What Is Amazon CloudSearch?

Amazon CloudSearch is a fully managed service in the cloud that makes it easy to set up, manage, and scale a search solution for your website or application.

With Amazon CloudSearch you can search large collections of data such as web pages, document files, forum posts, or product information. You can quickly add search capabilities without having to become a search expert or worry about hardware provisioning, setup, and maintenance. As your volume of data and traffic fluctuates, Amazon CloudSearch scales to meet your needs.

Note
This document describes the Amazon CloudSearch 2013-01-01 API. If you have 2011-02-01 search domains and need to reference the old documentation, you can download a PDF of the 2011-02-01 Developer Guide.

You can use Amazon CloudSearch to index and search both structured data and plain text. Amazon CloudSearch features:

- Full text search with language-specific text processing
- Boolean search
- Prefix searches
- Range searches
- Term boosting
- Faceting
- Highlighting
- Autocomplete suggestions

You can get search results in JSON or XML, sort and filter results based on field values, and sort results alphabetically, numerically, or according to custom expressions.

To build a search solution with Amazon CloudSearch, you take the following steps:

- **Create and configure a search domain.** A search domain includes your searchable data and the search instances that handle your search requests. If you have multiple collections of data that you want to make searchable, you can create multiple search domains.

- **Upload the data you want to search to your domain.** Amazon CloudSearch indexes your data and deploys the search index to one or more search instances.

- **Search your domain.** You send a search request to your domain's search endpoint as an HTTP/HTTPS GET request.

Are You New to Amazon CloudSearch?

For a high-level overview of Amazon CloudSearch, service highlights, and pricing information, see the Amazon CloudSearch detail page. If you are ready to start using Amazon CloudSearch, you should begin with Getting Started with Amazon CloudSearch (p. 8).
You can interact with Amazon CloudSearch through the AWS Management Console, AWS SDKs, or AWS CLI. While you can also submit API requests directly to Amazon CloudSearch, the SDKs and AWS CLI automatically sign your requests as needed and provide centralized tools for interacting with Amazon CloudSearch domains in conjunction with other AWS services. For information about the AWS SDKs, see Tools for Amazon Web Services. For information about installing and using the AWS CLI, see the AWS Command Line Interface User Guide.

For more information about configuring and managing your search domains, getting your data into Amazon CloudSearch, submitting search requests, and processing the responses, see:

- **Preparing Your Data** (p. 53)—how to format your data so you can upload it to an Amazon CloudSearch domain for indexing
- **Configure indexing options** (p. 57)—how to configure indexing options for an Amazon CloudSearch domain
- **Searching Your Data with Amazon CloudSearch** (p. 92)—how to use the Amazon CloudSearch query language
- **Controlling Search Results** (p. 124)—how to sort, filter, and paginate search results

### How Search Works

The collection of data that you want to search (sometimes referred to as your *corpus*) can consist of unstructured full-text documents, semi-structured documents such as those formatted in mark-up languages like XML, or structured data that conforms to a strict data model. Each item that you want to be able to search (such as a forum post or web page) is represented as a document. Every document has a unique ID and one or more fields that contain the data that you want to search and include in results.

To make your data searchable, you represent it as a batch of documents in either JSON or XML and upload the batch to your search domain. Amazon CloudSearch then generates a search index from your document data according to your domain's configuration options. You submit queries against this index to find the documents that meet specific search criteria.

As your data changes, you submit updates to add, change, or delete documents from your index. Updates are applied continuously in the order they are received.

For information about how to format your data, see **Preparing Your Data** (p. 53).

### Indexing in Amazon CloudSearch

To build a search index from your data, Amazon CloudSearch needs the following information:

- Which document fields do you want to search?
- Which document field values do you want to retrieve with the search results?
- Which document fields represent categories that you want to use to refine and filter search results?
- How should the text within a particular field be processed?

You define this metadata in your domain configuration by configuring indexing options. You use indexing options to specify the fields included in the search index and control how you can use those fields.

You must configure a corresponding index field for each document field that occurs in your data—there's a one-to-one mapping between document fields and the fields in your Amazon CloudSearch index. In addition to the index field name, you specify the following:

- The index field type
- Whether the field is searchable (text and text-array fields are always searchable)
Facets in Amazon CloudSearch

A facet is an index field that represents a category that you want to use to refine and filter search results. When you submit search requests to Amazon CloudSearch, you can request facet information to find out how many hits share the same value in a facet. You can display this information along with the search results and use it to enable users to interactively refine their searches. (This is often referred to as faceted navigation or faceted search.)

A facet can be any date, literal, or numeric field that has faceting enabled in your domain configuration. For each facet, Amazon CloudSearch calculates the number of hits that share the same value. You can define buckets to calculate facet counts for particular subsets of the facet values. Only buckets that have matches are included in the facet results.

For information about configuring facets, see configure indexing options (p. 57). For information about using facet information to support faceted navigation, see Getting and Using Facet Information in Amazon CloudSearch (p. 112).

Text Processing in Amazon CloudSearch

During indexing, Amazon CloudSearch processes the contents of text and text-array fields according to the language-specific analysis scheme configured for the field. An analysis scheme controls how the text is normalized, tokenized, and stemmed, and specifies any stopwords or synonyms to take into account during indexing. Amazon CloudSearch provides default analysis schemes for each supported language. For information about configuring custom analysis schemes, see Configuring Analysis Schemes (p. 63). For information about how Amazon CloudSearch normalizes and tokenizes text and applies configured text options when indexing text fields and processing search requests, see Text Processing in Amazon CloudSearch (p. 72).

Sorting Results in Amazon CloudSearch

You can customize how search results are ranked by defining expressions that calculate custom values for every document that matches your search criteria. For example, you might define an expression that takes into account the value in a document's popularity field as well as the default relevance score calculated by Amazon CloudSearch. Expressions are simply numeric expressions that use standard numeric operators and functions. Expressions can reference int and double fields, other expressions, a document's relevance score (_score), as well as the epoch time (_time). When you submit search requests, you specify the expression(s) you want to use to sort the search results. You can also reference expressions within your search criteria.

A document's relevance _score indicates how relevant a particular search hit is to the search request. To calculate the relevance score, Amazon CloudSearch takes into account how many times the search terms appear in a document relative to the other documents in the index.

For information about how to configure expressions for your domain, see Configuring Expressions (p. 125).
Search Requests in Amazon CloudSearch

You submit search requests to your domain's search endpoint as HTTP/HTTPS GET requests. You can specify a variety of options to constrain your search, request facet information, control ranking, and specify what you want to be returned in the results. You can get search results in either JSON or XML. By default, Amazon CloudSearch returns results in JSON.

When you submit a search request, Amazon CloudSearch performs text processing on the search string. The search string is processed to:

- Convert all characters to lowercase
- Split the string into separate terms on whitespace and punctuation boundaries
- Remove terms that are on the stopword list for the field being searched.
- Map stems and synonyms according to the stemming and synonym options configured for the field being searched.

After this preprocessing is complete, Amazon CloudSearch looks up the search terms in the index and identifies all of the documents that match the request. To generate a response, Amazon CloudSearch processes this list of search hits to filter and sort the matching documents and compute facets. Amazon CloudSearch then returns the response in JSON or XML.

By default, Amazon CloudSearch returns search results ranked according to the hits' relevance scores. Alternatively, your request can specify the index field or expression that you want to use to sort the hits. For example, you might want to sort hits by an index field that contains the price or an expression that calculates popularity.

For more information about searching, ranking, and paginating results, see Searching Your Data with Amazon CloudSearch (p. 92).

Automatic Scaling in Amazon CloudSearch

A search domain has one or more search instances, each with a finite amount of RAM and CPU resources for indexing data and processing requests. How many search instances a domain needs depends on the documents in your collection and the volume and complexity of your search requests.

Amazon CloudSearch can determine the size and number of search instances required to deliver low latency, high throughput search performance. When you upload your data and configure your index, Amazon CloudSearch builds an index and picks the appropriate initial search instance type. As you use your search domain, Amazon CloudSearch can scale to accommodate the amount of data uploaded to the domain and the volume and complexity of search requests.

When you create a search domain, a single instance is deployed for the domain. As the following illustration shows, you always have at least one instance for your domain. Amazon CloudSearch automatically scales the domain by adding instances as the volume of data or traffic increases.
Scaling for Data

When the amount of data you add to your domain exceeds the capacity of the initial search instance type, Amazon CloudSearch scales your search domain to a larger search instance type. After a domain exceeds the capacity of the largest search instance type, Amazon CloudSearch partitions the search index across multiple search instances. (The number of search instances required to hold the index partitions is sometimes referred to as the domain's width.)

When the volume of data in your domain shrinks, Amazon CloudSearch scales down your domain to fewer search instances or a smaller search instance type to minimize costs.

Note

If your domain has scaled up to accommodate your index size and you delete a large number of documents, the domain scales down the next time the full index is rebuilt. Although the index is automatically rebuilt periodically, to scale down as quickly as possible you can explicitly run indexing (p. 89) when you are done deleting documents.
Scaling for Traffic

As your search request volume or complexity increases, it takes more processing power to handle the load. A high volume of document uploads also increases the load on a domain's search instances. When a search instance nears its maximum load, Amazon CloudSearch deploys a duplicate search instance to provide additional processing power. (The number of duplicate search instances is sometimes referred to as the domain's depth.)

When traffic drops, Amazon CloudSearch removes search instances to minimize costs. For example, a new domain might scale up to handle the initial influx of documents, and scale back down after you have finished uploading your data and are only submitting updates.

If your domain experiences a sudden surge in traffic, Amazon CloudSearch deploys additional search instances. It takes a few minutes to set up the new instances, however, so you might see an increase in 5xx errors until the new instances can start processing requests. For more information about handling 5xx errors, see Handling Errors (p. 137).

Keep in mind that the type and complexity of your search requests affect overall search performance and in some cases increase the number of search instances required to operate your domain. Submitting a high volume of small or single-document batches can affect your search domain's performance. For more information, see Tuning Search Request Performance in Amazon CloudSearch (p. 108).

Accessing Amazon CloudSearch

You can access Amazon CloudSearch through the Amazon CloudSearch console, the AWS SDKs, or the AWS CLI.

- The Amazon CloudSearch console enables you to easily create, configure, and monitor your search domains, upload documents, and run test searches. Using the console is the easiest way to get started with Amazon CloudSearch and provides a central command center for the ongoing management of your search domains.
- The AWS SDKs support all of the Amazon CloudSearch API operations, making it easy to manage and interact with your search domains using your preferred technology. The SDKs automatically sign requests as needed using your AWS credentials.
- The AWS CLI wraps all of the Amazon CloudSearch API operations to provide a simple way to create and configure search domains, upload the data you want to search, and submit search requests. The AWS CLI automatically signs requests as needed using your AWS credentials.

Regions and Endpoints for Amazon CloudSearch

Amazon CloudSearch provides regional endpoints for accessing the configuration service and domain-specific endpoints for accessing the search and document services.

You use the configuration service to create and manage your search domains. The region-specific configuration service endpoints are of the form: cloudsearch.<region>.amazonaws.com. For example, cloudsearch.us-east-1.amazonaws.com. For a current list of supported regions, see Regions and Endpoints in the AWS General Reference.

To access the Amazon CloudSearch search and document services, you use separate domain-specific endpoints:

- http://doc-domainname-domainid.us-east-1.cloudsearch.amazonaws.com—a domain's document service endpoint is used to upload documents
Signing Amazon CloudSearch Requests

If you're using a language for which AWS provides an SDK, we recommend that you use the SDK to submit Amazon CloudSearch requests. All of the AWS SDKs greatly simplify the process of signing requests and save you a significant amount of time when compared to using the Amazon CloudSearch APIs directly. The SDKs integrate easily with your development environment and provide easy access to related commands. You can also use the Amazon CloudSearch console and AWS CLI to submit signed requests with no additional effort.

If you choose to call the Amazon CloudSearch APIs directly, you must sign your own requests. Configuration service requests must always be signed. Upload, search, and suggest requests must be signed, unless you configure anonymous access for those services. To sign a request, you calculate a digital signature using a cryptographic hash function, which returns a hash value based on the input. The input includes the text of your request and your secret access key. The hash function returns a hash value that you include in the request as your signature. The signature is part of the Authorization header of your request. After receiving your request, Amazon CloudSearch recalculates the signature using the same hash function and input that you used to sign the request. If the resulting signature matches the signature in the request, Amazon CloudSearch processes the request. Otherwise, the request is rejected.

Amazon CloudSearch supports authentication using AWS Signature Version 4. For more information, see Signature Version 4 Signing Process.
Getting Started with Amazon CloudSearch

To start searching your data with Amazon CloudSearch, you simply take the following steps:

• Create and configure a search domain
• Upload and index the data you want to search
• Send search requests to your domain

This tutorial shows you how to get up and running using the AWS Management Console for Amazon CloudSearch. To make it even easier to get started, we've generated a sample data set of 5,000 popular movie titles that you can download and examine, upload to your own search domain, and submit search queries against to see how Amazon CloudSearch works.

Using the AWS Management Console and the sample movie data, you'll have your own search domain up and running in about half an hour.

To begin, Get Signed Up (p. 8).

Topics
• Before You Begin with Amazon CloudSearch (p. 8)
• Step 1: Create an Amazon CloudSearch Domain (p. 8)
• Step 2: Upload Data to Amazon CloudSearch for Indexing (p. 10)
• Step 3: Search Your Amazon CloudSearch Domain (p. 11)
• Step 4: Delete Your Amazon CloudSearch Movies Domain (p. 15)

Before You Begin with Amazon CloudSearch

To use Amazon CloudSearch, you need an Amazon Web Services (AWS) account. Your AWS account enables you to access Amazon CloudSearch and other AWS services, such as Amazon Simple Storage Service (Amazon S3) and Amazon Elastic Compute Cloud (Amazon EC2). As with other AWS services, you pay only for the Amazon CloudSearch resources you use. There are no sign up fees and charges are not incurred until you create a search domain.

If you already have an AWS account, you are automatically signed up for Amazon CloudSearch.

To create an AWS account

2. Follow the instructions to sign up. You will need to enter payment information before you can begin using Amazon CloudSearch.

Step 1: Create an Amazon CloudSearch Domain

An Amazon CloudSearch domain encapsulates a collection of data you want to search, the search instances that process your search requests, and a configuration that controls how your data is indexed and searched. You create a separate search domain for each collection of data you want to make searchable. For each domain, you configure indexing options that describe the fields you want to include
in your index and how you want to use them, analysis schemes that specify language-specific text processing options for individual fields, expressions that you can use to customize how search results are ranked, and access policies that control access to the domain's document and search endpoints.

You interact with a search domain to:

- Configure index and search options
- Submit data for indexing
- Perform searches

Each domain has a unique endpoint through which you submit search requests to the domain. For example, the endpoint for a domain called movies created in the US East (N. Virginia) region might be:

Example

```
search-movies-mtshfsu2rje7ywr66uit3dei4m.us-east-1.cloudsearch.amazonaws.com
```

When creating a search domain, you specify a unique name for the domain. Domain names must start with a letter or number and be at least 3 and no more than 28 characters long. The allowed characters are: a-z, 0-9, and hyphen (-). By default, new domains are created in the US East (N. Virginia) region. To create a domain in another region, you must explicitly specify the region when creating the domain.

To configure the new domain, you must specify:

- Indexing options for the data you want to search.
- Access policies for the domain's document service and search service endpoints.

This tutorial shows you how to create and interact with a domain using the Amazon CloudSearch console. To learn more, see Creating a Search Domain (p. 25).

Important

The domain you're about to create will be live and you will incur the standard Amazon CloudSearch usage fees for the domain until you delete it. For more information about Amazon CloudSearch usage rates, go to the Amazon CloudSearch detail page.

To create your movies domain

2. Choose Create domain.
3. Enter a name for your new domain. Domain names must start with a letter or number and be at least 3 and no more than 28 characters. Domain names can contain the following characters: a-z (lower case), 0-9, and -. (Hyphen). Upper case letters and underscores are not allowed.
4. Leave the other settings as their defaults and choose Next.
5. Select Sample data and choose IMDb movies (demo) from the dropdown. You can also automatically configure a search domain by analyzing a sample of your data.
6. Choose Next.
7. Review the index fields being configured. Eleven fields are configured automatically for the imdb-movie data: actors, directors, genres, image_url, plot, rank, rating, release_date, running_time_secs, title, and year.

Note

By default, all options are enabled for each field. While this is convenient for development and testing, fine-tuning the options configured for each field according to how you use those fields can reduce the size of your index. If your domain uses more than a single small search instance, tuning can help minimize the cost of running your domain.
When you finish reviewing the indexing options, choose **Next**.

8. For simplicity in this tutorial, use an open access domain. Choose **Allow open access to the domain** and choose **Next**.

9. Review the domain configuration and click **Create** to create your domain.

Amazon CloudSearch initializes resources for the domain, which can take about ten minutes. During this initialization process, the status of the domain is **Processing**. Once the status changes to **Active**, you can upload your data and start searching.

**Step 2: Upload Data to Amazon CloudSearch for Indexing**

You upload the data you want to search to your domain so that Amazon CloudSearch can build and deploy a searchable index. To be indexed by Amazon CloudSearch, the data must be formatted in either JSON or XML. The Amazon CloudSearch console can automatically convert the following file types to the required format:

- Document batches formatted in JSON or XML (.json, .xml)
- Comma Separated Value (.csv)
- Text Documents (.txt)

When you upload a CSV file, Amazon CloudSearch parses each row separately. The first row defines the document fields, and each subsequent row becomes a separate document. For all other file types Amazon CloudSearch creates a single document and the contents of the file are mapped to a single text field. If metadata is available for the file, the metadata is mapped to corresponding document fields—the fields generated from the document metadata vary depending on the file type.

The sample IMDb movies data is already formatted in JSON.

This tutorial shows how to submit data through the Amazon CloudSearch console, but you can also **convert** (p. 57) and **upload documents** (p. 85) with the command line tools, and upload documents using the **documents/batch** (p. 223) resource. (To upload more than 5 MB of data, you must use the command line tools or API.)

**To upload the sample data to your movies domain**

2. In the left navigation pane, choose **Domains**. Choose the name of your **movies** domain to view the domain dashboard.
3. Choose **Actions**, **Upload documents**.
4. Select **Sample data** and choose **IMDb movies (demo)** from the dropdown.
5. Choose **Next**.
6. Review the upload summary and choose **Upload documents** to send the data to your domain for indexing.

**Note**

To see how the data is formatted, choose **Download the generated document batch**. For more information about preparing your own data, see **Preparing Your Data** (p. 53).

You now have a fully functional Amazon CloudSearch domain that you can start searching. Updates are applied continuously in the order they are received, so you can start searching your domain right away.
Step 3: Search Your Amazon CloudSearch Domain

You can use the search tester in the Amazon CloudSearch console to submit sample search requests and view the results. You can also submit sample search requests through a Web browser or using cURL. In your application, you can use any HTTP library to send search traffic to your Amazon CloudSearch domain.

Searching with the Search Tester

The search tester in the Amazon CloudSearch console enables you to submit sample search requests using any of the supported query parsers: simple, structured, lucene, or dismax. By default, requests are processed with the simple query parser. You can specify options for the selected parser, filter and sort the results, and browse the configured facets. The search hits are automatically highlighted in the search results. For information about how this is done, see Highlighting Search Hits in Amazon CloudSearch (p. 118). You can also select a suggester to get suggestions as you enter terms in the Search field. (You must configure a suggester before you can get suggestions. For more information see Getting Autocomplete Suggestions in Amazon CloudSearch (p. 119).)

By default, results are sorted according to an automatically-generated relevance score, _score.
For information about customizing how results are ranked, see Sorting Results in Amazon CloudSearch (p. 124).

To search your domain

2. In the left navigation panel, choose your movies domain to open its configuration.
3. Choose Run a test search.
4. To perform a simple text search, enter a search query and choose Run. By default, all text and text-array fields are searched.

To search particular fields, expand Options and enter a comma-separated list of the fields you want to search for in the Search fields field. You can append a weight to each field with a caret (^) to control the relative importance of each field in the search results. For example, specifying title^5, description weights hits in the title field five times more than hits in the description field when calculating relevance scores for each matching document.

To use the structured query syntax, select Structured from the Query parser menu. Once you've selected the structured query parser, enter your structured query in the Search field and choose Run. For example, to find all of the movies with star in the title that were released in the year 2000 or earlier, you could enter: (and title: 'star' year: {,2000}]). For more information, see Constructing Compound Queries (p. 95). To submit Lucene or DisMax queries, select the appropriate query parser.

You can specify additional options for the selected query parser to configure the default operator and control which operators can be used in a query. For more information, see Search Request Parameters (p. 231).

You can copy and paste the request URL to submit the request and view the response from a Web browser. Requests can be sent via HTTP or HTTPS.

Submitting Search Requests from a Web Browser

You can submit search requests directly to your search endpoint from any Web browser. You can use any of the query parsers (simple, structured, lucene, or dismax) and specify a variety of options to constrain...
your search, request facet information, customize ranking, and control what information is returned in the results.

For example, to search your movies domain and get the titles of all of the available Star Wars movies, append the following search string to your search endpoint. (2013-01-01 is the API version and must be specified.)

Example

```
/2013-01-01/search?q=star+wars&return=title
```

Note

Your domain's search endpoint is shown on the domain dashboard. You can also perform a search from the AWS Management Console, view the raw request and response, and copy the request URL from the Search Request field. A domain's search and document service endpoints remain the same for the life of the domain.

By default, Amazon CloudSearch returns the response in JSON. You can also get the search results formatted in XML by specifying the `format` parameter, `format=xml`. (Note that errors can be returned in either JSON or XML, depending on where the error originated.)

Searching Numeric Fields

You can use the structured query syntax, `q.parser=structured`, to find documents that have particular numeric attributes. You can search for an exact value or a range of values within any numeric field (double, double-array, int, int-array). To search for a range, you specify the upper and lower bounds, separated by a comma, and enclose the range in brackets or braces. Use square brackets ([,]) when you want to include the bounds, and curly braces ({,}) to exclude the bounds. For example:

- `year:[2000,}` matches documents whose year field contains a value greater than or equal to 2000
- `year:{,2000]` matches documents whose year field contains a value less than or equal to 2000

You can also search date fields for a specific date or date range, but you must enclose each date string in single quotes: `release_date:['2000-01-01T00:00:00Z','2011-01-01T00:00:00Z']`.

For example, the following structured query searches for "star" in the title field, finds all of the matching movies that were released before 2000, and returns the title, year, and relevance score for each one:

Example

```
q=(and title:'star' year:{,2000})&q.parser=structured&return=title,year,_score
```

The response shows the status of the request, the number of matching documents, and the requested fields for each hit.

```
{
    "status": {
        "rid": "hLPckLsoEQoELQo=",
    }...
```
Sorting the Search Results

By default, Amazon CloudSearch sorts the search results according to an automatically generated relevance _score. You can change how results are ranked by using the sort parameter in your search request to specify the field or expression you want to use for ranking. (An expression is a custom numeric expression that can be evaluated for each document in the set of matching documents. For information about defining your own expressions, see Configuring Expressions (p. 125).)

If you specify a text field with the sort parameter, the results are sorted alphabetically according to that field. For example, to sort results from your movies domain alphabetically by title, add &sort=title asc to your query string:

Example

```
2013-01-01/search?q=(and genres:'Sci-Fi' year:{,2000})&q.parser=structured&return=title,year&sort=title asc
```

Note that you must explicitly specify the sort direction, asc (ascending) or desc (descending). When you sort alphabetically, Amazon CloudSearch sorts by Unicode codepoint. This means numbers come before letters and uppercase letters come before lowercase letters. Numbers are sorted as strings; for example, 10 will come before 2.

Similarly, you can specify an integer field with the sort parameter to sort the results numerically.

If you specify a comma separated list of fields or expressions, the first field or expression is used as the primary sort criteria, the second is used as the secondary sort criteria, and so on.

For more information about ranking results, see Sorting Results in Amazon CloudSearch (p. 124)
Getting Facet Information

A facet is an index field that represents a category that you want to use to refine and filter search results. When you submit search requests to Amazon CloudSearch, you can request facet information to find out how many hits share the same value in a facet. You can display this information along with the search results and use it to enable users to interactively refine their searches. (This is often referred to as faceted navigation or faceted search.)

A facet can be any date, literal, or numeric field that has faceting enabled in your domain configuration. For each facet, Amazon CloudSearch calculates the number of hits that share the same value. You can define buckets to calculate facet counts for particular subsets of the facet values. Only buckets that have matches are included in the facet results.

To get facet counts with your search results

- Use the facet.FIELD option to specify a field for which you want to compute facets. For the sample IMDb movies data faceting is enabled for the following fields: genres, rank, rating, release_date, running_time_secs, and year. Facet options are specified as a JSON object. If the JSON object is empty, facet.FIELD={}, facet counts are computed for all field values, the facets are sorted by facet count, and the top 10 facets are returned in the results:

```
q=star&return=title&facet.genres={}
```

The facets appear below the hits in the results.

```
facets": { 
  "genres": {  
    "buckets": [  
      {"value": "Comedy","count": 41},  
      .  
      .  
      .  
      {"value": "Sport", "count": 7}  
    ]  
  }  
}
```

You can specify options to calculate facets for selected field values, specify the maximum number of facet values to include in the results, and control how the facets are sorted.

To define buckets to compute facet counts for selected field values, you specify the buckets option. For example, the following request sorts the facet counts for the year field by decade:

```
```

This constrains the facet counts to the three specified ranges:

```
"facets": {  
  "year": {  
    "buckets": [  
      {"value": "[1970,1979]", "count": 3},  
      {"value": "[1980,1989]","count": 7},  
      {"value": "[1990,1999]" ,"count": 12}  
    ]  
  }  
}
```
Getting Search Highlights

A search highlight is an excerpt of a text or text-array field that shows where the search term occurs within the field.

To get highlight information with your search results

- Use the `highlight.FIELD` option to specify the text or text-array field you want to get highlights for. The field must be highlight enabled in your domain's indexing options. For the sample IMDb movies data highlighting is enabled for the following fields: actors, directors, plot, and title. Highlight options are specified as a JSON object. If the JSON object is empty, `highlight.FIELD={}`, Amazon CloudSearch highlights all occurrences of the search term(s) by enclosing them in HTML emphasis tags, `<em>term</em>`, and the excerpts are returned as HTML.

```
q=title:'star'&q.parser=structured&return=_no_fields&highlight.title={}
```

The highlight information is included with each search hit.

```
"hit": [
   {
      "id": "tt0796366",
      "highlights": {
         "title": "<em>Star</em> Trek"
      }
   },
   {
      "id": "tt2488496",
      "highlights": {
         "title": "<em>Star Wars: Episode VII</em>"
      }
   }
]
```

For more information about specifying highlight options, see Highlighting Search Hits in Amazon CloudSearch [p. 118].

Step 4: Delete Your Amazon CloudSearch Movies Domain

When you are finished experimenting with your movies domain, you must delete it to avoid incurring additional usage fees.
Important
Deleting a domain deletes the index associated with the domain and takes the domain's document and search endpoints offline permanently.

To delete your imdb-movies domain

1. Go to the Amazon CloudSearch console at https://console.aws.amazon.com/cloudsearch/home and navigate to the list of domains.
2. Select the checkbox for the movies domain, then choose Delete and confirm deletion.

Note
It can take around 15 minutes to delete the domain and its resources.

Wondering where to go next? Are You New to Amazon CloudSearch? (p. 1) has a guide to the rest of the Amazon CloudSearch developer documentation. For more information about the Amazon CloudSearch query language, see Searching Your Data with Amazon CloudSearch (p. 92). If you're ready to set up a domain with your own data, see Preparing Your Data (p. 53) and upload documents (p. 85).
Migrating to the Amazon CloudSearch 2013-01-01 API

The Amazon CloudSearch 2013-01-01 API offers several new features, including support for multiple languages, highlighting search terms in the results, and getting suggestions. To use these features, you create and configure a new 2013-01-01 search domain, modify your data pipeline to populate the new domain using the 2013-01-01 data format, and update your query pipeline to submit requests in the 2013-01-01 request format. This migration guide summarizes the API changes and highlights the ones that are most likely to affect your application.

Creating 2013-01-01 Amazon CloudSearch Domains

If you created Amazon CloudSearch domains prior to the launch of the 2013-01-01 API, you can choose which API version to use when you create a new domain. To create a 2013-01-01 domain through the console, select the 2013-01-01 version in the Create Domain Wizard. To create a 2013-01-01 domain from the command line, download and install the AWS CLI and run the `aws cloudsearch create-domain` command.

Note
To create and interact with 2013-01-01 domains, you must use the AWS CLI tools. To create and interact with 2011-02-01 domains, you must use the v1 tools.

Configuring 2013-01-01 Amazon CloudSearch Domains

You can configure 2013-01-01 domains through the console, command line tools, or AWS SDKs. 2013-01-01 domains support several new configuration options:

- **Analysis Schemes**—you configure analysis schemes to specify language-specific text processing options for text and text-array fields. Amazon CloudSearch now supports 33 languages, as well as an option for multi-language fields. For more information, see Configuring Analysis Schemes (p. 63). For the complete list of supported languages, see Supported Languages (p. 73).

- **Availability Options**—you can enable the Multi-AZ option to expand a domain into a second availability zone to ensure availability in the event of a service disruption. For more information, see Configuring Availability Options (p. 39).

- **Scaling Options**—you can set the desired instance type and desired replication count to increase upload or search capacity, speed up search requests, and improve fault tolerance. For more information, see Configuring Scaling Options in Amazon CloudSearch (p. 36).

- **Suggesters**—you can configure suggesters to implement autocomplete functionality. For more information, see Configuring Suggesters for Amazon CloudSearch (p. 119).
Access to the Amazon CloudSearch configuration service is managed through IAM and now enables you to control access to specific configuration actions. Note that the Amazon CloudSearch ARN has also changed. Access to your domain's document and search endpoints is managed through the Amazon CloudSearch configuration service. For more information, see configure access policies (p. 27).

2013-01-01 domains also support an expanded set of indexing options:

- **Analysis Scheme**—you configure language-specific text-processing on a per field basis by specifying an analysis scheme for each text and text-array field. For more information, see Configuring Analysis Schemes (p. 63).

- **Field Types**—Amazon CloudSearch now supports 11 field types:
  - date—contains a timestamp. Dates and times are specified in UTC (Coordinated Universal Time) according to IETF RFC3339: yyyy-mm-ddT00:00:00Z. In UTC, for example, 5:00 PM August 23, 1970 is: 1970-08-23T17:00:00Z.
  - date-array—a date field that can contain multiple values.
  - double—contains a double-precision 64-bit floating point value.
  - double-array—a double field that can contain multiple values.
  - int—contains a 64-bit signed integer value.
  - int-array—an integer field that can contain multiple values.
  - latlon—contains a location stored as a latitude and longitude value pair.
  - literal—contains an identifier or other data that you want to be able to match exactly.
  - literal-array—a literal field that can contain multiple values.
  - text—contains arbitrary alphanumeric data.
  - text-array—a text field that can contain multiple values.

- **Highlight**—when you enable the highlight option for a field, you can retrieve excerpts that show where the search terms occur within that field. For more information, see Highlighting Search Hits in Amazon CloudSearch (p. 118).

- **Source**—you can specify a source for a field to copy data from one field to another, enabling you to use the same source data in different ways by configuring different options for the fields.

When configuring your 2013-01-01 domain, there are several things to keep in mind:

- By default, when you add a field, all options valid for that field type are enabled. While this is useful for development and testing, disabling options you don't need can reduce the size of your index and improve performance.
- You must use the separate array type fields for multi-valued fields.
- Only single-value fields can be sort enabled.
- Only text and text-array fields can be highlight enabled.
- All fields except text and text-array fields can be facet enabled.
- Literal fields are now case-sensitive.
- You no longer have to store floating point values as integers—use a double field.
- You can store locations using the new latlon field type. For more information, see location-based searching and sorting (p. 103).
- An int field is a 64-bit signed integer.
- Instead of configuring a default search field, you can specify which fields to search with the q.options parameter in your search requests. The q.options parameter also enables you to specify weights for each of the fields.
- When sorting and configuring expressions, you reference the default relevance score with the name _score. Due to changes in the relevance algorithm, the calculated scores will be different than they were under the 2011-02-01 API. For more information, see Configuring Expressions (p. 125).
• Expressions now support the logn, atan2, and haversin functions as well as the _score (text relevance score) and _time (epoch time) variables. If you store locations in latlon fields, you can reference the latitude and longitude values as FIELD.latitude and FIELD.longitude. You can also reference both int and double fields in expressions. The following functions are no longer supported: cs.text_relevance, erf, lgamma, rand, and time. For more information, see Configuring Expressions (p. 125).

For more information about configuring indexing options for a 2013-01-01 domain, see configure indexing options (p. 57). For more information about configuring availability options, scaling options, text processing options, suggesters, and expressions see Creating and Managing Search Domains (p. 25).

New Amazon CloudSearch Configuration Service Actions and Options

The following actions have been added to the 2013-01-01 Configuration Service API:

• DefineAnalysisScheme
• DefineExpression
• DefineSuggester
• DeleteAnalysisScheme
• DeleteExpression
• DeleteSuggester
• DescribeAnalysisSchemes
• DescribeAvailabilityOptions
• DescribeExpressions
• DescribeScalingParameters
• DescribeSuggesters
• ListDomainNames
• UpdateAvailabilityOptions
• UpdateScalingParameters

The deployed option has been added to the describe actions for index fields, access policies, and suggesters. Set the deployed option to true to show the active configuration and exclude pending changes.

Obsolete Amazon CloudSearch Configuration Service Actions and Options

The following actions are not supported in the 2013-01-01 Configuration Service API:

• DefineRankExpression
• DescribeRankExpression
• DeleteRankExpression
• DescribeDefaultSearchField
• DescribeStemmingOptions
• DescribeStopwordOptions
Uploading Data to 2013-01-01 Amazon CloudSearch Domains

With the 2013-01-01 API, you no longer have to specify document versions—updates are applied in the order they are received. You also no longer specify the lang attribute for each document—you control language-specific text processing by configuring an analysis scheme for each text and text-array field.

To upload your data to a 2013-01-01 domain, you need to:

• Omit the version and lang attributes from your document batches.
• Make sure all of the document fields correspond to index fields configured for your domain. Unrecognized fields are no longer ignored, they will generate an error.
• Post the document batches to your 2013-01-01 domain's doc endpoint. Note that you must specify the 2013-01-01 API version. For example, the following request posts the batch contained in data1.json to the doc-movies-123456789012.us-east-1.cloudsearch.amazonaws.com endpoint.

```
curl -X POST --upload-file data1.json doc-movies-123456789012.us-east-1.cloudsearch.amazonaws.com/2013-01-01/documents/batch --header "Content-Type: application/json"
```

The 2013-01-01 API supports prescaling your domain to increase upload capacity. If you have a large amount of data to upload, configure your domain's scaling options and select a larger desired instance type. Moving to a larger instance type enables you to upload batches in parallel and reduces the time it takes for the data to be indexed. For more information, see Configuring Scaling Options in Amazon CloudSearch (p. 36).

For more information about formatting your data, see Preparing Your Data (p. 53).

Searching 2013-01-01 Amazon CloudSearch Domains

Much of the effort required to migrate an existing Amazon CloudSearch search domain to the 2013-01-01 API is updating your query pipeline to submit 2013-01-01 compatible search requests.

• Use the 2013-01-01 API version in all requests.
• Use the q parameter to specify search criteria for all requests. The bq parameter is no longer supported. To use the structured (Boolean) search syntax, specify q.parser=structured in the request.
• Parameters cannot be repeated in a search request.
The wildcard character (*) is only supported when using the simple query parser. Use the prefix operator to perform prefix matching with the structured query parser. For example, q=(prefix 'oce')&q.parser=structured.

Use the field name _id to reference the document ID field in a search request. The docid field name is no longer supported.

Use the range operator search a field for a value within the specified range. The filter operator is no longer supported.

Use the new range syntax to search for ranges of values, including dates and locations stored in latlon fields. The double dot (..) notation is no longer supported. Separate the upper and lower bounds with a comma (,), and enclose the range in brackets or braces. A square bracket ([]) indicates that the bound is included, a curly brace ({,}) excludes the bound. For example, year:2008..2011 is now expressed as year:[2008,2011]. An open ended range such as year:..2011 is now expressed as year:{,2011}.

Use the term operator to search a field for a particular value. The field operator is no longer supported.

Use the q.options parameter to specify field weights. The cs.text_relevance function is no longer supported. For example, q.options={fields:['title^2','plot^0.5']}. Use the fq parameter to filter results without affecting how the matching documents are scored and sorted. Use a dot (.) as a separator rather than a hyphen (-) in the prefix parameters: expr.NAME, facet.FIELD, highlight.FIELD.

Use the facet.FIELD parameter to specify all facet options. The facet-FIELD-top-N, facet-FIELD-sort, and facet-FIELD-constraints parameters are no longer supported.

Use the sort parameter to specify the fields or expressions you want to use for sorting. You must explicitly specify the sort direction in the sort parameter. For example, sort=rank asc, date desc. The rank parameter is no longer supported.

Use expr.NAME to define an expression in a search request. The rank-RANKNAME parameter is no longer supported.

Use format=xml to get results as XML. The result-type parameter is no longer supported.

The 2013-01-01 search API also supports several new features:

- Term boosting—use the boost option in a structured query to increase the importance of one part of the query relative to the other parts. For more information, see Constructing Compound Queries (p. 95).
- Sloppy phrase search—use the near operator in a structured query to search a text or text-array field for multiple terms and find documents that contain the terms within the specified distance of one another. You can also perform a sloppy phrase search with the simple query parser by appending the ~ operator and a value to the phrase. For more information, see Searching for Phrases (p. 99).
- Fuzzy search—use the ~ operator to perform fuzzy searches with the simple query parser. Append the ~ operator and a value to a term to indicate how much terms can differ and still be considered a match. For more information, see Searching for Individual Terms (p. 97).
- Highlighting—use the highlight.FIELD parameter to highlight matches in a particular field. For more information, see Highlighting Search Hits in Amazon CloudSearch (p. 118).
- Autocomplete—configure a suggester and submit requests to the suggester resource to get a list of query completions and the documents in which they were found. For more information, see Getting Autocomplete Suggestions in Amazon CloudSearch (p. 119).
- Partial search results—use the partial=true parameter to retrieve partial results when one or more index partitions are unavailable. By default Amazon CloudSearch only returns results if every partition can be queried.
- Deep paging—use the cursor parameter to paginate results when you have a large result set. For more information, see Paginate the results (p. 131).
New Search Parameters and Options

- Match all documents—use the matchall structured query operator to retrieve all of the documents in the index.
- New query parsers—use the q.parser parameter to select the Lucene or DisMax parsers instead of the simple or structured parser, q.parser=lucene or q.parser=dismax.

You'll also notice some changes in behavior when searching:

- Strings are no longer tokenized on case boundaries and periods that aren't followed by a space are considered part of the term. For more information, see Text Processing in Amazon CloudSearch (p. 72).
- Literal fields are now case-sensitive.
- Search responses no longer include the rank, match expression, or CPU time. The only status information returned is the resource ID (rid) and processing time (time-ms).
- When you get facet information for an int field, min and max values are no longer returned.

For more information about searching your data, see Searching Your Data with Amazon CloudSearch (p. 92) and the Search API (p. 231).

New Parameters and Options in the Amazon CloudSearch 2013-01-01 Search API

The following parameters have been added to the 2013-01-01 Search API:

- cursor.FIELD
- expr.NAME
- facet.FIELD
- format
- fq
- highlight.FIELD
- partial
- pretty
- q.options
- q.parser
- return
- sort

The ~ operator has been added to the simple query language to support fuzzy searches and sloppy phrase searches.

The following operators have been added to the structured query language:

- boost
- matchall
- near
- phrase
- prefix
- range
Obsolete Amazon CloudSearch Search Parameters and Options

The following parameters are no longer supported in the 2013-01-01 search API:

- bq
- facet-FIELD-top-N
- facet-FIELD-sort
- facet-FIELD-constraints
- rank
- rank-RANKNAME
- return-fields
- result-type
- t-FIELD

The following operators and shortcuts are no longer supported in structured queries:

- field
- filter
- 
- |
- +
- *

Updated Limits in Amazon CloudSearch 2013-01-01

This table summarizes the changes and additions to the Amazon CloudSearch limits. For the complete list of Amazon CloudSearch limits, see Limits (p. 257).

<table>
<thead>
<tr>
<th>Change</th>
<th>Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved names</td>
<td>score is the only reserved name.</td>
</tr>
<tr>
<td>No limit on return data</td>
<td>Data returned from a text field is no longer truncated at 2 KB. However, keep in mind that the maximum document size is 1 MB.</td>
</tr>
<tr>
<td>No limit on stemming, stopword, or synonym dictionaries.</td>
<td>Stemming, stopword, and synonym dictionaries are configured in an analysis scheme and there is no limit on the size of an analysis scheme definition.</td>
</tr>
<tr>
<td>Maximum number of field values</td>
<td>An array type field can contain up to 1000 values.</td>
</tr>
<tr>
<td>Field size</td>
<td>The maximum size of literal fields is 4096 Unicode code points.</td>
</tr>
<tr>
<td>Change</td>
<td>Summary</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Int field range</td>
<td>An int field can contain values in the range -9,223,372,036,854,775,808 - 9,223,372,036,854,775,807 (inclusive).</td>
</tr>
<tr>
<td>Maximum number of highlights</td>
<td>The maximum number of occurrences of the search term(s) that can be highlighted is 5.</td>
</tr>
<tr>
<td>Maximum number of suggesters</td>
<td>The maximum number of suggesters you can configure for a domain is 10.</td>
</tr>
<tr>
<td>Maximum number of hits you can retrieve at once</td>
<td>The maximum number of hits you can retrieve at once is 10,000. The size parameter can contain values in the range 0 - 10000.</td>
</tr>
</tbody>
</table>
Creating and Managing Amazon CloudSearch Domains

A search domain encapsulates the data you want to search, indexing options that control how you can search the data and what information you can retrieve from your search domain, and the search instances that index your data and process search requests. You can create, monitor, and delete domains using the Amazon CloudSearch console, AWS CLI, or AWS SDKs. All domain management actions are implemented by the Amazon CloudSearch configuration service. For more information, see the Configuration API Reference for Amazon CloudSearch (p. 139).

Topics
- Creating an Amazon CloudSearch Domain (p. 25)
- Configuring Access for Amazon CloudSearch (p. 27)
- Configuring Scaling Options in Amazon CloudSearch (p. 36)
- Configuring Availability Options in Amazon CloudSearch (p. 39)
- Configuring Domain Endpoint Options in Amazon CloudSearch (p. 41)
- Monitoring Amazon CloudSearch Domains (p. 42)
- Deleting an Amazon CloudSearch Domain (p. 51)
- Tagging Amazon CloudSearch Domains (p. 52)

Creating an Amazon CloudSearch Domain

To search your data with Amazon CloudSearch, the first thing you need to do is create a search domain. If you have multiple collections of data that you want to make searchable, you can create multiple search domains. Before you can send search requests to a new domain, you must also configure access policies, configure index fields, and upload the data you want to search.

When you create a search domain, you must give it a unique name. Domain names must start with a letter or number and be at least 3 and no more than 28 characters long. The allowed characters are: a-z, 0-9, and hyphen (-). Upper case letters, underscores (_), and other special characters are not allowed in domain names.

By default, all new domains are created using the 2013-01-01 API version. If you have previously created search domains with the 2011-02-01 API version, you can opt to use the old API for your new domain. However, we recommend using the 2013-01-01 API for all new use cases. All domains will need to migrate to the 2013-01-01 API when the 2011-02-01 API is retired.

You can choose the AWS region where you want to create your search domain. Typically, you should choose the region closest to your operations. For example, if you reside in Europe, create your search domain in the Europe (Ireland) region (eu-west-1). For a current list of supported regions and endpoints, see Regions and Endpoints. For more information about choosing a region, see Regions and Endpoints for Amazon CloudSearch (p. 6).

Note
Amazon CloudSearch domains in different regions are entirely independent. For example, if you create a search domain called my-domain in us-east-1, and another domain called my-domain in eu-west-1, they are completely independent and do not share any data.
Each search domain has unique endpoints through which you upload data for indexing and submit search requests. A domain's document and search endpoints remain the same for the life of the domain. For example, the endpoints for a domain called imdb-movies might be:

```
doc-imdb-movies-nypdfbzrfkoudsurkxvgwbpi4.us-east-1.cloudsearch.amazonaws.com
search-imdb-movies-nypdfbzrfkoudsurkxvgwbpi4.us-east-1.cloudsearch.amazonaws.com
```

**Important**
By default, access to a new domain's document and search endpoints is blocked for all IP addresses. You must configure access policies for the domain to be able to submit search requests to the domain's search endpoint and upload data from the command line or through the domain's document endpoint. You can upload documents and search the domain through the Amazon CloudSearch console without configuring access policies.

You can create a search domain from the Amazon CloudSearch console (p. 26), using the `aws cloudsearch create-domain` command, or using one of the AWS SDKs.

**Topics**
- Creating a Domain Using the Amazon CloudSearch Console (p. 26)
- Creating a Domain Using the AWS CLI (p. 27)
- Creating an Amazon CloudSearch Domain Using the AWS SDKs (p. 27)

### Creating a Domain Using the Amazon CloudSearch Console

The Amazon CloudSearch console enables you to easily create new search domains and provides a variety of options for configuring indexing options.

**To create a domain**

1. Sign in to the AWS Management Console and open the Amazon CloudSearch console at https://console.aws.amazon.com/cloudsearch/home.
2. Choose Create domain.
3. Enter a name for your new domain. Domain names must start with a letter or number and be at least 3 and no more than 28 characters long. Domain names can contain the following characters: a-z (lower case), 0-9, and - (hyphen). Upper case letters, underscores (_), and other special characters are not allowed in domain names.

   Optionally, you can set the Desired instance type and Desired replication count to prescale your domain. For more information, see Configuring Scaling Options in Amazon CloudSearch (p. 36).
4. Choose Next.
5. In the configuring options, select Manual configuration and choose Next.
6. Configure the index fields for the domain. For instructions, see configure indexing options (p. 57).
7. Choose Next.
8. Configure the domain access policy. For instructions, see configure access policies (p. 27).

   **Note**
   Until you configure access policies, you will only be able to upload documents and submit search queries through the console. By default, the document and search endpoints are configured to block all IP addresses.
9. Choose Next.
10. Review the domain configuration and choose Create.
The domain's document and search service endpoints are displayed on the domain dashboard when the domain becomes active. At that point, you can upload documents for indexing and start searching your data.

Creating a Domain Using the AWS CLI

You use the `aws cloudsearch create-domain` command to create search domains. For information about installing and setting up the AWS CLI, see the AWS Command Line Interface User Guide.

To create a domain

- Run the `aws cloudsearch create-domain` command and specify the name of the domain you want to create with the `--domain-name` option. For example, to create a domain called *movies*:

  **Example**

  ```
  aws cloudsearch create-domain --domain-name movies
  {
    "DomainStatus": {
      "DomainId": "965407640801/movies",
      "Created": true,
      "Deleted": false,
      "SearchInstanceCount": 0,
      "DomainName": "movies",
      "SearchService": {},
      "RequiresIndexDocuments": false,
      "Processing": false,
      "DocService": {},
      "ARN": "arn:aws:cloudsearch:us-east-1:965407640801:domain/movies",
      "SearchPartitionCount": 0
    }
  }
  ```

The `aws cloudsearch create-domain` command returns immediately. It takes about ten minutes to create endpoints for a new domain. You can use the `aws cloudsearch describe-domains` command to view a summary of the domain's status and configuration. For more information, see Getting Information About an Amazon CloudSearch Domain (p. 42).

**Important**

Once a domain's endpoints are active, they remain the same for the life of the domain. You should cache the endpoints—there's no need to query for the endpoint before submitting a document or search service request and doing so is likely to result in your requests being throttled.

Creating an Amazon CloudSearch Domain Using the AWS SDKs

The AWS SDKs (except the Android and iOS SDKs) support all of the Amazon CloudSearch actions defined in the Amazon CloudSearch Configuration API, including `CreateDomain` (p. 144). For more information about installing and using the AWS SDKs, see AWS Software Development Kits.

Configuring Access for Amazon CloudSearch

You use AWS Identity and Access Management (IAM) access policies to control access to the Amazon CloudSearch configuration service and each search domain's document, search, and suggest services. An
IAM access policy is a JSON document that explicitly lists permissions that define what actions people or processes are allowed to perform. For an introduction to IAM access policies, see Overview of AWS IAM Policies.

You control access to the Amazon CloudSearch configuration service APIs and the domain services APIs independently. For example, you might choose to restrict who can modify the configuration of your production domain, but allow team members to create and manage their own domains for development and testing. Similarly, you might configure your development and test domains to accept anonymous requests to the upload, search, and suggest services, but lock down your production domain so that it accepts only authenticated requests from your application.

When AWS receives a request, it authenticates that the request is from a known AWS user, and then checks relevant policies to determine whether the user is authorized to perform the requested actions using the requested resources. If a user has not been explicitly granted permission to perform an action, the request is denied. During policy evaluation, if AWS encounters an explicit deny, the deny effect takes precedence over any explicit allow effects that are in force.

**Important**

To enable authentication, Amazon CloudSearch requests must be signed with an access key. The only exception is if you allow anonymous access to a domain's upload, search, or suggest services. For more information, see Signing Requests (p. 7).

Topics

- Writing Access Policies for Amazon CloudSearch (p. 28)
- Amazon CloudSearch Policy Examples (p. 30)
- Configuring Access for Amazon CloudSearch Using the AWS Management Console (p. 35)
- Configuring Access for Amazon CloudSearch with the AWS CLI (p. 35)
- Configuring Access to a Domain's Endpoints Using the AWS SDKs (p. 36)

Writing Access Policies for Amazon CloudSearch

Amazon CloudSearch supports both user-based policies and resource-based policies:

- **User-based policies** are attached to a particular IAM role, group, or user. A user-based policy specifies which of your account's search domains a person or process can access and what actions they can perform. To attach a user-based policy to a user, group, or role, you use the IAM console, AWS CLI, or AWS SDKs. You must define user-based policies to control access to the Amazon CloudSearch configuration service actions. (The user in this context isn't necessarily a person, it's just an identity with associated permissions. For example, you might create a user to represent an application that needs to have credentials to submit search requests to your domain.)

- **Resource-based policies** for Amazon CloudSearch are attached to a particular search domain. A resource-based policy specifies who has access to the search domain and which domain services they can use. Resource-based policies control access only to a particular domain's document, search, and suggest services; they cannot be used to configure access to the Amazon CloudSearch configuration service actions. To attach a resource-based policy to a domain, you use the Amazon CloudSearch console, AWS CLI or AWS SDKs.

In general, we recommend managing access to Amazon CloudSearch APIs by configuring user-based policies. This enables you to manage all of your permissions in one place and any changes you need to make take effect almost immediately. However, to allow public access to a domain's search service or restrict access based on IP addresses, you must configure a resource-based policy for the domain. (We recommend replacing your old IP based access policies with user-based policies at your earliest convenience.) You can also use resource-based policies to easily allow other accounts to access a domain. Keep in mind that processing changes to a domain's resource-based policies takes significantly longer than applying changes to user-based policies.
The IAM console can help you write both user-based and resource-based policies for Amazon CloudSearch. For more information, see Managing IAM Policies.

Contents of an Access Policy for Amazon CloudSearch

You specify the following information in your access policies for Amazon CloudSearch:

- **Version** specifies the policy language version that the statement is compatible with. The version is always set to 2012-10-17.
- **Resource** is the ARN (Amazon Resource Name) for the domain to which a user-based policy applies. Resource is not specified in resource-based policies configured through the Amazon CloudSearch configuration service, because the policy is attached directly to the resource. For more information about Amazon CloudSearch ARNs, see Amazon CloudSearch ARNs (p. 29).
- **Effect** specifies whether the statement authorizes or blocks access to the specified action(s). It must be **Allow** or **Deny**.
- **Sid** is an optional string that you can use to provide a descriptive name for the policy statement.
- **Action** specifies which Amazon CloudSearch actions the statement applies to. For the supported actions, see Amazon CloudSearch Actions (p. 30). You can use a wildcard (*) as the action to configure access for all actions when you need to grant administrative access to select users. (In this case, you might also want to enable multi-factor authorization for additional security. For more information, see Configuring MFA-Protected API Access.) Wildcards are also supported within action names. For example, "Action": ["cloudsearch:Describe*"] matches all of the configuration service Describe actions, such as DescribeDomains and DescribeServiceAccessPolicies.
- **Condition** specifies conditions for when the policy is in effect. When configuring anonymous, IP-based access, you would specify the IP addresses that the access rule applies to, for example "IpAddress": {"aws:SourceIp": ["192.0.2.0/32"]}.
- **Principal** specifies who is allowed access to the domain in a resource-based policy. Principal is not specified in user-based policies configured through IAM. The Principal value for a resource-based policy can specify other AWS accounts or users in your own account. For example, to grant access to the account 555555555555, you would specify "Principal": {"AWS": ["arn:aws:iam::555555555555:root"]}. Specifying a wildcard (*) enables anonymous access to the domain. Anonymous access is not recommended. If you enable anonymous access, you should at least specify a condition to restrict which IP addresses can submit requests to the domain. For more information, see Granting Access to a Domain from Selected IP Addresses (p. 33).

For examples of access policies for Amazon CloudSearch, see Amazon CloudSearch Policy Examples (p. 30).

Amazon CloudSearch ARNs

A policy's Amazon Resource Name (ARN) uniquely specifies the domain that the policy applies to. The ARN is a standard format that AWS uses to identify resources. The 12-digit number in the ARN is your AWS account ID. Amazon CloudSearch ARNs are of the form arn:aws:cloudsearch:REGION:ACCOUNT-ID:domain/DOMAIN-NAME.

The following list describes the variable elements in the ARN:

- **REGION** is the AWS region where the Amazon CloudSearch domain for which you are configuring permissions resides. You can use a wildcard (*) for the REGION for all regions.
- **ACCOUNT-ID** is your AWS account ID with no hyphens; for example, 111122223333.
- **DOMAIN-NAME** identifies a specific search domain. You can use a wildcard (*) for the DOMAIN-NAME for all of your account's domains in the specified region. If you have multiple domains whose names start with the same prefix, you can use a wildcard to match all of those domains. For example, dev-* matches dev-test, dev-movies, dev-sandbox, and so on. Note that if you name new domains with the same prefix, the policy also applies to those new domains.
For example, the following ARN identifies the movies domain in the us-east-1 region owned by account 111122223333:

```
arn:aws:cloudsearch:us-east-1:111122223333:domain/movies
```

The following example shows how the ARN is used to specify the resource in a user-based policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["cloudsearch:search"],
    }
  ]
}
```

A domain's ARN is displayed on the domain dashboard in the Amazon CloudSearch console and is also available by calling DescribeDomains.

**Important**

When specifying an ARN for a domain created with the 2011-02-01 API, you must use the former Amazon CloudSearch service name, cs. For example, arn:aws:cs:us-east-1:111122223333:domain/movies. If you need to define policies that configure access for both 2011 and 2013 domains, make sure to specify the correct ARN format for each domain. For more information, see [Configuration Service Access Policies Not Working](p. 253).

### Amazon CloudSearch Actions

The actions you specify control which Amazon CloudSearch APIs the statement applies to. All Amazon CloudSearch actions are prefixed with cloudsearch:, such as cloudsearch:search. The following list shows the supported actions:

- `cloudsearch:document` allows access to the document service API. Permission to use the document action is required to upload documents to a search domain for indexing.
- `cloudsearch:search` allows access to the search API. Permission to use the search action is required to submit search requests to a domain.
- `cloudsearch:suggest` allows access to the suggest API. Permission to use the suggest action is required to get suggestions from a domain.
- `cloudsearch:CONFIGURATION-ACTION` allows access to the specified configuration service action. Permission to use the DescribeDomains and ListDomainNames configuration actions is required to access the Amazon CloudSearch console. Configuration actions can be specified only in user-based policies. For the complete list of actions, see Actions (p. 141).

### Amazon CloudSearch Policy Examples

This section presents a few examples of Amazon CloudSearch access policies.

**Topics**

- [Granting Read-only Access to the Amazon CloudSearch Configuration Service](p. 31)
- [Granting Access to All Amazon CloudSearch Configuration Service Actions](p. 31)
- [Granting Unrestricted Access to All Amazon CloudSearch Services](p. 32)
- [Granting Permission to Upload Documents to an Amazon CloudSearch Domain](p. 32)
Granting Read-only Access to the Amazon CloudSearch Configuration Service

You can grant read-only access to the configuration service by allowing only the following actions. This might be useful if you want to allow users to view the configuration of a production domain without being able to make changes.

- `cloudsearch:DescribeAnalysisSchemes`
- `cloudsearch:DescribeAvailabilityOptions`
- `cloudsearch:DescribeDomains`
- `cloudsearch:DescribeExpressions`
- `cloudsearch:DescribeIndexFields`
- `cloudsearch:DescribeScalingParameters`
- `cloudsearch:DescribeServiceAccessPolicies`
- `cloudsearch:DescribeSuggesters`
- `cloudsearch:ListDomainNames`

The following user-based policy grants read-only access to the configuration service for a `movies` domain owned by the account `555555555555`. The policy uses wildcards for the actions, since it grants access to all actions that begin with `Describe` or `List`. Note that this will also grant access to any describe or list actions that might be added to the API in the future.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["cloudsearch:Describe*", "cloudsearch:List*"],
      "Resource": "arn:aws:cloudsearch:us-east-1:555555555555:domain/movies"
    }
  ]
}
```

Granting Access to All Amazon CloudSearch Configuration Service Actions

You can grant access to all Amazon CloudSearch configuration service actions by including an `Allow` statement that grants access to all configuration service actions, but not the domain services actions. This enables you to grant administrative access without authorizing a user to upload or retrieve data from a domain. One way to do this is to use a wildcard to grant access to all Amazon CloudSearch actions, and then include a deny statement that blocks access to the domain services actions. The following user-based policy grants access to the configuration service for all domains owned by the `111122223333` account in the `us-west-2` region.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["cloudsearch:*"],
      "Resource": "*"
    },
    {
      "Effect": "Deny",
      "Action": ["cloudsearch:Domain*"],
      "Resource": "*"
    }
  ]
}
```

API Version 2013-01-01
Granting Unrestricted Access to All Amazon CloudSearch Services

You can grant unrestricted access to all Amazon CloudSearch services, including all configuration service actions and all domain services with a user-based policy. To do this, you specify wildcards for the actions, region, and domain name. The following policy enables the user to access all Amazon CloudSearch actions for any domain in any region that's owned by the 111122223333 account.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["cloudsearch:*"],
         "Resource": "arn:aws:cloudsearch:*:111122223333:domain/*"
      }
   ]
}
```

Granting Permission to Upload Documents to an Amazon CloudSearch Domain

You can grant a user permission to upload documents to a search domain by specifying the `cloudsearch:document` action. For example, the following user-based policy enables the user to upload documents to the `movies` domain in `us-east-1` owned by the 111122223333 account.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["cloudsearch:document"],
      }
   ]
}
```

Granting Amazon CloudSearch Access to Another AWS Account

You have two options to configure cross-account access for a CloudSearch domain:
This topic provides an example of the second option, adding a resource-based policy to the CloudSearch domain. Assume that account #1 is owned by account id 111111111111 and account #2 is owned by account id 999999999999. Account #1 wants to grant access to account #2 to use the search service for the movies domain, which requires two steps:

1. Account #1 attaches a resource-based policy to the domain using the Amazon CloudSearch console that grants access to account #2.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid":"search_only",
            "Effect":"Allow",
            "Action": ["cloudsearch:search"],
            "Principal": {"AWS": ["arn:aws:iam::999999999999:root"]}
        }
    ]
}
```

2. Account #2 attaches a user-based managed policy to an IAM role owned by that account using the IAM console.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["cloudsearch:search"],
            "Resource": "arn:aws:cloudsearch:us-east-1:111111111111:domain/movies"
        }
    ]
}
```

**Important**

To configure resource-based policies for Amazon CloudSearch, you must have permission to use the `cloudsearch:UpdateServiceAccessPolicies` action.

**Granting Access to an Amazon CloudSearch Domain from Selected IP Addresses**

Resource-based access policies set through the Amazon CloudSearch configuration service support anonymous access, which enables you to submit unsigned requests to a search domain's services. To
allow anonymous access from selected IP addresses, use a wildcard for the `Principal` value and specify the allowed IP addresses as a `Condition` element in the policy.

**Important**
Allowing anonymous access from selected IP addresses is inherently less secure than requiring user credentials to access your search domains. We recommend against allowing anonymous access even if it is permitted only from select IP addresses. If you currently allow anonymous access, you should upgrade your applications to submit signed requests and control access by configuring user-based or resource-based policies.

If you are creating a resource-based policy that grants access to requests coming from an Amazon EC2 instance, you need to specify the instance's public IP address.

IP addresses are specified in the standard Classless Inter-Domain Routing (CIDR) format. For example, 10.24.34.0/24 specifies the range 10.24.34.0 - 10.24.34.255, while 10.24.34.0/32 specifies the single IP address 10.24.34.0. For more information about CIDR notation, see RFC 4632.

For example, the following policy grants access to the search action for the `movies` domain owned by AWS account 111122223333 from the IP address 192.0.2.0/32.

```json
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"search_only",
         "Effect":"Allow",
         "Principal":"*",
         "Action": ["cloudsearch:search"],
         "Condition": {"IpAddress": {"aws:SourceIp": "192.0.2.0/32"}}
      }
   ]
}
```

**Granting Public Access to an Amazon CloudSearch Domain's Search Service**

If you need to allow public access to your domain's search endpoint, you can configure a resource-based policy with no conditions. This enables unsigned requests to be sent from any IP address.

**Important**
Allowing public access to a search domain means you have no control over the volume of requests submitted to the domain. Malicious users could flood the domain with requests, impacting legitimate users as well as your operating costs.

For example, the following policy grants public access to the search action for the `movies` domain owned by AWS account 111122223333.

```json
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"public_search",
         "Effect":"Allow",
         "Principal":"*",
         "Action": ["cloudsearch:search"]
      }
   ]
}
```
Configuring Access for Amazon CloudSearch Using the AWS Management Console

To configure user-based policies

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Configure Amazon CloudSearch permissions by attaching a policy to a user, group, or role. For more information, see Managing Policies (AWS Management Console). For more information about user-based policies for Amazon CloudSearch see Writing Access Policies for Amazon CloudSearch (p. 28).

To configure resource-based policies

1. Sign in to the AWS Management Console and open the Amazon CloudSearch console at https://console.aws.amazon.com/cloudsearch/home.
2. Choose the name of the domain you want to configure.
4. When you’re done making changes to the domain access policy, choose Submit.

Your domain remains in a Processing state while Amazon CloudSearch updates the access policy.

Configuring Access for Amazon CloudSearch with the AWS CLI

You can configure both user-based policies and resource-based policies for Amazon CloudSearch with the AWS CLI. For information about installing and setting up the AWS CLI, see the AWS Command Line Interface User Guide.

To configure user-based policies

• Configure Amazon CloudSearch permissions by attaching a policy to a user, group, or role with the aws put-user-policy, aws put-group-policy, or aws put-role-policy command. For more information, see Managing Policies (AWS Management Console). For more information about user-based policies for Amazon CloudSearch see Writing Access Policies for Amazon CloudSearch (p. 28).

To configure resource-based policies

• Run the aws cloudsearch update-service-access-policies command and specify an access policy with the --access-policies option. The access policy must be enclosed in quotes and all quotes within the access policy must be escaped with a backslash. For more information about resource-based policies for Amazon CloudSearch see Writing Access Policies for Amazon CloudSearch (p. 28).

The following example configures the movies domain to accept search requests from the IP address 192.0.2.0.

```bash
aws cloudsearch update-service-access-policies --domain-name movies --access-policies "{"Version":"2012-10-17"},{"Statement":[]}"
```
Configuring Access to a Domain's Endpoints Using the AWS SDKs

The AWS SDKs (except the Android and iOS SDKs) support all of the Amazon CloudSearch actions defined in the Amazon CloudSearch Configuration API, including UpdateServiceAccessPolicies (p. 186). For more information about installing and using the AWS SDKs, see AWS Software Development Kits.

Configuring Scaling Options in Amazon CloudSearch

A search domain has one or more search instances, each with a finite amount of RAM and CPU resources for indexing data and processing requests. You can configure scaling options to control the instance type that is used, the number of instances your search index is distributed across (partition count), and the number of replicas of each index partition (replication count). All instances for a domain are always of the same type.

You can configure the desired instance type, partition count, or replication count for an Amazon CloudSearch domain to:

- **Increase upload capacity** By default, all search domains start out on a search.small instance. You can increase your domain's document upload capacity by changing the desired instance type. If you have a large amount of data to upload—for example, when you are initially populating your search domain—you can choose a larger instance type to increase the number of updates that can be submitted in parallel and reduce how long it takes to index your data. If you are already using the
Choosing Scaling Options

- **Speed up search requests.** Choosing a larger desired instance type can also speed up search requests. If you've tuned your requests and still aren't meeting your performance targets, try choosing a larger instance type. If you are already using the largest instance type, you can increase the desired partition count to further boost query performance. For more information, see Tuning Search Request Performance in Amazon CloudSearch (p. 108).

- **Increase search capacity.** By default, Amazon CloudSearch uses one instance per index partition. When Amazon CloudSearch scales the domain automatically, it adds replicas based on the resources needed to process the query traffic. To increase a domain's search capacity, you set the desired replication count. However, deploying additional instances takes some time. If you know in advance that you will need additional capacity—for example, before a big launch or announcement—add replicas ahead of time to ensure that your search domain is ready to handle the load.

- **Improve fault tolerance.** Increasing the desired replication count also improves the domain's fault-tolerance—if there's a problem with one of the replicas, the others will continue to handle requests while it is being recovered. However, note that the replicas reside in the same Availability Zone. If you need to ensure availability of your domain in the event of an Availability Zone service disruption, you should enable the MultiAZ option. For more information, see Configuring Availability Options (p. 39).

When you set the desired instance type, desired number of replicas, or desired partition count, Amazon CloudSearch scales your domain as necessary, but will never scale the domain to an instance type that's smaller than the desired type, use fewer replicas than the desired number of replicas, or reduce the partition count below the desired partition count.

**Note**
The automatic scaling progression is based on the instance type's available disk space. The search.small and search.medium instance types have the same amount of disk space, so both scale to search.large.

You can change your scaling options at any time. If your need for additional capacity is temporary, you can prescale your domain by setting the scaling options and then revert the changes after your volume of uploads or queries returns to your domain's steady state. When you make changes, you need to re-index your domain, which can take some time for the changes to take effect. How long it takes to re-index depends on the amount of data in your index. You can monitor the domain status to determine when indexing is complete—the status changes from PROCESSING to ACTIVE.

**Topics**

- Choosing Scaling Options in Amazon CloudSearch (p. 37)
- Configuring Scaling Options through the Amazon CloudSearch Console (p. 38)
- Configuring Scaling Options through the AWS CLI (p. 38)
- Configuring Scaling Options through the AWS SDK (p. 39)

**Choosing Scaling Options in Amazon CloudSearch**

When you set scaling options for a domain, you make a trade-off between cost and performance—changing the desired instance type, replication count, and partition count can significantly impact the cost of running your domain.

To determine which instance type to select to handle your upload traffic, monitor your upload performance as you increase the upload rate. If you start seeing a large number of 504 or 507 errors before you reach your desired upload rate, select a larger instance type. If you are already on the largest instance type, you can increase the number of partitions to further increase upload capacity.
For datasets of less than 1 GB of data or fewer than one million 1 KB documents, a small search instance should be sufficient. To upload data sets between 1 GB and 8 GB, we recommend setting the desired instance type to `search.large` before you begin uploading. For datasets between 8 GB and 16 GB, start with a `search.xlarge`. For datasets between 16 GB and 32 GB, start with a `search.2xlarge`. If you have more than 32 GB to upload, select the `search.2xlarge` instance type and increase the desired partition count to accommodate your data set. Each partition can contain up to 32 GB of data. Submit a Service Increase Limit Request if you need more upload capacity or have more than 500 GB to index.

To determine how many replicas you need to handle a given query volume, do some testing using a sample of your expected queries at the rate you need to support. Keep in mind that query performance depends heavily on the type of queries being processed. In general, searches that return a large volume of hits and complex structured queries are more resource intensive than simple text queries that match a small percentage of the documents in your search domain. If you expect a high volume of complex queries, choose a larger desired instance type and increase the desired replication count.

### Configuring Scaling Options through the Amazon CloudSearch Console

#### To configure a search domain’s scaling options

Note that changing the desired instance type and replication count can significantly increase the cost of running your domain.

1. On the Amazon CloudSearch console, choose the name of the domain you want to configure.
2. On the **Domain configuration** tab, choose **Edit** next to **Scaling options**.
3. Select an instance type from the **Desired instance type** menu.
4. Select the number of replicas you want to use from the **Desired replication count** menu.
5. If you selected the `search.2xlarge` instance type, configure the **Desired partition count**. Increase the partition count if you have more data to upload than will fit on a single `search.2xlarge` partition. For more information, see Bulk Uploads (p. 87).
6. Choose **Submit**.
7. After you finish making changes to your domain configuration, choose **Actions, Run indexing** to update and deploy your index to the new instances.

### Configuring Scaling Options through the AWS CLI

You use the `aws cloudsearch update-scaling-parameters` command to configure scaling options for a search domain. For information about installing and setting up the AWS CLI, see the [AWS Command Line Interface User Guide](#).

#### To configure a search domain’s scaling options

- Run the `aws cloudsearch update-scaling-parameters` command. You can specify the desired instance type and desired replication count. If you choose the largest instance type (`search.2xlarge`), you can also set the desired partition count. For example, the following command sets the desired instance type to `search.xlarge` and the desired replication count to two. You must specify both the `--domain-name` and `--scaling-parameters` options.

```
aws cloudsearch update-scaling-parameters --domain-name movies --scaling-parameters
  DesiredInstanceType=search.xlarge,DesiredReplicationCount=2
```
"ScalingParameters": {
  "Status": {
    "PendingDeletion": false,
    "State": "RequiresIndexDocuments",
    "CreationDate": "2014-06-25T21:41:21Z",
    "UpdateVersion": 10,
    "UpdateDate": "2014-06-25T21:41:21Z"
  },
  "Options": {
    "DesiredInstanceType": "search.xlarge",
    "DesiredReplicationCount": 2
  }
}

Important
When you specify --scaling-parameters, Amazon CloudSearch treats unspecified options as "reset to default" rather than "leave as-is."
For example, if you specify --scaling-parameters DesiredInstanceType=search.xlarge in a command and then --scaling-parameters DesiredReplicationCount=2 in a subsequent command, Amazon CloudSearch resets DesiredInstanceType to its default value during the second command.
If you want the change from the first command to persist, you must specify it again in all subsequent commands: --scaling-parameters DesiredInstanceType=search.xlarge,DesiredReplicationCount=2.

For the changes to take effect, you must initiate an index build. You can rebuild the index by calling aws cloudsearch index-documents.

Configuring Scaling Options through the AWS SDK

The AWS SDKs (except the Android and iOS SDKs) support all of the Amazon CloudSearch actions defined in the Amazon CloudSearch Configuration API, including UpdateScalingParameters (p. 182). For more information about installing and using the AWS SDKs, see AWS Software Development Kits.

Configuring Availability Options in Amazon CloudSearch

You can expand an Amazon CloudSearch domain to an additional Availability Zone in the same region to increase fault tolerance in the event of a service disruption. Availability Zones are physically separate locations with independent infrastructure engineered to be insulated from failures in other Availability Zones. For more information, see Regions and Availability Zones in the Amazon EC2 User Guide for Linux Instances.

When you turn on the Multi-AZ option, Amazon CloudSearch provisions and maintains extra instances for your search domain in a second Availability Zone to ensure high availability. The maximum number of Availability Zones a domain can be deployed in is two.

Turning on Multi-AZ does not affect a search domain's service endpoints or increase the volume of data or traffic your search domain can handle. Updates are automatically applied to the instances in both Availability Zones. Search traffic is distributed across all of the instances and the instances in either zone are capable of handling the full load in the event of a failure.
If there's an Availability Zone service disruption or the instances in one zone become degraded, Amazon CloudSearch routes all traffic to the other Availability Zone. Redundant instances are restored in a separate Availability Zone without any administrative intervention or disruption in service.

You expand an existing search domain to a second Availability Zone by turning on the Multi-AZ option. Similarly, you can turn off the Multi-AZ option to downgrade the domain to a single Availability Zone. Turning the Multi-AZ option on or off takes about half an hour.

You can configure a domain's availability options through the Amazon CloudSearch console, using the `aws cloudsearch update-availability-options` command, or the AWS SDKs.

**Important**

If your domain is running on a single search instance, enabling the Multi-AZ option adds a second search instance in a different availability zone, which doubles the cost of running your domain. Similarly, if your index is split across multiple partitions, a new instance is deployed in the second Availability Zone for each partition. Additional replicas are added to ensure that either Availability Zone has enough capacity to handle all of your traffic—when Multi-AZ is enabled, your domain will have at least one replica of each index partition. If you set the desired number of replicas and enable the Multi-AZ option, Amazon CloudSearch ensures that you have at least that many replicas available in total across the two availability zones. You can monitor the number of instances being used for your domain from the domain dashboard.

**Topics**

- Configuring Availability Options through the Amazon CloudSearch Console (p. 40)
- Configuring Amazon CloudSearch Availability Options Using the AWS CLI (p. 40)
- Configuring Availability Options through the AWS SDK (p. 41)

### Configuring Availability Options through the Amazon CloudSearch Console

If your domain currently uses a single search instance, enabling Multi-AZ adds a second search instance, which can significantly increase the cost of running your domain.

**To configure a search domain's availability options**

1. Within the Amazon CloudSearch console, choose the name of your domain.
2. In the **Domain configuration**, choose **Edit** next to **Availability options**.
3. Enable **Toggle Multi-AZ options**.
4. Choose **Submit**.

### Configuring Amazon CloudSearch Availability Options Using the AWS CLI

You use the `aws cloudsearch update-availability-options` command to configure availability options for a search domain. For information about installing and setting up the AWS CLI, see the AWS Command Line Interface User Guide.

**To configure a search domain's availability options**

- Run the `aws cloudsearch update-availability-options` command and specify the `--multi-az` option to turn on MultiAZ for the domain, or `--no-multi-az` to turn MultiAZ off. For example, the following request enables MultiAZ for the movies domain:

```bash
aws cloudsearch update-availability-options --multi-az movies
```
Configuring Availability Options through the AWS SDK

The AWS SDKs (except the Android and iOS SDKs) support all of the Amazon CloudSearch actions defined in the Amazon CloudSearch Configuration API, including `UpdateAvailabilityOptions` (p. 180). For more information about installing and using the AWS SDKs, see AWS Software Development Kits.

Configuring Domain Endpoint Options in Amazon CloudSearch

Amazon CloudSearch domains let you require that all traffic to the domain arrive over HTTPS. This security feature helps you block clients that send unencrypted requests to the domain.

Topics
- Configuring Domain Endpoint Options Using the Amazon CloudSearch Console (p. 41)
- Configuring Domain Endpoint Options Using the AWS CLI (p. 42)
- Configuring Domain Endpoint Options Using the AWS SDKs (p. 42)

Configuring Domain Endpoint Options Using the Amazon CloudSearch Console

To configure a search domain’s endpoint options

1. Within the Amazon CloudSearch console, choose the name of your domain to open its settings.
2. Under Domain configuration, choose Edit next to HTTPS options.
3. Enable Toggle HTTPS options.
4. Choose Submit.
Configuring Domain Endpoint Options Using the AWS CLI

Use the `aws cloudsearch update-domain-endpoint-options` command. For more information, see the [AWS CLI Command Reference](https://docs.aws.amazon.com/cli/latest/reference/cloudsearch/update-domain-endpoint-options.html).

Configuring Domain Endpoint Options Using the AWS SDKs

The AWS SDKs (except the Android and iOS SDKs) support all of the Amazon CloudSearch actions defined in the Amazon CloudSearch Configuration API, including the section called “DescribeDomainEndpointOptions” (p. 172) and the section called “UpdateDomainEndpointOptions” (p. 184). For more information about installing and using the AWS SDKs, see [AWS Software Development Kits](https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/get-started.html).

Monitoring Amazon CloudSearch Domains

The AWS Management Console enables you to easily monitor the status and configuration of your search domains and view your Amazon CloudSearch usage. You can also get configuration information about particular domains with the AWS CLI and AWS SDKs.

**Topics**
- [Getting Information About an Amazon CloudSearch Domain](https://docs.aws.amazon.com/cloudsearch/latest/ug/handling-search-domains.html#find-domains) (p. 42)
- [Monitoring an Amazon CloudSearch Domain with Amazon CloudWatch](https://docs.aws.amazon.com/cloudsearch/latest/ug/handling-search-domains.html#monitoring-search-domains) (p. 46)
- [Logging Amazon CloudSearch Configuration API Calls with AWS CloudTrail](https://docs.aws.amazon.com/cloudsearch/latest/ug/handling-search-domains.html#logging-search-config-api-calls) (p. 48)
- [Tracking your Amazon CloudSearch Usage and Charges](https://docs.aws.amazon.com/cloudsearch/latest/ug/handling-search-domains.html#tracking-search-usage-and-charges) (p. 50)

Getting Information About an Amazon CloudSearch Domain

You can retrieve the following information about each of your search domains:

- **Domain name**—The name of the domain.
- **ARN**—The domain's Amazon Resource Name (ARN).
- **Document endpoint**—The endpoint through which you can submit document updates.
- **Search endpoint**—The endpoint through which you can submit search requests.
- **Searchable documents**—The number of documents that have been indexed.
- **Access policies**—The access policies configured for the domain's document and search endpoints.
- **Analysis schemes**—The text analysis schemes that can be applied to the domain's index fields.
- **Index fields**—The name and type of each configured index field.
- **Expressions**—The expressions that can be used for sorting search results.
- **Suggesters**—The suggesters that can be used to retrieve suggestions for incomplete queries.

When a domain is first created, the domain status will indicate that the domain is currently being activated and no other information is available. Once your domain's document and search endpoints
are available, the domain status shows the endpoint addresses that you can use to add data and submit search requests. If you haven't submitted any data for indexing, the number of searchable documents is zero.

You can view all of the information about your domain through the Amazon CloudSearch console (p. 43). When you use the aws cloudsearch describe-domains command or the AWS SDKs, the domain's ARN is shown within the domain's access policies.

To get the number of searchable documents, use the console or submit a matchall request to your domain's search endpoint.

```
q=matchall&q.parser=structured&size=0
```

Topics

- Getting Domain Information Using the Amazon CloudSearch Console (p. 43)
- Getting Amazon CloudSearch Domain Information Using the AWS CLI (p. 44)
- Getting Domain Information Using the AWS SDKs (p. 46)

**Getting Domain Information Using the Amazon CloudSearch Console**

You can use the Amazon CloudSearch console to view information about all of your domains. The dashboard of the console shows a summary of each domain that you have created, including the domain name, status, and number of searchable documents. To update the table with the latest information, click the Refresh button at the top of the page.

A domain can be in one of five states:

- **Loading**—The domain has just been created and is still being initialized. You must wait until the domain status changes to PROCESSING, NEEDS INDEXING, or ACTIVE before you can start uploading documents.
- **Active**—The domain is running and all configured fields have been indexed.
- **Needs Indexing**—You have made changes to the domain configuration that require rebuilding the index. If you search the domain, these changes won't be reflected in the results. When you are done making changes, choose Actions, Run indexing to rebuild your index.
- **Processing**—Configuration changes are being applied to your domain. If you search the domain, the most recent configuration changes might not be reflected in the results.
- **Being Deleted**—You chose to delete the domain and its contents, and the domain and all of its resources are in the process of being removed. When deletion is complete, the domain will be removed from the list of domains.

From the Amazon CloudSearch dashboard, you can do the following:

- View the status of your search domains
- Access the dashboard for a particular domain
- Access the Amazon CloudSearch documentation and other resources

**To view detailed information about a particular domain**

1. Open the Amazon CloudSearch console at https://console.aws.amazon.com/cloudsearch/home.
2. Choose Domains from the left navigation pane.
The domain dashboard shows the status summary for the selected domain. From the domain dashboard, you can do the following:

- View the status of the domain
- Upload documents to the domain
- Search the domain
- Access the domain configuration pages
- Delete the domain

Getting Amazon CloudSearch Domain Information Using the AWS CLI

You use the `aws cloudsearch describe-domains` command to get the status of your search domains. To get specific information such as the access policies, availability options, and scaling options configured for a domain, you use the separate `describe` commands for each option. For information about installing and setting up the AWS CLI, see the AWS Command Line Interface User Guide.

To get domain status information

- Run the `aws cloudsearch describe-domains` command to get information about all of your domains. To get information about specific domains, use the `--domain-names` option to specify the domains that you are interested in. For example, the following request gets the status of the `movies` domain:

```bash
aws cloudsearch describe-domains --domain-names movies
```

```json
{
   "DomainStatusList": [
   {
      "SearchInstanceType": "search.small",
      "DomainId": "965407640801/movies",
      "Created": true,
      "Deleted": false,
      "SearchInstanceCount": 1,
      "DomainName": "movies",
      "SearchService": {
      "Endpoint": "search-movies-m4fcjhxugj6i76smhyiz7pfxsu.us-east-1.cloudsearch.amazonaws.com"
      },
      "RequiresIndexDocuments": false,
      "Processing": true,
      "DocService": {
      "Endpoint": "doc-movies-m4fcjhxugj6i76smhyiz7pfxsu.us-east-1.cloudsearch.amazonaws.com"
      },
      "ARN": "arn:aws:cloudsearch:us-east-1:965407640801:domain/movies",
      "SearchPartitionCount": 1
   }
   ]
}
```

The `describe-domains` command does not return the number of searchable documents in the domain. To get the number of searchable documents, use the console or submit a `matchall` request to your domain's search endpoint:

```bash
q=matchall&q.parser=structured&size=0
```
To get the analysis schemes configured for a domain

- Run the `aws cloudsearch describe-analysis-schemes` command. For example, the following request gets the analysis schemes configured for the movies domain:

```bash
aws cloudsearch describe-analysis-schemes --domain-name movies

{
    "AnalysisSchemes": [
    {
        "Status": {
            "PendingDeletion": false,
            "State": "Active",
            "CreationDate": "2014-03-28T19:27:30Z",
            "UpdateVersion": 31,
            "UpdateDate": "2014-03-28T19:27:30Z"
        },
        "Options": {
            "AnalysisSchemeLanguage": "en",
            "AnalysisSchemeName": "samplescheme",
            "AnalysisOptions": {
                "AlgorithmicStemming": "none",
                "Synonyms": "{"\"aliases\":{"\"youth\":["young adult"]},"groups":[["\"tool box\"","toolbox"],["\"band saw\"","bandsaw"],["\"drill press\"","drillpress"]],
                "StemmingDictionary": "[]",
                "Stopwords": "[]"
            }
        }
    }
    ]
}
```

To get the availability options configured for a domain

- Run the `aws cloudsearch describe-availability-options` command. For example, the following request gets the availability options configured for the movies domain. If Multi-AZ is enabled for the domain, the `Options` value is set to `true`:

```bash
aws cloudsearch describe-availability-options --domain-name movies

{
    "AvailabilityOptions": {
        "Status": {
            "PendingDeletion": false,
            "State": "Processing",
            "CreationDate": "2014-04-30T20:42:57Z",
            "UpdateVersion": 13,
            "UpdateDate": "2014-05-01T00:17:45Z"
        },
        "Options": true
    }
}
```

To get the expressions configured for a domain

- Run the `aws cloudsearch describe-expressions` command. For example, the following request gets the expressions configured for the movies domain:
aws cloudsearch describe-expressions --domain-name movies
{
    "Expression": {
        "Status": {
            "PendingDeletion": false,
            "State": "Processing",
            "CreationDate": "2014-05-01T01:15:18Z",
            "UpdateVersion": 52,
            "UpdateDate": "2014-05-01T01:15:18Z"
        },
        "Options": {
            "ExpressionName": "popularhits",
            "ExpressionValue": "((0.3*popularity)/10.0)+(0.7* _score)"
        }
    }
}

Getting Domain Information Using the AWS SDKs

The AWS SDKs (except the Android and iOS SDKs) support all of the Amazon CloudSearch actions defined in the Amazon CloudSearch Configuration API, including DescribeDomains (p. 166). For more information about installing and using the AWS SDKs, see AWS Software Development Kits.

The DescribeDomains action does not return the number of searchable documents in the domain. To get the number of searchable documents, use the console or submit a matchall request to your domain's search endpoint:

q=matchall&q.parser=structured&size=0

Monitoring an Amazon CloudSearch Domain with Amazon CloudWatch

Amazon CloudSearch automatically sends metrics to Amazon CloudWatch so that you can gather and analyze performance statistics. You can monitor these metrics by using the Amazon CloudSearch console, or by using the CloudWatch console, AWS CLI, or AWS SDKs. Each of your domain's search instances sends metrics to CloudWatch at one-minute intervals. The metrics are archived for two weeks; after that period, the data is discarded.

There is no charge for the Amazon CloudSearch metrics that are reported through CloudWatch. If you set alarms on the metrics, you will be billed at standard CloudWatch rates. You can use the metrics in all regions supported by Amazon CloudSearch.

Topics
- Amazon CloudSearch Metrics (p. 47)
- Dimensions for Amazon CloudSearch Metrics (p. 47)
- Generating SDK for Java Metrics for Amazon CloudSearch (p. 47)
- Viewing CloudWatch Metrics for an Amazon CloudSearch Domain (p. 48)

Not all statistics, such as Average or Sum, are applicable for every metric. However, all of these values are available through the Amazon CloudSearch console, or by using the CloudWatch console, AWS CLI, or AWS SDKs for all metrics. In the following table, each metric has a list of Valid Statistics that is applicable to that metric.
Amazon CloudSearch Metrics

The AWS/CloudSearch namespace includes the following metrics.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SuccessfulRequests</td>
<td>The number of search requests successfully processed by a search instance.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Maximum, Sum</td>
</tr>
<tr>
<td>SearchableDocuments</td>
<td>The number of searchable documents in the domain's search index.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Maximum</td>
</tr>
<tr>
<td>IndexUtilization</td>
<td>The percentage of the search instance's index capacity that has been used.</td>
</tr>
<tr>
<td></td>
<td>The Maximum value indicates the percentage of the domain's index capacity</td>
</tr>
<tr>
<td></td>
<td>that has been used.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Maximum</td>
</tr>
<tr>
<td>Partitions</td>
<td>The number of partitions the index is distributed across.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Minimum, Maximum</td>
</tr>
</tbody>
</table>

Dimensions for Amazon CloudSearch Metrics

Amazon CloudSearch sends the ClientId and DomainName dimensions to CloudWatch.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ClientId</td>
<td>The AWS account ID.</td>
</tr>
<tr>
<td>DomainName</td>
<td>The name of the search domain.</td>
</tr>
</tbody>
</table>

Generating SDK for Java Metrics for Amazon CloudSearch

The AWS SDK for Java can generate performance metrics for your Amazon CloudSearch client and send them to CloudWatch for visualization. For the Java VM arguments that enable this feature, see Enabling Metrics for the AWS SDK for Java in the AWS SDK for Java Developer Guide.

You can use the following code to test metrics generation. The code creates a new CloudWatch client and performs 2,500 searches. Because the SDK only sends metrics once per minute, long-running clients work best. The code uses the default credential provider chain.

```java
import com.amazonaws.client.builder.AwsClientBuilder;
import com.amazonaws.services.cloudsearchdomain.AmazonCloudSearchDomain;
```
```java
import com.amazonaws.services.cloudsearchdomain.AmazonCloudSearchDomainClientBuilder;
import com.amazonaws.services.cloudsearchdomain.model.SearchRequest;

public class Metrics {
    public static void main(String[] args) {
        String search_endpoint = "https://search-domain-id.us-west-1.cloudsearch.amazonaws.com";
        String region = "us-west-1";
        AwsClientBuilder.EndpointConfiguration endpointConfig = new AwsClientBuilder.EndpointConfiguration(search_endpoint, region);

        AmazonCloudSearchDomainClientBuilder builder = AmazonCloudSearchDomainClientBuilder.standard()
            .withEndpointConfiguration(endpointConfig);

        AmazonCloudSearchDomain client = builder.build();

        String query;
        SearchRequest request = new SearchRequest();
        com.amazonaws.services.cloudsearchdomain.model.SearchResult test =
            client.search(request);

        for (int i = 0; i < 2500; i++) {
            query = "test";
            request.setQuery(query);
            test = client.search(request);
            System.out.println(test.toString());
        }
    }
}
```

To verify that the SDK is sending metrics to CloudWatch, check the Metrics page of the CloudWatch console and look for AWSSDK/Java under the Custom Namespaces section. The metrics might take several minutes to display.

### Viewing CloudWatch Metrics for an Amazon CloudSearch Domain

The Amazon CloudSearch console graphs the metrics reported to CloudWatch. You can also access the metrics through the CloudWatch console, AWS CLI, and AWS SDKs. For more information, see Viewing, Graphing, and Publishing Metrics in the Amazon CloudWatch Developer Guide.

#### To view metrics for a search domain using the Amazon CloudSearch console

1. Open the Amazon CloudSearch console at https://console.aws.amazon.com/cloudsearch.
2. Choose Domains from the left navigation pane.
3. Click the name of the domain, and then go to the Monitoring tab.

### Logging Amazon CloudSearch Configuration API Calls with AWS CloudTrail

Amazon CloudSearch integrates with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Amazon CloudSearch. CloudTrail captures all configuration API calls for Amazon CloudSearch as events.
Note
CloudTrail only captures calls to the configuration API (p. 139), such as CreateDomain and UpdateServiceAccessPolicies, not the document service API (p. 223) nor the search API (p. 231).

The calls captured include calls from the Amazon CloudSearch console, CLI, or SDKs. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Amazon CloudSearch. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can determine the request that was made to Amazon CloudSearch, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Amazon CloudSearch Information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Amazon CloudSearch, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for Amazon CloudSearch, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

All Amazon CloudSearch configuration API actions are logged by CloudTrail and are documented in the section called "Configuration API Reference" (p. 139).

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.

Understanding Amazon CloudSearch Log File Entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the CreateDomain action.
Tracking your Amazon CloudSearch Usage and Charges

The AWS account activity page enables you to track your Amazon CloudSearch usage and charges.

To get your Amazon CloudSearch usage information

1. Go to [aws.amazon.com](http://aws.amazon.com) and choose My Account, Billing & Cost Management.
2. Choose Cost & Usage Reports, then choose AWS Usage Report.
3. Choose Amazon CloudSearch from the services dropdown.
4. Specify the information that you want to include in the report, then choose the download button for the data format that you want to download. Reports can be downloaded in XML or CSV format.
Deleting an Amazon CloudSearch Domain

If you are no longer using a search domain, you must delete it to avoid incurring additional usage fees. You will still be charged for a domain even if it does not contain any documents—deleting all documents does not delete the domain. Deleting a domain deletes the index associated with the domain and takes the domain's document and search endpoints offline permanently. It can take some time to completely remove a domain and decommission all of its resources. Small domains are typically deleted in a short amount of time, while especially large domains may require an extended amount of time to be deleted. During this process, the domain status is Being Deleted and your account is not charged.

You can delete a domain from the Amazon CloudSearch console, using the `aws cloudsearch delete-domain` command, or using the AWS SDKs.

**Topics**

- Deleting a Domain Using the Amazon CloudSearch Console (p. 51)
- Deleting a Domain Using the AWS CLI (p. 51)
- Deleting Amazon CloudSearch Domains Using the AWS SDKs (p. 51)

Deleting a Domain Using the Amazon CloudSearch Console

You can easily delete a domain from the domain dashboard in the Amazon CloudSearch console.

To delete a domain

2. In left Navigation pane, choose Domains.
3. Select the checkbox next to the domain that you want to delete, then choose **Delete** and confirm deletion.

Deleting a Domain Using the AWS CLI

Run the `aws cloudsearch delete-domain` command and specify the name of the domain you want to delete. For example, to delete the `movies` domain, you specify `--domain-name movies`.

```bash
aws cloudsearch delete-domain --domain-name movies
```

For information about installing and setting up the AWS CLI, see the [AWS Command Line Interface User Guide](https://docs.aws.amazon.com/cli/latest/userguide/cli-aws.html).

Deleting Amazon CloudSearch Domains Using the AWS SDKs

The AWS SDKs (except the Android and iOS SDKs) support all of the Amazon CloudSearch actions defined in the Amazon CloudSearch Configuration API, including `DeleteDomain` (p. 155). For more information about installing and using the AWS SDKs, see [AWS Software Development Kits](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/welcome.html).
Tagging Amazon CloudSearch Domains

Use Amazon CloudSearch tags to attach metadata to your search domains. AWS does not apply any semantic meaning to your tags; tags are interpreted strictly as character strings. All tags contain the following elements.

<table>
<thead>
<tr>
<th>Tag Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tag key</td>
<td>The tag key is the required name of the tag. Tag keys must be unique for the domain to which they are attached. For a list of basic restrictions on tag keys and values, see Tag Restrictions.</td>
</tr>
<tr>
<td>Tag value</td>
<td>The tag value is an optional string value of the tag. Tag values can be null and do not have to be unique in a tag set. For example, you can have a key-value pair in a tag set of project/Trinity and cost-center/Trinity. For a list of basic restrictions on tag keys and values, see Tag Restrictions.</td>
</tr>
</tbody>
</table>

Each Amazon CloudSearch domain has a tag set, which contains all the tags that are assigned to that domain. AWS does not automatically set any tags on Amazon CloudSearch domains. A tag set can contain as many as ten tags, or it can be empty. If you add a tag to an Amazon CloudSearch domain that has the same key as an existing tag for a resource, the new value overwrites the old value.

You can use a tag key to define a category, and the tag value can be an item in that category. For example, you could define a tag key of project and a tag value of Salix indicating that the domain is assigned to the Salix project. You could also use tags to designate domains for test or production environments by using keys such as environment=test and environment=production. We recommend that you use a consistent set of tag keys to make it easier to track metadata associated with your search domains.

You also can use tags to organize your AWS bill to reflect your own cost structure and to track costs by grouping expenses for similarly tagged resources. To do this, sign up to get your AWS account bill with tag key values included. Then, organize your billing information according to resources with the same tag key values to see the cost of combined resources. For example, you can tag several Amazon CloudSearch domains with key-value pairs, and then organize your billing information to see the total cost for each domain across several services. For more information, see Cost Allocation and Tagging in the AWS Billing and Cost Management documentation.

**Note**

Tags are cached for authorization purposes. Because of this, additions and updates to tags on Amazon CloudSearch domains might take several minutes before they are available.

**Working with Tags (Console)**

Use the following procedure to create a resource tag with the Amazon CloudSearch console.

**To create a tag**

1. Go to the Amazon CloudSearch console and choose the name of your domain to open its configuration panel.
2. Go to the Tags tab and choose Manage.
3. Enter a tag key and optional value, then choose Submit.

For more information about using the console to work with tags, see Working with the Tag Editor in the AWS Management Console Getting Started Guide.

API Version 2013-01-01
52
Controlling How Data is Indexed in Amazon CloudSearch

You control how your data is indexed by configuring indexing options and analysis schemes for your domain. Indexing options control how your data is mapped to index fields and what information you can search and retrieve from the index. The data you upload must contain the same fields configured in your domain's indexing options, and the field values must be compatible with the configured field types. Analysis schemes control how text and text-array fields are processed during indexing by defining language-specific stemming, stopword, and synonym options.

Topics
- Preparing Your Data for Amazon CloudSearch (p. 53)
- Configuring Index Fields for an Amazon CloudSearch Domain (p. 57)
- Using Dynamic Fields in Amazon CloudSearch (p. 61)
- Configuring Text Analysis Schemes for Amazon CloudSearch (p. 63)
- Text Processing in Amazon CloudSearch (p. 72)

Preparing Your Data for Amazon CloudSearch

You need to format your data in JSON or XML before you can upload it to your search domain for indexing. Each item that you want to be able to receive as a search result is represented as a document. Every document has a unique document ID and one or more fields that contain the data that you want to search and return in results. These document fields are used to populate the index fields you configure for your domain. For more information, see configure indexing options (p. 57).

Creating Document Batches (p. 54) describes how to format your data. For a detailed description of the Amazon CloudSearch JSON and XML schemas, see the Document Service API (p. 223).

Topics
- Mapping Document Data to Index Fields in Amazon CloudSearch (p. 53)
- Creating Document Batches in Amazon CloudSearch (p. 54)

Mapping Document Data to Index Fields in Amazon CloudSearch

To populate the fields in your index, Amazon CloudSearch reads the data from the corresponding document fields. Every field specified in your document data must be configured in your indexing options. Documents can contain a subset of the fields configured for the domain—every document does not have to contain all fields. In addition, you can populate additional fields in your index by copying the data from one field to another. This enables you to use the same source data in different ways by configuring different options for the fields.

An array field such as text-array can contain up to 1000 values. At search time, the document is returned as a hit if any of those values match the search query.
Creating Document Batches in Amazon CloudSearch

**Important**
Before uploading data to an Amazon CloudSearch domain, follow these guidelines:

- Group documents into **batches** before you upload them. Continuously uploading batches that consist of only one document has a huge, negative impact on the speed at which Amazon CloudSearch can process your updates. Instead, create batches that are as close to the limit as possible and upload them less frequently. For more information on maximum batch size and upload frequency, see **Limits** (p. 257).

- A domain's document and search endpoints remain the same for the life of the domain. You should cache the endpoints rather than retrieving them before every upload or search request. Querying the Amazon CloudSearch configuration service by calling `aws cloudsearch describe-domains` or `DescribeDomains` before every request will likely result in your requests being throttled.

You create document batches to describe the data that you want to make searchable. When you send document batches to a domain, the data is indexed automatically according to the domain's indexing options. The Amazon CloudSearch console can automatically generate document batches from a variety of source documents.

A document batch is a collection of add and delete operations that represent the documents you want to add, update, or delete from your domain. Batches can be described in either JSON or XML. See **Limits** (p. 257) for maximum batch size and document size.

To get the best possible upload performance, group add and delete operations in batches that are close to the maximum batch size. Submitting a large volume of single-document batches to the document service can increase the time it takes for your changes to become visible in search results. If you have a large amount of data to upload, you can send batches in parallel. The number of simultaneous uploaders you can use depends on the search instance type. You can prescale for bulk uploads by setting the desired instance type option for your domain. For more information, see **Configuring Scaling Options in Amazon CloudSearch** (p. 36).

For each document in a batch, you must specify:

- The operation you want to perform: **add** or **delete**.
- A unique ID for the document. A document ID can contain any letter or number and the following characters: _ - = # ; : / ? @ &. Document IDs must be at least 1 and no more than 128 characters long.
- A name-value pair for each document field. To specify the value for a `latlon` field, you specify the latitude and longitude as a comma-separated list; for example, "location_field": "35.628611,-120.694152". When specifying documents in JSON, the value for a field cannot be `null` (You can, however, omit the field entirely.)

For example, the following JSON batch adds one document and deletes one document:

```json
[
  {
    "type": "add",
    "id": "tt0484562",
    "fields": {
      "title": "The Seeker: The Dark Is Rising",
      "directors": ["Cunningham, David L."],
      "genres": ["Adventure","Drama","Fantasy","Thriller"],
      "actors": ["McShane, Ian","Eccleston, Christopher","Conroy, Frances",
      "Crewson, Wendy","Ludwig, Alexander","Cosmo, James",
      "Warner, Amelia","Hickey, John Benjamin","Piddock, Jim",
      "Lockhart, Emma"]
      
    }
  }
]```
The same batch formatted in XML looks like this:

```xml
<batch>
  <add id="tt0484562">
    <field name="title">The Seeker: The Dark Is Rising</field>
    <field name="directors">Cunningham, David L.</field>
    <field name="genres">Adventure</field>
    <field name="genres">Drama</field>
    <field name="genres">Fantasy</field>
    <field name="genres">Thriller</field>
    <field name="actors">McShane, Ian</field>
    <field name="actors">Eccleston, Christopher</field>
    <field name="actors">Conroy, Frances</field>
    <field name="actors">Ludwig, Alexander</field>
    <field name="actors">Crewson, Wendy</field>
    <field name="actors">Warner, Amelia</field>
    <field name="actors">Cosmo, James</field>
    <field name="actors">Hickey, John Benjamin</field>
    <field name="actors">Piddock, Jim</field>
    <field name="actors">Lockhart, Emma</field>
  </add>
  <delete id="tt0484575" />
</batch>
```

Amazon CloudSearch accepts a batch only if all documents in it are valid. You can verify the validity of your JSON or XML data using tools such as `xmllint` and `jsonlint`.

Both JSON and XML batches can only contain UTF-8 characters that are valid in XML. Valid characters are the control characters tab (0009), carriage return (000D), and line feed (000A), and the legal characters of Unicode and ISO/IEC 10646. FFFE, FFFF, and the surrogate blocks D800–DBFF and DC00–DFFF are invalid and will cause errors. (For more information, see Extensible Markup Language (XML) 1.0 (Fifth Edition).) You can use the following regular expression to match invalid characters so you can remove them: `/[^\u0009\u000a\u000d\u0020-퟿-�]/`.

When formatting your data in JSON, quotes (") and backslashes (\) within field values must be escaped with a backslash. For example:

```
"title":"Where the Wild Things Are"
"isbn":"0-06-025492-0"
"image":"images\covers\Where_The_Wild_Things_Are_(book)_cover.jpg"
"comment":"Sendak's "Where the Wild Things Are" is a children's classic."
```

When formatting your data in XML, ampersands (&) and less-than symbols (<) within field values need to be represented with the corresponding entity references (&amp; and &lt;). For example:

```
<field name="title">Little Cow &amp; the Turtle</field>
<field name="isbn">0-84466-4774</field>
<field name="image">images\covers\Little_Cow_&amp;_the_Turtle.jpg</field>
<field name="comment">&lt;insert comment&gt;</field>
```

If you have large blocks of user-generated content, you might want to wrap the entire field in a CDATA section, rather than replacing every occurrence with the entity reference. For example:
Adding and Updating Documents in Amazon CloudSearch

An add operation specifies either a new document that you want to add to the index or an existing document that you want to update.

When you add or update a document, you specify the document's ID and all of the fields the document contains. You don't have to specify every configured field for every document—documents can contain a subset of the configured fields. However, every field in the document must correspond to a field configured for the domain.

To add a document to a search domain

1. Specify an add operation that contains the ID of the document you want to add and each of the fields that you want to be able to search or return in results. If the document already exists, the add operation will replace it. (You cannot update selected fields, the document is overwritten with the new version.) For example, the following operation adds document tt0484562:

   ```json
   ```

2. Include the add operation in a document batch and upload the batch to your domain. You can upload data through the Amazon CloudSearch console or by posting a request directly to the domain's document service endpoint. For more information, see upload documents (p. 85).

Deleting Documents in Amazon CloudSearch

A delete operation specifies a document that you want to remove from a domain's index. Once a document is deleted, it will no longer be searchable or returned in results.

When posting updates to delete documents, you have to specify each document that you want to delete.

If your domain has scaled up to accommodate your index size and you delete a large number of documents, the domain scales down the next time the full index is rebuilt. Although the index is automatically rebuilt periodically, to scale down as quickly as possible you can explicitly run indexing (p. 89) when you are done deleting documents.

Note
To delete documents, you upload document batches that contain delete operations. You are billed for the total number of document batches uploaded to your search domain, including batches that contain delete operations. For more information about Amazon CloudSearch pricing, see aws.amazon.com/cloudsearch/pricing/.

To delete a document from a search domain

1. Specify a delete operation that contains the ID of the document you want to remove. For example, the following operation would remove document tt0484575:
Configuring Index Fields

Each document that you add to your search domain has a collection of fields that contain the data that can be searched or returned. Every document must have a unique document ID and at least one field.

Processing Source Data Using the Amazon CloudSearch Console

When you upload source documents or DynamoDB items through the Amazon CloudSearch console, they are automatically converted to the Amazon CloudSearch JSON format. You can use the console to upload up to 5 MB of data at a time. If you choose, you can download the generated JSON file. For more information about uploading data through the console, see upload documents (p. 85) and Uploading DynamoDB Data (p. 106).

Configuring Index Fields for an Amazon CloudSearch Domain

2. Include the delete operation in a document batch and upload the batch to your domain. You can upload batches through the Amazon CloudSearch console or by posting a request directly to the domain's document service endpoint. For more information, see upload documents (p. 85).

3. The delete operation removes documents from your index—they won't appear in search results—but to delete them entirely from Amazon CloudSearch, you must also rebuild your index (p. 178).

Processing Your Source Data for Amazon CloudSearch

To upload data for indexing, you need to format your data in either JSON or XML. The Amazon CloudSearch console provide a way to automatically generate properly formatted JSON or XML from several common file types: CSV, text, and HTML. You can also process batches formatted for the Amazon CloudSearch 2011-02-01 API to convert them to the 2013-01-01 format.

For most file types, each source file is represented as a separate document in the generated JSON or XML. If metadata is available for the file, the metadata is mapped to corresponding document fields—the fields generated from the document metadata vary depending on the file type. The contents of the source file are parsed into a single text field. If the file contains more than 1 MB of data, the data mapped to the text field is truncated so that the document does not exceed 1 MB.

CSV files are handled differently. When processing a CSV file, Amazon CloudSearch uses the contents of the first row to define the document fields, and creates a separate document for each following row. If there is a column header called docid, the values in that column are used as the document IDs. If necessary, the docid values are normalized to conform to the allowed character set. A document ID can contain any letter or number and the following characters: _ - = # ; : / ? @ &. If there is no docid column, a unique ID is generated for each document based on the filename and row number.

If you upload multiple types of files, CSV files are parsed row-by-row, and non-CSV files are treated as individual documents.

Note
Currently, only CSV files are parsed to automatically extract custom field data and generate multiple documents.

You can also process data stored in DynamoDB. Amazon CloudSearch represents each item read from the table as a separate document.

API Version 2013-01-01

57
In your domain configuration, you define an index field for each of the fields that occur in your documents. You cannot upload documents that contain unrecognized fields. However, every document does not have to contain all fields—documents can contain a subset of the fields configured for the domain.

Topics

- Configuring Individual Index Fields with the AWS CLI (p. 59)
- Configuring Index Fields Using the Amazon CloudSearch Console (p. 60)
- Configuring Amazon CloudSearch Index Fields Using the AWS SDKs (p. 60)

Amazon CloudSearch supports the following index field types:

- **date**—contains a timestamp. Dates and times are specified in UTC (Coordinated Universal Time) according to [IETF RFC3339](https://tools.ietf.org/html/rfc3339): `yyyy-mm-ddTHH:mm:ss.SSSZ`. In UTC, for example, 5:00 PM August 23, 1970 is `1970-08-23T17:00:00Z`. Note that you can also specify fractional seconds when specifying times in UTC. For example, `1967-01-31T23:50.650Z`.
- **date-array**—a date field that can contain multiple values.
- **double**—contains a double-precision 64-bit floating point value.
- **double-array**—a double field that can contain multiple values.
- **int**—contains a 64-bit signed integer value.
- **int-array**—an integer field that can contain multiple values.
- **latlon**—contains a location stored as a latitude and longitude value pair (`lat`, `lon`).
- **literal**—contains an identifier or other data that you want to be able to match exactly. Literal fields are case-sensitive.
- **literal-array**—a literal field that can contain multiple values.
- **text**—contains arbitrary alphanumeric data.
- **text-array**—a text field that can contain multiple values.

Regular index field names must begin with a letter and be at least 3 and no more than 64 characters long. The allowed characters are: a-z (lower-case letters), 0-9, and _ (underscore). The name `score` is reserved and cannot be specified as a field name. All field and expression names must be unique.

Dynamic field names must either begin or end with a wildcard (*). The string before or after the wildcard can contain the same set of characters as a regular index field. For more information about dynamic fields, see the section called “Using Dynamic Fields” (p. 61).

The options you can configure for a field vary according to the field type:

- **HighlightEnabled**—You can get highlighting information for the search hits in any HighlightEnabled text field. Valid for: `text`, `text-array`.
- **FacetEnabled**—You can get facet information for any FacetEnabled field. Text fields cannot be used for faceting. Valid for: `int`, `int-array`, `date`, `date-array`, `double`, `double-array`, `latlon`, `literal`, `literal-array`.
- **ReturnEnabled**—You can retrieve the value of any ReturnEnabled field with your search results. Note that this increases the size of your index, which can increase the cost of running your domain. When possible, it's best to retrieve large amounts of data from an external source, rather than embedding it in your index. Since it can take some time to apply document updates across the domain, critical data such as pricing information should be retrieved from an external source using the returned document IDs. Valid for: `int`, `int-array`, `date`, `date-array`, `double`, `double-array`, `latlon`, `literal`, `literal-array`, `text`, `text-array`.
• **SearchEnabled**—You can search the contents of any SearchEnabled field. Text fields are always searchable. Valid for: int, int-array, date, date-array, double, double-array, latlon, literal, literal-array, text, text-array.

• **SortEnabled**—You can sort the search results alphabetically or numerically using any SortEnabled field. Array-type fields cannot be SortEnabled. Only sort enabled numeric fields can be used in expressions. Valid for: int, date, latlon, double, literal, text.

You can also specify a default value and a source for any field. Specifying a default value can be important if you are using a numeric field in an expression and that field is not present in every document. Specifying a source copies data from one field to another, enabling you to use the same source data in different ways by configuring different options for the fields. You can use a wildcard (*) when specifying the source name to copy data from all fields that match the specified pattern.

When you add fields or modify existing fields, you must explicitly issue a request to re-index your data when you are done making configuration changes. For more information, see [rebuild the index](p. 89).

**Important**

If you change the type of a field and have documents in your index that contain data that is incompatible with the new field type, all fields being processed are put in the FailedToValidate state when you run indexing and the indexing operation fails. Rolling back the incompatible configuration change will enable you to successfully rebuild your index. If the change is necessary, you must update or remove the incompatible documents from your index to use the new configuration.

## Configuring Individual Index Fields with the AWS CLI

You use the `aws cloudsearch define-index-field` command to configure individual index fields for a search domain. For information about installing and setting up the AWS CLI, see the [AWS Command Line Interface User Guide](#).

### To add an index field to your domain

- Run the `aws cloudsearch define-index-field` command and specify the name of the new field with the `--name` option, and the field type with the `--type` option. The following example adds an int field called `year` to the movies domain.

**Example**

```bash
aws cloudsearch define-index-field --domain-name movies --name year --type int
{
    "IndexField": {
        "Status": {
            "PendingDeletion": false,
            "State": "RequiresIndexDocuments",
            "CreationDate": "2014-06-25T23:03:06Z",
            "UpdateVersion": 15,
            "UpdateDate": "2014-06-25T23:03:06Z"
        },
        "Options": {
            "IndexFieldType": "int",
            "IndexFieldName": "year"
        }
    }
}
```

API Version 2013-01-01

59
### Configuring Index Fields Using the Amazon CloudSearch Console

You can easily configure individual index fields for your domain through the Indexing Options panel in the Amazon CloudSearch console. Configuring index fields in the console requires the DefineIndexFields action, which the AWS CLI doesn't support.

#### Configuring Individual Fields Using the Amazon CloudSearch Console

**To configure a new index field**

2. In the left navigation pane, choose **Domains**.
3. Click the name of the domain that you want to configure, then go to the **Indexing options** tab.
4. Choose **New index field** to add a field specification to the list.
5. Specify a unique name for the field and select the field type. Field names must begin with a letter and be at least 3 and no more than 64 characters long. The allowed characters are: a-z (lower-case letters), 0-9, and _ (underscore). The name `score` is reserved and cannot be used as a field name.
6. Select the query details that you want to enable for the field. For more information, see [configure indexing options](#).
7. Select the analysis scheme to use for each text field. The analysis scheme specifies the language-specific text processing options that are used during indexing. By default, text fields use the `_en_default_` analysis scheme. For more information, see [Configuring Analysis Schemes](#).
8. Specify a default value for the field (optional). This value is used when no value is specified for the field in the document data.
9. Optionally, add additional fields in **Source field**.
10. Choose **Submit**.

#### Configuring Amazon CloudSearch Index Fields Using the AWS SDKs

The AWS SDKs (except the Android and iOS SDKs) support all of the Amazon CloudSearch actions defined in the Amazon CloudSearch Configuration API, including `DefineIndexField`. For more information about installing and using the AWS SDKs, see [AWS Software Development Kits](#).

---

**Note**

When you add fields or modify existing fields, you must explicitly issue a request to re-index your data when you are done making configuration changes. For more information, see [rebuild the index](#).
Using Dynamic Fields in Amazon CloudSearch

Dynamic fields provide a way to index documents without knowing in advance exactly what fields they contain. For example, consider the case where you want to search a set of products. You might not know the names of all of the possible product attributes across all product categories, but you can structure your data so that all text-based attributes are stored in fields that end in _t, and all integer values are stored in fields that end in _i. With dynamic fields, you can map the attribute fields to the appropriate field type without having to configure a field for every possible attribute. This reduces the amount of configuration that you need to do up front, and eliminates the need to modify your domain configuration every time a product with a new attribute is added. You can also use dynamic fields to essentially ignore new fields by mapping them to a field that is not searchable or returnable.

Topics
- Configuring Dynamic Fields in Amazon CloudSearch (p. 61)
- Using a Dynamic Field to Ignore Unrecognized Fields in Amazon CloudSearch (p. 62)
- Searching Dynamic Fields in Amazon CloudSearch (p. 62)

Configuring Dynamic Fields in Amazon CloudSearch

You designate a field as a dynamic field by specifying a wildcard (*) as the first, last, or only character in the field name. Dynamic field names must either begin or end with a wildcard (*). Multiple wildcards and wildcards embedded within a string are not supported.

A dynamic field's name defines a pattern. The wildcard matches zero or more arbitrary characters. Any unrecognized fields that match that pattern are configured with the dynamic field's indexing options. Regular index fields take precedence over dynamic fields. If a document field name matches both a regular index field and a dynamic field pattern, it is mapped to the regular index field.

Note
The options you can configure for dynamic fields are the same as for static fields (p. 57). Similarly, document field names that match a dynamic field must meet all the same criteria as static field names.

For example, if you establish the naming convention that _i is appended to the name of any new int field, you can define a dynamic field with the pattern *_i that sets the field type to int and configures a set of predefined indexing options for new int fields. When you add a field such as review_rating_i, it's configured according to the *_i options and indexed automatically.

If a document field matches more than one dynamic field pattern, the longest matching pattern is used. If the patterns are the same length, the dynamic field that occurs first when the field names are sorted alphabetically is used.

You can define * as a dynamic field to match any fields that don't map to an explicitly defined field or a longer dynamic field pattern. This is useful if you want to simply ignore unrecognized fields. For more information, see Using a Dynamic Field to Ignore Unrecognized Fields in Amazon CloudSearch (p. 62).

Dynamic fields count toward the total number of fields defined for a domain. A domain can have a maximum of 200 field definitions, which includes dynamic fields. However, the pattern defined by a single dynamic field typically matches multiple document fields, so the total number of fields in your index can exceed 200. For more information, see Limits (p. 257). When using dynamic fields, keep in mind that significantly increasing the number of fields in your index can impact query performance.

Adding new fields to your domain configuration can affect how fields that were generated dynamically are validated during indexing. If the validation fails, indexing will fail. For example, if you define a dynamic field called *_new and upload documents that contain a field called rating_new,
the rating_new field will be added to your index. If you then explicitly configure a field called rating_new, that new field configuration will be used to validate the contents of your document's rating_new field when you run indexing. If *_new is configured as a text field and you configure rating_new as an int field, validation will fail if the existing rating_new fields contain non-integer data.

For more information about configuring index fields, see configure indexing options (p. 57).

Using a Dynamic Field to Ignore Unrecognized Fields in Amazon CloudSearch

Amazon CloudSearch requires that you configure an index field for every field that occurs in the documents you are indexing. In some cases, however, you want to index a particular set of fields and simply ignore everything else. You can use dynamic fields to ignore all unrecognized fields by defining a literal field called * and disabling all indexing options for the field. Any unrecognized fields will inherit those options and will be added to your domain; however, the field contents won’t be searchable or returnable, so they’ll have minimal impact on the size of your index. (They do, however, count toward the total number of fields configured for the domain.) Similarly, you can selectively ignore fields that match a particular pattern, such as *_n.

To ignore unrecognized fields

1. Configure the fields that you want to index, search, or return in the results.
2. Add a dynamic field that matches any other fields that are found in the documents and disables all indexing options for them:
   - Specify * as the name of the field, with no prefix or suffix string. (You can also specify a more specific pattern to selectively disable fields.)
   - Set the field type to literal and disable the search, facet, and return options. Note that the maximum size of a literal field is 4096 Unicode code points.

Because longer dynamic field patterns are matched first, you can still use dynamic fields to configure options for fields that you want to use. Any fields that don’t map to a regular index field or a longer dynamic field will match the * pattern.

Note
When you create a dynamic field with the name *, it means that your index can potentially contain any valid field name. This also means that you can reference any valid field name in your search requests, whether or not it actually exists in your index.

Searching Dynamic Fields in Amazon CloudSearch

You can reference dynamically generated fields by name in your search requests and expressions, just like any other field. For example, to search the dynamically generated field color_t for the color red, you use the structured query parser:

```
q=color_t:'red'&q.parser=structured
```

If you've defined a catch-all dynamic field (*) to map any fields that don't match regular fields or more specific dynamic field patterns, you can specify any valid field name in your search requests, whether or not the field actually exists in your index.

Wildcards are not supported within field names, so you cannot reference the dynamic field itself. For example, specifying q=*_t: 'red' would return an error.
The options a dynamically generated field inherits from the dynamic field configuration control how you can use the field in your search requests, for example, whether you can search it, get facets or highlights, use it for sorting, or return it in results. Note that dynamically generated fields must be searched explicitly—dynamic fields are NOT included in the fields that are searched by default when you use the simple query parser or do not specify a field when searching with the structured query parser.

You can specify dynamic fields as sources for other fields if the target field is an array. A field’s source attribute supports wildcards, which enables you to specify a pattern that matches a group of dynamic fields. For example, to search all fields generated from the *_t dynamic field, you could create a field called all_t_fields and set its source attribute to *_. This copies the contents of all fields whose names end in _t into all_t_fields. Note, however, that searching this field will search all fields that match the pattern, not only dynamically generated fields.

For more information about constructing and submitting search requests, see Searching Your Data with Amazon CloudSearch (p. 92).

Configuring Text Analysis Schemes for Amazon CloudSearch

Amazon CloudSearch enables you to configure a language-specific analysis scheme for each text and text-array field. An analysis scheme controls how the contents of the field are processed during indexing. Although the defaults for each language work well in many cases, fine-tuning the analysis options enables you to optimize the search results based on your knowledge of the data you are searching. For a list of supported languages, see Supported Languages (p. 73).

An analysis scheme specifies the language of the text to be processed and the following analysis options:

- **Algorithmic stemming**—specifies the level of algorithmic stemming to perform. The available stemming levels vary depending on the language.
- **Japanese Tokenization Dictionary**—specifies overrides of the algorithmic tokenization when processing Japanese. The dictionary specifies how particular sets of characters should be grouped into words.
- **Stemming dictionary**—specifies overrides for the results of the algorithmic stemming. The dictionary maps specific related words to a common root word or stem.
- **Stopwords**—specifies words that should be ignored during indexing and searching.
- **Synonyms**—specifies words that have the same meaning as words that occur in your data and should produce the same search results.

During text processing, field values and search terms are converted to lowercase (case-folded), so stopwords, stems, and synonyms are not case-sensitive. For more information about how Amazon CloudSearch processes text during indexing and when handling search requests, see Text Processing in Amazon CloudSearch (p. 72).

You must specify a language for each analysis scheme and configure an analysis scheme for each text and text-array field. When you configure fields through the Amazon CloudSearch console, the analysis scheme defaults to the _en_default_ analysis scheme. If you do not specify analysis options for an analysis scheme, Amazon CloudSearch uses the default options for the specified language. For information about the defaults for each language, see Language Specific Settings (p. 73).

The easiest way to define analysis schemes is through the Analysis Schemes page in the Amazon CloudSearch console. You must apply an analysis scheme to a field for it to take effect. You can apply an analysis scheme to a field from the Indexing Options page. You can also define analysis schemes and configure an analysis scheme for each field through the command line tools and AWS SDKs.
When you apply a new analysis scheme to an index field or modify an analysis scheme that's in use, you must explicitly **rebuild the index (p. 89)** for the changes to be reflected in search results.

**Topics**
- Stemming in Amazon CloudSearch (p. 64)
- Stopwords in Amazon CloudSearch (p. 65)
- Synonyms in Amazon CloudSearch (p. 65)
- Configuring Analysis Schemes Using the Amazon CloudSearch Console (p. 66)
- Configuring Analysis Schemes Using the AWS CLI (p. 67)
- Configuring Analysis Schemes Using the AWS SDKs (p. 68)
- Indexing Bigrams for Chinese, Japanese, and Korean in Amazon CloudSearch (p. 68)
- Customizing Japanese Tokenization in Amazon CloudSearch (p. 69)

**Stemming in Amazon CloudSearch**

Stemming is the process of mapping related words to a common stem. A stem is typically the root or base word from which variants are derived. For example, *run* is the stem of *running* and *ran*. Stemming is performed during indexing as well as at query time. Stemming reduces the number of terms that are included in the index, and facilitates matches when the search term is a variant of a term that occurs in the content being searched. For example, if you map the term *running* to the stem *run* and then search for *running*, the request matches documents that contain *run* as well as *running*.

Amazon CloudSearch supports both algorithmic stemming and explicit stemming dictionaries. You configure algorithmic stemming by specifying the level of stemming that you want to use. The available levels of algorithmic stemming vary depending on the language:

- none—disable algorithmic stemming
- minimal—perform basic stemming by removing plural suffixes
- light—target the most common noun/adjective inflections and derived suffixes
- full—aggressively stem inflections and suffixes

In addition to controlling the degree of algorithmic stemming that's performed, you can specify a stemming dictionary that maps specific related words to a common stem. You specify the dictionary as a JSON object that contains a collection of string: value pairs that map a term to its stem, for example, `{"term1": "stem1", "term2": "stem2", "term3": "stem3"}`. The stemming dictionary is applied in addition to any algorithmic stemming. This enables you to override the results of the algorithmic stemming to correct specific cases of overstemming or understemming. The maximum size of a stemming dictionary is 500 KB. Stemming dictionary entries must be lowercase.

You use the `StemmingDictionary` key to define a custom stemming dictionary in an analysis scheme. Because you pass the dictionary to Amazon CloudSearch as a string, you must escape all double quotes within the string. For example, the following analysis scheme defines stems for *running* and *jumping*:

```
{
    "AnalysisSchemeName": "myscheme",
    "AnalysisSchemeLanguage": "en",
    "AnalysisOptions": {
        "AlgorithmicStemming": "light",
        "StemmingDictionary": "{"running": "run","jumping": "jump"}"
    }
}
```

If you do not specify the level of algorithmic stemming or a stemming dictionary in your analysis scheme, Amazon CloudSearch uses the default algorithmic stemming level for the specified language.
While stemming can help users find relevant documents that might otherwise be excluded from the search results, overstemming can result in too many matches with questionable relevance. The default level of algorithmic stemming configured for each language works well for most use cases. In general, it's best to start with the default and then make adjustments to optimize the relevance of the search results for your use case. For information about the defaults for each language, see Language Specific Settings (p. 73).

Stopwords in Amazon CloudSearch

Stopwords are words that should typically be ignored both during indexing and at search time because they are either insignificant or so common that including them would result in a massive number of matches.

During indexing, Amazon CloudSearch uses the stopword dictionary when it processes text and text-array fields. In most cases, stopwords are not included in the index. The stopword dictionary is also used to filter search requests.

A stopwords dictionary is a JSON array of terms, for example, ["a", "an", "the", "of"]. The stopwords dictionary must explicitly list each word that you want to ignore. Wildcards and regular expressions are not supported.

You use the Stopwords key to define a custom stopwords dictionary in an analysis scheme. Because you pass the dictionary to Amazon CloudSearch as a string, you must escape all double quotes within the string. For example, the following analysis scheme configures the stopwords a, an, and the:

```
{
   "AnalysisSchemeName": "myscheme",
   "AnalysisSchemeLanguage": "en",
   "AnalysisOptions": {
      "Stopwords": "[\"a\", \"an\", \"the\"]"
   }
}
```

If you do not specify a stopwords dictionary in your analysis scheme, Amazon CloudSearch uses the default stopword dictionary for the specified language. The default stopwords configured for each language work well for most use cases. In general, it's best to start with the default and then make adjustments to optimize the relevance of the search results for your use case. For information about the defaults for each language, see Language Specific Settings (p. 73).

Synonyms in Amazon CloudSearch

You can configure synonyms for terms that appear in the data that you are searching. That way, if a user searches for the synonym rather than the indexed term, the results will include documents that contain the indexed term. For example, you might define custom synonyms to do the following:

- Map common misspellings to the correct spelling
- Define equivalent terms, such as film and movie
- Map a general term to a more specific one, such as fish and barracuda
- Map multiple words to a single word or vice versa, such as tool box and toolbox

When you define a synonym, the synonym is added to the index everywhere the base token occurs. For example, if you define fish as a synonym of barracuda, the term fish is added to every document that contains the term barracuda. Adding a large number of synonyms can increase the size of the index as well as query latency—synonyms increase the number of matches and the more matches, the longer it takes to process the results.
The synonym dictionary is used during indexing to configure mappings for terms that occur in text fields. No synonym processing is done on search requests. By default, Amazon CloudSearch does not define any synonyms.

You can specify synonyms in two ways:

- **As a conflation group** where each term in the group is considered a synonym of every other term in the group.
- **As an alias** for a specific term. An alias is considered a synonym of the specified term, but the term is not considered a synonym of the alias.

A synonym dictionary is specified as a JSON object that defines the synonym groups and aliases. The `groups` value is an array of arrays, where each sub-array is a conflation group. The `aliases` value is an object that contains a collection of string:value pairs where the string specifies a term and the array of values specifies each of the synonyms for that term. The following example includes both conflation groups and aliases:

```json
{
  "groups": [["1st", "first", "one"], ["2nd", "second", "two"],
     "aliases": { "youth": ["child", "kid", "boy", "girl"],
                  "adult": ["men", "women"] }
}
```

Both groups and aliases support multiword synonyms. In the following example, multiword synonyms are used in a conflation group as well as an alias:

```json
{
  "groups": [["tool box", "toolbox"], ["band saw", "bandsaw"]],
  "aliases": { "workbench": ["work bench"] }
}
```

You use the Synonyms key to define a custom synonym dictionary in an analysis scheme. Because you pass the dictionary to Amazon CloudSearch as a string, you must escape all double quotes within the string. For example, the following analysis scheme configures aliases for the term `youth`:

```json
{
  "AnalysisSchemeName": "myscheme",
  "AnalysisSchemeLanguage": "en",
  "AnalysisOptions": {
    "Synonyms": "{\"aliases\": {\"youth\": [\"child\",\"kid\"]}}"
  }
}
```

### Configuring Analysis Schemes Using the Amazon CloudSearch Console

You can define analysis schemes from the **Analysis Schemes** pane in the Amazon CloudSearch console.

**To define an analysis scheme**

2. From the left navigation pane, choose **Domains**.
3. Choose the name of your domain to open its configuration.
4. Go to the **Advanced search options** tab.
5. In the **Analysis schemes** pane, choose **Add analysis scheme**.
6. Specify a name for the analysis scheme and select a language.
7. Choose Next.
8. In the next three steps, configure the scheme's text stopword, stemming, and synonym options. You can configure individual stopwords, stems, and synonyms, or edit the displayed dictionaries directly. The dictionaries are formatted in JSON. Stopwords are specified as an array of strings. Stems are specified as an object that contains one or more key:value pairs. Synonym aliases are also specified as a JSON object with one or move key:value pairs, where the alias values are specified as an array of strings. A synonym group is specified as a JSON array. (The synonym dictionary is an array of arrays.)

If you selected Japanese as the language, you also have the option of specifying a custom tokenization dictionary that overrides the default tokenization of specific phrases. For more information, see Customizing Japanese Tokenization (p. 69).
9. On the summary page, review the analysis scheme configuration and choose Save.

**Important**
To use an analysis scheme, you must apply it to one or more text or text-array fields and rebuild the index. You can configure a field's analysis scheme from the Indexing options tab. To rebuild your index, choose Actions, Run indexing.

### Configuring Analysis Schemes Using the AWS CLI

You use the `aws cloudsearch define-analysis-scheme` command to define language-specific text processing options, including stemming options, stopwords, and synonyms. For information about installing and setting up the AWS CLI, see the AWS Command Line Interface User Guide.

You specify an analysis scheme as part of the configuration of each text or text-array field. For more information, see configure indexing options (p. 57).

#### To define an analysis scheme

- Run the `aws cloudsearch define-analysis-scheme` command and specify the `--analysis-scheme` option and a JSON object that contains your analysis options. The analysis scheme must be valid JSON. The analysis option key and value pairs must be escaped in quotes, and all quotes within the option values must be escaped with a backslash. For the format of the analysis options, see `define-analysis-scheme` in the AWS CLI Command Reference. See Configuring Analysis Schemes (p. 65) for more information about specifying stemming, stopword, and synonym options.

If you specify Japanese (ja) as the language, you also have the option of specifying a custom tokenization dictionary that overrides the default tokenization of specific phrases. For more information, see Customizing Japanese Tokenization (p. 69).

**Tip**
The easiest way to configure an analysis scheme with the AWS CLI is to store the analysis scheme in a text file and specify that file as the `--analysis-scheme` value. This enables you to format the scheme so that it's easier to read. For example, the following scheme defines an English analysis scheme called `myscheme` that uses light algorithmic stemming and configures two stopwords:

```json
{
  "AnalysisSchemeName": "myscheme",
  "AnalysisSchemeLanguage": "en",
  "AnalysisOptions": {
    "AlgorithmicStemming": "light",
    "Stopwords": "[\"a\", \"the\"]"
  }
}
```
If you save this scheme in a text file called myscheme.txt, you can pass the file in as the value of the --analysis-scheme parameter:

```
aws cloudsearch define-analysis-scheme --region us-east-1 --domain-name movies --analysis-scheme file://myscheme.txt
```

**Important**
To use an analysis scheme, you must apply it to one or more text or text-array fields and rebuild the index. You can configure a field's analysis scheme with the `aws cloudsearch define-index-field` command. To rebuild the index, call `aws cloudsearch index-documents`.

### Configuring Analysis Schemes Using the AWS SDKs

The AWS SDKs (except the Android and iOS SDKs) support all of the Amazon CloudSearch actions defined in the Amazon CloudSearch Configuration API, including `DefineAnalysisScheme` (p. 145). For more information about installing and using the AWS SDKs, see [AWS Software Development Kits](https://docs.aws.amazon.com/sdk-for-java/v1/reference/AmazonCloudSearch/AmazonCloudSearch.html).

**Important**
To use an analysis scheme, you must apply it to one or more text or text-array fields and rebuild the index. You can configure a field's analysis scheme with the `define index field` method. To rebuild your index, you use the `index documents` method.

### Indexing Bigrams for Chinese, Japanese, and Korean in Amazon CloudSearch

Chinese, Japanese, and Korean do not have explicit word boundaries. Simply indexing individual characters (unigrams) can result in matches that aren't very relevant to a search query. One solution is to index bigrams. A bigram is every sequence of two adjacent characters in a string. For example, the following example shows bigrams for the string

```
我的 氣 塗船 裝滿 魚
```

While indexing bigrams can improve search result quality, keep in mind that it can significantly increase the size of your index.

**To index bigrams for Chinese, Japanese, and Korean**

1. Create a text analysis scheme and set the language to multiple languages (mul).
2. Configure the index field that contains the CJK data to use your multi-language analysis scheme.

When you assign an analysis scheme that sets a field's language to mul, Amazon CloudSearch automatically generates bigrams for all Chinese, Japanese, and Korean text within the field.

For more information about creating and using analysis schemes, see [Configuring Analysis Schemes](https://docs.aws.amazon.com/cloudsearch/latest/developerguide/configure-analyses-schemes.html) (p. 63).

If you are indexing Japanese content, you might also be interested in using a custom tokenization dictionary with the standard Japanese language processor. For more information, see [Customizing Japanese Tokenization](https://docs.aws.amazon.com/cloudsearch/latest/developerguide/cjktok.html) (p. 69).
Customizing Japanese Tokenization in Amazon CloudSearch

If you need more control over how Amazon CloudSearch tokenizes Japanese, you can add a custom Japanese tokenization dictionary to your analysis scheme. Configuring a custom tokenization dictionary enables you to override how specific entries are tokenized by the standard Japanese language processor. This can improve search result accuracy in some cases, particularly when you need to index and retrieve domain-specific phrases.

A tokenization dictionary is a collection of entries where each entry specifies a set of characters, how the characters should be tokenized, how each token should be pronounced (readings), and a part-of-speech tag. You specify the dictionary as an array, and each dictionary entry is an array of strings. The entries are of the following form:

```json
["<text>","<token 1> ... <token n>"","<reading 1> ... <reading n>"","<part-of-speech tag>"]
```

You must specify a reading for each token and the part-of-speech tag for the entry. See Japanese Part-of-Speech Tags (p. 70) for the part of speech tags that are treated as stopwords.

You use the JapaneseTokenizationDictionary key to define a custom tokenization dictionary in an analysis scheme. Because you pass the tokenization dictionary to Amazon CloudSearch as a string, you must escape all double quotes within the string. For example, the dictionary in the following analysis scheme specifies segmentation overrides for Kanji and Katakana compounds, and a custom reading for a proper name:

```json
"AnalysisSchemeName": "jascheme",
"AnalysisSchemeLanguage": "ja",
"AnalysisOptions": {
  "Stopwords": ":["a", "the"]",
  "AlgorithmicStemming": "full",
  "JapaneseTokenizationDictionary": [
    ["日本経済新聞","日本經濟新聞","日本経済新聞","ニホン ケイザイ シンプル","トートバッグ","トートバッグ","トートバッグ","朝青龍","朝青龍","アサショウリュウ","カスタム人"
  ]
}
```

When configuring an analysis scheme with the AWS CLI, you can store the analysis scheme in a text file and specify that file as the --analysis-scheme value. This enables you to format the scheme so that it's easier to read. For example, if you store the jascheme analysis scheme in a file called jascheme.txt, you can pass that file in when you call aws cloudsearch define-analysis-scheme:

```bash
aws cloudsearch define-analysis-scheme --region us-east-1 --domain-name mydomain --analysis-scheme file:///jascheme.txt
```
For more information about creating and using analysis schemes, see Configuring Analysis Schemes (p. 63).

Japanese Part-of-Speech Tags in Amazon CloudSearch

When you use a custom tokenization dictionary for Japanese, you specify a part-of-speech tag for each entry. If the part-of-speech tag matches one of the tags configured as a stop tag, the entry is treated as a stopword.

The following table shows the part of speech tags configured as stop tags in Amazon CloudSearch.

**Stop Tags**

<table>
<thead>
<tr>
<th>Tag</th>
<th>Part-of-Speech</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>助動詞</td>
<td>Auxiliary-verb</td>
<td>A verb that adds functional or grammatical meaning to the clause in which it appears.</td>

</table>
# Text Processing in Amazon CloudSearch

During indexing, Amazon CloudSearch processes text and text-array fields according to the analysis scheme configured for the field to determine what terms to add to the index. Before the analysis options are applied, the text is tokenized and normalized.

During tokenization, the stream of text in a field is split into separate tokens on detectable boundaries using the word break rules defined in the Unicode Text Segmentation algorithm. For more information, see [Unicode Text Segmentation](#).

According to the word break rules, strings separated by whitespace such as spaces and tabs are treated as separate tokens. In many cases, punctuation is dropped and treated as whitespace. For example, strings are split at hyphens (-) and the at symbol (@). However, periods that are not followed by whitespace are considered part of the token.

Note that strings are not split on case boundaries—*CamelCase* strings are not tokenized.

During normalization, upper case characters are converted to lower case. Accents are typically handled according to the stemming options configured in the field's analysis scheme. (The default analysis scheme for English removes accents.)

Once tokenization and normalization are complete, the stemming options, stopwords, and synonyms specified in the analysis scheme are applied.

When you submit a search request, the text you're searching for undergoes the same text processing so that it can be matched against the terms that appear in the index. However, no text analysis is performed on the search term when you perform a prefix search. This means that a search for a prefix that ends in *s* typically won't match the singular version of the term when stemming is enabled. This can happen for any term that ends in *s*, not just plurals. For example, if you search the *actor* field in the sample movie data for *Anders*, there are three matching movies. If you search for *Ander*+, you get those movies as well as several others. However, if you search for *Anders*+ there are no matches. This is because the term is stored in the index as *ander*, *anders* does not appear in the index.

If stemming is preventing your wildcard searches from returning all of the relevant matches, you can suppress stemming for the text field by setting the *AlgorithmicStemming* option to none, or you can map the data to a *literal* field instead of a *text* field.

Uploading and Indexing Data in Amazon CloudSearch

To make your data searchable, you need to format it in JSON or XML as described in Preparing Your Data (p. 53) and upload it to your search domain for indexing. In most cases, Amazon CloudSearch automatically indexes your data and the changes are visible in search results in just a few minutes. However, certain changes to your domain configuration put the domain in the NEEDS_INDEXING state. For those changes to take effect, you must explicitly run indexing to rebuild your index. Currently, you also need to periodically run indexing so your suggesters reflect the most recent data in your index. The following sections describe how to upload data to your domain and run indexing when it’s needed.

Important
Rebuilding your index after data uploads is unnecessary and can cause your domain to incur additional charges. You only need to rebuild your index after certain configuration changes or after you have deleted documents and want them permanently removed from the service.

Topics
- Uploading Data to an Amazon CloudSearch Domain (p. 85)
- Indexing Document Data with Amazon CloudSearch (p. 89)

Uploading Data to an Amazon CloudSearch Domain

Important
Before uploading data to an Amazon CloudSearch domain, follow these guidelines:

- Group documents into batches before you upload them. Continuously uploading batches that consist of only one document has a huge, negative impact on the speed at which Amazon CloudSearch can process your updates. Instead, create batches that are as close to the limit as possible and upload them less frequently. For more information on maximum batch size and upload frequency, see Limits (p. 257).

- A domain’s document and search endpoints remain the same for the life of the domain. You should cache the endpoints rather than retrieving them before every upload or search request. Querying the Amazon CloudSearch configuration service by calling aws cloudsearch describe-domains or DescribeDomains before every request will likely result in your requests being throttled.

You create document batches to describe the data that you want to upload to an Amazon CloudSearch domain. A document batch is a collection of add and delete operations that represent the documents you want to add, update, or delete from your domain. Batches can be described in either JSON or XML. When you upload document batches to a domain, the data is indexed automatically according to the domain’s indexing options.

As your data changes, you upload batches to add, change, or delete documents from your index. Amazon CloudSearch applies updates continuously. You only have to explicitly reindex your data when you make configuration changes that put your domain in the NEEDS_INDEXING state or need to update suggesters.

To upload data to your domain, it must be formatted as a valid JSON or XML batch. The fields specified in each document must correspond to index fields configured for the domain. However,
a document does not have to contain every configured index field. For information about creating
document batches, see Preparing Your Data (p. 53). For information about configuring index fields for a
domain, see configure indexing options (p. 57).

You are billed for the total number of document batches uploaded to your search domain, including
batches that contain delete operations. For more information about Amazon CloudSearch pricing, see
aws.amazon.com/cloudsearch/pricing/.

You can submit a document batch to a domain using the Amazon CloudSearch console (p. 87), AWS
CLI, or by posting it directly (p. 89) to the domain's document service endpoint.

For more information about the document service API, see the Document Service API (p. 223).

Topics
• Submitting Document Upload Requests to an Amazon CloudSearch Domain (p. 86)
• Bulk Uploads in Amazon CloudSearch (p. 87)
• Uploading Data Using the Amazon CloudSearch Console (p. 87)
• Uploading Data Using the AWS CLI (p. 89)
• Posting Documents to an Amazon CloudSearch Domain's Document Service Endpoint via
HTTP (p. 89)

Submitting Document Upload Requests to an
Amazon CloudSearch Domain

Important
Before uploading data to an Amazon CloudSearch domain, follow these guidelines:

• Group documents into batches before you upload them. Continuously uploading batches that
consist of only one document has a huge, negative impact on the speed at which Amazon
CloudSearch can process your updates. Instead, create batches that are as close to the limit as
possible and upload them less frequently. For more information on maximum batch size and
upload frequency, see Limits (p. 257).
• A domain's document and search endpoints remain the same for the life of the domain.
You should cache the endpoints rather than retrieving them before every upload or
search request. Querying the Amazon CloudSearch configuration service by calling aws
cloudsearch describe-domains or DescribeDomains before every request will likely
result in your requests being throttled.

We recommend using one of the AWS SDKs or the AWS CLI to submit document upload requests. The
SDKs and AWS CLI handle request signing for you and provide an easy way to perform all Amazon
CloudSearch actions. You can also use the Amazon CloudSearch console to upload individual batches and
import data from DynamoDB or S3.

For example, the following request uploads a batch using the AWS CLI.

```
aws cloudsearchdomain --endpoint-url http://doc-movies-y6gelr4lv3jeu4rvoelunxsl2e.us-
east-1.cloudsearch.amazonaws.com upload-documents --content-type
application/json --documents movie-data-2013.json
```

For development and testing purposes, you can allow anonymous access to your domain's document
service and submit unsigned HTTP POST requests directly to your domain's document service. In a
production environment, restrict access to your domain to specific IAM roles, groups, or users and submit
signed requests. For information about controlling access for Amazon CloudSearch, see configure access
policies (p. 27). For more information about request signing, see Signing AWS API Requests.
For example, the following POST request uploads a batch of documents formatted in JSON to the domain endpoint doc-movies-123456789012.us-east-1.cloudsearch.amazonaws.com.

```
curl -X POST --upload-file data1.json doc-movies-123456789012.us-east-1.cloudsearch.amazonaws.com/2013-01-01/documents/batch --header "Content-Type: application/json"
```

## Bulk Uploads in Amazon CloudSearch

Document batches are limited to one batch every 10 seconds and 5 MB per batch. To learn more, see [Limits](#limits) (p. 257). However, you can upload batches in parallel to reduce the amount of time it takes to upload all of your data.

### To perform a bulk upload:

- Set your desired instance type to a larger instance type than the default `search.small`. The number of upload threads you can use depends on the type of search instance your domain is using and the nature of your data and indexing options. Larger instance types have a higher upload capacity. Attempting to upload batches in parallel to a `search.small` instance usually results in a high rate of 504 or 507 errors. For more information about setting the desired instance type, see [Configuring Scaling Options in Amazon CloudSearch](#configuring-scaling-options-in-amazon-cloudsearch) (p. 36).

- Start uploading data once your configuration changes are active. If you encounter a high rate of 5xx errors, you either need to reduce your upload rate or switch to a larger instance type. If you are already using the largest instance type, you can increase the desired partition count to further increase upload capacity.

  **Important**
  
  If you submit a large volume of updates while your domain is in the PROCESSING state, it can increase the amount of time it takes for the updates to be applied to your search index. To avoid this update lag, wait until your domain is in the ACTIVE state before starting your bulk upload.

- When you are finished with your bulk upload, you can change the desired instance type back to a smaller instance type. If your index fits on a smaller type, Amazon CloudSearch will automatically scale your domain back down. Amazon CloudSearch will not scale to an instance type that's smaller than the desired instance type configured for your domain.

For datasets of less than 1 GB of data or fewer than one million 1 KB documents, a small search instance should be sufficient. To upload data sets between 1 GB and 8 GB, we recommend setting the desired instance type to `search.large` before you begin uploading. For datasets between 8 GB and 16 GB, start with a `search.xlarge`. For datasets between 16 GB and 32 GB, start with a `search.2xlarge`. If you have more than 32 GB to upload, select the `search.2xlarge` instance type and increase the desired partition count to accommodate your data set. Each partition can contain up to 32 GB of data. Submit a [Service Increase Limit Request](#service-increase-limit-request) if you need more upload capacity or have more than 500 GB to index.

## Uploading Data Using the Amazon CloudSearch Console

In the Amazon CloudSearch console, you can upload data from your local file system or Amazon S3 to your domain from the domain dashboard. The console can automatically convert the following types of files to document batches during the upload process:

- Document batches formatted in JSON or XML (.json, .xml)
- Comma Separated Value (.csv)
• Text Documents (.txt)

You can also convert and upload items from an DynamoDB table. For more information, see Uploading DynamoDB Data (p. 106).

Note
To upload data from Amazon S3 or DynamoDB, you must have permission to access both the service and the resources you want to upload. For more information, see Using Bucket Policies and User Policies and Using IAM to Control Access to DynamoDB Resources.

CSV files are parsed row-by-row and a separate document is generated for each row. All other types of files are treated as a single document. For more information about automatically generating document batches, see Preparing Your Data (p. 53).

To send data to a domain for indexing

1. Open the Amazon CloudSearch console at https://console.aws.amazon.com/cloudsearch/home.
2. In the left navigation pane, choose Domains.
3. Choose the name of your domain to open the domain configuration.
5. Select the location of the data you want to upload to your domain:

   • Local machine
   • Amazon S3
   • Amazon DynamoDB
   • Sample data

If you upload data that isn't formatted as document batches, it will automatically be converted during the upload process.

Note
If a batch is invalid, Amazon CloudSearch converts the content to a valid batch that contains a single content field and generic metadata fields. Since these are not normally the fields configured for the domain, you will get errors stating that the fields don't exist.

6. Upload your data.

   a. If you are uploading local files, select Choose file to locate the file(s) to upload.
   b. If you are uploading objects from Amazon S3, provide the URI of the bucket to upload from.
   c. If you are uploading items from DynamoDB, select the table to upload from. To limit the read capacity units that can be consumed while reading from the table, enter the maximum percentage of read capacity units. To start reading from a particular item, specify a start hash key.
   d. If you're uploading predefined sample data, choose the data set to use.

7. Choose Continue.
8. Review the documents to be uploaded and choose Upload documents.
9. In the Upload Summary, if a document batch has been automatically generated from your data, you can choose Download the generated document batch to get it. Choose Close to return to the domain dashboard.
Uploading Data Using the AWS CLI

You use the `aws cloudsearch upload-documents` command to send document batches to your search domain. For information about installing and setting up the AWS CLI, see the AWS Command Line Interface User Guide.

**To send document batches to a domain for indexing**

- Run the `aws cloudsearchdomain upload-documents` command to upload your batches to your domain:

  ```
  aws cloudsearchdomain upload-documents --endpoint-url http://doc-movies-y6gelr41v3jeu4roelunxsl2e.us-east-1.cloudsearch.amazonaws.com --content-type application/json --documents document-batch.json
  {
    "status": "success",
    "adds": 5000,
    "deletes": 0
  }
  ```

Posting Documents to an Amazon CloudSearch Domain's Document Service Endpoint via HTTP

You use the `documents/batch` resource to post document batches to your domain to add, update, or remove documents. For example:

```
```

Indexing Document Data with Amazon CloudSearch

When you send document updates to your domain, Amazon CloudSearch automatically updates the domain's search index with the new data. You don't have to do anything for the updates to be indexed. However, if you change the configuration of your domain's index fields or text options, you must explicitly rebuild your search index for those changes to be visible in search results. Because rebuilding the index can take a significant amount of time if you have a lot of data, you should finish making all of your configuration changes before re-indexing your documents.

**Important**

If you change the type of a field and have documents in your index that contain data that is incompatible with the new field type, all fields being processed are put in the FailedToValidate state when you run indexing and the indexing operation fails. Rolling back the incompatible configuration change will enable you to successfully rebuild your index. If the change is necessary, you must update or remove the incompatible documents from your index to use the new configuration.

When you make changes that require re-indexing, the domain status changes to Needs Indexing. While the index is being rebuilt, the domain's status is Processing. You can continue to submit search requests while indexing is in process, but the configuration changes won't be visible in search results.
until indexing completes and the domain's status changes to Active. You can also continue to upload document batches to your domain. However, if you submit a large volume of updates while your domain is in the Processing state, it can increase the amount of time it takes for the updates to be applied to your search index. If this becomes an issue, slow your update rate until the domain returns to the Active state.

**Note**

Depending on the volume of data, building a full index can take a considerable amount of compute power. Amazon CloudSearch automatically manages the resources needed to build the index in a timely fashion. Most data updates and simple domain configuration changes are built and deployed in minutes. Indexing large volumes of data and applying configuration changes that require rebuilding the full index will take longer to complete.

You can initiate indexing from the Amazon CloudSearch console (p. 90), using the aws cloudsearch index-documents command, or through the AWS SDKs.

**Topics**

- Indexing Documents Using the Amazon CloudSearch Console (p. 90)
- Indexing Documents Using the Amazon CloudSearch AWS CLI (p. 90)
- Indexing Documents with the AWS SDK (p. 91)

### Indexing Documents Using the Amazon CloudSearch Console

When you make changes that require your domain's index to be rebuilt, the status shown on the domain dashboard changes to NEEDS INDEXING. The console also displays a message at the top of the configuration pages prompting you to run indexing when you are done making changes.

**To run indexing**

1. Open the Amazon CloudSearch console at https://console.aws.amazon.com/cloudsearch/home.
2. From the left navigation pane, choose Domains.
3. Choose the name of the domain that needs indexing.
4. On the domain dashboard, choose Actions, Run indexing.

### Indexing Documents Using the Amazon CloudSearch AWS CLI

You use the aws cloudsearch index-documents command to rebuild your domain's search index. For information about installing and setting up the AWS CLI, see the AWS Command Line Interface User Guide.

**To explicitly index your domain**

- Run the `aws cloudsearch index-documents` command. The following example rebuilds the index for a domain called `movies`.

**Example**

```
aws cloudsearch index-documents --domain-name movies
```
Indexing Documents with the AWS SDK

The AWS SDKs (except the Android and iOS SDKs) support all of the Amazon CloudSearch actions defined in the Amazon CloudSearch Configuration API, including `IndexDocuments` (p. 178). For more information about installing and using the AWS SDKs, see `AWS Software Development Kits`. 
Searching Your Data with Amazon CloudSearch

You specify the terms or values you want to search for with the q parameter. How you specify the search criteria depends on which query parser you use. Amazon CloudSearch supports four query parsers:

- **simple**—search all text and text-array fields for the specified string. The simple query parser enables you to search for phrases, individual terms, and prefixes. You can designate terms as required or optional, or exclude matches that contain particular terms. To search particular fields, you can specify the fields you want to search with the q.options parameter. The simple query parser is used by default if the q.parser parameter is not specified.

- **structured**—search specific fields, construct compound queries using Boolean operators, and use advanced features such as term boosting and proximity searching.

- **lucene**—specify search criteria using the Apache Lucene query parser syntax. If you currently use the Lucene syntax, using the lucene query parser enables you to migrate your search services to an Amazon CloudSearch domain without having to completely rewrite your search queries in the Amazon CloudSearch structured search syntax.

- **dismax**—specify search criteria using the simplified subset of the Apache Lucene query parser syntax defined by the DisMax query parser. If you are currently using the DisMax syntax, using the dismax query parser enables you to migrate your search services to an Amazon CloudSearch domain without having to completely rewrite your search queries in the Amazon CloudSearch structured search syntax.

You can use additional search parameters to control how search results are returned and include additional information such as facets, highlights, and suggestions with your search results.

For information about all of the Amazon CloudSearch search parameters, see the Search API.

Submitting Search Requests to an Amazon CloudSearch Domain

We recommend using one of the AWS SDKs or the AWS CLI to submit search requests. The SDKs and AWS CLI handle request signing for you and provide an easy way to perform all Amazon CloudSearch actions. You can also use the Search Tester in the Amazon CloudSearch console to search your data,
browse the results, and view the generated request URLs and JSON and XML responses. For more information, see Searching with the Search Tester (p. 11).

Important

- Search endpoints don't change: A domain's document and search endpoints remain the same for the life of the domain. You should cache the endpoints rather than retrieving them before every upload or search request. Querying the Amazon CloudSearch configuration service by calling `aws cloudsearch describe-domains` or DescribeDomains before every request is likely to result in your requests being throttled.
- IP addresses do change: Your domain's IP address can change over time, so it's important to cache the endpoint as shown in the console and returned by the `aws cloudsearch describe-domains` command rather than the IP address. You should also re-resolve the endpoint DNS to an IP address regularly. For more information, see Setting the JVM TTL for DNS Name Lookups.

For example, the following request submits a simple text search for wolverine using the AWS CLI and returns just the IDs of the matching documents.

```
aws cloudsearchdomain --endpoint-url http://search-movies-y6gelrlr4lv3jew4rvoelunxs1l2e.us-east-1.cloudsearch.amazonaws.com search --search-query wolverine  --return _no_fields
{
    "status": {
        "id": "/rnE+e4oCAqfEEs=",
        "time-ms": 6
    },
    "hits": {
        "found": 3,
        "hit": [
            {
                "id": "tt1430132"
            },
            {
                "id": "tt0458525"
            },
            {
                "id": "tt1877832"
            }
        ],
        "start": 0
    }
}
```

By default, Amazon CloudSearch returns the response in JSON. You can get the results formatted in XML by specifying the `format` parameter. Setting the response format only affects responses to successful requests. The format of an error response depends on the origin of the error. Errors returned by the search service are always returned in JSON. 5xx errors due to server timeouts and other request routing problems are returned in XML.

Note

The AWS SDKs return fields as arrays. Single-value fields are returned as arrays with one element, such as:

```
"fields": {
    "plot": ["Katniss Everdeen reluctantly becomes the symbol of a mass rebellion against the autocratic Capitol."]
}
```

For development and testing purposes, you can allow anonymous access to your domain's search service and submit unsigned HTTP GET or POST requests directly to your domain's search endpoint.
In a production environment, restrict access to your domain to specific IAM roles, groups, or users and submit signed requests using the AWS SDKs or AWS CLI. For information about controlling access for Amazon CloudSearch, see configure access policies (p. 27). For more information about request signing, see Signing AWS API Requests.

You can use any method you want to send HTTP requests directly to your domain's search endpoint—you can enter the request URL directly in a Web browser, use cURL to submit the request, or generate an HTTP call using your favorite HTTP library. To specify your search criteria, you specify a query string that specifies the constraints for your search and what you want to get back in the response. The query string must be URL-encoded. The maximum size of a search request submitted via GET is 8190 bytes, including the HTTP method, URI, and protocol version. You can submit larger requests using HTTP POST; however, keep in mind that large, complex requests take longer to process and are more likely to time out. For more information, see Tuning Search Request Performance in Amazon CloudSearch (p. 108).

For example, the following request submits a structured query to the search-movies-rr2f34ofg56xneuemujamut52i.us-east-1.cloudsearch.amazonaws.com domain and gets the contents of the title field.

```
http://search-movies-rr2f34ofg56xneuemujamut52i.us-east-1.cloudsearch.amazonaws.com/2013-01-01/search?q=(and+(term+field%3Dtitle+'star')
(term+field%3Dyear+1977))&q.parser=structured&return=title
```

**Important**
Special characters in the query string must be URL-encoded. For example, you must encode the = operator in a structured query as %3D: (term+field%3Dtitle+'star'). If you don't encode the special characters when you submit the search request, you'll get an InvalidQueryString error.

### Searching with the Search Tester

The search tester in the Amazon CloudSearch console enables you to submit sample search requests using any of the supported query parsers: simple, structured, lucene, or dismax. By default, requests are processed with the simple query parser. You can specify options for the selected parser, filter and sort the results, and browse the configured facets. The search hits are automatically highlighted in the search results. For information about how this is done, see Highlighting Search Hits in Amazon CloudSearch (p. 118). You can also select a suggester to get suggestions as you enter terms in the Search field. (You must configure a suggester before you can get suggestions. For more information see Getting Autocomplete Suggestions in Amazon CloudSearch (p. 119).)

By default, results are sorted according to an automatically-generated relevance score, _score. For information about customizing how results are ranked, see Sorting Results in Amazon CloudSearch (p. 124).

### To search your domain

2. In the left navigation panel, choose the name of your domain to open its configuration.
3. Choose Run a test search.
4. To perform a simple text search, enter a search query and choose Run. By default, all text and text-array fields are searched.

To search particular fields, expand Options and enter a comma-separated list of the fields you want to search in the Search fields field. You can append a weight to each field with a caret (^) to control the relative importance of each field in the search results. For example, specifying title^5, description weights hits in the title field five times more than hits in the description field when calculating relevance scores for each matching document.
To use the structured query syntax, select **Structured** from the **Query parser** menu. Once you've selected the structured query parser, enter your structured query in the **Search** field and choose **Run**. For example, to find all of the movies with *star* in the title that were released in the year 2000 or earlier, you could enter: `(and title:'star' year:{,2000})`. For more information, see [Constructing Compound Queries](p. 95). To submit Lucene or DisMax queries, select the appropriate query parser.

You can specify additional options for the selected query parser to configure the default operator and control which operators can be used in a query. For more information, see [Search Request Parameters](p. 231).

You can copy and paste the request URL to submit the request and view the response from a Web browser. Requests can be sent via HTTP or HTTPS.

### Constructing Compound Queries in Amazon CloudSearch

You can use the structured query parser to combine match expressions using Boolean **and**, **or**, and **not** operators. To select the structured query parser, you include `q.parser=structured` in your query. The structured query operators are specified as **prefix** operators. The syntax is:

- `(and boost=N EXPRESSION1 EXPRESSION2 ... EXPRESSIONn)
- `(or boost=N EXPRESSION1 EXPRESSION2 ... EXPRESSIONn)
- `(not boost=N EXPRESSION)

For example, the following query matches all movies in the sample data set that contain *star* in the title, and either Harrison Ford or William Shatner appear in the *actors* field, but Zachary Quinto does not.

```(and title:'star' (or actors:'Harrison Ford' actors:'William Shatner')(not actors:'Zachary Quinto'))```

When using the structured query operators, you specify the name of the operator, options for the operator, and then the match expression being operated on, `(OPERATOR OPTIONS EXPRESSION)`. The match expression can be a simple text string, or a subclause of your compound query. Any options must be specified before the terms. For example, `(and (not field=genres 'Sci-Fi')(or (term field=title boost=2 'star')(term field=plot 'star'))).

Parentheses control the order of evaluation of the expressions. When an expression is enclosed in parentheses, that expression is evaluated first, and then the resulting value is used in the evaluation of the remainder of the compound query.

**Important**

You must URL-encode special characters in the query string. For example, you must encode the `=` operator in a structured query as `%3D`. Amazon CloudSearch returns an `InvalidQueryString` error if special characters are not URL-encoded. For a complete reference of URL-encodings, see the W3C [HTML URL Encoding Reference](https://www.w3.org/Style/URI/1998/NOTE-html-url-19980720).

For example, the following query searches the *title* field for the phrase *star wars* and excludes matches that have a value less than 2000 in the *year* field.

```(and (phrase field='title' 'star wars') (not (range field=year {,2000})))```

To submit this search request, you need to encode the query string and specify the structured query parser with the `q.parser` parameter.
The structured query syntax enables you to combine searches against multiple fields. If you don't specify a field to search, all text and text-array fields are searched. For example, the following query searches all text and text-array fields for the term star, and excludes documents that contain Zachary Quinto in the actors field.

\[(\text{and } \text{'star'} \text{ (not } \text{actors':Zachary Quinto')})\]

You can specify a boost value to increase the importance of one expression in a compound query in relation to the others. The boost value increases the scores of the matching documents. For example, the following query boosts matches for the term star if they occur in the title field rather than the description field.

\[(\text{and (range field=year [2013,}) \text{(or (term field=title boost=2 'star') (term field=plot 'star'))}}\]

Boost values must be greater than zero.

In addition to and, or, and not, the Amazon CloudSearch structured search syntax supports several specialized operators:

- **matchall**—Matches every document in the domain. Syntax: matchall.
- **near**—Supports sloppy phrase queries. The distance value specifies the maximum number of words that can separate the words in the phrase; for example, \((\text{near field='plot' distance=4 'naval mutiny demonstration'})\). Use the near operator to enable matching when the specified terms are in close proximity, but not adjacent. For more information about sloppy phrase searches, see Searching for Phrases (p. 99). Syntax: \((\text{near field=FIELD distance=N boost=N 'STRING'})\).
- **phrase**—Searches for a phrase in text or text-array fields; for example, \((\text{phrase field="title" 'teenage mutant ninja'})\). Supports boosting documents that match the expression. For more information about phrase searches, see Searching for Phrases (p. 99). Syntax: \((\text{phrase field=FIELD boost=N 'STRING'})\).
- **prefix**—Searches a text, text-array, literal, or literal-array field for the specified prefix followed by zero or more characters; for example, \((\text{prefix field='title' 'wait'})\). Supports boosting documents that match the expression. For more information about prefix searches, see Searching for Prefixes (p. 100). Syntax: \((\text{prefix field=FIELD boost=N 'STRING'})\).
- **range**—Searches for a range of values in a numeric field; for example: \((\text{range field=year [2000, 2013]})\). For more information about range searches, see Searching for a Range of Values (p. 102). Syntax: \((\text{range field=FIELD boost=N RANGE})\).
- **term**—Searches for an individual term or value in any field; for example: \((\text{and (term field=title 'star')(term field=year 1977)})\). Syntax: \((\text{term field=FIELD boost=N 'STRING'|VALUE})\).

For more information about searching particular types of data, see the following sections. For more information about the structured search syntax, see Structured Search Syntax (p. 237).

**Searching for Text in Amazon CloudSearch**

You can search both text and literal fields for a text string:
Text and text-array fields are always searchable. You can search for individual terms as well as phrases. Searches within text and text-array fields are not case-sensitive.

Literal and literal-array fields can only be searched if they are search enabled in the domain's indexing options. You can search for an exact match of your search string. Searches in literal fields are case-sensitive.

If you use the simple query parser or do not specify a field when searching with the structured query parser, by default all text and text-array fields are searched. Literal fields are not searched by default. You can specify which fields you want to search with the q.options parameter.

You can search the unique document ID field like any text field. To reference the document ID field in a search request, you use the field name _id. Document IDs are always returned in the search results.

### Topics

- Searching for Individual Terms in Amazon CloudSearch (p. 97)
- Searching for Phrases in Amazon CloudSearch (p. 99)
- Searching for Literal Strings in Amazon CloudSearch (p. 99)
- Searching for Prefixes in Amazon CloudSearch (p. 100)

### Searching for Individual Terms in Amazon CloudSearch

When you search text and text-array fields for individual terms, Amazon CloudSearch finds all documents that contain the search terms anywhere within the specified field, in any order. For example, in the sample movie data, the title field is configured as a text field. If you search the title field for star, you will find all of the movies that contain star anywhere in the title field, such as star, star wars, and a star is born. This differs from searching literal fields, where the field value must be identical to the search string to be considered a match.

The simple query parser provides an easy way to search text and text-array fields for one or more terms. The simple query parser is used by default unless you use the q.parser parameter to specify a different query parser.

For example, to search for katniss, specify katniss in the query string. By default, Amazon CloudSearch includes all return enabled fields in the search results. You can specify the return parameter to specify which fields you want to return.

By default, the response is returned in JSON:

```json
{
    "status": {
        "rid": "rd+5+r0oMAo6swY=",
        "time-ms": 9
    },
    "hits": {
        "found": 3,
        "start": 0,
        "hit": [
            {
                "id": "tt1951265",
                "fields": {
```
Searching for Individual Terms

To specify multiple terms, separate the terms with a space. For example: star wars. When you specify multiple search terms, by default documents must contain all of the terms to be considered a match. The terms can occur anywhere within the text field, in any order.

By default, all text and text-array fields are searched when you use the simple query parser. You can specify which fields you want to search by specifying the q.options parameter. For example, this query constrains the search to the title and description fields and boosts the importance of matches in the title field over matches in the description field.

q=star wars&q.options={fields: ['title^5','description']}

When you use the simple query parser, you can use the following prefixes to designate individual terms as required, optional, or to be excluded from the search results:

- **+**—matching documents must contain the term. This is the default—separating terms with a space is equivalent to preceding them with the + prefix.
- **-**—exclude documents that contain the term from the search results. The - operator only applies to individual terms. For example, to exclude documents that contain the term star in the default search field, specify: -star. Searching for search?q=-star wars retrieves all documents that do not contain the term star, but do contain the term wars.
- **|**—include documents that contain the term in the search results, even if they don't contain the other terms. The | operator only applies to individual terms. For example, to include documents that contain either of two terms, specify: term1 |term2. Searching for search?q=star wars |trek includes documents that contain both star and wars, or the term trek.

These prefixes only apply to individual terms in a simple query. To construct compound queries, you need to use the structured query parser, rather than the simple query parser. For example, to search for the terms star and wars using the structured query parser you would specify:

(and 'star' 'wars')

Note that this query matches documents that contain each of the terms in any of the fields being searched. The terms do not have to be in the same field to be considered a match. If, however, you specify (and 'star wars' 'luke'), star and wars must occur within the same field, and luke can occur in any of the fields.

If you don't specify any fields when you use the structured query parser, all text and text-array fields are searched by default, just like with the simple parser. Similarly, you can use the q.options
parameter to control which fields are searched and to boost the importance of selected fields. For more information, see Constructing Compound Queries (p. 95).

You can also perform fuzzy searches with the simple query parser. To perform a fuzzy search, append the ~ operator and a value that indicates how much terms can differ from the user query string and still be considered a match. For example, the specifying planit~1 searches for the term planit and allows matches to differ by up to one character, which means the results will include hits for planet.

**Searching for Phrases in Amazon CloudSearch**

When you search for a phrase, Amazon CloudSearch finds all documents that contain the complete phrase in the order specified. You can also perform sloppy phrase searches where the terms appear within the specified distance of one another.

To match a complete phrase rather than the individual terms in the phrase when you search with the simple query parser, enclose the phrase in double quotes. For example, the following query searches for the phrase with love.

```
q="with love"
```

To perform a sloppy phrase search with the simple query parser, append the ~ operator and a distance value. The distance value specifies the maximum number of words that can separate the words in the phrase. For example, the following query searches for the terms with love within three words of one another.

```
q="with love"~3
```

In a compound query, you use the phrase operator to specify the phrase you want to match; for example:

```
(phrase field=title 'star wars')
```

To perform a sloppy phrase search in a compound query, you use the near operator. The near operator enables you to specify the phrase you are looking for and how far apart the terms can be within a field and still be considered a match. For example, the following query matches documents that have the terms star and wars no more than three words apart in the title field.

```
(near field=title distance=3 'star wars')
```

For more information, see Constructing Compound Queries (p. 95).

**Searching for Literal Strings in Amazon CloudSearch**

When you search a literal field for a string, Amazon CloudSearch returns only those documents that contain an exact match for the complete search string in the specified field, including case. For example, if the title field is configured as a literal field and you search for Star, the value of the title field must be Star to be considered a match—star, star wars and a star is born will not be included in the search results. This differs from text fields, where searches are not case-sensitive and the specified search terms can appear anywhere within the field in any order.

To search a literal field, prefix the search string with the name of the literal field you want to search, followed by a colon. The search string must be enclosed in single quotes. For example, the following query searches for the literal string Sci-Fi.
genres:'Sci-Fi'

This example searches the genre field of each document and matches all documents whose genre field contains the value Sci-Fi. To be a match, the field value must be an exact match for the search string, including case. For example, documents that contain the value Sci-Fi in the genre field will not be included in the search results if you search for sci-fi or young adult sci-fi.

In a compound query, you use the term operator syntax to search literal fields. For example, (term field=genres 'Sci-Fi'). For more information, see Constructing Compound Queries (p. 95).

You can use literal fields in conjunction with faceting to enable users to drill down into the results according to the faceted attributes. For more information about faceting, see Getting and Using Facet Information in Amazon CloudSearch (p. 112).

Searching for Prefixes in Amazon CloudSearch

You can search text, text-array, literal, and literal-array fields for a prefix rather than for a complete term. This matches results that contain the prefix followed by zero or more characters. You must specify at least one character as the prefix. (To match all documents, use the matchall operator in a structured query.) In general, you should use a prefix that contains at least two characters to avoid matching an excessive number of documents.

When you search a text or text-array field, terms that match the prefix can occur anywhere within the contents of the field. When you search literal fields, the entire search string, up to and including the prefix characters, must match exactly.

• Simple query parser—use the * (asterisk) wildcard operator to search for a prefix, for example pre*.
• Structured query parser—use the prefix operator to search for a prefix, for example prefix 'pre'

For example, the following query searches for the prefix oce in the title field and returns the title of each hit:

q=oce*&q.options={fields:['title']}&return=title

If you perform this search against the sample movie data, it returns as Ocean's Eleven and Ocean's Twelve:
In a compound query, you use the `prefix` operator to search for prefixes. For example, to search the title field for the prefix `oce`, you specify:

```
q.parser=structured&q=(prefix field%3Dtitle 'oce')
```

Note the URL encoding. For more information, see Constructing Compound Queries (p. 95).

**Note**

When performing wildcard searches on text fields, keep in mind that Amazon CloudSearch tokenizes the text fields during indexing and performs stemming according to the analysis scheme configured for the field. Normally, Amazon CloudSearch performs the same text processing on the search query. However, when you search for a prefix with the wildcard operator (*) or `prefix` operator, no stemming is performed on the prefix. This means that a search for a prefix that ends in `s` won’t match the singular version of the term. This can happen for any term that ends in `s`, not just plurals. For example, if you search the actor field in the sample movie data for Anders, there are three matching movies. If you search for Ande*, you get those movies as well as several others. However, if you search for Anders* there are no matches. This is because the term is stored in the index as andez, anders does not appear in the index. For more information about how Amazon CloudSearch processes text and how it can affect searches, see Text Processing in Amazon CloudSearch (p. 72).

### Searching for Numbers in Amazon CloudSearch

You can use structured queries to search any search enabled numeric field for a particular value or range of values (p. 102). Amazon CloudSearch supports four numeric field types: `double`, `double-array`, `int`, and `int-array`. For more information, see configure indexing options (p. 57).

The basic syntax for searching a field for a single value is `FIELD:VALUE`. For example, `year:2010` searches the sample movie data for movies released in 2010.

You must use the structured query parser to use the field syntax. Note that numeric values are not enclosed in quotes—quotes designate a value as a string. To search for a range of values, use a comma (,) to separate the upper and lower bounds, and enclose the range using brackets or braces. For more information, see Searching for a Range of Values (p. 102).

In a compound query, you use the `term` operator syntax to search for a single value: `(term field=year 2010)`.

### Searching for Dates and Times in Amazon CloudSearch

You can use structured queries to search any search enabled date field for a particular date and time or a date-time range (p. 102). Amazon CloudSearch supports two date field types, date and `date-array`. For more information, see configure indexing options (p. 57).

Dates and times are specified in UTC (Coordinated Universal Time) according to IETF RFC3339: `yyyy-mm-ddTHH:mm:ss.SSSZ`. In UTC, for example, 5:00 PM August 23, 1970 is: `1970-08-23T17:00:00Z`. Note that you can also specify fractional seconds when specifying times in UTC. For example, `1967-01-31T23:20:50.650Z`.
Searching for a Range of Values in Amazon CloudSearch

You can use structured queries to search a field for a range of values. To specify a range of values, use a comma (,) to separate the upper and lower bounds and enclose the range using brackets or braces. A square brace, [ or ], indicates that the bound is included in the range, a curly brace, { or }, excludes the bound.

For example, to search the sample data set for movies released from 2008 to 2010 (inclusive), specify the range as [2008, 2010].

To specify an open-ended range, omit the bound. For example, year: [2002,} matches all movies released from 2002 onward, and year: {,1970} matches all movies released through 1970. When you omit a bound, you must use a curly brace.

In a compound query, you use the range operator syntax to search for a range of values; for example: (range field=year [1967,}).

Searching for a Date Range

To search for a range of dates (or times) in a date field, you use the same bracketed range syntax that you use for numeric values, but you must enclose the date string in single quotes. For example, the following request searches the movie data for all movies with a release date of January 1, 2013 or later:

q.parser=structured&q=release_date:['2013-01-01T00:00:00Z',}

Use the following syntax to search for a fixed range:

q.parser=structured&q=release_date:['2013-01-01T00:00:00Z','2013-01-02T23:59:59Z']

Searching for a Location Range

You can perform a bounding box search by searching for a range of locations. To search for a range of locations in a latlon field, you use the same bracketed range syntax that you use for numeric values, but you must enclose the latitude/longitude pair in single quotes.

For example, if you include a location field in each document, you could specify your bounding box filter as location: ['nn.n,nn.n', 'nn.n,nn.n']. In the following example, the matches for restaurant are filtered so that only matches within the downtown area of Paso Robles, CA are included in the results.

q='restaurant'&fq=location: ['35.628611,-120.694152','35.621966,-120.686706']&q.parser=structured
For more information, see location-based searching and sorting (p. 103).

**Searching for a Text Range**

You can also search a text or literal field for a range of values using the bracketed range syntax. Like dates, the text strings must be enclosed in single quotes. For example, the following request searches the movie data for a range of document IDs. To reference a document's ID, you use the special field name `_id`.

```
_id:['tt1000000','tt1005000']
```

**Searching and Ranking Results by Geographic Location in Amazon CloudSearch**

If you store locations in your document data using a `latlon` field, you can use the `haversin` function in an Amazon CloudSearch expression to compute the distance between two locations. Storing locations with your document data also enables you to easily search within particular areas.

**Topics**

- Searching Within an Area in Amazon CloudSearch (p. 103)
- Sorting Results by Distance in Amazon CloudSearch (p. 103)

**Searching Within an Area in Amazon CloudSearch**

To associate a location with a search document, you can store the location's latitude and longitude in a `latlon` field using decimal degree notation. The values are specified as a comma-separated list, `lat,lon`—for example `35.628611,-120.694152`. Associating a location with a document enables you to easily constrain search hits to a particular area with the `fq` parameter.

**To use a bounding box to constrain results to a particular area**

1. Determine the latitude and longitude of the upper-left and lower-right corners of the area you are interested in.
2. Use the `fq` parameter to filter the matching documents using those bounding box coordinates. For example, if you include a `location` field in each document, you could specify your bounding box filter as `fq=location:['nn.n,nn.n','nn.n,nn.n']`. In the following example, the matches for `restaurant` are filtered so that only matches within the downtown area of Paso Robles, CA are included in the results.

```
q='restaurant'&fq=location:
  ['35.628611,-120.694152','35.621966,-120.686706']&q.parser=structured
```

**Sorting Results by Distance in Amazon CloudSearch**

You can define an expression as part of your search request to sort results by distance. Amazon CloudSearch expressions support the `haversin` function, which computes the great-circle distance between two points on a sphere using the latitude and longitude of each point. (For more information, see Haversine formula.) The resulting distance is returned in kilometers.
To calculate the distance between each matching document and the user, you pass the user's location into the \texttt{haversin} function and reference the document locations stored in a \texttt{latlon} field. You specify the user latitude and longitude in decimal degree notation and access the latitude and longitude stored in a \texttt{latlon} as \texttt{FIELD.latitude} and \texttt{FIELD.longitude}. For example, \texttt{expr.distance=haversin(userlat,userlon, location.latitude,location.longitude)}.

To use the expression to sort the search results, you specify the \texttt{sort} parameter.

For example, the following query searches for restaurants and sorts the results by distance from the user.

\texttt{q=restaurant&expr.distance=haversin(35.621966,-120.686706,location.latitude,location.longitude)&sort=distance}\texttt{asc}

Note that you must explicitly specify the sort direction, \texttt{asc} or \texttt{desc}.

You can include the distance calculated for each document in the search results by specifying the name of the expression with the \texttt{return} parameter. For example, \texttt{return=distance}.

You can also use the distance value in more complex expressions to take other characteristics into account, such as a document's relevance _score. In the following example, a second rank expression uses both the document's calculated distance and its relevance _score.

\texttt{expr.distance=haversin(38.958687,-77.343149,latitude,longitude)&expr.myrank=_score/log10(distance)&sort=myrank+desc}

\textbf{Tip}

For these sample queries to work, you must \textcolor{blue}{configure your index (p. 57)} with a \texttt{latlon} field and have \texttt{location} data in your documents:

\begin{verbatim}
{
   "fields": {
      "location": "40.05830,-74.40570"
   }
}
\end{verbatim}

If the field doesn't exist, you might receive the following error message when performing a search:

\begin{verbatim}
Syntax error in query: field (location) does not exist.
\end{verbatim}

For more information about using expressions to sort search results, see \textcolor{blue}{Controlling Search Results (p. 124)}.

\section*{Searching DynamoDB Data with Amazon CloudSearch}

You can specify a DynamoDB table as a source when configuring indexing options or uploading data to a search domain through the console. This enables you to quickly set up a search domain to experiment with searching data stored in DynamoDB database tables.

To keep your search domain in sync with changes to the table, you can send updates to both your table and your search domain, or you can periodically load the entire table into a new search domain.

\textbf{Topics}

- \textcolor{blue}{Configuring an Amazon CloudSearch Domain to Search DynamoDB Data (p. 105)}
Configuring an Amazon CloudSearch Domain to Search DynamoDB Data

The easiest way to configure a search domain to search DynamoDB data is to use the Amazon CloudSearch console. The console's configuration wizard analyzes your table data and suggests indexing options based on the attributes in the table. You can modify the suggested configuration to control which table attributes are indexed.

**Note**
To upload data from DynamoDB, you must have permission to access both the service and the resources you want to upload. For more information, see [Using IAM to Control Access to DynamoDB Resources](#).

When you automatically configure a search domain from a DynamoDB table, a maximum of 200 unique attributes can be mapped to index fields. (You cannot configure more than 200 fields for a search domain, so you can only upload data from DynamoDB tables with 200 or fewer attributes.) When Amazon CloudSearch detects an attribute that has a small number of distinct values, the field is facet enabled in the suggested configuration.

**Important**
When you use a DynamoDB table to configure a domain, the data is not automatically uploaded to the domain for indexing. You must upload the data for indexing as a separate step after you configure the domain.

Configuring a Domain to Search DynamoDB using the Amazon CloudSearch Console

You can use the Amazon CloudSearch console to analyze data from a DynamoDB table to configure a search domain. A maximum of 5 MB is read from the table regardless of the table size. By default, Amazon CloudSearch reads from the beginning of the table. You can specify a start key to begin reading from a particular item.

**To configure a search domain using a DynamoDB table**

2. From the left navigation pane, choose **Domains**.
3. Choose the name of the domain to open its details panel.
4. Go to the **Indexing options** tab and choose **Configuration wizard**.
5. Select **Amazon DynamoDB**.
6. Select the DynamoDB table that you want to analyze.
   - To limit the read capacity units that can be consumed while reading from the table, enter the maximum percentage of read capacity units you want to use.
   - To start reading from a particular item, specify a **Start hash key**. If the table uses a hash and range type primary key, specify both the hash attribute and the range attribute for the item.
7. Choose **Next**.
8. Review the suggested configuration. You can edit these fields and add additional fields.
9. When you finish, choose **Confirm**.
10. If you haven't uploaded data to your domain yet, clear the **Run indexing now** checkbox to exit without indexing. If you're done making configuration changes and are ready to index your data with
the new configuration, make sure Run indexing now is selected. When you're ready to apply the changes, choose Finish.

Uploading Data to Amazon CloudSearch from DynamoDB

You can upload DynamoDB data to a search domain through the Amazon CloudSearch console or with the Amazon CloudSearch command line tools. When you upload data from a DynamoDB table, Amazon CloudSearch converts it to document batches so it can be indexed. You select define index fields for each of the attributes in your domain configuration. For more information, see Configuring an Amazon CloudSearch Domain to Search DynamoDB Data (p. 105).

You can upload data from more than one DynamoDB table to the same Amazon CloudSearch domain. However, keep in mind that you can upload a maximum of 200 attributes from all tables combined. If an item with the same key appears in more than one uploaded table, the last-applied item overwrites all previous versions.

When converting table data to document batches, Amazon CloudSearch generates a document for each item it reads from the table, and represents each item attribute as a document field. The unique ID for each document is either read from the docid item attribute (if it exists) or assigned an alphanumeric value based on the primary key.

When Amazon CloudSearch generates documents for table items:

- Sets of strings and sets of numbers are represented as multi-value fields. If a DynamoDB set contains more than 100 values, only the first 100 values are added to the multi-value field.
- DynamoDB binary attributes are ignored.
- Attribute names are modified to conform to the Amazon CloudSearch naming conventions for field names:
  - All uppercase letters are converted to lowercase.
  - If the DynamoDB attribute name does not begin with a letter, the field name is prefixed with f_.
  - Any characters other than a-z, 0-9, and _ (underscore) are replaced by an underscore. If this transformation results in a duplicate field name, a number is appended to make the field name unique. For example, the attribute names hät, h-t, hât would be mapped to h_t, h_t1, and h_t2 respectively.
  - If the DynamoDB attribute name exceeds 64 characters, the first 56 characters of the attribute name are concatenated with the 8-character MD5 hash of the full attribute name to form the field name.
  - If the attribute name is body, it is mapped to the field name f_body.
  - If the attribute name is _score it is mapped to the field name f_ _score.
- Number attributes are mapped to Amazon CloudSearch int fields and the values are transformed to 32-bit unsigned integers:
  - If a number attribute contains a decimal value, only the integral part of the value is stored. Everything to the right of the decimal point is dropped.
  - If the value is larger than can be stored as an unsigned integer, the value is truncated.
  - Negative integers are treated as unsigned positive integers.

Uploading DynamoDB Data to a Domain through the Amazon CloudSearch Console

You can use the Amazon CloudSearch console to upload up to 5 MB of data from a DynamoDB table to a search domain.
To upload DynamoDB data using the console

1. Open the Amazon CloudSearch console at https://console.aws.amazon.com/cloudsearch/home.
2. From the left navigation pane, choose Domains.
3. Choose the name of the domain to open its configuration.
5. Select Amazon DynamoDB.
6. From the dropdown, select the DynamoDB table that contains your data.
   - To limit the read capacity units that can be consumed while reading from the table, enter the maximum percentage of read capacity units.
   - To start reading from a particular item, specify a Start hash key. If the table uses a hash and range type primary key, specify both the hash attribute and the range attribute for the item.
7. When you finish specifying the table options, choose Next.
8. Review the items that will be uploaded. You can also save the generated document batch by choosing Download the generated document batch. Then choose Upload documents.

Synchronizing a Search Domain with a DynamoDB Table

To keep your search domain in sync with updates to your DynamoDB table, you can either programmatically track and apply updates to your domain, or periodically create a new domain and upload the entire table again. If you have a large amount of data, it's best to track and apply updates programmatically.

Programmatically Synchronizing Updates

To synchronize changes and additions to your DynamoDB table, you can create a separate update table to track the changes to the table you are searching and periodically upload the contents of the update table to the corresponding search domain.

To remove documents from the search domain, you must generate and upload document batches that contain a delete operation for each deleted document. One option is to use a separate DynamoDB table to track deleted items, periodically process the table to generate a batch of delete operations, and upload the batch to your search domain.

To make sure that you don't lose any changes that are made during the initial data upload, you must begin collecting tracking changes before the initial data upload. While you might update some Amazon CloudSearch documents with identical data, you ensure that no changes are lost and your search domain contains an up-to-date version of every document.

How often you synchronize updates depends on the volume of changes and your update latency tolerance. One approach is to accumulate changes over a fixed time period and at the end of the time period upload the changes and delete the period's tracking tables.

For example, to synchronize changes and additions once a day, at the beginning of each day you could create a table called updates_YYYY_MM_DD to collect the daily updates. At the end of the day, you upload the updates_YYYY_MM_DD table to your search domain. After the upload is complete, you can delete the update table and create a new one for the next day.

Switching to a New Search Domain

If you don't want to track and apply individual updates to your table, you can periodically load the entire table into a new search domain and then switch your query traffic over to the new domain.
To switch to a new search domain

1. Create a new search domain and copy the configuration from your existing domain.
2. Upload the entire DynamoDB table to the new domain. For more information, see Uploading Data to Amazon CloudSearch from DynamoDB (p. 106).
3. After the new domain is active, update the DNS entry that directs query traffic to the old search domain to point to the new domain. For example, if you use Amazon Route 53, you can simply update the recordset with your new search service endpoint.
4. Delete the old domain.

Filtering Matching Documents in Amazon CloudSearch

You use the fq parameter to filter the documents that match the search criteria specified with the q parameter without affecting the relevance scores of the documents included in the search results. Specifying a filter just controls which matching documents are included in the results, it has no effect on how they are scored and sorted.

The fq parameter supports the structured query syntax described in Search API (p. 231).

For example, you could add an available field to your documents to indicate whether or not an item is in stock, and filter on that field to limit the results to in-stock items:

```
search?q=star+wars&fq=available:'true'&return=title
```

Tuning Search Request Performance in Amazon CloudSearch

Search requests can become very resource intensive to process, which can have an impact on the performance and cost of running your search domain. In general, searches that return a large volume of hits and complex structured queries are more resource intensive than simple text queries that match a small percentage of the documents in your search domain.

If you experience slow response times, frequently encounter internal server errors (typically 507 or 509 errors), or see the number of instance hours your search domain consumes increase without a substantial increase in the volume of data you're searching, you can fine-tune your search requests to help reduce the processing overhead. This section reviews what to look for and steps you can take to tune your search requests.

Analyzing Query Latency

Before you can tune your requests, you must analyze your current search performance. Log your search requests and response times so that you can see which requests take the longest to process. Slow searches can disproportionately affect overall performance by tying up your search domain's resources. Optimizing the slowest search requests speeds up all of your searches.

Topics
- Reducing the Number of Hits (p. 109)
- Simplifying Structured Queries (p. 109)
Reducing the Number of Hits

Query latency is directly proportional to the number of matching documents. Searches that match the most documents are generally the slowest.

Eliminating two types of searches that commonly result in a huge number of matching documents can significantly improve overall performance:

- Queries that match every document in your corpus (matchall). While this can be a convenient way to list all the documents in your domain, it's a resource intensive query. If you have a lot of documents, not only can it cause other requests to time out, it's likely to time out itself.
- Prefix (wildcard) searches with only one or two characters specified. If you're using this type of search to provide instant results as the user types, wait until the user has entered at least two characters before you start submitting requests and displaying the possible matches.

To reduce the number of documents that match your requests, you can also do the following:

- Eliminate irrelevant words from your corpus so they aren't using for matching. The easiest way to do this is to add them to the stopwords list dictionary for the analysis scheme(s) you're using. Alternatively, you can preprocess your data to strip out irrelevant words. Eliminating irrelevant words also has the benefit of reducing the size of your index, which can help reduce costs.
- Explicitly filter the results based on the value of a particular field using the \texttt{fq} parameter.

If you still have requests that match a lot of documents, you can reduce latency by minimizing the amount of processing to be done on the result set:

- Minimize the facet information that you request. Generating the facet counts adds to the time it takes to process the request and increases the likelihood that other requests will time out. If you do request facet information, keep in mind that the more facets you specify, the longer it takes to process the request.
- Avoid using your own expressions for sorting. The additional processing required to sort the results increases the likelihood that requests will time out. If you must customize how the results are sorted, it is generally faster to use a field than to use an expression.

Keep in mind that returning a large amount of data in the search results can increase the transport time and affect query latency. Minimize the number of return fields you use to improve performance and reduce the size of your index.

Simplifying Structured Queries

The more clauses there are in the query criteria, the longer it takes to process the query.

If you have complex structured queries that don't perform well, you need to find a way to reduce the number of clauses. In some cases, you might simply be able to set a limit or reformulate the query. In others, you might need to modify your domain configuration to accommodate simpler queries.
Querying Your Search Domain for More Information in Amazon CloudSearch

When you submit a search request, Amazon CloudSearch returns a collection of the documents that match your search criteria. You can also retrieve:

- The contents of selected fields
- Facet information that enables you to categorize the results
- Statistics for the values contained in numeric fields
- Highlights that show the search hits in the field data
- Autocomplete suggestions

Topics

- Retrieving Data from Index Fields in Amazon CloudSearch (p. 110)
- Getting Statistics for Numeric Fields in Amazon CloudSearch (p. 111)
- Getting and Using Facet Information in Amazon CloudSearch (p. 112)
- Highlighting Search Hits in Amazon CloudSearch (p. 118)
- Getting Autocomplete Suggestions in Amazon CloudSearch (p. 119)

Retrieving Data from Index Fields in Amazon CloudSearch

By default, the search results include all return enabled fields. To return a subset of the return enabled fields or return expression values for the matching documents, you can specify the return parameter. To return only the document IDs for the matching documents, specify return=_no_fields. To retrieve the relevance score calculated for each document, specify return=_score. You specify multiple return fields as a comma separated list. For example, return=title,_score returns just the title and relevance score of each matching document.

Only fields configured to be return enabled can be included in the search results. Making fields return enabled increases the size of your index, which can increase the cost of running your domain. You should only store document data in the search index by making fields return enabled when it's difficult or costly to retrieve the data using other means. Because it can take some time to apply document updates across the domain, you should retrieve critical data such as pricing information by using the returned document IDs instead of returned from the index.

For example, to include the title and relevance _score in the search results, specify the following:

```
search?q=star -wars&return=title,_score&size=3
```

The specified fields are included with each hit in the search results:

```
{
```

API Version 2013-01-01
110
Getting Statistics for Numeric Fields in Amazon CloudSearch

Amazon CloudSearch can return the following statistics for facet-enabled numeric fields:

- **count**–The number of documents that contain a value in the specified field.
- **max**–The maximum value found in the specified field.
- **mean**–The average of the values found in the specified field.
- **min**–The minimum value found in the specified field.
- **missing**–The number of documents that do not contain a value in the specified field.
- **stddev**–A measure to quantify the amount of deviation, or variation, in the field values. A low standard deviation indicates that the values across all documents are close to the mean. A high standard deviation indicates that the values are spread out over a large range. The standard deviation is calculated by taking the square root of the variance, which is the average of the squared differences from the mean.
- **sum**–The sum of the field values across all documents.
- **sumOfSquares**–The sum of all field values squared.

To get statistics for a field you use the `stats.FIELD` parameter. `FIELD` is the name of a facet-enabled numeric field. You specify an empty JSON object, `stats.FIELD={}`, to get all of the available statistics for the specified field. (The `stats.FIELD` parameter does not support any options; you must pass an empty JSON object.) You can request statistics for multiple fields in the same request.

You can get statistics only for facet-enabled numeric fields: `date`, `date-array`, `double`, `double-array`, `int`, or `int-array`. Note that only the count, max, min, and missing statistics are returned for
date and date-array fields. For more information about enabling a field to return facets, see configure indexing options (p. 57).

For example, to search for star and get statistics for the year field, specify the following:

```
search?q=star&stats.year={}
```

### Getting and Using Facet Information in Amazon CloudSearch

A facet is an index field that represents a category that you want to use to refine and filter search results. When you submit search requests to Amazon CloudSearch, you can request facet information to find out how many documents share the same value in a particular field. You can display this information along with the search results, and use it to enable users to interactively refine their searches. (This is often referred to as faceted navigation or faceted search.)

You can get facet information for any facet-enabled field by specifying the facet.FIELD parameter in your search request. By default, Amazon CloudSearch returns facet counts for the top 10 values. For more information about enabling a field to return facets, see configure indexing options (p. 57). For a description of the facet.FIELD parameter, see Search Request Parameters (p. 231) in the Search API reference.

You can specify facet options to control the sorting of the facet values for each field, limit the number of facet values returned, or choose what facet values to count and return.

### Getting Facet Information in Amazon CloudSearch

To get facet information for a field, you use the facet.FIELD parameter. FIELD is the name of a facet-enabled field. You specify facet options as a JSON object. If the JSON object is empty (facet.FIELD={}), facet counts are computed for all field values, the facets are sorted by facet count, and the top 10 facets are returned in the results. You can request facet information for multiple fields in the same request.

You can retrieve facet information in two ways:

- sort—Returns facet information sorted either by facet counts or facet values.
- buckets—Returns facet information for particular facet values or ranges.

### Sorting Facet Information

You specify the sort option to control how the facet information is sorted. There are two sort options: count and bucket:

- Use count to sort the facets by facet counts. For example, facet.year={sort: 'count'} counts the number of matches that have the same year value and sorts the facet information by that number.
- Use bucket to sort the facets by the facet values. For example, facet.year={sort: 'bucket'}. 

---

API Version 2013-01-01
112
When you use the `sort` option, you can specify the `size` option to control the maximum number of facet values returned in the results. The `size` option is valid only when you use the `sort` option.

In the following example, facet information is calculated for the `genres` field, the genres are sorted by facet value, and the first 5 genres are returned in the results:

```
facet.genres={sort: 'bucket', size: 5}
```

**Bucketing Facet Information**

You can explicitly specify the facet values or ranges that you want to count by using the `buckets` option. Buckets are specified as an array of values or ranges, for example, `facet.color={buckets: ["red", "green", "blue"]}`.

To specify a range of values, use a comma (,) to separate the upper and lower bounds and enclose the range using brackets or braces. A square bracket, [ or ], indicates that the bound is included in the range, a curly brace, { or }, excludes the bound. You can omit the upper or lower bound to specify an open-ended range. When omitting a bound, you must use a curly brace. For example, `facet.year={buckets: ["[1970,1979)", [1980,1989]", [1990,1999]", [2000,2009]", [2010,)"]}`. For a timestamp, you can use `q=-poet&facet.release_date={buckets:
["[1980-01-01T00:00:00Z, 1986-01-01T00:00:01Z)"]}`.

The `sort` and `size` options are not valid if you specify buckets.

Amazon CloudSearch supports two methods for calculating bucket counts, `filter` and `interval`. By default, the `filter` method is used, which simply submits an additional filter query for each bucket to get the bucket counts. While this works well in many cases, if you have a high update rate or are retrieving a large number of facets, performance can suffer because those queries can't take advantage of the internal caching mechanism.

If you're experiencing slow query performance for bucketed facets, try setting the buckets method to `interval`, which post-processes the result set rather than submitting multiple queries:

```
```

We recommend doing your own performance testing to determine which method is best for your application. In general, the `filter` method is faster if you have a fairly low update rate and aren't retrieving a large number of buckets. However, if you have a high update rate or a lot of buckets, using the `interval` method to post-process the result set can result in significantly faster query performance.

**Using Facet Information in Amazon CloudSearch**

You can display facet information to enable users to more easily browse search results and identify the information they are interested in. For example, if a user is trying to find one of the Star Trek movies, but can't remember the full title, they might start by searching for `star`. If you want to display top facets for `genre`, you would include `facet.FIELD` in the query, along with the number of facet values that you want to retrieve for each facet:

```
search?q=star&facet.genres={sort: 'count', size: 5}&format=xml&return=_no_fields
```

The preceding example gives you the following information in the search response:

```
<results>
```

API Version 2013-01-01

113
Multi-Select Facets in Amazon CloudSearch

If you want to display the available facets and enable users to select multiple values to refine the results, you can submit one request to get the documents that match the facet constraints and additional requests to get the facet counts.

For example, in the sample movie data, the genres, rating, and year fields are facet enabled. If the user searches for the term *poet*, you can submit the following request to get the matching movies and the facet counts for the genres, rating, and year fields:

```
q=poet&facet.genres={}&facet.rating={}&facet.year={}&return=_no_fields
```

Because no `facet.FIELD` options are specified, Amazon CloudSearch counts all of the facet values and returns the top 10 values for each facet:

```
{
    "status" : {
        "rid" : "it3T8tIoDgrUSvA=",
        "time-ms" : 5
    },
    "hits" : {
        "found" : 14,
        "start" : 0,
        "hit" : [
            { "id" : "tt0097165" },
            { "id" : "tt0059113" },
            { "id" : "tt0108174" },
            { "id" : "tt1067765" },
            { "id" : "tt1311071" },
            { "id" : "tt0810784" },
            { "id" : "tt0819714" },
            { "id" : "tt0203009" },
            { "id" : "tt0114702" },
            { "id" : "tt0107840" }
        ],
        "facets" : {
            "genres" : {
                "buckets" : [
                    { "value" : "Comedy" },
                    { "value" : "Drama" },
                    { "value" : "Adventure" },
                    { "value" : "Sci-Fi" },
                    { "value" : "Action" }
                ]
            }
        }
    }
}
```
When the user refines the search by selecting facet values, you use those facet selections to filter the results. For example, if the user selects 2013, 2012, and 1993, the following request gets the matching movies released during those years:

```
q=poet&qf=(or year:2013 year:2012 year:1993)&facet.genres={}&facet.rating={}&facet.year={}&return=_no_fields
```

This gets the documents that match the user's selection and the facet counts with the filter applied:

```
{
  "status" : {
    "rid" : "zMP38tIoDwrUSvA=",
    "time-ms" : 6
  },
  "hits" : {
    "found" : 6,
    "start" : 0,
    "hit" : [
      {
        "id" : "tt0108174"},
      {
        "id" : "tt1067765"},
      {
        "id" : "tt1311071"},
      {
        "id" : "tt0107840"},
      {
        "id" : "tt1462411"},
      {
        "id" : "tt0455323"}
    ]
  }
}
```
This is what you want to show for the genres and ratings. However, to enable the user to change the year filter, you need to get the facet counts for the years that aren't selected. To do this, you submit a second request to retrieve the facet counts for the year field without the filter:

```
q=poet&facet.year=&size=0
```

There's no need to retrieve the matching documents, so the `size` parameter is set to zero to minimize the request latency. The request returns just the facet information for the `year` field:

```
{
  "status": {
    "rid": "x/7r0NIoRhqlHfo=",
    "time-ms": 4
  },
  "hits": {
    "found": 14,
    "start": 0,
    "hit": []
  },
  "facets": {
    "year": {
      "buckets": [
        {"value": "2013","count": 3},
        {"value": "1993","count": 2},
        {"value": "1965","count": 1},
        {"value": "1989","count": 1},
        {"value": "1995","count": 1},
        {"value": "2001","count": 1},
        {"value": "2004","count": 1},
        {"value": "2006","count": 1},
        {"value": "2008","count": 1},
        {"value": "2009","count": 1}]
    }
  }
}
```
To minimize the response time, you can send this request in parallel with the request to get the filtered results. However, keep in mind that these additional requests can impact your overall query performance, and it might be necessary to scale your domain up to handle the additional traffic. (For more information about scaling, see Configuring Scaling Options in Amazon CloudSearch (p. 36)).

If the user further refines the search by selecting a genre or rating, you add that to the filter criteria to get the matching documents. For example, the following request gets the movies released in 2013, 2012, or 1993 that have a rating of 6.3:

```
q=poet&qf=(and rating:6.3 (or year:2013 year:2012 year:1993))&facet.genres={}&return=_no_fields
```

Getting the facet information for genres in this request returns the facet counts with the rating and year filters applied:

```
{
  "status" : {
    "rid" : "l66b89IoEArUSvA=",
    "time-ms" : 6
  },
  "hits" : {
    "found" : 2,
    "start" : 0,
    "hit" : [  
      {"id" : "tt1462411"},
      {"id" : "tt0455323"} ]
  },
  "facets" : {
    "genres" : {
      "buckets" : [  
        {"value" : "Drama","count" : 2}]
    }
  }
}
```

To enable the user to select a different rating, you submit an additional request to get the rating facet counts with only the year filter applied:

```
q=poet&qf=(or year:2013 year:2012 year:1993)&facet.rating={}&size=0
```

This request gets the following response:

```
{
  "status" : {
    "rid" : "jqWj89IoEQrUSvA=",
    "time-ms" : 5
  },
  "hits" : {
    "found" : 6,
    "start" : 0,
    "hit" : []
  },
  "facets" : {
    "rating" : {
      "buckets" : [  
        {"value" : "6.3","count" : 2},
        {"value" : "5.3","count" : 1},
        {"value" : "6.2","count" : 1},
        {"value" : "6.4","count" : 1},
        {"value" : "7.1","count" : 1}]
    }
  }
}
```
Similarly, you need another request to get the year facet counts with only the rating filter applied:

```
q=poet&qf=rating:6.3&facet.year={}&size=0
```

This request gets the following response:

```
{
   "status": {
      "rid": "4L6F8NIoDQrUSvA=",
      "time-ms": 4
   },
   "hits": {
      "found": 3,
      "start": 0,
      "hit": []
   },
   "facets": {
      "year": {
         "buckets": [
            {"value": "1995","count": 1},
            {"value": "2012","count": 1},
            {"value": "2013","count": 1}
         ]
      }
   }
}
```

Highlighting Search Hits in Amazon CloudSearch

Amazon CloudSearch can return excerpts with the search results to show where the search terms occur within a particular field of a matching document. For example, in the following excerpt the search terms luke skywalker are highlighted within the plot field:

```
highlights": {
   "plot": "After the rebels have been brutally overpowered by the Empire on their newly established base, *Luke* "Skywalker" takes advanced Jedi training with Master Yoda, while his friends are pursued by Darth Vader as part of his plan to capture *Luke*.
```

If you search for a phrase, the matching documents must contain that phrase. However, when you retrieve highlights, the terms in the phrase are highlighted individually. If you search for the phrase "Luke Skywalker" and retrieve highlights for the plot field as shown in the previous example, the term Luke is highlighted even when it isn’t followed by Skywalker. Highlights are returned for the first 10 KB of data in a field. If the field contains more than 10 KB of data and the search terms appear past the 10 KB limit, they are not highlighted.

You can get highlights for any highlight enabled field by specifying the highlight.FIELD parameter in your search request. For example, to get highlights for the plot field shown, you could specify the following:

```
search?q=star wars&highlight.plot={}
```
For more information about enabling a field to return highlights, see configure indexing options (p. 57).

You can control how many occurrences of the search term(s) within an excerpt are highlighted, how they should be highlighted, and whether the excerpt is returned as plain text or HTML. When Amazon CloudSearch returns excerpts as HTML, non-alphanumeric characters are escaped with HTML entity encoding. This is done to minimize the risks associated with embedding untrusted HTML content, since the field might have originally been populated with user-generated content.

You specify highlight options as a JSON object. If the JSON object is empty, highlight.FIELD={}, Amazon CloudSearch highlights all occurrences of the search term(s) by enclosing them in HTML emphasis tags, <em>term</em>, and the excerpts are returned as HTML.

- To specify whether the excerpt should be returned as text or html, use the format option; for example, highlight.plot={format: 'text'}.
- To specify the maximum number of occurrences of the search term(s) you want to highlight, use the max_phrases option; for example, highlight.plot={max_phrases: 3}. The default is 1, the maximum is 5.
- To specify the string to prepend to each highlighted term, use the pre_tag option; for example, highlight.plot={pre_tag: '<strong>', post_tag: '</strong>'}.
- To specify the string to append to each highlighted term, use the post_tag option; for example, highlight.plot={pre_tag: '<strong>', post_tag: '</strong>'}.

Getting Autocomplete Suggestions in Amazon CloudSearch

This section describes how to configure suggesters so you can retrieve suggestions. Suggestions are possible matches for an incomplete search query—they enable you to display likely matches before users finish typing their queries. In Amazon CloudSearch, suggestions are based on the contents of a particular text field. When you request suggestions, Amazon CloudSearch finds all of the documents whose values in the suggester field start with the specified query string—the beginning of the field must match the query string to be considered a match. The return data includes the field value and document ID for each match. You can configure suggesters to find matches for the exact query string, or to perform approximate string matching (fuzzy matching) to correct for typographical errors and misspellings.

For more information about the suggest API, see Suggest (p. 247) in the Search API (p. 231).

Topics
- Configuring Suggesters for Amazon CloudSearch (p. 119)
- Retrieving Suggestions in Amazon CloudSearch (p. 122)

Configuring Suggesters for Amazon CloudSearch

When you configure a suggester, you must specify the name of the text field you want to search for possible matches and a unique name for the suggester. Fields used for suggestions must be return enabled. Only the first 512 bytes of data in the field are used to generate suggestions.

Suggester names must begin with a letter and be at least three and no more than 64 characters long. The allowed characters are: a-z (lower-case letters), 0-9, and _ (underscore). The suggester name is specified in the query string when you retrieve suggestions, so it's best to use short names. The name score is reserved and cannot be used as a suggester name.

Suggesters also support two options:
• **FuzzyMatching**—You can set the level of fuzziness allowed when suggesting matches for a string to none, low, or high. With none, the specified string is treated as an exact prefix. With low, suggestions must differ from the specified string by no more than one character. With high, suggestions can differ by up to two characters. The default is none.

• **SortExpression**—You can configure this expression to compute a score for each suggestion to control how they are sorted. The scores are rounded to the nearest integer, with a floor of 0 and a ceiling of $2^{31}-1$. A document's relevance score is not computed for suggestions, so sort expressions cannot reference the `_score` value. To sort suggestions using a numeric field or existing expression, simply specify the name of the field or expression. If no expression is configured for the suggester, the suggestions are sorted in alphabetical order. Note that an expression defined within a suggester cannot be referenced in search requests or other expressions. If want to use an expression for other purposes, add it to your domain configuration and reference it by name from the suggester. For more information about expressions, see [Configuring Expressions](p. 125).

If you want to get suggestions from multiple text fields, you define a suggester for each field and submit separate suggestion requests to get matches from each suggester. You can configure up to ten suggesters. Suggesters can consume significant amounts of memory and disk space, particularly if you use text-heavy source fields and set fuzzy matching to high.

**Tip**
Instead of configuring suggesters to use all possibilities from all documents, consider indexing the most popular 1,000 or 10,000 search queries and configuring suggesters to use those. You can store the queries in a separate Amazon CloudSearch index or in a field used only for suggestions.

The easiest way to define suggesters is through the [Suggesters page](p. 120) in the Amazon CloudSearch console. You can also define suggesters using the AWS SDKs or AWS CLI.

**Important**
After you add a suggester to your search domain, you must run indexing before you can use it to retrieve suggestions. As you add and delete documents, you must periodically rebuild your index to update the suggestions. Suggestions won't reflect added or deleted documents until you call `IndexDocuments`.

### Configuring Suggesters through the Amazon CloudSearch Console

You can easily add, update, and delete suggesters through the Amazon CloudSearch console.

**To add a suggester**

2. In the left navigation pane, choose **Domains**.
3. Choose the name of the domain to open its configuration.
4. Go to the **Advanced search options** tab.
5. In the **Suggesters** pane, choose **Add suggesters**.
6. Enter a name for the new suggester.
7. For **Source field**, specify the text field to use for suggestions.
8. To include suggestions that correct for minor misspellings or typos, set **Fuzzy matching** to **Low** or **High**. When set to low, the suggestions include terms that differ from the user query string by a single character. When set to high, the suggestions include terms that differ by up to two characters.
9. To control how the suggestions are sorted, enter a numeric expression in the **Sort expression** field. The expression can simply be the name of the numeric field you want to use to sort the suggestions,
the name of an existing expression, or any valid expression. For more information about expressions, see Configuring Expressions (p. 125).

10. Click Save changes.

11. When you're done configuring suggesters for your search domain, you must re-index your domain before you can use the suggesters. To run indexing, go to the domain dashboard and choose Actions, Run indexing.

Configuring Suggesters with the AWS CLI

You can add or update suggesters with the aws cloudsearch define-suggester command. To remove a suggester, you use aws cloudsearch delete-suggester.

To add or update a suggester

- Run the aws cloudsearch define-suggester command. You specify the configuration of the suggester in JSON with the --suggester option. The suggester configuration must be enclosed in quotes and all quotes within the configuration must be escaped with a backslash. For the format of the suggester configuration, see define-suggester in the AWS CLI Command Reference. For example, the following command configures a suggester called mysuggester to return suggestions based on the title field.

```bash
aws cloudsearch define-suggester --domain-name movies --suggester "{"SuggesterName":"mysuggester", "DocumentSuggesterOptions":{"SourceField":"title"}}"
```

You can use the --fuzzy-matching option to include suggestions that correct for minor misspellings or typos. Valid values for fuzzy matching are none, low, and high. (The default is none.) When set to low, the suggestions will include terms that differ from the user query string by a single character. When set to high, the suggestions will include terms that differ by up to two characters. For example, the following command configures mysuggester to include suggestions that differ from the user query string by just one character:

```bash
aws cloudsearch define-suggester --domain-name movies --suggester "{"SuggesterName":"mysuggester", "DocumentSuggesterOptions":{"SourceField":"title"}}"
```

You can use the --sort-expression option to control how the returned suggestions are sorted. You can use any valid expression for sorting. (Often, this will just be the name of a numeric field or a predefined expression.) For example, to sort the suggestions returned by mysuggester according to the value in the year field, specify:

```bash
aws cloudsearch define-suggester --domain-name movies --suggester "{"SuggesterName":"mysuggester", "DocumentSuggesterOptions":{"SourceField":"title"}}"
```
To delete a suggester

- Run the `aws cloudsearch delete-suggester` command and specify the `--name` option. For example, to delete `mysuggester`:

```
aws cloudsearch delete-suggester --name mysuggester --delete
```

Configuring Suggesters Using the AWS SDKs

The AWS SDKs (except the Android and iOS SDKs) support all of the Amazon CloudSearch actions defined in the Amazon CloudSearch Configuration API, including `DefineSuggester` (p. 151). For more information about installing and using the AWS SDKs, see AWS Software Development Kits.

Retrieving Suggestions in Amazon CloudSearch

You retrieve suggestions by sending requests to the `suggest` resource on a domain's search endpoint via HTTP GET. For example:

```
http://search-movies-rr2f34ofg56xneuemujamut52i.us-east-1.cloudsearch.amazonaws.com/2013-01-01/suggest?q=oce&suggester=mysuggester
```

You must specify the API version in the request and the query string must be URL-encoded. The maximum size of a suggestion request is 8190 bytes, including the HTTP method, URI, and protocol version.

The `suggest` resource supports four parameters:

- `q`—The string that you want to get suggestions for.
- `suggester`—The name of the suggester you want to use.
- `size`—The number of suggestions to retrieve. By default, the top ten suggestions are returned. (The suggestions are sorted according to the sort expression defined in the suggester. If no sort expression is defined in the suggester, the suggestions are sorted in alphabetical order.)
- `format`—The content type of the response, `json` or `xml`. By default, suggestions are returned in JSON.

The `q` and `suggester` parameters must be specified. No suggestions are returned if you request suggestions for an empty string. The `size` and `format` parameters are optional.

The following example gets suggestions for the string `oce` based on the contents of the `title` field.

```
http://search-imdb2-m2brrr7ex7z6sqqhgwjdmcuvd4.us-east-1.cloudsearch.amazonaws.com/2013-01-01/suggest?q=oce&suggester=title

{
  "status": {
    "rid": "666f5s0oDAr8pVk=",
    "time-ms": 2
  },
  "suggest": {
    "query": "oce",
    "found": 3,
    "suggestions": [
```

API Version 2013-01-01
Controlling How Search Results are Returned in Amazon CloudSearch

You can specify parameters in your search request to control how the search results are sorted, return results in XML rather than JSON, and paginate through the result set. You can define expressions that calculate a custom value that can be used to specify search constraints or sort results.

Topics
- Sorting Results in Amazon CloudSearch (p. 124)
- Using Relative Field Weighting to Customize Relevance Ranking in Amazon CloudSearch (p. 125)
- Configuring Expressions in Amazon CloudSearch (p. 125)
- Getting Results as XML in Amazon CloudSearch (p. 130)
- Paginating Results in Amazon CloudSearch (p. 131)

Sorting Results in Amazon CloudSearch

By default, search results are sorted according to their relevance to the search request. A document's relevance score (_score) is based on how often the search terms appear in the document compared to how common the term is across all documents in the domain. Relevance scores are positive values that can vary widely depending on your data and queries. The scores for each clause in your query are additive, so queries with more clauses will naturally have higher scores than queries with just one or two. If you know what your typical queries will look like, you can do some test queries to get an idea of the range of scores you're likely to see.

To change how search results are sorted, you can:

- Use a text or literal field to sort results alphabetically. Note that Amazon CloudSearch sorts by Unicode codepoint, so numbers come before letters and uppercase letters come before lowercase letters. Numbers are sorted as strings, not by value; for example, 10 will come before 2.
- Use an int or double field to sort results numerically.
- Use a date field to sort results by date.
- Use a custom expression to sort results.

To use a field to sort the search results, you must configure the field to be SortEnabled. Only single-value fields can be SortEnabled—you cannot use the array-type fields for sorting. For more information about configuring fields, see configure indexing options (p. 57).

To use an expression for sorting, you construct a numeric expression using int fields, other expressions, a document's relevance score, and numeric operators and functions. You can define expressions in your domain configuration, or within a search request. For more information about configuring expressions, see Configuring Expressions (p. 125).

Tip
To sort results randomly, you can use a simple _rand expression:

/2013-01-01/search?expr.r=_rand&q=test&return=r%2Cplot%2Ctitle&sort=r+desc
This expression is stable, which lets you page back and forth without losing the initial, randomized sort. If you want to use a different randomized sort, you can add a-z and 0-9 characters after the _rand value, such as:

/2013-01-01/search?expr=r=_rand1a2b3c&q=test&return=r%2Cplot%2Ctitle&sort=r+desc

You use the sort parameter to specify the field or expression you want to use to sort the results. You must explicitly specify the sort direction along with the name of the field or expression. For example, sort=year asc or sort=year desc.

When you use a field for sorting, documents without a value in that field are listed last. If you specify a comma separated list of fields or expressions, the first field or expression is used as the primary sort criteria, the second is used as the secondary sort criteria, and so on.

If you do not specify the sort parameter, the search results are ranked using the documents' default relevance scores with the highest-scoring documents listed first. This is equivalent to specifying sort=_score desc.

You can use the q.options parameter to specify field weights to apply when calculating a document's relevance _score. For more information, see Using Relative Field Weighting to Customize Text Relevance (p. 125).

**Using Relative Field Weighting to Customize Relevance Ranking in Amazon CloudSearch**

You can assign weights to selected fields so you can boost the relevance _score of documents with matches in key fields such as a title field, and minimize the impact of matches in less important fields. By default all fields have a weight of 1.

Field weights are set with the q.options fields option. You specify fields as an array of strings. To set the weight for a field, you append a caret (^) and a positive numeric value to the field name. You cannot set a field weight to zero or use mathematical functions or expressions to define a field weight.

For example, if you want matches within the title field to score higher than matches within the plot field, you could set the weight of the title field to 2 and the weight of the plot field to 0.5:

```plaintext
q.options={fields:['title^2','plot^0.5']}
```

In addition to controlling field weights, the fields option defines the set of fields that are searched by default if you use the simple query parser or don't specify a field in part of a compound expression when using the structured query parser. For more information, see Search Request Parameters (p. 231) in the Search API Reference.

To reference the weighted relevance score in the definition of an expression, you use _score. You can use the weighted _score value in conjunction with numeric fields, other expressions, and the standard numeric operators and functions. For more information, see Configuring Expressions (p. 125).

**Configuring Expressions in Amazon CloudSearch**

You can define numeric expressions and use them to sort search results. Expressions can also be returned in search results. You can add expressions to the domain configuration or define expressions within search requests.
Writing Expressions for Amazon CloudSearch

Amazon CloudSearch expressions can contain:

- Single value, sort enabled numeric fields (int, double, date). (You must specify a specific field, wildcards are not supported.)
- Other expressions
- The _score variable, which references a document's relevance score
- The _time variable, which references the current epoch time
- The _rand variable, which returns a randomly generated value
- Integer, floating point, hex, and octal literals
- Arithmetic operators: + - * / %
- Bitwise operators: | & ^ ~ << >> >>>
- Boolean operators (including the ternary operator): && || ! ?:
- Comparison operators: < <= == >= >
- Mathematical functions: abs ceil exp floor ln log10 logn max min pow sqrt
- Trigonometric functions: acos acosh asin asinh atan atan2 atanh cos cosh sin sinh tanh tan
- The haversin distance function

JavaScript order of precedence rules apply for operators. You can override operator precedence by using parentheses.

Shortcut evaluation is used when evaluating logical expressions—if the value of the expression can be determined after evaluating the first argument, the second argument is not evaluated. For example, in the expression a || b, b is only evaluated if a is not true.

Expressions always return an integer value from 0 to the maximum 64-bit signed integer value (2^63 - 1). Intermediate results are calculated as double-precision floating point values and the return value is rounded to the nearest integer. If the expression is invalid or evaluates to a negative value, it returns 0. If the expression evaluates to a value greater than the maximum, it returns the maximum value.

Expression names must begin with a letter and be at least 3 and no more than 64 characters long. The following characters are allowed: a-z (lower-case letters), 0-9, and _ (underscore). The name score is reserved and cannot be used as an expression name.

For example, if you define an int field named popularity for your domain, you could use that field in conjunction with the default relevance _score to construct a custom expression.

\[(0.3*\text{popularity})+(0.7*\text{_score})\]

Note that this simple example assumes that the popularity ranking and the relevance _score values are in about the same range. To tune your expressions for ranking results, you need to do some testing to determine how to weight the components of your expressions to get the results you want.
Using Date Fields in Amazon CloudSearch Expressions

The value from a date field is stored as an epoch time with millisecond resolution. This means you can use the mathematical and comparison operators to construct expressions using dates stored in your documents and the current epoch time (_time). For example, using the following expression to sort search results from the movies domain pushes movies with recent release dates toward the top of the list.

\[
\text{score}/(_\text{time} - \text{release\_date})
\]

Defining Amazon CloudSearch Expressions in Search Requests

You can define and use expressions directly within a search request so that you can iterate quickly while you fine-tune expressions that you use to sort results. By defining an expression within a search request, you can also incorporate contextual information into the expression, such as the user's geographic location. You can override an expression defined in the domain configuration by defining an expression with the same name within a search request.

When you define an expression within a search request, it is not stored as part of your domain configuration. If you want to use the expression in other requests, you must define the expression in each request or add the expression to your domain configuration. Defining an expression in every request rather than adding it to the domain configuration increases the request overhead, which can result in slower response times and potentially increase the cost of running your domain. For information about adding expressions to the domain configuration, see Configuring Expressions (p. 125).

You can define and use multiple expressions in a search request. The definition of an expression can reference other expressions defined within the request, as well as expressions configured as part of the domain configuration.

There are no restrictions on how you can use expressions that you define in a search request. You can use the expression to sort the search results, define other expressions, or return computed information in the search results.

To define an expression in a search request

1. Use the `expr.NAME` parameter, where NAME is the name of the expression you are defining. For example:
   
   ```
   expr.rank1=log10(clicks)*_score
   ```

2. To use the expression to sort the results, specify the name of the expression with the `sort` parameter:
   
   ```
   search?q=terminator&expr.rank1=log10(clicks)*_score&sort=rank1 desc
   ```

3. To include the computed value in the search results, add the expression to the list of return fields:
   
   ```
   search?q=terminator&expr.rank1=log10(clicks)*_score&sort=rank1 desc&return=rank1
   ```

For example, the following request creates two expressions that are used to sort the results and returns one of them in the search results:
Configuring Reusable Expressions for a Search Domain in Amazon CloudSearch

When you define an expression in a domain's configuration, you can reference the expression in any search request. Adding an expression to the domain configuration reduces the overhead of specifying it in every request, and helps maximize response times and minimize costs.

When you add an expression to your domain configuration, it takes some time for the change to be processed and the new expression to become active. To quickly test changes to an expression, you can define and use the expression directly in a search request, as described in query time expressions (p. 127). After you have finished testing and tuning an expression, you should add it to your domain configuration.

Topics
• Configuring Expressions Using the Amazon CloudSearch Console (p. 128)
• Configuring Amazon CloudSearch Expressions Using the AWS CLI (p. 128)
• Configuring Expressions Using the Amazon CloudSearch Configuration API (p. 129)

Configuring Expressions Using the Amazon CloudSearch Console

To configure an expression
1. Open the Amazon CloudSearch console at https://console.aws.amazon.com/cloudsearch/home.
2. From the left navigation pane, choose Domains.
3. Choose the name of the domain to open its configuration.
4. Go to the Advanced search options tab.
5. In the Expressions pane, choose Add expression.
6. Enter a name for the new expression.
7. For Value, enter the numerical expression that you want to evaluate at search time. You can select Insert to add special values and mathematical and trigonometric functions.
8. Choose Save.

Configuring Amazon CloudSearch Expressions Using the AWS CLI

You use the aws cloudsearch define-expression command to define computed expressions for a domain.

To configure an expression
• Run the aws cloudsearch define-expression command to define a new expression. You specify a name for the expression with the --name option, and the numeric expression that you want to evaluate with the --expression option. For example, the following request creates an expression called popularhits that takes into account a document's popularity and relevance _score.
Configuring Expressions Using the Amazon CloudSearch Configuration API

The AWS SDKs (except the Android and iOS SDKs) support all of the Amazon CloudSearch actions defined in the Amazon CloudSearch Configuration API, including `DefineExpression` (p. 147). For more information about installing and using the AWS SDKs, see AWS Software Development Kits.

Comparing Expressions in Amazon CloudSearch

You can use the Amazon CloudSearch console to compare expressions and see how changes to the expression and field weights affect how Amazon CloudSearch sorts search results.

**To compare expressions**

1. Open the Amazon CloudSearch console at https://console.aws.amazon.com/cloudsearch/home.
2. In the left navigation pane, choose Domains.
3. Choose the name of the domain to open its configuration.
4. Choose Actions, Compare expressions.
5. In the Search box, enter the terms you want to search for. Amazon CloudSearch ranks the search results using the specified expressions and weights. It refreshes the results whenever you make changes to the expressions or weights.
6. In each expression editor, specify the rank expressions to compare. You can add new expressions or select an existing expression from the Saved expressions menu. Amazon CloudSearch evaluates new expressions when you submit a search request.
7. Specify the field weights to use for each expression. You can also edit the field weights directly in the expression. Field weights must be in the range 0.0 to 10.0, inclusive. By default, the weight for all fields is set to 1.0. You can set individual field weights to control how much matches in particular text or literal fields affect a document's relevance score. You can also change the default weight.

   **Note**
   Adjusting field weights only affects result ranking if the expression references the _score value. You can modify the expression to change how the weight relevance _score contributes to a document's overall ranking. For more information, see Using Relative Field Weighting to Customize Text Relevance (p. 125).
9. The search results for the two expressions are shown side-by-side. (If the expression is empty, the results are sorted according to the default relevance score.) Four icons highlight the differences:

- **Green up arrow**
  The document is ranked higher in the search results using the second expression.

- **Red down arrow**
  The document is ranked lower in the search results using the second expression.

- **Yellow plus**
  The document is included in the search results using the second expression, but was omitted from the search results using the first expression.

- **Red minus**
  The document was omitted from the search results using the second expression, but was included in the search results using the first expression.

**Note**
You can save expressions to your domain configuration directly from the **Compare expressions** pane. To save either expression, choose **Save expression**.

---

**Getting Results as XML in Amazon CloudSearch**

By default, Amazon CloudSearch search responses are formatted in JSON. To get results as XML, specify the query parameter `format=xml` in your search request:

```
search?q=star+warss&return=_no_fields&format=xml
```

Search responses formatted in XML contain exactly the same information as a JSON response:

```
<results>
  <status rid="3abhhs8oEAgMHnk=" time-ms="2"/>
  <hits found="9" start="0">
    <hit id="tt0076759"/>
    <hit id="tt0086190"/>
    <hit id="tt0121766"/>
    <hit id="tt2488496"/>
    <hit id="tt1408101"/>
    <hit id="tt0489049"/>
    <hit id="tt0120915"/>
    <hit id="tt0080684"/>
    <hit id="tt0121765"/>
  </hits>
</results>
```

For detailed information about the JSON and XML response formats for search requests, see [Search Response](p. 243).
Paginating Results in Amazon CloudSearch

By default, Amazon CloudSearch returns the top ten hits according to the specified sort order. To control the number of hits returned in a result set, you use the `size` parameter.

To get the next set of hits beginning from a particular offset, you can use the `start` parameter. Note that the result set is zero-based—the first result is at index 0. You can get the first 10,000 hits using the `size` and `start` parameters. To page through more than 10,000 hits, use the `cursor` parameter. For more information, see Deep Paging Beyond 10,000 Hits (p. 131).

For example, `search?q=wolverine` returns the first 10 hits that contain `wolverine`, starting at index 0. The following example sets the `start` parameter to 10 to get the next set of ten hits.

```plaintext
search?q=wolverine&start=10
```

If you want to retrieve 25 hits at a time, set the `size` parameter to 25. To get the first set of hits, you don't have to set the `start` parameter.

```plaintext
search?q=wolverine&size=25
```

For subsequent requests, use the `start` parameter to retrieve the set of hits you want. For example, to get the third batch of 25 hits, specify the following:

```plaintext
search?q=wolverine&size=25&start=50
```

Deep Paging Beyond 10,000 Hits in Amazon CloudSearch

Using `size` and `start` to page through results works well if you only need to access the first few pages of results. However, if you need to page through thousands of hits, using a cursor is more efficient. To page through more than 10,000 hits, you must use a cursor. (You can only access the first 10,000 hits using the `size` and `start` parameters.)

To page through results using a cursor, you specify `cursor=initial` in your initial search request and include the `size` parameter to specify how many hits you want to get. Amazon CloudSearch returns a cursor value in the response that you use to get the next set of hits. Cursors return sequential sets of hits; however, you can use them to simulate random access of a deep page if you need to. Keep in mind that cursors are intended to be used to page through a result set within a reasonable amount of time of the initial request. Using a stale cursor can return stale results if updates have been posted to the index in the interim.

**Important**

When you use a cursor to page through a result set that is sorted by document score (`_score`), you can get inconsistent results if the index is updated between requests. This can also occur if your domain's replication count is greater than one, because updates are applied in an eventually consistent manner across the instances in the domain. If this is an issue, avoid sorting the results by score. You can either use the `sort` option to sort by a particular field, or use `fq` instead of `q` to specify your search criteria. (Document scores are not calculated for filter queries.)

For example, the following request sets the `cursor` value to `initial` and the `size` parameter to 100 to get the first set of hits.

```plaintext
search?q=-star&cursor=initial&size=100
```
The cursor for the next set of hits is included in the response.

```json
{
    "status": {
        "rid": "z67+5L0oHgo6swY=",
        "time-ms": 7
    },
    "hits": {
        "found": 1649,
        "start": 0,
        "cursor": "Vb-HSS4YQW9JSVFKeFpvQ2wwZERBek16SXp0ems9Aw",
        "hit": [
            {
                "id": "tt0397892"
            },
            
            {
                "id": "tt0332379"
            }
        ]
    }
}
```

In the next request, the `cursor` parameter specifies the returned cursor value.

```text
search?q=-star&cursor=Vb-HSS4YQW9JSVFKeFpvQ2wwZERBek16SXp0ems9Aw&size=100
```
**Integrating Amazon CloudSearch with API Gateway**

This chapter provides information about integrating Amazon CloudSearch with Amazon API Gateway. API Gateway lets you create and host REST APIs that make calls to other services. Some use cases for using API Gateway with Amazon CloudSearch include the following:

- Further securing the Amazon CloudSearch search endpoint using API keys or Amazon Cognito user pools
- Using CloudWatch to monitor and log search calls to the Amazon CloudSearch domain
- Restricting users to a more limited subset of the Amazon CloudSearch API
- Enforcing a rate limit on the number of requests

To learn more about the benefits of API Gateway, see the [API Gateway Developer Guide](#).

**Topics**

- Prerequisites (p. 133)
- Creating and Configuring an API (Console) (p. 134)
- Testing the API (Console) (p. 135)

**Prerequisites**

Before you integrate Amazon CloudSearch with API Gateway, you must have the following resources.

<table>
<thead>
<tr>
<th>Prerequisite</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon CloudSearch Domain</td>
<td>For testing purposes, the domain should have some searchable data. The IMDb movies data is an excellent option. The domain must have the following access policy:</td>
</tr>
<tr>
<td></td>
<td>`{</td>
</tr>
<tr>
<td></td>
<td>&quot;Version&quot;: &quot;2012-10-17&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;Statement&quot;: [</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;Effect&quot;: &quot;Allow&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;Principal&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;AWS&quot;: &quot;arn:aws:iam::123456789012:role/my-api-gateway-role&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>&quot;Action&quot;: [</td>
</tr>
<tr>
<td></td>
<td>&quot;cloudsearch:search&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;cloudsearch:suggest&quot;</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>This policy configures the Amazon CloudSearch domain so that only API Gateway (and probably the account owner) can access it. To learn more, see the section called “Creating a Search Domain” (p. 25) and Configuring Access for Amazon CloudSearch (p. 27).</td>
</tr>
</tbody>
</table>
Creating and Configuring an API (Console)

The steps involved in creating an API vary depending on whether the request uses parameters, requires a request body, needs specific headers, and many other factors. The following procedure creates an API that has one function: performing searches on an Amazon CloudSearch domain. For more complete information about configuring APIs, see Creating an API in Amazon API Gateway.

To create an API (console)

2. Choose Create API (or choose Get Started if this is your first time using API Gateway).
3. Choose Build under REST API (not private).
4. Provide a name and optional description, then choose Create API.
5. Choose Actions, Create Method. From the dropdown menu, choose GET and confirm.
6. For Integration type, choose AWS Service.
7. For **AWS Region**, choose the Region in which your Amazon CloudSearch domain resides.
8. For **AWS Service**, choose CloudSearch.
9. For **AWS Subdomain**, specify the subdomain for your Amazon CloudSearch domain's search endpoint.

   For example, if your domain's search endpoint is search-my-test-asdf5asdfsadfasdasdfus-west-1.cloudsearch.amazonaws.com, specify search-my-test-asdf5asdfsadfasdasdf.

10. For **HTTP Method**, choose GET.
11. For **Action Type**, choose Use path override and enter /2013-01-01/search.
12. For **Execution role**, specify the ARN for my-api-gateway-role, such as arn:aws:iam::123456789012:role/my-api-gateway-role.
13. For **Content Handling**, choose Passthrough, use the default timeout, and then choose Save.
15. For **Request Validator**, choose Validate query string parameters and headers, and then confirm.
16. Expand **URL Query String Parameters**. Choose Add query string, name the string q, and confirm. Mark the query string as required.
17. Choose **Method Execution** to return to the method summary.
18. Choose Integration Request.
19. Expand **URL Query String Parameters**. Choose Add query string, name the string q, provide a mapping of method.request.querystring.q, and then confirm.

# Testing the API (Console)

At this point, you've created an API that has one method. Before deploying the API, you should test it.

**To test the API (console)**

1. Navigate to the **Method Execution** page.
2. Choose Test.
3. Under **Query Strings**, enter a query string that will match some data in the Amazon CloudSearch domain. If you are using the IMDb movie data, try q=thor.
4. Choose Test.
5. Verify that the response body contains search results, such as the following:

```json
{
    "status": {
        "rid": "rcWTo8Isv1EK+own",
        "time-ms": 1
    },
    "hits": {
        "found": 7,
        "start": 0,
        "hit": [
            {
                "id": "tt0800369",
                "fields": {
                    "rating": "7.0",
                    "genres": [
                        "Action",
                        "Adventure",
                        "Fantasy"
                    ]
            }
        ]
    }
}
```
At this point, you have a functional API. You can add methods to enable more robust search requests, deploy the API and configure rate limiting, create and require the use of API keys, add Amazon Cognito user pool authentication, and much more. For more information, see the API Gateway Developer Guide.
Handling Errors in Amazon CloudSearch

This section provides information about how to handle errors when interacting with Amazon CloudSearch programmatically. For information about specific error codes returned by the Amazon CloudSearch services, see:

- Search Service Errors (p. 249)
- documents/batch Status Codes (p. 229)
- Configuration Service Common Errors (p. 222). For the specific errors that can be returned from a particular action, see the documentation for that action (p. 141).

Topics

- Error Types in Amazon CloudSearch (p. 137)
- Retrying Requests in Amazon CloudSearch (p. 138)

Error Types in Amazon CloudSearch

The HTTP status codes returned by the Amazon CloudSearch APIs indicate whether the request completed successfully, or if a client or server error occurred while processing the request:

- 2xx status codes indicate that the client request was processed successfully.
- 4xx status codes indicate that there was a problem with the client request. Common client request errors include providing invalid credentials and omitting required parameters. When you get a 4xx error, you need to correct the problem and resubmit a properly formed client request.
- 5xx status codes indicate that a server error occurred while processing the client request. Server errors are typically transient and are often the result of server timeouts, throttling, or capacity limitations. We recommend catching and retrying all 5xx errors.

An HTTP status code is returned for every request. In addition, the body of the response provides additional warning and error information.

Messages in a search response indicate the severity level, the warning or error code, and a description of the problem with the search request. For a list of the warnings and errors that can be returned by the search service, see Search Response Properties (JSON) (p. 245) or Search Response Elements (XML) (p. 246).

Errors and warnings in a documents/batch response provide information about parsing and validation issues encountered while processing the document data. For more information, see documents/batch Response (JSON) (p. 225) or documents/batch Response (XML) (p. 228).

Errors returned in a configuration service response provide information about what caused the request to return a 4xx or 5xx status code. For information about the common errors that all actions use, see Common Errors (p. 222). Action-specific errors are listed in the action topics in the Configuration API Reference for Amazon CloudSearch (p. 139).
Retrying Requests in Amazon CloudSearch

For your application to run smoothly, you need to build in logic to catch and respond to errors. One typical approach is to implement your request within a try block or if-then statement.

We recommend catching and retrying all server errors (5xx). Because errors can be generated from anywhere within the request pipeline, you should implement a fallback for unexpected 5xx errors in addition to any special handling for specific status codes.

507 and 509 errors typically indicate that your search service is overloaded. This can be due to the volume or complexity of search requests that you are submitting. Amazon CloudSearch normally scales automatically to handle the load. Because it takes some time to deploy additional search instances, we recommend using an exponential backoff retry policy to temporarily reduce the request rate and minimize request failures. For more information, see Error Retries and Exponential Backoff.

Certain usage patterns, such as submitting complex search queries to a single small search instance, can sometimes result in timeouts without triggering automatic scaling. If you repeatedly experience a high error rate, you can explicitly request additional capacity through the Amazon CloudSearch Service Limit Request form.

Client errors (4xx) typically indicate that you need to revise the request to correct the problem—simply retrying the same request will most likely result in the same error. 409 errors returned by the configuration service can indicate that the request was rejected because a resource limit has been reached. For more information, see Limits (p. 257).
Amazon CloudSearch API Reference

You use three APIs to interact with Amazon CloudSearch:

- **Configuration API (p. 139)**—Set up and manage your search domain.
- **Document Service API (p. 223)**—Submit the data you want to search.
- **Search API (p. 231)**—Search your domain.

Configuration API Reference for Amazon CloudSearch

You use the Amazon CloudSearch Configuration API to create, configure, and manage search domains. For more information configuring search domains, see [Creating and Managing Search Domains (p. 25)](Creating-and-Managing-Search-Domains).

The other APIs you use to interact with Amazon CloudSearch are:

- **Document Service API (p. 223)**—Submit the data you want to search.
- **Search API (p. 231)**—Search your domain.

Topics

- [Submitting Configuration Requests in Amazon CloudSearch (p. 139)](Submitting-Configuration-Requests-in-CloudSearch)
- [Actions (p. 141)](Actions)
- [Data Types (p. 187)](Data-Types)
- [Common Parameters (p. 220)](Common-Parameters)
- [Common Errors (p. 222)](Common-Errors)

Submitting Configuration Requests in Amazon CloudSearch

**Important**

The easiest way to submit configuration requests is to use the Amazon CloudSearch console, Amazon CloudSearch command line tools, or the AWS SDK for Java, JavaScript, .NET, PHP, Ruby, or Python (Boto). The command line tools and SDKs handle the signing process for you and ensure that Amazon CloudSearch configuration requests are properly formed. For more information about the AWS SDKs, see [AWS Software Development Kits](AWS-Software-Development-Kits).

You submit Amazon CloudSearch configuration requests to the Amazon CloudSearch endpoint for your region using the AWS Query protocol. For the current list of supported regions and endpoints, see [Regions and Endpoints](Regions-and-Endpoints).

AWS Query requests are HTTP or HTTPS requests submitted via HTTP GET or POST with a Query parameter named Action. You must specify the API version in all configuration requests and that version must match the API version specified when the domain was created.

You must include authorization parameters and a digital signature in every request. Amazon CloudSearch supports AWS Signature Version 4. For detailed signing instructions, see [Signature V4 Signing Process](Signature-V4-Signing-Process) in the AWS General Reference.
Note
Amazon CloudSearch throttles excessive requests to the configuration service. Throttling occurs by action, so excessive DescribeDomains requests don’t cause Amazon CloudSearch to throttle DescribeIndexFields requests. The request limit changes based on the needs of the service, but allows many calls to each action per hour.

Structure of a Configuration Request

This reference shows Amazon CloudSearch configuration requests as URLs, which can be used directly in a browser. (Although the GET requests are shown as URLs, the parameter values are shown unencoded to make them easier to read. Keep in mind that you must URL encode parameter values when submitting requests.) The URL contains three parts:

- **Endpoint**—the Web service entry point to act on, cloudsearch.us-east-1.amazonaws.com.
- **Action**—the Amazon CloudSearch configuration action you want to perform. For a complete list of actions, see Actions (p. 141).
- **Parameters**—any request parameters required for the specified action. Each query request must also include some common parameters to handle authentication. For more information, see Request Authentication (p. 140).

You must specify the Version parameter in every Amazon CloudSearch configuration request. The current Amazon CloudSearch API version is 2013-01-01.

For example, the following GET request creates a new search domain called movies:

```
https://cloudsearch.us-east-1.amazonaws.com
?Action=CreateDomain
&DomainName=movies
&Version=2013-01-01
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIAIOSFODNN7EXAMPLE/20120712/us-east-1/cloudsearch/aws4_request
&X-Amz-Date=2012-07-12T21:41:29.094Z
&X-Amz-SignedHeaders=host
&X-Amz-Signature=c7600a00fea082dac002b247f9d6812f25195fbaf7f0a6fc4ce08a39666c6a103c8dcb
```

Request Authentication

Requests submitted to the Configuration API are authenticated using your AWS access keys. You must include authorization parameters and a digital signature in every request. Amazon CloudSearch supports AWS Signature Version 4. For detailed signing instructions, see Signature V4 Signing Process in the AWS General Reference.

Note
If you are just getting started signing your own AWS requests, take a look at how the SDKs implement signing. The source for most of the AWS SDKs is available at https://github.com/aws.

For example, to construct a CreateDomain request, you need the following information:

```
Region name: us-east-1
Service name: cloudsearch
API version: 2013-01-01
Date: 2014-03-12T21:41:29.094Z
Access key: AKIAIOSFODNN7EXAMPLE
Secret key: w3JalrXUtfnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
```

API Version 2013-01-01

140
### Actions

The following actions are supported:

- **BuildSuggesters** (p. 143)
- **CreateDomain** (p. 144)
- **DefineAnalysisScheme** (p. 145)
- **DefineExpression** (p. 147)
- **DefineIndexField** (p. 149)
- **DefineSuggester** (p. 151)
- **DeleteAnalysisScheme** (p. 153)
- **DeleteDomain** (p. 155)
- **DeleteExpression** (p. 156)
- **DeleteIndexField** (p. 158)
- **DeleteSuggester** (p. 160)
- **DescribeAnalysisSchemes** (p. 162)
- **DescribeAvailabilityOptions** (p. 164)
- **DescribeDomains** (p. 166)
- **DescribeExpressions** (p. 167)
- **DescribeIndexFields** (p. 169)
- **DescribeScalingParameters** (p. 171)
- **DescribeServiceAccessPolicies** (p. 174)
- **DescribeSuggesters** (p. 176)
- **IndexDocuments** (p. 178)
- **ListDomainNames** (p. 179)
• UpdateAvailabilityOptions (p. 180)
• UpdateScalingParameters (p. 182)
• UpdateServiceAccessPolicies (p. 186)
BuildSuggesters

Description
Indexes the search suggestions. For more information, see Configuring Suggesters in the Amazon CloudSearch Developer Guide.

Request Parameters
For information about the common parameters that all actions use, see Common Parameters (p. 220).

DomainName
A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

Type: String

Required: Yes

Response Elements
The following element is returned in a structure named BuildSuggestersResult.

FieldNames
A list of field names.

Type: String list

Length constraints: Minimum length of 1. Maximum length of 64.

Errors
For information about the errors that are common to all actions, see Common Errors (p. 222).

Base
An error occurred while processing the request.

HTTP Status Code: 400

Internal
An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500

ResourceNotFound
The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
CreateDomain

Description

Creates a new search domain. For more information, see Creating a Search Domain in the Amazon CloudSearch Developer Guide.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

DomainName

A name for the domain you are creating. Allowed characters are a-z (lower-case letters), 0-9, and hyphen (-). Domain names must start with a letter or number and be at least 3 and no more than 28 characters long.

Type: String

Required: Yes

Response Elements

The following element is returned in a structure named CreateDomainResult.

DomainStatus

The current status of the search domain.

Type: DomainStatus (p. 201)

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.

HTTP Status Code: 400

Internal

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500

LimitExceeded

The request was rejected because a resource limit has already been met.

HTTP Status Code: 409
DefineAnalysisScheme

Description

Configures an analysis scheme that can be applied to a text or text-array field to define language-specific text processing options. For more information, see Configuring Analysis Schemes in the Amazon CloudSearch Developer Guide.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

AnalysisScheme

Configuration information for an analysis scheme. Each analysis scheme has a unique name and specifies the language of the text to be processed. The following options can be configured for an analysis scheme: Synonyms, Stopwords, StemmingDictionary, JapaneseTokenizationDictionary and AlgorithmicStemming.

Type: AnalysisScheme (p. 190)

Required: Yes

DomainName

A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

Type: String

Required: Yes

Response Elements

The following element is returned in a structure named DefineAnalysisSchemeResult.

AnalysisScheme

The status and configuration of an AnalysisScheme.

Type: AnalysisSchemeStatus (p. 191)

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.

HTTP Status Code: 400

Internal

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.
HTTP Status Code: 500

InvalidType
The request was rejected because it specified an invalid type definition.

HTTP Status Code: 409

LimitExceeded
The request was rejected because a resource limit has already been met.

HTTP Status Code: 409

ResourceNotFound
The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
DefineExpression

Description

Configures an Expression for the search domain. Used to create new expressions and modify existing ones. If the expression exists, the new configuration replaces the old one. For more information, see Configuring Expressions in the Amazon CloudSearch Developer Guide.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

DomainName

A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

Type: String
Required: Yes

Expression

A named expression that can be evaluated at search time. Can be used to sort the search results, define other expressions, or return computed information in the search results.

Type: Expression (p. 204)
Required: Yes

Response Elements

The following element is returned in a structure named DefineExpressionResult.

Expression

The value of an Expression and its current status.

Type: ExpressionStatus (p. 205)

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.

HTTP Status Code: 400

Internal

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500
InvalidType

The request was rejected because it specified an invalid type definition.

HTTP Status Code: 409

LimitExceeded

The request was rejected because a resource limit has already been met.

HTTP Status Code: 409

ResourceNotFound

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
DefineIndexField

Description

Configures an IndexField for the search domain. Used to create new fields and modify existing ones. You must specify the name of the domain you are configuring and an index field configuration. The index field configuration specifies a unique name, the index field type, and the options you want to configure for the field. The options you can specify depend on the IndexFieldType. If the field exists, the new configuration replaces the old one. For more information, see Configuring Index Fields in the Amazon CloudSearch Developer Guide.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

DomainName

A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and _ (hyphen).

Type: String

Required: Yes

IndexField

The index field and field options you want to configure.

Type: IndexField (p. 205)

Required: Yes

Response Elements

The following element is returned in a structure named DefineIndexFieldResult.

IndexField

The value of an IndexField and its current status.

Type: IndexFieldStatus (p. 208)

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.

HTTP Status Code: 400

Internal

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.
HTTP Status Code: 500

**InvalidType**

The request was rejected because it specified an invalid type definition.

HTTP Status Code: 409

**LimitExceeded**

The request was rejected because a resource limit has already been met.

HTTP Status Code: 409

**ResourceNotFoundException**

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
DefineSuggester

Description
Configures a suggester for a domain. A suggester enables you to display possible matches before users finish typing their queries. When you configure a suggester, you must specify the name of the text field you want to search for possible matches and a unique name for the suggester. For more information, see Getting Search Suggestions in the Amazon CloudSearch Developer Guide.

Request Parameters
For information about the common parameters that all actions use, see Common Parameters (p. 220).

DomainName
A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

Type: String
Required: Yes

Suggester
Configuration information for a search suggester. Each suggester has a unique name and specifies the text field you want to use for suggestions. The following options can be configured for a suggester: FuzzyMatching, SortExpression.

Type: Suggester (p. 216)
Required: Yes

Response Elements
The following element is returned in a structure named DefineSuggesterResult.

Suggester
The value of a Suggester and its current status.
Type: SuggesterStatus (p. 216)

Errors
For information about the errors that are common to all actions, see Common Errors (p. 222).

Base
An error occurred while processing the request.
HTTP Status Code: 400

Internal
An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.
HTTP Status Code: 500

**InvalidType**

The request was rejected because it specified an invalid type definition.

HTTP Status Code: 409

**LimitExceeded**

The request was rejected because a resource limit has already been met.

HTTP Status Code: 409

**ResourceNotFound**

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
DeleteAnalysisScheme

Description
Deletes an analysis scheme. For more information, see Configuring Analysis Schemes in the Amazon CloudSearch Developer Guide.

Request Parameters
For information about the common parameters that all actions use, see Common Parameters (p. 220).

AnalysisSchemeName
The name of the analysis scheme you want to delete.
Type: String
Length constraints: Minimum length of 1. Maximum length of 64.
Required: Yes

DomainName
A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).
Type: String
Required: Yes

Response Elements
The following element is returned in a structure named DeleteAnalysisSchemeResult.

AnalysisScheme
The status of the analysis scheme being deleted.
Type: AnalysisSchemeStatus (p. 191)

Errors
For information about the errors that are common to all actions, see Common Errors (p. 222).

Base
An error occurred while processing the request.
HTTP Status Code: 400

Internal
An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.
HTTP Status Code: 500
InvalidType

The request was rejected because it specified an invalid type definition.

HTTP Status Code: 409

ResourceNotFound

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
DeleteDomain

Description
Permanently deletes a search domain and all of its data. Once a domain has been deleted, it cannot be recovered. For more information, see Deleting a Search Domain in the Amazon CloudSearch Developer Guide.

Request Parameters
For information about the common parameters that all actions use, see Common Parameters (p. 220).

DomainName
The name of the domain you want to permanently delete.
Type: String
Required: Yes

Response Elements
The following element is returned in a structure named DeleteDomainResult.

DomainStatus
The current status of the search domain.
Type: DomainStatus (p. 201)

Errors
For information about the errors that are common to all actions, see Common Errors (p. 222).

Base
An error occurred while processing the request.
HTTP Status Code: 400

Internal
An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.
HTTP Status Code: 500
DeleteExpression

Description

Removes an Expression from the search domain. For more information, see Configuring Expressions in the Amazon CloudSearch Developer Guide.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

DomainName

A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

Type: String

Required: Yes

ExpressionName

The name of the Expression to delete.

Type: String

Length constraints: Minimum length of 1. Maximum length of 64.

Required: Yes

Response Elements

The following element is returned in a structure named DeleteExpressionResult.

Expression

The status of the expression being deleted.

Type: ExpressionStatus (p. 205)

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.

HTTP Status Code: 400

Internal

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500
InvalidType

The request was rejected because it specified an invalid type definition.

HTTP Status Code: 409

ResourceNotFound

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
DeleteIndexField

Description

Removes an IndexField from the search domain. For more information, see Configuring Index Fields in the Amazon CloudSearch Developer Guide.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

DomainName

A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

Type: String

Required: Yes

IndexFieldName

The name of the index field you want to remove from the domain's indexing options.

Type: String

Length constraints: Minimum length of 1. Maximum length of 64.

Required: Yes

Response Elements

The following element is returned in a structure named DeleteIndexFieldResult.

IndexField

The status of the index field being deleted.

Type: IndexFieldStatus (p. 208)

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.

HTTP Status Code: 400

Internal

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500
InvalidType

The request was rejected because it specified an invalid type definition.

HTTP Status Code: 409

ResourceNotFoundException

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
DeleteSuggester

Description
Deletes a suggester. For more information, see Getting Search Suggestions in the Amazon CloudSearch Developer Guide.

Request Parameters
For information about the common parameters that all actions use, see Common Parameters (p. 220).

DomainName
A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

Type: String
Required: Yes

SuggesterName
Specifies the name of the suggester you want to delete.

Type: String
Length constraints: Minimum length of 1. Maximum length of 64.
Required: Yes

Response Elements
The following element is returned in a structure named DeleteSuggesterResult.

Suggester
The status of the suggester being deleted.

Type: SuggesterStatus (p. 216)

Errors
For information about the errors that are common to all actions, see Common Errors (p. 222).

Base
An error occurred while processing the request.

HTTP Status Code: 400

Internal
An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500
InvalidType

The request was rejected because it specified an invalid type definition.

HTTP Status Code: 409

ResourceNotFound

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
DescribeAnalysisSchemes

Description

Gets the analysis schemes configured for a domain. An analysis scheme defines language-specific text processing options for a text field. Can be limited to specific analysis schemes by name. By default, shows all analysis schemes and includes any pending changes to the configuration. Set the Deployed option to true to show the active configuration and exclude pending changes. For more information, see Configuring Analysis Schemes in the Amazon CloudSearch Developer Guide.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

**AnalysisSchemeNames.member.N**

The analysis schemes you want to describe.

Type: String list

Length constraints: Minimum length of 1. Maximum length of 64.

Required: No

**Deployed**

Whether to display the deployed configuration (true) or include any pending changes (false). Defaults to false.

Type: Boolean

Required: No

**DomainName**

The name of the domain you want to describe.

Type: String

Required: Yes

Response Elements

The following element is returned in a structure named DescribeAnalysisSchemesResult.

**AnalysisSchemes**

The analysis scheme descriptions.

Type: AnalysisSchemeStatus (p. 191) list

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

**Base**

An error occurred while processing the request.
HTTP Status Code: 400

**Internal**

An internal error occurred while processing the request. If this problem persists, report an issue from the [Service Health Dashboard](#).

HTTP Status Code: 500

**ResourceNotFoundException**

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
### DescribeAvailabilityOptions

#### Description

Gets the availability options configured for a domain. By default, shows the configuration with any pending changes. Set the Deployed option to `true` to show the active configuration and exclude pending changes. For more information, see Configuring Availability Options in the Amazon CloudSearch Developer Guide.

#### Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

- **Deployed**
  - Whether to display the deployed configuration (`true`) or include any pending changes (`false`). Defaults to `false`.
  - Type: Boolean
  - Required: No

- **DomainName**
  - The name of the domain you want to describe.
  - Type: String
  - Required: Yes

#### Response Elements

The following element is returned in a structure named DescribeAvailabilityOptionsResult.

- **AvailabilityOptions**
  - The availability options configured for the domain. Indicates whether Multi-AZ is enabled for the domain.
  - Type: AvailabilityOptionsStatus (p. 191)

#### Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

- **Base**
  - An error occurred while processing the request.
  - HTTP Status Code: 400

- **DisabledOperation**
  - The request was rejected because it attempted an operation which is not enabled.
  - HTTP Status Code: 409
Internal

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500

InvalidType

The request was rejected because it specified an invalid type definition.

HTTP Status Code: 409

LimitExceeded

The request was rejected because a resource limit has already been met.

HTTP Status Code: 409

ResourceNotFound

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
DescribeDomains

Description

Gets information about the search domains owned by this account. Can be limited to specific domains. Shows all domains by default. To get the number of searchable documents in a domain, use the console or submit a matchall request to your domain's search endpoint: q=matchall&q.parser=structured&size=0. For more information, see Getting Information about a Search Domain in the Amazon CloudSearch Developer Guide.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

DomainNames.member.N

The names of the domains you want to include in the response.

Type: String list

Required: No

Response Elements

The following element is returned in a structure named DescribeDomainsResult.

DomainStatusList

A list that contains the status of each requested domain.

Type: DomainStatus (p. 201) list

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.

HTTP Status Code: 400

Internal

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500
DescribeExpressions

Description

Gets the expressions configured for the search domain. Can be limited to specific expressions by name. By default, shows all expressions and includes any pending changes to the configuration. Set the Deployed option to true to show the active configuration and exclude pending changes. For more information, see Configuring Expressions in the Amazon CloudSearch Developer Guide.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

Deployed

Whether to display the deployed configuration (true) or include any pending changes (false). Defaults to false.

Type: Boolean

Required: No

DomainName

The name of the domain you want to describe.

Type: String

Required: Yes

ExpressionNames.member.N

Limits the DescribeExpressions response to the specified expressions. If not specified, all expressions are shown.

Type: String list

Length constraints: Minimum length of 1. Maximum length of 64.

Required: No

Response Elements

The following element is returned in a structure named DescribeExpressionsResult.

Expressions

The expressions configured for the domain.

Type: ExpressionStatus (p. 205) list

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.
HTTP Status Code: 400

**Internal**

An internal error occurred while processing the request. If this problem persists, report an issue from the [Service Health Dashboard](#).

HTTP Status Code: 500

**ResourceNotFoundException**

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
DescribeIndexFields

Description

Gets information about the index fields configured for the search domain. Can be limited to specific fields by name. By default, shows all fields and includes any pending changes to the configuration. Set the Deployed option to true to show the active configuration and exclude pending changes. For more information, see Getting Domain Information in the Amazon CloudSearch Developer Guide.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

Deployed

Whether to display the deployed configuration (true) or include any pending changes (false). Defaults to false.

Type: Boolean

Required: No

DomainName

The name of the domain you want to describe.

Type: String

Required: Yes

FieldNames.member.N

A list of the index fields you want to describe. If not specified, information is returned for all configured index fields.

Type: String list

Length constraints: Minimum length of 1. Maximum length of 64.

Required: No

Response Elements

The following element is returned in a structure named DescribeIndexFieldsResult.

IndexFields

The index fields configured for the domain.

Type: IndexFieldStatus (p. 208) list

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.
HTTP Status Code: 400

Internal

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500

ResourceNotFound

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
DescribeScalingParameters

Description
Gets the scaling parameters configured for a domain. A domain's scaling parameters specify the desired search instance type and replication count. For more information, see Configuring Scaling Options in the Amazon CloudSearch Developer Guide.

Request Parameters
For information about the common parameters that all actions use, see Common Parameters (p. 220).

DomainName
A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

Type: String
Required: Yes

Response Elements
The following element is returned in a structure named DescribeScalingParametersResult.

ScalingParameters
The status and configuration of a search domain's scaling parameters.

Type: ScalingParametersStatus (p. 215)

Errors
For information about the errors that are common to all actions, see Common Errors (p. 222).

Base
An error occurred while processing the request.

HTTP Status Code: 400

Internal
An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500

ResourceNotFound
The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
DescribeDomainEndpointOptions

Description

Returns the domain's endpoint options, specifically whether all requests to the domain must arrive over HTTPS. For more information, see Configuring Domain Endpoint Options in the Amazon CloudSearch Developer Guide.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

DomainName

A string that represents the name of a domain.

Type: String
Required: Yes

deployed

Whether to retrieve the latest configuration (which might be in a Processing state) or the current, active configuration (?deployed=true).

Type: Boolean
Required: No

Response Elements

DomainEndpointOptions

The status and configuration of a search domain's endpoint options.

Type: DomainEndpointOptionsStatus (p. 200)

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.

HTTP Status Code: 400

Internal

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500

LimitExceeded

The request was rejected because a resource limit has already been met.

HTTP Status Code: 409
ResourceNotFound

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
DescribeServiceAccessPolicies

Description

Gets information about the access policies that control access to the domain's document and search endpoints. By default, shows the configuration with any pending changes. Set the Deployed option to true to show the active configuration and exclude pending changes. For more information, see Configuring Access for a Search Domain in the Amazon CloudSearch Developer Guide.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

Deployed

Whether to display the deployed configuration (true) or include any pending changes (false). Defaults to false.

Type: Boolean

Required: No

DomainName

The name of the domain you want to describe.

Type: String

Required: Yes

Response Elements

The following element is returned in a structure named DescribeServiceAccessPoliciesResult.

AccessPolicies

The access rules configured for the domain specified in the request.

Type: AccessPoliciesStatus (p. 188)

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.

HTTP Status Code: 400

Internal

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500
ResourceNotFound

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
DescribeSuggesters

Description

Gets the suggesters configured for a domain. A suggester enables you to display possible matches before users finish typing their queries. Can be limited to specific suggesters by name. By default, shows all suggesters and includes any pending changes to the configuration. Set the Deployed option to true to show the active configuration and exclude pending changes. For more information, see Getting Search Suggestions in the Amazon CloudSearch Developer Guide.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

Deployed

Whether to display the deployed configuration (true) or include any pending changes (false). Defaults to false.

Type: Boolean

Required: No

DomainName

The name of the domain you want to describe.

Type: String

Required: Yes

SuggesterNames.member.N

The suggesters you want to describe.

Type: String list

Length constraints: Minimum length of 1. Maximum length of 64.

Required: No

Response Elements

The following element is returned in a structure named DescribeSuggestersResult.

Suggesters

The suggesters configured for the domain specified in the request.

Type: SuggesterStatus (p. 216) list

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.
HTTP Status Code: 400

**Internal**

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500

**ResourceNotFound**

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
IndexDocuments

Description

Tells the search domain to start indexing its documents using the latest indexing options. This operation must be invoked to activate options whose OptionStatus (p. 214) is RequiresIndexDocuments.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

DomainName

A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

Type: String

Required: Yes

Response Elements

The following element is returned in a structure named IndexDocumentsResult.

FieldNames

The names of the fields that are currently being indexed.

Type: String list

Length constraints: Minimum length of 1. Maximum length of 64.

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.

HTTP Status Code: 400

Internal

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500

ResourceNotFoundException

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
ListDomainNames

Description
Lists all search domains owned by an account.

Response Elements
The following element is returned in a structure named ListDomainNamesResult.

DomainNames
The names of the search domains owned by an account.
Type: String to String map

Errors
For information about the errors that are common to all actions, see Common Errors (p. 222).

Base
An error occurred while processing the request.
HTTP Status Code: 400
UpdateAvailabilityOptions

Description

Configures the availability options for a domain. Enabling the Multi-AZ option expands an Amazon
CloudSearch domain to an additional Availability Zone in the same Region to increase fault tolerance in
the event of a service disruption. Changes to the Multi-AZ option can take about half an hour to become
active. For more information, see Configuring Availability Options in the Amazon CloudSearch Developer
Guide.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

DomainName

A string that represents the name of a domain. Domain names are unique across the domains owned
by an account within an AWS region. Domain names start with a letter or number and can contain
the following characters: a-z (lowercase), 0-9, and - (hyphen).

Type: String

Required: Yes

MultiAZ

You expand an existing search domain to a second Availability Zone by setting the Multi-AZ option
to true. Similarly, you can turn off the Multi-AZ option to downgrade the domain to a single
Availability Zone by setting the Multi-AZ option to false.

Type: Boolean

Required: Yes

Response Elements

The following element is returned in a structure named UpdateAvailabilityOptionsResult.

AvailabilityOptions

The newly-configured availability options. Indicates whether Multi-AZ is enabled for the domain.

Type: AvailabilityOptionsStatus (p. 191)

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.

HTTP Status Code: 400

DisabledOperation

The request was rejected because it attempted an operation which is not enabled.
HTTP Status Code: 409
**Internal**
An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500
**InvalidType**
The request was rejected because it specified an invalid type definition.

HTTP Status Code: 409
**LimitExceeded**
The request was rejected because a resource limit has already been met.

HTTP Status Code: 409
**ResourceNotFound**
The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
**UpdateScalingParameters**

**Description**

Configures scaling parameters for a domain. A domain's scaling parameters specify the desired search instance type and replication count. Amazon CloudSearch will still automatically scale your domain based on the volume of data and traffic, but not below the desired instance type and replication count. If the Multi-AZ option is enabled, these values control the resources used per Availability Zone. For more information, see Configuring Scaling Options in the Amazon CloudSearch Developer Guide.

**Request Parameters**

For information about the common parameters that all actions use, see Common Parameters (p. 220).

**DomainName**

A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

Type: String
Required: Yes

**ScalingParameters**

The desired instance type and desired number of replicas of each index partition.

Type: ScalingParameters (p. 215)
Required: Yes

**Response Elements**

The following element is returned in a structure named UpdateScalingParametersResult.

**ScalingParameters**

The status and configuration of a search domain's scaling parameters.

Type: ScalingParametersStatus (p. 215)

**Errors**

For information about the errors that are common to all actions, see Common Errors (p. 222).

**Base**

An error occurred while processing the request.

HTTP Status Code: 400

**Internal**

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500

API Version 2013-01-01
Page 182
InvalidType

The request was rejected because it specified an invalid type definition.

HTTP Status Code: 409

LimitExceeded

The request was rejected because a resource limit has already been met.

HTTP Status Code: 409

ResourceNotFound

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409
UpdateDomainEndpointOptions

Description

Updates the domain's endpoint options, specifically whether all requests to the domain must arrive over HTTPS. For more information, see Configuring Domain Endpoint Options in the Amazon CloudSearch Developer Guide.

Request Parameters

DomainName

A string that represents the name of a domain.

Type: String

Required: Yes

DomainEndpointOptions

Container for the endpoint options.

Type: DomainEndpointOptions (p. 200)

Required: Yes

Response Elements

DomainEndpointOptionsStatus

The status and configuration of a domain's endpoint options.

Type: DomainEndpointOptionsStatus (p. 200)

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.

HTTP Status Code: 400

Internal

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500

InvalidType

The request was rejected because it specified an invalid type definition.

HTTP Status Code: 409

LimitExceeded

The request was rejected because a resource limit has already been met.
HTTP Status Code: 409

**ResourceNotFoundException**

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409

**ValidationException**

The request contains invalid input or is missing required input.

HTTP status code 400.

**DisabledOperation**

The request was rejected because it attempted an operation which is not enabled.

HTTP Status Code: 409
UpdateServiceAccessPolicies

Description

Configures the access rules that control access to the domain's document and search endpoints. For more information, see Configuring Access for an Amazon CloudSearch Domain.

Request Parameters

For information about the common parameters that all actions use, see Common Parameters (p. 220).

AccessPolicies

The access rules you want to configure. These rules replace any existing rules.

Type: String

Required: Yes

DomainName

A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).

Type: String

Required: Yes

Response Elements

The following element is returned in a structure named UpdateServiceAccessPoliciesResult.

AccessPolicies

The access rules configured for the domain.

Type: AccessPoliciesStatus (p. 188)

Errors

For information about the errors that are common to all actions, see Common Errors (p. 222).

Base

An error occurred while processing the request.

HTTP Status Code: 400

Internal

An internal error occurred while processing the request. If this problem persists, report an issue from the Service Health Dashboard.

HTTP Status Code: 500
InvalidType

The request was rejected because it specified an invalid type definition.

HTTP Status Code: 409

LimitExceeded

The request was rejected because a resource limit has already been met.

HTTP Status Code: 409

ResourceNotFound

The request was rejected because it attempted to reference a resource that does not exist.

HTTP Status Code: 409

Data Types

The Amazon CloudSearch Configuration Service API contains several data types that various actions use. This section describes each data type in detail.

Note

The order of each element in the response is not guaranteed. Applications should not assume a particular order.

The following data types are supported:

- AccessPoliciesStatus (p. 188)
- AnalysisOptions (p. 189)
- AnalysisScheme (p. 190)
- AnalysisSchemeStatus (p. 191)
- AvailabilityOptionsStatus (p. 191)
- BuildSuggestersResult (p. 191)
- CreateDomainResult (p. 192)
- DateArrayOptions (p. 192)
- DateOptions (p. 193)
- DefineAnalysisSchemeResult (p. 194)

AccessPoliciesStatus

Description

The configured access rules for the domain's document and search endpoints, and the current status of those rules.

Contents

Options

Access rules for a domain's document or search service endpoints. For more information, see Configuring Access for a Search Domain in the Amazon CloudSearch Developer Guide. The maximum size of a policy document is 100 KB.
Type: String
Required: Yes

**Status**

The status of domain configuration option.

Type: `OptionStatus (p. 214)`

Required: Yes

**AnalysisOptions**

**Description**

Synonyms, stopwords, and stemming options for an analysis scheme. Includes tokenization dictionary for Japanese.

**Contents**

**AlgorithmicStemming**

The level of algorithmic stemming to perform: none, minimal, light, or full. The available levels vary depending on the language. For more information, see Language Specific Text Processing Settings in the Amazon CloudSearch Developer Guide.

Type: String

Valid Values: none | minimal | light | full

Required: No

**JapaneseTokenizationDictionary**

A JSON array that contains a collection of terms, tokens, readings and part of speech for Japanese Tokenization. The Japanese tokenization dictionary enables you to override the default tokenization for selected terms. This is only valid for Japanese language fields.

Type: String

Required: No

**StemmingDictionary**

A JSON object that contains a collection of string:value pairs that each map a term to its stem. For example, {"term1": "stem1", "term2": "stem2", "term3": "stem3"}. The stemming dictionary is applied in addition to any algorithmic stemming. This enables you to override the results of the algorithmic stemming to correct specific cases of overstemming or understemming. The maximum size of a stemming dictionary is 500 KB.

Type: String

Required: No

**Stopwords**

A JSON array of terms to ignore during indexing and searching. For example, ["a", "an", "the", "of"]. The stopwords dictionary must explicitly list each word you want to ignore. Wildcards and regular expressions are not supported.
**Synonyms**

A JSON object that defines synonym groups and aliases. A synonym group is an array of arrays, where each sub-array is a group of terms where each term in the group is considered a synonym of every other term in the group. The aliases value is an object that contains a collection of string:value pairs where the string specifies a term and the array of values specifies each of the aliases for that term. An alias is considered a synonym of the specified term, but the term is not considered a synonym of the alias. For more information about specifying synonyms, see Synonyms in the Amazon CloudSearch Developer Guide.

**AnalysisScheme**

**Description**

Configuration information for an analysis scheme. Each analysis scheme has a unique name and specifies the language of the text to be processed. The following options can be configured for an analysis scheme: Synonyms, Stopwords, StemmingDictionary, JapaneseTokenizationDictionary and AlgorithmicStemming.

**Contents**

**AnalysisOptions**

Synonyms, stopwords, and stemming options for an analysis scheme. Includes tokenization dictionary for Japanese.

Type: AnalysisOptions (p. 189)

Required: No

**AnalysisSchemeLanguage**

An IETF RFC 4646 language code or mul for multiple languages.

Type: String

Valid Values: ar | bg | ca | cs | da | de | el | en | es | eu | fa | fi | fr | ga | gl | he | hi | hu | hy | id | it | ja | ko | lv | mul | nl | no | pt | ro | ru | sv | th | tr | zh-Hans | zh-Hant

Required: Yes

**AnalysisSchemeName**

Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).

Type: String

Length constraints: Minimum length of 1. Maximum length of 64.

Required: Yes
**AnalysisSchemeStatus**

**Description**

The status and configuration of an AnalysisScheme.

**Contents**

**Options**

Configuration information for an analysis scheme. Each analysis scheme has a unique name and specifies the language of the text to be processed. The following options can be configured for an analysis scheme: Synonyms, Stopwords, StemmingDictionary, JapaneseTokenizationDictionary and AlgorithmicStemming.

Type: [AnalysisScheme](p. 190)

Required: Yes

**Status**

The status of domain configuration option.

Type: [OptionStatus](p. 214)

Required: Yes

**AvailabilityOptionsStatus**

**Description**

The status and configuration of the domain's availability options.

**Contents**

**Options**

The availability options configured for the domain.

Type: Boolean

Required: Yes

**Status**

The status of domain configuration option.

Type: [OptionStatus](p. 214)

Required: Yes

**BuildSuggestersResult**

**Description**

The result of a BuildSuggesters request. Contains a list of the fields used for suggestions.
Contents

FieldNames

A list of field names.

Type: String list

Length constraints: Minimum length of 1. Maximum length of 64.

Required: No

CreateDomainResult

Description

The result of a CreateDomainRequest. Contains the status of a newly created domain.

Contents

DomainStatus

The current status of the search domain.

Type: DomainStatus (p. 201)

Required: No

DateArrayOptions

Description

Options for a field that contains an array of dates. Present if IndexFieldType specifies the field is of type date-array. All options are enabled by default.

Contents

DefaultValue

A value to use for the field if the field isn't specified for a document.

Type: String

Length constraints: Minimum length of 0. Maximum length of 1024.

Required: No

FacetEnabled

Whether facet information can be returned for the field.

Type: Boolean

Required: No

ReturnEnabled

Whether the contents of the field can be returned in the search results.

Type: Boolean
Data Types

Required: No

**SearchEnabled**

Whether the contents of the field are searchable.

Type: Boolean

Required: No

**SourceFields**

A list of source fields to map to the field.

Type: String

Required: No

**DateOptions**

**Description**

Options for a date field. Dates and times are specified in UTC (Coordinated Universal Time) according to IETF RFC3339: yyyy-mm-ddT00:00:00Z. Present if IndexFieldType specifies the field is of type date. All options are enabled by default.

**Contents**

**DefaultValue**

A value to use for the field if the field isn't specified for a document.

Type: String

Length constraints: Minimum length of 0. Maximum length of 1024.

Required: No

**FacetEnabled**

Whether facet information can be returned for the field.

Type: Boolean

Required: No

**ReturnEnabled**

Whether the contents of the field can be returned in the search results.

Type: Boolean

Required: No

**SearchEnabled**

Whether the contents of the field are searchable.

Type: Boolean

Required: No

**SortEnabled**

Whether the field can be used to sort the search results.
Type: Boolean

Required: No

**SourceField**

A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field's name defines a pattern that begins or ends with a wildcard. Any document fields that don't map to a regular index field but do match a dynamic field's pattern are configured with the dynamic field's indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name score is reserved and cannot be used as a field name. To reference a document's ID, you can use the name _id.

Type: String

Length constraints: Minimum length of 1. Maximum length of 64.

Required: No

**DefineAnalysisSchemeResult**

**Description**

The result of a DefineAnalysisScheme request. Contains the status of the newly-configured analysis scheme.

**Contents**

**AnalysisScheme**

The status and configuration of an AnalysisScheme.

Type: [AnalysisSchemeStatus](#)

Required: Yes

**DefineExpressionResult**

**Description**

The result of a DefineExpression request. Contains the status of the newly-configured expression.

**Contents**

**Expression**

The value of an Expression and its current status.

Type: [ExpressionStatus](#)

Required: Yes
**DefineIndexFieldResult**

**Description**
The result of a DefineIndexField request. Contains the status of the newly-configured index field.

**Contents**

*IndexField*

The value of an IndexField and its current status.

Type: [IndexFieldStatus](p. 208)

Required: Yes

**DefineSuggesterResult**

**Description**
The result of a DefineSuggester request. Contains the status of the newly-configured suggester.

**Contents**

*Suggester*

The value of a Suggester and its current status.

Type: [SuggesterStatus](p. 216)

Required: Yes

**DeleteAnalysisSchemeResult**

**Description**
The result of a DeleteAnalysisScheme request. Contains the status of the deleted analysis scheme.

**Contents**

*AnalysisScheme*

The status of the analysis scheme being deleted.

Type: [AnalysisSchemeStatus](p. 191)

Required: Yes

**DeleteDomainResult**

**Description**
The result of a DeleteDomain request. Contains the status of a newly deleted domain, or no status if the domain has already been completely deleted.
Contents

DomainStatus

The current status of the search domain.

Type: DomainStatus (p. 201)

Required: No

DeleteExpressionResult

Description

The result of a DeleteExpression request. Specifies the expression being deleted.

Contents

Expression

The status of the expression being deleted.

Type: ExpressionStatus (p. 205)

Required: Yes

DeleteIndexFieldResult

Description

The result of a DeleteIndexField request.

Contents

IndexField

The status of the index field being deleted.

Type: IndexFieldStatus (p. 208)

Required: Yes

DeleteSuggesterResult

Description

The result of a DeleteSuggester request. Contains the status of the deleted suggester.

Contents

Suggester

The status of the suggester being deleted.
Type:  SuggesterStatus (p. 216)
Required: Yes

**DescribeAnalysisSchemesResult**

**Description**

The result of a DescribeAnalysisSchemes request. Contains the analysis schemes configured for the domain specified in the request.

**Contents**

**AnalysisSchemes**

The analysis scheme descriptions.
Type:  AnalysisSchemeStatus (p. 191) list
Required: Yes

**DescribeAvailabilityOptionsResult**

**Description**

The result of a DescribeAvailabilityOptions request. Indicates whether or not the Multi-AZ option is enabled for the domain specified in the request.

**Contents**

**AvailabilityOptions**

The availability options configured for the domain. Indicates whether Multi-AZ is enabled for the domain.
Type:  AvailabilityOptionsStatus (p. 191)
Required: No

**DescribeDomainsResult**

**Description**

The result of a DescribeDomains request. Contains the status of the domains specified in the request or all domains owned by the account.

**Contents**

**DomainStatusList**

A list that contains the status of each requested domain.
Type:  DomainStatus (p. 201) list
Required: Yes
DescribeExpressionsResult

Description
The result of a DescribeExpressions request. Contains the expressions configured for the domain specified in the request.

Contents
Expressions
The expressions configured for the domain.
Type: ExpressionStatus (p. 205) list
Required: Yes

DescribeIndexFieldsResult

Description
The result of a DescribeIndexFields request. Contains the index fields configured for the domain specified in the request.

Contents
IndexFields
The index fields configured for the domain.
Type: IndexFieldStatus (p. 208) list
Required: Yes

DescribeScalingParametersResult

Description
The result of a DescribeScalingParameters request. Contains the scaling parameters configured for the domain specified in the request.

Contents
ScalingParameters
The status and configuration of a search domain's scaling parameters.
Type: ScalingParametersStatus (p. 215)
Required: Yes

DescribeServiceAccessPoliciesResult

Description
The result of a DescribeServiceAccessPolicies request.
Contents

AccessPolicies

The access rules configured for the domain specified in the request.

Type: AccessPoliciesStatus (p. 188)

Required: Yes

DescribeSuggestersResult

Description

The result of a DescribeSuggesters request.

Contents

Suggesters

The suggesters configured for the domain specified in the request.

Type: SuggesterStatus (p. 216) list

Required: Yes

DocumentSuggesterOptions

Description

Options for a search suggester.

Contents

FuzzyMatching

The level of fuzziness allowed when suggesting matches for a string: none, low, or high. With none, the specified string is treated as an exact prefix. With low, suggestions must differ from the specified string by no more than one character. With high, suggestions can differ by up to two characters. The default is none.

Type: String

Valid Values: none | low | high

Required: No

SortExpression

An expression that computes a score for each suggestion to control how they are sorted. The scores are rounded to the nearest integer, with a floor of 0 and a ceiling of 2^31-1. A document's relevance score is not computed for suggestions, so sort expressions cannot reference the _score value. To sort suggestions using a numeric field or existing expression, simply specify the name of the field or expression. If no expression is configured for the suggester, the suggestions are sorted with the closest matches listed first.

Type: String
Data Types

Required: No

SourceField

The name of the index field you want to use for suggestions.

Type: String

Length constraints: Minimum length of 1. Maximum length of 64.

Required: Yes

DomainEndpointOptions

Description

Whether to require that all requests to the domain arrive over HTTPS. We recommend Policy-Min-TLS-1-2-2019-07 for TLSSecurityPolicy. For compatibility with older clients, the default is Policy-Min-TLS-1-0-2019-07.

Contents

EnforceHTTPS

Enables or disables the requirement that all requests to the domain arrive over HTTPS.

Type: Boolean

Valid Values: true | false

Required: No

TLSSecurityPolicy

The minimum required TLS version.

Type: String

Required: No

DomainEndpointOptionsStatus

Description

The configuration and status of the domain's endpoint options.

Contents

Options

The current configuration.

Type: DomainEndpointOptions (p. 200)

Status

The status of the configuration option.
DomainStatus

Description

The current status of the search domain.

Contents

ARN

The Amazon Resource Name (ARN) of the search domain. See Identifiers for IAM Entities in Using AWS Identity and Access Management for more information.

Type: String

Required: No

Created

True if the search domain is created. It can take several minutes to initialize a domain when CreateDomain (p. 144) is called. Newly created search domains are returned from DescribeDomains (p. 166) with a false value for Created until domain creation is complete.

Type: Boolean

Required: No

Deleted

True if the search domain has been deleted. The system must clean up resources dedicated to the search domain when DeleteDomain (p. 155) is called. Newly deleted search domains are returned from DescribeDomains (p. 166) with a true value for IsDeleted for several minutes until resource cleanup is complete.

Type: Boolean

Required: No

DocService

The service endpoint for updating documents in a search domain.

Type: ServiceEndpoint (p. 216)

Required: No

DomainId

An internally generated unique identifier for a domain.

Type: String

Length constraints: Minimum length of 1. Maximum length of 64.

Required: Yes

DomainName

A string that represents the name of a domain. Domain names are unique across the domains owned by an account within an AWS region. Domain names start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).
Type: String
Required: Yes

Limits
Type: Limits (p. 211)
Required: No

Processing
True if processing is being done to activate the current domain configuration.
Type: Boolean
Required: No

RequiresIndexDocuments
True if IndexDocuments (p. 178) needs to be called to activate the current domain configuration.
Type: Boolean
Required: Yes

SearchInstanceCount
The number of search instances that are available to process search requests.
Type: Integer
Required: No

SearchInstanceType
The instance type that is being used to process search requests.
Type: String
Required: No

SearchPartitionCount
The number of partitions across which the search index is spread.
Type: Integer
Required: No

SearchService
The service endpoint for requesting search results from a search domain.
Type: ServiceEndpoint (p. 216)
Required: No

DoubleArrayOptions

Description
Options for a field that contains an array of double-precision 64-bit floating point values. Present if IndexFieldType specifies the field is of type double-array. All options are enabled by default.
Contents

DefaultValue
A value to use for the field if the field isn't specified for a document.
Type: Double
Required: No

FacetEnabled
Whether facet information can be returned for the field.
Type: Boolean
Required: No

ReturnEnabled
Whether the contents of the field can be returned in the search results.
Type: Boolean
Required: No

SearchEnabled
Whether the contents of the field are searchable.
Type: Boolean
Required: No

SourceFields
A list of source fields to map to the field.
Type: String
Required: No

DoubleOptions
Description
Options for a double-precision 64-bit floating point field. Present if IndexField\_Type specifies the field is of type double. All options are enabled by default.

Contents

DefaultValue
A value to use for the field if the field isn't specified for a document. This can be important if you are using the field in an expression and that field is not present in every document.
Type: Double
Required: No

FacetEnabled
Whether facet information can be returned for the field.
Type: Boolean
Required: No
**ReturnEnabled**
Whether the contents of the field can be returned in the search results.
Type: Boolean
Required: No
**SearchEnabled**
Whether the contents of the field are searchable.
Type: Boolean
Required: No
**SortEnabled**
Whether the field can be used to sort the search results.
Type: Boolean
Required: No
**SourceField**
The name of the source field to map to the field.
Type: String
Length constraints: Minimum length of 1. Maximum length of 64.
Required: No

**Expression**

**Description**
A named expression that can be evaluated at search time. Can be used to sort the search results, define other expressions, or return computed information in the search results.

**Contents**

**ExpressionName**
Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).
Type: String
Length constraints: Minimum length of 1. Maximum length of 64.
Required: Yes

**ExpressionValue**
The expression to evaluate for sorting while processing a search request. The Expression syntax is based on JavaScript expressions. For more information, see Configuring Expressions in the Amazon CloudSearch Developer Guide.
Type: String
Length constraints: Minimum length of 1. Maximum length of 10240.
Required: Yes

**ExpressionStatus**

**Description**
The value of an Expression and its current status.

**Contents**

**Options**
The expression that is evaluated for sorting while processing a search request.

Type: [Expression](p. 204)
Required: Yes

**Status**
The status of domain configuration option.

Type: [OptionStatus](p. 214)
Required: Yes

**IndexDocumentsResult**

**Description**
The result of an IndexDocuments request. Contains the status of the indexing operation, including the fields being indexed.

**Contents**

**FieldNames**
The names of the fields that are currently being indexed.

Type: String list
Length constraints: Minimum length of 1. Maximum length of 64.
Required: No

**IndexField**

**Description**
Configuration information for a field in the index, including its name, type, and options. The supported options depend on the [IndexFieldType](p. 205).
Contents

DateArrayOptions

Options for a field that contains an array of dates. Present if IndexFieldType specifies the field is of type date-array. All options are enabled by default.

Type: DateArrayOptions (p. 192)

Required: No

DateOptions

Options for a date field. Dates and times are specified in UTC (Coordinated Universal Time) according to IETF RFC3339: yyyy-mm-ddT00:00:00Z. Present if IndexFieldType specifies the field is of type date. All options are enabled by default.

Type: DateOptions (p. 193)

Required: No

DoubleArrayOptions

Options for a field that contains an array of double-precision 64-bit floating point values. Present if IndexFieldType specifies the field is of type double-array. All options are enabled by default.

Type: DoubleArrayOptions (p. 202)

Required: No

DoubleOptions

Options for a double-precision 64-bit floating point field. Present if IndexFieldType specifies the field is of type double. All options are enabled by default.

Type: DoubleOptions (p. 203)

Required: No

IndexFieldName

A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field's name defines a pattern that begins or ends with a wildcard. Any document fields that don't map to a regular index field but do match a dynamic field's pattern are configured with the dynamic field's indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name score is reserved and cannot be used as a field name. To reference a document's ID, you can use the name _id.

Type: String

Length constraints: Minimum length of 1. Maximum length of 64.

Required: Yes

IndexFieldType

The type of field. The valid options for a field depend on the field type. For more information about the supported field types, see Configuring Index Fields in the Amazon CloudSearch Developer Guide.
Type: String

Valid Values: int | double | literal | text | date | latlon | int-array | double-array | literal-array | text-array | date-array

Required: Yes

IntArrayOptions

Options for a field that contains an array of 64-bit signed integers. Present if IndexFieldType specifies the field is of type int-array. All options are enabled by default.

Type: IntArrayOptions (p. 208)

Required: No

IntOptions

Options for a 64-bit signed integer field. Present if IndexFieldType specifies the field is of type int. All options are enabled by default.

Type: IntOptions (p. 209)

Required: No

LatLonOptions

Options for a latlon field. A latlon field contains a location stored as a latitude and longitude value pair. Present if IndexFieldType specifies the field is of type latlon. All options are enabled by default.

Type: LatLonOptions (p. 210)

Required: No

LiteralArrayOptions

Options for a field that contains an array of literal strings. Present if IndexFieldType specifies the field is of type literal-array. All options are enabled by default.

Type: LiteralArrayOptions (p. 212)

Required: No

LiteralOptions

Options for literal field. Present if IndexFieldType specifies the field is of type literal. All options are enabled by default.

Type: LiteralOptions (p. 212)

Required: No

TextArrayOptions

Options for a field that contains an array of text strings. Present if IndexFieldType specifies the field is of type text-array. A text-array field is always searchable. All options are enabled by default.

Type: TextArrayOptions (p. 217)

Required: No

TextOptions

Options for text field. Present if IndexFieldType specifies the field is of type text. A text field is always searchable. All options are enabled by default.
Data Types

Type: TextOptions (p. 218)
Required: No

IndexFieldStatus

Description
The value of an IndexField and its current status.

Contents

Options
Configuration information for a field in the index, including its name, type, and options. The supported options depend on the IndexFieldType.

Type: IndexField (p. 205)
Required: Yes

Status
The status of domain configuration option.

Type: OptionStatus (p. 214)
Required: Yes

IntArrayOptions

Description
Options for a field that contains an array of 64-bit signed integers. Present if IndexFieldType specifies the field is of type int-array. All options are enabled by default.

Contents

DefaultValue
A value to use for the field if the field isn't specified for a document.

Type: Long
Required: No

FacetEnabled
Whether facet information can be returned for the field.

Type: Boolean
Required: No

ReturnEnabled
Whether the contents of the field can be returned in the search results.
Type: Boolean
Required: No

**SearchEnabled**

Whether the contents of the field are searchable.

Type: Boolean
Required: No

**SourceFields**

A list of source fields to map to the field.

Type: String
Required: No

**IntOptions**

**Description**

Options for a 64-bit signed integer field. Present if IndexFieldType specifies the field is of type int. All options are enabled by default.

**Contents**

**DefaultValue**

A value to use for the field if the field isn't specified for a document. This can be important if you are using the field in an expression and that field is not present in every document.

Type: Long
Required: No

**FacetEnabled**

Whether facet information can be returned for the field.

Type: Boolean
Required: No

**ReturnEnabled**

Whether the contents of the field can be returned in the search results.

Type: Boolean
Required: No

**SearchEnabled**

Whether the contents of the field are searchable.

Type: Boolean
Required: No
**SortEnabled**

Whether the field can be used to sort the search results.

Type: Boolean

Required: No

**SourceField**

The name of the source field to map to the field.

Type: String

Length constraints: Minimum length of 1. Maximum length of 64.

Required: No

**LatLonOptions**

**Description**

Options for a latlon field. A latlon field contains a location stored as a latitude and longitude value pair. Present if IndexFieldType specifies the field is of type latlon. All options are enabled by default.

**Contents**

**DefaultValue**

A value to use for the field if the field isn't specified for a document.

Type: String

Length constraints: Minimum length of 0. Maximum length of 1024.

Required: No

**FacetEnabled**

Whether facet information can be returned for the field.

Type: Boolean

Required: No

**ReturnEnabled**

Whether the contents of the field can be returned in the search results.

Type: Boolean

Required: No

**SearchEnabled**

Whether the contents of the field are searchable.

Type: Boolean

Required: No

**SortEnabled**

Whether the field can be used to sort the search results.
Type: Boolean

Required: No

**SourceField**

A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field's name defines a pattern that begins or ends with a wildcard. Any document fields that don't map to a regular index field but do match a dynamic field's pattern are configured with the dynamic field's indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name `score` is reserved and cannot be used as a field name. To reference a document's ID, you can use the name `_id`.

Type: String

Length constraints: Minimum length of 1. Maximum length of 64.

Required: No

**Limits**

**Description**

No action documentation available.

**Contents**

**MaximumPartitionCount**

Type: Integer

Required: Yes

**MaximumReplicationCount**

Type: Integer

Required: Yes

**ListDomainNamesResult**

**Description**

The result of a ListDomainNames request. Contains a list of the domains owned by an account.

**Contents**

**DomainNames**

The names of the search domains owned by an account.

Type: String to String
Required: No

**LiteralArrayOptions**

**Description**

Options for a field that contains an array of literal strings. Present if IndexFieldType specifies the field is of type literal-array. All options are enabled by default.

**Contents**

**DefaultValue**

A value to use for the field if the field isn't specified for a document.

Type: String

Length constraints: Minimum length of 0. Maximum length of 1024.

Required: No

**FacetEnabled**

Whether facet information can be returned for the field.

Type: Boolean

Required: No

**ReturnEnabled**

Whether the contents of the field can be returned in the search results.

Type: Boolean

Required: No

**SearchEnabled**

Whether the contents of the field are searchable.

Type: Boolean

Required: No

**SourceFields**

A list of source fields to map to the field.

Type: String

Required: No

---

**LiteralOptions**

**Description**

Options for literal field. Present if IndexFieldType specifies the field is of type literal. All options are enabled by default.
Contents

DefaultValue

A value to use for the field if the field isn't specified for a document.

Type: String

Length constraints: Minimum length of 0. Maximum length of 1024.

Required: No

FacetEnabled

Whether facet information can be returned for the field.

Type: Boolean

Required: No

ReturnEnabled

Whether the contents of the field can be returned in the search results.

Type: Boolean

Required: No

SearchEnabled

Whether the contents of the field are searchable.

Type: Boolean

Required: No

SortEnabled

Whether the field can be used to sort the search results.

Type: Boolean

Required: No

SourceField

A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field's name defines a pattern that begins or ends with a wildcard. Any document fields that don't map to a regular index field but do match a dynamic field's pattern are configured with the dynamic field's indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name score is reserved and cannot be used as a field name. To reference a document's ID, you can use the name _id.

Type: String

Length constraints: Minimum length of 1. Maximum length of 64.
Required: No

OptionStatus

Description
The status of domain configuration option.

Contents

CreationDate
A timestamp for when this option was created.
Type: DateTime
Required: Yes

PendingDeletion
Indicates that the option will be deleted once processing is complete.
Type: Boolean
Required: No

State
The state of processing a change to an option. Possible values:
- RequiresIndexDocuments: the option's latest value will not be deployed until IndexDocuments (p. 178) has been called and indexing is complete.
- Processing: the option's latest value is in the process of being activated.
- Active: the option's latest value is completely deployed.
- FailedToValidate: the option value is not compatible with the domain's data and cannot be used to index the data. You must either modify the option value or update or remove the incompatible documents.
Type: String
Valid Values: RequiresIndexDocuments | Processing | Active | FailedToValidate
Required: Yes

UpdateDate
A timestamp for when this option was last updated.
Type: DateTime
Required: Yes

UpdateVersion
A unique integer that indicates when this option was last updated.
Type: Integer
Required: No
ScalingParameters

Description
The desired instance type and desired number of replicas of each index partition.

Contents

DesiredInstanceType

The instance type that you want to preconfigure for your domain. For example, search.medium.

Type: String

Required: No

DesiredPartitionCount

The number of partitions you want to preconfigure for your domain. Only valid when you select search.2xlarge as the instance type.

Type: Integer

Required: No

DesiredReplicationCount

The number of replicas you want to preconfigure for each index partition.

Type: Integer

Required: No

ScalingParametersStatus

Description
The status and configuration of a search domain's scaling parameters.

Contents

Options

The desired instance type and desired number of replicas of each index partition.

Type: ScalingParameters (p. 215)

Required: Yes

Status

The status of domain configuration option.
Type: OptionStatus (p. 214)
Required: Yes

ServiceEndpoint

Description
The endpoint to which service requests can be submitted.

Contents

Endpoint
The endpoint to which service requests can be submitted. For example, search-imdb-movies-oopcnjfn6ugofer3zx5iadxxca.eu-west-1.cloudsearch.amazonaws.com or doc-imdb-movies-oopcnjfn6ugofer3zx5iadxxca.eu-west-1.cloudsearch.amazonaws.com.

Type: String
Required: No

Suggester

Description
Configuration information for a search suggester. Each suggester has a unique name and specifies the text field you want to use for suggestions. The following options can be configured for a suggester: FuzzyMatching, SortExpression.

Contents

DocumentSuggesterOptions
Options for a search suggester.

Type: DocumentSuggesterOptions (p. 199)
Required: Yes

SuggesterName
Names must begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore).

Type: String
Length constraints: Minimum length of 1. Maximum length of 64.
Required: Yes

SuggesterStatus

Description
The value of a Suggester and its current status.
Options

Configuration information for a search suggester. Each suggester has a unique name and specifies the text field you want to use for suggestions. The following options can be configured for a suggester: FuzzyMatching, SortExpression.

Type: Suggester (p. 216)

Required: Yes

Status

The status of domain configuration option.

Type: OptionStatus (p. 214)

Required: Yes

TextArrayOptions

Description

Options for a field that contains an array of text strings. Present if IndexField Type specifies the field is of type text-array. A text-array field is always searchable. All options are enabled by default.

Contents

AnalysisScheme

The name of an analysis scheme for a text-array field.

Type: String

Required: No

DefaultValue

A value to use for the field if the field isn't specified for a document.

Type: String

Length constraints: Minimum length of 0. Maximum length of 1024.

Required: No

HighlightEnabled

Whether highlights can be returned for the field.

Type: Boolean

Required: No

ReturnEnabled

Whether the contents of the field can be returned in the search results.

Type: Boolean

Required: No
**SourceFields**

A list of source fields to map to the field.

Type: String
Required: No

**TextOptions**

Description

Options for text field. Present if IndexFieldType specifies the field is of type text. A text field is always searchable. All options are enabled by default.

Contents

**AnalysisScheme**

The name of an analysis scheme for a text field.

Type: String
Required: No

**DefaultValue**

A value to use for the field if the field isn't specified for a document.

Type: String
Length constraints: Minimum length of 0. Maximum length of 1024.

Required: No

**HighlightEnabled**

Whether highlights can be returned for the field.

Type: Boolean
Required: No

**ReturnEnabled**

Whether the contents of the field can be returned in the search results.

Type: Boolean
Required: No

**SortEnabled**

Whether the field can be used to sort the search results.

Type: Boolean
Required: No

**SourceField**

A string that represents the name of an index field. CloudSearch supports regular index fields as well as dynamic fields. A dynamic field's name defines a pattern that begins or ends with a wildcard. Any
document fields that don't map to a regular index field but do match a dynamic field's pattern are configured with the dynamic field's indexing options.

Regular field names begin with a letter and can contain the following characters: a-z (lowercase), 0-9, and _ (underscore). Dynamic field names must begin or end with a wildcard (*). The wildcard can also be the only character in a dynamic field name. Multiple wildcards, and wildcards embedded within a string are not supported.

The name score is reserved and cannot be used as a field name. To reference a document's ID, you can use the name _id.

Type: String
Length constraints: Minimum length of 1. Maximum length of 64.
Required: No

UpdateAvailabilityOptionsResult

Description
The result of a UpdateAvailabilityOptions request. Contains the status of the domain's availability options.

Contents
AvailabilityOptions
The newly-configured availability options. Indicates whether Multi-AZ is enabled for the domain.
Type: AvailabilityOptionsStatus (p. 191)
Required: No

UpdateScalingParametersResult

Description
The result of a UpdateScalingParameters request. Contains the status of the newly-configured scaling parameters.

Contents
ScalingParameters
The status and configuration of a search domain's scaling parameters.
Type: ScalingParametersStatus (p. 215)
Required: Yes

UpdateServiceAccessPoliciesResult

Description
The result of an UpdateServiceAccessPolicies request. Contains the new access policies.
Common Parameters

This section lists the request parameters that all actions use. Any action-specific parameters are listed in the topic for the action.

Action

The action to be performed.

Default: None

Type: string

Required: Yes

AuthParams

The parameters that are required to authenticate a Conditional request. Contains:

- AWSAccessKeyId
- SignatureVersion
- Timestamp
- Signature

Default: None

Required: Conditional

AWSAccessKeyId

The access key ID that corresponds to the secret access key that you used to sign the request.

Default: None

Type: string

Required: Yes

Expires

The date and time when the request signature expires, expressed in the format YYYY-MM-DDThh:mm:ssZ, as specified in the ISO 8601 standard.

Condition: Requests must include either Timestamp or Expires, but not both.

Default: None

Type: string

Required: Conditional
SecurityToken

The temporary security token that was obtained through a call to AWS Security Token Service. For a list of services that support AWS Security Token Service, go to Using Temporary Security Credentials to Access AWS in Using Temporary Security Credentials.

Default: None
Type: string
Required: No

Signature

The digital signature that you created for the request. For information about generating a signature, go to the service’s developer documentation.

Default: None
Type: string
Required: Yes

SignatureMethod

The hash algorithm that you used to create the request signature.

Default: None
Type: string
Valid Values: HmacSHA256 | HmacSHA1
Required: Yes

SignatureVersion

The signature version you use to sign the request. Set this to the value that is recommended for your service.

Default: None
Type: string
Required: Yes

Timestamp

The date and time when the request was signed, expressed in the format YYYY-MM-DDThh:mm:ssZ, as specified in the ISO 8601 standard.

Condition: Requests must include either Timestamp or Expires, but not both.
Default: None
Type: string
Required: Conditional

Version

The API version that the request is written for, expressed in the format YYYY-MM-DD.
Default: None
Type: string
Required: Yes

Common Errors

This section lists the common errors that all actions return. Any action-specific errors are listed in the topic for the action.

**IncompleteSignature**

The request signature does not conform to AWS standards.

HTTP Status Code: 400

**InternalFailure**

The request processing has failed because of an unknown error, exception or failure.

HTTP Status Code: 500

**InvalidAction**

The action or operation requested is invalid. Verify that the action is typed correctly.

HTTP Status Code: 400

**InvalidClientTokenId**

The X.509 certificate or AWS access key ID provided does not exist in our records.

HTTP Status Code: 403

**InvalidParameterCombination**

Parameters that must not be used together were used together.

HTTP Status Code: 400

**InvalidParameterValue**

An invalid or out-of-range value was supplied for the input parameter.

HTTP Status Code: 400

**InvalidQueryParameter**

The AWS query string is malformed or does not adhere to AWS standards.

HTTP Status Code: 400

**MalformedQueryString**

The query string contains a syntax error.

HTTP Status Code: 404

**MissingAction**

The request is missing an action or a required parameter.

HTTP Status Code: 400
MissingAuthenticationToken

The request must contain either a valid (registered) AWS access key ID or X.509 certificate.

HTTP Status Code: 403

MissingParameter

A required parameter for the specified action is not supplied.

HTTP Status Code: 400

optInRequired

The AWS access key ID needs a subscription for the service.

HTTP Status Code: 403

RequestExpired

The request reached the service more than 15 minutes after the date stamp on the request or more than 15 minutes after the request expiration date (such as for pre-signed URLs), or the date stamp on the request is more than 15 minutes in the future.

HTTP Status Code: 400

ServiceUnavailable

The request has failed due to a temporary failure of the server.

HTTP Status Code: 503

Throttling

The request was denied due to request throttling.

HTTP Status Code: 400

ValidationErrors

The input fails to satisfy the constraints specified by an AWS service.

HTTP Status Code: 400

Document Service API Reference for Amazon CloudSearch

You use the document service API to add, replace, or delete documents in your Amazon CloudSearch domain. For more information managing the documents in your search domain, see upload documents (p. 85).

The other APIs you use to interact with Amazon CloudSearch are:

- Configuration API Reference for Amazon CloudSearch (p. 139)—Set up and manage your search domain.
- Search API (p. 231)—Search your domain.

documents/batch

This section describes the HTTP request and response messages for the documents/batch resource.
You create document batches to describe the data that you want to upload to an Amazon CloudSearch domain. A document batch is a collection of add and delete operations that represent the documents you want to add, update, or delete from your domain. Batches can be described in either JSON or XML. A batch provides all of the information Amazon CloudSearch needs for indexing. Each item that you want to be able to return as a search result (such as a product) is represented as a document—a batch is simply a collection of add and delete requests for individual documents. Every document has a unique ID and one or more fields that contain the data that you want to search and return in results.

To update a document, you specify an add request with the document ID of the document you want to update. For more information, see Adding and Updating Documents in Amazon CloudSearch (p. 56). Similarly, to delete a document, you submit a delete request with the document ID of the document you want to delete. For information about deleting documents, see Deleting Documents in Amazon CloudSearch (p. 56).

For more information about submitting data for indexing, see upload documents (p. 85).

**documents/batch JSON API**

**documents/batch Requests**

The body of a documents/batch request uses JSON or XML to specify the document operations you want to perform. A JSON representation of a batch is a collection of objects that define individual add and delete operations. The type property identifies whether an object represents an add or delete operation. For example, the following JSON batch adds one document and deletes one document:

```json
[
  {
    "type": "add",
    "id": "tt0484562",
    "fields": {
      "title": "The Seeker: The Dark Is Rising",
      "directors": ["Cunningham, David L."],
      "genres": ["Adventure","Drama","Fantasy","Thriller"],[
      "actors": ["McShane, Ian","Eccleston, Christopher","Conroy, Frances",
                  "Crewson, Wendy","Ludwig, Alexander","Cosmo, James",
                  "Warner, Amelia","Hickey, John Benjamin","Piddock, Jim",
                  "Lockhart, Emma"]
    }
  },
  {
    "type": "delete",
    "id": "tt0484575"
  }
]
```

**Note**

When specifying document batches in JSON, the value for a field cannot be `null`.

The **JSON schema** representation of a batch is shown below:

```json
{
  "type": "array",
  "minItems": 1,
  "items": {
    "type": "object",
    "properties": {
      "type": {
        "type": "string",
        "enum": ["add", "delete"],
        "required": true
      },
      "id": {
        "type": "string",
        "required": true
      }
    }
  }
}
```
documents/batch Request Properties (JSON)

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>The operation type, add or delete.</td>
<td>Yes</td>
</tr>
<tr>
<td>id</td>
<td>An alphanumeric string. Allowed characters are: A-Z (upper-case letters), -a-z (lower-case letters), 0-9, _ (underscore), - (hyphen), / (forward slash), # (hash sign), : (colon). The max length is 128 characters.</td>
<td>Yes</td>
</tr>
<tr>
<td>fields</td>
<td>A collection of one or more field_name properties that define the fields the document contains.</td>
<td>Conditional</td>
</tr>
<tr>
<td>field_name</td>
<td>Specifies a field within the document being added. Field names must begin with a letter and can contain the following characters: a-z (lower case), 0-9, and _ (underscore). Field names must be at least 3 and no more than 64 characters. The name score is reserved and cannot be used as a field name. To specify multiple values for a field, you specify an array of values instead of a single value. For example: &quot;genre&quot;: [&quot;Adventure&quot;, &quot;Drama&quot;, &quot;Fantasy&quot;, &quot;Thriller&quot;]</td>
<td>Conditional</td>
</tr>
</tbody>
</table>

documents/batch Response (JSON)

The response body lists the number of adds and deletes that were performed and any errors or warnings that were generated.

The JSON schema representation of a document service API response is shown below:
documents/batch Response Properties (JSON)

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>The result status, which is either success or error.</td>
</tr>
<tr>
<td>adds</td>
<td>The number of add document operations that were performed. Always zero when the status is error.</td>
</tr>
<tr>
<td>deletes</td>
<td>The number of delete document operations that were performed. Always zero when the status is error. For information on permanently deleting documents, see the section called “Deleting Documents” (p. 56).</td>
</tr>
<tr>
<td>errors</td>
<td>Provides information about a parsing or validation error. Specified only if the status is error.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>warning</td>
<td>Provides information about a warning generated during parsing or validation.</td>
</tr>
</tbody>
</table>

## documents/batch XML API

### XML documents/batch Requests

The body of a documents/batch request specifies the document operations you want to perform in XML. For example:

```xml
<batch>
  <add id="tt0484562">
    <field name="title">The Seeker: The Dark Is Rising</field>
    <field name="director">Cunningham, David L.</field>
    <field name="genre">Adventure</field>
    <field name="genre">Drama</field>
    <field name="genre">Fantasy</field>
    <field name="genre">Thriller</field>
    <field name="actor">McShane, Ian</field>
    <field name="actor">Eccleston, Christopher</field>
    <field name="actor">Conroy, Frances</field>
    <field name="actor">Ludwig, Alexander</field>
    <field name="actor">Crewson, Wendy</field>
    <field name="actor">Warner, Amelia</field>
    <field name="actor">Cosmo, James</field>
    <field name="actor">Hickey, John Benjamin</field>
    <field name="actor">Piddock, Jim</field>
    <field name="actor">Lockhart, Emma</field>
  </add>
  <delete id="tt0301199" />
</batch>
```

### documents/batch Request Elements (XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>batch</td>
<td>The collection of add or delete operations that you want to submit to your search domain. A batch must contain at least one add or delete element.</td>
<td>Yes</td>
</tr>
<tr>
<td>add</td>
<td>Specifies a document that you want to add to your search domain. The id attributes is required and an add element must contain at least one field.</td>
<td>No</td>
</tr>
</tbody>
</table>
| field      | Specifies a field in the document being added. The name attribute and a field value are required. Field names must begin with a letter and can | Conditional
<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>contain the following characters: a-z (lower case), 0-9, and _ (underscore). The name score is reserved and cannot be used as a field name. The field value can be text or CDATA.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>To specify multiple values for a field, you include multiple field elements with the same name. For example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>&lt;field name=&quot;genre&quot;&gt;Adventure&lt;/field&gt;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>&lt;field name=&quot;genre&quot;&gt;Drama&lt;/field&gt;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>&lt;field name=&quot;genre&quot;&gt;Fantasy&lt;/field&gt;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>&lt;field name=&quot;genre&quot;&gt;Thriller&lt;/field&gt;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Constraints:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• name—An alphanumeric string that begins with a letter. Can contain a-z (lower case), 0-9, _ (underscore), - (hyphen), and . (period).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Condition: At least one field must be specified in an add element.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>delete</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Specifies a document that you want to remove from your search domain. The id attribute is required. A delete element must be empty. For information on permanently deleting documents, see the section called “Deleting Documents” (p. 56).</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>Constraints:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• id—An alphanumeric string. Any characters other than A-Z (upper or lower case) and 0-9 are illegal.</td>
<td></td>
</tr>
</tbody>
</table>

**documents/batch Response (XML)**

The response body lists the number of adds and deletes that were performed and any errors or warnings that were generated.

The RelaxNG schema of a document service API response is:

```xml
start = response
response = element response {
  attribute status { "success" | "error" },
  attribute adds { xsd:integer },
  attribute deletes { xsd:integer },
  element errors {
    element error {
      text
    }+
  }? &
  element warnings {
    element warning {
```
documents/batch Response Elements (XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| result  | Contains elements that list the errors and warnings generated when parsing and validating the request. Attributes:  
- status—The result status, which is either success or error.  
- adds—The number of added documents. If the status is error, this is always zero.  
- deletes—The number of deleted documents. If the status is error, this is always zero.  
Constraints: If the status is error, the results element contains a list of errors. If the status is success, the results element can contain a list of warnings, but no errors. |
| errors  | Contains a collection of error elements that identify the errors that occurred when parsing and validating the request. |
| error   | Provides information about a parsing or validation error. The value provides a description of the error. |
| warnings| Contains a collection of warning elements that identify the warnings that were generated when parsing and validating the request. |
| warning | Provides information about a parsing or validation warning. The value provides a description of the error. |

documents/batch Status Codes

A document service request can return three types of status codes:

- 5xx status codes indicate that there was an internal server error. We recommend catching and retrying all 5xx error codes as they typically represent transient error conditions.
- 4xx status codes indicate that the request was malformed.
- 2xx status codes indicate that the request was processed successfully.

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
<th>HTTP Status Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>No Content-Type</td>
<td>The Content-Type header is missing.</td>
<td>400</td>
</tr>
<tr>
<td>No Content-Length</td>
<td>The Content-Length header is missing.</td>
<td>411</td>
</tr>
<tr>
<td>Incorrect Path</td>
<td>URL path does not match &quot;/YYYY-MM-DD/documents/batch&quot;.</td>
<td>404</td>
</tr>
</tbody>
</table>
**Error** | **Description** | **HTTP Status Code**
---|---|---
Invalid HTTP Method | The HTTP method is not POST. Requests must be posted to documents/batch. | 405
Invalid Accept Type | Accept header specifies a content type other than "application/xml" or "application/json". Responses can be sent only as XML or JSON. | 406
Request Too Large | The length of the request body is larger than the maximum allowed value. | 413
Invalid Content Type | The content type is something other than "application/json" or "application/xml". | 415
Invalid Character Set | The character set is something other than "ASCII", "ISO-8859-1", or "UTF-8". | 415

**Common Request Headers**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content-Type</td>
<td>A standard MIME type describing the format of the object data. For more information, see <a href="https://www.w3.org/Protocols/rfc2616/rfc2616-sec14.html">W3C RFC 2616 Section 14</a>.</td>
<td>Required</td>
</tr>
<tr>
<td></td>
<td>Default: application/json</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Constraints: application/json or application/xml only</td>
<td></td>
</tr>
<tr>
<td>Content-Length</td>
<td>The length in bytes of the body of the request.</td>
<td>Yes</td>
</tr>
<tr>
<td>Accept</td>
<td>A standard MIME type describing the format of the response data. For more information, see <a href="https://www.w3.org/Protocols/rfc2616/rfc2616-sec14.html">W3C RFC 2616 Section 14</a>.</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>Default: the content-type of the request</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Constraints: application/json or application/xml only</td>
<td></td>
</tr>
</tbody>
</table>

**Common Response Headers**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content-Type</td>
<td>A standard MIME type describing the format of the object data. For more information, see <a href="https://www.w3.org/Protocols/rfc2616/rfc2616-sec14.html">W3C RFC 2616 Section 14</a>.</td>
</tr>
<tr>
<td></td>
<td>Default: the value of the Accept header in the request, or the Content-Type of the request if the Accept header is missing or doesn't specify either application/xml or application/json.</td>
</tr>
<tr>
<td></td>

</tr>
</tbody>
</table>
## Search API Reference for Amazon CloudSearch

### Topics
- [Search](p. 231)
- Submitting Suggest Requests in Amazon CloudSearch (p. 246)
- [Suggest](p. 247)
- Search Service Errors (p. 249)

You use the Search API to submit search or suggestion requests to your Amazon CloudSearch domain. For more information about searching, see Searching Your Data with Amazon CloudSearch (p. 92). For more information about suggestions, see Getting Autocomplete Suggestions in Amazon CloudSearch (p. 119).

The other APIs you use to interact with Amazon CloudSearch are:

- Configuration API (p. 139)—Set up and manage your search domain.
- Document Service API (p. 223)—Submit the data you want to search.

### Search

This section describes the HTTP request and response messages for the search resource.

#### Search Syntax

```
GET /2013-01-01/search
```

#### Search Request Headers

**HOST**

The search request endpoint for the domain you're querying. You can use DescribeDomains (p. 166) to retrieve your domain's search request endpoint.

Required: Yes

#### Search Request Parameters

**cursor**

Retrieves a cursor value you can use to page through large result sets. Use the size parameter to control the number of hits you want to include in each response. You can specify either the cursor or start parameter in a request, they are mutually exclusive. For more information, see Paginate the results (p. 131).

To get the first cursor, specify cursor=initial in your initial request. In subsequent requests, specify the cursor value returned in the hits section of the response.

### Table: Content-Length

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content-Length</td>
<td>The length in bytes of the body in the response.</td>
</tr>
</tbody>
</table>

API Version 2013-01-01

231
For example, the following request sets the cursor value to initial and the size parameter to 100 to get the first set of hits. The cursor for the next set of hits is included in the response.

```json
search?q=john&cursor=initial&size=100&return=_no_fields
{
    "status": {
        "rid": "+/XuSs0oHwojC6o",
        "time-ms": 15
    },
    "hits": {
        "found": 503,
        "start": 0,
        "cursor": "VegKzpYYW9JSVFRU1wVwWwZERBd09EUTNPRGM9ZA",
        "hit": [
            {"id": "tt0120601"},
            {"id": "tt1801552"},
            ...
        ]
    }
}
```

To get the next set of hits, you specify the cursor value and the number of hits to retrieve.

```json
search?q=john&cursor=VegKzpYYW9JSVFRU1wVwWwZERBd09EUTNPRGM9ZA&size=100
```

Type: String

Required: No

expr.NAME

Defines an expression that can be used to sort results. You can also specify an expression as a return field. For more information about defining and using expressions, see Configuring Expressions (p. 125).

You can define and use multiple expressions in a search request. For example, the following request creates two expressions that are used to sort the results and includes them in the search results:

```json
search?q=(and (term field=genres 'Sci-Fi')(term field=genres 'Comedy'))&q.parser=structured &expr.expression1=_score*rating &expr.expression2=(1/rank)*year &sort=expression1 desc,expression2 desc &return=title,rating,rank,year,_score,expression1,expression2
```

Type: String

Required: No

facet.FIELD

Specifies a field that you want to get facet information for—FIELD is the name of the field. The specified field must be facet enabled in the domain configuration. Facet options are specified as a JSON object. If the JSON object is empty, facet.FIELD={}, facet counts are computed for all field values, the facets are sorted by facet count, and the top 10 facets are returned in the results.

You can specify three options in the JSON object:

- **sort** specifies how you want to sort the facets in the results: bucket or count. Specify bucket to sort alphabetically or numerically by facet value (in ascending order). Specify count to sort by the facet counts computed for each facet value (in descending order). To retrieve facet counts for particular values or ranges of values, use the buckets option instead of sort.

...
• `buckets` specifies an array of the facet values or ranges you want to count. Buckets are returned in the order they are specified in the request. To specify a range of values, use a comma (,) to separate the upper and lower bounds and enclose the range using brackets or braces. A square bracket, [ or ], indicates that the bound is included in the range, a curly brace, { or }, excludes the bound. You can omit the upper or lower bound to specify an open-ended range. When omitting a bound, you must use a curly brace. The `sort` and `size` options are not valid if you specify `buckets`.

• `size` specifies the maximum number of facets to include in the results. By default, Amazon CloudSearch returns counts for the top 10. The `size` parameter is only valid when you specify the `sort` option; it cannot be used in conjunction with `buckets`.

For example, the following request gets facet counts for the `year` field, sorts the facet counts by value and returns counts for the top three:

```
facet.year={sort:"bucket", size:3}
```

To specify which values or range of values you want to calculate facet counts for, use the `buckets` option. For example, the following request calculates and returns the facet counts by decade:

```
facet.year={buckets:
    "[1990,1999]","[2000,2009]",
    "[2010,]"
}
```

You can also specify individual values as buckets:

```
facet.genres={buckets:
    ["Action","Adventure","Sci-Fi"]
}
```

Note that the facet values are case-sensitive—with the sample IMDb movie data, if you specify ["action","adventure","sci-fi"] instead of ["Action","Adventure","Sci-Fi"], all facet counts are zero.

Type: String  
Required: No

`format`  
Specifies the content type of the response.  
Type: String  
Valid Values: json|xml  
Default: json  
Required: No

`fq`  
Specifies a structured query that filters the results of a search without affecting how the results are scored and sorted. You use `fq` in conjunction with the `q` parameter to filter the documents that match the constraints specified in the `q` parameter. Specifying a filter just controls which matching documents are included in the results, it has no effect on how they are scored and sorted. The `fq` parameter supports the full structured query syntax. For more information about using filters, see Filtering Matching Documents (p. 108). For more information about structured queries, see Structured Search Syntax (p. 237).  
Type: String  
Required: No
highlight.FIELD

Retrieves highlights for matches in the specified text or text-array field. Highlight options are specified as a JSON object. If the JSON object is empty, the returned field text is treated as HTML and the first match is highlighted with emphasis tags: `<em>search-term</em>`.

You can specify four options in the JSON object:

- **format**—specifies the format of the data in the text field: text or html. When data is returned as HTML, all non-alphanumeric characters are encoded. The default is html.
- **max_phrases**—specifies the maximum number of occurrences of the search term(s) you want to highlight. By default, the first occurrence is highlighted.
- **pre_tag**—specifies the string to prepend to an occurrence of a search term. The default for HTML highlights is `<em>`. The default for text highlights is `*`.
- **post_tag**—specifies the string to append to an occurrence of a search term. The default for HTML highlights is `</em>`. The default for text highlights is `*`.

Examples:

```
highlight.plot={},
highlight.plot={format:'text',max_phrases:2,pre_tag:'<b>',post_tag:'</b>'}
```

Type: String

Required: No

partial

Controls whether partial results are returned if one or more index partitions are unavailable. When your search index is partitioned across multiple search instances, by default Amazon CloudSearch only returns results if every partition can be queried. This means that the failure of a single search instance can result in 5xx (internal server) errors. When you specify `partial=true`, Amazon CloudSearch returns whatever results are available and includes the percentage of documents searched in the search results (`percent-searched`). This enables you to more gracefully degrade your users' search experience. For example, rather than displaying no results, you could display the partial results and a message indicating that the results might be incomplete due to a temporary system outage.

Type: Boolean

Default: False

Required: No

pretty

Formats JSON output so it's easier to read.

Type: Boolean

Default: False

Required: No

q

The search criteria for the request. How you specify the search criteria depends on the query parser used for the request and the parser options specified in the `q.options` parameter. By default, the simple query parser is used to process requests. To use the structured, lucene, or dismax query parser, you must also specify the `q.parser` parameter. For more information about specifying search criteria, see [Searching Your Data with Amazon CloudSearch](p. 92).

Type: String

Required: Yes
q.options

Configure options for the query parser specified in the q.parser parameter. The options are specified as a JSON object, for example: `q.options={defaultOperator: 'or', fields: ['title^5','description']}.`

The options you can configure vary according to which parser you use:

- **defaultOperator**—The default operator used to combine individual terms in the search string. For example: `defaultOperator: 'or'`. For the dismax parser, you specify a percentage that represents the percentage of terms in the search string (rounded down) that must match, rather than a default operator. A value of 0% is the equivalent to OR, and a value of 100% is equivalent to AND. The percentage must be specified as a value in the range 0-100 followed by the percent (%) symbol. For example, `defaultOperator: 50%`. Valid values: and, or, a percentage in the range 0%-100% (dismax). Default: and (simple, structured, lucene) or 100 (dismax). Valid for: simple, structured, lucene, and dismax.

- **fields**—An array of the fields to search when no fields are specified in a search. If no fields are specified in a search and this option is not specified, all statically configured text and text-array fields are searched. You can specify a weight for each field to control the relative importance of each field when Amazon CloudSearch calculates relevance scores. To specify a field weight, append a caret (^) symbol and the weight to the field name. For example, to boost the importance of the title field over the description field you could specify: `fields: ['title^5', 'description']`. Valid values: The name of any configured field and an optional numeric value greater than zero. Default: All statically configured text and text-array fields. Dynamic fields and literal fields are not searched by default. Valid for: simple, structured, lucene, and dismax.

- **operators**—An array of the operators or special characters you want to disable for the simple query parser. If you disable the and, or, or not operators, the corresponding operators (+, |, -) have no special meaning and are dropped from the search string. Similarly, disabling prefix disables the wildcard operator (*) and disabling phrase disables the ability to search for phrases by enclosing phrases in double quotes. Disabling precedence disables the ability to control order of precedence using parentheses. Disabling near disables the ability to use the ~ operator to perform a sloppy phrase search. Disabling the fuzzy operator disables the ability to use the ~ operator to perform a fuzzy search. escape disables the ability to use a backslash (\) to escape special characters within the search string. Disabling whitespace is an advanced option that prevents the parser from tokenizing on whitespace, which can be useful for Vietnamese. (It prevents Vietnamese words from being split incorrectly.) For example, you could disable all operators other than the phrase operator to support just simple term and phrase queries: `operators:['and', 'not', 'or', 'prefix']`. Valid values: and, escape, fuzzy, near, not, or, phrase, precedence, prefix, whitespace. Default: All operators and special characters are enabled. Valid for: simple.

- **phraseFields**—An array of the text or text-array fields you want to use for phrase searches. When the terms in the search string appear in close proximity within a field, the field scores higher. You can specify a weight for each field to boost that score. The phraseSlop option controls how much the matches can deviate from the search string and still be boosted. To specify a field weight, append a caret (^) symbol and the weight to the field name. For example, to boost phrase matches in the title field over the abstract field, you could specify: `phraseFields: ['title^3', 'abstract']`. Valid values: The name of any text or text-array field and an optional numeric value greater than zero. Default: No fields. If you don't specify any fields with phraseFields, proximity scoring is disabled even if phraseSlop is specified. Valid for: dismax.

- **phraseSlop**—An integer value that specifies how much matches can deviate from the search phrase and still be boosted according to the weights specified in the phraseFields option. For example, `phraseSlop: 2`. You must also specify phraseFields to enable proximity scoring. Valid values: positive integers. Default: 0. Valid for: dismax.

- **explicitPhraseSlop**—An integer value that specifies how much a match can deviate from the search phrase when the phrase is enclosed in double quotes in the search string. (Phrases that
tieBreaker—When a term in the search string is found in a document's field, a score is calculated for that field based on how common the word is in that field compared to other documents. If the term occurs in multiple fields within a document, by default only the highest scoring field contributes to the document's overall score. You can specify a tieBreaker value to enable the matches in lower-scoring fields to contribute to the document's score. That way, if two documents have the same max field score for a particular term, the score for the document that has matches in more fields will be higher. The formula for calculating the score with a tieBreaker is:

\[
\text{score} = \text{(max field score)} + \text{(tieBreaker)} \times \text{(sum of the scores for the rest of the matching fields)}
\]

For example, the following query searches for the term *dog* in the title, description, and review fields and sets *tieBreaker* to 0.1:

```json
q=dog&q.parser=dismax&q.options={fields:['title', 'description', 'review'],
tieBreaker: 0.1}
```

If *dog* occurs in all three fields of a document and the scores for each field are title=1, description=3, and review=1, the overall score for the term *dog* is:

\[3 + 0.1 \times (1+1) = 3.2\]

Set *tieBreaker* to 0 to disregard all but the highest scoring field (pure max). Set to 1 to sum the scores from all fields (pure sum). Valid values: 0.0 to 1.0. Default: 0.0. Valid for: dismax.

Type: JSON object

Default: See individual option descriptions.

Required: No

**q.parser**

Specifies which query parser to use to process the request: simple, structured, lucene, and dismax. If *q.parser* is not specified, Amazon CloudSearch uses the simple query parser.

- **simple**—perform simple searches of text and text-array fields. By default, the simple query parser searches all statically configured text and text-array fields. You can specify which fields to search by with the *q.options* parameter. If you prefix a search term with a plus sign (+) documents must contain the term to be considered a match. (This is the default, unless you configure the default operator with the *q.options* parameter.) You can use the – (NOT), | (OR), and * (wildcard) operators to exclude particular terms, find results that match any of the specified terms, or search for a prefix. To search for a phrase rather than individual terms, enclose the phrase in double quotes. For more information, see Searching Your Data with Amazon CloudSearch (p. 92).

- **structured**—perform advanced searches by combining multiple expressions to define the search criteria. You can also search within particular fields, search for values and ranges of values, and use advanced options such as term boosting, matchall, and near. For more information, see Constructing Compound Queries (p. 95).

- **lucene**—search using the Apache Lucene query parser syntax. For more information, see Apache Lucene Query Parser Syntax.

- **dismax**—search using the simplified subset of the Apache Lucene query parser syntax defined by the DisMax query parser. For more information, see DisMax Query Parser Syntax.
Type: String
Default: simple
Required: No

return

The field and expression values to include in the response, specified as a comma-separated list. By default, a search response includes all return enabled fields (return=_all_fields). To return only the document IDs for the matching documents, specify return=_no_fields. To retrieve the relevance score calculated for each document, specify return=_score. You specify multiple return fields as a comma separated list. For example, return=title,_score returns just the title and relevance score of each matching document.

Type: String
Required: No

size

The maximum number of search hits to return.

Type: Positive integer
Default: 10
Required: No

sort

A comma-separated list of fields or custom expressions to use to sort the search results. You must specify the sort direction (asc or desc) for each field. For example, sort=year desc,title asc. You can specify a maximum of 10 fields and expressions. To use a field to sort results, it must be sort enabled in the domain configuration. Array type fields cannot be used for sorting. If no sort parameter is specified, results are sorted by their default relevance scores in descending order: sort=_score desc. You can also sort by document ID (sort=_id) and version (sort=_version).

Type: String
Required: No

start

The offset of the first search hit you want to return. You can specify either the start or cursor parameter in a request, they are mutually exclusive. For more information, see Page 131.

Type: Positive integer
Default: 0 (the first hit)
Required: No

Structured Search Syntax

You use the Amazon CloudSearch structured search syntax to define search criteria when using the structured query parser, and to specify filter criteria with the fq parameter.

When using the structured query operators, you specify the name of the operator, options for the operator, and then the terms being operated on, (OPERATOR OPTIONS STRING|EXPRESSION). Any
options must be specified before the string or expression. For example, (and (not field=genres 'Sci-Fi') (or (term field=title boost=2 'star') (term field=plot 'star'))).

**Important**
You must URL-encode special characters in the query string. For example, you must encode the ' operator in a structured query as %3D: (term+field%3Dtitle+'star'). Amazon CloudSearch returns an InvalidQueryString error if special characters are not URL-encoded. For a complete reference of URL-encodings, see the W3C [HTML URL Encoding Reference](https://www.w3.org/International/questions/qa-url-encoding).

If you do not specify the field you want to search when using the structured query parser, all statically configured text and text-array fields are searched. Dynamic fields and literal fields are not searched by default. You can specify which fields you want to search by default with the q.options parameter.

Parentheses control the order of evaluation of the expressions in a compound query. When an expression is enclosed in parentheses, that expression is evaluated first, and then the resulting value is used in the evaluation of the remainder of the query. The expressions can contain any of the structured query operators.

You can also use the structured query parser to search for a simple text string—just enclose the string you want to search for in single quotes:

```
q='black swan'&q.parser="structured"
```

For more information about constructing compound queries with the structured query operators, see [Constructing Compound Queries](#).

**FIELD**

Syntax: `FIELD: 'STRING'|value`

Searches the specified field for a string, numeric value, date, or range of numeric values or dates.

Strings must be enclosed in single quotes. Any single quotation marks or backslashes in the string must be escaped with a backslash. To specify a range of values, use a comma (,) to separate the upper and lower bounds and enclose the range using brackets or braces. A square bracket, [ or ], indicates that the bound is included in the range, a curly brace, { or }, excludes the bound. You can omit the upper or lower bound to specify an open-ended range. When omitting a bound, you must use a curly brace.

Dates and times are specified in UTC (Coordinated Universal Time) according to [IETF RFC3339](https://tools.ietf.org/html/rfc3339): `yyyy-mm-ddTHH:mm:ss.SSSZ`. In UTC, for example, 5:00 PM August 23, 1970 is: `1970-08-23T17:00:00Z`. Note that you can also specify fractional seconds when specifying times in UTC. For example, `1967-01-31T23:20:50.650Z`.

Examples:

```
title:'star'
year:2000
year:[1998,2000]
year:{2011}
release_date:['2013-01-01T00:00:00Z',}
```

and

```
 Syntax: (and boost=N EXPRESSION EXPRESSION ... EXPRESSIONn)
```

Includes a document only if it matches all of the specified expressions. (Boolean AND operator) The expressions can contain any of the structured query operators, or a simple search string. Search strings must be enclosed in single quotes. Note that to match documents that contain the specified terms in any of the fields being searched, you specify each term as a separate expression: ( and
'star' 'wars'). If you specify (and 'star wars'), star and wars must occur within the same field to be considered a match.

The boost value is a positive numeric value that increases the importance of this part of the search query relative to the other parts.

Example:

```
(and title:'star' actors:'Harrison Ford' year:{,2000})
```

**matchall**

Syntax: `matchall`

Matches every document in the domain. By default, returns the first 10. Use the size and start parameters to page through the results.

**near**

Syntax: `(near field=FIELD distance=N boost=N 'STRING')`

Searches a text or text-array field for the specified multi-term string and matches documents that contain the terms within the specified distance of one another. (This is sometimes called a sloppy phrase search.) If you omit the field option, Amazon CloudSearch searches all statically configured text and text-array fields by default. Dynamic fields and literal fields are not searched by default. You can specify which fields you want to search by default by specifying the q.options fields option.

The distance value must be a positive integer. For example, to find all documents where teenage occurs within 10 words of vampire in the plot field, you specify a distance value of 10: `(near field=plot distance=10 'teenage vampire')`.

The boost value is a positive numeric value that increases the importance of this part of the search query relative to the other parts.

Example:

```
(near field=plot distance=10 'teenage vampire')
```

**not**

Syntax: `(not boost=N EXPRESSION)`

Excludes a document if it matches the specified expression. (Boolean NOT operator.) The expression can contain any of the structured query operators, or a simple search string. Search strings must be enclosed in single quotes.

The boost value is a positive numeric value that increases the importance of this part of the search query relative to the other parts.

Example:

```
(not (or actors:'Harrison Ford' year:{,2010}))
```

**or**

Syntax: `(or boost=N EXPRESSION1 EXPRESSION2 ... EXPRESSIONn)`
Includes a document if it matches any of the specified expressions. (Boolean OR operator.) The expressions can contain any of the structured query operators, or a simple search string. Search strings must be enclosed in single quotes.

The boost value is a positive numeric value that increases the importance of this part of the search query relative to the other parts.

Example:

(or actors:'Alec Guinness' actors:'Harrison Ford' actors:'James Earl Jones')

**phrase**

Syntax: `(phrase field=FIELD boost=N 'STRING')`

Searches a text or text-array field for the specified phrase. If you omit the field option, Amazon CloudSearch searches all statically configured text and text-array fields by default. Dynamic fields and literal fields are not searched by default. You can specify which fields you want to search by default by specifying the q.options fields option.

Use the phrase operator to combine a phrase search with other search criteria in a structured query. For example, `q=(and (term field=title 'star') (range field=year {,2000}))` matches all documents that contain `star` in the title field and have a year value less than or equal to 2000.

The boost value is a positive numeric value that increases the importance of this part of the search query relative to the other parts.

Example:

(phrase field=plot 'teenage girl')

**prefix**

Syntax: `(prefix field=FIELD boost=N 'STRING')`

Searches a text, text-array, literal, or literal-array field for the specified prefix followed by zero or more characters. If you omit the field option, Amazon CloudSearch searches all statically configured text and text-array fields by default. Dynamic fields and literal fields are not searched by default. You can specify which fields you want to search by default by specifying the q.options fields option.

Use the prefix operator to combine a prefix search with other search criteria in a structured query. For example, `q=(and (prefix field=title 'sta') (range field=year {,2000}))` matches all documents that contain the prefix `sta` in the title field and have a year value of less than or equal to 2000.

The boost value is a positive numeric value that increases the importance of this part of the search query relative to the other parts.

**Note**

To implement search suggestions, you should configure and query a suggester, rather than performing prefix searches. For more information see [Suggestion Requests](#).

Example:

(prefix field=title 'star')
range

Syntax: (range field=FIELD boost=N RANGE)

Searches a numeric field (double, double-array, int, int-array) or date field (date, date-array) for values in the specified range. Matches documents that have at least one value in the field within the specified range. The field option must be specified.

Use the range operator to combine a range search with other search criteria in a structured query. For example,

```
q=(and (term field=title 'star') (range field=year {,2000}))
```

matches all documents that contain star in the title field and have a year value of less than or equal to 2000.

To specify a range of values, use a comma (,) to separate the upper and lower bounds and enclose the range using brackets or braces. A square bracket, [ or ], indicates that the bound is included in the range, a curly brace, { or }, excludes the bound. You can omit the upper or lower bound to specify an open-ended range. When omitting a bound, you must use a curly brace.

Dates and times are specified in UTC (Coordinated Universal Time) according to IETF RFC3339: yyyy-mm-ddTHH:mm:ss.SSSZ. In UTC, for example, 5:00 PM August 23, 1970 is: 1970-08-23T17:00:00Z. Note that you can also specify fractional seconds when specifying times in UTC. For example, 1967-01-31T23:20:50.650Z.

The boost value is a positive numeric value that increases the importance of this part of the search query relative to the other parts.

Examples:

```plaintext
(range field=year [1990,2000])
(range field=year {,2000})
(range field=year [1990,])
```

term

Syntax: (term field=FIELD boost=N 'STRING'|VALUE)

Searches the specified field for a string, numeric value, or date. The field option must be specified when searching for a value. If you omit the field option, Amazon CloudSearch searches all statically configured text and text-array fields by default. Dynamic fields and literal fields are not searched by default. You can specify which fields you want to search by default by specifying the q.options fields option.

Use the term operator to combine a term search with other search criteria in a structured query. For example,

```
q=(and (term field=title 'star') (range field=year {,2000}))
```

matches all documents that contain star in the title field and have a year value of less than or equal to 2000.

Strings and dates must be enclosed in single quotes. Any single quotation marks or backslashes in a string must be escaped with a backslash.

Dates and times are specified in UTC (Coordinated Universal Time) according to IETF RFC3339: yyyy-mm-ddTHH:mm:ss.SSSZ. In UTC, for example, 5:00 PM August 23, 1970 is: 1970-08-23T17:00:00Z. Note that you can also specify fractional seconds when specifying times in UTC. For example, 1967-01-31T23:20:50.650Z.

The boost value is a positive numeric value that increases the importance of this part of the search query relative to the other parts.

Examples:

```plaintext
(term field=title 'star')
```
Simple Search Syntax

You use the Amazon CloudSearch simple search syntax to define search criteria when using the simple query parser. The simple query parser is used by default if you do not specify the q.parser parameter.

You use the simple query parser to search for individual terms or phrases. By default, all statically configured text and text-array fields are searched. Dynamic fields and literal fields are not searched by default. You can use the q.options parameter to specify which fields you want to search, change the default operator used to combine individual terms in the search string, or disable any of the simple parser operators (and, escape, fuzzy, near, not, or, phrase, precedence, prefix, whitespace).

For more information about using the simple query parser, see text (p. 96).

+ (and)

Syntax: +TERM

Requires the specified term. To match, documents must contain the specified term.

Example: +star

\ (escape)

Syntax: \CHAR

Escapes special characters that you want to search for. You must escape the following characters if you want them to be part of the query: + - & | ! ( ) { } [ ] ^ " ~ * : \. 

Example: M\*A\*S\*H

~ (fuzzy)

Syntax: TERM~N

Performs a fuzzy search. Append the ~ operator and a value to a term to indicate how much terms can differ and still be considered a match.

Example: stor~1

~ (near)

Syntax: "PHRASE"~N

Performs a sloppy phrase search. Append the ~ operator and a value to a phrase to indicate how far apart the terms can be and still be considered a match for the phrase.

Example: "star wars"~4

- (not)

Syntax: -TERM

Prohibits the specified term. To match, documents must not contain the term.

Example: star -wars

| (or)

Syntax: |TERM

Makes the specified term optional.
Example: star wars
"..." (phrase)
Syntax: "PHRASE"
Performs a search for the entire phrase. Can be combined with the ~ operator to perform a sloppy phrase search.
Example: "star wars"
(?) (precedence)
Syntax: (...) Controls the order in which the query constraints are evaluated. The contents of the inner-most parentheses are evaluated first.
Example: +(war|trek)+star
* (prefix)
Syntax: CHAR*S
Matches documents that contain terms that have the specified prefix.
Example: sta*

Search Response
When a request completes successfully, the response body contains the search results. By default, search results are returned in JSON. If the format parameter is set to xml, search results are returned in XML.
Unless you explicitly specify the return parameter, the document ID and all returnable fields are included for each matching document (hit). The response also shows the total number of hits found (found) and the index of the first document listed (start). By default, the response contains the first 10 hits. You specify the size parameter in your request to control how many hits are included in each response. To page through the hits, you can use the start or cursor parameter. For more information, see Paginate the results (p. 131).

The following example shows a typical JSON response.

```
{
  "status": {
    "rid": "rtKz7zkoeAojlvk=",
    "time-ms": 10
  },
  "hits": {
    "found": 3,
    "start": 0,
    "hit": [
      {
        "id": "tt1142977",
        "fields": {
          "rating": "6.9",
          "genres": [
            "Animation",
            "Comedy",
            "Family",
            "Horror",
            "Sci-Fi"
          ],
          "plot": "Young Victor conducts a science experiment to"
        }
      }
    ]
  }
}
```
bring his beloved dog Sparky back to life, only to face unintended, sometimes monstrous, consequences.

The following example shows the equivalent XML response.

```xml
<results>
<status rid="itzL7rkoeQojlvk=" time-ms="34"/>
<hits found="3" start="0">
  <hit id="tt1142977">
    <field name="rating">6.9</field>
    <field name="genres">Animation</field>
    <field name="genres">Comedy</field>
    <field name="genres">Family</field>
    <field name="genres">Horror</field>
    <field name="genres">Sci-Fi</field>
    <field name="plot">Young Victor conducts a science experiment to bring his beloved dog Sparky back to life, only to face unintended, sometimes monstrous, consequences.</field>
    <field name="release_date">2012-09-20T00:00:00Z</field>
    <field name="title">Frankenweenie</field>
    <field name="rank">1462</field>
    <field name="running_time_secs">5220</field>
    <field name="directors">Tim Burton</field>

</hits>
</results>
```
Setting the response format only affects responses to successful requests. The format of an error response depends on the origin of the error. Errors returned by the search service are always returned in JSON. 5xx errors due to server timeouts and other request routing problems are returned in XML. When a request returns an error code, the body of the response contains information about the error that occurred. If an error occurs while the request body is parsed and validated, the error code is set to 400 and the response body includes a list of the errors and where they occurred.

**Search Response Headers**

**Content-Type**

A standard MIME type describing the format of the object data. For more information, see [W3C RFC 2616 Section 14.](https://www.rfc-editor.org/rfc/rfc2616)

Valid values: application/json or application/xml

Default: application/json

**Content-Length**

The length in bytes of the body in the response.

**Search Response Properties (JSON)**

**status**

Contains the resource id (rid) and the time it took to process the request (time-ms).

rid

The encrypted Resource ID.

time-ms

How long it took to process the search request in milliseconds.

**hits**

Contains the number of matching documents (found), the index of the first document included in the response (start), and an array (hit) that lists the document IDs and data for each hit.

found

The total number of hits that match the search request after Amazon CloudSearch finished processing the request.

start

The index of the first hit returned in this response.

**hit**

An array that lists the document IDs and data for each hit.

id

The unique identifier for a document.

fields

A list of returned fields.

facets

Contains facet information and facet counts.
FACETFIELD

A field for which facets were calculated.

buckets

An array of the calculated facet values and counts.

value

The facet value being counted.

count

The number of hits that contain the facet value in FACETFIELD.

Search Response Elements (XML)

results

Contains the search results. Any errors that occurred while processing the request are returned as messages in the info element.

status

Contains the resource id (rid) and the time it took to process the request (time-ms).

hits

Contains hit statistics and a collection of hit elements. The found attribute is the total number of hits that match the search request after Amazon CloudSearch finished processing the results. The contained hit elements are ordered according to their relevance scores or the sort option specified in the search request.

hit

A document that matched the search request. The id attribute is the document's unique id.

Contains a d (data) element for each returned field.

field

A field returned from a hit. Hit elements contain a d (data) element for each returned field.

facets

Contains a facet element for each facet requested in the search request.

facet

Contains a bucket element for each value of a field for which a facet count was calculated. The Facet.FIELD size option can be used to specify how many constraints to return. By default, facet counts are returned for the top 10 constraints. The Facet.FIELD buckets option can be used to explicitly specify which values to count.

bucket

A facet field value and the number of occurrences (count) of that value within the search hits.

Submitting Suggest Requests in Amazon CloudSearch

You submit suggest requests via HTTP GET to your domain's search endpoint at 2013-01-01/suggest. For information about controlling access to the suggest service, see configure access policies (p. 27).
You must specify the API version in all suggest requests and that version must match the API version specified when the domain was created.

For example, the following request gets suggestions from the search-movies-rr2f34ogf56xneuemujamut52i.us-east-1.cloudsearch.amazonaws.com domain for the query string oce using the suggester called title.

```
http://search-imdb-hd6ebyouhw2lczkueyuqksnuzu.us-west-2.cloudsearch.amazonaws.com/2013-01-01/suggest -d"q=oce&suggester=suggest_title"
```

You can use any method you want to send GET requests to your domain's search endpoint—you can enter the request URL directly in a Web browser, use cURL to submit the request, or generate an HTTP call using your favorite HTTP library. You can also use the Search Tester in the Amazon CloudSearch console to get suggestions. For more information, see Searching with the Search Tester (p. 11).

**Important**
A domain's document and search endpoints remain the same for the life of the domain. You should cache the endpoints rather than retrieving them before every upload or search request. Querying the Amazon CloudSearch configuration service by calling `aws cloudsearch describe-domains` or `DescribeDomains` before every request is likely to result in your requests being throttled.

By default, Amazon CloudSearch returns the response in JSON. You can get the results formatted in XML by specifying the `format` parameter, `format=xml`. Setting the response format only affects responses to successful requests. The format of an error response depends on the origin of the error. Errors returned by the search service are always returned in JSON. 5xx errors due to server timeouts and other request routing problems are returned in XML.

---

**Suggest**

**Suggestion Requests**

**Suggest Syntax in Amazon CloudSearch**

```
GET /2013-01-01/suggest
```

**Suggest Request Headers in Amazon CloudSearch**

**HOST**

The search request endpoint for the domain you're querying. You can use `DescribeDomains` (p. 166) to retrieve your domain's search request endpoint.

Required: Yes

**Suggest Request Parameters in Amazon CloudSearch**

**q**

The string to get suggestions for.

Type: String

Required: Yes

**suggester**

The name of the suggester to use to find suggested matches.
Suggest

Type: String
Required: Yes

size
The maximum number of suggestions to return.
Type: Positive integer
Default: 10
Required: No

format
Specifies the content type of the response.
Type: String
Valid Values: json|xml
Default: json
Required: No

Suggest Response

When a request completes successfully, the response body contains the suggestions. By default, suggestions are returned in JSON. Set the format parameter to xml to get the results in XML.

Setting the response format only affects responses to successful requests. The format of an error response depends on the origin of the error. Errors returned by the search service are always returned in JSON. 5xx errors due to server timeouts and other request routing problems are returned in XML. When a request returns an error code, the body of the response contains information about the error that occurred. If an error occurs while the request body is parsed and validated, the error code is set to 400 and the response body includes a list of the errors and where they occurred.

The following example shows a JSON response to a request for suggestions:

```json
{
    "status": {
        "rid": "qO5MSs0oCwr8pVk=",
        "time-ms": 2
    },
    "suggest": {
        "query": "oce",
        "found": 3,
        "suggestions": [
            {
                "suggestion": "Ocean's Eleven",
                "score": 0,
                "id": "tt0054135"
            },
            {
                "suggestion": "Ocean's Thirteen",
                "score": 0,
                "id": "tt0496806"
            },
            {
                "suggestion": "Ocean's Twelve",
                "score": 0
            }
        ]
    }
}
```
The following example shows the equivalent XML response:

```xml
<results>
  <status rid="/pS2z580oDQz8pVk=" time-ms="2"/>
  <suggest query="oce" found="3">
    <suggestions>
      <item suggestion="Ocean's Eleven" score="0" id="tt0054135"/>
      <item suggestion="Ocean's Thirteen" score="0" id="tt0496806"/>
      <item suggestion="Ocean's Twelve" score="0" id="tt0349903"/>
    </suggestions>
  </suggest>
</results>
```

### Search Service Errors

A search or suggestion request can return three types of status codes:

- **5xx status codes** indicate that there was an internal server error. You should catch and retry all 5xx error codes as they typically represent transient error conditions. For more information, see [Handling Errors](p. 137).
- **4xx status codes** indicate that the request was malformed. Correct the error(s) before resubmitting your request.
- **2xx status codes** indicate that the request was processed successfully.

The format of an error response depends on the origin of the error. Errors returned by the search service are always returned in JSON. 5xx errors due to server timeouts and other request routing problems are returned in XML.

Errors returned by the search service contain the following information:

- **error**
  - Contains an error message returned by the search service. The `code` and `msg` properties are included for each error.
- **code**
  - The error code.
- **msg**
  - A description of the error that was returned by the search service.
Troubleshooting Amazon CloudSearch

The following topics describe solutions to problems you might encounter when using Amazon CloudSearch.

Topics

• Uploading Documents (p. 250)
• Deleting All Documents in an Amazon CloudSearch Domain (p. 251)
• Amazon CloudSearch Domain Not Scaling Down After Deleting Documents (p. 251)
• Document Update Latency (p. 251)
• Large Number of 5xx Errors When Uploading Documents to an Amazon CloudSearch Domain (p. 251)
• Search Latency and Timeouts in Amazon CloudSearch (p. 252)
• Search Latency for Faceted Queries in Amazon CloudSearch (p. 252)
• Sudden Increase in 5xx Errors When Searching an Amazon CloudSearch Domain (p. 252)
• Indexing Failures after Updating Indexing Options in Amazon CloudSearch (p. 252)
• Domain Not Found When Submitting Indexing Options in Amazon CloudSearch Requests (p. 253)
• Number of Searchable Documents Not Returned with Domain Information (p. 253)
• Configuration Service Access Policies Not Working in Amazon CloudSearch (p. 253)
• Search and Document Service Access Policies Not Working in Amazon CloudSearch (p. 254)
• Amazon CloudSearch Console Permissions Errors (p. 254)
• Using Wildcards to Search Text Fields Doesn’t Produce Expected Results (p. 254)
• Inconsistent Results When Using Cursors for Deep Paging (p. 255)
• Certificate Errors When Using an SDK (p. 255)

Uploading Documents

If your document data is not formatted correctly or contains invalid values, you will get errors when you attempt to upload it or use it to configure fields for your domain. Here are some common problems and their solutions:

• **Invalid JSON**—if you are using JSON, the first thing to do is make sure there are no JSON syntax errors in your document batch. To do that, run it through a validation tool such as the [JSON Validator](https://jsonLint.com). This will identify any fundamental issues with the data.

• **Invalid XML**—document batches must be well-formed XML. You are especially likely to encounter issues if your fields contain XML data—the data must be XML-encoded or enclosed in CDATA sections. To identify any problems, run your document batch through a validation tool such as the [W3C Markup Validation Service](https://validator.w3.org).

• **Not Recognized as a Document Batch**—if Amazon CloudSearch doesn’t recognize your data as a valid document batch when you upload data using the console, Amazon CloudSearch generates a valid batch that contains a single content field and generic metadata fields such as `content_encoding`, `content_type`, and `resourcename`. Since these are not normally the fields configured for the domain, you get errors stating that the fields don’t exist. Similarly, if you attempt to configure a domain from an invalid batch, Amazon CloudSearch responds with the content and meta-data fields instead of the fields in the batch.
First, make sure that the batch is valid XML or JSON. If it is, check for invalid document IDs and make sure you have specified the operation type for each document. For add operations, make sure that the type, ID, and at least one field are specified for each document. Delete operations only need to specify the type and ID. For more information about formatting your data, see Creating Document Batches (p. 54).

- **Document IDs with bad values**—A document ID can contain any letter or number and the following characters: _ - = # ; : / ? @ &. Document IDs must be at least 1 and no more than 128 characters long.
- **Multi-valued fields without a value**—when specifying document data in JSON, you cannot specify an empty array as the value of a field. Multi-valued fields must contain at least one value.
- **Bad characters**—one problem that can be difficult to detect if you do not filter your data while generating your document batch is that can contain characters that are invalid in XML. Both JSON and XML batches can contain only UTF-8 characters that are valid in XML. You can use a validation tool such as the JSON Validator or W3C Markup Validation Service to identify invalid characters.

### Deleting All Documents in an Amazon CloudSearch Domain

Amazon CloudSearch currently does not provide a mechanism for deleting all of the documents in a domain.

### Amazon CloudSearch Domain Not Scaling Down After Deleting Documents

If your domain has scaled up to accommodate your index size and you delete a large number of documents, the domain scales down the next time the full index is rebuilt. Although the index is automatically rebuilt periodically, to scale down as quickly as possible you can explicitly run indexing (p. 89) when you are done deleting documents.

### Document Update Latency

Sending a large volume of single-document batches can increase the amount of time it takes each document to become searchable. If you have a large amount of update traffic, you need to batch your updates. We recommend using a batch size close to the 5 MB limit. For more information, see Creating Document Batches (p. 54).

You can load up to 10,000 document batches per day (every 24 hours), with each batch size up to 5 MB. Loading more data per day significantly increases the latency of document updates. To mitigate this risk, you can increase your update capacity by selecting a larger instance type. For more information, see Configuring Scaling Options in Amazon CloudSearch (p. 36).

### Large Number of 5xx Errors When Uploading Documents to an Amazon CloudSearch Domain

If you parallelize uploads and your domain is on a search.small instance, you might experience an unacceptably high rate of 504 or 507 errors. Setting the desired instance type to a larger instance type will increase your update capacity and reduce the error rate. For more information about handling 5xx
Search Latency and Timeouts in Amazon CloudSearch

If you are experiencing slow response times, frequently encountering internal server errors (typically 507 or 509 errors), or seeing the number of instance hours your search domain is consuming increase without a substantial increase in the volume of data you're searching, fine-tuning your search requests to reduce the processing overhead can help. For more information, see Tuning Search Request Performance in Amazon CloudSearch (p. 108). Increasing the desired replication count can also speed up search request processing. For more information, see Configuring Scaling Options in Amazon CloudSearch (p. 36).

507 and 509 errors typically indicate that your search service is overloaded. This can be due to the volume or complexity of search requests that you are submitting. Amazon CloudSearch normally scales automatically to handle the load. Because it takes some time to deploy additional search instances, we recommend using an exponential backoff retry policy to temporarily reduce the request rate and minimize request failures. For more information, see Error Retries and Exponential Backoff.

Certain usage patterns, such as submitting complex search queries to a single small search instance, can sometimes result in timeouts without triggering automatic scaling. If you repeatedly experience a high error rate, you can explicitly request additional capacity through the Amazon CloudSearch Service Limit Request form.

Search Latency for Faceted Queries in Amazon CloudSearch

If you are bucketing facet information with the buckets option and experiencing slow query performance, try setting the buckets method to interval. For more information, see Bucketing Facet Information (p. 113).

Sudden Increase in 5xx Errors When Searching an Amazon CloudSearch Domain

If your search domain experiences a sudden spike in traffic, Amazon CloudSearch responds by adding search instances to your domain to handle the increased load. However, it takes a few minutes to set up the new instances. You are likely to see a temporary increase in 5xx errors until the new instances are ready to start processing requests. For more information about handling 5xx errors, see Handling Errors (p. 137). For information about pre-scaling your domain to handle an expected spike in search requests, see Configuring Scaling Options in Amazon CloudSearch (p. 36).

Indexing Failures after Updating Indexing Options in Amazon CloudSearch

If you make changes to a domain's index configuration, in certain cases you might encounter Failed to Validate errors when you run indexing. This means that the index field options you set are not compatible with the documents that are already in your index. Specifically, you changed the type of
an index field, and there are documents in your index that contain data that is incompatible with that
type. For example, this might happen if you change a literal field to an int field, and some of your
documents contain alphanumeric data in that field. When this happens, Amazon CloudSearch sets
the status of ALL fields that were being processed to the FailedToValidate state. Rolling back the
incompatible configuration change will enable you to successfully rebuild your index. If the change is
necessary, you must update or remove the incompatible documents from your index to use the new
configuration. If you can't identify the change that caused the error or need assistance identifying the
incompatible documents, contact support.

Domain Not Found When Submitting Amazon
CloudSearch Requests

You cannot access a 2013-01-01 domain with the 2011-02-01 command line tools or SDKs. Similarly,
you cannot access a 2011-02-01 domain with the 2013-01-01 command line tools or SDKs. Make sure
you are specifying the correct API version in your request and using the appropriate command line tools
or SDK.

Number of Searchable Documents Not Returned
with Domain Information

The aws cloudsearch describe-domains and DescribeDomains do not return the number of
searchable documents in the domain. To get the number of searchable documents, use the console or
submit a matchall request to your domain’s search endpoint.

```
q=matchall&q.parser=structured&size=0
```

Configuration Service Access Policies Not Working
in Amazon CloudSearch

If you have both 2011 and 2013 domains, have configured IAM policies for accessing the configuration
service, and are getting not authorized errors, note that the Amazon CloudSearch ARN is different for
the 2011-02-01 API and the 2013-01-01 API. To allow users to access both 2011 and 2013 domains, you
must allow access to both ARNs in the IAM policy. For example:

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudsearch:*",
      ],
      "Resource": "arn:aws:cloudsearch:*",
      "Resource": "arn:aws:cs:"
    }
  ]
}
```

If your 2011 policy granted access to particular domains or actions, you must include those restrictions
in your policy. Note that the only supported action for 2011 domains is cloudsearch: * and you might
encounter other errors when attempting to configure resource-level permissions for domains created with the 2011-01-01 API.

### Search and Document Service Access Policies Not Working in Amazon CloudSearch

If you have configured access policies for your domain's search and document service endpoints, but are getting the error `403 Request forbidden by administrative rules`, it is likely due to one of the following issues.

- Make sure the API version and resource name are specified in your requests. For example, to upload documents with the 2013-01-01 API, you must append `/2013-01-01/documents/batch` to your domain's document service endpoint:

  ```text
  doc-movies-123456789012.us-east-1.cloudsearch.amazonaws.com/2013-01-01/documents/batch
  ```

  To submit search requests using the 2013-01-01 API, you must append `/2013-01-01/search` to your domain's search endpoint:

  ```text
  search-movies-123456789012.us-east-1.cloudsearch.amazonaws.com/2013-01-01/search?q=star+wars&return=title
  ```

  To get suggestions using the 2013-01-01 API, you must append `/2013-01-01/suggest` to your domain's search endpoint:

  ```text
  search-movies-123456789012.us-east-1.cloudsearch.amazonaws.com/2013-01-01/suggest?q=kat&suggester=mysuggester
  ```

- If you are connecting from an EC2 instance, make sure the access policy specifies your EC2 instance's public IP address.

- If the machine you are connecting from is behind a router, make sure the access policy specifies your public facing IP address.

For more information, see [configure access policies](p. 27).

### Amazon CloudSearch Console Permissions Errors

To access the console, you must have permissions for the DescribeDomains action. Access to particular domains and actions might be restricted by the configured IAM access policies. In addition, uploading data from an Amazon S3 bucket or DynamoDB table requires access to those services and resources. For more information about Amazon CloudSearch access policies, see [configure access policies](p. 27).

### Using Wildcards to Search Text Fields Doesn't Produce Expected Results

When you submit a search request, the text you're searching for undergoes the same text processing so that it can be matched against the terms that appear in the index. However, no text analysis is performed
on the search term when you perform a prefix search. This means that a search for a prefix that ends in s typically won’t match the singular version of the term when stemming is enabled. This can happen for any term that ends in s, not just plurals. For example, if you search the actor field in the sample movie data for Anders, there are three matching movies. If you search for Andér*, you get those movies as well as several others. However, if you search for Anders* there are no matches. This is because the term is stored in the index as andér, anders does not appear in the index.

If stemming is preventing your wildcard searches from returning all of the relevant matches, you can suppress stemming for the text field by setting the AlgorithmicStemming option to none, or you can map the data to a literal field instead of a text field.

For more information about how Amazon CloudSearch processes text, see Text Processing in Amazon CloudSearch (p. 72).

Inconsistent Results When Using Cursors for Deep Paging

When you use a cursor to page through a result set that is sorted by document score (_score), you can get inconsistent results if the index is updated between requests. This can also occur if your domain’s replication count is greater than one, because updates are applied in an eventually consistent manner across the instances in the domain. If this is an issue, avoid sorting the results by score. You can either use the sort option to sort by a particular field, or use fq instead of q to specify your search criteria. (Document scores are not calculated for filter queries.)

Certificate Errors When Using an SDK

Because AWS SDKs use the CA certificates from your computer, changes to the certificates on the AWS servers can cause connection failures when you attempt to use an SDK. Error messages vary, but typically contain the following text:

SSL3_GET_SERVER_CERTIFICATE:certificate verify failed

You can prevent these failures by keeping your computer’s CA certificates and operating system up-to-date. If you encounter this issue in a corporate environment and do not manage your own computer, you might need to ask an administrator to assist with the update process.

The following list shows minimum operating system and Java versions:

- Microsoft Windows versions that have updates from January 2005 or later installed contain at least one of the required CAs in their trust list.
- Mac OS X 10.4 with Java for Mac OS X 10.4 Release 5 (February 2007), Mac OS X 10.5 (October 2007), and later versions contain at least one of the required CAs in their trust list.
- Red Hat Enterprise Linux 5 (March 2007), 6, and 7 and CentOS 5, 6, and 7 all contain at least one of the required CAs in their default trusted CA list.
- Java 1.4.2_12 (May 2006), 5 Update 2 (March 2005), and all later versions, including Java 6 (December 2006), 7, and 8, contain at least one of the required CAs in their default trusted CA list.

The three certificate authorities are:

- Amazon Root CA 1
- Starfield Services Root Certificate Authority - G2
• Starfield Class 2 Certification Authority

Root certificates from the first two authorities are available from Amazon Trust Services, but keeping your computer up-to-date is the more straightforward solution. To learn more about ACM-provided certificates, see AWS Certificate Manager FAQs.

**Note**
These certificates are not yet required, but are scheduled for deployment to the AWS servers in November 2017.
## Understanding Amazon CloudSearch Limits

This table shows naming and size restrictions within Amazon CloudSearch. You can submit a request if you need to increase the maximum number of partitions for a search domain. For information about increasing other limits such as the maximum number of search domains, contact Amazon CloudSearch.

The current Amazon CloudSearch limits are summarized in the following table.

<table>
<thead>
<tr>
<th>Item</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Batch size</strong></td>
<td>The maximum batch size is 5 MB.</td>
</tr>
<tr>
<td><strong>Data loading volume</strong></td>
<td>You can load one document batch every 10 seconds (approximately 10,000 batches every 24 hours), with each batch size up to 5 MB.</td>
</tr>
<tr>
<td></td>
<td>Exceeding this limit significantly increases the latency of document updates and could result in throttling. To mitigate this risk, you can increase your update capacity by selecting a larger instance type. For more information, see Creating Document Batches (p. 54).</td>
</tr>
<tr>
<td><strong>Document size</strong></td>
<td>The maximum document size is 1 MB.</td>
</tr>
<tr>
<td><strong>Document fields</strong></td>
<td>Documents can have no more than 200 fields.</td>
</tr>
<tr>
<td><strong>Expressions</strong></td>
<td>• Up to 50 expressions can be configured for a domain.</td>
</tr>
<tr>
<td></td>
<td>• The maximum size of an expression is 10240 bytes.</td>
</tr>
<tr>
<td></td>
<td>• The maximum value that can be returned by an expression is max(int64_t).</td>
</tr>
<tr>
<td><strong>Highlighting</strong></td>
<td>• The maximum number of occurrences of the search term(s) that can be highlighted is 5.</td>
</tr>
<tr>
<td></td>
<td>• Highlights are only returned for the first 10 KB of data in a text field.</td>
</tr>
<tr>
<td><strong>Index fields</strong></td>
<td>• Up to 200 index fields can be configured for a domain. A dynamic field counts as one index field, but typically matches multiple document fields. Dynamic fields can cause the total number of fields in your index to exceed 200. If you use dynamic fields, keep the number of index fields below 1,000 to avoid performance issues.</td>
</tr>
<tr>
<td></td>
<td>• Up to 1000 values can be specified in a field.</td>
</tr>
<tr>
<td>Item</td>
<td>Limit</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>• Up to 20 sources can be specified for an array-type field.</td>
</tr>
<tr>
<td></td>
<td>• The maximum size of a literal field is 4096 UTF-8 code points.</td>
</tr>
<tr>
<td></td>
<td>• The maximum size of a default value for a field is 1 KB.</td>
</tr>
<tr>
<td></td>
<td>• An int field can contain values from -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807 (inclusive).</td>
</tr>
<tr>
<td></td>
<td>• Individual terms within a text or text-array field are treated as stopwords if they exceed 256 characters.</td>
</tr>
<tr>
<td>Naming conventions</td>
<td>• Domain Names: Allowed characters are a-z (lower-case letters), 0-9, and hyphen (-). Domain names must start with a letter or number and be at least 3 and no more than 28 characters long.</td>
</tr>
<tr>
<td></td>
<td>• Field Names: Allowed characters are a-z (lower-case letters), 0-9, and _ (underscore). Field names must begin with a letter and be at least 1 and no more than 64 characters long. The name _score is reserved and cannot be used as a field name.</td>
</tr>
<tr>
<td></td>
<td>• Expression Names: Allowed characters are a-z (lower-case letters), 0-9, and _ (underscore). Expression names must begin with a letter and be at least 3 and no more than 64 characters long. The name _score is reserved and cannot be used as an expression name.</td>
</tr>
<tr>
<td></td>
<td>• Document IDs: A document ID (_id) can contain any letter or number and the following characters: _ - = # ; : / ? @ &amp;. Document IDs must be at least 1 and no more than 128 characters long.</td>
</tr>
<tr>
<td>Policy document size</td>
<td>The maximum size of an Amazon CloudSearch policy document is 100 KB.</td>
</tr>
<tr>
<td>Region restriction</td>
<td>The ap-northeast-2 region supports only m4 instance types.</td>
</tr>
<tr>
<td>_score</td>
<td>A document's text relevance score is a positive floating point value.</td>
</tr>
<tr>
<td>Search domains</td>
<td>Each AWS account can create up to 100 search domains.</td>
</tr>
<tr>
<td>Search partitions</td>
<td>A search index can be split across a maximum of 10 partitions. You can <a href="https://aws.amazon.com/premiumsupport/">submit a request</a> if you need to increase this limit.</td>
</tr>
<tr>
<td></td>
<td>To avoid search query failures, Amazon CloudSearch domains can grow beyond this maximum partition limit, but new document additions are rejected. If you encounter this scenario, delete documents and trigger the <code>IndexDocuments</code> API. Alternately, request a limit increase.</td>
</tr>
<tr>
<td></td>
<td>You can monitor the Amazon CloudWatch <code>IndexUtilization</code> and <code>Partitions</code> metrics to take action before exceeding the maximum partition limit.</td>
</tr>
<tr>
<td>Item</td>
<td>Limit</td>
</tr>
<tr>
<td>----------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>Search replicas</td>
<td>Each search partition can have up to 5 replicas.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td>Enabling Multi-AZ doubles the number of replicas.</td>
</tr>
<tr>
<td>Search requests</td>
<td>• compound queries: Can contain a maximum of 1024 clauses.</td>
</tr>
<tr>
<td></td>
<td>• GET requests: The maximum size of a search request submitted as an HTTP GET request is 8190 bytes.</td>
</tr>
<tr>
<td></td>
<td>• facet parameter: The maximum number of facet values you can return is 10,000.</td>
</tr>
<tr>
<td></td>
<td>• size parameter: Can contain values in the range 0 - 10000. The sum of the size and start parameters cannot exceed 10,000. If you need to page through more than 10,000 hits, use a cursor.</td>
</tr>
<tr>
<td></td>
<td>• sort parameter: Can contain up to 10 int fields and expressions.</td>
</tr>
<tr>
<td></td>
<td>• start parameter: Can contain values in the range 0 - 10000. The sum of the size and start parameters cannot exceed 10,000. If you need to page through more than 10,000 hits, use a cursor.</td>
</tr>
<tr>
<td>Suggesters</td>
<td>• You can define a maximum of 10 suggesters for a domain.</td>
</tr>
<tr>
<td></td>
<td>• Only the first 512 bytes of a text field are used to generate suggestions.</td>
</tr>
<tr>
<td></td>
<td>• The scores computed from a suggester's SortExpression are rounded to the nearest integer, with a floor of 0 and a ceiling of $2^{31}-1$.</td>
</tr>
<tr>
<td>Synonym dictionary size</td>
<td>The maximum size of a Amazon CloudSearch synonym dictionary is 100 KB.</td>
</tr>

# Amazon CloudSearch Resources

The following table lists resources that you might find useful as you work with Amazon CloudSearch.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AWS SDKs</strong></td>
<td>Most of the <a href="https://aws.amazon.com/sdk/">AWS SDKs</a> support Amazon CloudSearch, including the Java, .NET, Node.js, PHP, Python, and Ruby SDKs.</td>
</tr>
<tr>
<td><strong>Amazon CloudSearch Sample Data</strong></td>
<td>Download the <a href="https://www.imdb.com/interfaces/">IMDb Sample Data</a> to get a search domain up and running quickly with the command line tools or Configuration Service API and see how to format your own data for Amazon CloudSearch.</td>
</tr>
<tr>
<td><strong>Amazon CloudSearch Discussion Forum</strong></td>
<td>The forum where Amazon CloudSearch users can post questions and discuss various Amazon CloudSearch topics.</td>
</tr>
<tr>
<td><strong>Amazon CloudSearch Pricing</strong></td>
<td>Pricing information for Amazon CloudSearch.</td>
</tr>
<tr>
<td><strong>Request to Increase Limits</strong></td>
<td>The form to request an increase in the maximum number of search instances or partitions for a search domain.</td>
</tr>
<tr>
<td><strong>Amazon CloudSearch 2011-02-01 Developer Guide</strong></td>
<td>The 2011-02-01 Amazon CloudSearch Developer Guide is available in PDF only: <a href="https://aws.amazon.com/s3/">Download PDF</a>.</td>

# Document History for Amazon CloudSearch

This topic describes important changes to Amazon CloudSearch.

## Relevant Dates to this History:

- **Current product version**—2013-01-01
- **Latest product release**—6 January 2021
- **Latest documentation update**—6 January 2021

<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Release Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>New instance types</td>
<td>Amazon CloudSearch now uses newer instance types for new domains. These instance types provide a more intuitive scaling progression and better performance at the same price.</td>
<td>6 January 2021</td>
</tr>
<tr>
<td>Enforce HTTPS</td>
<td>You can now require that all requests to your Amazon CloudSearch domain arrive over HTTPS. To learn more, see the section called “Configuring Domain Endpoint Options” (p. 41).</td>
<td>13 November 2019</td>
</tr>
<tr>
<td>Support for resource tagging</td>
<td>Amazon CloudSearch added support for resource tagging. For more information, see Tagging Amazon CloudSearch Domains (p. 52) in this service guide.</td>
<td>10 February 2016</td>
</tr>
<tr>
<td>AP (Seoul) support</td>
<td>Amazon CloudSearch added support for the AP (Seoul) ap-northeast-2 region. For a list of regions supported by Amazon CloudSearch, see AWS Regions and Endpoints in the AWS General Reference.</td>
<td>28 January 2016</td>
</tr>
<tr>
<td>Integration with Amazon CloudWatch and support for index field statistics</td>
<td>You can now use Amazon CloudWatch to monitor your Amazon CloudSearch domains. CloudWatch is a monitoring service for AWS cloud resources and the applications you run on AWS. Amazon CloudSearch automatically sends metrics to CloudWatch so that you can gather and analyze performance statistics. You can monitor these metrics by using the Amazon CloudSearch console, or by using the CloudWatch console, AWS CLI, or AWS SDKs. There is no charge for the Amazon CloudSearch metrics that are reported through CloudWatch. For more information about using CloudWatch to monitor search domains, see Monitoring a Domain with Amazon CloudWatch (p. 46). You also can now retrieve statistics against facet-enabled numeric fields. Amazon CloudSearch can return the following statistics against indexed numeric fields in the documents: count, min, max, mean, missing, stddev, sum, and sumOfSquares. To learn more about index field statistics, see Querying For More Information (p. 110).</td>
<td>5 March 2015</td>
</tr>
<tr>
<td>Support for M3 instance types</td>
<td>You can now use M3 instances to power your Amazon CloudSearch domains. Amazon CloudSearch now supports</td>
<td>10 February 2015</td>
</tr>
<tr>

</tr>
<tr>
<td>-------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Support for Dynamic Fields</td>
<td>Dynamic fields provide a way to index documents without knowing in advance exactly what fields they contain. A dynamic field's name defines a pattern that contains a wildcard (*) as the first, last, or only character. Any unrecognized document field that matches the pattern is configured with the dynamic field's indexing options. For more information, see Using Dynamic Fields in Amazon CloudSearch (p. 61).</td>
<td>11 December 2014</td>
</tr>
<tr>
<td>Enhanced Japanese Language Processing and CloudTrail Support</td>
<td>You can now control how Amazon CloudSearch tokenizes Japanese by adding a custom Japanese tokenization dictionary to the analysis scheme that you use for fields that contain Japanese. Configuring a custom tokenization dictionary can improve search result accuracy by facilitating indexing and retrieval of domain-specific phrases. To learn more about using custom dictionaries, see Customizing Japanese Tokenization (p. 69). You can also index bigrams for Chinese, Japanese, and Korean. For more information, see Indexing Bigrams for Chinese, Japanese, and Korean (p. 68). You can also now use AWS CloudTrail to get a history of Amazon CloudSearch configuration API calls and related events for your account. CloudTrail is a web service that records your account’s API calls and delivers the resulting log files to your Amazon S3 bucket. You can also use CloudTrail to track changes that were made to your AWS resources. For example, you can use the API call history to perform a security analysis or troubleshoot operational issues. CloudTrail also makes it easier for you to demonstrate compliance with internal policies or regulatory standards. For more information, see the Security at Scale: Logging in AWS whitepaper. For more information about using CloudTrail to log Amazon CloudSearch calls, see Logging Amazon CloudSearch Configuration API Calls with AWS CloudTrail (p. 48).</td>
<td>15 October 2014</td>
</tr>
<tr>
<td>Documentation Update</td>
<td>This update clarifies that you must URL-encode search query strings and provides additional information about getting facet information for selected buckets. For more information about bucketing facets, see Getting Facet Information (p. 112).</td>
<td>19 September 2014</td>
</tr>
</tbody>
</table>
### Change | Description | Release Date
--- | --- | ---
Enhanced IAM Integration | You can now use IAM to control access to each domain’s document, search, and suggest services and use AWS Signature Version 4 to sign all Amazon CloudSearch requests. Requests are signed automatically when you use the latest AWS SDKs and the AWS CLI. For more information, see [configure access policies](p. 27). In conjunction with this release, there is an update of the Amazon CloudSearch command line tools. The updated CLTs now automatically sign document upload requests submitted through the `cs-import-documents` command. You can download the new CLT bundle from the [Amazon CloudSearch developer tools page](#). **Important** This CLT update contains just two commands: `cs-import-documents` and `cs-configure-from-batches`. All configuration actions should be performed using the AWS CLI. The AWS CLI also supports uploading documents and submitting search and suggest requests. For more information, see the [AWS Command Line Interface User Guide](#). | 14 August 2014 |
Enhanced Amazon CloudSearch Support in the AWS SDKs and AWS CLI | The AWS SDKs and AWS CLI now provide full support for all Amazon CloudSearch 2013-01-01 API operations, including creating, configuring, and managing search domains, uploading documents, and submitting search requests. For information about installing and using the AWS CLI, see the [AWS Command Line Interface User Guide](#). **Note** To generate document batches and automatically configure indexing options based on the contents of a batch, you still need to use the standalone Amazon CloudSearch command line tools. | 26 June 2014 |
Hebrew Language Support and Desired Partition Count Scaling Option | Amazon CloudSearch now supports Hebrew in addition to the 33 other [Supported Languages](p. 73). This update also adds a new scaling option, desired partition count. You can use this option to preconfigure the number of index partitions for a domain that uses the m2.2xlarge search instance type. If you have a large amount of search data, preconfiguring a domain to use more partitions can enable you to load data faster. You can also configure a domain with additional partitions to drop the per-partition document count and speed up complex queries. Amazon CloudSearch will still scale the domain up or down based on the volume of data or traffic, but the number of partitions will never drop below your desired partition count. For more information, see [Configuring Scaling Options in Amazon CloudSearch](p. 36). | 24 March 2014 |

</tr>
</thead>
<tbody>
<tr>
<td>Amazon CloudSearch</td>
<td>Amazon CloudSearch has a new API version with many improvements and new features. The new API is not backward-compatible with the 2011-02-01 API. To use the new features, you must create a new search domain with the 2013-01-01 API. In conjunction with this release, there is also a new set of command line tools. Note that the new tools require a Java 7 compatible JRE, so you might need to update Java to use the tools.</td>
