows how to use `deregister-on-premises-instance`.

**AWS CLI**

**To deregister an on-premises instance**

The following `deregister-on-premises-instance` example deregisters an on-premises instance with AWS CodeDeploy, but it does not delete the IAM user associated with the instance, nor does it disassociate in AWS CodeDeploy the on-premises instance tags from the instance. It also does not uninstall the AWS CodeDeploy Agent from the instance nor remove the on-premises configuration file from the instance.

```bash
aws deploy deregister-on-premises-instance --instance-name AssetTag12010298EX
```

This command produces no output.

- For API details, see [DeregisterOnPremisesInstance](#) in *AWS CLI Command Reference*.

**deregister**

The following code example shows how to use `deregister`.

**AWS CLI**

**To deregister an on-premises instance**

The following `deregister` example deregisters an on-premises instance with AWS CodeDeploy. It does not delete the IAM user that is associated with the instance. It disassociates in AWS CodeDeploy the on-premises tags from the instance. It does not uninstall the AWS CodeDeploy Agent from the instance nor remove the on-premises configuration file from the instance.
aws deploy deregister \
    --instance-name AssetTag12010298EX \
    --no-delete-iam-user \
    --region us-west-2

Output:

Retrieving on-premises instance information... DONE
IamUserArn: arn:aws:iam::80398EXAMPLE:user/AWS/CodeDeploy/AssetTag12010298EX
Tags: Key=Name,Value=CodeDeployDemo-OnPrem
Removing tags from the on-premises instance... DONE
Deregistering the on-premises instance... DONE
Run the following command on the on-premises instance to uninstall the codedeploy-agent:
aws deploy uninstall

• For API details, see Deregister in AWS CLI Command Reference.

get-application-revision

The following code example shows how to use get-application-revision.

AWS CLI

To get information about an application revision

The following get-application-revision example displays information about an application revision that is associated with the specified application.

aws deploy get-application-revision \ 
    --application-name WordPress_App \ 
    --s3-location \ 
    bucket=CodeDeployDemoBucket,bundleType=zip,eTag=dd56cfdEXAMPLE8e768f9d77fEXAMPLE,key=WordPressApp.zip

Output:

{
    "applicationName": "WordPress_App",
    "revisionInfo": {
        "description": "Application revision registered by Deployment ID: d-A1B2C3111",
    ...
    }
For API details, see [GetApplicationRevision](https://docs.aws.amazon.com/cli/latest/reference/deploy/get-application.html) in *AWS CLI Command Reference*.

**get-application**

The following code example shows how to use `get-application`.

**AWS CLI**

**To get information about an application**

The following `get-application` example displays information about an application that is associated with the user’s AWS account.

```
aws deploy get-application --application-name WordPress_App
```

Output:

```
{
    "application": {
        "applicationName": "WordPress_App",
        "applicationId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
        "createTime": 1407878168.078,
        "linkedToGitHub": false
    }
}
```
get-deployment-config

The following code example shows how to use get-deployment-config.

**AWS CLI**

**To get information about a deployment configuration**

The following get-deployment-config example displays information about a deployment configuration that is associated with the user's AWS account.

```bash
aws deploy get-deployment-config --deployment-config-name ThreeQuartersHealthy
```

Output:

```json
{
   "deploymentConfigInfo": {
      "deploymentConfigId": "a1b2c3d4-5678-90ab-cdef-111111EXAMPLE",
      "minimumHealthyHosts": {
         "type": "FLEET_PERCENT",

      },
      "createTime": 1411081164.379,
      "deploymentConfigName": "ThreeQuartersHealthy"
   }
}
```

- For API details, see [GetDeploymentConfig](https://docs.aws.amazon.com/cli/latest/reference/deploy/get-deployment-config.html) in *AWS CLI Command Reference*.

get-deployment-group

The following code example shows how to use get-deployment-group.

**AWS CLI**

**To view information about a deployment group**

The following get-deployment-group example displays information about a deployment group that is associated with the specified application.
aws deploy get-deployment-group \
   --application-name WordPress_App \
   --deployment-group-name WordPress_DG

Output:

```json
{
   "deploymentGroupInfo": {
      "applicationName": "WordPress_App",
      "autoScalingGroups": ["CodeDeployDemo-ASG"],
      "deploymentConfigName": "CodeDeployDefault.OneAtATime",

         }
      ],
      "deploymentGroupId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
      "serviceRoleArn": "arn:aws:iam::123456789012:role/CodeDeployDemoRole",
      "deploymentGroupName": "WordPress_DG"
   }
}
```

- For API details, see [GetDeploymentGroup](#) in *AWS CLI Command Reference*.

**get-deployment-instance**

The following code example shows how to use `get-deployment-instance`.

**AWS CLI**

**To get information about a deployment instance**

The following `get-deployment-instance` example displays information about a deployment instance that is associated with the specified deployment.

```
aws deploy get-deployment-instance --deployment-id d-QA4G4F9EX --instance-id i-902e9fEX
```
Output:

```json

```
**get-deployment-target**

The following code example shows how to use `get-deployment-target`.

**AWS CLI**

To return information about a deployment target

The following `get-deployment-target` example returns information about a deployment target that is associated with the specified deployment.

```bash
aws deploy get-deployment-target \

**get-deployment**

The following code example shows how to use `get-deployment`.

**AWS CLI**

**To get information about a deployment**

The following `get-deployment` example displays information about a deployment that is associated with the user's AWS account.

```bash
aws deploy get-deployment --deployment-id d-A1B2C3123
```

**Output:**

```json
{
    "deploymentInfo": {
        "applicationName": "WordPress_App",
        "status": "Succeeded",
        "deploymentOverview": {

        "deploymentGroupName": "WordPress_DG"
    }
}
```
get-on-premises-instance

The following code example shows how to use `get-on-premises-instance`.

**AWS CLI**

To get information about an on-premises instance

The following `get-on-premises-instance` example retrieves information about the specified on-premises instance.

```bash
aws deploy get-on-premises-instance --instance-name AssetTag12010298EX
```

Output:

```
{
  "instanceInfo": {
    "iamUserArn": "arn:aws:iam::123456789012:user/AWS/CodeDeploy/AssetTag12010298EX",

        "Key": "Name"
      }
    ],
    "instanceName": "AssetTag12010298EX",
    "registerTime": 1425579465.228,
    "instanceArn": "arn:aws:codedeploy:us-east-1:123456789012:instance/AssetTag12010298EX_4IwLNI2Alh"
  }
}
```

For API details, see [GetOnPremisesInstance](#) in *AWS CLI Command Reference*.
install

The following code example shows how to use install.

AWS CLI

To install an on-premises instance

The following install example copies the on-premises configuration file from the specified location on the instance to the location on the instance that the AWS CodeDeploy Agent expects to find it. It also installs the AWS CodeDeploy Agent on the instance. It does not create any IAM user, nor register the on-premises instance with AWS CodeDeploy, nor associate any on-premises instance tags in AWS CodeDeploy for the instance.

```
aws deploy install \
  --override-config \
  --config-file C:\temp\codedeploy.onpremises.yml \
  --region us-west-2 \
  --agent-installer s3://aws-codedeploy-us-west-2/latest/codedeploy-agent.msi
```

Output:

```
Creating the on-premises instance configuration file... DONE
Installing the AWS CodeDeploy Agent... DONE
```

- For API details, see Install in AWS CLI Command Reference.

list-application-revisions

The following code example shows how to use list-application-revisions.

AWS CLI

To get information about application revisions

The following list-application-revisions example displays information about all application revisions that are associated with the specified application.

```
aws deploy list-application-revisions \
  --application-name WordPress_App \
  --s3-bucket CodeDeployDemoBucket \
```
--deployed exclude \n--s-3-key-prefix WordPress_ \n--sort-by lastUsedTime \n--sort-order descending

Output:

```json
{
   "revisions": [{
      "revisionType": "S3",
      "s3Location": {
         "version": "uTecLusvCB_JqHFXtfUcyfV8bEXAMPLE",
         "bucket": "CodeDeployDemoBucket",
         "key": "WordPress_App.zip",
         "bundleType": "zip"
      }
   }, {
      "revisionType": "S3",
      "s3Location": {
         "version": "tMk.UxgDpMEVb7V187ZM6wVAWEXAMPLE",
         "bucket": "CodeDeployDemoBucket",
         "key": "WordPress_App_2-0.zip",
         "bundleType": "zip"
      }
   }]
}
```

- For API details, see [ListApplicationRevisions](#) in *AWS CLI Command Reference*.

### list-applications

The following code example shows how to use `list-applications`.

**AWS CLI**

#### To get information about applications

The following `list-applications` example displays information about all applications that are associated with the user's AWS account.
aws deploy list-applications

Output:

```json
{
   "applications": [
      "WordPress_App",
      "MyOther_App"
   ]
}
```

- For API details, see `ListApplications` in *AWS CLI Command Reference*.

**list-deployment-configs**

The following code example shows how to use `list-deployment-configs`.

**AWS CLI**

**To get information about deployment configurations**

The following `list-deployment-configs` example displays information about all deployment configurations that are associated with the user's AWS account.

aws deploy list-deployment-configs

Output:

```json
{
   "deploymentConfigsList": [
      "ThreeQuartersHealthy",
      "CodeDeployDefault.AllAtOnce",
      "CodeDeployDefault.HalfAtATime",
      "CodeDeployDefault.OneAtATime"
   ]
}
```

- For API details, see `ListDeploymentConfigs` in *AWS CLI Command Reference*. 

Actions and scenarios
list-deployment-groups

The following code example shows how to use list-deployment-groups.

AWS CLI

To get information about deployment groups

The following list-deployment-groups example displays information about all deployment groups that are associated with the specified application.

```
aws deploy list-deployment-groups --application-name WordPress_App
```

Output:

```
{
    "applicationName": "WordPress_App",
    "deploymentGroups": [
        "WordPress_DG",
        "WordPress_Beta_DG"
    ]
}
```

- For API details, see ListDeploymentGroups in AWS CLI Command Reference.

list-deployment-instances

The following code example shows how to use list-deployment-instances.

AWS CLI

To get information about deployment instances

The following list-deployment-instances example displays information about all deployment instances that are associated with the specified deployment.

```
aws deploy list-deployment-instances \
    --deployment-id d-A1B2C3111 \
    --instance-status-filter Succeeded
```

Output:
For API details, see ListDeploymentInstances in AWS CLI Command Reference.

list-deployment-targets

The following code example shows how to use list-deployment-targets.

AWS CLI

To retrieve a list of target IDs that are associated with a deployment

The following list-deployment-targets example retrieves a list of target IDs associated with deployments that have a status of "Failed" or "InProgress."

```
aws deploy list-deployment-targets \
    --deployment-id "d-A1B2C3111" \
    --target-filters "{"TargetStatus":["Failed","InProgress"]}"
```

Output:

```
{
    "targetIds": [ 
        "i-0f1558aaf90e5f1f9"
    ]
}
```

For more information, see ListDeploymentTargets in the AWS CodeDeploy API Reference.

For API details, see ListDeploymentTargets in AWS CLI Command Reference.

list-deployments

The following code example shows how to use list-deployments.
AWS CLI

To get information about deployments

The following `list-deployments` example displays information about all deployments that are associated with the specified application and deployment group.

```bash
aws deploy list-deployments \
   --application-name WordPress_App \
   --create-time-range start=2014-08-19T00:00:00,end=2014-08-20T00:00:00 \
   --deployment-group-name WordPress_DG \
   --include-only-statuses Failed
```

Output:

```json
{
   "deployments": [
      "d-EXAMPLE11",
      "d-EXAMPLE22",
      "d-EXAMPLE33"
   ]
}
```

- For API details, see [ListDeployments](#) in *AWS CLI Command Reference*.

**list-git-hub-account-token-names**

The following code example shows how to use `list-git-hub-account-token-names`.

**AWS CLI**

To lists the names of stored connections to GitHub accounts

The following `list-git-hub-account-token-names` example lists the names of the stored connections to GitHub accounts for the current AWS user.

```bash
aws deploy list-git-hub-account-token-names
```

Output:

```json
{
}
```
For more information, see ListGitHubAccountTokenNames in the AWS CodeDeploy API Reference.

- For API details, see ListGitHubAccountTokenNames in AWS CLI Command Reference.

**list-on-premises-instances**

The following code example shows how to use list-on-premises-instances.

**AWS CLI**

To get information about one or more on-premises instances

The following list-on-premises-instances example retrieves a list of available on-premises instance names for instances that are registered in AWS CodeDeploy and also have the specified on-premises instance tag associated in AWS CodeDeploy with the instance.

```
aws deploy list-on-premises-instances \
  --registration-status Registered \
  --tag-filters Key=Name,Value=CodeDeployDemo-OnPrem,Type=KEY_AND_VALUE
```

Output:

```
{
   "instanceNames": [
      "AssetTag12010298EX"
   ]
}
```

- For API details, see ListOnPremisesInstances in AWS CLI Command Reference.

**list-tags-for-resource**

The following code example shows how to use list-tags-for-resource.
AWS CLI

To list tags for a resource (application)

The following list-tags-for-resource example lists the tags applied to an application named testApp in CodeDeploy.

```bash
aws deploy list-tags-for-resource \
```

Output:

```
{
   "Tags": [
   {
      "Key": "Type",
      "Value": "testType"
   },
   {
      "Key": "Name",
      "Value": "testName"
   }
   ]
}
```

For more information, see Tagging instances for deployment groups in CodeDeploy in the AWS CodeDeploy User Guide.

- For API details, see ListTagsForResource in AWS CLI Command Reference.

push

The following code example shows how to use push.

AWS CLI

To bundle and deploy an AWS CodeDeploy compatible application revision to Amazon S3

The following push example bundles and deploys an application revision to Amazon S3 and then associates the application revision with the specified application.

```bash
aws deploy push \
```
The output describes how to use the `create-deployment` command to create a deployment that uses the uploaded application revision.

To deploy with this revision, run:

```bash
aws deploy create-deployment --application-name WordPress_App
   --deployment-config-name <deployment-config-name> --
   deployment-group-name <deployment-group-name> --s3-location
   bucket=CodeDeployDemoBucket,key=WordPressApp.zip,bundleType=zip,eTag="cecc9b8a08eac650a6e71fdb88EXAMPLE50a6e71fdb88EXAMPLE",version=LFsJAUdEXAMPLEfvKtvi79L8EXAMPLE
```

- For API details, see `Push` in *AWS CLI Command Reference*.

**register-application-revision**

The following code example shows how to use `register-application-revision`.

**AWS CLI**

To register information about an already-uploaded application revision

The following `register-application-revision` example registers information about an already-uploaded application revision stored in Amazon S3 with AWS CodeDeploy.

```bash
aws deploy register-application-revision
   --application-name WordPress_App
   --description "Revised WordPress application"
   --s3-location
   bucket=CodeDeployDemoBucket,key=RevisedWordPressApp.zip,bundleType=zip,eTag="cecc9b8a08eac650a6e71fdb88EXAMPLE50a6e71fdb88EXAMPLE"
```

This command produces no output.

- For API details, see `RegisterApplicationRevision` in *AWS CLI Command Reference*.

**register-on-premises-instance**

The following code example shows how to use `register-on-premises-instance`.
AWS CLI

To register an on-premises instance

The following register-on-premises-instance example registers an on-premises instance with AWS CodeDeploy. It does not create the specified IAM user, nor does it associate in AWS CodeDeploy any on-premises instances tags with the registered instance.

```
aws deploy register-on-premises-instance \
  --instance-name AssetTag12010298EX \
```

This command produces no output.

- For API details, see RegisterOnPremisesInstance in AWS CLI Command Reference.

register

The following code example shows how to use register.

AWS CLI

To register an on-premises instance

The following register example registers an on-premises instance with AWS CodeDeploy, associates in AWS CodeDeploy the specified on-premises instance tag with the registered instance, and creates an on-premises configuration file that can be copied to the instance. It does not create the IAM user, nor does it install the AWS CodeDeploy Agent on the instance.

```
aws deploy register \
  --instance-name AssetTag12010298EX \
  --iam-user-arn arn:aws:iam::80398EXAMPLE:user/CodeDeployUser-OnPrem \
  --tags Key=Name,Value=CodeDeployDemo-OnPrem \
  --region us-west-2
```

Output:

Registering the on-premises instance... DONE
Adding tags to the on-premises instance... DONE
Copy the on-premises configuration file named codedeploy.onpremises.yml to the on-premises instance, and run the following command on the on-premises instance to install and configure the AWS CodeDeploy Agent:
aws deploy install --config-file codedeploy.onpremises.yml

- For API details, see Register in AWS CLI Command Reference.

**remove-tags-from-on-premises-instances**

The following code example shows how to use `remove-tags-from-on-premises-instances`.

**AWS CLI**

**To remove tags from one or more on-premises instances**

The following `remove-tags-from-on-premises-instances` example disassociates the specified on-premises tags in AWS CodeDeploy from on-premises instances. It does not deregister the on-premises instances in AWS CodeDeploy, nor uninstall the AWS CodeDeploy Agent from the instance, nor remove the on-premises configuration file from the instances, nor delete the IAM users that are associated with the instances.

```
aws deploy remove-tags-from-on-premises-instances \
    --instance-names AssetTag12010298EX AssetTag23121309EX \
    --tags Key=Name,Value=CodeDeployDemo-OnPrem
```

This command produces no output.

- For API details, see RemoveTagsFromOnPremisesInstances in AWS CLI Command Reference.

**stop-deployment**

The following code example shows how to use `stop-deployment`.

**AWS CLI**

**To attempt to stop a deployment**

The following `stop-deployment` example attempts to stop an in-progress deployment that is associated with the user’s AWS account.

```
aws deploy stop-deployment --deployment-id d-A1B2C3111
```

Output:

```
{
```
"status": "Succeeded",
"statusMessage": "No more commands will be scheduled for execution in the
deployment instances"
}

- For API details, see StopDeployment in AWS CLI Command Reference.

tag-resource

The following code example shows how to use tag-resource.

AWS CLI

To tag a resource (application)

The following tag-resource example adds two tags with keys Name and Type, and values
testName and testType to an application named testApp in CodeDeploy:

```bash
aws deploy tag-resource \
--tags Key=Name,Value=testName Key=Type,Value=testType
```

If successful, this command produces no output.

For more information, see Tagging instances for deployment groups in CodeDeploy in the AWS
CodeDeploy User Guide.

- For API details, see TagResource in AWS CLI Command Reference.

uninstall

The following code example shows how to use uninstall.

AWS CLI

To uninstall an on-premises instance

The following uninstall example uninstalls the AWS CodeDeploy Agent from the on-
premises instance and removes the on-premises configuration file from the instance. It doesn’t
deregister the instance in AWS CodeDeploy, nor disassociate any on-premises instance tags
in AWS CodeDeploy from the instance, nor delete the IAM user that is associated with the
instance.
This command produces no output.

- For API details, see **Uninstall** in *AWS CLI Command Reference*.

**untag-resource**

The following code example shows how to use `untag-resource`.

**AWS CLI**

*To remove tags from a resource (application)*

The following `untag-resource` example removes two tags with keys `Name` and `Type` from an application named `testApp` in CodeDeploy.

```
aws deploy untag-resource \\
  --tag-keys Name Type
```

If successful, this command produces no output.

For more information, see **Tagging instances for deployment groups in CodeDeploy** in the *AWS CodeDeploy User Guide*.

- For API details, see **UntagResource** in *AWS CLI Command Reference*.

**update-application**

The following code example shows how to use `update-application`.

**AWS CLI**

*To change details of an application*

The following `update-application` example changes the name of an application that is associated with the user's AWS account.

```
aws deploy update-application \\
  --application-name WordPress_App \\
  --new-application-name My_WordPress_App
```
This command produces no output.

- For API details, see UpdateApplication in AWS CLI Command Reference.

**update-deployment-group**

The following code example shows how to use update-deployment-group.

**AWS CLI**

To change information about a deployment group

The following update-deployment-group example changes the settings of a deployment group that is associated with the specified application.

```bash
aws deploy update-deployment-group \
   --application-name WordPress_App \
   --auto-scaling-groups My_CodeDeployDemo_ASG \
   --current-deployment-group-name WordPress_DG \
   --deployment-config-name CodeDeployDefault.AllAtOnce \
   --ec2-tag-filters Key=Name,Type=KEY_AND_VALUE,Value=My_CodeDeployDemo \
   --new-deployment-group-name My_WordPress_DepGroup \
   --service-role-arn arn:aws:iam::80398EXAMPLE:role/CodeDeployDemo-2
```

This command produces no output.

- For API details, see UpdateDeploymentGroup in AWS CLI Command Reference.

**CodeGuru Reviewer examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with CodeGuru Reviewer.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.
Actions

associate-repository

The following code example shows how to use associate-repository.

AWS CLI

**Example 1: To create a Bitbucket repository association**

The following associate-repository example creates a repository association using an existing Bitbucket repository.

```bash
aws codeguru-reviewer associate-repository \
   --repository 'Bitbucket={Owner=sample-owner, Name=mySampleRepo, \
   ConnectionArn=arn:aws:codestar-connections:us-west-2:123456789012:connection/ \
   a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 }'
```

Output:

```json
{
   "RepositoryAssociation": {
      "ProviderType": "Bitbucket",
      "Name": "mySampleRepo",
      "LastUpdatedTimeStamp": 1596216896.979,
      "AssociationId": "association:a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
      "CreatedTimeStamp": 1596216896.979,
      "ConnectionArn": "arn:aws:codestar-connections:us-west-2:123456789012:connection/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
      "State": "Associating",
      "StateReason": "Pending Repository Association",
      "Owner": "sample-owner"
   }
}
```

For more information, see [Create a Bitbucket repository association in Amazon CodeGuru Reviewer](https://docs.aws.amazon.com/codeguru-reviewer/latest/userguide/repositories-associate.html) in the *Amazon CodeGuru Reviewer User Guide*. 
Example 2: To create a GitHub Enterprise repository association

The following associate-repository example creates a repository association using an existing GitHub Enterprise repository.

```bash
aws codeguru-reviewer associate-repository \
    --repository 'GitHubEnterpriseServer={Owner=sample-owner, Name=mySampleRepo, ConnectionArn=arn:aws:codestar-connections:us-west-2:123456789012:connection/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111}'
```

Output:

```json
{
    "RepositoryAssociation": {
        "ProviderType": "GitHubEnterpriseServer",
        "Name": "mySampleRepo",
        "LastUpdatedTimeStamp": 1596216896.979,
        "AssociationId": "association:a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
        "CreatedTimeStamp": 1596216896.979,
        "ConnectionArn": "arn:aws:codestar-connections:us-west-2:123456789012:connection/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "State": "Associating",
        "StateReason": "Pending Repository Association",
        "Owner": "sample-owner"
    }
}
```

For more information, see Create a GitHub Enterprise Server repository association in Amazon CodeGuru Reviewer in the Amazon Codeguru Reviewer User Guide.

Example 3: To create an AWS CodeCommit repository association

The following associate-repository example creates a repository association using an existing AWS CodeCommit repository.

```bash
aws codeguru-reviewer associate-repository \
    --repository CodeCommit={Name=mySampleRepo}
```

Output:
For more information, see Create an AWS CodeCommit repository association in Amazon CodeGuru Reviewer in the Amazon CodeGuru Reviewer User Guide.

- For API details, see AssociateRepository in AWS CLI Command Reference.

create-code-review

The following code example shows how to use create-code-review.

AWS CLI

To create a code review.

The following create-code-review creates a review of code in the mainline branch of an AWS CodeCommit repository that is named my-repository-name.

```bash
aws codeguru-reviewer create-code-review \
  --name my-code-review \
  --repository-association-arn arn:aws:codeguru-reviewer:us-west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \
  --type '{"RepositoryAnalysis": {"RepositoryHead": {"BranchName": "mainline"}}}'
```

Output:

```json
{
  "CodeReview": {
```
For more information, see Create code reviews in Amazon CodeGuru Reviewer in the Amazon CodeGuru Reviewer User Guide.

- For API details, see CreateCodeReview in AWS CLI Command Reference.

describe-code-review

The following code example shows how to use describe-code-review.

AWS CLI

List details about a code review.

The following describe-code-review lists information about a review of code in the "mainline" branch of an AWS CodeCommit repository that is named "my-repo-name".

```
aws codeguru-reviewer put-recommendation-feedback \
```
--recommendation-id
3be1b2e5d7ef6e298a06499379ee290c9c596cf688fdcadb08285ddb0dd390eb \

}
```

For more information, see [View code review details](https://docs.aws.amazon.com/codeguru-reviewer/latest/userguide) in the [Amazon CodeGuru Reviewer User Guide](https://docs.aws.amazon.com/codeguru-reviewer/latest/userguide).

**describe-recommendation-feedback**

The following code example shows how to use `describe-recommendation-feedback`.

**AWS CLI**

To view information about feedback on a recommendation
The following `describe-recommendation-feedback` displays information about feedback on a recommendation. This recommendation has one ThumbsUp reaction.

```
aws codeguru-reviewer describe-recommendation-feedback \
   --recommendation-id 3be1b2e5d7ef6e298a06499379ee290c9c596cf688fdcadb08285ddb0dd390eb

   }
}
```

For more information, see View recommendations and provide feedback and Step 4: Provide feedback in the Amazon CodeGuru Reviewer User Guide.

- For API details, see DescribeRecommendationFeedback in AWS CLI Command Reference.

**describe-repository-association**

The following code example shows how to use `describe-repository-association`.

**AWS CLI**

**Example 1: To return information about a GitHub repository association**
The following describe-repository-association example returns information about a repository association that uses a GitHub Enterprise repository and is in the Associated state.

```bash
aws codeguru-reviewer describe-repository-association \
```

Output:

```
{
   "RepositoryAssociation": {
      "AssociationId": "b822717e-0711-4e8a-bada-0e738289c75e",

**Example 2: To return information about a failed repository association**

The following describe-repository-association example returns information about a repository association that uses a GitHub Enterprise repository and is in the Failed state.

```bash
aws codeguru-reviewer describe-repository-association \
```

Output:

```
{
   "RepositoryAssociation": {
      "ProviderType": "GitHubEnterpriseServer",

For more information, see Create a GitHub Enterprise Server repository association in Amazon CodeGuru Reviewer in the Amazon CodeGuru Reviewer User Guide.

Example 3: To return information about a disassociating repository association

The following describe-repository-association example returns information about a repository association that uses a GitHub Enterprise repository and is in the Disassociating state.

```
aws codeguru-reviewer describe-repository-association
```

Output:

```
{
  "RepositoryAssociation": {

  }
}
```
For more information, see Create a GitHub Enterprise Server repository association in Amazon CodeGuru Reviewer in the Amazon CodeGuru Reviewer User Guide.

- For API details, see DescribeRepositoryAssociation in AWS CLI Command Reference.

**disassociate-repository**

The following code example shows how to use disassociate-repository.

**AWS CLI**

**To disassociate a repository association**

The following disassociate-repository disassociates a repository association that is using an AWS CodeCommit repository.

```bash
aws codeguru-reviewer disassociate-repository \
```

Output:

```json
{
  "RepositoryAssociation": {
    "AssociationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",

**list-code-reviews**

The following code example shows how to use list-code-reviews.

**AWS CLI**

**To list code reviews created in your AWS account in the last 90 days.**

The following list-code-reviews example lists the code reviews created in the last 90 days using pull requests.

```bash
aws codeguru-reviewer list-code-reviews \

list-recommendation-feedback

The following code example shows how to use `list-recommendation-feedback`.

**AWS CLI**

To list customer recommendation feedback for a recommendation on an associated repository

The following `list-recommendation-feedback` Lists customer feedback on all recommendations on a code review. This code review has one piece of feedback, a "ThumbsUp", from a customer.

```bash
aws codeguru-reviewer list-recommendation-feedback
```

Output:

list-recommendations

The following code example shows how to use `list-recommendations`.
To list the recommendations for a completed code review

The following list-recommendations example lists the recommendations for a completed code review. This code review has one recommendation.

```bash
aws codeguru-reviewer list-recommendations \

**list-repository-associations**

The following code example shows how to use list-repository-associations.
AWS CLI

To list the repository associations in your AWS account

The following list-repository-associations example returns a list of repository association summary objects in your account. You can filter the returned list by ProviderType, Name, State, and Owner.

```bash
aws codeguru-reviewer list-repository-associations
```

Output:

```json

**list-tags-for-resource**

The following code example shows how to use list-tags-for-resource.
**AWS CLI**

**To list the tags on an associated repository**

The following `list-tags-for-resource` lists the tags on an associated repository. This associated repository has two tags.

```
aws codeguru-reviewer list-tags-for-resource \
```

Output:

```
{
   "Tags": {
      "Status": "Secret",
      "Team": "Saanvi"
   }
}
```

For more information, see [View tags for a CodeGuru Reviewer associated repository (AWS CLI)](https://docs.aws.amazon.com/codeguru-reviewer/latest/userguide/aws-cli-list-tags-for-resource.html) in the *Amazon CodeGuru Reviewer User Guide*.

**put-recommendation-feedback**

The following code example shows how to use `put-recommendation-feedback`.

**AWS CLI**

**To add a recommendation to a code review**

The following `put-recommendation-feedback` puts a ThumbsUp recommendation on a code review.

```
aws codeguru-reviewer put-recommendation-feedback \
   --recommendation-id 3be1b2e5d7ef6e298a06499379ee290c9c596cf688fdbcdb08285ddb0dd390eb
```
This command produces no output.

For more information, see Step 4: Provide feedback in the Amazon CodeGuru Reviewer User Guide.

- For API details, see PutRecommendationFeedback in AWS CLI Command Reference.

The following code example shows how to use tag-resource.

AWS CLI

To add a tag to an associated repository

The following tag-resource adds two tags to an associated repository

```
aws codeguru-reviewer tag-resource 
  --tags Status=Secret,Team=Saanvi
```

This command produces no output.

For more information, see Add a tag to a CodeGuru Reviewer associated repository (AWS CLI) and Add or update tags for a CodeGuru Reviewer associated repository (AWS CLI) in the Amazon CodeGuru Reviewer User Guide.

- For API details, see TagResource in AWS CLI Command Reference.

The following code example shows how to use untag-resource.

AWS CLI

To untag an associated repository

The following untag-resource removes two tags with keys "Secret" and "Team" from an associated repository.
aws codeguru-reviewer untag-resource \
   --resource-arn arn:aws:codeguru-reviewer:us-west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \
   --tag-keys Status Team

This command produces no output.

For more information, see Remove tags from a CodeGuru Reviewer associated repository (AWS CLI) in the Amazon CodeGuru Reviewer User Guide.

- For API details, see UntagResource in AWS CLI Command Reference.

**CodePipeline examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with CodePipeline.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Actions**

**acknowledge-job**

The following code example shows how to use acknowledge-job.

**AWS CLI**

To retrieve information about a specified job
This example returns information about a specified job, including the status of that job if it exists. This is only used for job workers and custom actions. To determine the value of nonce and the job ID, use `aws codepipeline poll-for-jobs`.

**Command:**

```bash
aws codepipeline acknowledge-job --job-id f4f4ff82-2d11-EXAMPLE --nonce 3
```

**Output:**

```json
{
   "status": "InProgress"
}
```

- For API details, see [AcknowledgeJob](#) in *AWS CLI Command Reference*.

### create-custom-action-type

The following code example shows how to use `create-custom-action-type`.

**AWS CLI**

**To create a custom action**

This example creates a custom action for AWS CodePipeline using an already-created JSON file (here named `MyCustomAction.json`) that contains the structure of the custom action. For more information about the requirements for creating a custom action, including the structure of the file, see the AWS CodePipeline User Guide.

```bash
aws codepipeline create-custom-action-type --cli-input-json file://MyCustomAction.json
```

**Contents of JSON file `MyCustomAction.json`:**

```json
{
   "category": "Build",
   "provider": "MyJenkinsProviderName",
   "version": "1",
   "settings": {
      "entityUrlTemplate": "https://192.0.2.4/job/{Config:ProjectName}/"
   }
}
```
"executionUrlTemplate": "https://192.0.2.4/job/{Config:ProjectName}/lastSuccessfulBuild/{ExternalExecutionId}/",
"configurationProperties": [
{
"name": "MyJenkinsExampleBuildProject",
"required": true,
"key": true,
"secret": false,
"drawable": false,
"queryable": false,
"description": "The name of the build project must be provided when this action is added to the pipeline.",
"type": "String"
}
],
"inputArtifactDetails": {
"maximumCount": 1,
"minimumCount": 0
},
"outputArtifactDetails": {
"maximumCount": 1,
"minimumCount": 0
}
}

This command returns the structure of the custom action.

- For API details, see CreateCustomActionType in AWS CLI Command Reference.

create-pipeline

The following code example shows how to use create-pipeline.

AWS CLI

To create a pipeline

This example creates a pipeline in AWS CodePipeline using an already-created JSON file (here named MySecondPipeline.json) that contains the structure of the pipeline. For more information about the requirements for creating a pipeline, including the structure of the file, see the AWS CodePipeline User Guide.

Command:
aws codepipeline create-pipeline --cli-input-json file://MySecondPipeline.json

JSON file sample contents:

```json
{
    "pipeline": {
        "roleArn": "arn:aws:iam::111111111111:role/AWS-CodePipeline-Service",
        "stages": [
            {
                "name": "Source",
                "actions": [
                    {
                        "inputArtifacts": [],
                        "name": "Source",
                        "actionTypeId": {
                            "category": "Source",
                            "owner": "AWS",
                            "version": "1",
                            "provider": "S3"
                        },
                        "outputArtifacts": [
                            {
                                "name": "MyApp"
                            }
                        ],
                        "configuration": {
                            "S3Bucket": "awscodepipeline-demo-bucket",

                    }
                ]
            }
        ],
        "name": "Beta",
        "actions": [
            {
                "inputArtifacts": [
                    {
                        "name": "MyApp"
                    }
                ],
                "name": "CodePipelineDemoFleet",
                "runOrder": 1
            }
        ]
    }
}
```
Output:

This command returns the structure of the pipeline.

- For API details, see CreatePipeline in AWS CLI Command Reference.

delete-custom-action-type

The following code example shows how to use delete-custom-action-type.

AWS CLI

To delete a custom action

This example deletes a custom action in AWS CodePipeline by using an already-created JSON file (here named DeleteMyCustomAction.json) that contains the action type, provider name,
and version number of the action to be deleted. Use the list-action-types command to view the correct values for category, version, and provider.

Command:

```bash
aws codepipeline delete-custom-action-type --cli-input-json file://DeleteMyCustomAction.json
```

JSON file sample contents:

```json
{
    "category": "Build",
    "version": "1",
    "provider": "MyJenkinsProviderName"
}
```

Output:

None.

- For API details, see [DeleteCustomActionType](https://docs.aws.amazon.com/cli/latest/reference/codepipeline/delete-custom-action-type.html) in *AWS CLI Command Reference*.

### delete-pipeline

The following code example shows how to use `delete-pipeline`.

**AWS CLI**

#### To delete a pipeline

This example deletes a pipeline named `MySecondPipeline` from AWS CodePipeline. Use the list-pipelines command to view a list of pipelines associated with your AWS account.

Command:

```bash
aws codepipeline delete-pipeline --name MySecondPipeline
```

Output:

None.
delete-webhook

The following code example shows how to use delete-webhook.

AWS CLI

To delete a webhook

The following delete-webhook example deletes a webhook for a GitHub version 1 source action. You must use the deregister-webhook-with-third-party command to deregister the webhook before you delete it.

```bash
aws codepipeline delete-webhook
   --name my-webhook
```

This command produces no output.

For more information, see [Delete the webhook for your GitHub source](https://docs.aws.amazon.com/codepipeline/latest/userguide/delete-webhook.html) in the AWS CodePipeline User Guide.

For API details, see [DeleteWebhook](https://docs.aws.amazon.com/cli/latest/api/awscli/commands-codepipeline/delete-webhook.html) in AWS CLI Command Reference.

deregister-webhook-with-third-party

The following code example shows how to use deregister-webhook-with-third-party.

AWS CLI

To deregister a webhook

The following deregister-webhook-with-third-party example deletes a webhook for a GitHub version 1 source action. You must deregister the webhook before you delete it.

```bash
aws codepipeline deregister-webhook-with-third-party
   --webhook-name my-webhook
```

This command produces no output.

For more information, see [Delete the webhook for your GitHub source](https://docs.aws.amazon.com/codepipeline/latest/userguide/delete-webhook.html) in the AWS CodePipeline User Guide.

For API details, see `DeregisterWebhookWithThirdParty` in *AWS CLI Command Reference*.

**disable-stage-transition**

The following code example shows how to use `disable-stage-transition`.

**AWS CLI**

**To disable a transition to a stage in a pipeline**

This example disables transitions into the Beta stage of the MyFirstPipeline pipeline in AWS CodePipeline.

Command:

```bash
aws codepipeline disable-stage-transition --pipeline-name MyFirstPipeline --stage-name Beta --transition-type Inbound
```

Output:

None.

For API details, see `DisableStageTransition` in *AWS CLI Command Reference*.

**enable-stage-transition**

The following code example shows how to use `enable-stage-transition`.

**AWS CLI**

**To enable a transition to a stage in a pipeline**

This example enables transitions into the Beta stage of the MyFirstPipeline pipeline in AWS CodePipeline.

Command:

```bash
aws codepipeline enable-stage-transition --pipeline-name MyFirstPipeline --stage-name Beta --transition-type Inbound
```
The following code example shows how to use `get-job-details`.

**AWS CLI**

**To get details of a job**

This example returns details about a job whose ID is represented by `f4f4ff82-2d11-EXAMPLE`. This command is only used for custom actions. When this command is called, AWS CodePipeline returns temporary credentials for the Amazon S3 bucket used to store artifacts for the pipeline, if required for the custom action. This command will also return any secret values defined for the action, if any are defined.

**Command:**

```bash/aws codepipeline get-job-details --job-id f4f4ff82-2d11-EXAMPLE```

**Output:**

get-pipeline-state

The following code example shows how to use get-pipeline-state.

AWS CLI

To get information about the state of a pipeline

This example returns the most recent state of a pipeline named MyFirstPipeline.

Command:

```bash
aws codepipeline get-pipeline-state --name MyFirstPipeline
```

Output:

```json

**list-action-executions**

The following code example shows how to use list-action-executions.

**AWS CLI**

**To list action executions**

The following list-action-executions example views action execution details for a pipeline, such as action execution ID, input artifacts, output artifacts, execution result, and status.

```
aws codepipeline list-action-executions \\

**list-action-types**

The following code example shows how to use list-action-types.

**AWS CLI**

**To view the action types available**

Used by itself, the list-action-types command returns the structure of all actions available to your AWS account. This example uses the --action-owner-filter option to return only custom actions.

Command:

```
aws codepipeline list-action-types --action-owner-filter Custom
```

Output:

list-pipeline-executions

The following code example shows how to use list-pipeline-executions.

AWS CLI

To view pipeline execution history

The following list-pipeline-executions example shows the pipeline execution history for a pipeline in your AWS account.

```
aws codepipeline list-pipeline-executions \
  --pipeline-name MyPipeline

**list-pipelines**

The following code example shows how to use list-pipelines.

**AWS CLI**

**To view a list of pipelines**

This example lists all AWS CodePipeline pipelines associated with the user's AWS account.

**Command:**

```
aws codepipeline list-pipelines
```

**Output:**

list-tags-for-resource

The following code example shows how to use list-tags-for-resource.

AWS CLI

To list tags

The following list-tags-for-resource example retrieves a list of all tags attached to the specified pipeline resource.

```bash
aws codepipeline list-tags-for-resource \
   --resource-arn arn:aws:codepipeline:us-east-1:123456789012:MyPipeline
```

Output:

```json
{
   "tags": {
      "Project": "ProjectA",
      "IscontainerBased": "true"
   }
}
```

For more information, see View tags for a pipeline (CLI) in the AWS CodePipeline User Guide.

list-webhooks

The following code example shows how to use list-webhooks.

AWS CLI

To list webhooks

The following list-webhooks example retrieves a list of all tags attached to the specified pipeline resource.

```bash
aws codepipeline list-webhooks \
   --endpoint-url "https://codepipeline.eu-central-1.amazonaws.com"
```
--region "eu-central-1"

Output:

**poll-for-jobs**

The following code example shows how to use poll-for-jobs.

**AWS CLI**

**To view any available jobs**

This example returns information about any jobs for a job worker to act upon. This example uses a pre-defined JSON file (MyActionTypeInfo.json) to supply information about the action
type for which the job worker processes jobs. This command is only used for custom actions. When this command is called, AWS CodePipeline returns temporary credentials for the Amazon S3 bucket used to store artifacts for the pipeline. This command will also return any secret values defined for the action, if any are defined.

Command:

```
aws codepipeline poll-for-jobs --cli-input-json file://MyActionTypeInfo.json
```

JSON file sample contents:

```json
{
  "actionTypeId": {
    "category": "Test",
    "owner": "Custom",
    "provider": "MyJenkinsProviderName",
    "version": "1"
  },
  "maxBatchSize": 5,
  "queryParam": {
    "ProjectName": "MyJenkinsTestProject"
  }
}
```

Output:

```json

**put-webhook**

The following code example shows how to use put-webhook.

**AWS CLI**

**To create a webhook**

The following put-webhook example creates a webhook for a GitHub version 1 source action. After you create the webhook, you must use the register-webhook-with-third-party command to register it.

```
aws codepipeline put-webhook \\
   --cli-input-json file://webhook_json.json \\
   --region "eu-central-1"
```

**Contents of webhook_json.json:**

```
{
   "webhook": {
      "name": "my-webhook",
      "targetPipeline": "pipeline_name",
      "targetAction": "source_action_name",

**retry-stage-execution**

The following code example shows how to use `retry-stage-execution`.

**AWS CLI**

**To retry a failed action**

The following `retry-stage-execution` example retries a stage that has a failed action.

```bash
aws codepipeline retry-stage-execution \
```
Output:

```
{
   "pipelineExecutionId": "b59babff-5f34-EXAMPLE"
}

### start-pipeline-execution

The following code example shows how to use `start-pipeline-execution`.

**AWS CLI**

**To run the latest revision through a pipeline**

This example runs the latest revision present in the source stage of a pipeline through the pipeline named "MyFirstPipeline".

Command:

```
aws codepipeline start-pipeline-execution --name MyFirstPipeline
```

Output:

```
{
   "pipelineExecutionId": "3137f7cb-7cf7-EXAMPLE"
}
```

- For API details, see [StartPipelineExecution](https://docs.aws.amazon.com/cli/latest/reference/codepipeline/start-pipeline-execution.html) in *AWS CLI Command Reference*.

**AWS CLI**

**To stop a pipeline execution**

The following `stop-pipeline-execution` example defaults to waiting until in-progress actions finish, and then stops the pipeline. You cannot choose to stop and wait if the execution is already in a Stopping state. You can choose to stop and abandon an execution that is already in a Stopping state.

```bash
aws codepipeline stop-pipeline-execution \
   --pipeline-name MyFirstPipeline \
   --pipeline-execution-id d-EXAMPLE \
   --reason "Stopping pipeline after the build action is done"
```

This command returns no output.

For more information, see [Stop a pipeline execution (CLI)](https://docs.aws.amazon.com/codepipeline/latest/userguide/stop-pipeline-execution-cli.html) in the *AWS CodePipeline User Guide*.

- For API details, see [StopPipelineExecution](https://docs.aws.amazon.com/cli/latest/reference/codepipeline/stop-pipeline-execution.html) in *AWS CLI Command Reference*.

**tag-resource**

The following code example shows how to use `tag-resource`.

**AWS CLI**

**To tag a resource**

The following `tag-resource` example associates a set of provided tags with a pipeline. Use this command to add or edit tags.

```bash
aws codepipeline tag-resource \
   --resource-arn arn:aws:codepipeline:us-east-1:123456789012:MyPipeline \
   --tags key=Project,value=ProjectA key=IscontainerBased,value=true
```

This command produces no output.

For more information, see [Add tags to a pipeline (CLI)](https://docs.aws.amazon.com/codepipeline/latest/userguide/add-tags-to-a-pipeline-cli.html) in the *AWS CodePipeline User Guide*.

- For API details, see [TagResource](https://docs.aws.amazon.com/cli/latest/reference/codepipeline/tag-resource.html) in *AWS CLI Command Reference*. 
untag-resource

The following code example shows how to use untag-resource.

AWS CLI

To remove AWS tags from a connections resource

The following untag-resource example removes a tag from the specified resource.

```
aws codepipeline untag-resource \
   --resource-arn arn:aws:codepipeline:us-east-1:123456789012:MyPipeline \
   --tag-keys Project IscontainerBased
```

This command produces no output.

For more information, see Remove tags from a pipeline (CLI) in the AWS CodePipeline User Guide.

- For API details, see UntagResource in AWS CLI Command Reference.

update-pipeline

The following code example shows how to use update-pipeline.

AWS CLI

To update the structure of a pipeline

This example uses the update-pipeline command with the --cli-input-json argument. This example uses a pre-defined JSON file (MyFirstPipeline.json) to update the structure of a pipeline. AWS CodePipeline recognizes the pipeline name contained in the JSON file, and then applies any changes from modified fields in the pipeline structure to update the pipeline.

Use the following guidelines when creating the pre-defined JSON file:

If you are working with a pipeline structure retrieved using the get-pipeline command, you must remove the metadata section from the pipeline structure in the JSON file (the "metadata": { } lines and the "created," "pipelineARN," and "updated" fields within). The pipeline name cannot be changed.

Command:
aws codepipeline update-pipeline --cli-input-json file://MyFirstPipeline.json

Sample JSON file contents:

```json

Actions

associate-team-member

The following code example shows how to use associate-team-member.

AWS CLI

To add a team member to a project

The following associate-team-member example makes the intern user a viewer on the project with the specified ID.

```bash
aws codestar associate-team-member
```
This command produces no output.

- For API details, see AssociateTeamMember in AWS CLI Command Reference.

**create-project**

The following code example shows how to use `create-project`.

**AWS CLI**

**To create a project**

The following `create-project` example uses a JSON input file to create a CodeStar project.

```bash
aws codestar create-project \
  --cli-input-json file://create-project.json
```

**Contents of `create-project.json`:**

```json
{
  "name": "Custom Project",
  "id": "custom-project",
  "sourceCode": [
    {

create-user-profile

The following code example shows how to use create-user-profile.

AWS CLI

To create a user profile

The following create-user-profile example creates a user profile for the IAM user with the specified ARN.
--email-address intern@example.com

Output:

```
{
    "userArn": "arn:aws:iam::123456789012:user/intern",
    "displayName": "Intern",
    "emailAddress": "intern@example.com",
    "sshPublicKey": "",
    "createdTimestamp": 1572552308.607,
    "lastModifiedTimestamp": 1572552308.607
}
```

- For API details, see CreateUserProfile in AWS CLI Command Reference.

**delete-project**

The following code example shows how to use delete-project.

**AWS CLI**

To delete a project

The following delete-project example deletes the specified project.

```
aws codestar delete-project \ 
    --project-id my-project
```

Output:

```
{
    "projectArn": "arn:aws:codestar:us-east-2:123456789012:project/my-project"
}
```

- For API details, see DeleteProject in AWS CLI Command Reference.

**delete-user-profile**

The following code example shows how to use delete-user-profile.
**AWS CLI**

**To delete a user profile**

The following delete-user-profile example deletes the user profile for the user with the specified ARN.

```bash
aws codestar delete-user-profile \
   --user-arn arn:aws:iam::123456789012:user/intern
```

Output:

```json
{

**describe-project**

The following code example shows how to use describe-project.

**AWS CLI**

**To view a project**

The following describe-project example retrieves details about the specified project.

```bash
aws codestar describe-project \
   --id my-project
```

Output:

```json
{
   "name": "my project",
   "id": "my-project",
   "arn": "arn:aws:codestar:us-west-2:123456789012:project/my-project",

**describe-user-profile**

The following code example shows how to use `describe-user-profile`.

**AWS CLI**

**To view a user profile**

The following `describe-user-profile` example retrieves details about the user profile for the user with the specified ARN.

```bash
aws codestar describe-user-profile \
    --user-arn arn:aws:iam::123456789012:user/intern
```

**Output:**

```json
{
    "userArn": "arn:aws:iam::123456789012:user/intern",
    "displayName": "Intern",

    "lastModifiedTimestamp": 1572553495.47
}
```

• For API details, see `DescribeUserProfile` in `AWS CLI Command Reference`.

**disassociate-team-member**

The following code example shows how to use `disassociate-team-member`.

**AWS CLI**

**To remove a team member**
The following disassociate-team-member example removes the user with the specified ARN from the project my-project.

```bash
aws codestar disassociate-team-member \
   --project-id my-project \
   --user-arn arn:aws:iam::123456789012:user/intern
```

This command produces no output.

- For API details, see [DisassociateTeamMember](https://docs.aws.amazon.com/cli/latest/reference/codestar/disassociate-team-member.html) in *AWS CLI Command Reference*.

**list-projects**

The following code example shows how to use list-projects.

**AWS CLI**

**To view projects**

The following list-projects example retrieves a list of projects in the current Region.

```bash
aws codestar list-projects

**list-tags-for-project**

The following code example shows how to use list-tags-for-project.

**AWS CLI**

To view tags for a project
The following `list-tags-for-project` example retrieves the tags attached to the specified project.

```bash
aws codestar list-tags-for-project \
--id my-project
```

Output:

```json
{
   "tags": {
      "Department": "Marketing",
      "Team": "Website"
   }
}
```

- For API details, see [ListTagsForProject](https://docs.aws.amazon.com/cli/latest/reference/codestar/list-tags-for-project.html) in *AWS CLI Command Reference*.

### list-team-members

The following code example shows how to use `list-team-members`.

**AWS CLI**

**To view a list of team members**

The following `list-team-members` example retrieves a list of users associated with the specified project.

```bash
aws codestar list-team-members \
--project-id my-project
```

Output:

```json
{
   "teamMembers": [
      {
         "userArn": "arn:aws:iam::123456789012:user/admin",

         "remoteAccessAllowed": false
      },
      {
```
The following code example shows how to use `list-user-profiles`.

### AWS CLI

**To view a list of user profiles**

The following `list-user-profiles` example retrieves a list of all user profiles in the current Region.

```
aws codestar list-user-profiles
```

**Output:**

```json
{
  "userProfiles": [
    {
      "userArn": "arn:aws:iam::123456789012:user/admin",
      "displayName": "me",

    }
  ]
}
```

- For API details, see [ListUserProfiles](https://docs.aws.amazon.com/cli/latest/reference/codestar/list-user-profiles.html) in *AWS CLI Command Reference*.
**tag-project**

The following code example shows how to use `tag-project`.

**AWS CLI**

To attach a tag to a project

The following `tag-project` example adds a tag named `Department` and a value of `Marketing` to the specified project.

```bash
aws codestar tag-project \
   --id my-project \
   --tags Department=Marketing
```

Output:

```json
{
   "tags": {
      "Department": "Marketing"
   }
}
```

- For API details, see [TagProject](https://docs.aws.amazon.com/cli/latest/topic/aws-codemodeling-service-codemarsterguide-reference.html) in *AWS CLI Command Reference*.

**untag-project**

The following code example shows how to use `untag-project`.

**AWS CLI**

To remove a tag from a project

The following `untag-project` example removes any tag with a key name of `Team` from the specified project.

```bash
aws codestar untag-project \
   --id my-project \
   --tags Team
```

This command produces no output.
update-project

The following code example shows how to use update-project.

AWS CLI

To update a project

The following update-project example adds a description to the specified project.

```sh
aws codestar update-project \
  --id my-project \
  --description "My first CodeStar project"
```

This command produces no output.

update-team-member

The following code example shows how to use update-team-member.

AWS CLI

To modify a team member

The following update-team-member example makes the specified user a contributor on a project and grants them remote access to project resources.

```sh
aws codestar update-team-member \
  --project-id my-project \
  --user-arn arn:aws:iam::123456789012:user/intern \
  --project-role Contributor \
  --remote-access-allowed
```

Output:

```
{
  "userArn": "arn:aws:iam::123456789012:user/intern",
  "projectRole": "Contributor",
}
```
update-user-profile

The following code example shows how to use update-user-profile.

AWS CLI

To modify a user profile

The following update-user-profile example adds the specified SSH key to the specified user.

```bash
aws codestar update-user-profile \
    --ssh-public-key intern \
    --user-arn arn:aws:iam::123456789012:user/intern
```

Output:

```json
{
    "userArn": "arn:aws:iam::123456789012:user/intern",
    "displayName": "Intern",
    "emailAddress": "intern@example.com",
    "sshPublicKey": "intern",
    "createdTimestamp": 1572552308.607,
    "lastModifiedTimestamp": 1572553495.47
}
```

**create-notification-rule**

The following code example shows how to use `create-notification-rule`.

**AWS CLI**

**To create a notification rule**

The following `create-notification-rule` example uses a JSON file named `rule.json` to create a notification rule named `MyNotificationRule` for a repository named `MyDemoRepo` in the specified AWS account. Notifications with the FULL detail type are sent to the specified target Amazon SNS topic when branches and tags are created.

```
aws codestar-notifications create-notification-rule \
--cli-input-json file://rule.json
```

**Contents of `rule.json`:**

```
{

- For API details, see [DeleteNotificationRule](#) in *AWS CLI Command Reference*. 
**delete-target**

The following code example shows how to use `delete-target`.

**AWS CLI**

**To delete a notification rule target**

The following `delete-target` example removes the specified target from all notification rules configured to use it as a target, and then deletes the target.

```bash
aws codestar-notifications delete-target \
    --target-address arn:aws:sns:us-east-1:123456789012:MyNotificationTopic \
    --force-unsubscribe-all
```

This command produces no output.

For more information, see [Delete a Notification Rule Target](#) in the *AWS Developer Tools Console User Guide*.

- For API details, see [DeleteTarget](#) in *AWS CLI Command Reference*.

**describe-notification-rule**

The following code example shows how to use `describe-notification-rule`.

**AWS CLI**

**To retrieve details of a notification rule**

The following `describe-notification-rule` example retrieves the details of the specified notification rule.

```bash
aws codestar-notifications describe-notification-rule \
    --arn arn:aws:codestar-notifications:us-west-2:123456789012:notificationrule/dc82df7a-EXAMPLE
```

Output:

```json
{
    "LastModifiedTimestamp": 1569199844.857,
    "EventTypes": [
```
For more information, see [View Notification Rules](http://aws.amazon.com/documentation/developertools/console/reference) in the *AWS Developer Tools Console User Guide*.

- For API details, see [DescribeNotificationRule](http://aws.amazon.com/documentation/cli/reference) in *AWS CLI Command Reference*.

**list-event-types**

The following code example shows how to use `list-event-types`.

### AWS CLI

**To get a list of event types for a notification rule**

The following `list-event-types` example retrieves a filtered list of all available notification event types for CodeDeploy applications. If instead you use no filter, the command returns all notification event types for all resource types.

```
aws codestar-notifications list-event-types
```
Output:

```json
{
  "EventTypes": [
    {
      "EventTypeId": "codedeploy-application-deployment-succeeded",
      "ServiceName": "CodeDeploy",
      "EventTypeName": "Deployment: Succeeded",
      "ResourceType": "Application"
    },
    {
      "EventTypeId": "codedeploy-application-deployment-failed",
      "ServiceName": "CodeDeploy",
      "EventTypeName": "Deployment: Failed",
      "ResourceType": "Application"
    },
    {
      "EventTypeId": "codedeploy-application-deployment-started",
      "ServiceName": "CodeDeploy",
      "EventTypeName": "Deployment: Started",
      "ResourceType": "Application"
    }
  ]
}
```

For more information, see [Create a Notification Rule](https://docs.aws.amazon.com/AWSDevToolsConsole/latest/userguide/notificationrules-create.html) in the AWS Developer Tools Console User Guide.

- For API details, see [ListEventTypes](https://docs.aws.amazon.com/cli/latest/reference/codedeploy/list-event-types.html) in AWS CLI Command Reference.

**list-notification-rules**

The following code example shows how to use `list-notification-rules`.

**AWS CLI**

*To retrieve a list of notification rules*

The following `list-notification-rules` example retrieves a list of all notification rules in the specified AWS Region.
aws codestar-notifications list-notification-rules --region us-east-1

Output:

```json
{
    "NotificationRules": [
        {
            "Id": "dc82df7a-EXAMPLE",
            "Arn": "arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/dc82df7a-EXAMPLE"
        },
        {
            "Id": "8d1f0983-EXAMPLE",
            "Arn": "arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/8d1f0983-EXAMPLE"
        }
    ]
}
```

For more information, see [View Notification Rules](#) in the *AWS Developer Tools Console User Guide*.

- For API details, see [ListNotificationRules](#) in *AWS CLI Command Reference*.

**list-tags-for-resource**

The following code example shows how to use `list-tags-for-resource`.

**AWS CLI**

**To get a list of tags attached to a notification rule**

The following `list-tags-for-resource` example retrieves a list of all tags attached to the specified notification rule. In this example, the notification rule currently has no tags associated with it.

```bash
aws codestar-notifications list-tags-for-resource \
    --arn arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/fe1efd35-EXAMPLE
```

Output:
For more information, see Create a Notification Rule in the AWS Developer Tools Console User Guide.

- For API details, see ListTagsForResource in AWS CLI Command Reference.

**list-targets**

The following code example shows how to use list-targets.

**AWS CLI**

To retrieve a list of notification rule targets

The following list-targets example retrieves a list of all notification rule targets in the specified AWS Region.

```bash
aws codestar-notifications list-targets \
   --region us-east-1
```

Output:

```json
{
   "Targets": [
   {
      "TargetAddress": "arn:aws:sns:us-east-1:123456789012:MySNSTopicForNotificationRules",
      "TargetType": "SNS",
      "TargetStatus": "ACTIVE"
   },
   {
      "TargetAddress": "arn:aws:sns:us-east-1:123456789012:MySNSTopicForNotificationsAboutMyDemoRepo",
      "TargetType": "SNS",
      "TargetStatus": "ACTIVE"
   }
   ]
}
```
subscribe

The following code example shows how to use subscribe.

AWS CLI

To add a target to a notification rule

The following subscribe example adds an Amazon SNS topic as a target for the specified notification rule.

```bash
aws codestar-notifications subscribe \
  --arn arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/dc82df7a-EXAMPLE \
  --target TargetType=SNS,TargetAddress=arn:aws:sns:us-east-1:123456789012:MyNotificationTopic
```

Output:

```json
{
  "Arn": "arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/dc82df7a-EXAMPLE"
}
```

For more information, see Add or Remove an Amazon SNS Topic as a Target for a Notification Rule in the AWS Developer Tools Console User Guide.

• For API details, see Subscribe in AWS CLI Command Reference.

tag-resource

The following code example shows how to use tag-resource.

AWS CLI

To add a tag to a notification rule
The following `tag-resource` example adds a tag with the key name of `Team` and the value of `Li_Juan` to the specified notification rule.

```bash
aws codestar-notifications tag-resource \
  --arn arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/fe1efd35-EXAMPLE \
  --tags Team=Li_Juan
```

Output:

```
{
    "Tags": {
      "Team": "Li_Juan"
    }
}
```

For more information, see [Create a Notification Rule](https://aws.amazon.com/documentation/codestar-notifications/) in the *AWS Developer Tools Console User Guide*.

- For API details, see [TagResource](https://docs.aws.amazon.com/cli/latest/reference/codestar-notifications/tag-resource.html) in *AWS CLI Command Reference*.

### unsubscribe

The following code example shows how to use `unsubscribe`.

**AWS CLI**

#### To remove a target from a notification rule

The following `unsubscribe` example removes an Amazon SNS topic as a target from the specified notification rule.

```bash
aws codestar-notifications unsubscribe \
  --arn arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/dc82df7a-EXAMPLE \
  --target TargetType=SNS,TargetAddress=arn:aws:sns:us-east-1:123456789012:MyNotificationTopic
```

Output:

```
{
}
```
"Arn": "arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/dc82df7a-EXAMPLE"
"TargetAddress": "arn:aws:sns:us-east-1:123456789012:MyNotificationTopic"
}

For more information, see Add or Remove an Amazon SNS Topic as a Target for a Notification Rule in the AWS Developer Tools Console User Guide.

- For API details, see Unsubscribe in AWS CLI Command Reference.

**untag-resource**

The following code example shows how to use untag-resource.

**AWS CLI**

**To remove a tag from a notification rule**

The following untag-resource example removes the tag with the key name Team from the specified notification rule.

```
aws codestar-notifications untag-resource 
   --arn arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/fe1efd35-EXAMPLE 
   --tag-keys Team
```

This command produces no output.

For more information, see Edit a Notification Rule in the AWS Developer Tools Console User Guide.

- For API details, see UntagResource in AWS CLI Command Reference.

**update-notification-rule**

The following code example shows how to use update-notification-rule.

**AWS CLI**

**To update a notification rule**
The following update-notification-rule example updates a notification rule named MyNotificationRule in the AWS account 123456789012 using a JSON file named update.json.

```
aws codestar-notifications update-notification-rule \
   --cli-input-json file://update.json
```

Contents of update.json:

```
{
   "Name": "MyUpdatedNotificationRule",
   "EventTypeIds": [
      "codecommit-repository-branches-and-tags-created"
   ],
   "Targets": [
      {
         "TargetType": "SNS",
         "TargetAddress": "arn:aws:sns:us-east-1:123456789012:MyNotificationTopic"
      }
   ],
   "Status": "ENABLED",
   "DetailType": "FULL"
}
```

Output:

```
{
   "Arn": "arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/dc82df7a-EXAMPLE"
}
```

For more information, see [Edit a notification rule](https://docs.aws.amazon.com/developer/tools/console/UserGuide) in the AWS Developer Tools Console User Guide.

**CodeConnections examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with CodeConnections.
**Actions** are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

**Scenarios** are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Actions**

**create-connection**

The following code example shows how to use `create-connection`.

**AWS CLI**

**To create a connection**

The following `create-connection` example shows how to create a connection to a third-party repository. This example creates a connection where the third-party provider is Bitbucket.

A connection created through the AWS CLI or AWS CloudFormation is in Pending status by default. After you create a connection with the CLI or AWS CloudFormation, use the console to edit the connection to make its status Available.

```
aws codestar-connections create-connection \
  --provider-type Bitbucket \
  --connection-name MyConnection
```

Output:

```json
{
  "ConnectionArn": "arn:aws:codestar-connections:us-east-1:123456789012:connection/aEXAMPLE-8aad-4d5d-8878-dfcb0bc441f"
}
```
create-host

The following code example shows how to use create-host.

AWS CLI

To create a host

The following create-host example shows how to create a host to represent the endpoint for the infrastructure where your third-party provider is installed. This example creates a host where the third-party installed provider is GitHub Enterprise Server.

A host created through the AWS CLI is in Pending status by default. After you create a host with the CLI, use the console or the CLI to set up the host to make its status Available.

```bash
aws codestar-connections create-host  
   --name MyHost  
   --provider-type GitHubEnterpriseServer  
   --provider-endpoint "https://my-instance.dev"
```

Output:

```json
{
   "HostArn": "arn:aws:codestar-connections:us-east-1:123456789012:host/My-Host-28aef605"
}
```

For more information, see Create a host (CLI) in the Developer Tools console User Guide.

- For API details, see CreateHost in AWS CLI Command Reference.

delete-connection

The following code example shows how to use delete-connection.

AWS CLI

To delete a connection
The following delete-connection example shows how to delete a connection.

```
aws codestar-connections delete-connection \
   --connection-arn arn:aws:codestar-connections:us-west-2:123456789012:connection/aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f
```

This command produces no output.

For more information, see Delete a connection (CLI) in the Developer Tools console User Guide.

- For API details, see DeleteConnection in AWS CLI Command Reference.

delete-host

The following code example shows how to use delete-host.

AWS CLI

To delete a host

The following delete-host example shows how to delete a host. Before you can delete a host, you must delete all connections associated with the host.

```
aws codestar-connections delete-host \
   --host-arn "arn:aws:codestar-connections:us-east-1 :123456789012:host/My-Host-28aef605"
```

This command produces no output.

For more information, see Delete a host (CLI) in the Developer Tools console User Guide.

- For API details, see DeleteHost in AWS CLI Command Reference.

get-connection

The following code example shows how to use get-connection.

AWS CLI

To get information about a connection

The following get-connection example shows details about a connection.
aws codestar-connections get-connection
   --connection-arn arn:aws:codestar-connections:us-east-1:123456789012:connection/aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f

Output:

```json
{
   "Connection": {
      "ConnectionName": "MyConnection",
      "ConnectionArn": "arn:aws:codestar-connections:us-east-1:123456789012:connection/aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f",
      "ProviderType": "Bitbucket",
      "OwnerAccountId": "123456789012",
      "ConnectionStatus": "AVAILABLE"
   }
}
```

For more information, see View connection details in the Developer Tools console User Guide.

- For API details, see GetConnection in AWS CLI Command Reference.

### get-host

The following code example shows how to use get-host.

**AWS CLI**

**To get information about a host**

The following get-host example shows details about a host:

```bash
aws codestar-connections get-host
   --host-arn arn:aws:codestar-connections:us-east-1:123456789012:host/MyHost-28aef605
```

Output:

```json
{
   "Name": "MyHost",
   "Status": "AVAILABLE",
   "ProviderType": "GitHubEnterpriseServer",
   "ProviderEndpoint": "https://test-instance-1.dev/
```
list-connections

The following code example shows how to use list-connections.

AWS CLI

To list connections

The following list-connections example retrieves a list of all connections in your account for the Bitbucket provider type:

```
aws codestar-connections list-connections \
   --provider-type Bitbucket \
   --max-results 5 \
   --next-token: next-token
```

Output:

```
{
   "Connections": [
   {
      "ConnectionName": "my-connection",
      "ProviderType": "Bitbucket",
      "Status": "PENDING",
      "ARN": "arn:aws:codestar-connections:us-east-1:123456789012:connection/aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f",
      "OwnerAccountId": "123456789012"
   },
   {
      "ConnectionName": "my-other-connection",
      "ProviderType": "Bitbucket",
      "Status": "AVAILABLE",
      "ARN": "arn:aws:codestar-connections:us-east-1:123456789012:connection/aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f",
      "OwnerAccountId": "123456789012"
   }
   ]
}
```
For more information, see List connections (CLI) in the Developer Tools console User Guide.

• For API details, see ListConnections in AWS CLI Command Reference.

list-hosts

The following code example shows how to use list-hosts.

AWS CLI

To list hosts

The following list-hosts example retrieves a list of all hosts in your account.

```bash
aws codestar-connections list-hosts
```

Output:

```json
{
   "Hosts": [
      {
         "Name": "My-Host",
         "HostArn": "arn:aws:codestar-connections:us-east-1:123456789012:host/My-Host-28aef605",
         "ProviderType": "GitHubEnterpriseServer",
         "ProviderEndpoint": "https://my-instance.test.dev",
         "Status": "AVAILABLE"
      }
   ]
}
```

For more information, see List hosts (CLI) in the Developer Tools console User Guide.

• For API details, see ListHosts in AWS CLI Command Reference.

list-tags-for-resource

The following code example shows how to use list-tags-for-resource.
AWS CLI

To list tags

The following list-tags-for-resource example retrieves a list of all tags attached to the specified connections resource.

```bash
aws codestar-connections list-tags-for-resource \
 --resource-arn arn:aws:codestar-connections:us-east-1:123456789012:connection/aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f
```

Output:

```json
{
   "Tags": [
      {
         "Key": "Project",
         "Value": "ProjectA"
      },
      {
         "Key": "ReadOnly",
         "Value": "true"
      }
   ]
}
```

For more information, see View tags for a connections resource in the Developer Tools console User Guide.

- For API details, see ListTagsForResource in AWS CLI Command Reference.

**tag-resource**

The following code example shows how to use tag-resource.

AWS CLI

To tag a resource

The following tag-resource example associates a set of provided tags with a connection. Use this command to add or edit tags.

```bash
aws codestar-connections tag-resource \
```
This command produces no output.

For more information, see Add tags to a connections resource in the Developer Tools console User Guide.
- For API details, see TagResource in AWS CLI Command Reference.

**untag-resource**

The following code example shows how to use untag-resource.

**AWS CLI**

To remove AWS tags from a connections resource

The following untag-resource removes a tag from the specified resource.

```
aws codestar-connections untag-resource \
  --resource-arn arn:aws:codestar-connections:us-east-1:123456789012:connection/EXAMPLE-8aad-4d5d-8878-dfcab0bc441f \
  --tag-keys Project ReadOnly
```

Output:

```
{
  "Tags": []
}
```

For more information, see Remove tags from a connections resource in the Developer Tools console User Guide.
- For API details, see UntagResource in AWS CLI Command Reference.

**Amazon Cognito Identity examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Amazon Cognito Identity.
Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Actions

create-identity-pool

The following code example shows how to use create-identity-pool.

AWS CLI

To create an identity pool with Cognito identity pool provider

This example creates an identity pool named MyIdentityPool. It has a Cognito identity pool provider. Unauthenticated identities are not allowed.

Command:

```
```

Output:

```
{
   "IdentityPoolId": "us-west-2:11111111-1111-1111-1111-111111111111",
   "IdentityPoolName": "MyIdentityPool",
   "AllowUnauthenticatedIdentities": false,
   "CognitoIdentityProviders": [
```
For API details, see CreatIdentityPool in AWS CLI Command Reference.

delete-identities

The following code example shows how to use delete-identities.

AWS CLI

To delete identity pool

This example deletes an identity pool.

Command:

```
```

Output:

```
{
    "UnprocessedIdentityIds": []
}
```

For API details, see DeletIdentities in AWS CLI Command Reference.

delete-identity-pool

The following code example shows how to use delete-identity-pool.

AWS CLI

To delete identity pool
The following `delete-identity-pool` example deletes the specified identity pool.

Command:

```bash
aws cognito-identity delete-identity-pool
   --identity-pool-id "us-west-2:11111111-1111-1111-1111-111111111111"
```

This command produces no output.

- For API details, see `DeleteIdentityPool` in *AWS CLI Command Reference*.

`describe-identity-pool`

The following code example shows how to use `describe-identity-pool`.

**AWS CLI**

To describe an identity pool

This example describes an identity pool.

Command:

```bash
```

Output:

```json
{
   "IdentityPoolId": "us-west-2:11111111-1111-1111-1111-111111111111",
   "IdentityPoolName": "MyIdentityPool",
   "AllowUnauthenticatedIdentities": false,
   "CognitoIdentityProviders": [
      {
         "ProviderName": "cognito-idp.us-west-2.amazonaws.com/us-west-2_111111111",
         "ClientId": "3n4b5urk1ft4fl3mg5e62d9ado",
         "ServerSideTokenCheck": false
      }
   ]
}
```

- For API details, see `DescribeIdentityPool` in *AWS CLI Command Reference*.
get-identity-pool-roles

The following code example shows how to use get-identity-pool-roles.

AWS CLI

To get identity pool roles

This example gets identity pool roles.

Command:

```
```

Output:

```
{
   "IdentityPoolId": "us-west-2:11111111-1111-1111-1111-111111111111",
   "Roles": {
      "authenticated": "arn:aws:iam::111111111111:role/Cognito_MyIdentityPoolAuth_Role",
      "unauthenticated": "arn:aws:iam::111111111111:role/Cognito_MyIdentityPoolUnauth_Role"
   }
}
```

- For API details, see [GetIdentityPoolRoles](#) in AWS CLI Command Reference.

list-identity-pools

The following code example shows how to use list-identity-pools.

AWS CLI

To list identity pools

This example lists identity pools. There is a maximum of 20 identities listed.

Command:

```
aws cognito-identity list-identity-pools --max-results 20
```
Output:

```
{
  "IdentityPools": [
    {
      "IdentityPoolId": "us-west-2:11111111-1111-1111-1111-111111111111",
      "IdentityPoolName": "MyIdentityPool"
    },
    {
      "IdentityPoolId": "us-west-2:11111111-1111-1111-1111-111111111111",
      "IdentityPoolName": "AnotherIdentityPool"
    },
    {
      "IdentityPoolId": "us-west-2:11111111-1111-1111-1111-111111111111",
      "IdentityPoolName": "IdentityPoolRegionA"
    }
  ]
}
```

- For API details, see `ListIdentityPools` in *AWS CLI Command Reference*.

**set-identity-pool-roles**

The following code example shows how to use `set-identity-pool-roles`.

**AWS CLI**

**To set identity pool roles**

The following `set-identity-pool-roles` example sets an identity pool role.

```
aws cognito-identity set-identity-pool-roles \
  --identity-pool-id "us-west-2:11111111-1111-1111-1111-111111111111" \
  --roles authenticated="arn:aws:iam::111111111111:role/\n  Cognito_MyIdentityPoolAuth_Role"
```

- For API details, see `SetIdentityPoolRoles` in *AWS CLI Command Reference*.

**update-identity-pool**

The following code example shows how to use `update-identity-pool`.
**AWS CLI**

**To update an identity pool**

This example updates an identity pool. It sets the name to MyIdentityPool. It adds Cognito as an identity provider. It disallows unauthenticated identities.

**Command:**

```bash
```

**Output:**

```json
{
  "IdentityPoolId": "us-west-2:11111111-1111-1111-1111-111111111111",
  "IdentityPoolName": "MyIdentityPool",
  "AllowUnauthenticatedIdentities": false,
  "CognitoIdentityProviders": [
    {
      "ProviderName": "cognito-idp.us-west-2.amazonaws.com/us-west-2_11111111",

**Amazon Cognito Identity Provider examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Amazon Cognito Identity Provider.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.
Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Actions

add-custom-attributes

The following code example shows how to use add-custom-attributes.

AWS CLI

To add a custom attribute

This example adds a custom attribute CustomAttr1 to a user pool. It is a String type, and requires a minimum of 1 character and a maximum of 15. It is not required.

Command:

```bash
aws cognito-idp add-custom-attributes --user-pool-id us-west-2_aaaaaaaaaa --custom-attributes
   Name="CustomAttr1",AttributeDataType="String",DeveloperOnlyAttribute=false,Required=false,StringAttributeConstraints="{MinLength=1,MaxLength=15}"
```

- For API details, see AddCustomAttributes in AWS CLI Command Reference.

admim-disable-user

The following code example shows how to use admim-disable-user.

AWS CLI

To disable a user

This example disables user jane@example.com.
Command:

```bash
aws cognito-idp admin-disable-user --user-pool-id us-west-2_aaaaaaaaa --username jane@example.com
```

- For API details, see `AdmimDisableUser` in *AWS CLI Command Reference*.

**admin-enable-user**

The following code example shows how to use `admin-enable-user`.

**AWS CLI**

**To enable a user**

This example enables username jane@example.com.

Command:

```bash
aws cognito-idp admin-enable-user --user-pool-id us-west-2_aaaaaaaaa --username jane@example.com
```

- For API details, see `AdmimEnableUser` in *AWS CLI Command Reference*.

**admin-add-user-to-group**

The following code example shows how to use `admin-add-user-to-group`.

**AWS CLI**

**To add a user to a group**

This example adds user Jane to group MyGroup.

Command:

```bash
aws cognito-idp admin-add-user-to-group --user-pool-id us-west-2_aaaaaaaaa --username Jane --group-name MyGroup
```

- For API details, see `AdminAddUserToGroup` in *AWS CLI Command Reference*. 
admin-confirm-sign-up

The following code example shows how to use admin-confirm-sign-up.

AWS CLI

To confirm user registration

This example confirms user jane@example.com.

Command:

```
aws cognito-idp admin-confirm-sign-up --user-pool-id us-west-2_aaaaaaaaa --username jane@example.com
```

For API details, see AdminConfirmSignUp in AWS CLI Command Reference.

admin-create-user

The following code example shows how to use admin-create-user.

AWS CLI

To create a user

The following admin-create-user example creates a user with the specified settings email address and phone number.

```
aws cognito-idp admin-create-user \
   --user-pool-id us-west-2_aaaaaaaaa \n   --username diego \n   --user-attributes Name=email,Value=diego@example.com \n   Name=phone_number,Value="+15555551212" \n   --message-action SUPPRESS
```

Output:

```
{
   "User": {
      "Username": "diego",
      "Attributes": [
```
null

For API details, see `AdminCreateUser` in *AWS CLI Command Reference*.

**admin-delete-user-attributes**

The following code example shows how to use `admin-delete-user-attributes`.

**AWS CLI**

**To delete a user attribute**

This example deletes a custom attribute CustomAttr1 for user diego@example.com.

Command:

```
aws cognito-idp admin-delete-user-attributes --user-pool-id us-west-2_aaaaaaaaa --username diego@example.com --user-attribute-names "custom:CustomAttr1"
```

For API details, see `AdminDeleteUserAttributes` in *AWS CLI Command Reference*.

**admin-delete-user**

The following code example shows how to use `admin-delete-user`.
AWS CLI

**To delete a user**

This example deletes a user.

Command:

```
aws cognito-idp admin-delete-user --user-pool-id us-west-2_aaaaaaaaa --username diego@example.com
```

**admin-forget-device**

The following code example shows how to use admin-forget-device.

**AWS CLI**

**To forget a device**

This example forgets device for username jane@example.com

Command:

```
aws cognito-idp admin-forget-device --user-pool-id us-west-2_aaaaaaaaa --username jane@example.com --device-key us-west-2_abcd_1234-5678
```

**admin-get-device**

The following code example shows how to use admin-get-device.

**AWS CLI**

**To get a device**

This example gets a device for username jane@example.com

Command:
aws cognito-idp admin-get-device --user-pool-id us-west-2_aaaaaaaaa --username jane@example.com --device-key us-west-2_abcd_1234-5678

For API details, see AdminGetDevice in AWS CLI Command Reference.

admin-get-user

The following code example shows how to use admin-get-user.

AWS CLI

To get a user

This example gets information about username jane@example.com.

Command:

```
aws cognito-idp admin-get-user --user-pool-id us-west-2_aaaaaaaaa --username jane@example.com
```

Output:

```

      "Value": "true"
    }
  ]
}
```
For API details, see AdminGetUser in AWS CLI Command Reference.

admin-initiate-auth

The following code example shows how to use admin-initiate-auth.

AWS CLI

To initiate authorization

This example initiates authorization using the ADMIN_NO_SRP_AUTH flow for username jane@example.com

The client must have sign-in API for server-based authentication (ADMIN_NO_SRP_AUTH) enabled.

Use the session information in the return value to call admin-respond-to-auth-challenge.

Command:

```bash
aws cognito-idp admin-initiate-auth --user-pool-id us-west-2_aaaaaaaaa --client-id 3n4b5urk1ft4f13mg5e62d9ado --auth-flow ADMIN_NO_SRP_AUTH --auth-parameters USERNAME=jane@example.com,PASSWORD=password
```

Output:

```javascript

- For API details, see [AdminInitiateAuth](#) in *AWS CLI Command Reference*.

**admin-list-devices**

The following code example shows how to use `admin-list-devices`.

**AWS CLI**

**To list devices for a user**

This example lists devices for username jane@example.com.

Command:

```
aws cognito-idp admin-list-devices --user-pool-id us-west-2_aaaaaaaaa --username jane@example.com
```

- For API details, see [AdminListDevices](#) in *AWS CLI Command Reference*.

**admin-list-groups-for-user**

The following code example shows how to use `admin-list-groups-for-user`.

**AWS CLI**

**To list groups for a user**

This example lists groups for username jane@example.com.

Command:

```
aws cognito-idp admin-list-groups-for-user --user-pool-id us-west-2_aaaaaaaaa --username diego@example.com
```
Output:

```
{
  "Groups": [
    {
      "Description": "Sample group",

      "CreationDate": 1548097827.125
    }
  ]
}
```

- For API details, see AdminListGroupsForUser in AWS CLI Command Reference.

**admin-list-user-auth-events**

The following code example shows how to use admin-list-user-auth-events.

**AWS CLI**

To list authorization events for a user

This example lists authorization events for username diego@example.com.

Command:

```
aws cognito-idp admin-list-user-auth-events --user-pool-id us-west-2_aaaaaaaaa --username diego@example.com
```

- For API details, see AdminListUserAuthEvents in AWS CLI Command Reference.

**admin-remove-user-from-group**

The following code example shows how to use admin-remove-user-from-group.

**AWS CLI**

To remove a user from a group
This example removes jane@example.com from SampleGroup.

Command:

```
aws cognito-idp admin-remove-user-from-group --user-pool-id us-west-2_aaaaaaaaa --username jane@example.com --group-name SampleGroup
```

- For API details, see AdminRemoveUserFromGroup in AWS CLI Command Reference.

**admin-reset-user-password**

The following code example shows how to use admin-reset-user-password.

**AWS CLI**

**To reset a user password**

This example resets the password for diego@example.com.

Command:

```
aws cognito-idp admin-reset-user-password --user-pool-id us-west-2_aaaaaaaaa --username diego@example.com
```

- For API details, see AdminResetUserPassword in AWS CLI Command Reference.

**admin-set-user-mfa-preference**

The following code example shows how to use admin-set-user-mfa-preference.

**AWS CLI**

**To set the user MFA preference**

This example sets the SMS MFA preference for username diego@example.com.

Command:

```
aws cognito-idp admin-set-user-mfa-preference --user-pool-id us-west-2_aaaaaaaaa --username diego@example.com --sms-mfa-settings Enabled=false,PreferredMfa=false
```
• For API details, see AdminSetUserMfaPreference in AWS CLI Command Reference.

admin-set-user-settings

The following code example shows how to use admin-set-user-settings.

AWS CLI

To set user settings

This example sets the MFA delivery preference for username diego@example.com to EMAIL.

Command:

```bash
aws cognito-idp admin-set-user-settings --user-pool-id us-west-2_aaaaaaaaa --username diego@example.com --mfa-options DeliveryMedium=EMAIL
```

• For API details, see AdminSetUserSettings in AWS CLI Command Reference.

admin-update-auth-event-feedback

The following code example shows how to use admin-update-auth-event-feedback.

AWS CLI

To provide feedback for an authorization event

This example sets the feedback value for an authorization event identified by event-id to Valid.

Command:

```bash
aws cognito-idp admin-update-auth-event-feedback --user-pool-id us-west-2_aaaaaaaaa --username diego@example.com --event-id c2c2cf89-c0d3-482d-aba6-99d78a5b0bfe --feedback-value Valid
```

• For API details, see AdminUpdateAuthEventFeedback in AWS CLI Command Reference.

admin-update-device-status

The following code example shows how to use admin-update-device-status.
**AWS CLI**

**To update device status**

This example sets the device remembered status for the device identified by device-key to not_remembered.

**Command:**

```
aws cognito-idp admin-update-device-status --user-pool-id us-west-2_aaaaaaaaaa --username diego@example.com --device-key xxxx --device-remembered-status not_remembered
```

- For API details, see [AdminUpdateDeviceStatus](#) in *AWS CLI Command Reference*.

**admin-update-user-attributes**

The following code example shows how to use admin-update-user-attributes.

**AWS CLI**

**To update user attributes**

This example updates a custom user attribute CustomAttr1 for user diego@example.com.

**Command:**

```
aws cognito-idp admin-update-user-attributes --user-pool-id us-west-2_aaaaaaaaaa --username diego@example.com --user-attributes Name="custom:CustomAttr1",Value="Purple"
```

- For API details, see [AdminUpdateUserAttributes](#) in *AWS CLI Command Reference*.

**change-password**

The following code example shows how to use change-password.

**AWS CLI**

**To change a password**

This example changes a password.
Command:

```bash
aws cognito-idp change-password --previous-password OldPassword --proposed-password NewPassword --access-token ACCESS_TOKEN
```

- For API details, see ChangePassword in AWS CLI Command Reference.

**confirm-forgot-password**

The following code example shows how to use confirm-forgot-password.

**AWS CLI**

**To confirm a forgotten password**

This example confirms a forgotten password for username diego@example.com.

Command:

```bash
aws cognito-idp confirm-forgot-password --client-id 3n4b5urk1ft4fl3mg5e62d9ado --username=diego@example.com --password PASSWORD --confirmation-code CONF_CODE
```

- For API details, see ConfirmForgotPassword in AWS CLI Command Reference.

**confirm-sign-up**

The following code example shows how to use confirm-sign-up.

**AWS CLI**

**To confirm sign-up**

This example confirms sign-up for username diego@example.com.

Command:

```bash
aws cognito-idp confirm-sign-up --client-id 3n4b5urk1ft4fl3mg5e62d9ado --username=diego@example.com --confirmation-code CONF_CODE
```

- For API details, see ConfirmSignUp in AWS CLI Command Reference.
**create-group**

The following code example shows how to use `create-group`.

**AWS CLI**

**To create a group**

This example creates a group with a description.

Command:

```
aws cognito-idp create-group --user-pool-id us-west-2_aaaaaaaa --group-name MyNewGroup --description "New group."
```

Output:

```
{
    "Group": {
        "GroupName": "MyNewGroup",
        "UserPoolId": "us-west-2_aaaaaaaa",
        "Description": "New group.",
        "LastModifiedDate": 1548270073.795,
        "CreationDate": 1548270073.795
    }
}
```

**To create a group with a role and precedence**

This example creates a group with a description. It also includes a role and precedence.

Command:

```
aws cognito-idp create-group --user-pool-id us-west-2_aaaaaaaa --group-name MyNewGroupWithRole --description "New group with a role." --role-arn arn:aws:iam::11111111111:role/MyNewGroupRole --precedence 2
```

Output:

```
{
    "Group": {
        "GroupName": "MyNewGroupWithRole",
        "UserPoolId": "us-west-2_aaaaaaaa",
        "Description": "New group with a role.",

        "CreationDate": 1548270073.795
    }
}
```
create-user-import-job

The following code example shows how to use create-user-import-job.

AWS CLI

To create a user import job

This example creates a user import job named MyImportJob.

For more information about importing users, see Importing Users into User Pools From a CSV File.

Command:

```
aws cognito-idp create-user-import-job --user-pool-id us-west-2_aaaaaaaaa --job-name MyImportJob --cloud-watch-logs-role-arn arn:aws:iam::111111111111:role/CognitoCloudWatchLogsRole
```

Output:

```json
{
   "UserImportJob": {
      "JobName": "MyImportJob",
      "JobId": "import-qQ0Dct2fRh",
      "UserPoolId": "us-west-2_aaaaaaaaa",

      "ImportedUsers": 0,
   }
}
```
Upload the .csv file with curl using the pre-signed URL:

Command:

curl -v -T "PATH_TO_CSV_FILE" -H "x-amz-server-side-encryption:aws:kms" "PRE_SIGNED_URL"

- For API details, see [CreateUserImportJob](awscli) in AWS CLI Command Reference.

create-user-pool-client

The following code example shows how to use create-user-pool-client.

AWS CLI

To create a user pool client

This example creates a new user pool client with two explicit authorization flows: USER_PASSWORD_AUTH and ADMIN_NO_SRP_AUTH.

Command:

```bash
aws cognito-idp create-user-pool-client --user-pool-id us-west-2_aaaaaaaaaa
  --client-name MyNewClient --no-generate-secret --explicit-auth-flows
  "USER_PASSWORD_AUTH" "ADMIN_NO_SRP_AUTH"
```

Output:

```

Actions and scenarios
create-user-pool-domain

The following code example shows how to use create-user-pool-domain.

AWS CLI

To create a user pool domain

This example creates a new user pool domain. with two explicit authorization flows: USER_PASSWORD_AUTH and ADMIN_NO_SRP_AUTH.

Command:

```
aws cognito-idp create-user-pool-domain --user-pool-id us-west-2_aaaaaaaaaa --domain my-new-domain
```

create-user-pool

The following code example shows how to use create-user-pool.

AWS CLI

To create a minimally configured user pool

This example creates a user pool named MyUserPool using default values. There are no required attributes and no application clients. MFA and advanced security is disabled.

Command:

```
aws cognito-idp create-user-pool --pool-name MyUserPool
```
Output:

To create a user pool with two required attributes

This example creates a user pool MyUserPool. The pool is configured to accept email as a username attribute. It also sets the email source address to a validated address using Amazon Simple Email Service.

Command:

```bash
aws cognito-idp create-user-pool --pool-name MyUserPool --username-attributes "email" --email-configuration=SourceArn="arn:aws:ses:us-east-1:111111111111:identity/jane@example.com",ReplyToEmailAddress="jane@example.com"

**delete-group**

The following code example shows how to use delete-group.

**AWS CLI**

To delete a group

This example deletes a group.

Command:

```
aws cognito-idp delete-group --user-pool-id us-west-2_aaaaaaaaa --group-name MyGroupName
```

- For API details, see DeleteGroup in AWS CLI Command Reference.

**delete-identity-provider**

The following code example shows how to use delete-identity-provider.
AWS CLI

To delete an identity provider

This example deletes an identity provider.

Command:

```
aws cognito-idp delete-identity-provider --user-pool-id us-west-2_aaaaaaaaaa --provider-name Facebook
```

• For API details, see [DeleteIdentityProvider](#) in AWS CLI Command Reference.

delete-resource-server

The following code example shows how to use delete-resource-server.

AWS CLI

To delete a resource server

This example deletes a resource server named weather.example.com.

Command:

```
aws cognito-idp delete-resource-server --user-pool-id us-west-2_aaaaaaaaaa --identifier weather.example.com
```

• For API details, see [DeleteResourceServer](#) in AWS CLI Command Reference.

delete-user-attributes

The following code example shows how to use delete-user-attributes.

AWS CLI

To delete user attributes

This example deletes the user attribute "FAVORITE_ANIMAL".

Command:
aws cognito-idp delete-user-attributes --access-token ACCESS_TOKEN --user-attribute-names "FAVORITE_ANIMAL"

- For API details, see [DeleteUserAttributes](#) in [AWS CLI Command Reference](#).

### delete-user-pool-client

The following code example shows how to use `delete-user-pool-client`.

**AWS CLI**

**To delete a user pool client**

This example deletes a user pool client.

Command:

```bash
aws cognito-idp delete-user-pool-client --user-pool-id us-west-2_aaaaaaaa --client-id 38fjsnc484p94kpqsnret7mpld0
```

- For API details, see [DeleteUserPoolClient](#) in [AWS CLI Command Reference](#).

### delete-user-pool-domain

The following code example shows how to use `delete-user-pool-domain`.

**AWS CLI**

**To delete a user pool domain**

The following `delete-user-pool-domain` example deletes a user pool domain named `my-domain`.

```bash
aws cognito-idp delete-user-pool-domain \
    --user-pool-id us-west-2_aaaaaaaa \
    --domain my-domain
```

- For API details, see [DeleteUserPoolDomain](#) in [AWS CLI Command Reference](#).
**delete-user-pool**

The following code example shows how to use `delete-user-pool`.

**AWS CLI**

**To delete a user pool**

This example deletes a user pool using the user pool id, us-west-2_aaaaaaaaa.

Command:

```bash
aws cognito-idp delete-user-pool --user-pool-id us-west-2_aaaaaaaaa
```

- For API details, see [DeleteUserPool](https://docs.aws.amazon.com/cli/latest/reference/cognito-idp/delete-user-pool.html) in *AWS CLI Command Reference*.

**delete-user**

The following code example shows how to use `delete-user`.

**AWS CLI**

**To delete a user**

This example deletes a user.

Command:

```bash
aws cognito-idp delete-user --access-token ACCESS_TOKEN
```

- For API details, see [DeleteUser](https://docs.aws.amazon.com/cli/latest/reference/cognito-idp/delete-user.html) in *AWS CLI Command Reference*.

**describe-identity-provider**

The following code example shows how to use `describe-identity-provider`.

**AWS CLI**

**To describe an identity provider**

This example describes an identity provider named Facebook.

Command:
aws cognito-idp describe-identity-provider --user-pool-id us-west-2_aaaaaaaaa --provider-name Facebook

Output:

```json

AWS CLI

To forget a device

This example forgets device a device.

Command:

```bash
aws cognito-idp forget-device --device-key us-west-2_abcd_1234-5678
```

- For API details, see `ForgetDevice` in *AWS CLI Command Reference*.

forgot-password

The following code example shows how to use forgot-password.

AWS CLI

To force a password change

The following forgot-password example sends a message to jane@example.com to change their password.

```bash
aws cognito-idp forgot-password --client-id 38fjsnc484p94kpsnet7mpld0 --username jane@example.com
```

Output:

```

- For API details, see `ForgotPassword` in *AWS CLI Command Reference*.

get-csv-header

The following code example shows how to use get-csv-header.
AWS CLI

To create a csv header

This example creates a csv header.

For more information about importing users, see Importing Users into User Pools From a CSV File.

Command:

```
aws cognito-idp get-csv-header --user-pool-id us-west-2_aaaaaaaaa
```

Output:

```
{
    "UserPoolId": "us-west-2_aaaaaaaaa",
    "CSVHeader": [
        "name",
        "given_name",

**get-group**

The following code example shows how to use get-group.

**AWS CLI**

**To get information about a group**

This example gets information about a group named MyGroup.

Command:

```
aws cognito-idp get-group --user-pool-id us-west-2_aaaaaaaaa --group-name MyGroup
```

Output:

```
{
  "Group": {
    "GroupName": "MyGroup",
    "UserPoolId": "us-west-2_aaaaaaaaa",

    "LastModifiedDate": 1548270073.795,
    "CreationDate": 1548270073.795
  }
}
```

- For API details, see `GetGroup` in *AWS CLI Command Reference*.

**get-signing-certificate**

The following code example shows how to use get-signing-certificate.

**AWS CLI**

**To get a signing certificate**
This example gets a signing certificate for a user pool.

Command:

```
aws cognito-idp get-signing-certificate --user-pool-id us-west-2_aaaaaaaaa
```

Output:

```
{
    "Certificate": "CERTIFICATE_DATA"
}
```

---

get-ui-customization

The following code example shows how to use `get-ui-customization`.

**AWS CLI**

**To get UI customization information**

This example gets UI customization information for a user pool.

Command:

```
aws cognito-idp get-ui-customization --user-pool-id us-west-2_aaaaaaaaa
```

Output:

```
{
    "UICustomization": {
        "UserPoolId": "us-west-2_aaaaaaaaa",

    }
}
```
• For API details, see `GetUiCustomization` in AWS CLI Command Reference.

**list-user-import-jobs**

The following code example shows how to use `list-user-import-jobs`.

**AWS CLI**

**To list user import jobs**

This example lists user import jobs.

For more information about importing users, see Importing Users into User Pools From a CSV File.

**Command:**

```bash
aws cognito-idp list-user-import-jobs --user-pool-id us-west-2aaaaaaaaa --max-results 20
```
Output:

### list-user-pools

The following code example shows how to use `list-user-pools`.

**AWS CLI**

**To list user pools**

This example lists up to 20 user pools.

Command:

```bash
aws cognito-idp list-user-pools --max-results 20
```

Output:

```json
{
   "UserPools": [
   {

}
```

### list-users-in-group

The following code example shows how to use `list-users-in-group`.

**Actions and scenarios**
**AWS CLI**

**To list users in a group**

This example lists users in group MyGroup.

**Command:**

```bash/aws cognito-idp list-users-in-group --user-pool-id us-west-2_aaaaaaaaa --group-name MyGroup```

**Output:**

```json
{

      ]
    }
  ]
}
```
For API details, see ListUsersInGroup in AWS CLI Command Reference.

list-users

The following code example shows how to use list-users.

AWS CLI

To list users

This example lists up to 20 users.

Command:

```
aws cognito-idp list-users --user-pool-id us-west-2_aaaaaaaaa --limit 20
```

Output:

```
{
   "Users": [
   {
      "Username": "22704aa3-fc10-479a-97eb-2af5806bd327",

```
For API details, see [ListUsers](awscli://cognito-idp/list-users) in *AWS CLI Command Reference*.

**resend-confirmation-code**

The following code example shows how to use `resend-confirmation-code`.

**AWS CLI**

**To resend a confirmation code**

The following `resend-confirmation-code` example sends a confirmation code to the user jane.

```
aws cognito-idp resend-confirmation-code \
  --client-id 12a3b456c7de890f11g123hijk \
  --username jane
```

**Output:**

```
{
  "CodeDeliveryDetails": {
    "Destination": "j***@e***.com",
    "DeliveryMedium": "EMAIL",
  }
}
```
For more information, see Signing up and confirming user accounts in the Amazon Cognito Developer Guide.

- For API details, see ResendConfirmationCode in AWS CLI Command Reference.

**respond-to-auth-challenge**

The following code example shows how to use respond-to-auth-challenge.

**AWS CLI**

**To respond to an authorization challenge**

This example responds to an authorization challenge initiated with initiate-auth. It is a response to the NEW_PASSWORD_REQUIRED challenge. It sets a password for user jane@example.com.

**Command:**

```
aws cognito-idp respond-to-auth-challenge --client-id 3n4b5urk1ft4f13mg5e62d9ado
   --challenge-name NEW_PASSWORD_REQUIRED --challenge-responses
   USERNAME=jane@example.com,NEW_PASSWORD="password" --session "SESSION_TOKEN"
```

**Output:**

      }
   }
}
```
set-risk-configuration

The following code example shows how to use set-risk-configuration.

AWS CLI

To set risk configuration

This example sets the risk configuration for a user pool. It sets the sign-up event action to NO_ACTION.

Command:

```bash
aws cognito-idp set-risk-configuration --user-pool-id us-west-2_aaaaaaaaa --compromised-credentials-risk-configuration EventFilter=SIGN_UP,Actions={EventAction=NO_ACTION}
```

Output:

```

```

set-ui-customization

The following code example shows how to use set-ui-customization.

• For API details, see RespondToAuthChallenge in AWS CLI Command Reference.

• For API details, see SetRiskConfiguration in AWS CLI Command Reference.
AWS CLI

To set UI customization

This example customizes the CSS setting for a user pool.

Command:

```
aws cognito-idp set-ui-customization --user-pool-id us-west-2_aaaaaaaaaa --css

set-user-mfa-preference

The following code example shows how to use set-user-mfa-preference.

**AWS CLI**

**To set user MFA settings**

The following `set-user-mfa-preference` example modifies the MFA delivery options. It changes the MFA delivery medium to SMS.

```
aws cognito-idp set-user-mfa-preference \
    --access-token "eyJra12345EXAMPLE" \

For more information, see [Adding MFA to a user pool](#) in the *Amazon Cognito Developer Guide*.

- For API details, see [SetUserMfaPreference](#) in *AWS CLI Command Reference*.

**set-user-settings**

The following code example shows how to use `set-user-settings`.

**AWS CLI**

To set user settings

This example sets the MFA delivery preference to EMAIL.

Command:

```bash
aws cognito-idp set-user-settings --access-token ACCESS_TOKEN --mfa-options DeliveryMedium=EMAIL
```

- For API details, see [SetUserSettings](#) in *AWS CLI Command Reference*.

**sign-up**

The following code example shows how to use `sign-up`.

**AWS CLI**

To sign up a user

This example signs up jane@example.com.

Command:

```bash
aws cognito-idp sign-up --client-id 3n4b5urk1ft4fl3mg5e62d9ado --username jane@example.com --password PASSWORD --user-attributes Name="email",Value="jane@example.com" Name="name",Value="Jane"

For API details, see `SignUp` in *AWS CLI Command Reference*.

### start-user-import-job

The following code example shows how to use `start-user-import-job`.

**AWS CLI**

**To start a user import job**

This example starts a user input job.

For more information about importing users, see Importing Users into User Pools From a CSV File.

**Command:**

```
aws cognito-idp start-user-import-job --user-pool-id us-west-2_aaaaaaaaa --job-id import-TZqNqVRnW

**stop-user-import-job**

The following code example shows how to use `stop-user-import-job`.

**AWS CLI**

To stop a user import job

This example stops a user input job.

For more information about importing users, see Importing Users into User Pools From a CSV File.

**Command:**

```
aws cognito-idp stop-user-import-job --user-pool-id us-west-2_aaaaaaaaa --job-id import-TZqNQvDRnW

update-auth-event-feedback

The following code example shows how to use update-auth-event-feedback.

**AWS CLI**

**To update auth event feedback**

This example updates authorization event feedback. It marks the event "Valid".

Command:

```bash
aws cognito-idp update-auth-event-feedback --user-pool-id us-west-2_aaaaaaaaaa --username diego@example.com --event-id EVENT_ID --feedback-token FEEDBACK_TOKEN --feedback-value "Valid"
```

update-device-status

The following code example shows how to use update-device-status.

**AWS CLI**

**To update device status**

This example updates the status for a device to "not_remembered".

Command:

```bash
aws cognito-idp update-device-status --access-token ACCESS_TOKEN --device-key DEVICE_KEY --device-remembered-status "not_remembered"
```

update-group

The following code example shows how to use update-group.

**AWS CLI**

**To update a group**
This example updates the description and precedence for MyGroup.

Command:

```bash
aws cognito-idp update-group --user-pool-id us-west-2_aaaaaaaaa --group-name MyGroup --description "New description" --precedence 2
```

Output:

**update-resource-server**

The following code example shows how to use update-resource-server.

**AWS CLI**

**To update a resource server**

This example updates the the resource server Weather. It adds a new scope.

Command:

```bash
aws cognito-idp update-resource-server --user-pool-id us-west-2_aaaaaaaaa --identifier weather.example.com --name Weather --scopes
ScopeName=NewScope,ScopeDescription="New scope description"
```

Output:

### update-user-attributes

The following code example shows how to use `update-user-attributes`.

#### AWS CLI

**To update user attributes**

This example updates the user attribute "nickname".

**Command:**

```shell
aws cognito-idp update-user-attributes --access-token ACCESS_TOKEN --user-attributes Name="nickname",Value="Dan"
```

- For API details, see [UpdateUserAttributes](#) in [AWS CLI Command Reference](#).

### update-user-pool-client

The following code example shows how to use `update-user-pool-client`.

#### AWS CLI

**To update a user pool client**

This example updates the name of a user pool client. It also adds a writeable attribute "nickname".
Command:

```bash
aws cognito-idp update-user-pool-client --user-pool-id us-west-2_aaaaaaaaa --client-id 3n4b5urk1ft4fl3mg5e62d9ado --client-name "NewClientName" --write-attributes "nickname"

### update-user-pool

The following code example shows how to use `update-user-pool`.

**AWS CLI**

**To update a user pool**

This example adds tags to a user pool.

Command:

```bash
aws cognito-idp update-user-pool --user-pool-id us-west-2_aaaaaaaaa --user-pool-tags Team=Blue,Area=West
```

Amazon Comprehend examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Amazon Comprehend.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

### classify-document

The following code example shows how to use `classify-document`.

#### AWS CLI

**To classify document with model-specific endpoint**

The following `classify-document` example classifies a document with an endpoint of a custom model. The model in this example was trained on a dataset containing sms messages labeled as spam or non-spam, or, "ham".

```
aws comprehend classify-document
   --text "CONGRATULATIONS! TXT 1235550100 to win $5000"
```

Output:

```json
{
}
```

- For API details, see ClassifyDocument in AWS CLI Command Reference.

contains-pii-entities

The following code example shows how to use contains-pii-entities.

AWS CLI

To analyze the input text for the presence of PII information

The following contains-pii-entities example analyzes the input text for the presence of personally identifiable information (PII) and returns the labels of identified PII entity types such as name, address, bank account number, or phone number.

```
aws comprehend contains-pii-entities \
  --language-code en \
  --text "Hello Zhang Wei, I am John. Your AnyCompany Financial Services, LLC credit card account 1111-XXXX-1111-XXXX has a minimum payment of $24.53 that is due by July 31st. Based on your autopay settings, we will withdraw your payment on the due date from your bank account number XXXXXX1111 with the routing number XXXXX0000. Customer feedback for Sunshine Spa, 100 Main St, Anywhere. Send comments to Alice at AnySpa@example.com."
```

Output:

```json
{
}
```
For more information, see **Personally Identifiable Information (PII)** in the *Amazon Comprehend Developer Guide*.

- For API details, see **ContainsPiiEntities** in *AWS CLI Command Reference*.

### create-dataset

The following code example shows how to use create-dataset.

#### AWS CLI

**To create a flywheel dataset**

The following `create-dataset` example creates a dataset for a flywheel. This dataset will be used as additional training data as specified by the --dataset-type tag.

```bash
aws comprehend create-dataset \
  --dataset-name example-dataset \
```
create-document-classifier

The following code example shows how to use create-document-classifier.

AWS CLI

To create a document classifier to categorize documents

The following create-document-classifier example begins the training process for a document classifier model. The training data file, training.csv, is located at the --input-data-config tag. training.csv is a two column document where the labels, or, classifications are provided in the first column and the documents are provided in the second column.

aws comprehend create-document-classifier  
--document-classifier-name example-classifier  

For more information, see Flywheel Overview in Amazon Comprehend Developer Guide.

- For API details, see CreateDataset in AWS CLI Command Reference.
Output:

```json
{
}
```

For more information, see [Custom Classification](https://docs.aws.amazon.com/comprehend/latest/dg/custom-classification.html) in the *Amazon Comprehend Developer Guide*.

### create-endpoint

The following code example shows how to use create-endpoint.

**AWS CLI**

**To create an endpoint for a custom model**

The following `create-endpoint` example creates an endpoint for synchronous inference for a previously trained custom model.

```
aws comprehend create-endpoint \
   --endpoint-name example-classifier-endpoint-1 \
   --desired-inference-units 1
```

Output:

```json
{
}
```

For more information, see [Managing Amazon Comprehend endpoints](https://docs.aws.amazon.com/comprehend/latest/dg/endpoints.html) in the *Amazon Comprehend Developer Guide*.

- For API details, see [CreateEndpoint](https://docs.aws.amazon.com/cli/latest/reference/comprehend/create-endpoint.html) in AWS CLI Command Reference.
create-entity-recognizer

The following code example shows how to use create-entity-recognizer.

AWS CLI

To create a custom entity recognizer

The following create-entity-recognizer example begins the training process for a custom entity recognizer model. This example uses a CSV file containing training documents, raw_text.csv, and a CSV entity list, entity_list.csv to train the model. entity-list.csv contains the following columns: text and type.

```bash
aws comprehend create-entity-recognizer \\
  --recognizer-name example-entity-recognizer \\
  --data-access-role-arn arn:aws:iam::111122223333:role/service-role/AmazonComprehendServiceRole-example-role \\
  --input-data-config "EntityTypes=[{{Type=DEVICE}}],Documents={S3Uri=s3://DOC-EXAMPLE-BUCKET/trainingdata/raw_text.csv},EntityList={S3Uri=s3://DOC-EXAMPLE-BUCKET/trainingdata/entity_list.csv}" \\
  --language-code en
```

Output:

```json
{
  "EntityRecognizerArn": "arn:aws:comprehend:us-west-2:111122223333:example-entity-recognizer/entityrecognizer1"
}
```

For more information, see Custom entity recognition in the Amazon Comprehend Developer Guide.
- For API details, see CreateEntityRecognizer in AWS CLI Command Reference.

create-flywheel

The following code example shows how to use create-flywheel.

AWS CLI

To create a flywheel
The following `create-flywheel` example creates a flywheel to orchestrate the ongoing training of either a document classification or entity recognition model. The flywheel in this example is created to manage an existing trained model specified by the `--active-model-arn` tag. When the flywheel is created, a data lake is created at the `--input-data-lake` tag.

```
aws comprehend create-flywheel \
   --flywheel-name example-flywheel \
   --data-access-role-arn arn:aws:iam::111122223333:role/service-role/AmazonComprehendServiceRole-example-role \
   --data-lake-s3-uri "s3://DOC-EXAMPLE-BUCKET"
```

**Output:**

```
{
   "FlywheelArn": "arn:aws:comprehend:us-west-2:111122223333:flywheel/example-flywheel"
}
```

For more information, see [Flywheel Overview](https://docs.aws.amazon.com/comprehend/latest/dg/flywheel-overview.html) in *Amazon Comprehend Developer Guide*.

- For API details, see [CreateFlywheel](https://docs.aws.amazon.com/cli/latest/reference/comprehend/create-flywheel.html) in *AWS CLI Command Reference*.

### delete-document-classifier

The following code example shows how to use `delete-document-classifier`.

**AWS CLI**

**To delete a custom document classifier**

The following `delete-document-classifier` example deletes a custom document classifier model.

```
aws comprehend delete-document-classifier \
```

This command produces no output.
For more information, see Managing Amazon Comprehend endpoints in the Amazon Comprehend Developer Guide.

- For API details, see DeleteDocumentClassifier in AWS CLI Command Reference.

**delete-endpoint**

The following code example shows how to use delete-endpoint.

**AWS CLI**

To delete an endpoint for a custom model

The following delete-endpoint example deletes a model-specific endpoint. All endpoints must be deleted in order for the model to be deleted.

```
aws comprehend delete-endpoint 
```

This command produces no output.

For more information, see Managing Amazon Comprehend endpoints in the Amazon Comprehend Developer Guide.

- For API details, see DeleteEndpoint in AWS CLI Command Reference.

**delete-entity-recognizer**

The following code example shows how to use delete-entity-recognizer.

**AWS CLI**

To delete a custom entity recognizer model

The following delete-entity-recognizer example deletes a custom entity recognizer model.

```
aws comprehend delete-entity-recognizer 
```
This command produces no output.

For more information, see Managing Amazon Comprehend endpoints in the Amazon Comprehend Developer Guide.

- For API details, see DeleteEntityRecognizer in AWS CLI Command Reference.

**delete-flywheel**

The following code example shows how to use delete-flywheel.

**AWS CLI**

To delete a flywheel

The following delete-flywheel example deletes a flywheel. The data lake or the model associated with the flywheel is not deleted.

```
aws comprehend delete-flywheel \\
```

This command produces no output.

For more information, see Flywheel overview in the Amazon Comprehend Developer Guide.

- For API details, see DeleteFlywheel in AWS CLI Command Reference.

**delete-resource-policy**

The following code example shows how to use delete-resource-policy.

**AWS CLI**

To delete a resource-based policy

The following delete-resource-policy example deletes a resource-based policy from an Amazon Comprehend resource.

```
aws comprehend delete-resource-policy \\
```
This command produces no output.

For more information, see Copying custom models between AWS accounts in the Amazon Comprehend Developer Guide.

- For API details, see DeleteResourcePolicy in AWS CLI Command Reference.

**describe-dataset**

The following code example shows how to use describe-dataset.

**AWS CLI**

To describe a flywheel dataset

The following describe-dataset example gets the properties of a flywheel dataset.

```bash
aws comprehend describe-dataset \
```

Output:

```json

**describe-document-classification-job**

The following code example shows how to use describe-document-classification-job.
AWS CLI

To describe a document classification job

The following describe-document-classification-job example gets the properties of an asynchronous document classification job.

```bash
aws comprehend describe-document-classification-job \
   --job-id 123456abcdef0e11022f22a11EXAMPLE

describe-flywheel

The following code example shows how to use describe-flywheel.

AWS CLI

To describe a flywheel

The following describe-flywheel example gets the properties of a flywheel. In this example, the model associated with the flywheel is a custom classifier model that is trained to classify documents as either spam or nonspam, or, "ham".

```bash
aws comprehend describe-flywheel \\

put-resource-policy

The following code example shows how to use put-resource-policy.

AWS CLI

To attach a resource-based policy

The following put-resource-policy example attaches a resource-based policy to a model so that can be imported by another AWS account. The policy is attached to the model in account 111122223333 and allows account 444455556666 import the model.

```bash
aws comprehend put-resource-policy \
```

Output:

```json
{
  "PolicyRevisionId": "aaa111d069d07afaa2aa3106aEXAMPLE"
}
```

For more information, see Copying custom models between AWS accounts in the Amazon Comprehend Developer Guide.

• For API details, see PutResourcePolicy in AWS CLI Command Reference.

start-document-classification-job

The following code example shows how to use start-document-classification-job.

AWS CLI

To start document classification job

The following start-document-classification-job example starts a document classification job with a custom model on all of the files at the address specified
by the --input-data-config tag. In this example, the input S3 bucket contains SampleSMStext1.txt, SampleSMStext2.txt, and SampleSMStext3.txt. The model was previously trained on document classifications of spam and non-spam, or, "ham", SMS messages. When the job is complete, output.tar.gz is put at the location specified by the --output-data-config tag. output.tar.gz contains predictions.jsonl which lists the classification of each document. The Json output is printed on one line per file, but is formatted here for readability.

```
aws comprehend start-document-classification-job \
   --job-name exampleclassificationjob \
   --input-data-config "S3Uri=s3://DOC-EXAMPLE-BUCKET-INPUT/jobdata/" \
   --output-data-config "S3Uri=s3://DOC-EXAMPLE-DESTINATION-BUCKET/testfolder/" \
   --data-access-role-arn arn:aws:iam::111122223333:role/service-role/AmazonComprehendServiceRole-example-role \
```

Contents of SampleSMStext1.txt:

"CONGRATULATIONS! TXT 2155550100 to win $5000"

Contents of SampleSMStext2.txt:

"Hi, when do you want me to pick you up from practice?"

Contents of SampleSMStext3.txt:

"Plz send bank account # to 2155550100 to claim prize!!"

Output:

```
{
   "JobId": "e758dd56b824aa717ceab551fEXAMPLE",
   "JobStatus": "SUBMITTED"
}
```

Contents of predictions.jsonl:
For more information, see Custom Classification in the Amazon Comprehend Developer Guide.

- For API details, see StartDocumentClassificationJob in AWS CLI Command Reference.

### start-dominant-language-detection-job

The following code example shows how to use start-dominant-language-detection-job.

**AWS CLI**

**To start an asynchronous language detection job**

The following start-dominant-language-detection-job example starts an asynchronous language detection job for all of the files located at the address specified by the --input-data-config tag. The S3 bucket in this example contains Sampletext1.txt. When the job is complete, the folder, output, is placed in the location specified by the --output-data-config tag. The folder contains output.txt which contains the dominant language of each of the text files as well as the pre-trained model's confidence score for each prediction.

```bash
code
aws comprehend start-dominant-language-detection-job 
   --job-name example_language_analysis_job 
   --language-code en 
   --input-data-config "S3Uri=s3://DOC-EXAMPLE-BUCKET/" 
   --output-data-config "S3Uri=s3://DOC-EXAMPLE-DESTINATION-BUCKET/testfolder/" 
   --data-access-role-arn arn:aws:iam::111122223333:role/service-role/AmazonComprehendServiceRole-example-role 
   --language-code en
```

**Contents of Sampletext1.txt:**

"Physics is the natural science that involves the study of matter and its motion and behavior through space and time, along with related concepts such as energy and force."
Output:

```json
{
    "JobId": "123456abcdef0e11022f22a11EXAMPLE",
    "JobStatus": "SUBMITTED"
}
```

Contents of output.txt:

```json
{"File": "Sampletext1.txt", "Languages": ["LanguageCode": "en", "Score": 0.9913753867149353]}, "Line": 0}
```

For more information, see Async analysis for Amazon Comprehend insights in the Amazon Comprehend Developer Guide.

**start-entities-detection-job**

The following code example shows how to use start-entities-detection-job.

**AWS CLI**

**Example 1: To start a standard entity detection job using the pre-trained model**

The following start-entities-detection-job example starts an asynchronous entities detection job for all files located at the address specified by the --input-data-config tag. The S3 bucket in this example contains Sampletext1.txt, Sampletext2.txt, and Sampletext3.txt. When the job is complete, the folder, output, is placed in the location specified by the --output-data-config tag. The folder contains output.txt which lists all of the named entities detected within each text file as well as the pre-trained model's confidence score for each prediction. The Json output is printed on one line per input file, but is formatted here for readability.

```
aws comprehend start-entities-detection-job \
    --job-name entitiestest \
    --language-code en \
    --input-data-config "S3Uri=s3://DOC-EXAMPLE-BUCKET/" \
    --output-data-config "S3Uri=s3://DOC-EXAMPLE-DESTINATION-BUCKET/testfolder/"
```
Contents of Sampletext1.txt:

"Hello Zhang Wei, I am John. Your AnyCompany Financial Services, LLC credit card account 1111-XXXX-1111-XXXX has a minimum payment of $24.53 that is due by July 31st."

Contents of Sampletext2.txt:

"Dear Max, based on your autopay settings for your account example1.org account, we will withdraw your payment on the due date from your bank account number XXXXXX1111 with the routing number XXXXXX0000."

Contents of Sampletext3.txt:

"Jane, please submit any customer feedback from this weekend to AnySpa, 123 Main St, Anywhere and send comments to Alice at AnySpa@example.com."

Output:

```json
{
   "JobId": "123456abcdeb0e11022f22a11EXAMPLE",
   "JobStatus": "SUBMITTED"
}
```

Contents of output.txt with line indents for readability:

Example 2: To start a custom entity detection job

The following start-entities-detection-job example starts an asynchronous custom entities detection job for all files located at the address specified by the --input-data-config tag. In this example, the S3 bucket in this example contains SampleFeedback1.txt, SampleFeedback2.txt, and SampleFeedback3.txt. The entity recognizer model was trained on customer support Feedbacks to recognize device names. When the job is complete, an the folder, output, is put at the location specified by the --output-data-config tag. The folder contains output.txt, which lists all of the named entities detected within each text file as well as the pre-trained model's confidence score for each prediction. The Json output is printed on one line per file, but is formatted here for readability.
Contents of SampleFeedback1.txt:

"I've been on the AnyPhone app have had issues for 24 hours when trying to pay bill. Cannot make payment. Sigh. | Oh man! Lets get that app up and running. DM me, and we can get to work!"

Contents of SampleFeedback2.txt:

"Hi, I have a discrepancy with my new bill. Could we get it sorted out? A rep added stuff I didn't sign up for when I did my AnyPhone 10 upgrade. | We can absolutely get this sorted!"

Contents of SampleFeedback3.txt:

"Is the by 1 get 1 free AnySmartPhone promo still going on? | Hi Christian! It ended yesterday, send us a DM if you have any questions and we can take a look at your options!"

Output:

```json
{
   "JobId": "019ea9edac758806850fa8a79ff83021",
   "JobStatus": "SUBMITTED"
}
```

Contents of output.txt with line indents for readability:

**AWS CLI**

**To start an asynchronous events detection job**

The following `start-events-detection-job` example starts an asynchronous events detection job for all files located at the address specified by the `--input-data-config` tag. Possible target event types include BANKRUPTCY, EMPLOYMENT, CORPORATE_ACQUISITION, INVESTMENT_GENERAL, CORPORATE_MERGER, IPO, RIGHTS_ISSUE, SECONDARY_OFFERING, SHELF_OFFERING, TENDER_OFFERING, and STOCK_SPLIT. The S3 bucket in this example contains SampleText1.txt, SampleText2.txt, and SampleText3.txt. When the job is complete, the folder, output, is placed in the location specified by the `--output-data-config` tag. The folder contains SampleText1.txt.out, SampleText2.txt.out, and SampleText3.txt.out. The JSON output is printed on one line per file, but is formatted here for readability.

```
aws comprehend start-events-detection-job \
  --job-name events-detection-1 \
  --input-data-config "S3Uri=s3://DOC-EXAMPLE-BUCKET/EventsData" \
  --output-data-config "S3Uri=s3://DOC-EXAMPLE-DESTINATION-BUCKET/testfolder/" \

```

**Contents of SampleText1.txt:**

"Company AnyCompany grew by increasing sales and through acquisitions. After purchasing competing firms in 2020, AnyBusiness, a part of the AnyBusinessGroup, gave Jane Does firm a going rate of one cent a gallon or forty-two cents a barrel."

**Contents of SampleText2.txt:**

"In 2021, AnyCompany officially purchased AnyBusiness for 100 billion dollars, surprising and exciting the shareholders."

**Contents of SampleText3.txt:**
"In 2022, AnyCompany stock crashed 50. Eventually later that year they filed for bankruptcy."

Output:

**start-targeted-sentiment-detection-job**

The following code example shows how to use `start-targeted-sentiment-detection-job`.

**AWS CLI**

To start an asynchronous targeted sentiment analysis job

The following `start-targeted-sentiment-detection-job` example starts an asynchronous targeted sentiment analysis detection job for all files located at the address specified by the `--input-data-config` tag. The S3 bucket folder in this example contains `SampleMovieReview1.txt`, `SampleMovieReview2.txt`, and `SampleMovieReview3.txt`. When the job is complete, `output.tar.gz` is placed at the location specified by the `--output-data-config` tag. `output.tar.gz` contains the files `SampleMovieReview1.txt.out`, `SampleMovieReview2.txt.out`, and `SampleMovieReview3.txt.out`, which each contain all of the named entities and associated sentiments for a single input text file.

```
aws comprehend start-targeted-sentiment-detection-job \
  --job-name targeted_movie_review_analysis1 \
  --language-code en \
  --input-data-config "S3Uri=s3://DOC-EXAMPLE-BUCKET/MovieData" \
  --output-data-config "S3Uri=s3://DOC-EXAMPLE-DESTINATION-BUCKET/testfolder/"

start-topics-detection-job

The following code example shows how to use start-topics-detection-job.

AWS CLI

To start a topics detection analysis job
The following `start-topics-detection-job` example starts an asynchronous topics detection job for all files located at the address specified by the `--input-data-config` tag. When the job is complete, the folder, `output`, is placed at the location specified by the `--output-data-config` tag. `output` contains `topic-terms.csv` and `doc-topics.csv`. The first output file, `topic-terms.csv`, is a list of topics in the collection. For each topic, the list includes, by default, the top terms by topic according to their weight. The second file, `doc-topics.csv`, lists the documents associated with a topic and the proportion of the document that is concerned with the topic.

```bash
aws comprehend start-topics-detection-job \
  --job-name example_topics_detection_job \
  --language-code en \
  --input-data-config "S3Uri=s3://DOC-EXAMPLE-BUCKET/" \
  --output-data-config "S3Uri=s3://DOC-EXAMPLE-DESTINATION-BUCKET/testfolder/" \
  --data-access-role-arn arn:aws:iam::111122223333:role/service-role/AmazonComprehendServiceRole-example-role \
  --language-code en
```

Output:

```json
{
  "JobId": "123456abcdeb0e11022f22a11EXAMPLE",
  "JobArn": "arn:aws:comprehend:us-west-2:111122223333:key-phrases-detection-job/123456abcdeb0e11022f22a11EXAMPLE",

stop-training-document-classifier

The following code example shows how to use stop-training-document-classifier.

**AWS CLI**

To stop the training of a document classifier model

The following stop-training-document-classifier example stops the training of a document classifier model while in-progress.

```
aws comprehend stop-training-document-classifier \
```

This command produces no output.

For more information, see Creating and managing custom models in the Amazon Comprehend Developer Guide.

- For API details, see StopTrainingDocumentClassifier in AWS CLI Command Reference.
**stop-training-entity-recognizer**

The following code example shows how to use `stop-training-entity-recognizer`.

**AWS CLI**

**To stop the training of an entity recognizer model**

The following `stop-training-entity-recognizer` example stops the training of an entity recognizer model while in-progress.

```bash
aws comprehend stop-training-entity-recognizer

**tag-resource**

The following code example shows how to use `tag-resource`.

**AWS CLI**

**Example 1: To tag a resource**

The following `tag-resource` example adds a single tag to an Amazon Comprehend resource.

```bash
aws comprehend tag-resource \
   --tags Key=Location,Value=Seattle
```

This command has no output.

For more information, see [Tagging your resources](https://aws.amazon.com/comprehend/) in the *Amazon Comprehend Developer Guide*.

**Example 2: To add multiple tags to a resource**

The following `tag-resource` example adds multiple tags to an Amazon Comprehend resource.
aws comprehend tag-resource \ 
   --tags Key=location,Value=Seattle Key=Department,Value=Finance

This command has no output.

For more information, see Tagging your resources in the Amazon Comprehend Developer Guide. For API details, see TagResource in AWS CLI Command Reference.

untag-resource

The following code example shows how to use untag-resource.

AWS CLI

Example 1: To remove a single tag from a resource

The following untag-resource example removes a single tag from an Amazon Comprehend resource.

aws comprehend untag-resource \ 
   --tag-keys Location

This command produces no output.

For more information, see Tagging your resources in the Amazon Comprehend Developer Guide.

Example 2: To remove multiple tags from a resource

The following untag-resource example removes multiple tags from an Amazon Comprehend resource.

aws comprehend untag-resource \ 
   --tag-keys Location Department

This command produces no output.
For more information, see Tagging your resources in the Amazon Comprehend Developer Guide.

- For API details, see UntagResource in AWS CLI Command Reference.

**update-endpoint**

The following code example shows how to use update-endpoint.

**AWS CLI**

**Example 1: To update an endpoint's inference units**

The following update-endpoint example updates information about an endpoint. In this example, the number of inference units is increased.

```bash
aws comprehend update-endpoint \
  --desired-inference-units 2
```

This command produces no output.

For more information, see Managing Amazon Comprehend endpoints in the Amazon Comprehend Developer Guide.

**Example 2: To update an endpoint's active model**

The following update-endpoint example updates information about an endpoint. In this example, the active model is changed.

```bash
aws comprehend update-endpoint \
```

This command produces no output.

For more information, see Managing Amazon Comprehend endpoints in the Amazon Comprehend Developer Guide.

- For API details, see UpdateEndpoint in AWS CLI Command Reference.
update-flywheel

The following code example shows how to use update-flywheel.

AWS CLI

To update a flywheel configuration

Amazon Comprehend Medical examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Amazon Comprehend Medical.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**detect-entities-v2**

The following code example shows how to use `detect-entities-v2`.

**AWS CLI**

**Example 1: To detect entities directly from text**

The following `detect-entities-v2` example shows the detected entities and labels them according to type, directly from input text.

```
aws comprehendmedical detect-entities-v2 \
    --text "Sleeping trouble on present dosage of Clonidine. Severe rash on face and leg, slightly itchy."
```

**Output:**
For more information, see Detect Entities Version 2 in the Amazon Comprehend Medical Developer Guide.

Example 2: To detect entities from a file path

The following detect-entities-v2 example shows the detected entities and labels them according to type from a file path.

```
aws comprehendmedical detect-entities-v2 \
   --text file://medical_entities.txt

```

Output:
For more information, see Ontology linking batch analysis in the Amazon Comprehend Medical Developer Guide.

• For API details, see StopSnomedctInferenceJob in AWS CLI Command Reference.

AWS Config examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with AWS Config.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Actions

delete-config-rule

The following code example shows how to use delete-config-rule.

AWS CLI

To delete an AWS Config rule

The following command deletes an AWS Config rule named MyConfigRule:

```
aws configservice delete-config-rule --config-rule-name MyConfigRule
```
• For API details, see `DeleteConfigRule` in *AWS CLI Command Reference*.

**delete-delivery-channel**

The following code example shows how to use `delete-delivery-channel`.

**AWS CLI**

To delete a delivery channel

The following command deletes the default delivery channel:

```bash
aws configservice delete-delivery-channel --delivery-channel-name default
```

• For API details, see `DeleteDeliveryChannel` in *AWS CLI Command Reference*.

**delete-evaluation-results**

The following code example shows how to use `delete-evaluation-results`.

**AWS CLI**

To manually delete evaluation results

The following command deletes the current evaluation results for the AWS managed rule `s3-bucket-versioning-enabled`:

```bash
aws configservice delete-evaluation-results --config-rule-name s3-bucket-versioning-enabled
```

• For API details, see `DeleteEvaluationResults` in *AWS CLI Command Reference*.

**deliver-config-snapshot**

The following code example shows how to use `deliver-config-snapshot`.

**AWS CLI**

To deliver a configuration snapshot
The following command delivers a configuration snapshot to the Amazon S3 bucket that belongs to the default delivery channel:

```
aws configservice deliver-config-snapshot --delivery-channel-name default
```

Output:

```
{
    "configSnapshotId": "d033b00-a683-44af-921e-examplefb794"
}
```

- For API details, see `DeliverConfigSnapshot` in *AWS CLI Command Reference*.

### `describe-compliance-by-config-rule`

The following code example shows how to use `describe-compliance-by-config-rule`.

#### AWS CLI

**To get compliance information for your AWS Config rules**

The following command returns compliance information for each AWS Config rule that is violated by one or more AWS resources:

```
aws configservice describe-compliance-by-config-rule --compliance-types NON_COMPLIANT
```

In the output, the value for each `CappedCount` attribute indicates how many resources do not comply with the related rule. For example, the following output indicates that 3 resources do not comply with the rule named `InstanceTypesAreT2micro`.

Output:

```
{
    "ComplianceByConfigRules": [
        {
            "Compliance": {
                "ComplianceContributorCount": {
                    "CappedCount": 3,
                    "CapExceeded": false
                }
            }
        }
    ]
}
```
The following code example shows how to use `describe-compliance-by-resource`.

**AWS CLI**

The following command returns compliance information for each EC2 instance that is recorded by AWS Config and that violates one or more rules:

```
aws configservice describe-compliance-by-resource --resource-type AWS::EC2::Instance --compliance-types NON_COMPLIANT
```

In the output, the value for each `CappedCount` attribute indicates how many rules the resource violates. For example, the following output indicates that instance `i-1a2b3c4d` violates 2 rules.

```
{
    "ComplianceByResources": [ 
        
```

- For API details, see [DescribeComplianceByConfigRule](https://docs.aws.amazon.com/cli/latest/reference/configservice/describe-compliance-by-config-rule.html) in *AWS CLI Command Reference*.

describe-config-rule-evaluation-status

The following code example shows how to use describe-config-rule-evaluation-status.

AWS CLI

To get status information for an AWS Config rule

The following command returns the status information for an AWS Config rule named MyConfigRule:

```
aws configservice describe-config-rule-evaluation-status --config-rule-names MyConfigRule
```

Output:
For API details, see [DescribeConfigRuleEvaluationStatus](https://docs.aws.amazon.com/cli/latest/reference/configservice/describe-config-rules.html) in *AWS CLI Command Reference*.

**describe-config-rules**

The following code example shows how to use `describe-config-rules`.

**AWS CLI**

**To get details for an AWS Config rule**

The following command returns details for an AWS Config rule named `InstanceTypesAreT2micro`:

```bash
aws configservice describe-config-rules --config-rule-names InstanceTypesAreT2micro
```

**Output:**

```json
{
  "ConfigRules": [
    {
      "ConfigRuleState": "ACTIVE",
      "Description": "Evaluates whether EC2 instances are the t2.micro type.",
      "ConfigRuleName": "InstanceTypesAreT2micro",
      "Source": {
        "Owner": "CUSTOM_LAMBDA",
        "SourceIdentifier": "arn:aws:lambda:us-east-1:123456789012:function:InstanceTypeCheck",
```
"SourceDetails": [

"InputParameters": "{"desiredInstanceType":"t2.micro"}",
"Scope": {
  "ComplianceResourceTypes": [
    "AWS::EC2::Instance"
  ],
  "ConfigRuleId": "config-rule-abcdef"
}
}]

- For API details, see [DescribeConfigRules](https://docs.aws.amazon.com/cli/latest/reference/configservice/describe-config-rules.html) in *AWS CLI Command Reference*.

**describe-configuration-recorder-status**

The following code example shows how to use `describe-configuration-recorder-status`.

**AWS CLI**

To get status information for the configuration recorder

The following command returns the status of the default configuration recorder:

```bash
aws configservice describe-configuration-recorder-status
```

**Output:**

```json
{
  "ConfigurationRecordersStatus": [
    {
      "name": "default",
      "lastStatus": "SUCCESS",
      "recording": true,
      "lastStatusChangeTime": 1452193834.344,
      "lastStartTime": 1441039997.819
    }
  ]
}
```
describe-configuration-recorders

The following code example shows how to use describe-configuration-recorders.

AWS CLI

To get details about the configuration recorder

The following command returns details about the default configuration recorder:

```bash
aws configservice describe-configuration-recorders
```

Output:

```json
{
   "ConfigurationRecorders": [
      {
         "recordingGroup": {
            "allSupported": true,
            "resourceTypes": [],
            "includeGlobalResourceTypes": true
         },
         "roleARN": "arn:aws:iam::123456789012:role/config-ConfigRole-A1B2C3D4E5F6",
         "name": "default"
      }
   ]
}
```

• For API details, see [DescribeConfigurationRecorderStatus](#) in AWS CLI Command Reference.

describe-delivery-channel-status

The following code example shows how to use describe-delivery-channel-status.
To get status information for the delivery channel

The following command returns the status of the delivery channel:

```
aws configservice describe-delivery-channel-status
```

Output:

```
{
   "DeliveryChannelsStatus": [
   {
      "configStreamDeliveryInfo": {
         "lastStatusChangeTime": 1452193834.381,
         "lastStatus": "SUCCESS"
      },
      "configHistoryDeliveryInfo": {
         "lastSuccessfulTime": 1450317838.412,
         "lastStatus": "SUCCESS",

      },
      "configSnapshotDeliveryInfo": {
         "lastSuccessfulTime": 1452185597.094,
         "lastStatus": "SUCCESS",
         "lastAttemptTime": 1452185597.094
      }
   },
   "name": "default"
   ]
}
```

For API details, see `DescribeDeliveryChannelStatus` in AWS CLI Command Reference.

describe-delivery-channels

The following code example shows how to use `describe-delivery-channels`.

AWS CLI

To get details about the delivery channel
The following command returns details about the delivery channel:

```bash
aws configservice describe-delivery-channels
```

Output:

```json
{
  "DeliveryChannels": [
    {
      "name": "default",
      "s3BucketName": "config-bucket-123456789012"
    }
  ]
}
```

- For API details, see [DescribeDeliveryChannels](https://docs.aws.amazon.com/cli/latest/reference/configservice/describe-delivery-channels.html) in *AWS CLI Command Reference*.

### get-compliance-details-by-config-rule

The following code example shows how to use `get-compliance-details-by-config-rule`.

**AWS CLI**

**To get the evaluation results for an AWS Config rule**

The following command returns the evaluation results for all of the resources that don't comply with an AWS Config rule named `InstanceTypesAreT2micro`:

```bash
aws configservice get-compliance-details-by-config-rule --config-rule-name InstanceTypesAreT2micro --compliance-types NON_COMPLIANT
```

Output:

```json
{
  "EvaluationResults": [
    {
      "EvaluationResultIdentifier": {
        "OrderingTimestamp": 1450314635.065,
        "EvaluationResultQualifier": {

```
For API details, see GetComplianceDetailsByConfigRule in AWS CLI Command Reference.

get-compliance-details-by-resource

The following code example shows how to use get-compliance-details-by-resource.
AWS CLI

To get the evaluation results for an AWS resource

The following command returns the evaluation results for each rule with which the EC2 instance i-1a2b3c4d does not comply:

```
aws configservice get-compliance-details-by-resource --resource-type AWS::EC2::Instance --resource-id i-1a2b3c4d --compliance-types NON_COMPLIANT
```

Output:

```
{
   "EvaluationResults": [
   {
      "EvaluationResultIdentifier": {
         "OrderingTimestamp": 1450314635.065,
         "EvaluationResultQualifier": {
            "ResourceType": "AWS::EC2::Instance",
            "ResourceId": "i-1a2b3c4d",
            "ConfigRuleName": "InstanceTypesAreT2micro"
         }
      },
      "ResultRecordedTime": 1450314643.288,
      "ConfigRuleInvokedTime": 1450314643.034,
      "ComplianceType": "NON_COMPLIANT"
   },
   {
      "EvaluationResultIdentifier": {
         "OrderingTimestamp": 1450314635.065,
         "EvaluationResultQualifier": {
            "ResourceType": "AWS::EC2::Instance",
            "ResourceId": "i-1a2b3c4d",
            "ConfigRuleName": "RequiredTagForEC2Instances"
         }
      },
      "ResultRecordedTime": 1450314645.261,
      "ConfigRuleInvokedTime": 1450314642.948,
      "ComplianceType": "NON_COMPLIANT"
   }
   ]
}
```
get-compliance-summary-by-config-rule

The following code example shows how to use `get-compliance-summary-by-config-rule`.

AWS CLI

To get the compliance summary for your AWS Config rules

The following command returns the number of rules that are compliant and the number that are noncompliant:

```bash
aws configservice get-compliance-summary-by-config-rule
```

In the output, the value for each CappedCount attribute indicates how many rules are compliant or noncompliant.

Output:

```json
{
   "ComplianceSummary": {
      "NonCompliantResourceCount": {
         "CappedCount": 3,
         "CapExceeded": false
      },
      "ComplianceSummaryTimestamp": 1452204131.493,
      "CompliantResourceCount": {
         "CappedCount": 2,
         "CapExceeded": false
      }
   }
}
```

For API details, see `GetComplianceSummaryByConfigRule` in AWS CLI Command Reference.

get-compliance-summary-by-resource-type

The following code example shows how to use `get-compliance-summary-by-resource-type`.

For API details, see `GetComplianceDetailsByResource` in AWS CLI Command Reference.
AWS CLI

To get the compliance summary for all resource types

The following command returns the number of AWS resources that are noncompliant and the number that are compliant:

```bash
aws configservice get-compliance-summary-by-resource-type
```

In the output, the value for each `CappedCount` attribute indicates how many resources are compliant or noncompliant.

Output:

```json
{
   "ComplianceSummariesByResourceType": [
      {
         "ComplianceSummary": {
            "NonCompliantResourceCount": {
               "CappedCount": 16,
               "CapExceeded": false
            },
            "ComplianceSummaryTimestamp": 1453237464.543,
            "CompliantResourceCount": {
               "CappedCount": 10,
               "CapExceeded": false
            }
         }
      }
   ]
}
```

To get the compliance summary for a specific resource type

The following command returns the number of EC2 instances that are noncompliant and the number that are compliant:

```bash
aws configservice get-compliance-summary-by-resource-type --resource-types AWS::EC2::Instance
```

In the output, the value for each `CappedCount` attribute indicates how many resources are compliant or noncompliant.
Output:

```json
{
    "ComplianceSummariesByResourceType": [
        {
            "ResourceType": "AWS::EC2::Instance",
            "ComplianceSummary": {
                "NonCompliantResourceCount": {
                    "CappedCount": 3,
                    "CapExceeded": false
                },
                "ComplianceSummaryTimestamp": 1452204923.518,
                "CompliantResourceCount": {
                    "CappedCount": 7,
                    "CapExceeded": false
                }
            }
        }
    ]
}
```

- For API details, see [GetComplianceSummaryByResourceType](#) in *AWS CLI Command Reference*.

**get-resource-config-history**

The following code example shows how to use `get-resource-config-history`.

**AWS CLI**

*To get the configuration history of an AWS resource*

The following command returns a list of configuration items for an EC2 instance with an ID of `i-1a2b3c4d`:

```bash
aws configservice get-resource-config-history --resource-type AWS::EC2::Instance --resource-id i-1a2b3c4d
```

- For API details, see [GetResourceConfigHistory](#) in *AWS CLI Command Reference*.

**get-status**

The following code example shows how to use `get-status`.
To get the status for AWS Config

The following command returns the status of the delivery channel and configuration recorder:

```bash
aws configservice get-status
```

Output:

```
Configuration Recorders:
name: default
recorder: ON
last status: SUCCESS

Delivery Channels:
name: default
last stream delivery status: SUCCESS
last history delivery status: SUCCESS
last snapshot delivery status: SUCCESS
```

- For API details, see [GetStatus](#) in *AWS CLI Command Reference*.

list-discovered-resources

The following code example shows how to use list-discovered-resources.

AWS CLI

To list resources that AWS Config has discovered

The following command lists the EC2 instances that AWS Config has discovered:

```bash
aws configservice list-discovered-resources --resource-type AWS::EC2::Instance
```

Output:

```
{
    "resourceIdentifiers": [
```
{  
  "resourceType": "AWS::EC2::Instance",
  "resourceId": "i-1a2b3c4d"
},
{  
  "resourceType": "AWS::EC2::Instance",
  "resourceId": "i-2a2b3c4d"
},
{  
  "resourceType": "AWS::EC2::Instance",
  "resourceId": "i-3a2b3c4d"
}
]

• For API details, see [ListDiscoveredResources](#) in *AWS CLI Command Reference*. 

**put-config-rule**

The following code example shows how to use `put-config-rule`.

**AWS CLI**

**To add an AWS managed Config rule**

The following command provides JSON code to add an AWS managed Config rule:

```bash
aws configservice put-config-rule --config-rule file://
RequiredTagsForEC2Instances.json
```

`RequiredTagsForEC2Instances.json` is a JSON file that contains the rule configuration:

```json
{
  "ConfigRuleName": "RequiredTagsForEC2Instances",
  "Description": "Checks whether the CostCenter and Owner tags are applied to EC2 instances.",
  "Scope": {
    "ComplianceResourceTypes": [
      "AWS::EC2::Instance"
    ]
  },
  "Source": {
```
For the `ComplianceResourceTypes` attribute, this JSON code limits the scope to resources of the `AWS::EC2::Instance` type, so AWS Config will evaluate only EC2 instances against the rule. Because the rule is a managed rule, the `Owner` attribute is set to AWS, and the `SourceIdentifier` attribute is set to the rule identifier, `REQUIRED_TAGS`. For the `InputParameters` attribute, the tag keys that the rule requires, `CostCenter` and `Owner`, are specified.

If the command succeeds, AWS Config returns no output. To verify the rule configuration, run the `describe-config-rules` command, and specify the rule name.

**To add a customer managed Config rule**

The following command provides JSON code to add a customer managed Config rule:

```
aws configservice put-config-rule --config-rule file://InstanceTypesAreT2micro.json
```

`InstanceTypesAreT2micro.json` is a JSON file that contains the rule configuration:

```json
{
    "ConfigRuleName": "InstanceTypesAreT2micro",
    "Description": "Evaluates whether EC2 instances are the t2.micro type.",
    "Scope": {
        "ComplianceResourceTypes": [
            "AWS::EC2::Instance"
        ]
    },
    "Source": {
        "Owner": "CUSTOM_LAMBDA",
        "SourceIdentifier": "arn:aws:lambda:us-east-1:123456789012:function:InstanceTypeCheck",
        "SourceDetails": [
            {
                "EventSource": "aws.config",
                "MessageType": "ConfigurationItemChangeNotification"
            }
        ]
    }
}
```
For the ComplianceResourceTypes attribute, this JSON code limits the scope to resources of the AWS::EC2::Instance type, so AWS Config will evaluate only EC2 instances against the rule. Because this rule is a customer managed rule, the Owner attribute is set to CUSTOM_LAMBDA, and the SourceIdentifier attribute is set to the ARN of the AWS Lambda function. The SourceDetails object is required. The parameters that are specified for the InputParameters attribute are passed to the AWS Lambda function when AWS Config invokes it to evaluate resources against the rule.

If the command succeeds, AWS Config returns no output. To verify the rule configuration, run the describe-config-rules command, and specify the rule name.

- For API details, see PutConfigRule in AWS CLI Command Reference.

**put-configuration-recorder**

The following code example shows how to use put-configuration-recorder.

**AWS CLI**

**Example 1: To record all supported resources**

The following command creates a configuration recorder that tracks changes to all supported resource types, including global resource types:

```
aws configservice put-configuration-recorder \
  --configuration-recorder name=default,roleARN=arn:aws:iam::123456789012:role/config-role \
  --recording-group allSupported=true,includeGlobalResourceTypes=true
```

If the command succeeds, AWS Config returns no output. To verify the settings of your configuration recorder, run the describe-configuration-recorders command.

**Example 2: To record specific types of resources**

The following command creates a configuration recorder that tracks changes to only those types of resources that are specified in the JSON file for the --recording-group option:
recordingGroup.json is a JSON file that specifies the types of resources that AWS Config will record:

```json
{
    "allSupported": false,
    "includeGlobalResourceTypes": false,
    "resourceTypes": [
        "AWS::EC2::EIP",
        "AWS::EC2::Instance",
        "AWS::EC2::NetworkAcl",
        "AWS::EC2::SecurityGroup",
        "AWS::CloudTrail::Trail",
        "AWS::EC2::Volume",
        "AWS::EC2::VPC",
        "AWS::IAM::User",
        "AWS::IAM::Policy"
    ]
}
```

Before you can specify resource types for the resourceTypes key, you must set the allSupported and includeGlobalResourceTypes options to false or omit them.

If the command succeeds, AWS Config returns no output. To verify the settings of your configuration recorder, run the describe-configuration-recorders command.

**Example 3: To select all supported resources excluding specific types of resources**

The following command creates a configuration recorder that tracks changes to all current and future supported resource types excluding those types of resources that are specified in the JSON file for the --recording-group option:

```bash
aws configservice put-configuration-recorder \
    --configuration-recorder name=default,roleARN=arn:aws:iam::123456789012:role/config-role \
    --recording-group file://recordingGroup.json
```
recordingGroup.json is a JSON file that specifies the types of resources that AWS Config will record:

```json
{
    "allSupported": false,
    "exclusionByResourceTypes": {
        "resourceTypes": [
            "AWS::Redshift::ClusterSnapshot",
            "AWS::RDS::DBClusterSnapshot",
            "AWS::CloudFront::StreamingDistribution"
        ],
    },
    "includeGlobalResourceTypes": false,
    "recordingStrategy": {
        "useOnly": "EXCLUSION_BY_RESOURCE_TYPES"
    }
}
```

Before you can specify resource types to excluding from recording: 1) You must set the allSupported and includeGlobalResourceTypes options to false or omit them, and 2) You must set the useOnly field of RecordingStrategy to EXCLUSION_BY_RESOURCE_TYPES.

If the command succeeds, AWS Config returns no output. To verify the settings of your configuration recorder, run the describe-configuration-recorders command.

- For API details, see [PutConfigurationRecorder](https://docs.aws.amazon.com/cli/latest/reference/configservice/put-configuration-recorder.html) in *AWS CLI Command Reference*.

**put-delivery-channel**

The following code example shows how to use `put-delivery-channel`.

**AWS CLI**

**To create a delivery channel**

The following command provides the settings for the delivery channel as JSON code:

```
aws configservice put-delivery-channel --delivery-channel file://deliveryChannel.json
```

The `deliveryChannel.json` file specifies the delivery channel attributes:
This example sets the following attributes:

name - The name of the delivery channel. By default, AWS Config assigns the name default to a new delivery channel. You cannot update the delivery channel name with the put-delivery-channel command. For the steps to change the name, see Renaming the Delivery Channel.
s3BucketName - The name of the Amazon S3 bucket to which AWS Config delivers configuration snapshots and configuration history files. If you specify a bucket that belongs to another AWS account, that bucket must have policies that grant access permissions to AWS Config. For more information, see Permissions for the Amazon S3 Bucket.
snsTopicARN - The Amazon Resource Name (ARN) of the Amazon SNS topic to which AWS Config sends notifications about configuration changes. If you choose a topic from another account, the topic must have policies that grant access permissions to AWS Config. For more information, see Permissions for the Amazon SNS Topic.

configSnapshotDeliveryProperties - Contains the deliveryFrequency attribute, which sets how often AWS Config delivers configuration snapshots and how often it invokes evaluations for periodic Config rules.

If the command succeeds, AWS Config returns no output. To verify the settings of your delivery channel, run the describe-delivery-channels command.

- For API details, see PutDeliveryChannel in AWS CLI Command Reference.

start-config-rules-evaluation

The following code example shows how to use start-config-rules-evaluation.

AWS CLI

To run an on-demand evaluation for AWS Config rules
The following command starts an evaluation for two AWS managed rules:

```bash
aws configservice start-config-rules-evaluation --config-rule-names s3-bucket-versioning-enabled cloudtrail-enabled
```

### start-configuration-recorder

The following code example shows how to use `start-configuration-recorder`.

**AWS CLI**

**To start the configuration recorder**

The following command starts the default configuration recorder:

```bash
aws configservice start-configuration-recorder --configuration-recorder-name default
```

If the command succeeds, AWS Config returns no output. To verify that AWS Config is recording your resources, run the `get-status` command.

- For API details, see [StartConfigurationRecorder](https://docs.aws.amazon.com/cli/latest/reference/configservice/start-configuration-recorder.html) in *AWS CLI Command Reference*.

### stop-configuration-recorder

The following code example shows how to use `stop-configuration-recorder`.

**AWS CLI**

**To stop the configuration recorder**

The following command stops the default configuration recorder:

```bash
aws configservice stop-configuration-recorder --configuration-recorder-name default
```

If the command succeeds, AWS Config returns no output. To verify that AWS Config is not recording your resources, run the `get-status` command.

- For API details, see [StopConfigurationRecorder](https://docs.aws.amazon.com/cli/latest/reference/configservice/stop-configuration-recorder.html) in *AWS CLI Command Reference*. 
subscribe

The following code example shows how to use subscribe.

AWS CLI

To subscribe to AWS Config

The following command creates the default delivery channel and configuration recorder. The command also specifies the Amazon S3 bucket and Amazon SNS topic to which AWS Config will deliver configuration information:

```bash
```

Output:

```
Using existing S3 bucket: config-bucket-123456789012
Subscribe succeeded:

Amazon Connect examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with Amazon Connect.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

create-user

The following code example shows how to use create-user.

AWS CLI

To create a user

The following create-user example adds a user with the specified attributes to the specified Amazon Connect instance.

```bash
aws connect create-user \
  --username Mary \
  --password Pass@Word1 \
  --identity-info FirstName=Mary,LastName=Major \
  --phone-config PhoneType=DESK_PHONE,AutoAccept=true,AfterContactWorkTimeLimit=60,DeskPhoneNumber=+15555555212 \
  --security-profile-id 12345678-1111-2222-aaaa-a1b2c3d4f5g7 \
  --routing-profile-id 87654321-9999-3434-abcd-x1y2z3a1b2c3 \
  --instance-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```
Output:

```json

    "UserArn": "arn:aws:connect:us-west-2:123456789012:instance/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111/agent/87654321-2222-1234-1234-111234567891"
}
```

For more information, see Add Users in the Amazon Connect Administrator Guide.

- For API details, see CreateUser in AWS CLI Command Reference.

**delete-user**

The following code example shows how to use delete-user.

**AWS CLI**

**To delete a user**

The following delete-user example deletes the specified user from the specified Amazon Connect instance.

```
aws connect delete-user \\
   --instance-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \\
   --user-id 87654321-2222-1234-1234-111234567891
```

This command produces no output.

For more information, see Manage Users in the Amazon Connect Administrator Guide.

- For API details, see DeleteUser in AWS CLI Command Reference.

**describe-user-hierarchy-group**

The following code example shows how to use describe-user-hierarchy-group.

**AWS CLI**

**To display the details for a hierarchy group**

The following describe-user-hierarchy-group example displays the details for the specified Amazon Connect hierarchy group.
The following code example shows how to use `describe-user-hierarchy-structure`.

**AWS CLI**

To display the details for a hierarchy structure

The following `describe-user-hierarchy-structure` example displays the details for the hierarchy structure for the specified Amazon Connect instance.

```bash
aws connect describe-user-hierarchy-group
   --instance-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

### list-routing-profiles

The following code example shows how to use `list-routing-profiles`.

#### AWS CLI

**To list the routing profiles in an instance**

The following `list-routing-profiles` example lists the routing profiles in the specified Amazon Connect instance.

```
aws connect list-routing-profiles \
    --instance-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

**Output:**
For more information, see Create a Routing Profile in the Amazon Connect Administrator Guide.

- For API details, see ListRoutingProfiles in AWS CLI Command Reference.

list-security-profiles

The following code example shows how to use list-security-profiles.

AWS CLI

To list the security profiles in an instance

The following list-security-profiles example lists the security profiles in the specified Amazon Connect instance.

    aws connect list-security-profiles \
      --instance-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111

Output:

list-user-hierarchy-groups

The following code example shows how to use list-user-hierarchy-groups.

AWS CLI

To list the user hierarchy groups in an instance

The following list-user-hierarchy-groups example lists the user hierarchy groups in the specified Amazon Connect instance.

```
aws connect list-user-hierarchy-groups \
   --instance-id 40c83b68-ea62-414c-97bb-d018e39e158e
```

Output:
For more information, see Set Up Agent Hierarchies in the Amazon Connect Administrator Guide.

- For API details, see ListUserHierarchyGroups in AWS CLI Command Reference.

**list-users**

The following code example shows how to use list-users.

**AWS CLI**

**To list the user hierarchy groups in an instance**

The following `list-users` example lists the users in the specified Amazon Connect instance.

```
aws connect list-users \
  --instance-id 40c83b68-ea62-414c-97bb-d018e39e158e
```

**Output:**

- For API details, see ListUsers in AWS CLI Command Reference.

update-contact-attributes

The following code example shows how to use update-contact-attributes.

AWS CLI

**To update a contact's attribute**

The following update-contact-attributes example updates the greetingPlayed attribute for the specified Amazon Connect user.

```
aws connect update-contact-attributes \
    --initial-contact-id 1111111-2222-3333-4444-12345678910 \
    --instance-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \
    --attributes greetingPlayed=false
```

This command produces no output.

For more information, see Use Amazon Connect Contact Attributes in the Amazon Connect Administrator Guide.

- For API details, see UpdateContactAttributes in AWS CLI Command Reference.
update-user-hierarchy

The following code example shows how to use update-user-hierarchy.

AWS CLI

To update a user's hierarchy

The following update-user-hierarchy example updates the agent hierarchy for the specified Amazon Connect user.

```
aws connect update-user-hierarchy \
   --hierarchy-group-id 12345678-a1b2-c3d4-e5f6-123456789abc \
   --user-id 87654321-2222-1234-1234-111234567891 \
   --instance-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

This command produces no output.

For more information, see Configure Agent Settings in the Amazon Connect Administrator Guide.

- For API details, see UpdateUserHierarchy in AWS CLI Command Reference.

update-user-identity-info

The following code example shows how to use update-user-identity-info.

AWS CLI

To update a user's identity information

The following update-user-identity-info example updates the identity information for the specified Amazon Connect user.

```
aws connect update-user-identity-info \
   --identity-info FirstName=Mary,LastName=Major,Email=marym@example.com \
   --user-id 87654321-2222-1234-1234-111234567891 \
   --instance-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

This command produces no output.

For more information, see Configure Agent Settings in the Amazon Connect Administrator Guide.

- For API details, see UpdateUserIdentityInfo in AWS CLI Command Reference.
update-user-phone-config

The following code example shows how to use `update-user-phone-config`.

**AWS CLI**

**To update a user's phone configuration**

The following `update-user-phone-config` example updates the phone configuration for the specified user.

```bash
aws connect update-user-phone-config \
  --phone-config
    PhoneType=SOFT_PHONE,AutoAccept=false,AfterContactWorkTimeLimit=60,DeskPhoneNumber=+18005551212 \

    --instance-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

This command produces no output.

For more information, see [Configure Agent Settings](#) in the [Amazon Connect Administrator Guide](#).

- For API details, see [UpdateUserPhoneConfig](#) in [AWS CLI Command Reference](#).

update-user-routing-profile

The following code example shows how to use `update-user-routing-profile`.

**AWS CLI**

**To update a user's routing profile**

The following `update-user-routing-profile` example updates the routing profile for the specified Amazon Connect user.

```bash
aws connect update-user-routing-profile \
  --routing-profile-id 12345678-1111-3333-2222-4444EXAMPLE \
  --user-id 87654321-2222-1234-1234-111234567891 \
  --instance-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

This command produces no output.
For more information, see Configure Agent Settings in the Amazon Connect Administrator Guide.

- For API details, see UpdateUserRoutingProfile in AWS CLI Command Reference.

**update-user-security-profiles**

The following code example shows how to use update-user-security-profiles.

**AWS CLI**

**To update a user's security profiles**

The following update-user-security-profiles example updates the security profile for the specified Amazon Connect user.

```bash
aws connect update-user-security-profiles
   --security-profile-ids 12345678-1234-1234-1234-1234567892111

   --instance-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

This command produces no output.

For more information, see Assign Permissions: Security Profiles in the Amazon Connect Administrator Guide.

- For API details, see UpdateUserSecurityProfiles in AWS CLI Command Reference.

**AWS Cost and Usage Report examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with AWS Cost and Usage Report.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.
Actions

delete-report-definition

The following code example shows how to use delete-report-definition.

AWS CLI

To delete an AWS Cost and Usage Report

This example deletes an AWS Cost and Usage Report.

Command:

```bash
aws cur --region us-east-1 delete-report-definition --report-name "ExampleReport"
```

For API details, see DeleteReportDefinition in AWS CLI Command Reference.

describe-report-definitions

The following code example shows how to use describe-report-definitions.

AWS CLI

To retrieve a list of AWS Cost and Usage Reports

This example describes a list of AWS Cost and Usage Reports owned by an account.

Command:

```bash
aws cur --region us-east-1 describe-report-definitions --max-items 5
```

Output:

```json
{
  "ReportDefinitions": [
  {
    "ReportName": "ExampleReport",
...
The following code example shows how to use put-report-definition.

**AWS CLI**

**To create an AWS Cost and Usage Reports**

The following put-report-definition example creates a daily AWS Cost and Usage Report that you can upload into Amazon Redshift or Amazon QuickSight.

```
aws cur put-report-definition --report-definition file://report-definition.json
```

**Contents of report-definition.json:**

```json
{
    "ReportName": "ExampleReport",
    "TimeUnit": "DAILY",
    "Format": "textORcsv",
    "Compression": "ZIP",

**get-cost-and-usage**

The following code example shows how to use `get-cost-and-usage`.

AWS CLI

To retrieve the S3 usage of an account for the month of September 2017

The following `get-cost-and-usage` example retrieves the S3 usage of an account for the month of September 2017.
```bash
aws ce get-cost-and-usage \
  --time-period Start=2017-09-01,End=2017-10-01 \ 
  --granularity MONTHLY \

get-dimension-values

The following code example shows how to use get-dimension-values.

AWS CLI

To retrieve the tags for the dimension SERVICE, with a value of "Elastic"

This example retrieves the tags for the dimension SERVICE, with a value of "Elastic" for January 01 2017 through May 18 2017.

Command:

```bash
aws ce get-dimension-values --search-string Elastic --time-period Start=2017-01-01,End=2017-05-18 --dimension SERVICE
```

Output:

```json
{
  "TotalSize": 6,
  "DimensionValues": [
    {
      "Attributes": {},
      "Value": "Amazon ElastiCache"
    },

get-reservation-coverage

The following code example shows how to use get-reservation-coverage.

AWS CLI

To retrieve the reservation coverage for EC2 t2.nano instances in the us-east-1 region

This example retrieves the reservation coverage for EC2 t2.nano instances in the us-east-1 region for July-September of 2017.

Command:

```bash
aws ce get-reservation-coverage --time-period Start=2017-07-01,End=2017-10-01 --group-by Type=Dimension,Key=REGION --filter file://filters.json
```

filters.json:

```

   ],
   "ReturnSize": 6
}
```

- For API details, see [GetReservationCoverage](#) in *AWS CLI Command Reference*.

**get-reservation-purchase-recommendation**

The following code example shows how to use `get-reservation-purchase-recommendation`. 
AWS CLI

To retrieve the reservation recommendations for Partial Upfront EC2 RIs with a three year term

The following get-reservation-purchase-recommendation example retrieves recommendations for Partial Upfront EC2 instances with a three-year term, based on the last 60 days of EC2 usage.

```
aws ce get-reservation-purchase-recommendation \
  --service "Amazon Redshift" \
  --lookback-period-in-days SIXTY_DAYS \
  --term-in-years THREE_YEARS \
  --payment-option PARTIAL_UPFRONT
```

Output:

```
{
  "Recommendations": [],
  "Metadata": {
    "GenerationTimestamp": "2018-08-08T15:20:57Z",
    "RecommendationId": "00d59dde-a1ad-473f-8ff2-iexample3330b"
  }
}
```

- For API details, see [GetReservationPurchaseRecommendation](#) in *AWS CLI Command Reference*.

get-reservation-utilization

The following code example shows how to use get-reservation-utilization.

AWS CLI

To retrieve the reservation utilization for your account

The following get-reservation-utilization example retrieves the RI utilization for all t2.nano instance types from 2018-03-01 to 2018-08-01 for the account.

```
aws ce get-reservation-utilization \ 
  --time-period Start=2018-03-01,End=2018-08-01 \ 
  --filter file://filters.json
```
Contents of filters.json:

```json
{
  "Dimensions": {
    "Key": "INSTANCE_TYPE",
    "Values": [
      "t2.nano"

  }
}
```

**get-tags**

The following code example shows how to use `get-tags`.

**AWS CLI**

**To retrieve keys and values for a cost allocation tag**

This example retrieves all cost allocation tags with a key of "Project" and a value that contains "secretProject".
Command:

```
aws ce get-tags --search-string secretProject --time-period
  Start=2017-01-01,End=2017-05-18 --tag-key Project
```

Output:

```
{
  "ReturnSize": 2,
  "Tags": [
    "secretProject1",
    "secretProject2"
  ],
  "TotalSize": 2
}
```

**create-default-role**

The following code example shows how to use `create-default-role`.

---

*Actions and scenarios*
AWS CLI

To create the required IAM role for Amazon DLM

The following `dlm create-default-role` example creates the `AWSDataLifecycleManagerDefaultRole` default role for managing snapshots.

```
aws dlm create-default-role \\
   --resource-type snapshot
```

This command produces no output.

For more information, see [Default service roles for Amazon Data Lifecycle Manager](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/default-service-roles.html) in the *Amazon Elastic Compute Cloud User Guide*.

- For API details, see [CreateDefaultRole](https://docs.aws.amazon.com/cli/latest/reference/dlm/create-default-role.html) in *AWS CLI Command Reference*.

create-lifecycle-policy

The following code example shows how to use `create-lifecycle-policy`.

AWS CLI

To create a lifecycle policy

The following `create-lifecycle-policy` example creates a lifecycle policy that creates a daily snapshot of volumes at the specified time. The specified tags are added to the snapshots, and tags are also copied from the volume and added to the snapshots. If creating a new snapshot exceeds the specified maximum count, the oldest snapshot is deleted.

```
aws dlm create-lifecycle-policy \\
   --description "My first policy" \\
   --state ENABLED \\
   --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \\

aws dlm delete-lifecycle-policy --policy-id policy-0123456789abcdef0
```

- For API details, see `DeleteLifecyclePolicy` in *AWS CLI Command Reference*.

get-lifecycle-policies

The following code example shows how to use `get-lifecycle-policies`.

AWS CLI

To get a summary of your lifecycle policies

The following `get-lifecycle-policies` example lists all of your lifecycle policies.

```
aws dlm get-lifecycle-policies
```

Output:

```
{
   "Policies": [
   {
     "PolicyId": "policy-0123456789abcdef0",

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Topics**
**Actions**

**activate-pipeline**

The following code example shows how to use activate-pipeline.

**AWS CLI**

**To activate a pipeline**

This example activates the specified pipeline:

```aws datapipeline activate-pipeline --pipeline-id df-00627471SOVYZEXAMPLE```

To activate the pipeline at a specific date and time, use the following command:

```aws datapipeline activate-pipeline --pipeline-id df-00627471SOVYZEXAMPLE --start-timestamp 2015-04-07T00:00:00Z```

- For API details, see [ActivatePipeline](#) in [AWS CLI Command Reference](#).

**add-tags**

The following code example shows how to use add-tags.

**AWS CLI**

**To add a tag to a pipeline**

This example adds the specified tag to the specified pipeline:

```aws datapipeline add-tags --pipeline-id df-00627471SOVYZEXAMPLE --tags key=environment,value=production key=owner,value=sales```

To view the tags, use the describe-pipelines command. For example, the tags added in the example command appear as follows in the output for describe-pipelines:

```{...}```
"tags": [ 
{
    "value": "production",
    "key": "environment"
},
{
    "value": "sales",
    "key": "owner"
}
]

• For API details, see [AddTags](#) in *AWS CLI Command Reference*.

**create-pipeline**

The following code example shows how to use `create-pipeline`.

**AWS CLI**

**To create a pipeline**

This example creates a pipeline:

```bash
aws datapipeline create-pipeline --name my-pipeline --unique-id my-pipeline-token
```

The following is example output:

```json
{
    "pipelineId": "df-00627471SOVYZEXAMPLE"
}
```

• For API details, see [CreatePipeline](#) in *AWS CLI Command Reference*.

**deactivate-pipeline**

The following code example shows how to use `deactivate-pipeline`.

**AWS CLI**

**To deactivate a pipeline**
This example deactivates the specified pipeline:

```bash
aws datapipeline deactivate-pipeline --pipeline-id df-00627471SOVYZEXAMPLE
```

To deactivate the pipeline only after all running activities finish, use the following command:

```bash
aws datapipeline deactivate-pipeline --pipeline-id df-00627471SOVYZEXAMPLE --no-cancel-active
```

- For API details, see [DeactivatePipeline](#) in [AWS CLI Command Reference](#).

### delete-pipeline

The following code example shows how to use `delete-pipeline`.

**AWS CLI**

**To delete a pipeline**

This example deletes the specified pipeline:

```bash
aws datapipeline delete-pipeline --pipeline-id df-00627471SOVYZEXAMPLE
```

- For API details, see [DeletePipeline](#) in [AWS CLI Command Reference](#).

### describe-pipelines

The following code example shows how to use `describe-pipelines`.

**AWS CLI**

**To describe your pipelines**

This example describes the specified pipeline:

```bash
aws datapipeline describe-pipelines --pipeline-ids df-00627471SOVYZEXAMPLE
```

The following is example output:

```json

**AWS CLI**

**To list your pipelines**

This example lists your pipelines:

```bash
aws datapipeline list-pipelines
```

The following is example output:

```json
{
   "pipelineIdList": [
      {
         "id": "df-00627471SOVYZEXAMPLE",
         "name": "my-pipeline"
      },
      {
         "id": "df-09028963KNVMREXAMPLE",
```
For API details, see ListPipelines in AWS CLI Command Reference.

**list-runs**

The following code example shows how to use list-runs.

**AWS CLI**

**Example 1: To list your pipeline runs**

The following list-runs example lists the runs for the specified pipeline.

```
aws datapipeline list-runs --pipeline-id df-00627471SOVYZEXAMPLE
```

**Output:**

<table>

Example 2: To list the pipeline runs between the specified dates

The following list-runs example uses the --start-interval to specify the dates to include in the output.

```
aws datapipeline list-runs --pipeline-id df-01434553B58A2SHZUK05 --start-interval 2017-10-07T00:00:00,2017-10-08T00:00:00
```

- For API details, see ListRuns in AWS CLI Command Reference.

put-pipeline-definition

The following code example shows how to use put-pipeline-definition.

AWS CLI

To upload a pipeline definition

This example uploads the specified pipeline definition to the specified pipeline:

```
aws datapipeline put-pipeline-definition --pipeline-id df-00627471SOVYZEXAMPLE --pipeline-definition file://my-pipeline-definition.json
```

The following is example output:

```
{
   "validationErrors": [],
   "errored": false,
   "validationWarnings": []
}
```

- For API details, see PutPipelineDefinition in AWS CLI Command Reference.

remove-tags

The following code example shows how to use remove-tags.

AWS CLI

To remove a tag from a pipeline
This example removes the specified tag from the specified pipeline:

```bash
aws datapipeline remove-tags --pipeline-id df-00627471SOVYZEXAMPLE --tag-keys environment
```

- For API details, see [RemoveTags](#) in *AWS CLI Command Reference*.

**DataSync examples using AWS CLI**

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with DataSync.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**update-location-azure-blob**

The following code example shows how to use `update-location-azure-blob`.

**AWS CLI**

**To update your transfer location with a new agent**

The following `update-location-object-storage` example updates your DataSync location for Microsoft Azure Blob Storage with a new agent.

```bash
aws ds update-location-azure-blob
```
This command produces no output.

For more information, see Replacing your agent in the AWS DataSync User Guide.

- For API details, see UpdateLocationAzureBlob in AWS CLI Command Reference.

update-location-hdfs

The following code example shows how to use update-location-hdfs.

**AWS CLI**

**To update your transfer location with a new agent**

The following update-location-hdfs example updates your DataSync HDFS location with a new agent. You only need the --kerberos-keytab and --kerberos-krb5-conf options if your HDFS cluster uses Kerberos authentication.

```
aws datasync update-location-hdfs \
   --location-arn arn:aws:datasync:us-west-2:123456789012:location/loc-abcdef01234567890 \

For more information, see Replacing your agent in the AWS DataSync User Guide.

- For API details, see UpdateLocationHdfs in AWS CLI Command Reference.

update-location-nfs

The following code example shows how to use update-location-nfs.

AWS CLI

To update your transfer location with a new agent

The following update-location-nfs example updates your DataSync NFS location with a new agent.
aws datasync update-location-nfs
--on-prem-config AgentArns=arn:aws:datasync:us-west-2:123456789012:agent/agent-1234567890abcdef0

This command produces no output.

For more information, see Replacing your agent in the AWS DataSync User Guide.

update-location-object-storage

The following code example shows how to use update-location-object-storage.

AWS CLI

To update your transfer location with a new agent

The following update-location-object-storage example updates your DataSync object storage location with a new agent.

aws datasync update-location-object-storage
--agent-arns arn:aws:datasync:us-west-2:123456789012:agent/agent-1234567890abcdef0

**create-cluster**

The following code example shows how to use `create-cluster`. 
AWS CLI

To create a DAX cluster

The following `create-cluster` example creates a DAX cluster with the specified settings.

```bash
aws dax create-cluster \
   --cluster-name daxcluster \
   --node-type dax.r4.large \
   --replication-factor 3 \
   --iam-role-arn roleARN \

### create-parameter-group

The following code example shows how to use `create-parameter-group`.

**AWS CLI**

To create a parameter group

The following `create-parameter-group` example creates a parameter group with the specified settings.

```bash
aws dax create-parameter-group
    --parameter-group-name daxparametergroup
    --description "A new parameter group"
```

**Output:**

```json
{
    "ParameterGroup": {
        "ParameterGroupName": "daxparametergroup",
        "Description": "A new parameter group"
    }
}

### create-subnet-group

The following code example shows how to use `create-subnet-group`.
AWS CLI

To create a DAX subnet group

The following `create-subnet-group` example creates a subnet group with the specified settings.

```
aws dax create-subnet-group \
    --subnet-group-name daxSubnetGroup \
    --subnet-ids subnet-11111111 subnet-22222222

decrease-replication-factor

The following code example shows how to use `decrease-replication-factor`.

AWS CLI

To remove one or more nodes from the cluster
The following `decrease-replication-factor` example decreases the number of nodes in the specified DAX cluster to one.

```
aws dax decrease-replication-factor \
   --cluster-name daxcluster \
   --new-replication-factor 1
```

Output:

```json
{
   "Cluster": {
      "ClusterName": "daxcluster",

**delete-cluster**

The following code example shows how to use `delete-cluster`.

**AWS CLI**

**To delete a DAX cluster**

The following `delete-cluster` example deletes the specified DAX cluster.

```bash
aws dax delete-cluster
  --cluster-name daxcluster
```

**Output:**

```json
{
  "Cluster": {
    "ClusterName": "daxcluster",

**delete-parameter-group**

The following code example shows how to use delete-parameter-group.

**AWS CLI**

*To delete a parameter group*

The following delete-parameter-group example deletes the specified DAX parameter group.

```bash
aws dax delete-parameter-group
   --parameter-group-name daxparametergroup
```

Output:

```
{
   "DeletionMessage": "Parameter group daxparametergroup has been deleted."
}
```

For more information, see Managing DAX Clusters in the Amazon DynamoDB Developer Guide.

- For API details, see DeleteParameterGroup in AWS CLI Command Reference.

**delete-subnet-group**

The following code example shows how to use delete-subnet-group.

**AWS CLI**

*To delete a subnet group*

The following delete-subnet-group example deletes the specified DAX subnet group.
aws dax delete-subnet-group \
   --subnet-group-name daxSubnetGroup

**Output:**

```json
{
   "DeletionMessage": "Subnet group daxSubnetGroup has been deleted."

**describe-clusters**

The following code example shows how to use `describe-clusters`.

**AWS CLI**

To return information about all provisioned DAX clusters

The following `describe-clusters` example displays details about all provisioned DAX clusters.

```bash
aws dax describe-clusters

**describe-events**

The following code example shows how to use describe-events.

**AWS CLI**

**To return all events related to DAX clusters and parameter groups**

The following describe-events example displays details of events that are related to DAX clusters and parameter groups.

```
aws dax describe-events

**describe-parameter-groups**

The following code example shows how to use `describe-parameter-groups`.

**AWS CLI**

To describe the parameter groups defined in DAX

The following `describe-parameter-groups` example retrieves details about the parameter groups that are defined in DAX.

```
aws dax describe-parameter-groups
```

Output:

```
{
    "ParameterGroups": [
    {
        "ParameterGroupName": "default.dax1.0",

**describe-subnet-groups**

The following code example shows how to use `describe-subnet-groups`.

**AWS CLI**

**To describe subnet groups defined in DAX**

The following `describe-subnet-groups` example retrieves details for the subnet groups defined in DAX.

```
aws dax describe-subnet-groups
```

**Output:**

```
{
    "SubnetGroups": [
        {

increase-replication-factor

The following code example shows how to use increase-replication-factor.

**AWS CLI**

To increase the replication factor for a DAX cluster

The following increase-replication-factor example increases the specified DAX cluster's replication factor to 3.

```bash
aws dax increase-replication-factor \
  --cluster-name daxcluster \
  --new-replication-factor 3
```

Output:

list-tags

The following code example shows how to use list-tags.

AWS CLI

To list tags on a DAX resource

The following list-tags example lists the tag keys and values attached to the specified DAX cluster.

```bash
aws dax list-tags \
```

Output:

```json
{
   "Tags": [
      {
         "Key": "ClusterUsage",
         "Value": "prod"
      }

}
```

For more information, see Managing DAX Clusters in the Amazon DynamoDB Developer Guide.

- For API details, see ListTags in AWS CLI Command Reference.

tag-resource

The following code example shows how to use tag-resource.

AWS CLI

To tag a DAX resource

The following tag-resource example attaches the specified tag key name and associated value to the specified DAX cluster to describe the cluster usage.

```bash
aws dax tag-resource \
```

Actions and scenarios
```
--resource-name arn:aws:dax:us-west-2:123456789012:cache/daxcluster \
--tags="Key=ClusterUsage,Value=prod"
```

Output:

**untag-resource**

The following code example shows how to use untag-resource.

**AWS CLI**

**To remove tags from a DAX resource**

The following untag-resource example removes the tag with the specified key name from a DAX cluster.

```
aws dax untag-resource  \
   --resource-name arn:aws:dax:us-west-2:123456789012:cache/daxcluster \
   --tag-keys="ClusterUsage"
```

Output:

```
{
   "Tags": []
}
```

**Actions**

**accept-invitation**

The following code example shows how to use *accept-invitation*.

**AWS CLI**

To accept an invitation to become a member account in a behavior graph

The following accept-invitation example accepts an invitation to become a member account in behavior graph arn:aws:detective:us-east-1:111122223333:graph:123412341234.

```
aws detective accept-invitation \ 
```

This command produces no output.

For more information, see [Responding to a behavior graph invitation](#) in the *Amazon Detective Administration Guide*.
For API details, see `AcceptInvitation` in `AWS CLI Command Reference`.

**create-graph**

The following code example shows how to use `create-graph`.

**AWS CLI**

To enable Amazon Detective and create a new behavior graph

The following `create-graph` example enables Detective for the AWS account that runs the command in the Region where the command is run. A new behavior graph is created that has that account as its administrator account. The command also assigns the value Finance to the Department tag.

```
aws detective create-graph \
  --tags '{"Department": "Finance"}"
```

Output:

```
{
  "GraphArn": "arn:aws:detective:us-east-1:111122223333:graph:027c7c4610ea4aacaf0b883093cab899"
}
```

For more information, see `Enabling Amazon Detective` in the Amazon Detective Administration Guide.

For API details, see `CreateGraph` in `AWS CLI Command Reference`.

**create-members**

The following code example shows how to use `create-members`.

**AWS CLI**

To invite member accounts to a behavior graph

The following `create-members` example invites two AWS accounts to become member accounts in the behavior graph `arn:aws:detective:us-east-1:111122223333:graph:123412341234`. For each account, the request provides the AWS
account ID and the account root user email address. The request includes a custom message to insert into the invitation email.

```bash
aws detective create-members \
   --accounts AccountId=444455556666,EmailAddress=mmajor@example.com \
   AccountId=123456789012,EmailAddress=jstiles@example.com \
   --graph-arn arn:aws:detective:us-east-1:111122223333:graph:123412341234 \
   --message "This is Paul Santos. I need to add your account to the data we use for security investigation in Amazon Detective. If you have any questions, contact me at psantos@example.com."
```

Output:

```

To invite member accounts without sending invitation emails

The following create-members example invites two AWS accounts to become member accounts in the behavior graph arn:aws:detective:us-east-1:111122223333:graph:123412341234. For each account, the request provides the AWS account ID and the account root user email address. The member accounts do not receive invitation emails.

```bash
aws detective create-members \
   --accounts AccountId=444455556666,EmailAddress=mmajor@example.com \
   AccountId=123456789012,EmailAddress=jstiles@example.com \
   --graph-arn arn:aws:detective:us-east-1:111122223333:graph:123412341234 \
   --disable-email-notification
```

Output:

- For API details, see **DeleteGraph** in *AWS CLI Command Reference*.

**delete-members**

The following code example shows how to use `delete-members`.

**AWS CLI**

To remove member accounts from a behavior graph

The following `delete-members` example removes two member accounts from the behavior graph arn:aws:detective:us-east-1:111122223333:graph:123412341234. To identify the accounts, the request provides the AWS account IDs.

```bash
aws detective delete-members \
   --account-ids 444455556666 123456789012 \
```
Output:

```json

**disassociate-membership**

The following code example shows how to use `disassociate-membership`.

**AWS CLI**

To resign membership from a behavior graph

The following disassociate-membership example removes the AWS account that runs the command from the behavior graph arn:aws:detective:us-east-1:111122223333:graph:123412341234.

```
aws detective disassociate-membership \

**get-members**

The following code example shows how to use `get-members`.

**AWS CLI**

To retrieve information about selected behavior graph member accounts
The following `get-members` example retrieves information about two member accounts in the behavior graph `arn:aws:detective:us-east-1:111122223333:graph:123412341234`. For the two accounts, the request provides the AWS account IDs.

```bash
aws detective get-members \
   --account-ids 444455556666 123456789012 \n   --graph-arn arn:aws:detective:us-east-1:111122223333:graph:123412341234

list-graphs

The following code example shows how to use list-graphs.

AWS CLI

To view a list of behavior graphs that your account is the administrator for

The following list-graphs example retrieves the behavior graphs that the calling account is the administrator for within the current Region.

```
aws detective list-graphs
```

Output:

```
{
   "GraphList": [
   
   {
      "CreatedTime": 1579736111000

- For API details, see ListGraphs in AWS CLI Command Reference.

list-invitations

The following code example shows how to use list-invitations.

AWS CLI

To view a list of behavior graphs that an account is a member of or is invited to

The following list-invitations example retrieves the behavior graphs that the calling account has been invited to. The results include only open and accepted invitations. They do not include rejected invitations or removed memberships.

```
aws detective list-invitations
```

Output:
For more information, see Viewing your list of behavior graph invitations<https://docs.aws.amazon.com/detective/latest/adminguide/member-view-graph-invitations.html> in the Amazon Detective Administration Guide.

- For API details, see ListInvitations in AWS CLI Command Reference.

list-members

The following code example shows how to use list-members.

AWS CLI

To list the member accounts in a behavior graph

The following list-members example retrieves the invited and enabled member accounts for the behavior graph `arn:aws:detective:us-east-1:111122223333:graph:123412341234`. The results do not include member accounts that were removed.

```bash
aws detective list-members \
```

Output:

```json
{
    "MemberDetails": [
        {
            "AccountId": "444455556666",

list-tags-for-resource

The following code example shows how to use list-tags-for-resource.

AWS CLI

To retrieve the tags assigned to a behavior graph

The following list-tags-for-resource example returns the tags assigned to the specified behavior graph.
aws detective list-tags-for-resource \

Output:

{
   "Tags": {
      "Department": "Finance"
   }
}

For more information, see Managing tags for a behavior graph in the Amazon Detective Administration Guide.

• For API details, see ListTagsForResource in AWS CLI Command Reference.

reject-invitation

The following code example shows how to use reject-invitation.

AWS CLI

To reject an invitation to become a member account in a behavior graph

The following reject-invitation example rejects an invitation to become a member account in the behavior graph arn:aws:detective:us-east-1:111122223333:graph:123412341234.

aws detective reject-invitation \

This command produces no output.

• For API details, see RejectInvitation in AWS CLI Command Reference.
**tag-resource**

The following code example shows how to use `tag-resource`.

**AWS CLI**

**To assign a tag to a resource**

The following `tag-resource` example assigns a value for the Department tag to the specified behavior graph.

```bash
aws detective tag-resource \
   --tags '{"Department":"Finance"}"
```

This command produces no output.

For more information, see [Managing tags for a behavior graph](#) in the *Amazon Detective Administration Guide*.

create-device-pool

The following code example shows how to use create-device-pool.

AWS CLI

To create a device pool

The following command creates an Android device pool for a project:

```
```

You can get the project ARN from the output of create-project or list-projects. The file device-pool-rules.json is a JSON document in the current folder that specifies the device platform:

```
[
  {
    "attribute": "PLATFORM",
```
"operator": "EQUALS",
"value": "\"ANDROID\""
}
]

Output:

{
  "devicePool": {
    "rules": [
      {
        "operator": "EQUALS",
        "attribute": "PLATFORM",
        "value": "\"ANDROID\"

  }
}

- For API details, see CreateDevicePool in AWS CLI Command Reference.

create-project

The following code example shows how to use create-project.

AWS CLI

To create a project

The following command creates a new project named my-project:

aws devicefarm create-project --name my-project

Output:

{

• For API details, see CreateProject in AWS CLI Command Reference.

create-upload

The following code example shows how to use create-upload.

AWS CLI

To create an upload

The following command creates an upload for an Android app:

```bash
aws devicefarm create-upload --project-arn "arn:aws:devicefarm:us-west-2:123456789012:project:070fc3ca-7ec1-4741-9c1f-d3e044efc506" --name app.apk --type ANDROID_APP
```

You can get the project ARN from the output of create-project or list-projects.

Output:

```json
{

### get-upload

The following code example shows how to use `get-upload`.

```bash
aws devicefarm get-upload --arn "arn:aws:devicefarm:us-west-2:123456789012:upload:070fc3ca-7ec1-4741-9c1f-d3e044efc506/dd72723a-ae9e-4087-09e6-f4cea3599514"
```

You can get the upload ARN from the output of `create-upload`.

**Output:**

```json
{
  "upload": {
    "status": "SUCCEEDED",
    "name": "app.apk",
    "created": 1505262773.186,
  }
}
```
• For API details, see GetUpload in AWS CLI Command Reference.

list-projects

The following code example shows how to use list-projects.

AWS CLI

To list projects

The following retrieves a list of projects:

```
aws devicefarm list-projects
```

Output:

```

AWS Direct Connect examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with AWS Direct Connect.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

accept-direct-connect-gateway-association-proposal

The following code example shows how to use accept-direct-connect-gateway-association-proposal.

AWS CLI

To accept a gateway association proposal

The following accept-direct-connect-gateway-association-proposal accepts the specified proposal.

```
aws directconnect accept-direct-connect-gateway-association-proposal \

allocate-connection-on-interconnect

The following code example shows how to use allocate-connection-on-interconnect.

AWS CLI

To create a hosted connection on an interconnect

The following allocate-connection-on-interconnect command creates a hosted connection on an interconnect:

```bash
aws directconnect allocate-connection-on-interconnect --bandwidth 500Mbps --connection-name mydcinterconnect --owner-account 123456789012 --interconnect-id dxcon-fgktov66 --vlan 101
```

Output:
For API details, see `AllocateConnectionOnInterconnect` in *AWS CLI Command Reference*.

**allocate-hosted-connection**

The following code example shows how to use `allocate-hosted-connection`.

**AWS CLI**

To create a hosted connection on an interconnect

The following `allocate-hosted-connection` example creates a hosted connection on the specified interconnect.

```
aws directconnect allocate-hosted-connection \
  --bandwidth 500Mbps \
  --connection-name mydcinterconnect \
  --owner-account 123456789012 \
  -connection-id dxcon-fgktov66 \

allocate-private-virtual-interface

The following code example shows how to use allocate-private-virtual-interface.

AWS CLI

To provision a private virtual interface

The following allocate-private-virtual-interface command provisions a private virtual interface to be owned by a different customer:

```bash
aws directconnect allocate-private-virtual-interface --connection-id dxcon-ffjrkx17 --owner-account 123456789012 --new-private-virtual-interface-allocation

allocate-transit-virtual-interface

The following code example shows how to use allocate-transit-virtual-interface.

AWS CLI

To provision a transit virtual interface to be owned by the specified AWS account

The following allocate-transit-virtual-interface example provisions a transit virtual interface for the specified account.

```
aws directconnect allocate-transit-virtual-interface \

**associate-connection-with-lag**

The following code example shows how to use `associate-connection-with-lag`.

**AWS CLI**

**To associate a connection with a LAG**

The following example associates the specified connection with the specified LAG.

**Command:**

```
aws directconnect associate-connection-with-lag --lag-id dxlag-fhccu14t --connection-id dxcon-fg9607vm
```

**Output:**

```

**associate-hosted-connection**

The following code example shows how to use `associate-hosted-connection`.

**AWS CLI**

**To associate a hosted connection with a LAG**
The following example associates the specified hosted connection with the specified LAG.

Command:

```
aws directconnect associate-hosted-connection --parent-connection-id dxlag-fhccu14t --connection-id dxcon-fg9607vm
```

Output:

```

**associate-virtual-interface**

The following code example shows how to use `associate-virtual-interface`.

**AWS CLI**

**To associate a virtual interface with a connection**

The following example associates the specified virtual interface with the specified LAG. Alternatively, to associate the virtual interface with a connection, specify the ID of an AWS Direct Connect connection for `--connection-id`; for example, `dxcon-ffnikghc`.

Command:

```
aws directconnect associate-virtual-interface --connection-id dxlag-ffjhj9lx --virtual-interface-id dxvif-fgputw0j
```
Output:

**confirm-connection**

The following code example shows how to use `confirm-connection`.

**AWS CLI**

To confirm the creation of a hosted connection on an interconnect

The following `confirm-connection` command confirms the creation of a hosted connection on an interconnect:

```bash
aws directconnect confirm-connection --connection-id dxcon-fg2wi7hy
```

Output:

```json
{
    "connectionState": "pending"

```

For API details, see `ConfirmConnection` in *AWS CLI Command Reference*.

**confirm-private-virtual-interface**

The following code example shows how to use `confirm-private-virtual-interface`.

**AWS CLI**

To accept ownership of a private virtual interface

The following `confirm-private-virtual-interface` command accepts ownership of a private virtual interface created by another customer:

```bash
aws directconnect confirm-private-virtual-interface --virtual-interface-id dxvif-fgy8orxu --virtual-gateway-id vgw-e4a47df9

```

For more information, see Accepting a Hosted Virtual Interface in the AWS Direct Connect User Guide.

- For API details, see ConfirmTransitVirtualInterface in AWS CLI Command Reference.

create-bgp-peer

The following code example shows how to use create-bgp-peer.

AWS CLI

To create an IPv6 BGP peering session

The following example creates an IPv6 BGP peering session on private virtual interface dxvif-fg1vuj3d. The peer IPv6 addresses are automatically allocated by Amazon.

Command:

```
aws directconnect create-bgp-peer --virtual-interface-id dxvif-fg1vuj3d --new-bgp-peer asn=64600,addressFamily=ipv6
```

Output:

create-connection

The following code example shows how to use create-connection.

AWS CLI

To create a connection from your network to an AWS Direct Connect location

The following create-connection command creates a connection from your network to an AWS Direct Connect location:

```bash
aws directconnect create-connection --location TIVIT --bandwidth 1Gbps --connection-name "Connection to AWS"
```

Output:

```json
{
    "ownerAccount": "123456789012",
    "connectionId": "dxcon-fg31dyv6",
    "connectionState": "requested",
    "bandwidth": "1Gbps",
    "location": "TIVIT",
    "connectionName": "Connection to AWS",
    "region": "sa-east-1"
}
```

- For API details, see [CreateConnection](#) in [AWS CLI Command Reference](#).

create-direct-connect-gateway-association-proposal

The following code example shows how to use create-direct-connect-gateway-association-proposal.

AWS CLI

To create a proposal to associate the specified transit gateway with the specified Direct Connect gateway

The following create-direct-connect-gateway-association-proposal example creates a proposal that associates the specified transit gateway with the specified Direct Connect gateway.
aws directconnect create-direct-connect-gateway-association-proposal \
  --direct-connect-gateway-id 11460968-4ac1-4fd3-bdb2-00599EXAMPLE \
  --direct-connect-gateway-owner-account 111122223333 \
  --gateway-id tgw-02f776b1a7EXAMPLE \
  --add-allowed-prefixes-to-direct-connect-gateway cidr=192.168.1.0/30

Output:

```json
{
  "directConnectGatewayAssociationProposal": {
    "proposalId": "cb7f41cb-8128-43a5-93b1-dcaedEXAMPLE",
    "directConnectGatewayId": "11460968-4ac1-4fd3-bdb2-00599EXAMPLE",

**create-direct-connect-gateway-association**

The following code example shows how to use create-direct-connect-gateway-association.

**AWS CLI**

To associate a virtual private gateway with a Direct Connect gateway
The following example associates virtual private gateway vgw-6efe725e with Direct Connect gateway 5f294f92-bafb-4011-916d-9b0bexample. You must run the command in the region in which the virtual private gateway is located.

Command:

```bash
aws directconnect create-direct-connect-gateway-association --direct-connect-gateway-id 5f294f92-bafb-4011-916d-9b0bexample --virtual-gateway-id vgw-6efe725e
```

Output:

```json
{
   "directConnectGatewayAssociation": {
      "associationState": "associating",
      "virtualGatewayOwnerAccount": "123456789012",
      "directConnectGatewayId": "5f294f92-bafb-4011-916d-9b0bexample",
      "virtualGatewayId": "vgw-6efe725e",
      "virtualGatewayRegion": "us-east-2"
   }
}
```

### create-direct-connect-gateway

The following code example shows how to use `create-direct-connect-gateway`.

**AWS CLI**

**To create a Direct Connect gateway**

The following example creates a Direct Connect gateway with the name DxGateway1.

Command:

```bash
aws directconnect create-direct-connect-gateway --direct-connect-gateway-name "DxGateway1"
```

Output:

```json
{
}
```
"directConnectGateway": {
    "amazonSideAsn": 64512,
    "directConnectGatewayId": "5f294f92-bafb-4011-916d-9b0bexample",
    "ownerAccount": "123456789012",
    "directConnectGatewayName": "DxGateway1",
    "directConnectGatewayState": "available"
}
}

- For API details, see CreateDirectConnectGateway in AWS CLI Command Reference.

create-interconnect

The following code example shows how to use create-interconnect.

AWS CLI

To create an interconnect between a partner's network and AWS

The following create-interconnect command creates an interconnect between an AWS Direct Connect partner's network and a specific AWS Direct Connect location:

```
aws directconnect create-interconnect --interconnect-name "1G Interconnect to AWS" --bandwidth 1Gbps --location TIVIT
```

Output:

```
{
    "region": "sa-east-1",
    "bandwidth": "1Gbps",
    "location": "TIVIT",
    "interconnectName": "1G Interconnect to AWS",
    "interconnectId": "dxcon-fgktov66",
    "interconnectState": "requested"
}
```

- For API details, see CreateInterconnect in AWS CLI Command Reference.

create-lag

The following code example shows how to use create-lag.
AWS CLI

To create a LAG with new connections

The following example creates a LAG and requests two new AWS Direct Connect connections for the LAG with a bandwidth of 1 Gbps.

Command:

```bash
aws directconnect create-lag --location CSVA1 --number-of-connections 2 --connections-bandwidth 1Gbps --lag-name 1GBLag
```

Output:

```json
{
  "awsDevice": "CSVA1-23u8tlpaz8iks",
  "numberOfConnections": 2,
  "lagState": "pending",
  "ownerAccount": "123456789012",
  "lagName": "1GBLag",
  "connections": [
    {
      "ownerAccount": "123456789012",
      "connectionId": "dxcon-ffqr6x5q",
      "lagId": "dxlag-ffjhj91x",
      "connectionState": "requested",
      "bandwidth": "1Gbps",
      "location": "CSVA1",
      "connectionName": "Requested Connection 1 for Lag dxlag-ffjhj91x",
      "region": "us-east-1"
    },
    {
      "ownerAccount": "123456789012",
      "connectionId": "dxcon-fflqyj95",
      "lagId": "dxlag-ffjhj91x",
      "connectionState": "requested",
      "bandwidth": "1Gbps",
      "location": "CSVA1",
      "connectionName": "Requested Connection 2 for Lag dxlag-ffjhj91x",
      "region": "us-east-1"
    }
  ],
  "lagId": "dxlag-ffjhj91x"
}
```
To create a LAG using an existing connection

The following example creates a LAG from an existing connection in your account, and requests a second new connection for the LAG with the same bandwidth and location as the existing connection.

Command:

```
aws directconnect create-lag --location EqDC2 --number-of-connections 2 --connections-bandwidth 1Gbps --lag-name 2ConnLAG --connection-id dxcon-fgk145dr
```

Output:

```
{
  "awsDevice": "EqDC2-4h6ce2r1bes6",
  "numberOfConnections": 2,
  "lagState": "pending",
  "ownerAccount": "123456789012",
  "lagName": "2ConnLAG",
  "connections": [
    {

      "connectionState": "requested",
      "bandwidth": "1Gbps",
      "location": "EqDC2",
      "connectionName": "Requested Connection 1 for Lag dxlag-fhccu14t",
      "region": "us-east-1"
    },
    {
      "ownerAccount": "123456789012",
      "connectionId": "dxcon-fgk145dr",
      "lagId": "dxlag-fhccu14t",
      "connectionState": "down",
      "bandwidth": "1Gbps",
      "location": "EqDC2",
      "region": "us-east-1"
    }
  ]
}
```
create-private-virtual-interface

The following code example shows how to use create-private-virtual-interface.

AWS CLI

To create a private virtual interface

The following `create-private-virtual-interface` command creates a private virtual interface:

```
aws directconnect create-private-virtual-interface --
  connection-id dxcon-ffjrkx17 --new-private-virtual-interface
  virtualInterfaceName=PrivateVirtualInterface,vlan=101,asn=65000,authKey=asdf34example,amazonAddress=192.168.1.1/30,customerAddress=192.168.1.2/30,virtualGatewayId=vgw-aba37db6
```

Output:

```
{
  "virtualInterfaceState": "pending",
  "asn": 65000,
  "vlan": 101,
  "customerAddress": "192.168.1.2/30",
  "ownerAccount": "123456789012",
  "connectionId": "dxcon-ffjrkx17",
  "virtualGatewayId": "vgw-aba37db6",
  "virtualInterfaceId": "dxvif-ffhhk74f",
  "authKey": "asdf34example",
  "routeFilterPrefixes": []
}
```
For API details, see CreatePrivateVirtualInterface in AWS CLI Command Reference.

create-public-virtual-interface

The following code example shows how to use create-public-virtual-interface.

**AWS CLI**

To create a public virtual interface

The following create-public-virtual-interface command creates a public virtual interface:

```bash
aws directconnect create-public-virtual-interface --
  connection-id dxcon-ffjrxx17 --new-public-virtual-interface
  virtualInterfaceName=PublicVirtualInterface,vlan=2000,asn=65000,authKey=asdf34example,amazonAddress=203.0.113.1/30,customerAddress=203.0.113.2/30,routeFilterPrefixes=
  [cidr=203.0.113.0/30],
  {cidr=203.0.113.4/30]}
```

Output:

```json

    "virtualInterfaceId": "dxvif-fgh0hrck",
    "authKey": "asdf34example",
    "routeFilterPrefixes": [
```
For API details, see CreatePublicVirtualInterface in AWS CLI Command Reference.

create-transit-virtual-interface

The following code example shows how to use create-transit-virtual-interface.

AWS CLI

To create a transit virtual interface

The following create-transit-virtual-interface example creates a transit virtual interface for the specified connection.

```bash
aws directconnect create-transit-virtual-interface \
  --connection-id dxlag-fEXAMPLE \
  --new-transit-virtual-interface "virtualInterfaceName=Example Transit Virtual Interface,vlan=126,asn=65110,mtu=1500,authKey=0xzxgA9YoW9hS8u58vEXmple,amazonAddress=192.168.1.1/30,customerAddress=192.168.1.2/30,addressFamily=ipv4,directConnectGatewayId=8384da05-13ce-4a91-aada-5a1baEXAMPLE,tags=[{key=Tag,value=Example}]"

delete-bgp-peer

The following code example shows how to use delete-bgp-peer.

**AWS CLI**

**To delete a BGP peer from a virtual interface**

The following example deletes the IPv6 BGP peer from virtual interface dxvif-fg1vuj3d.

Command:

```
aws directconnect delete-bgp-peer --virtual-interface-id dxvif-fg1vuj3d --asn 64600
--customer-address 2001:db8:1100:2f0:0:1:9cb4:4216/125

**delete-connection**

The following code example shows how to use delete-connection.

**AWS CLI**

To delete a connection

The following delete-connection command deletes the specified connection:
aws directconnect delete-connection --connection-id dxcon-fg31dyv6

Output:

```json
{
    "ownerAccount": "123456789012",
    "connectionId": "dxcon-fg31dyv6",

### delete-direct-connect-gateway-association

The following code example shows how to use `delete-direct-connect-gateway-association`.

**AWS CLI**

**To delete a Direct Connect gateway association**

The following `delete-direct-connect-gateway-association` example deletes the Direct Connect gateway association with a transit gateway that has the specified association ID.

```bash
aws directconnect delete-direct-connect-gateway-association --association-id be85116d-46eb-4b43-a27a-da0c2ad648de
```

Output:

```json
{
    "directConnectGatewayAssociation": {

- For API details, see [DeleteDirectConnectGatewayAssociation](#) in *AWS CLI Command Reference*.

### delete-direct-connect-gateway

The following code example shows how to use `delete-direct-connect-gateway`.

**AWS CLI**

**To delete a Direct Connect gateway**

The following example deletes Direct Connect gateway `5f294f92-bafb-4011-916d-9b0bexample`.

**Command:**

```
aws directconnect delete-direct-connect-gateway --direct-connect-gateway-id 5f294f92-bafb-4011-916d-9b0bexample
```

**Output:**

```
{
  "directConnectGateway": {
    "amazonSideAsn": 64512,
    "directConnectGatewayId": "5f294f92-bafb-4011-916d-9b0bexample",
    "ownerAccount": "123456789012",
    "directConnectGatewayName": "DxGateway1",
    "directConnectGatewayState": "deleting"
  }
}
```
delete-interconnect

The following code example shows how to use delete-interconnect.

AWS CLI

To delete an interconnect

The following delete-interconnect command deletes the specified interconnect:

```bash
aws directconnect delete-interconnect --interconnect-id dxcon-fgktov66
```

Output:

```json
{
  "interconnectState": "deleted"
}
```

For API details, see DeleteInterconnect in AWS CLI Command Reference.

delete-lag

The following code example shows how to use delete-lag.

AWS CLI

To delete a LAG

The following example deletes the specified LAG.

Command:

```bash
aws directconnect delete-lag --lag-id dxlag-ffrhowd9
```

Output:

```json
{
}
```
delete-virtual-interface

The following code example shows how to use delete-virtual-interface.

AWS CLI

To delete a virtual interface

The following delete-virtual-interface command deletes the specified virtual interface:

```bash
aws directconnect delete-virtual-interface --virtual-interface-id dxvif-ffhhk74f
```

Output:

```json
{
   "virtualInterfaceState": "deleting"
}
```

For API details, see [DeleteVirtualInterface] in AWS CLI Command Reference.

describe-connection-loa

The following code example shows how to use describe-connection-loa.

AWS CLI

To describe your LOA-CFA for a connection using Linux or Mac OS X
The following example describes your LOA-CFA for connection dxcon-fh6ayh1d. The contents of the LOA-CFA are base64-encoded. This command uses the --output and --query parameters to control the output and extract the contents of the loaContent structure. The final part of the command decodes the content using the base64 utility, and sends the output to a PDF file.

```bash
aws directconnect describe-connection-loa --connection-id dxcon-fh6ayh1d --output text --query loa.loaContent|base64 --decode > myLoaCfa.pdf
```

**To describe your LOA-CFA for a connection using Windows**

The previous example requires the use of the base64 utility to decode the output. On a Windows computer, you can use certutil instead. In the following example, the first command describes your LOA-CFA for connection dxcon-fh6ayh1d and uses the --output and --query parameters to control the output and extract the contents of the loaContent structure to a file called myLoaCfa.base64. The second command uses the certutil utility to decode the file and send the output to a PDF file.

```bash
aws directconnect describe-connection-loa --connection-id dxcon-fh6ayh1d --output text --query loa.loaContent > myLoaCfa.base64

certutil -decode myLoaCfa.base64 myLoaCfa.pdf
```

For more information about controlling AWS CLI output, see [Controlling Command Output from the AWS Command Line Interface](https://docs.aws.amazon.com/cli/latest/reference/directconnect/directconnect-describe-connection-loa.html) in the *AWS Command Line Interface User Guide*.

- For API details, see [DescribeConnectionLoa](https://docs.aws.amazon.com/cli/latest/reference/directconnect/directconnect-describe-connection-loa.html) in *AWS CLI Command Reference*.

**describe-connections-on-interconnect**

The following code example shows how to use `describe-connections-on-interconnect`.

**AWS CLI**

**To list connections on an interconnect**

The following `describe-connections-on-interconnect` command lists connections that have been provisioned on the given interconnect:
aws directconnect describe-connections-on-interconnect --interconnect-id dxcon-fgktov66

Output:

```
{
   "connections": [ 
   {
      "partnerName": "TIVIT",
      "vlan": 101,
      "ownerAccount": "123456789012",

   }
   ]
}
```

- For API details, see DescribeConnectionsOnInterconnect in AWS CLI Command Reference.

**describe-connections**

The following code example shows how to use describe-connections.

**AWS CLI**

**To list all connections in the current region**

The following describe-connections command lists all connections in the current region:

```
aws directconnect describe-connections
```

Output:

```
{
   "connections": [ 
   {
      "awsDevice": "EqDC2-123h49s71dabc",
      "ownerAccount": "123456789012",
```

• For API details, see DescribeConnections in AWS CLI Command Reference.

describe-direct-connect-gateway-association-proposals

The following code example shows how to use describe-direct-connect-gateway-association-proposals.

AWS CLI

To describe your Direct Connect gateway association proposals

The following describe-direct-connect-gateway-association-proposals example displays details about your Direct Connect gateway association proposals.

aws directconnect describe-direct-connect-gateway-association-proposals

Output:

Actions and scenarios
describe-direct-connect-gateways

The following code example shows how to use describe-direct-connect-gateways.

AWS CLI

To describe your Direct Connect gateways

The following example describe all of your Direct Connect gateways.

Command:

```
aws directconnect describe-direct-connect-gateways
```

Output:

```
{
  "directConnectGateways": [
    {
      "amazonSideAsn": 64512,

      "directConnectGatewayState": "available"
    }
  ]
}
```

- For API details, see [DescribeDirectConnectGateways](aws CLI Command Reference).

describe-hosted-connections

The following code example shows how to use describe-hosted-connections.
AWS CLI

To list connections on an interconnect

The following example lists connections that have been provisioned on the given interconnect.

Command:

```bash
aws directconnect describe-hosted-connections --connection-id dxcon-fgktov66
```

Output:

```json
{
   "connections": [
      {
         "partnerName": "TIVIT",

         "region": "sa-east-1"
      }
   ]
}
```

- For API details, see [DescribeHostedConnections](#) in AWS CLI Command Reference.

describe-interconnect-loa

The following code example shows how to use describe-interconnect-loa.

AWS CLI

To describe your LOA-CFA for an interconnect using Linux or Mac OS X

The following example describes your LOA-CFA for interconnect dxcon-fh6ayh1d. The contents of the LOA-CFA are base64-encoded. This command uses the --output and --query parameters to control the output and extract the contents of the loaContent structure. The
final part of the command decodes the content using the base64 utility, and sends the output to a PDF file.

```
aws directconnect describe-interconnect-loa --interconnect-id dxcon-fh6ayh1d --output text --query loa.loaContent|base64 --decode > myLoaCfa.pdf
```

To describe your LOA-CFA for an interconnect using Windows

The previous example requires the use of the base64 utility to decode the output. On a Windows computer, you can use certutil instead. In the following example, the first command describes your LOA-CFA for interconnect dxcon-fh6ayh1d and uses the --output and --query parameters to control the output and extract the contents of the loaContent structure to a file called myLoaCfa.base64. The second command uses the certutil utility to decode the file and send the output to a PDF file.

```
aws directconnect describe-interconnect-loa --interconnect-id dxcon-fh6ayh1d --output text --query loa.loaContent > myLoaCfa.base64

certutil -decode myLoaCfa.base64 myLoaCfa.pdf
```

For more information about controlling AWS CLI output, see Controlling Command Output from the AWS Command Line Interface in the AWS Command Line Interface User Guide.

- For API details, see DescribeInterconnectLoa in AWS CLI Command Reference.

describe-interconnects

The following code example shows how to use describe-interconnects.

AWS CLI

To list interconnects

The following describe-interconnects command lists the interconnects owned by your AWS account:

```
aws directconnect describe-interconnects
```

Output:
For API details, see [DescribeInterconnects](#) in *AWS CLI Command Reference*.

**describe-lags**

The following code example shows how to use `describe-lags`.

**AWS CLI**

To describe your LAGs

The following command describes all of your LAGs for the current region.

Command:

```
aws directconnect describe-lags
```

Output:

```json
{
   "lags": [
      {
         "awsDevice": "EqDC2-19y7z3m17xpuz",
         "numberOfConnections": 2,
         "lagState": "down",
         "ownerAccount": "123456789012",
         "lagName": "DA-LAG",
         "connections": [
            {
            ...
```
For API details, see DescribeLags in AWS CLI Command Reference.

describe-loa

The following code example shows how to use describe-loa.

AWS CLI

To describe your LOA-CFA for a connection using Linux or Mac OS X

The following example describes your LOA-CFA for connection dxcon-fh6ayh1d. The contents of the LOA-CFA are base64-encoded. This command uses the --output and --query parameters to control the output and extract the contents of the loaContent structure. The
The final part of the command decodes the content using the base64 utility, and sends the output to a PDF file.

```bash
aws directconnect describe-loa --connection-id dxcon-fh6ayh1d --output text --query loa.loaContent|base64 --decode > myLoaCfa.pdf
```

**To describe your LOA-CFA for a connection using Windows**

The previous example requires the use of the base64 utility to decode the output. On a Windows computer, you can use certutil instead. In the following example, the first command describes your LOA-CFA for connection dxcon-fh6ayh1d and uses the `--output` and `--query` parameters to control the output and extract the contents of the `loaContent` structure to a file called `myLoaCfa.base64`. The second command uses the `certutil` utility to decode the file and send the output to a PDF file.

```bash
aws directconnect describe-loa --connection-id dxcon-fh6ayh1d --output text --query loa.loaContent > myLoaCfa.base64

certutil -decode myLoaCfa.base64 myLoaCfa.pdf
```

For more information about controlling AWS CLI output, see [Controlling Command Output from the AWS Command Line Interface](https://docs.aws.amazon.com/cli/latest/userguide/cli-conditional-output-control.html) in the *AWS Command Line Interface User Guide*.

- For API details, see [DescribeLoa](https://docs.aws.amazon.com/cli/latest/reference/directconnect/describe-loa.html) in *AWS CLI Command Reference*.

**describe-locations**

The following code example shows how to use `describe-locations`.

**AWS CLI**

**To list AWS Direct Connect partners and locations**

The following `describe-locations` command lists AWS Direct Connect partners and locations in the current region:

```bash
aws directconnect describe-locations
```

Output:
For API details, see DescribeLocations in AWS CLI Command Reference.

**describe-tags**

The following code example shows how to use describe-tags.

**AWS CLI**

To describe tags for your AWS Direct Connect resources

The following command describes the tags for the connection dxcon-abcabc12.

**Command:**

```
```

**Output:**

```
{  
   "resourceTags": [  
      {  
         "tags": [  
            {  
               "value": "VAConnection",

            }  
         ]  
      }  
   ]  
}
```
describe-virtual-gateways

The following code example shows how to use describe-virtual-gateways.

AWS CLI

To list virtual private gateways

The following describe-virtual-gateways command lists virtual private gateways owned by your AWS account:

```bash
aws directconnect describe-virtual-gateways
```

Output:

```json
{
   "virtualGateways": [
      {
         "virtualGatewayId": "vgw-aba37db6",
         "virtualGatewayState": "available"
      }
   ]
}
```

• For API details, see DescribeVirtualGateways in AWS CLI Command Reference.

describe-virtual-interfaces

The following code example shows how to use describe-virtual-interfaces.

AWS CLI

To list all virtual interfaces
The following `describe-virtual-interfaces` command lists the information about all virtual interfaces associated with your AWS account:

```bash
aws directconnect describe-virtual-interfaces --connection-id dxcon-ffjrkx17
```

Output:

```json
{
  "virtualInterfaces": [
    {
      "virtualInterfaceState": "down",
      "asn": 65000,
      "vlan": 101,

For API details, see DescribeVirtualInterfaces in AWS CLI Command Reference.

disassociate-connection-from-lag

The following code example shows how to use disassociate-connection-from-lag.

AWS CLI

To disassociate a connection from a LAG

The following example disassociates the specified connection from the specified LAG.

Command:

```
aws directconnect disassociate-connection-from-lag --lag-id dxlag-fhccu14t --connection-id dxcon-fg9607vm
```

Output:

```
{
  "ownerAccount": "123456789012",
}```
For API details, see DisassociateConnectionFromLag in AWS CLI Command Reference.

**tag-resource**

The following code example shows how to use tag-resource.

**AWS CLI**

**To add a tag to an AWS Direct Connect resource**

The following command adds a tag with a key of Name and a value of VAConnection to the connection dxcon-abcabc12. If the command succeeds, no output is returned.

Command:

```
aws directconnect tag-resource --resource-arn arn:aws:directconnect:us-east-1:123456789012:dxcon/dxcon-abcabc12 --tags "key=Name,value=VAConnection"
```

For API details, see TagResource in AWS CLI Command Reference.

**untag-resource**

The following code example shows how to use untag-resource.

**AWS CLI**

**To remove a tag from an AWS Direct Connect resource**

The following command removes the tag with the key Name from connection dxcon-abcabc12. If the command succeeds, no output is returned.

Command:

- For API details, see UntagResource in AWS CLI Command Reference.

update-direct-connect-gateway-association

The following code example shows how to use update-direct-connect-gateway-association.

AWS CLI

To update the specified attributes of the Direct Connect gateway association

The following update-direct-connect-gateway-association example adds the specified CIDR block to a Direct Connect gateway association.

```
aws directconnect update-direct-connect-gateway-association \
   --association-id 820a6e4f-5374-4004-8317-3f64bEXAMPLE \
   --add-allowed-prefixes-to-direct-connect-gateway cidr=192.168.2.0/30
```

Output:

```json
{
   "directConnectGatewayAssociation": {
      "directConnectGatewayId": "11460968-4ac1-4fd3-bdb2-00599EXAMPLE",

         }
      ]
   }
}
```
update-lag

The following code example shows how to use update-lag.

AWS CLI

To update a LAG

The following example changes the name of the specified LAG.

Command:

```
aws directconnect update-lag --lag-id dxlag-ffjhj9lx --lag-name 2ConnLag
```

Output:

```
{
    "awsDevice": "CSVA1-23u8tlpaz8iks",

**update-virtual-interface-attributes**

The following code example shows how to use `update-virtual-interface-attributes`.

**AWS CLI**

**To update the MTU of a virtual interface**

The following `update-virtual-interface-attributes` example updates the MTU of the specified virtual interface.

```bash
aws directconnect update-virtual-interface-attributes \
    --virtual-interface-id dxvif-fEXAMPLE \
    --mtu 1500

AWS Directory Service examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with AWS Directory Service.

**Actions** are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

**Scenarios** are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

AWS DMS examples using AWS CLI

The following code examples show you how to perform actions and implement common scenarios by using the AWS Command Line Interface with AWS DMS.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.
Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Actions

add-tags-to-resource

The following code example shows how to use add-tags-to-resource.

AWS CLI

To add tags to a resource

The following add-tags-to-resource example adds tags to a replication instance.

```bash
aws dms add-tags-to-resource \
  --resource-arn arn:aws:dms:us-east-1:123456789012:rep:T3OM7OUB5NM2LCVZF7JPGJRNUE \
  --tags Key=Environment,Value=PROD Key=Project,Value=dbMigration
```

This command produces no output.

For more information, see Tagging Resources in the AWS Database Migration Service User Guide.

- For API details, see AddTagsToResource in AWS CLI Command Reference.

create-endpoint

The following code example shows how to use create-endpoint.

AWS CLI

To create an endpoint

The following create-endpoint example creates an endpoint for an Amazon S3 source.

```bash
aws dms create-endpoint \
  --endpoint-type source \
  --engine-name s3 \
```
--endpoint-identifier src-endpoint \
--s3-settings file://s3-settings.json

Contents of s3-settings.json:

```
{
    "BucketName":"my-corp-data",
    "BucketFolder":"sourcedata",
    "ServiceAccessRoleArn":"arn:aws:iam::123456789012:role/my-s3-access-role"
}
```

Output:

```
{
    "Endpoint": {
        "EndpointIdentifier": "src-endpoint",
        "EndpointType": "SOURCE",
        "EngineName": "s3",

        }
    }
}
```

For more information, see Working with AWS DMS Endpoints in the AWS Database Migration Service User Guide.

- For API details, see CreateEndpoint in AWS CLI Command Reference.
create-event-subscription

The following code example shows how to use create-event-subscription.

AWS CLI

To list event subscriptions

The following create-event-subscription example creates an event subscription to an Amazon SNS topic (my-sns-topic).

```
aws dms create-event-subscription \
  --subscription-name my-dms-events \
```

Output:

```
{
  "EventSubscription": {
    "CustomerId": "123456789012",
    "CustomerSubscriptionId": "my-dms-events",
    "Status": "creating",

    "Enabled": true
  }
}
```

For more information, see Working with Events and Notifications in the AWS Database Migration Service User Guide.

- For API details, see CreateEventSubscription in AWS CLI Command Reference.

create-replication-instance

The following code example shows how to use create-replication-instance.

AWS CLI

To create a replication instance

The following create-replication-instance example creates a replication instance.
aws dms create-replication-instance \
   --replication-instance-identifier my-repl-instance \
   --replication-instance-class dms.t2.micro \
   --allocated-storage 5

Output:

{
   "ReplicationInstance": {

create-replication-subnet-group

The following code example shows how to use create-replication-subnet-group.

AWS CLI

To create a subnet group

The following create-replication-subnet-group example creates a group consisting of 3 subnets.

```bash
aws dms create-replication-subnet-group \
  --replication-subnet-group-identifier my-subnet-group \
  --replication-subnet-group-description "my subnet group" \
  --subnet-ids subnet-da327bf6 subnet-bac383e0 subnet-d7c825e8

### create-replication-task

The following code example shows how to use create-replication-task.

**AWS CLI**

**To create a replication task**

The following `create-replication-task` example creates a replication task.

```bash
aws dms create-replication-task 
   --replication-task-identifier movedata 
   --replication-instance-arn $RI_ARN 
   --migration-type full-load 
   --table-mappings file://table-mappings.json
```

Contents of `table-mappings.json`:

```json
{
   "rules": [
      {
         "rule-type": "selection",
         "rule-id": "1",
         "rule-name": "1",

**delete-connection**

The following code example shows how to use delete-connection.

**AWS CLI**

To delete a connection

The following delete-connection example disassociates an endpoint from a replication instance.
aws dms delete-connection
   --endpoint-arn arn:aws:dms:us-east-1:123456789012:endpoint:6GGI6YPWGVYULKIB732KEVWA \
   --replication-instance-arn arn:aws:dms:us-east-1:123456789012:rep:T3OM70UB5NM2LCVF7JPGJRNUE

Output:

**delete-endpoint**

The following code example shows how to use delete-endpoint.

**AWS CLI**

**To delete an endpoint**

The following delete-endpoint example deletes an endpoint.

```bash
aws dms delete-endpoint \
   --endpoint-arn arn:aws:dms:us-east-1:123456789012:endpoint:OUJJVXO4XZ4CYTSEG5XGMN2R3Y

### delete-event-subscription

The following code example shows how to use `delete-event-subscription`.

#### AWS CLI

**To delete an event subscription**

The following `delete-event-subscription` example deletes a subscription to an Amazon SNS topic.

```bash
aws dms delete-event-subscription
   --subscription-name "my-dms-events"
```
delete-replication-instance

The following code example shows how to use delete-replication-instance.

AWS CLI

To delete a replication instance

The following delete-replication-instance example deletes a replication instance.

del-replication-subnet-group

The following code example shows how to use delete-replication-subnet-group.
AWS CLI

**To delete a subnet group**

The following `delete-replication-subnet-group` example deletes a subnet group.

```bash
aws dms delete-replication-subnet-group
   --replication-subnet-group-identifier my-subnet-group
```

Output:

```
(none)
```

**delete-replication-task**

The following code example shows how to use `delete-replication-task`.

AWS CLI

**To delete a replication task**

The following `delete-replication-task` example deletes a replication task.

```bash
aws dms delete-replication-task
   --replication-task-arn arn:aws:dms:us-east-1:123456789012:task:K55IUCGBASJS5VHZJIINA45FII

### describe-account-attributes

The following code example shows how to use `describe-account-attributes`.

**AWS CLI**

**To describe account attributes**

The following `describe-account-attributes` example lists the attributes for your AWS account.

```
aws dms describe-account-attributes
```

**Output:**

```
{
    "AccountQuotas": [
        {
            "AccountQuotaName": "ReplicationInstances",

```
For API details, see [DescribeAccountAttributes](https://docs.aws.amazon.com/cli/latest/reference/dms/describe-account-attributes.html) in AWS CLI Command Reference.

**describe-certificates**

The following code example shows how to use `describe-certificates`.

**AWS CLI**

**To list the available certificates**

The following `describe-certificates` example lists the available certificates in your AWS account.

```
aws dms describe-certificates
```

**Output:**

```
{

- For API details, see DescribeCertificates in AWS CLI Command Reference.

**describe-connections**

The following code example shows how to use describe-connections.

**AWS CLI**

**To describe connections**

The following describe-connections example lists the connections that you have tested between a replication instance and an endpoint.

```
aws dms describe-connections
```

Output:

```
{
  "Connections": [
    {
      "Status": "successful",
      "ReplicationInstanceIdentifier": "test",
      "EndpointIdentifier": "testsrc1",

  ]
}
```

For more information, see Creating Source and Target Endpoints in the AWS Database Migration Service User Guide.

- For API details, see DescribeConnections in AWS CLI Command Reference.

**describe-endpoint-types**

The following code example shows how to use describe-endpoint-types.
AWS CLI

To list the available endpoint types

The following describe-endpoint-types example lists the MySQL endpoint types that are available.

```
aws dms describe-endpoint-types \
   --filters "Name=engine-name,Values=mysql"
```

Output:

```
{
   "SupportedEndpointTypes": [
   {
      "EngineName": "mysql",
      "SupportsCDC": true,
      "EndpointType": "source",

describe-endpoints

The following code example shows how to use describe-endpoints.

AWS CLI

To describe endpoints
The following `describe-endpoints` example lists the endpoints in your AWS account.

```bash
aws dms describe-endpoints
```

**Output:**

<table>
<thead>
<tr>
<th>Endpoint ID</th>
<th>Username</th>
<th>Status</th>
<th>EndpointArn</th>
<th>ServerName</th>
<th>EndpointType</th>
<th>KmsKeyId</th>
<th>DatabaseName</th>
<th>EngineName</th>

describe-event-categories

The following code example shows how to use describe-event-categories.

AWS CLI

To describe event categories

The following describe-event-categories example lists the available event categories.

```bash
aws dms describe-event-categories
```

Output:

```json
{
   "EventCategoryGroupList": [

**describe-event-subscriptions**

The following code example shows how to use `describe-event-subscriptions`.

**AWS CLI**

To describe event subscriptions

The following `describe-event-subscriptions` example lists the event subscriptions to an Amazon SNS topic.

```bash
code example
aws dms describe-event-subscriptions
```

Output:

```json
{
   "EventSubscriptionsList": [
      {
         "CustomerAwsId": "123456789012",
         "CustSubscriptionId": "my-dms-events",
         "Status": "deleting",
         "Enabled": true
      }
   ]
}
```

For more information, see *Working with Events and Notifications* in the *AWS Database Migration Service User Guide*.

- For API details, see `DescribeEventSubscriptions` in *AWS CLI Command Reference*.

**describe-events**

The following code example shows how to use `describe-events`.

**AWS CLI**

To list DMS events
The following `describe-events` example lists the events that originated from a replication instance.

```bash
aws dms describe-events --source-type "replication-instance"
```

Output:

```
{
   "Events": [
   {
      "SourceIdentifier": "my-repl-instance",
      "SourceType": "replication-instance",
      "Message": "Replication application shutdown",
      "EventCategories": [],
      "Date": 1590771645.776
   }
   ]
}
```

For more information, see Working with Events and Notifications in the AWS Database Migration Service User Guide.

- For API details, see `DescribeEvents` in AWS CLI Command Reference.

**describe-orderable-replication-instances**

The following code example shows how to use `describe-orderable-replication-instances`.

**AWS CLI**

**To describe orderable replication instances**

The following `describe-orderable-replication-instances` example lists replication instance types that you can order.

```bash
aws dms describe-orderable-replication-instances
```

Output:

```
{
```
