Designing a data lake for growth and scale on the AWS Cloud

Wei Shao, Amazon Web Services (AWS)

October 2021 (document history)

Organizations are increasingly designing and building data lakes on the Amazon Web Services (AWS) Cloud as part of their data modernization strategy. Data lakes can be repositories that store your structured and unstructured data at any scale and make it available to a wide range of internal and external users.

However, it can take significant time and effort to ingest data into data lakes that serve your growing business use cases. To help reduce costs and maximize the value that is generated from the data, many organizations plan a one-time ingestion of data into their data lake and then consume this data multiple times. Designing a data lake architecture that scales with data production, sharing, and consumption is critical for delivering value to business stakeholders when your data lake grows.

A scalable data lake architecture provides your organization with a solid foundation to gain value from your data lake while bringing more data into it. By continuously gaining data insights without being slowed down or interrupted because of scalability constraints, a scalable data lake also helps your organization remain competitive.

Typically, a data lake has data producers and data consumers. Data producers create data assets by collecting, processing, and storing data from their data domain. These collective data assets form the content of your data lake. Data producers can choose to selectively share their data assets with the data lake's data consumers.

Data consumers need the data from the data producers to fulfill their business use cases and can also occasionally combine this data with their own data. Data producers and data consumers are typically, but not always, part of your organization. Importantly, they can both be data producers or data consumers at the same time.

A scalable data lake architecture helps you to achieve the following outcomes:

- Onboard data producers at scale without requiring them to maintain the entire data sharing process. This helps data producers onboard their data into the data lake and focus on collecting, processing, and storing data from their data domain.
• Enable data consumers to access data from multiple data producers without increasing your overall costs and management overhead.

This guide describes the common scaling challenges that can occur when organizations grow their data lake, provides a data lake reference architecture, and outlines approaches for onboarding and granting access to data producers and data consumers. The data lake reference architecture in this guide leverages the different features and capabilities provided by AWS Lake Formation. The guide is intended for teams that are responsible for designing data lakes on the AWS Cloud, including enterprise data architects, data platform architects, designers, or data domain leads.

**Targeted business outcomes**

You should expect the following three outcomes after designing a data lake for growth and scale on the AWS Cloud:

• Lower data sharing and data consumption overheads across multiple lines of business in your organization.
• A secure and consistent approach that helps your organization include external data producers and share data with them in your data lake.
• Continuously gain data insights without being slowed down or interrupted because of scalability constraints.
Common scaling challenges

A data lake goes through several stages when its data grows after the initial deployment. If you didn't use scalable architecture to design your data lake, your organization might encounter challenges and can be disadvantaged by the data lake's growth.

The following sections explain how a typical data lake's growth can cause scaling challenges.

Initial data lake deployment

The following diagram shows a data lake's architecture after its initial deployment by Line of business A.

The diagram shows the following components:

- The data producer account collects and processes data, stores the processed data, and prepares it for consumption.
- Data in the data producer account is stored in Amazon Simple Storage Service (Amazon S3) buckets, which can have multiple data layers.
- You can use AWS services for data processing (for example, AWS Glue and Amazon EMR).
- The data producer not only produces and stores data in the data lake but then also needs to decide what data to share with a data consumer and how to share it. AWS Lake Formation manages the data lake in the data producer account, in addition to managing cross-account data sharing from the data producer to the data consumer.

- The data consumer account consumes shared data from the data producer account for specific business use cases.

Data consumers increase

The following diagram shows that more data is brought into the data lake when Line of business A's data grows. The data lake then attracts more data consumers to leverage and gain value from the data.

The diagram shows how an organization generates nearly continuous value from an existing data asset and that this attracts more data consumers. However, when data consumers increase, the data producer only has the following two options to accommodate this growth:

- Manually manage data sharing and access by individual data consumers, which is not a scalable approach.
• Develop an automated or semi-automated process for data sharing and managing data access. Although this could be a scalable option, it requires significant time and effort to design and build because internal and external data consumers have different security control requirements. In the future, additional time and effort would also be required for any solution improvements.

**Data producers increase**

The following diagram shows the data lake architecture when multiple lines of business join as data producers.

The data lake's architecture becomes increasingly complicated, even with only three data producers and three data consumers.

Each data producer needs to handle data sharing and data access management for multiple data consumers. It is unrealistic to expect all data producers to develop an automated or semi-automated process for data sharing and data access management. Some data producers might choose to not share their data and therefore avoid unaffordable management overhead. Similarly, each data consumer needs to interact with multiple data producers to understand their different data consumption processes. This means that individual data consumers face increasing management overhead for handling different data-sharing patterns.
In many organizations, this data lake causes bottlenecks and cannot grow or scale. This might mean that your organization must redesign and rebuild its data lake to remove the bottleneck, which can cost significant time, resources, and money.
Reference architecture

The following diagram shows this guide's reference architecture for growing and scaling a data lake on the AWS Cloud.

The diagram shows the following components:

1. A data producer layer in different AWS accounts.
2. A data consumer layer in different AWS accounts.
3. A centralized catalog in an AWS account.
4. Although each line of business only has one data producer and one data consumer, the guide's reference architecture supports multiple data producers and data consumers for each line of business. It's typical to onboard one data producer with one or multiple data consumers that include both data-serving and application types. For more information about this, see the Reference architecture components section of this guide.
5. The centralized catalog is the interface used by data producers and data consumers to share and consume data.
The reference architecture's approach makes it possible to standardize data sharing and consumption, and independently scale data producers and data consumers without growing your management overhead. The reference architecture also enables data production and distribution across different data producers. Any data producer can be part of the data lake, share their data, and contribute to the overall value provided by the data lake.

This approach enables your organization to harvest data value throughout your lines of business and external data owners, without causing a bottleneck by constraining data collection and processing in a single pipeline.
Reference architecture components

The following diagram shows the three components of this guide's reference architecture: data producers, data consumers, and the centralized catalog.

The diagram shows the following components:

1. A data producer account.
2. A centralized catalog.
3. Two data consumer accounts, which include data-serving and application types.

**Note**

The diagram shows only one data producer and two data consumers, but this guide's reference architecture supports multiple data producers and data consumers when the data lake grows.
Understanding each component helps your organization to implement reusable patterns and scale your data lake by independently and consistently onboarding new data producers and data consumers.

The following sections discuss the reference architecture's components:

- **Data producers**
- **Centralized catalog**
- **Data consumers**

### Data producers

A data producer collects, processes, and stores data from their data domain, in addition to monitoring and ensuring the quality of their data assets. The following diagram shows the data producer account as a component of this guide's reference architecture.
Each data producer has a private Data Catalog managed by AWS Lake Formation in their AWS account that is used by their internal data process. Data producers provide the centralized catalog with selective permissions to their data, which means that Lake Formation in the centralized catalog account can access data that the data producer wants to share.

This means that data producers don't directly interact with data consumers. Instead, the data producer account and its data storage location are completely abstracted and hidden from the data consumer. This approach reduces costs by removing unnecessary overhead for data producers that experience an increase in their data consumers.
A change to the data producer's data location doesn't impact the data consumer if the new data location is registered by the centralized catalog. If the data producer wants to stop sharing a particular piece of data, they can remove the centralized catalog's permissions. This prevents data consumers from accessing the data and removes the need to manually revoke access for each data consumer.

By using public and private data catalogs, data producers can choose what to share with data consumers, while independently managing internal data access through a private data catalog.

The following table describes the two AWS services that data producers use to share data with the centralized catalog.

<table>
<thead>
<tr>
<th>Service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Amazon Simple Storage Service (Amazon S3)</strong></td>
<td>Adjust the bucket policy for S3 buckets to provide data access to the AWS Identity and Access Management (IAM) roles in the centralized catalog. Data producers can also share data stored in other data applications or services by using Amazon S3 as the intermediate data layer.</td>
</tr>
<tr>
<td><strong>AWS Key Management Service (AWS KMS)</strong></td>
<td>Provide permissions for the AWS managed keys to the IAM roles in the centralized catalog and the AWS KMS keys used to encrypt the shared Amazon S3 data in the data producer accounts.</td>
</tr>
</tbody>
</table>

**Centralized catalog**

The following diagram shows how the centralized catalog connects data producers and data consumers in the data lake.
The centralized catalog stores and manages the shared data catalog for the data producer accounts. The centralized catalog also hosts the shared data's technical metadata (for example, table name and schema) and is the location where data consumers come to access data.

Data consumers can access data from multiple data producers in the centralized catalog and can then mix this data with their own data for further processing. Using a centralized catalog removes the need for data consumers to directly connect with different data producers and reduces operational overhead.

Because the centralized catalog has visibility into data sharing and data consumption by data producers and consumers, it can be an ideal location to apply your centralized data governance functions (for example, access auditing).

The following sections describe how the centralized catalog uses AWS Lake Formation and AWS Glue.

**AWS Lake Formation**

*AWS Lake Formation* helps create databases in an AWS Glue Data Catalog that point to the locations of multiple data producers in your data lake. An AWS Identity and Access Management (IAM) role is created for Lake Formation in the centralized catalog. By using Lake Formation, the centralized catalog can selectively share data resources (for example, database, tables, or columns) with data consumers. The Lake Formation managed resources are shared with data consumers by using one of the following two methods:
• **Named resource method** – This method shares managed resources across accounts. Databases, tables, or column names must be specified and a resource can be shared to an organization, organizational unit (OU), or AWS account. To reduce the sharing and management overhead, we recommend that you share resources at higher levels where possible (for example, in an organization or OU instead of an AWS account). However, you must make sure that this approach meets your organization’s data security control requirements.

• **Note**: This method works well for data consumers with an application type, where AWS services consume data from the data producer. The data access requirement from this type of data consumer is application-driven, prescriptive, and relatively static.

• **Lake Formation tag-based access control (LF-TBAC) method** – LF-TBAC is particularly useful for data consumers with a data-serving type. However, Lake Formation tagged resources can currently only be shared at the AWS account level and not at the organization or OU level.

**AWS Glue**

You must create databases in AWS Glue for each data producer in your centralized catalog. Because the centralized catalog uses AWS Glue to host databases from all data producers, you must make sure that the database name is unique across all data producers and that it reflects the data producer and their type of data. For example, you can use the following database naming structure: `<Data_Producer>-<Environment>-<Data_Group>`

- `<Data_Producer>` – The data producer’s name.
- `<Environment>` – The data lake environment, such as dev for a development environment, sit for a system integration test environment, or prod for a production environment.
- `<Data_Group>` – The name of the data group that is used to separate data from a data producer into logical groups. You can use the source system name, ID, or abbreviation as the name. A database description also helps to describe the content and purpose of the database.

You can use an AWS Glue crawler on the data producer’s data to maintain its schema in the centralized catalog’s database. If data is regularly created on the same frequency by a data producer, you can use a single AWS Glue crawler. In all other cases, you should use multiple AWS Glue crawlers to accommodate different crawling frequencies. Depending on your business use case, the crawler can either be scheduled for a predefined frequency or initiated by events.

You can also maintain table schema in AWS Glue by calling the AWS Glue API to create or update the schema. Although this can provide flexibility, additional effort is required for code development.
and maintenance. Make sure that you evaluate the use case and business value and then choose the option that meets your requirements and has the least overhead.

**Data consumers**

Data consumers consume the data from the data producer after the centralized catalog shares it using AWS Lake Formation. The following diagram shows two data consumers in the data lake.

![Diagram showing data consumers](image)

There are two types of data consumer: *application* and *data-serving*. The following table describes these two types.

| **Application type** | Application data consumers run applications in their own AWS accounts. The applications consume the AWS Identity and Access Management (IAM) roles to access the shared data from a data producer and then process it according to their logic.

Typically, this type of data consumer has prescriptive data requirements to fulfill an application's needs. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Data-serving type</strong></td>
<td>Data-serving data consumers are typically meant for individuals (for example, data...</td>
</tr>
</tbody>
</table>
Multiple data-serving data consumers can exist in one organization’s data lake. For example, different lines of business might choose to set up their own data-serving data consumers to help users consume data from the data lake. These data consumers have their own IAM role principals configured in their AWS account (for example, IAM roles associated with AWS IAM Identity Center) that are used by end users in the data consumer account to access shared data through AWS services (for example, Amazon Athena).

Typically, this type of data consumer has wide-ranging and continuously increasing data requirements.

AWS Lake Formation is the most important AWS service used by a data consumer for cross-account data sharing and accessing the centralized catalog. After databases are shared by the centralized catalog, the shared resources are available in Lake Formation in the data consumer account. Data access can then be granted to local IAM principals in the data consumer account, with permission from the data producer, if required. The shared data can then be used by AWS services integrated with Lake Formation (for example, Amazon Athena and AWS Glue). You can use the following AWS services to access shared data in the data consumer account:

- **Amazon Athena** is an interactive query service that helps directly analyze data in Amazon Simple Storage Service (Amazon S3) using standard SQL. For more information about Athena and Lake Formation, see How Athena accesses data registered with Lake Formation in the Amazon Athena documentation.

- **Amazon Redshift Spectrum** helps you to efficiently query and retrieve structured and semi-structured data from files in Amazon S3 without having to load the data into Amazon Redshift tables. For more information about Redshift Spectrum and Lake Formation, see Using Redshift Spectrum with Lake Formation in the Amazon Redshift documentation.
• **AWS Glue** is a fully managed extract, transform, and load (ETL) service that makes it simple and cost-effective to categorize your data, clean it, enrich it, and move it reliably between different data stores and data streams. An AWS Glue ETL job’s associated IAM role can access the data lake data managed by Lake Formation if it has the required access permissions.

• **Amazon EMR** helps run big data frameworks (for example, [Apache Hadoop](https://hadoop.apache.org) and [Apache Spark](https://spark.apache.org)) to process and analyze large amounts of data. For more information about Amazon EMR and Lake Formation, see [Integrate Amazon EMR with Lake Formation](https://docs.aws.amazon.com/emr/latest/UG/integrate-lake-formation.html) in the Amazon EMR documentation.

• **Amazon QuickSight** is a scalable, serverless, embeddable, and machine learning (ML)-powered business intelligence service that you can use to analyze and visualize data from your data lake. For more information about Amazon QuickSight and Lake Formation, see [Authorizing connections through Lake Formation](https://docs.aws.amazon.com/quicksight/latest/userguide/lake-formation.html) in the Amazon QuickSight documentation.

• **Amazon SageMaker Data Wrangler (Data Wrangler)** reduces the time it takes to aggregate and prepare data for ML. For more information about Data Wrangler and Lake Formation, see [Prepare ML Data with Amazon SageMaker Data Wrangler](https://docs.aws.amazon.com/sagemaker/latest/dg/feature-data-wrangler.html) in the Amazon SageMaker documentation.
Onboarding and granting access

This guide's data lake reference architecture helps you to independently scale data producers and data consumers, in addition to defining and establishing a consistent process for onboarding and granting access to those data consumers.

The following sections describe the onboarding process for data producers and data consumers and how to grant access in a data consumer account. This guide uses the **named resource method** between the centralized catalog and data consumers. The process for the **LF-TBAC method** is similar but slightly different. We recommend that you evaluate and configure these approaches to meet your organization's data governance practices and policies.

For more information about these two methods, see the **Centralized catalog** section of this guide.

Onboarding data producers

The following diagram shows how to onboard a new data producer to your data lake.

<table>
<thead>
<tr>
<th>Data producer</th>
<th>Centralized catalog</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Diagram" /></td>
<td></td>
</tr>
</tbody>
</table>

The diagram shows the following onboarding process:

1. The data producer selectively provides the centralized catalog with access to its data (for example, an Amazon Simple Storage Service (Amazon S3) bucket and AWS KMS key). Access is provided to the centralized catalog's AWS Identity and Access Management (IAM) principals to register the data producer's data lake location in AWS Lake Formation and the IAM principals used to maintain the data producer's catalog.
2. Register the data producer's data lake location (for example, an S3 bucket) that uses the centralized catalog's Lake Formation.
3. Create the database, tables, and table schemas for the new data from the data producer in the AWS Glue Data Catalog.
Onboarding data consumers

The following diagram shows how to onboard a new data consumer to your data lake.

1. The data consumer requests approval to view the data producer's data and specifies the data that it needs to access.

2. The data producer's data steward reviews the request from the data consumer and evaluates whether to:
   - Share some or all tables in the requested databases. We recommend database-level sharing when there are no data security implications of sharing all tables with the data consumer, which helps avoid the management overhead of table-level sharing.
   - Share at the data consumer's organization, OU, or account level.

3. When approved by the data producer, the required Data Catalog resources are shared with the data consumer in the centralized catalog.

4. Resource links can be created in the data consumer's account by using Lake Formation and then point to the shared Data Catalog resources in the centralized catalog.

After the onboarding process is complete, the data consumer's Lake Formation administrator can see the database catalog resource from the centralized catalog and the resource link. At this stage, no one else in the data consumer's account can access the data producer's data.
Grant Select access in a data consumer account

The following diagram shows the process for granting Select access to shared data resources with a local IAM principal in the data consumer account. The local IAM principal can be the IAM role for individual users or an IAM role that is consumed by specific AWS services.

### Note

When the data being shared is of low sensitivity, you can delegate access granting to the data consumer itself without requiring approval from the data producer. This is because trust and sharing are already established between them.

The diagram shows the following process:

1. The individual IAM principal in the data consumer account requests Select access to the resource link from the IAM principal in the data consumer account.
2. The data producer’s data steward reviews the request from the data consumer and provides approval if all requirements are met.
3. Select access is granted and this allows the IAM principal to consume the requested data.
FAQ

This section provides answers to commonly raised questions about designing a data lake for growth and scale on the AWS Cloud.

Is this data lake reference architecture more applicable to enterprise organizations?

This guide's data lake reference architecture can be applied to data lakes belonging to organizations of any size. The reference architecture standardizes the data exchange interface, lowers the overhead and cost to maintain and grow the data lake, and can be applied to any scale that your organization's data lake grows to.

Can I still use this reference architecture if my organization only has one data producer?

This guide's data lake reference architecture is still relevant and beneficial even if your organization only has one data producer. Without the centralized catalog, your data producer has to handle the growth of data consumers, which adds increasing complexity and overhead. Your data lake is also a long-term asset for your organization and typically organizations add more data producers. For example, you might need an additional data producer to store sensitive data for compliance reasons or because your organization acquires another business unit that has its own data producer.

My data lake directly connects one data producer with multiple data consumers. Is this guide's data lake reference architecture still relevant?

The data lake reference architecture would benefit your organization in the long term. You could use a two-step approach and begin by building the centralized catalog for new data consumers. You could then connect your existing data consumers to the centralized catalog.
Should my organization follow the onboarding and access granting workflow without making changes to it?

No, the main purpose of that section is to illustrate the logical activity blocks required during the onboarding process. All organizations should customize the process and might even have multiple processes, depending on the sensitivity of their data.

Another consideration is that the process flow uses the resource-based sharing approach in AWS Lake Formation. There are other data-sharing methods supported by Lake Formation, such as tag-based sharing, where differences in the process can be tailored for the specific sharing method.

AWS Prescriptive Guidance glossary

The following are commonly used terms in strategies, guides, and patterns provided by AWS Prescriptive Guidance. To suggest entries, please use the Provide feedback link at the end of the glossary.

Numbers

7 Rs

Seven common migration strategies for moving applications to the cloud. These strategies build upon the 5 Rs that Gartner identified in 2011 and consist of the following:

- Refactor/re-architect – Move an application and modify its architecture by taking full advantage of cloud-native features to improve agility, performance, and scalability. This typically involves porting the operating system and database. Example: Migrate your on-premises Oracle database to the Amazon Aurora PostgreSQL-Compatible Edition.
- Replatform (lift and reshape) – Move an application to the cloud, and introduce some level of optimization to take advantage of cloud capabilities. Example: Migrate your on-premises Oracle database to Amazon Relational Database Service (Amazon RDS) for Oracle in the AWS Cloud.
- Repurchase (drop and shop) – Switch to a different product, typically by moving from a traditional license to a SaaS model. Example: Migrate your customer relationship management (CRM) system to Salesforce.com.
- Rehost (lift and shift) – Move an application to the cloud without making any changes to take advantage of cloud capabilities. Example: Migrate your on-premises Oracle database to Oracle on an EC2 instance in the AWS Cloud.
- Relocate (hypervisor-level lift and shift) – Move infrastructure to the cloud without purchasing new hardware, rewriting applications, or modifying your existing operations. You migrate servers from an on-premises platform to a cloud service for the same platform. Example: Migrate a Microsoft Hyper-V application to AWS.
- Retain (revisit) – Keep applications in your source environment. These might include applications that require major refactoring, and you want to postpone that work until a later time, and legacy applications that you want to retain, because there’s no business justification for migrating them.
• Retire – Decommission or remove applications that are no longer needed in your source environment.

ABAC

See attribute-based access control.

abstracted services

See managed services.

ACID

See atomicity, consistency, isolation, durability.

active-active migration

A database migration method in which the source and target databases are kept in sync (by using a bidirectional replication tool or dual write operations), and both databases handle transactions from connecting applications during migration. This method supports migration in small, controlled batches instead of requiring a one-time cutover. It’s more flexible but requires more work than active-passive migration.

active-passive migration

A database migration method in which in which the source and target databases are kept in sync, but only the source database handles transactions from connecting applications while data is replicated to the target database. The target database doesn't accept any transactions during migration.

aggregate function

A SQL function that operates on a group of rows and calculates a single return value for the group. Examples of aggregate functions include SUM and MAX.

AI

See artificial intelligence.

AIOps

See artificial intelligence operations.
anonymization

The process of permanently deleting personal information in a dataset. Anonymization can help protect personal privacy. Anonymized data is no longer considered to be personal data.

anti-pattern

A frequently used solution for a recurring issue where the solution is counter-productive, ineffective, or less effective than an alternative.

application control

A security approach that allows the use of only approved applications in order to help protect a system from malware.

application portfolio

A collection of detailed information about each application used by an organization, including the cost to build and maintain the application, and its business value. This information is key to the portfolio discovery and analysis process and helps identify and prioritize the applications to be migrated, modernized, and optimized.

artificial intelligence (AI)

The field of computer science that is dedicated to using computing technologies to perform cognitive functions that are typically associated with humans, such as learning, solving problems, and recognizing patterns. For more information, see What is Artificial Intelligence?

artificial intelligence operations (AIOps)

The process of using machine learning techniques to solve operational problems, reduce operational incidents and human intervention, and increase service quality. For more information about how AIOps is used in the AWS migration strategy, see the operations integration guide.

asymmetric encryption

An encryption algorithm that uses a pair of keys, a public key for encryption and a private key for decryption. You can share the public key because it isn’t used for decryption, but access to the private key should be highly restricted.

atomicity, consistency, isolation, durability (ACID)

A set of software properties that guarantee the data validity and operational reliability of a database, even in the case of errors, power failures, or other problems.
attribute-based access control (ABAC)

The practice of creating fine-grained permissions based on user attributes, such as department, job role, and team name. For more information, see ABAC for AWS in the AWS Identity and Access Management (IAM) documentation.

authoritative data source

A location where you store the primary version of data, which is considered to be the most reliable source of information. You can copy data from the authoritative data source to other locations for the purposes of processing or modifying the data, such as anonymizing, redacting, or pseudonymizing it.

Availability Zone

A distinct location within an AWS Region that is insulated from failures in other Availability Zones and provides inexpensive, low-latency network connectivity to other Availability Zones in the same Region.

AWS Cloud Adoption Framework (AWS CAF)

A framework of guidelines and best practices from AWS to help organizations develop an efficient and effective plan to move successfully to the cloud. AWS CAF organizes guidance into six focus areas called perspectives: business, people, governance, platform, security, and operations. The business, people, and governance perspectives focus on business skills and processes; the platform, security, and operations perspectives focus on technical skills and processes. For example, the people perspective targets stakeholders who handle human resources (HR), staffing functions, and people management. For this perspective, AWS CAF provides guidance for people development, training, and communications to help ready the organization for successful cloud adoption. For more information, see the AWS CAF website and the AWS CAF whitepaper.

AWS Workload Qualification Framework (AWS WQF)

A tool that evaluates database migration workloads, recommends migration strategies, and provides work estimates. AWS WQF is included with AWS Schema Conversion Tool (AWS SCT). It analyzes database schemas and code objects, application code, dependencies, and performance characteristics, and provides assessment reports.
bad bot

A bad bot is intended to disrupt or cause harm to individuals or organizations.

BCP

See business continuity planning.

behavior graph

A unified, interactive view of resource behavior and interactions over time. You can use a behavior graph with Amazon Detective to examine failed logon attempts, suspicious API calls, and similar actions. For more information, see Data in a behavior graph in the Detective documentation.

big-endian system

A system that stores the most significant byte first. See also endianness.

binary classification

A process that predicts a binary outcome (one of two possible classes). For example, your ML model might need to predict problems such as “Is this email spam or not spam?” or “Is this product a book or a car?”

bloom filter

A probabilistic, memory-efficient data structure that is used to test whether an element is a member of a set.

blue/green deployment

A deployment strategy where you create two separate but identical environments. You run the current application version in one environment (blue) and the new application version in the other environment (green). This strategy helps you quickly roll back with minimal impact.

bot

A software application that runs automated tasks over the internet and simulates human activity or interaction. Some bots are useful or beneficial, such as web crawlers that index information on the internet. Some other bots, known as bad bots, are intended to disrupt or cause harm to individuals or organizations.
botnet

Networks of bots that are infected by malware and are under the control of a single party, known as a bot herder or bot operator. Botnets are the best-known mechanism to scale bots and their impact.

branch

A contained area of a code repository. The first branch created in a repository is the main branch. You can create a new branch from an existing branch, and you can then develop features or fix bugs in the new branch. A branch you create to build a feature is commonly referred to as a feature branch. When the feature is ready for release, you merge the feature branch back into the main branch. For more information, see About branches (GitHub documentation).

break-glass access

In exceptional circumstances and through an approved process, a quick means for a user to gain access to an AWS account that they don't typically have permissions to access. For more information, see the Implement break-glass procedures indicator in the AWS Well-Architected guidance.

brownfield strategy

The existing infrastructure in your environment. When adopting a brownfield strategy for a system architecture, you design the architecture around the constraints of the current systems and infrastructure. If you are expanding the existing infrastructure, you might blend brownfield and greenfield strategies.

buffer cache

The memory area where the most frequently accessed data is stored.

business capability

What a business does to generate value (for example, sales, customer service, or marketing). Microservices architectures and development decisions can be driven by business capabilities. For more information, see the Organized around business capabilities section of the Running containerized microservices on AWS whitepaper.

business continuity planning (BCP)

A plan that addresses the potential impact of a disruptive event, such as a large-scale migration, on operations and enables a business to resume operations quickly.
C

CAF

See AWS Cloud Adoption Framework.

canary deployment

The slow and incremental release of a version to end users. When you are confident, you deploy the new version and replace the current version in its entirety.

CCoE

See Cloud Center of Excellence.

CDC

See change data capture.

change data capture (CDC)

The process of tracking changes to a data source, such as a database table, and recording metadata about the change. You can use CDC for various purposes, such as auditing or replicating changes in a target system to maintain synchronization.

chaos engineering

Intentionally introducing failures or disruptive events to test a system's resilience. You can use AWS Fault Injection Service (AWS FIS) to perform experiments that stress your AWS workloads and evaluate their response.

CI/CD

See continuous integration and continuous delivery.

classification

A categorization process that helps generate predictions. ML models for classification problems predict a discrete value. Discrete values are always distinct from one another. For example, a model might need to evaluate whether or not there is a car in an image.

client-side encryption

Encryption of data locally, before the target AWS service receives it.
Cloud Center of Excellence (CCoE)

A multi-disciplinary team that drives cloud adoption efforts across an organization, including developing cloud best practices, mobilizing resources, establishing migration timelines, and leading the organization through large-scale transformations. For more information, see the CCoE posts on the AWS Cloud Enterprise Strategy Blog.

cloud computing

The cloud technology that is typically used for remote data storage and IoT device management. Cloud computing is commonly connected to edge computing technology.

cloud operating model

In an IT organization, the operating model that is used to build, mature, and optimize one or more cloud environments. For more information, see Building your Cloud Operating Model.

cloud stages of adoption

The four phases that organizations typically go through when they migrate to the AWS Cloud:

• Project – Running a few cloud-related projects for proof of concept and learning purposes
• Foundation – Making foundational investments to scale your cloud adoption (e.g., creating a landing zone, defining a CCoE, establishing an operations model)
• Migration – Migrating individual applications
• Re-invention – Optimizing products and services, and innovating in the cloud

These stages were defined by Stephen Orban in the blog post The Journey Toward Cloud-First & the Stages of Adoption on the AWS Cloud Enterprise Strategy blog. For information about how they relate to the AWS migration strategy, see the migration readiness guide.

CMDB

See configuration management database.

code repository

A location where source code and other assets, such as documentation, samples, and scripts, are stored and updated through version control processes. Common cloud repositories include GitHub or AWS CodeCommit. Each version of the code is called a branch. In a microservice structure, each repository is devoted to a single piece of functionality. A single CI/CD pipeline can use multiple repositories.
cold cache

A buffer cache that is empty, not well populated, or contains stale or irrelevant data. This affects performance because the database instance must read from the main memory or disk, which is slower than reading from the buffer cache.

cold data

Data that is rarely accessed and is typically historical. When querying this kind of data, slow queries are typically acceptable. Moving this data to lower-performing and less expensive storage tiers or classes can reduce costs.

computer vision (CV)

A field of AI that uses machine learning to analyze and extract information from visual formats such as digital images and videos. For example, AWS Panorama offers devices that add CV to on-premises camera networks, and Amazon SageMaker provides image processing algorithms for CV.

configuration drift

For a workload, a configuration change from the expected state. It might cause the workload to become noncompliant, and it's typically gradual and unintentional.

configuration management database (CMDB)

A repository that stores and manages information about a database and its IT environment, including both hardware and software components and their configurations. You typically use data from a CMDB in the portfolio discovery and analysis stage of migration.

conformance pack

A collection of AWS Config rules and remediation actions that you can assemble to customize your compliance and security checks. You can deploy a conformance pack as a single entity in an AWS account and Region, or across an organization, by using a YAML template. For more information, see Conformance packs in the AWS Config documentation.

continuous integration and continuous delivery (CI/CD)

The process of automating the source, build, test, staging, and production stages of the software release process. CI/CD is commonly described as a pipeline. CI/CD can help you automate processes, improve productivity, improve code quality, and deliver faster. For more information, see Benefits of continuous delivery. CD can also stand for continuous deployment. For more information, see Continuous Delivery vs. Continuous Deployment.
CV

See computer vision.

D

data at rest

Data that is stationary in your network, such as data that is in storage.

data classification

A process for identifying and categorizing the data in your network based on its criticality and sensitivity. It is a critical component of any cybersecurity risk management strategy because it helps you determine the appropriate protection and retention controls for the data. Data classification is a component of the security pillar in the AWS Well-Architected Framework. For more information, see Data classification.

data drift

A meaningful variation between the production data and the data that was used to train an ML model, or a meaningful change in the input data over time. Data drift can reduce the overall quality, accuracy, and fairness in ML model predictions.

data in transit

Data that is actively moving through your network, such as between network resources.

data mesh

An architectural framework that provides distributed, decentralized data ownership with centralized management and governance.

data minimization

The principle of collecting and processing only the data that is strictly necessary. Practicing data minimization in the AWS Cloud can reduce privacy risks, costs, and your analytics carbon footprint.

data perimeter

A set of preventive guardrails in your AWS environment that help make sure that only trusted identities are accessing trusted resources from expected networks. For more information, see Building a data perimeter on AWS.
data preprocessing

To transform raw data into a format that is easily parsed by your ML model. Preprocessing data can mean removing certain columns or rows and addressing missing, inconsistent, or duplicate values.

data provenance

The process of tracking the origin and history of data throughout its lifecycle, such as how the data was generated, transmitted, and stored.

data subject

An individual whose data is being collected and processed.

data warehouse

A data management system that supports business intelligence, such as analytics. Data warehouses commonly contain large amounts of historical data, and they are typically used for queries and analysis.

database definition language (DDL)

Statements or commands for creating or modifying the structure of tables and objects in a database.

database manipulation language (DML)

Statements or commands for modifying (inserting, updating, and deleting) information in a database.

DDL

See database definition language.

deep ensemble

To combine multiple deep learning models for prediction. You can use deep ensembles to obtain a more accurate prediction or for estimating uncertainty in predictions.

deep learning

An ML subfield that uses multiple layers of artificial neural networks to identify mapping between input data and target variables of interest.
defense-in-depth

An information security approach in which a series of security mechanisms and controls are thoughtfully layered throughout a computer network to protect the confidentiality, integrity, and availability of the network and the data within. When you adopt this strategy on AWS, you add multiple controls at different layers of the AWS Organizations structure to help secure resources. For example, a defense-in-depth approach might combine multi-factor authentication, network segmentation, and encryption.

deleagted administrator

In AWS Organizations, a compatible service can register an AWS member account to administer the organization's accounts and manage permissions for that service. This account is called the delegated administrator for that service. For more information and a list of compatible services, see Services that work with AWS Organizations in the AWS Organizations documentation.

deployment

The process of making an application, new features, or code fixes available in the target environment. Deployment involves implementing changes in a code base and then building and running that code base in the application's environments.

dervelopment environment

See environment.

detective control

A security control that is designed to detect, log, and alert after an event has occurred. These controls are a second line of defense, alerting you to security events that bypassed the preventative controls in place. For more information, see Detective controls in Implementing security controls on AWS.

development value stream mapping (DVSM)

A process used to identify and prioritize constraints that adversely affect speed and quality in a software development lifecycle. DVSM extends the value stream mapping process originally designed for lean manufacturing practices. It focuses on the steps and teams required to create and move value through the software development process.

digital twin

A virtual representation of a real-world system, such as a building, factory, industrial equipment, or production line. Digital twins support predictive maintenance, remote monitoring, and production optimization.
dimension table

In a **star schema**, a smaller table that contains data attributes about quantitative data in a fact table. Dimension table attributes are typically text fields or discrete numbers that behave like text. These attributes are commonly used for query constraining, filtering, and result set labeling.

disaster

An event that prevents a workload or system from fulfilling its business objectives in its primary deployed location. These events can be natural disasters, technical failures, or the result of human actions, such as unintentional misconfiguration or a malware attack.

disaster recovery (DR)

The strategy and process you use to minimize downtime and data loss caused by a **disaster**. For more information, see *Disaster Recovery of Workloads on AWS: Recovery in the Cloud* in the AWS Well-Architected Framework.

DML

See **database manipulation language**.

domain-driven design

An approach to developing a complex software system by connecting its components to evolving domains, or core business goals, that each component serves. This concept was introduced by Eric Evans in his book, *Domain-Driven Design: Tackling Complexity in the Heart of Software* (Boston: Addison-Wesley Professional, 2003). For information about how you can use domain-driven design with the strangler fig pattern, see *Modernizing legacy Microsoft ASP.NET (ASMX) web services incrementally by using containers and Amazon API Gateway*.

DR

See **disaster recovery**.

drift detection

Tracking deviations from a baselined configuration. For example, you can use AWS CloudFormation to **detect drift in system resources**, or you can use AWS Control Tower to **detect changes in your landing zone** that might affect compliance with governance requirements.

DVSM

See **development value stream mapping**.
EDA

See exploratory data analysis.

edge computing

The technology that increases the computing power for smart devices at the edges of an IoT network. When compared with cloud computing, edge computing can reduce communication latency and improve response time.

encryption

A computing process that transforms plaintext data, which is human-readable, into ciphertext.

encryption key

A cryptographic string of randomized bits that is generated by an encryption algorithm. Keys can vary in length, and each key is designed to be unpredictable and unique.

endianness

The order in which bytes are stored in computer memory. Big-endian systems store the most significant byte first. Little-endian systems store the least significant byte first.

endpoint

See service endpoint.

endpoint service

A service that you can host in a virtual private cloud (VPC) to share with other users. You can create an endpoint service with AWS PrivateLink and grant permissions to other AWS accounts or to AWS Identity and Access Management (IAM) principals. These accounts or principals can connect to your endpoint service privately by creating interface VPC endpoints. For more information, see Create an endpoint service in the Amazon Virtual Private Cloud (Amazon VPC) documentation.

enterprise resource planning (ERP)

A system that automates and manages key business processes (such as accounting, MES, and project management) for an enterprise.
envelope encryption

The process of encrypting an encryption key with another encryption key. For more information, see Envelope encryption in the AWS Key Management Service (AWS KMS) documentation.

environment

An instance of a running application. The following are common types of environments in cloud computing:

- development environment – An instance of a running application that is available only to the core team responsible for maintaining the application. Development environments are used to test changes before promoting them to upper environments. This type of environment is sometimes referred to as a test environment.
- lower environments – All development environments for an application, such as those used for initial builds and tests.
- production environment – An instance of a running application that end users can access. In a CI/CD pipeline, the production environment is the last deployment environment.
- upper environments – All environments that can be accessed by users other than the core development team. This can include a production environment, preproduction environments, and environments for user acceptance testing.

epic

In agile methodologies, functional categories that help organize and prioritize your work. Epics provide a high-level description of requirements and implementation tasks. For example, AWS CAF security epics include identity and access management, detective controls, infrastructure security, data protection, and incident response. For more information about epics in the AWS migration strategy, see the program implementation guide.

ERP

See enterprise resource planning.

exploratory data analysis (EDA)

The process of analyzing a dataset to understand its main characteristics. You collect or aggregate data and then perform initial investigations to find patterns, detect anomalies, and check assumptions. EDA is performed by calculating summary statistics and creating data visualizations.
fact table

The central table in a star schema. It stores quantitative data about business operations. Typically, a fact table contains two types of columns: those that contain measures and those that contain a foreign key to a dimension table.

fail fast

A philosophy that uses frequent and incremental testing to reduce the development lifecycle. It is a critical part of an agile approach.

fault isolation boundary

In the AWS Cloud, a boundary such as an Availability Zone, AWS Region, control plane, or data plane that limits the effect of a failure and helps improve the resilience of workloads. For more information, see AWS Fault Isolation Boundaries.

feature branch

See branch.

features

The input data that you use to make a prediction. For example, in a manufacturing context, features could be images that are periodically captured from the manufacturing line.

feature importance

How significant a feature is for a model's predictions. This is usually expressed as a numerical score that can be calculated through various techniques, such as Shapley Additive Explanations (SHAP) and integrated gradients. For more information, see Machine learning model interpretability with :AWS.

feature transformation

To optimize data for the ML process, including enriching data with additional sources, scaling values, or extracting multiple sets of information from a single data field. This enables the ML model to benefit from the data. For example, if you break down the “2021-05-27 00:15:37” date into “2021”, “May”, “Thu”, and “15”, you can help the learning algorithm learn nuanced patterns associated with different data components.

FGAC

See fine-grained access control.
fine-grained access control (FGAC)

The use of multiple conditions to allow or deny an access request.

flash-cut migration

A database migration method that uses continuous data replication through change data capture to migrate data in the shortest time possible, instead of using a phased approach. The objective is to keep downtime to a minimum.

go blocking

See geographic restrictions.

geographic restrictions (go blocking)

In Amazon CloudFront, an option to prevent users in specific countries from accessing content distributions. You can use an allow list or block list to specify approved and banned countries. For more information, see Restricting the geographic distribution of your content in the CloudFront documentation.

Gitflow workflow

An approach in which lower and upper environments use different branches in a source code repository. The Gitflow workflow is considered legacy, and the trunk-based workflow is the modern, preferred approach.

greenfield strategy

The absence of existing infrastructure in a new environment. When adopting a greenfield strategy for a system architecture, you can select all new technologies without the restriction of compatibility with existing infrastructure, also known as brownfield. If you are expanding the existing infrastructure, you might blend brownfield and greenfield strategies.

guardrail

A high-level rule that helps govern resources, policies, and compliance across organizational units (OUs). Preventive guardrails enforce policies to ensure alignment to compliance standards. They are implemented by using service control policies and IAM permissions boundaries. Detective guardrails detect policy violations and compliance issues, and generate alerts.
for remediation. They are implemented by using AWS Config, AWS Security Hub, Amazon GuardDuty, AWS Trusted Advisor, Amazon Inspector, and custom AWS Lambda checks.

**H**

**HA**

See [high availability](#).

**heterogeneous database migration**

Migrating your source database to a target database that uses a different database engine (for example, Oracle to Amazon Aurora). Heterogeneous migration is typically part of a re-architecting effort, and converting the schema can be a complex task. [AWS provides AWS SCT](#) that helps with schema conversions.

**high availability (HA)**

The ability of a workload to operate continuously, without intervention, in the event of challenges or disasters. HA systems are designed to automatically fail over, consistently deliver high-quality performance, and handle different loads and failures with minimal performance impact.

**historian modernization**

An approach used to modernize and upgrade operational technology (OT) systems to better serve the needs of the manufacturing industry. A [historian](#) is a type of database that is used to collect and store data from various sources in a factory.

**homogeneous database migration**

Migrating your source database to a target database that shares the same database engine (for example, Microsoft SQL Server to Amazon RDS for SQL Server). Homogeneous migration is typically part of a rehosting or replatforming effort. You can use native database utilities to migrate the schema.

**hot data**

Data that is frequently accessed, such as real-time data or recent translational data. This data typically requires a high-performance storage tier or class to provide fast query responses.
hotfix

An urgent fix for a critical issue in a production environment. Due to its urgency, a hotfix is usually made outside of the typical DevOps release workflow.

hypercare period

Immediately following cutover, the period of time when a migration team manages and monitors the migrated applications in the cloud in order to address any issues. Typically, this period is 1–4 days in length. At the end of the hypercare period, the migration team typically transfers responsibility for the applications to the cloud operations team.

I

IaC

See *infrastructure as code*.

identity-based policy

A policy attached to one or more IAM principals that defines their permissions within the AWS Cloud environment.

idle application

An application that has an average CPU and memory usage between 5 and 20 percent over a period of 90 days. In a migration project, it is common to retire these applications or retain them on premises.

IIoT

See *industrial Internet of Things*.

immutable infrastructure

A model that deploys new infrastructure for production workloads instead of updating, patching, or modifying the existing infrastructure. Immutable infrastructures are inherently more consistent, reliable, and predictable than mutable infrastructure. For more information, see the [Deploy using immutable infrastructure] best practice in the AWS Well-Architected Framework.

inbound (ingress) VPC

In an AWS multi-account architecture, a VPC that accepts, inspects, and routes network connections from outside an application. The [AWS Security Reference Architecture] recommends
setting up your Network account with inbound, outbound, and inspection VPCs to protect the two-way interface between your application and the broader internet.

incremental migration

A cutover strategy in which you migrate your application in small parts instead of performing a single, full cutover. For example, you might move only a few microservices or users to the new system initially. After you verify that everything is working properly, you can incrementally move additional microservices or users until you can decommission your legacy system. This strategy reduces the risks associated with large migrations.

Industry 4.0

A term that was introduced by Klaus Schwab in 2016 to refer to the modernization of manufacturing processes through advances in connectivity, real-time data, automation, analytics, and AI/ML.

infrastructure

All of the resources and assets contained within an application's environment.

infrastructure as code (IaC)

The process of provisioning and managing an application's infrastructure through a set of configuration files. IaC is designed to help you centralize infrastructure management, standardize resources, and scale quickly so that new environments are repeatable, reliable, and consistent.

industrial Internet of Things (IIoT)

The use of internet-connected sensors and devices in the industrial sectors, such as manufacturing, energy, automotive, healthcare, life sciences, and agriculture. For more information, see Building an industrial Internet of Things (IIoT) digital transformation strategy.

inspection VPC

In an AWS multi-account architecture, a centralized VPC that manages inspections of network traffic between VPCs (in the same or different AWS Regions), the internet, and on-premises networks. The AWS Security Reference Architecture recommends setting up your Network account with inbound, outbound, and inspection VPCs to protect the two-way interface between your application and the broader internet.
Internet of Things (IoT)

The network of connected physical objects with embedded sensors or processors that communicate with other devices and systems through the internet or over a local communication network. For more information, see What is IoT?

Interpretability

A characteristic of a machine learning model that describes the degree to which a human can understand how the model's predictions depend on its inputs. For more information, see Machine learning model interpretability with AWS.

IoT

See Internet of Things.

IT information library (ITIL)

A set of best practices for delivering IT services and aligning these services with business requirements. ITIL provides the foundation for ITSM.

IT service management (ITSM)

Activities associated with designing, implementing, managing, and supporting IT services for an organization. For information about integrating cloud operations with ITSM tools, see the operations integration guide.

ITIL

See IT information library.

ITSM

See IT service management.

Label-based access control (LBAC)

An implementation of mandatory access control (MAC) where the users and the data itself are each explicitly assigned a security label value. The intersection between the user security label and data security label determines which rows and columns can be seen by the user.
landing zone

A landing zone is a well-architected, multi-account AWS environment that is scalable and secure. This is a starting point from which your organizations can quickly launch and deploy workloads and applications with confidence in their security and infrastructure environment. For more information about landing zones, see Setting up a secure and scalable multi-account AWS environment.

large migration

A migration of 300 or more servers.

LBAC

See label-based access control.

least privilege

The security best practice of granting the minimum permissions required to perform a task. For more information, see Apply least-privilege permissions in the IAM documentation.

lift and shift

See 7 Rs.

little-endian system

A system that stores the least significant byte first. See also endianness.

lower environments

See environment.

machine learning (ML)

A type of artificial intelligence that uses algorithms and techniques for pattern recognition and learning. ML analyzes and learns from recorded data, such as Internet of Things (IoT) data, to generate a statistical model based on patterns. For more information, see Machine Learning.

main branch

See branch.
malware

Software that is designed to compromise computer security or privacy. Malware might disrupt computer systems, leak sensitive information, or gain unauthorized access. Examples of malware include viruses, worms, ransomware, Trojan horses, spyware, and keyloggers.

managed services

AWS services for which AWS operates the infrastructure layer, the operating system, and platforms, and you access the endpoints to store and retrieve data. Amazon Simple Storage Service (Amazon S3) and Amazon DynamoDB are examples of managed services. These are also known as abstracted services.

manufacturing execution system (MES)

A software system for tracking, monitoring, documenting, and controlling production processes that convert raw materials to finished products on the shop floor.

MAP

See Migration Acceleration Program.

mechanism

A complete process in which you create a tool, drive adoption of the tool, and then inspect the results in order to make adjustments. A mechanism is a cycle that reinforces and improves itself as it operates. For more information, see Building mechanisms in the AWS Well-Architected Framework.

member account

All AWS accounts other than the management account that are part of an organization in AWS Organizations. An account can be a member of only one organization at a time.

MES

See manufacturing execution system.

Message Queuing Telemetry Transport (MQTT)

A lightweight, machine-to-machine (M2M) communication protocol, based on the publish/subscribe pattern, for resource-constrained IoT devices.

microservice

A small, independent service that communicates over well-defined APIs and is typically owned by small, self-contained teams. For example, an insurance system might include
microservices that map to business capabilities, such as sales or marketing, or subdomains, such as purchasing, claims, or analytics. The benefits of microservices include agility, flexible scaling, easy deployment, reusable code, and resilience. For more information, see [Integrating microservices by using AWS serverless services](https://aws.amazon.com/solutions/architecture/microservices/).

**microservices architecture**

An approach to building an application with independent components that run each application process as a microservice. These microservices communicate through a well-defined interface by using lightweight APIs. Each microservice in this architecture can be updated, deployed, and scaled to meet demand for specific functions of an application. For more information, see [Implementing microservices on AWS](https://aws.amazon.com/solutions/architecture/microservices/).

**Migration Acceleration Program (MAP)**

An AWS program that provides consulting support, training, and services to help organizations build a strong operational foundation for moving to the cloud, and to help offset the initial cost of migrations. MAP includes a migration methodology for executing legacy migrations in a methodical way and a set of tools to automate and accelerate common migration scenarios.

**migration at scale**

The process of moving the majority of the application portfolio to the cloud in waves, with more applications moved at a faster rate in each wave. This phase uses the best practices and lessons learned from the earlier phases to implement a migration factory of teams, tools, and processes to streamline the migration of workloads through automation and agile delivery. This is the third phase of the [AWS migration strategy](https://aws.amazon.com/migration-strategy/).

**migration factory**

Cross-functional teams that streamline the migration of workloads through automated, agile approaches. Migration factory teams typically include operations, business analysts and owners, migration engineers, developers, and DevOps professionals working in sprints. Between 20 and 50 percent of an enterprise application portfolio consists of repeated patterns that can be optimized by a factory approach. For more information, see the [discussion of migration factories](https://aws.amazon.com/solutions/architecture/migration-factories/) and the [Cloud Migration Factory guide](https://aws.amazon.com/solutions/architecture/migration-factories/) in this content set.

**migration metadata**

The information about the application and server that is needed to complete the migration. Each migration pattern requires a different set of migration metadata. Examples of migration metadata include the target subnet, security group, and AWS account.
migration pattern

A repeatable migration task that details the migration strategy, the migration destination, and the migration application or service used. Example: Rehost migration to Amazon EC2 with AWS Application Migration Service.

Migration Portfolio Assessment (MPA)

An online tool that provides information for validating the business case for migrating to the AWS Cloud. MPA provides detailed portfolio assessment (server right-sizing, pricing, TCO comparisons, migration cost analysis) as well as migration planning (application data analysis and data collection, application grouping, migration prioritization, and wave planning). The MPA tool (requires login) is available free of charge to all AWS consultants and APN Partner consultants.

Migration Readiness Assessment (MRA)

The process of gaining insights about an organization's cloud readiness status, identifying strengths and weaknesses, and building an action plan to close identified gaps, using the AWS CAF. For more information, see the migration readiness guide. MRA is the first phase of the AWS migration strategy.

migration strategy

The approach used to migrate a workload to the AWS Cloud. For more information, see the 7 Rs entry in this glossary and see Mobilize your organization to accelerate large-scale migrations.

ML

See machine learning.

modernization

Transforming an outdated (legacy or monolithic) application and its infrastructure into an agile, elastic, and highly available system in the cloud to reduce costs, gain efficiencies, and take advantage of innovations. For more information, see Strategy for modernizing applications in the AWS Cloud.

modernization readiness assessment

An evaluation that helps determine the modernization readiness of an organization's applications; identifies benefits, risks, and dependencies; and determines how well the organization can support the future state of those applications. The outcome of the assessment is a blueprint of the target architecture, a roadmap that details development phases and
milestones for the modernization process, and an action plan for addressing identified gaps. For more information, see Evaluating modernization readiness for applications in the AWS Cloud.

monolithic applications (monoliths)

Applications that run as a single service with tightly coupled processes. Monolithic applications have several drawbacks. If one application feature experiences a spike in demand, the entire architecture must be scaled. Adding or improving a monolithic application's features also becomes more complex when the code base grows. To address these issues, you can use a microservices architecture. For more information, see Decomposing monoliths into microservices.

MPA

See Migration Portfolio Assessment.

MQTT

See Message Queuing Telemetry Transport.

multiclass classification

A process that helps generate predictions for multiple classes (predicting one of more than two outcomes). For example, an ML model might ask "Is this product a book, car, or phone?" or "Which product category is most interesting to this customer?"

mutable infrastructure

A model that updates and modifies the existing infrastructure for production workloads. For improved consistency, reliability, and predictability, the AWS Well-Architected Framework recommends the use of immutable infrastructure as a best practice.

O

OAC

See origin access control.

OAI

See origin access identity.

OCM

See organizational change management.
offline migration

A migration method in which the source workload is taken down during the migration process. This method involves extended downtime and is typically used for small, non-critical workloads.

OI

See operations integration.

OLA

See operational-level agreement.

online migration

A migration method in which the source workload is copied to the target system without being taken offline. Applications that are connected to the workload can continue to function during the migration. This method involves zero to minimal downtime and is typically used for critical production workloads.

OPC-UA

See Open Process Communications - Unified Architecture.

Open Process Communications - Unified Architecture (OPC-UA)

A machine-to-machine (M2M) communication protocol for industrial automation. OPC-UA provides an interoperability standard with data encryption, authentication, and authorization schemes.

operational-level agreement (OLA)

An agreement that clarifies what functional IT groups promise to deliver to each other, to support a service-level agreement (SLA).

operational readiness review (ORR)

A checklist of questions and associated best practices that help you understand, evaluate, prevent, or reduce the scope of incidents and possible failures. For more information, see Operational Readiness Reviews (ORR) in the AWS Well-Architected Framework.

operational technology (OT)

Hardware and software systems that work with the physical environment to control industrial operations, equipment, and infrastructure. In manufacturing, the integration of OT and information technology (IT) systems is a key focus for Industry 4.0 transformations.
operations integration (OI)

The process of modernizing operations in the cloud, which involves readiness planning, automation, and integration. For more information, see the operations integration guide.

organization trail

A trail that's created by AWS CloudTrail that logs all events for all AWS accounts in an organization in AWS Organizations. This trail is created in each AWS account that's part of the organization and tracks the activity in each account. For more information, see Creating a trail for an organization in the CloudTrail documentation.

organizational change management (OCM)

A framework for managing major, disruptive business transformations from a people, culture, and leadership perspective. OCM helps organizations prepare for, and transition to, new systems and strategies by accelerating change adoption, addressing transitional issues, and driving cultural and organizational changes. In the AWS migration strategy, this framework is called people acceleration, because of the speed of change required in cloud adoption projects. For more information, see the OCM guide.

origin access control (OAC)

In CloudFront, an enhanced option for restricting access to secure your Amazon Simple Storage Service (Amazon S3) content. OAC supports all S3 buckets in all AWS Regions, server-side encryption with AWS KMS (SSE-KMS), and dynamic PUT and DELETE requests to the S3 bucket.

origin access identity (OAI)

In CloudFront, an option for restricting access to secure your Amazon S3 content. When you use OAI, CloudFront creates a principal that Amazon S3 can authenticate with. Authenticated principals can access content in an S3 bucket only through a specific CloudFront distribution. See also OAC, which provides more granular and enhanced access control.

ORR

See operational readiness review.

OT

See operational technology.

outbound (egress) VPC

In an AWS multi-account architecture, a VPC that handles network connections that are initiated from within an application. The AWS Security Reference Architecture recommends
setting up your Network account with inbound, outbound, and inspection VPCs to protect the two-way interface between your application and the broader internet.

**P**

permissions boundary

An IAM management policy that is attached to IAM principals to set the maximum permissions that the user or role can have. For more information, see Permissions boundaries in the IAM documentation.

personally identifiable information (PII)

Information that, when viewed directly or paired with other related data, can be used to reasonably infer the identity of an individual. Examples of PII include names, addresses, and contact information.

PII

See personally identifiable information.

playbook

A set of predefined steps that capture the work associated with migrations, such as delivering core operations functions in the cloud. A playbook can take the form of scripts, automated runbooks, or a summary of processes or steps required to operate your modernized environment.

PLC

See programmable logic controller.

PLM

See product lifecycle management.

policy

An object that can define permissions (see identity-based policy), specify access conditions (see resource-based policy), or define the maximum permissions for all accounts in an organization in AWS Organizations (see service control policy).
polyglot persistence

Independently choosing a microservice's data storage technology based on data access patterns and other requirements. If your microservices have the same data storage technology, they can encounter implementation challenges or experience poor performance. Microservices are more easily implemented and achieve better performance and scalability if they use the data store best adapted to their requirements. For more information, see Enabling data persistence in microservices.

portfolio assessment

A process of discovering, analyzing, and prioritizing the application portfolio in order to plan the migration. For more information, see Evaluating migration readiness.

predicate

A query condition that returns true or false, commonly located in a WHERE clause.

predicate pushdown

A database query optimization technique that filters the data in the query before transfer. This reduces the amount of data that must be retrieved and processed from the relational database, and it improves query performance.

preventative control

A security control that is designed to prevent an event from occurring. These controls are a first line of defense to help prevent unauthorized access or unwanted changes to your network. For more information, see Preventative controls in Implementing security controls on AWS.

principal

An entity in AWS that can perform actions and access resources. This entity is typically a root user for an AWS account, an IAM role, or a user. For more information, see Principal in Roles terms and concepts in the IAM documentation.

Privacy by Design

An approach in system engineering that takes privacy into account throughout the whole engineering process.

private hosted zones

A container that holds information about how you want Amazon Route 53 to respond to DNS queries for a domain and its subdomains within one or more VPCs. For more information, see Working with private hosted zones in the Route 53 documentation.
proactive control

A **security control** designed to prevent the deployment of noncompliant resources. These controls scan resources before they are provisioned. If the resource is not compliant with the control, then it isn’t provisioned. For more information, see the [Controls reference guide](#) in the AWS Control Tower documentation and see [Proactive controls](#) in *Implementing security controls on AWS*.

product lifecycle management (PLM)

The management of data and processes for a product throughout its entire lifecycle, from design, development, and launch, through growth and maturity, to decline and removal.

production environment

See [environment](#).

programmable logic controller (PLC)

In manufacturing, a highly reliable, adaptable computer that monitors machines and automates manufacturing processes.

pseudonymization

The process of replacing personal identifiers in a dataset with placeholder values. Pseudonymization can help protect personal privacy. Pseudonymized data is still considered to be personal data.

publish/subscribe (pub/sub)

A pattern that enables asynchronous communications among microservices to improve scalability and responsiveness. For example, in a microservices-based [MES](#), a microservice can publish event messages to a channel that other microservices can subscribe to. The system can add new microservices without changing the publishing service.

**Q**

query plan

A series of steps, like instructions, that are used to access the data in a SQL relational database system.
query plan regression

When a database service optimizer chooses a less optimal plan than it did before a given change to the database environment. This can be caused by changes to statistics, constraints, environment settings, query parameter bindings, and updates to the database engine.

R

RACI matrix

See responsible, accountable, consulted, informed (RACI).

ransomware

A malicious software that is designed to block access to a computer system or data until a payment is made.

RASCI matrix

See responsible, accountable, consulted, informed (RACI).

RCAC

See row and column access control.

read replica

A copy of a database that’s used for read-only purposes. You can route queries to the read replica to reduce the load on your primary database.

re-architect

See 7 Rs.

recovery point objective (RPO)

The maximum acceptable amount of time since the last data recovery point. This determines what is considered an acceptable loss of data between the last recovery point and the interruption of service.

recovery time objective (RTO)

The maximum acceptable delay between the interruption of service and restoration of service.

refactor

See 7 Rs.
Region

A collection of AWS resources in a geographic area. Each AWS Region is isolated and independent of the others to provide fault tolerance, stability, and resilience. For more information, see [Specify which AWS Regions your account can use](#).

regression

An ML technique that predicts a numeric value. For example, to solve the problem of "What price will this house sell for?" an ML model could use a linear regression model to predict a house's sale price based on known facts about the house (for example, the square footage).

rehost

See [7 Rs](#).

release

In a deployment process, the act of promoting changes to a production environment.

relocate

See [7 Rs](#).

replatform

See [7 Rs](#).

repurchase

See [7 Rs](#).

resiliency

An application's ability to resist or recover from disruptions. [High availability](#) and [disaster recovery](#) are common considerations when planning for resiliency in the AWS Cloud. For more information, see [AWS Cloud Resilience](#).

resource-based policy

A policy attached to a resource, such as an Amazon S3 bucket, an endpoint, or an encryption key. This type of policy specifies which principals are allowed access, supported actions, and any other conditions that must be met.

responsible, accountable, consulted, informed (RACI) matrix

A matrix that defines the roles and responsibilities for all parties involved in migration activities and cloud operations. The matrix name is derived from the responsibility types defined in the
matrix: responsible (R), accountable (A), consulted (C), and informed (I). The support (S) type is optional. If you include support, the matrix is called a \textit{RASCI matrix}, and if you exclude it, it's called a \textit{RACI matrix}.

responsive control

A security control that is designed to drive remediation of adverse events or deviations from your security baseline. For more information, see \textit{Responsive controls} in \textit{Implementing security controls on AWS}.

retain

See \textit{7 Rs}.

retire

See \textit{7 Rs}.

rotation

The process of periodically updating a \textit{secret} to make it more difficult for an attacker to access the credentials.

row and column access control (RCAC)

The use of basic, flexible SQL expressions that have defined access rules. RCAC consists of row permissions and column masks.

RPO

See \textit{recovery point objective}.

RTO

See \textit{recovery time objective}.

runbook

A set of manual or automated procedures required to perform a specific task. These are typically built to streamline repetitive operations or procedures with high error rates.

\textbf{S}

SAML 2.0

An open standard that many identity providers (IdPs) use. This feature enables federated single sign-on (SSO), so users can log into the AWS Management Console or call the AWS API
operations without you having to create user in IAM for everyone in your organization. For more information about SAML 2.0-based federation, see About SAML 2.0-based federation in the IAM documentation.

SCADA

See supervisory control and data acquisition.

SCP

See service control policy.

secret

In AWS Secrets Manager, confidential or restricted information, such as a password or user credentials, that you store in encrypted form. It consists of the secret value and its metadata. The secret value can be binary, a single string, or multiple strings. For more information, see What's in a Secrets Manager secret? in the Secrets Manager documentation.

security control

A technical or administrative guardrail that prevents, detects, or reduces the ability of a threat actor to exploit a security vulnerability. There are four primary types of security controls: preventative, detective, responsive, and proactive.

security hardening

The process of reducing the attack surface to make it more resistant to attacks. This can include actions such as removing resources that are no longer needed, implementing the security best practice of granting least privilege, or deactivating unnecessary features in configuration files.

security information and event management (SIEM) system

Tools and services that combine security information management (SIM) and security event management (SEM) systems. A SIEM system collects, monitors, and analyzes data from servers, networks, devices, and other sources to detect threats and security breaches, and to generate alerts.

security response automation

A predefined and programmed action that is designed to automatically respond to or remediate a security event. These automations serve as detective or responsive security controls that help you implement AWS security best practices. Examples of automated response actions include modifying a VPC security group, patching an Amazon EC2 instance, or rotating credentials.
server-side encryption

Encryption of data at its destination, by the AWS service that receives it.

service control policy (SCP)

A policy that provides centralized control over permissions for all accounts in an organization in AWS Organizations. SCPs define guardrails or set limits on actions that an administrator can delegate to users or roles. You can use SCPs as allow lists or deny lists, to specify which services or actions are permitted or prohibited. For more information, see Service control policies in the AWS Organizations documentation.

service endpoint

The URL of the entry point for an AWS service. You can use the endpoint to connect programmatically to the target service. For more information, see AWS service endpoints in AWS General Reference.

service-level agreement (SLA)

An agreement that clarifies what an IT team promises to deliver to their customers, such as service uptime and performance.

service-level indicator (SLI)

A measurement of a performance aspect of a service, such as its error rate, availability, or throughput.

service-level objective (SLO)

A target metric that represents the health of a service, as measured by a service-level indicator.

shared responsibility model

A model describing the responsibility you share with AWS for cloud security and compliance. AWS is responsible for security of the cloud, whereas you are responsible for security in the cloud. For more information, see Shared responsibility model.

SIEM

See security information and event management system.

single point of failure (SPOF)

A failure in a single, critical component of an application that can disrupt the system.
SLA

See service-level agreement.

SLI

See service-level indicator.

SLO

See service-level objective.

split-and-seed model

A pattern for scaling and accelerating modernization projects. As new features and product releases are defined, the core team splits up to create new product teams. This helps scale your organization's capabilities and services, improves developer productivity, and supports rapid innovation. For more information, see Phased approach to modernizing applications in the AWS Cloud.

SPOF

See single point of failure.

star schema

A database organizational structure that uses one large fact table to store transactional or measured data and uses one or more smaller dimensional tables to store data attributes. This structure is designed for use in a data warehouse or for business intelligence purposes.

strangler fig pattern

An approach to modernizing monolithic systems by incrementally rewriting and replacing system functionality until the legacy system can be decommissioned. This pattern uses the analogy of a fig vine that grows into an established tree and eventually overcomes and replaces its host. The pattern was introduced by Martin Fowler as a way to manage risk when rewriting monolithic systems. For an example of how to apply this pattern, see Modernizing legacy Microsoft ASP.NET (ASMX) web services incrementally by using containers and Amazon API Gateway.

subnet

A range of IP addresses in your VPC. A subnet must reside in a single Availability Zone.
supervisory control and data acquisition (SCADA)

In manufacturing, a system that uses hardware and software to monitor physical assets and production operations.

symmetric encryption

An encryption algorithm that uses the same key to encrypt and decrypt the data.

synthetic testing

Testing a system in a way that simulates user interactions to detect potential issues or to monitor performance. You can use Amazon CloudWatch Synthetics to create these tests.

tags

Key-value pairs that act as metadata for organizing your AWS resources. Tags can help you manage, identify, organize, search for, and filter resources. For more information, see Tagging your AWS resources.

target variable

The value that you are trying to predict in supervised ML. This is also referred to as an outcome variable. For example, in a manufacturing setting the target variable could be a product defect.

task list

A tool that is used to track progress through a runbook. A task list contains an overview of the runbook and a list of general tasks to be completed. For each general task, it includes the estimated amount of time required, the owner, and the progress.

test environment

See environment.

training

To provide data for your ML model to learn from. The training data must contain the correct answer. The learning algorithm finds patterns in the training data that map the input data attributes to the target (the answer that you want to predict). It outputs an ML model that captures these patterns. You can then use the ML model to make predictions on new data for which you don’t know the target.
transit gateway

A network transit hub that you can use to interconnect your VPCs and on-premises networks. For more information, see What is a transit gateway in the AWS Transit Gateway documentation.

trunk-based workflow

An approach in which developers build and test features locally in a feature branch and then merge those changes into the main branch. The main branch is then built to the development, preproduction, and production environments, sequentially.

trusted access

Granting permissions to a service that you specify to perform tasks in your organization in AWS Organizations and in its accounts on your behalf. The trusted service creates a service-linked role in each account, when that role is needed, to perform management tasks for you. For more information, see Using AWS Organizations with other AWS services in the AWS Organizations documentation.

tuning

To change aspects of your training process to improve the ML model's accuracy. For example, you can train the ML model by generating a labeling set, adding labels, and then repeating these steps several times under different settings to optimize the model.

two-pizza team

A small DevOps team that you can feed with two pizzas. A two-pizza team size ensures the best possible opportunity for collaboration in software development.

U

uncertainty

A concept that refers to imprecise, incomplete, or unknown information that can undermine the reliability of predictive ML models. There are two types of uncertainty: Epistemic uncertainty is caused by limited, incomplete data, whereas aleatoric uncertainty is caused by the noise and randomness inherent in the data. For more information, see the Quantifying uncertainty in deep learning systems guide.
undifferentiated tasks

Also known as *heavy lifting*, work that is necessary to create and operate an application but that doesn’t provide direct value to the end user or provide competitive advantage. Examples of undifferentiated tasks include procurement, maintenance, and capacity planning.

upper environments

See environment.

V

vacuuming

A database maintenance operation that involves cleaning up after incremental updates to reclaim storage and improve performance.

version control

Processes and tools that track changes, such as changes to source code in a repository.

VPC peering

A connection between two VPCs that allows you to route traffic by using private IP addresses. For more information, see What is VPC peering in the Amazon VPC documentation.

vulnerability

A software or hardware flaw that compromises the security of the system.

W

warm cache

A buffer cache that contains current, relevant data that is frequently accessed. The database instance can read from the buffer cache, which is faster than reading from the main memory or disk.

warm data

Data that is infrequently accessed. When querying this kind of data, moderately slow queries are typically acceptable.
window function

A SQL function that performs a calculation on a group of rows that relate in some way to the current record. Window functions are useful for processing tasks, such as calculating a moving average or accessing the value of rows based on the relative position of the current row.

workload

A collection of resources and code that delivers business value, such as a customer-facing application or backend process.

workstream

Functional groups in a migration project that are responsible for a specific set of tasks. Each workstream is independent but supports the other workstreams in the project. For example, the portfolio workstream is responsible for prioritizing applications, wave planning, and collecting migration metadata. The portfolio workstream delivers these assets to the migration workstream, which then migrates the servers and applications.

WORM

See write once, read many.

WQF

See AWS Workload Qualification Framework.

write once, read many (WORM)

A storage model that writes data a single time and prevents the data from being deleted or modified. Authorized users can read the data as many times as needed, but they cannot change it. This data storage infrastructure is considered immutable.

Z

zero-day exploit

An attack, typically malware, that takes advantage of a zero-day vulnerability.

zero-day vulnerability

An unmitigated flaw or vulnerability in a production system. Threat actors can use this type of vulnerability to attack the system. Developers frequently become aware of the vulnerability as a result of the attack.
zombie application

An application that has an average CPU and memory usage below 5 percent. In a migration project, it is common to retire these applications.
