AWS Prescriptive Guidance Patterns

Amazon Web Services (AWS) Prescriptive Guidance patterns provide step-by-step instructions, architecture, tools, and code for implementing specific cloud migration, modernization, and deployment scenarios. These patterns, which are vetted by subject matter experts at AWS, are meant for builders and hands-on users who are planning to, or are in the process of, migrating to AWS. They also support users who are already on AWS and are looking for ways to optimize or modernize their cloud operations.

You can use these patterns to move your on-premises or cloud workloads of varying complexity to AWS and to accelerate your cloud adoption, optimization, and modernization efforts, regardless of whether you're in the proof of concept, planning, or implementation phase of your project. For example, for a cloud migration project:

- In the planning phase, you can evaluate the different options available to migrate to AWS. You can choose the right pattern that fits your needs, depending on whether you want to relocate, rehost, replatform, or rearchitecture. You can also understand the different tools available for migration, and start planning to procure licenses or start initial conversations with vendors.
- In the proof of concept and implementation phases, you can follow the step-by-step instructions provided in the pattern to migrate your workload to AWS. Each pattern includes details such as prerequisites, target reference architectures, tools, step-by-step tasks, best practices, troubleshooting, and code.
- If you're already using the AWS Cloud, you can find patterns that will help you modernize, optimize, scale, and secure your use of cloud resources.

To view lists of patterns by technical domain, use the following links or the filtering and search options on the AWS Prescriptive Guidance home page.

### Summary

This pattern describes how to connect and analyze Amazon Redshift data in Microsoft SQL Server Analysis Services, by using the Intellisoft OLE DB Provider or CData ADO.NET Provider for database access.

Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud. SQL Server Analysis Services is an online analytical processing (OLAP) tool that you can use to analyze data from data marts and data warehouses such as Amazon Redshift. You can use SQL Server Analysis Services to create OLAP cubes from your data for rapid, advanced data analysis.

### Prerequisites and limitations

**Assumptions**

- This pattern describes how to set up SQL Server Analysis Services and Intellisoft OLE DB Provider or CData ADO.NET Provider for Amazon Redshift on an Amazon Elastic Compute Cloud (Amazon EC2) instance. Alternatively, you can install both on a host in your corporate data center.

**Prerequisites**

- An active AWS account
- An Amazon Redshift cluster with credentials

### Architecture

**Source technology stack**

- An Amazon Redshift cluster

**Target technology stack**

- Microsoft SQL Server Analysis Services

**Source and target architecture**
Tools

- Microsoft Visual Studio 2019 (Community Edition)
- Intellisoft OLE DB Provider for Amazon Redshift (Trial) or CData ADO.NET Provider for Amazon Redshift (Trial)

Automate encryption enforcement in AWS Glue using an AWS CloudFormation template

Created by Diogo Guedes (AWS)

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: Production</th>
<th>Technologies: Analytics; Security, identity, compliance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS Glue Encryption Enforcement</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

| Workload: All other workloads | AWS services: Amazon EventBridge; AWS Glue; AWS KMS; AWS Lambda; AWS CloudFormation |

**Summary**

This pattern shows you how to set up and automate encryption enforcement in AWS Glue by using an AWS CloudFormation template. The template creates all the required configurations and resources for enforcing encryption. These resources include an initial configuration, a preventive control created by an Amazon EventBridge rule, and an AWS Lambda function.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- Permissions to deploy the CloudFormation template and its resources

**Limitations**

This security control is regional. You must deploy the security control in each AWS Region where you want to set up encryption enforcement in AWS Glue.

**Architecture**

**Target technology stack**

- Amazon CloudWatchLogs (from AWS Lambda)
- Amazon EventBridge rule
- AWS CloudFormation stack
- AWS CloudTrail
- AWS Identity and Access Management (IAM) managed role and policy
- AWS Key Management Service (AWS KMS)
- AWS KMS alias
- AWS Lambda function
Target architecture
The following diagram shows how to automate encryption enforcement in AWS Glue.

The diagram shows the following workflow:
1. A CloudFormation template creates all the resources, including the initial configuration and detective control for encryption enforcement in AWS Glue.
2. An EventBridge rule detects a state change in the encryption configuration.
3. A Lambda function is invoked for evaluation and logging through CloudWatch Logs. For non-compliant detection, the Parameter Store is recovered with an Amazon Resource Name (ARN) for an AWS KMS key. The service is remediated to compliant status with encryption enabled.

Automation and scale
If you’re using AWS Organizations, you can use AWS CloudFormation StackSets to deploy this template in multiple accounts where you want to enable encryption enforcement in AWS Glue.

Tools

- **Amazon CloudWatch** helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- **Amazon EventBridge** is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- **AWS CloudFormation** helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- **AWS CloudTrail** helps you enable operational and risk auditing, governance, and compliance of your AWS account.
- **AWS Glue** is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
• **AWS Key Management Service (AWS KMS)** helps you create and control cryptographic keys to help protect your data.

• **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

• **AWS Systems Manager** helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.

**Code**

The code for this pattern is available in the GitHub [aws-custom-guardrail-event-driven](https://github.com/aws-custom-guardrail-event-driven) repository.

**Best practices**

AWS Glue supports data encryption at rest for [authoring jobs in AWS Glue](https://aws.amazon.com/documentation/glue/) and [developing scripts using development endpoints](https://aws.amazon.com/documentation/glue/details/develop-scripts-endpoints/).

Consider the following best practices:

• Configure ETL jobs and development endpoints to use AWS KMS keys to write encrypted data at rest.

• Encrypt the metadata stored in the [AWS Glue Data Catalog](https://docs.aws.amazon.com/glue/latest/dg/data-catalog.html) by using keys that you manage through AWS KMS.

• Use AWS KMS keys to encrypt job bookmarks and the logs generated by crawlers and ETL jobs.

Build an ETL service pipeline to load data incrementally from Amazon S3 to Amazon Redshift using AWS Glue

Summary of building an ETL pipeline from Amazon S3 to Amazon Redshift using AWS Glue

This pattern provides guidance on how to configure Amazon Simple Storage Service (Amazon S3) for optimal data lake performance, and then load incremental data changes from Amazon S3 into Amazon Redshift by using AWS Glue, performing extract, transform, and load (ETL) operations.

The source files in Amazon S3 can have different formats, including comma-separated values (CSV), XML, and JSON files. This pattern describes how you can use AWS Glue to convert the source files into a cost-optimized and performance-optimized format like Apache Parquet. You can query Parquet files directly from Amazon Athena and Amazon Redshift Spectrum. You can also load Parquet files into Amazon Redshift, aggregate them, and share the aggregated data with consumers, or visualize the data by using Amazon QuickSight.

Prerequisites and limitations for building an ETL pipeline from Amazon S3 to Amazon Redshift using AWS Glue

Prerequisites

• An active AWS account.
• An S3 source bucket that has the right privileges and contains CSV, XML, or JSON files.

Assumptions

• The CSV, XML, or JSON source files are already loaded into Amazon S3 and are accessible from the account where AWS Glue and Amazon Redshift are configured.
• Best practices for loading the files, splitting the files, compression, and using a manifest are followed, as discussed in the Amazon Redshift documentation.
• The source file structure is unaltered.
• The source system is able to ingest data into Amazon S3 by following the folder structure defined in Amazon S3.
• The Amazon Redshift cluster spans a single Availability Zone. (This architecture is appropriate because AWS Lambda, AWS Glue, and Amazon Athena are serverless.) For high availability, cluster snapshots are taken at a regular frequency.
Limitations

- The file formats are limited to those that are currently supported by AWS Glue.
- Real-time downstream reporting isn’t supported.

Architecture for building an ETL pipeline from Amazon S3 to Amazon Redshift using AWS Glue

Source technology stack

- S3 bucket with CSV, XML, or JSON files

Target technology stack

- S3 data lake (with partitioned Parquet file storage)
- Amazon Redshift

Target architecture

Data flow
Tools for building an ETL pipeline from Amazon S3 to Amazon Redshift using AWS Glue

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service. Amazon S3 can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.

- **AWS Lambda** – AWS Lambda lets you run code without provisioning or managing servers. AWS Lambda is an event-driven service; you can set up your code to automatically initiate from other AWS services.

- **Amazon Redshift** – Amazon Redshift is a fully managed, petabyte-scale data warehouse service. With Amazon Redshift, you can query petabytes of structured and semi-structured data across your data warehouse and your data lake using standard SQL.

- **AWS Glue** – AWS Glue is a fully managed ETL service that makes it easier to prepare and load data for analytics. AWS Glue discovers your data and stores the associated metadata (for example, table definitions and schema) in the AWS Glue Data Catalog. Your cataloged data is immediately searchable, can be queried, and is available for ETL.

- **AWS Secrets Manager** – AWS Secrets Manager facilitates protection and central management of secrets needed for application or service access. The service stores database credentials, API keys, and other secrets, and eliminates the need to hardcode sensitive information in plaintext format. Secrets Manager also offers key rotation to meet security and compliance needs. It has built-in integration for Amazon Redshift, Amazon Relational Database Service (Amazon RDS), and Amazon DocumentDB. You can store and centrally manage secrets by using the Secrets Manager console, the command-line interface (CLI), or Secrets Manager API and SDKs.

- **Amazon Athena** – Amazon Athena is an interactive query service that makes it easy to analyze data that's stored in Amazon S3. Athena is serverless and integrated with AWS Glue, so it can directly query the data that's cataloged using AWS Glue. Athena is elastically scaled to deliver interactive query performance.
Epics for building an ETL pipeline from Amazon S3 to Amazon Redshift using AWS Glue

Create the S3 buckets and folder structure

<table>
<thead>
<tr>

</table>

### Create a secret in Secrets Manager

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a new secret to store the Amazon Redshift sign-in credentials in Secrets Manager.</td>
<td>This secret stores the credentials for the admin user as well as individual database service users. For instructions, see the Secrets Manager documentation. Choose Amazon Redshift Cluster as the secret type. Additionally, on the Secret rotation page, turn on the rotation. This will create the appropriate user in the Amazon Redshift cluster and will rotate the key secrets at defined intervals.</td>
<td>Data engineer</td>
</tr>
<tr>
<td>Create an IAM policy to restrict Secrets Manager access.</td>
<td>Restrict Secrets Manager access to only Amazon Redshift administrators and AWS Glue.</td>
<td>Data engineer</td>
</tr>
</tbody>
</table>
# Configure AWS Glue

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>In the AWS Glue Data Catalog, add a connection for Amazon Redshift.</td>
<td>For instructions, see the <a href="https://docs.aws.amazon.com/glue/latest/dg/">AWS Glue documentation</a>.</td>
<td>Data engineer</td>
</tr>
<tr>
<td>Create and attach an IAM service role for AWS Glue to access</td>
<td>For more information, see the <a href="https://docs.aws.amazon.com/glue/latest/dg/">AWS Glue documentation</a>.</td>
<td>Data engineer</td>
</tr>
<tr>
<td>Secrets Manager, Amazon Redshift, and S3 buckets.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Define the AWS Glue Data Catalog for the source.</td>
<td>This step involves creating a database and required tables in the AWS Glue Data Catalog. You can either use a crawler to catalog the tables in the AWS Glue database, or define them as Amazon Athena external tables. You can also access the external tables defined in Athena through the AWS Glue Data Catalog. See the AWS documentation for more information about defining the Data Catalog and creating an external table in Athena.</td>
<td>Data engineer</td>
</tr>
<tr>
<td>Create an AWS Glue job to process source data.</td>
<td>The AWS Glue job can be a Python shell or PySpark to standardize, deduplicate, and cleanse the source data files. To optimize performance and avoid having to query the entire S3 source bucket, partition the S3 bucket by date, broken down by year, month, day, and hour as a pushdown predicate for the AWS Glue job. For more information, see the <a href="https://docs.aws.amazon.com/glue/latest/dg/">AWS Glue documentation</a>. Load the processed and transformed data to the processed S3 bucket partitions in Parquet format. You can query the Parquet files from Athena.</td>
<td>Data engineer</td>
</tr>
<tr>
<td>Create an AWS Glue job to load data into Amazon Redshift.</td>
<td>The AWS Glue job can be a Python shell or PySpark to load the data by upserting the data, followed by a complete refresh. For details, see the <a href="https://docs.aws.amazon.com/glue/latest/dg/">AWS Glue documentation</a> and the Additional information section.</td>
<td>Data engineer</td>
</tr>
</tbody>
</table>
### Epics

#### (Optional) Schedule AWS Glue jobs by using triggers as necessary.

The incremental data load is primarily driven by an Amazon S3 event that causes an AWS Lambda function to call the AWS Glue job. Use AWS Glue trigger-based scheduling for any data loads that demand time-based instead of event-based scheduling.

<table>
<thead>
<tr>
<th>Skills required</th>
<th>Data engineer</th>
</tr>
</thead>
</table>

### Create a Lambda function

#### Task

- **Create and attach an IAM service-linked role for AWS Lambda to access S3 buckets and the AWS Glue job.**

Create an IAM service-linked role for AWS Lambda with a policy to read Amazon S3 objects and buckets, and a policy to access the AWS Glue API to start an AWS Glue job. For more information, see the [Knowledge Center](#).

<table>
<thead>
<tr>
<th>Skills required</th>
<th>Data engineer</th>
</tr>
</thead>
</table>

- **Create a Lambda function to run the AWS Glue job based on the defined Amazon S3 event.**

The Lambda function should be initiated by the creation of the Amazon S3 manifest file. The Lambda function should pass the Amazon S3 folder location (for example, `source_bucket/year/month/date/hour`) to the AWS Glue job as a parameter. The AWS Glue job will use this parameter as a pushdown predicate to optimize file access and job processing performance. For more information, see the [AWS Glue documentation](#).

<table>
<thead>
<tr>
<th>Skills required</th>
<th>Data engineer</th>
</tr>
</thead>
</table>

- **Create an Amazon S3 PUT object event to detect object creation, and call the respective Lambda function.**

The Amazon S3 PUT object event should be initiated only by the creation of the manifest file. The manifest file controls the Lambda function and the AWS Glue job concurrency, and processes the load as a batch instead of processing individual files that arrive in a specific partition of the S3 source bucket. For more information, see the [Lambda documentation](#).

<table>
<thead>
<tr>
<th>Skills required</th>
<th>Data engineer</th>
</tr>
</thead>
</table>

Additional information for building an ETL pipeline from Amazon S3 to Amazon Redshift using AWS Glue

**Detailed approach for upsert and complete refresh**

**Upsert**: This is for datasets that require historical aggregation, depending on the business use case. Follow one of the approaches described in [Updating and inserting new data](https://docs.aws.amazon.com/redshift/latest/dg/transaction-upserts.html) (Amazon Redshift documentation) based on your business needs.

**Complete refresh**: This is for small datasets that don't need historical aggregations. Follow one of these approaches:

1. Truncate the Amazon Redshift table.
2. Load the current partition from the staging area

or:

1. Create a temporary table with current partition data.
2. Drop the target Amazon Redshift table.
3. Rename the temporary table to the target table.
Calculate value at risk (VaR) by using AWS services

Summary

This pattern describes how to implement a value at risk (VaR) calculation system by using AWS services. In an on-premises environment, most VaR systems use a large, dedicated infrastructure and in-house or commercial grid scheduling software to run batch processes. This pattern presents a simple, reliable, and scalable architecture to handle VaR processing in the AWS Cloud. It builds a serverless architecture that uses Amazon Kinesis Data Streams as a streaming service, Amazon Simple Queue Service (Amazon SQS) as a managed queue service, Amazon ElastiCache as a caching service, and AWS Lambda to process orders and calculate risk.

VaR is a statistical measure that traders and risk managers use to estimate potential loss in their portfolio beyond a certain confidence level. Most VaR systems involve running a large number of mathematical and statistical calculations and storing the results. These calculations require significant compute resources, so VaR batch processes have to be broken into smaller sets of compute tasks. Splitting a large batch into smaller tasks is possible because these tasks are mostly independent (that is, calculations for one task don’t depend on other tasks).

Another important requirement for a VaR architecture is compute scalability. This pattern uses a serverless architecture that automatically scales in or out based on compute load. Because the batch or online compute demand is difficult to predict, dynamic scaling is required to complete the process within the timeline imposed by a service-level agreement (SLA). Also, a cost-optimized architecture should be able to scale down each compute resource as soon as the tasks on that resource are complete.

AWS services are well-suited for VaR calculations because they offer scalable compute and storage capacity, analytics services for processing in a cost-optimized way, and different types of schedulers to run your risk management workflows. Also, you pay only for the compute and storage resources that you use on AWS.

Prerequisites and limitations

Prerequisites

• An active AWS account.
• Input files, which depend on your business requirements. A typical use case involves the following input files:
  • Market data file (input to the VaR calculation engine)
  • Trade data file (unless trade data comes through a stream).
  • Configuration data file (model and other static configuration data)
  • Calculation engine model files (quantitative libraries)
  • Time series data file (for historical data such as the stock price for the last five years)
• If the market data or other input comes in through a stream, Amazon Kinesis Data Streams set up, and Amazon Identity and Access Management (IAM) permissions configured to write to the stream.
This pattern builds an architecture in which trade data is written from a trading system to a Kinesis data stream. Instead of using a streaming service, you can save your trade data in small batch files, store them in an Amazon Simple Storage Service (Amazon S3) bucket, and invoke an event to start processing the data.

**Limitations**

- Kinesis data stream sequencing is guaranteed on each shard, so trade orders that are written to multiple shards are not guaranteed to be delivered in the same order as write operations.
- The AWS Lambda runtime limit is currently 15 minutes. (For more information, see the [Lambda FAQ](#).)

## Architecture

### Target architecture

The following architecture diagram displays the AWS services and workflows for the risk assessment system.

The diagram illustrates the following:

1. Trades stream in from the order management system.
2. The *ticket position netting* Lambda function processes the orders and writes consolidated messages for each ticker to a risk queue in Amazon SQS.
3. The *risk calculation engine* Lambda function processes the messages from Amazon SQS, performs risk calculations, and updates the VaR profit and loss (PnL) information in the risk cache in Amazon ElastiCache.
4. The *read ElastiCache data* Lambda function retrieves the risk results from ElastiCache and stores them in a database and S3 bucket.
For more information about these services and steps, see the Epics section.

Automation and scale

You can deploy the entire architecture by using the AWS Cloud Development Kit (AWS CDK) or AWS CloudFormation templates. The architecture can support both batch processing and intraday (real-time) processing.

Scaling is built into the architecture. As more trades are written into the Kinesis data stream and are waiting to be processed, additional Lambda functions can be invoked to process those trades and can then scale down after processing is complete. Processing through multiple Amazon SQS risk calculation queues is also an option. If strict ordering or consolidation is required across queues, processing cannot be parallelized. However, for an end-of-the-day batch or a mini intraday batch, the Lambda functions can process in parallel and store the final results in ElastiCache.

Tools

AWS services

- **Amazon Aurora MySQL-Compatible Edition** is a fully managed, MySQL-compatible relational database engine that helps you set up, operate, and scale MySQL deployments. This pattern uses MySQL as an example, but you can use any RDBMS system to store data.
- **Amazon ElastiCache** helps you set up, manage, and scale distributed in-memory cache environments in the AWS Cloud.
- **Amazon Kinesis Data Streams** helps you collect and process large streams of data records in real time.
- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- **Amazon Simple Queue Service (Amazon SQS)** provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Code

This pattern provides an example architecture for a VaR system in the AWS Cloud and describes how you can use Lambda functions for VaR calculations. To create your Lambda functions, see the code examples in the Lambda documentation. For assistance, contact AWS Professional Services.

Best practices

- Keep each VaR compute task as small and lightweight as possible. Experiment with different numbers of trades in each compute task to see which one is most optimized for compute time and cost.
- Store reusable objects in Amazon ElastiCache. Use a framework such as Apache Arrow to reduce serialization and deserialization.
- Consider Lambda’s time limitation. If you think your compute tasks might exceed 15 minutes, try to break them down into smaller tasks to avoid the Lambda timeout. If this is not possible, you might consider a container orchestration solution with AWS Fargate, Amazon Elastic Container Service (Amazon ECS), and Amazon Elastic Kubernetes Service (Amazon EKS).
## Epics

### Trade flow to risk system

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start writing trades.</td>
<td>New, settled, or partially settled trades are written from the order management system to a risk stream. This pattern uses Amazon Kinesis as the managed streaming service. The trade order ticker's hash is used to put trade orders across multiple shards.</td>
<td>Amazon Kinesis</td>
</tr>
</tbody>
</table>

### Run Lambda functions for order processing

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start risk processing with Lambda.</td>
<td>Run an AWS Lambda function for the new orders. Based on the number of pending trade orders, Lambda will automatically scale. Each Lambda instance has one or more orders and retrieves the latest position for each ticker from Amazon ElastiCache. (You can use a CUSIP ID, a Curve name, or an index name for other financial derivative products as a key to store and retrieve data from ElasticCache.) In ElastiCache, the total position (quantity) and the key-value pair <code>&lt;ticker, net position&gt;</code>, where net position is the scaling factor, are updated once for each ticker.</td>
<td>Amazon Kinesis, AWS Lambda, Amazon ElastiCache</td>

</tbody>
</table>

Summary

NORMALIZE is a Teradata extension to the ANSI SQL standard. When a SQL table includes a column that has a PERIOD data type, NORMALIZE combines values that meet or overlap in that column, to form a single period that consolidates multiple, individual period values. To use NORMALIZE, at least one column in the SQL SELECT list must be of Teradata's temporal PERIOD data type. For more information about NORMALIZE, see the Teradata documentation.

Amazon Redshift doesn't support NORMALIZE, but you can implement this functionality by using native SQL syntax and the LAG window function in Amazon Redshift. This pattern focuses on using the Teradata NORMALIZE extension with the ON MEETS OR OVERLAPS condition, which is the most popular format. It explains how this feature works in Teradata and how it can be converted into Amazon Redshift native SQL syntax.

Prerequisites and limitations

Prerequisites

- Basic Teradata SQL knowledge and experience
- Amazon Redshift knowledge and experience

Architecture

Source technology stack

- Teradata data warehouse

Target technology stack

- Amazon Redshift

Target architecture

For a high-level architecture for migrating a Teradata database to Amazon Redshift, see the pattern Migrate a Teradata database to Amazon Redshift using AWS SCT data extraction agents. The migration doesn't automatically convert the Teradata NORMALIZE phrase to Amazon Redshift SQL. You can convert this Teradata extension by following the guidelines in this pattern.
Tools

Code

To illustrate the concept and functionality of NORMALIZE, consider the following table definition in Teradata:

```sql
CREATE TABLE systest.project
(
    emp_id    INTEGER,
    project_name VARCHAR(20),
    dept_id    INTEGER,
    duration   PERIOD(DATE)
);
```

Run the following SQL code to insert sample data into the table:

```sql
BEGIN TRANSACTION;
INSERT INTO systest.project VALUES (10, 'First Phase', 1000, PERIOD(DATE '2010-01-10', DATE '2010-03-20') );
INSERT INTO systest.project VALUES (10, 'First Phase', 2000, PERIOD(DATE '2010-03-20', DATE '2010-07-15') );
INSERT INTO systest.project VALUES (10, 'Second Phase', 2000, PERIOD(DATE '2010-06-15', DATE '2010-08-18') );
INSERT INTO systest.project VALUES (20, 'First Phase', 2000, PERIOD(DATE '2010-03-10', DATE '2010-07-20') );
INSERT INTO systest.project VALUES (20, 'Second Phase', 1000, PERIOD(DATE '2020-05-10', DATE '2020-09-20') );
END TRANSACTION;

Results:

```sql
select * from systest.project order by 1,2,3;
```

*** Query completed. 4 rows found. 4 columns returned.
*** Total elapsed time was 1 second.

<table>
<thead>
<tr>
<th>emp_id</th>
<th>project_name</th>
<th>dept_id</th>
<th>duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>First Phase</td>
<td>1000</td>
<td>('10/01/10', '10/03/20')</td>
</tr>
<tr>
<td>10</td>
<td>First Phase</td>
<td>2000</td>
<td>('10/03/20', '10/07/15')</td>
</tr>
<tr>
<td>10</td>
<td>Second Phase</td>
<td>2000</td>
<td>('10/06/15', '10/08/18')</td>
</tr>
<tr>
<td>20</td>
<td>First Phase</td>
<td>2000</td>
<td>('10/03/10', '10/07/20')</td>
</tr>
<tr>
<td>20</td>
<td>Second Phase</td>
<td>1000</td>
<td>('20/05/10', '20/09/20')</td>
</tr>
</tbody>
</table>

Teradata NORMALIZE use case

Now add the Teradata NORMALIZE SQL clause to the SELECT statement:

```sql
SELECT NORMALIZE ON MEETS OR OVERLAPS emp_id, duration
FROM systest.project
ORDER BY 1,2;
```

This NORMALIZE operation is performed on a single column (emp_id). For emp_id=10, the three overlapping period values in duration coalesce into a single period value, as follows:
The following `SELECT` statement performs a **NORMALIZE** operation on `project_name` and `dept_id`. Note that the `SELECT` list contains only one **PERIOD** column, `duration`.

```
SELECT NORMALIZE project_name, dept_id, duration
FROM systest.project;
```

**Output:**

```
project_name           dept_id          duration
---------------------- ----------- ------------------------
First Phase            1000         ('10/01/10', '10/03/20')
Second Phase           2000         ('10/03/10', '10/07/20')
First Phase            2000         ('10/03/10', '10/07/20')
Second Phase           1000         ('20/05/10', '20/09/20')
```

**Amazon Redshift equivalent SQL**

Amazon Redshift currently doesn't support the **PERIOD** data type in a table. Instead, you need to divide a Teradata **PERIOD** data field into two parts: `start_date`, `end_date`, as follows:

```
CREATE TABLE systest.project
(   emp_id INTEGER,
    project_name VARCHAR(20),
    dept_id INTEGER,
    start_date DATE,
    end_date DATE
);
```

Insert sample data into the table:

```
BEGIN TRANSACTION;

INSERT INTO systest.project VALUES (10, 'First Phase', 1000, DATE '2010-01-10', DATE '2010-03-20');
INSERT INTO systest.project VALUES (10, 'First Phase', 2000, DATE '2010-03-20', DATE '2010-07-15');
INSERT INTO systest.project VALUES (10, 'Second Phase', 2000, DATE '2010-06-15', DATE '2010-08-18');
INSERT INTO systest.project VALUES (20, 'First Phase', 2000, DATE '2020-05-10', DATE '2020-09-20');

END TRANSACTION;
```

**Output:**

```
emp_id | project_name | dept_id | start_date | end_date
------------|-------------|---------|------------|-----------
10      | First Phase | 1000    | 2010-01-10 | 2010-03-20
10      | First Phase | 2000    | 2010-03-20 | 2010-07-15
```
To rewrite Teradata's **NORMALIZE** clause, you can use the **LAG window function** in Amazon Redshift. This function returns the values for a row at a given offset above (before) the current row in the partition.

You can use the **LAG** function to identify each row that begins a new period by determining if a period meets or overlaps with the previous period (0 if yes and 1 if no). When this flag is cumulatively summed up, it provides a group identifier that can be used in the outer **Group By** clause to arrive at the desired result in Amazon Redshift.

Here's a sample Amazon Redshift SQL statement that uses **LAG()**:

```sql
SELECT emp_id, start_date, end_date,
    (CASE WHEN start_date <= LAG(end_date) OVER (PARTITION BY emp_id ORDER BY start_date, end_date) THEN 0 ELSE 1 END) AS GroupStartFlag
FROM systest.project
ORDER BY 1,2;
```

**Output:**

<table>
<thead>
<tr>
<th>emp_id</th>
<th>start_date</th>
<th>end_date</th>
<th>groupstartflag</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>2010-01-10</td>
<td>2010-03-20</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>2010-03-20</td>
<td>2010-07-15</td>
<td>0</td>
</tr>
<tr>
<td>10</td>
<td>2010-06-15</td>
<td>2010-08-18</td>
<td>0</td>
</tr>
<tr>
<td>20</td>
<td>2010-03-10</td>
<td>2010-07-20</td>
<td>1</td>
</tr>
<tr>
<td>20</td>
<td>2020-05-10</td>
<td>2020-09-20</td>
<td>1</td>
</tr>
</tbody>
</table>

The following Amazon Redshift SQL statement normalizes only on the **emp_id** column:

```sql
SELECT T2.emp_id, MIN(T2.start_date) as new_start_date, MAX(T2.end_date) as new_end_date
FROM
    ( SELECT T1.*, SUM(GroupStartFlag) OVER (PARTITION BY emp_id ORDER BY start_date ROWS UNBOUNDED PRECEDING) As GroupID
    FROM
        ( SELECT emp_id, start_date, end_date,
            (CASE WHEN start_date <= LAG(end_date) OVER (PARTITION BY emp_id ORDER BY start_date, end_date) THEN 0 ELSE 1 END) AS GroupStartFlag
        FROM systest.project ) T1
    ) T2
GROUP BY T2.emp_id, T2.GroupID
ORDER BY 1,2;
```

**Output:**

<table>
<thead>
<tr>
<th>emp_id</th>
<th>new_start_date</th>
<th>new_end_date</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>2010-01-10</td>
<td>2010-08-18</td>
</tr>
<tr>
<td>20</td>
<td>2010-03-10</td>
<td>2010-07-20</td>
</tr>
<tr>
<td>20</td>
<td>2020-05-10</td>
<td>2020-09-20</td>
</tr>
</tbody>
</table>

The following Amazon Redshift SQL statement normalizes on both the **project_name** and **dept_id** columns:

```sql
SELECT T2.emp_id, MIN(T2.start_date) as new_start_date, MAX(T2.end_date) as new_end_date
FROM
    ( SELECT T1.*, SUM(GroupStartFlag) OVER (PARTITION BY emp_id ORDER BY start_date ROWS UNBOUNDED PRECEDING) As GroupID
    FROM
        ( SELECT emp_id, start_date, end_date,
            (CASE WHEN start_date <= LAG(end_date) OVER (PARTITION BY emp_id ORDER BY start_date, end_date) THEN 0 ELSE 1 END) AS GroupStartFlag
        FROM systest.project ) T1
    ) T2
GROUP BY T2.emp_id, T2.GroupID, T2.project_name, T2.dept_id
ORDER BY 1,2;
```

Summary

RESET WHEN is a Teradata feature used in SQL analytical window functions. It is an extension to the ANSI SQL standard. RESET WHEN determines the partition over which an SQL window function operates based on some specified condition. If the condition evaluates to TRUE, a new, dynamic sub-partition is created inside the existing window partition. For more information about RESET WHEN, see the Teradata documentation.

Amazon Redshift doesn’t support RESET WHEN in SQL window functions. To implement this functionality, you have to convert RESET WHEN to the native SQL syntax in Amazon Redshift, and use multiple, nested functions. This pattern demonstrates how you can use the Teradata RESET WHEN feature and how you can convert it to Amazon Redshift SQL syntax.

Prerequisites and limitations

Prerequisites

- Basic knowledge of the Teradata data warehouse and its SQL syntax
- Good understanding of Amazon Redshift and its SQL syntax

Architecture

Source technology stack

- Teradata data warehouse

Target technology stack

- Amazon Redshift

Architecture

For a high-level architecture for migrating a Teradata database to Amazon Redshift, see the pattern Migrate a Teradata database to Amazon Redshift using AWS SCT data extraction agents. The migration doesn’t automatically convert the Teradata RESET WHEN phrase to Amazon Redshift SQL. You can convert this Teradata extension by following the guidelines in the next section.
Tools

Code

To illustrate the concept of RESET WHEN, consider the following table definition in Teradata:

```sql
create table systest.f_account_balance
( account_id integer NOT NULL,
  month_id integer,
  balance integer )
unique primary index (account_id, month_id);
```

Run the following SQL code to insert sample data into the table:

```sql
BEGIN TRANSACTION;
Insert Into systest.f_account_balance values (1,1,60);
Insert Into systest.f_account_balance values (1,2,99);
Insert Into systest.f_account_balance values (1,3,94);
Insert Into systest.f_account_balance values (1,4,90);
Insert Into systest.f_account_balance values (1,5,80);
Insert Into systest.f_account_balance values (1,6,88);
Insert Into systest.f_account_balance values (1,7,90);
Insert Into systest.f_account_balance values (1,8,92);
Insert Into systest.f_account_balance values (1,9,10);
Insert Into systest.f_account_balance values (1,10,60);
Insert Into systest.f_account_balance values (1,11,80);
Insert Into systest.f_account_balance values (1,12,10);
END TRANSACTION;
```

The sample table has the following data:

<table>
<thead>
<tr>
<th>account_id</th>
<th>month_id</th>
<th>balance</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>60</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>99</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>94</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
<td>90</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>80</td>
</tr>
<tr>
<td>1</td>
<td>6</td>
<td>88</td>
</tr>
<tr>
<td>1</td>
<td>7</td>
<td>90</td>
</tr>
<tr>
<td>1</td>
<td>8</td>
<td>92</td>
</tr>
<tr>
<td>1</td>
<td>9</td>
<td>10</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>60</td>
</tr>
<tr>
<td>1</td>
<td>11</td>
<td>80</td>
</tr>
<tr>
<td>1</td>
<td>12</td>
<td>10</td>
</tr>
</tbody>
</table>

For each account, let's say that you want to analyze the sequence of consecutive monthly balance increases. When one month's balance is less than, or equal to, the previous month's balance, the requirement is to reset the counter to zero and restart.
Teradata \texttt{RESET WHEN} use case

To analyze this data, Teradata SQL uses a window function with a nested aggregate and a \texttt{RESET WHEN} phrase, as follows:

\begin{verbatim}
SELECT account_id, month_id, balance,
     ( ROW_NUMBER() OVER (PARTITION BY account_id ORDER BY month_id
      RESET WHEN balance <= SUM(balance) over (PARTITION BY account_id ORDER BY month_id ROWS BETWEEN 1 PRECEDING AND 1 PRECEDING) ) -1 ) as balance_increase
FROM systest.f_account_balance
ORDER BY 1,2;
\end{verbatim}

Output:

<table>
<thead>
<tr>
<th>account_id</th>
<th>month_id</th>
<th>balance</th>
<th>balance_increase</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>60</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>99</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>94</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
<td>90</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>80</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>6</td>
<td>88</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>7</td>
<td>90</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>8</td>
<td>92</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td>9</td>
<td>10</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>60</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>11</td>
<td>80</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>12</td>
<td>10</td>
<td>0</td>
</tr>
</tbody>
</table>

The query is processed as follows in Teradata:

1. The \texttt{SUM(balance)} aggregate function calculates the sum of all balances for a given account in a given month.
2. We check to see if a balance in a given month (for a given account) is greater than the balance of the previous month.
3. If the balance increased, we track a cumulative count value. If the \texttt{RESET WHEN} condition evaluates to \texttt{false}, which means that the balance has increased over successive months, we continue to increase the count.
4. The \texttt{ROW_NUMBER()} ordered analytical function calculates the count value. When we reach a month whose balance is less than, or equal to, the balance of the previous month, the \texttt{RESET WHEN} condition evaluates to \texttt{true}. If so, we start a new partition and \texttt{ROW_NUMBER()} restarts the count from 1. We use \texttt{ROWS BETWEEN 1 PRECEDING AND 1 PRECEDING} to access the value of the previous row.
5. We subtract 1 to ensure that the count value starts with 0.

\textit{Amazon Redshift equivalent SQL}
Amazon Redshift doesn’t support the **RESET WHEN** phrase in an SQL analytical window function. To produce the same result, you must rewrite the Teradata SQL using Amazon Redshift native SQL syntax and nested sub-queries, as follows:

```sql
SELECT account_id, month_id, balance,
    (ROW_NUMBER() OVER(PARTITION BY account_id, new_dynamic_part ORDER BY month_id) -1) as balance_increase
FROM
    ( SELECT account_id, month_id, balance, prev_balance,
        SUM(dynamic_part) OVER (PARTITION BY account_id ORDER BY month_id ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW) As new_dynamic_part
        FROM ( SELECT account_id, month_id, balance,
            SUM(balance) over (PARTITION BY account_id ORDER BY month_id ROWS BETWEEN 1 PRECEDING AND 1 PRECEDING) as prev_balance,
            (CASE When balance <= prev_balance Then 1 Else 0 END) as dynamic_part
            FROM systest.f_account_balance ) A
    ) B
ORDER BY 1,2;
```

Because Amazon Redshift doesn’t support nested window functions in the **SELECT** clause of a single SQL statement, you must use two nested sub-queries.

- In the inner sub-query (alias A), a dynamic partition indicator (**dynamic_part**) is created and populated. **dynamic_part** is set to 1 if one month’s balance is less than or equal to the preceding month’s balance; otherwise, it’s set to 0.
- In the next layer (alias B), a **new_dynamic_part** attribute is generated as the result of a **SUM** window function.
- Finally, you add **new_dynamic_part** as a new partition attribute (**dynamic partition**) to the existing partition attribute (**account_id**) and apply the same **ROW_NUMBER()** window function as in Teradata (and minus one).

After these changes, Amazon Redshift SQL generates the same output as Teradata.

Enforce tagging of Amazon EMR clusters at launch

Created by Priyanka Chaudhary (AWS)

| Environment: Production | Technologies: Analytics; Security, identity, compliance | AWS services: Amazon EMR; AWS Lambda; Amazon CloudWatch Events |

Summary

This pattern provides a security control that ensures that Amazon EMR clusters are tagged when they are created.

Amazon EMR is an Amazon Web Services (AWS) service for processing and analyzing vast amounts of data. Amazon EMR offers an expandable, low-configuration service as an easier alternative to running in-house cluster computing. You can use tagging to categorize AWS resources in different ways, such as by purpose, owner, or environment. For example, you can tag your Amazon EMR clusters by assigning custom metadata to each cluster. A tag consists of a key and value that you define. We recommend that you create a consistent set of tags to meet your organization’s requirements. When you add a tag to an Amazon EMR cluster, the tag is also propagated to each active Amazon Elastic Compute Cloud (Amazon EC2) instance that is associated with the cluster. Similarly, when you remove a tag from an Amazon EMR cluster, that tag is removed from each associated, active EC2 instance as well.

The detective control monitors API calls and initiates an Amazon CloudWatch Events event for the RunJobFlow, AddTags, RemoveTags, and CreateTags APIs. The event calls AWS Lambda, which runs a Python script. The Python function gets the Amazon EMR cluster ID from the JSON input from the event and performs the following checks:

- Check if the Amazon EMR cluster is configured with tag names that you specify.
- If not, send an Amazon Simple Notification Service (Amazon SNS) notification to the user with the relevant information: the Amazon EMR cluster name, violation details, AWS Region, AWS account, and Amazon Resource Name (ARN) for Lambda that this notification is sourced from.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon Simple Storage Service (Amazon S3) bucket to upload the provided Lambda code. Or, you can create an S3 bucket for this purpose, as described in the Epics section.
- An active email address where you would like to receive violation notifications.
- A list of mandatory tags you want to check for.

Limitations

- This security control is regional. You must deploy it in each AWS Region that you want to monitor.

Product versions
• Amazon EMR release 4.8.0 and later.

Architecture

Workflow architecture

Automation and scale

• If you are using AWS Organizations, you can use AWS Cloudformation StackSets to deploy this template in multiple accounts that you want to monitor.

Tools

AWS services

• AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

• Amazon CloudWatch Events - Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.

• Amazon EMR - Amazon EMR is a web service that simplifies running big data frameworks and processing vast amounts of data efficiently.

• AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.

• Amazon S3 – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.

• Amazon SNS – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

Code

This pattern includes the following attachments:

• EMRTagValidation.zip – The Lambda code for the security control.
• EMRTagValidation.yml – The CloudFormation template that sets up the event and Lambda function.

### Set up the S3 bucket

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Define the S3 bucket.</td>
<td>On the Amazon S3 console, choose or create an S3 bucket to host the Lambda code .zip file. This S3 bucket must be in the same AWS Region as the Amazon EMR cluster you want to monitor. An Amazon S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. The S3 bucket name cannot include leading slashes.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Upload the Lambda code.</td>
<td>Upload the Lambda code .zip file provided in the Attachments section to the S3 bucket.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>

### Deploy the AWS CloudFormation template

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Launch the AWS CloudFormation template.</td>
<td>Open the AWS CloudFormation console in the same AWS Region as your S3 bucket and deploy the template. For more information about deploying AWS CloudFormation templates, see Creating a stack on the AWS CloudFormation console in the CloudFormation documentation.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Complete the parameters in the template.</td>
<td>When you launch the template, you’ll be prompted for the following information:</td>
<td>Cloud architect</td>
</tr>
<tr>
<td></td>
<td>• <strong>S3 bucket</strong>: Specify the bucket that you created or selected in the first epic. This is where you uploaded the attached Lambda code (.zip file).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>S3 key</strong>: Specify the location of the Lambda .zip file in your S3 bucket (for example, filename.zip or filename.zip)</td>
<td></td>
</tr>
</tbody>
</table>
### Task Description

<table>
<thead>
<tr>
<th>Task</th>

Ensure Amazon EMR logging to Amazon S3 is enabled at launch

Created by Priyanka Chaudhary (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Technologies:</th>
<th>Security, identity, compliance; Serverless; Analytics</th>
<th>Workload:</th>
<th>Open-source</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>Amazon EMR; Amazon S3; Amazon SNS; Amazon CloudWatch</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern provides a security control that monitors logging configuration for Amazon EMR clusters running on Amazon Web Services (AWS).

Amazon EMR is an AWS tool for big data processing and analysis. Amazon EMR offers the expandable low-configuration service as an alternative to running in-house cluster computing. Amazon EMR provides two types of EMR clusters:

- **Transient Amazon EMR clusters**: Transient Amazon EMR clusters automatically shut down and stop incurring costs when processing is finished.
- **Persistent Amazon EMR clusters**: Persistent Amazon EMR clusters continue to run after the data processing job is complete.

Amazon EMR and Hadoop both produce log files that report status on the cluster. By default, these are written to the master node in the `/mnt/var/log/` directory. Depending on how you configure the cluster when you launch it, you can also save these logs to Amazon Simple Storage Service (Amazon S3) and view them through the graphical debugging tool. Note that Amazon S3 logging can be specified only when the cluster is launched. With this configuration, logs are sent from the primary node to the Amazon S3 location every 5 minutes. For transient clusters, Amazon S3 logging is important because the clusters disappear when processing is complete, and these log files can be used to debug any failed jobs.

The pattern uses an AWS CloudFormation template to deploy a security control that monitors for API calls and starts Amazon CloudWatch Events on "RunJobFlow." The trigger invokes AWS Lambda, which runs a Python script. The Lambda function retrieves the EMR cluster ID from the event JSON input and also checks for an Amazon S3 log URI. If an Amazon S3 URI is not found, the Lambda function sends an Amazon Simple Notification Service (Amazon SNS) notification detailing the EMR cluster name, violation details, AWS Region, AWS account, and the Lambda Amazon Resource Name (ARN) that the notification is sourced from.

Prerequisites and limitations

**Prerequisites**

- An active AWS account
- An S3 bucket for the Lambda code .zip file
- An email address where you want to receive the violation notification
Limitations

- This detective control is regional and must be deployed in the AWS Regions you intend to monitor.

Product versions

- Amazon EMR release 4.8.0 and later

Architecture

Target technology stack

- Amazon CloudWatch Events event
- Amazon EMR
- Lambda function
- S3 bucket
- Amazon SNS

Target architecture

Automation and scale

- If you are using AWS Organizations, you can use AWS CloudFormation StackSets to deploy this template in multiple accounts that you want to monitor.

Tools

Tools

- AWS CloudFormation – AWS CloudFormation helps you model and set up AWS resources using infrastructure as code.
- AWS CloudWatch Events – AWS CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- Amazon EMR – Amazon EMR is a managed cluster platform that simplifies running big data frameworks.
- AWS Lambda – AWS Lambda supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
• Amazon S3 – Amazon S3 is a web services interface that you can use to store and retrieve any amount of data from anywhere on the web.
• Amazon SNS – Amazon SNS is a web service that coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses.

Code

• A .zip file of the project is available as an attachment.

Generate test data using an AWS Glue job and Python

Summary

This pattern shows you how to quickly and easily generate millions of sample files concurrently by creating an AWS Glue job written in Python. The sample files are stored in an Amazon Simple Storage Service (Amazon S3) bucket. The ability to quickly generate a large number of sample files is important for testing or evaluating services in the AWS Cloud. For example, you can test the performance of AWS Glue Studio or AWS Glue DataBrew jobs by performing data analysis on millions of small files in an Amazon S3 prefix.

Although you can use other AWS services to generate sample datasets, we recommend that you use AWS Glue. You don't need to manage any infrastructure because AWS Glue is a serverless data processing service. You can just bring your code and run it in an AWS Glue cluster. Additionally, AWS Glue provisions, configures, and scales the resources required to run your jobs. You pay only for the resources that your jobs use while running.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI), installed and configured to work with the AWS account

Product versions

- Python 3.9
- AWS CLI version 2

Limitations

The maximum number of AWS Glue jobs per trigger is 50. For more information, see AWS Glue endpoints and quotas.

Architecture

The following diagram depicts an example architecture centered around an AWS Glue job that writes its output (that is, sample files) to an S3 bucket.
The diagram includes the following workflow:

1. You use the AWS CLI, AWS Management Console, or an API to initiate the AWS Glue job. The AWS CLI or API enables you to automate the parallelization of the invoked job and reduce the runtime for generating sample files.

2. The AWS Glue job generates file content randomly, converts the content into CSV format, and then stores the content as an Amazon S3 object under a common prefix. Each file is less than a kilobyte. The AWS Glue job accepts two user-defined job parameters: START_RANGE and END_RANGE. You can use these parameters to set file names and the number of files generated in Amazon S3 by each job run. You can run multiple instances of this job in parallel (for example, 100 instances).

Tools

- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- **AWS Glue** is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Best practices

Consider the following AWS Glue best practices as you implement this pattern:

- **Use the right AWS Glue worker type to reduce cost.** We recommend that you understand the different properties of worker types, and then choose the right worker type for your workload based on CPU and memory requirements. For this pattern, we recommend that you use a Python shell job as your job type to minimize DPU and reduce cost. For more information, see [Adding jobs in AWS Glue](https://docs.aws.amazon.com/glue/latest/dg/case-study-add-job.html) in the AWS Glue Developer Guide.

- **Use the right concurrency limit to scale your job.** We recommend that you base the maximum concurrency of your AWS Glue job on your time requirement and required number of files.

- **Start generating a small number of files at first.** To reduce cost and save time when you build your AWS Glue jobs, start with a small number of files (such as 1,000). This can make troubleshooting easier. If generating a small number of files is successful, then you can scale to a larger number of files.

- **Run locally first.** To reduce cost and save time when you build your AWS Glue jobs, start the development locally and test your code. For instructions on setting up a Docker container that can
help you write AWS Glue extract, transform, and load (ETL) jobs both in a shell and in an integrated
development environment (IDE), see the Developing AWS Glue ETL jobs locally using a container post
on the AWS Big Data Blog.

For more AWS Glue best practices, see Best practices in the AWS Glue documentation.

Epics

Create a destination S3 bucket and IAM role

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an S3 bucket for storing the files. | Create an S3 bucket and a prefix within it.  
**Note:** This pattern uses the s3://{your-s3-bucket-name}/small-files/ location for demonstration purposes. | App developer |
| Create and configure an IAM role. | You must create an IAM role that your AWS Glue job can use to write to your S3 bucket.  
1. Create an IAM role (for example, called "AWSGlueServiceRole-smallfiles").  
2. Choose AWS Glue as the policy's trusted entity.  
3. Attach an AWS managed policy called "AWSGlueServiceRole" to the role.  
4. Create an inline policy or customer managed policy called "s3-small-file-access" based on the following configuration. Replace "{bucket}" with your bucket name. | App developer |

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": [
```

49
### Create and configure an AWS Glue job to handle concurrent runs

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an AWS Glue job.</td>
<td>You must create an AWS Glue job that generates your content and stores it in an S3 bucket. Create an <a href="https://docs.aws.amazon.com/glue/latest/dkg/creating-a-glue-job.html">AWS Glue job</a>, and then configure your job by completing the following steps:</td>
<td>App developer</td>
</tr>
</tbody>
</table>

1. Sign in to the AWS Management Console and open the [AWS Glue console](https://console.aws.amazon.com/glue).  
2. In the navigation pane, under **Data Integration and ETL**, choose **Jobs**.  
3. In the **Create job** section, choose **Python Shell script editor**.  
4. In the **Options** section, select **Create a new script with boilerplate code**, and then choose **Create**.  
5. Choose **Job details**.  
6. For **Name**, enter `create_small_files`.  
7. For **IAM Role**, select the IAM role that you created earlier.  
8. In the **This job runs** section, choose **A new script to be authored by you**.  
9. Expand **Advanced properties**.  
10. For **Maximum concurrency**, enter 100 for demonstration purposes. **Note:** Maximum concurrency defines how many instances of the job that you can run in parallel.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>11. Choose Save.</td>
<td>Update the job code.</td>
<td>App developer</td>
</tr>
</tbody>
</table>

1. Open the AWS Glue console.
2. In the navigation pane, choose Jobs.
3. In the Your jobs section, choose the job that you created earlier.
4. Choose the Script tab, and then update the script based on the following code. Update the BUCKET_NAME, PREFIX, and text_str variables with your values.

```python
from awsglue.utils import getResolvedOptions
import sys
import boto3
from random import randrange

# Two arguments
args = getResolvedOptions(sys.argv, ['START_RANGE', 'END_RANGE'])

START_RANGE = int(args['START_RANGE'])
END_RANGE = int(args['END_RANGE'])

BUCKET_NAME = '{BUCKET_NAME}'
PREFIX = 'small-files/input/
s3 = boto3.resource('s3')
for x in range(START_RANGE, END_RANGE):
    # generate file name
    file_name = f'input_{x}.txt'
    # generate text
    text_str = str(randrange(100000))+","+str(randrange(100000))+","+
    # write in s3
    s3.Object(BUCKET_NAME, PREFIX + file_name).put(Body=text_str)
```

5. Choose Save.
Run the AWS Glue job from the command line or console

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run the AWS Glue job from the command line.</td>
<td>To run your AWS Glue job from the AWS CLI, run the following command using your values:</td>
<td>App developer</td>
</tr>
</tbody>
</table>

```bash
# define parameters
NUMBER_OF_FILES=10000000;
PARALLELIZATION=50;

# initialize
_SB=0;

# generate commands
for i in $(seq 1 $PARALLELIZATION);
do
echo aws glue start-job-run --job-name create_small_files --arguments '""--START_RANGE":"$(((NUMBER_OF_FILES/
```

**Note:** For instructions on running the AWS Glue job from the AWS Management Console, see the *Run the AWS Glue job in the AWS Management Console* story in this pattern.

**Tip:** We recommend using the AWS CLI to run AWS Glue jobs if you want to run multiple executions at a time with different parameters, as shown in the example above.

To generate all AWS CLI commands that are required to generate a defined number of files using a certain parallelization factor, run the following bash code (using your values):

```bash
# define parameters
NUMBER_OF_FILES=10000000;
PARALLELIZATION=50;

# initialize
_SB=0;

# generate commands
for i in $(seq 1 $PARALLELIZATION);
do
echo aws glue start-job-run --job-name create_small_files --arguments '""--START_RANGE":"$(((NUMBER_OF_FILES/
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Task 1** PARALLELIZATION) * (i-1) + _SB))"","-- END_RANGE":"$(((NUMBER_OF_FILES/PARALLELIZATION) * (i)))'"'; _SB=1; done | If you use the script above, consider the following:  
• The script simplifies the invocation and generation of small files at scale.  
• Update NUMBER_OF_FILES and PARALLELIZATION with your values.  
• The script above prints a list of commands that you must run. Copy those output commands, and then run them in your terminal.  
• If you want to run the commands directly from within the script, remove the echo statement in line 11.  

**Note**: To see an example of output from the above script, see *Shell script output* in the Additional information section of this pattern. | App developer |

Run the AWS Glue job in the AWS Management Console.  
1. Sign in to the AWS Management Console and open the AWS Glue console.  
2. In the navigation pane, under Data Integration and ETL, choose Jobs.  
3. In the Your jobs section, choose your job.  
4. In the Parameters (optional) section, update your parameters.  
5. Choose Action, and then choose Run job.  
6. Repeat steps 3-5 as many times as you require. For example, to create 10 million files, repeat this process 10 times.
## Task

**Check the status of your AWS Glue job.**

1. Open the [AWS Glue console](https://aws.amazon.com/glue).
2. In the navigation pane, choose Jobs.
3. In the **Your jobs** section, choose the job that you created earlier (that is, `create_small_files`).
4. For insight into the progress and generation of your files, review the **Run ID**, **Run Status**, and other columns.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Check the status of your AWS Glue job.</td>
<td>1. Open the <a href="https://aws.amazon.com/glue">AWS Glue console</a>.&lt;br&gt;2. In the navigation pane, choose Jobs.&lt;br&gt;3. In the <strong>Your jobs</strong> section, choose the job that you created earlier (that is, <code>create_small_files</code>).&lt;br&gt;4. For insight into the progress and generation of your files, review the <strong>Run ID</strong>, <strong>Run Status</strong>, and other columns.</td>
<td>App developer</td>
</tr>
</tbody>
</table>

- AWS Glue best practices
- Load testing applications

## Additional information

### Benchmarking test

This pattern was used to generate 10 million files using different parallelization parameters as part of a benchmarking test. The following table shows the output of the test:

<table>
<thead>
<tr>
<th>Parallelization</th>
<th>Number of files generated by a job run</th>
<th>Job duration</th>
<th>Speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>1,000,000</td>
<td>6 hours, 40 minutes</td>
<td>Very slow</td>
</tr>
<tr>
<td>50</td>
<td>200,000</td>
<td>80 minutes</td>
<td>Moderate</td>
</tr>
<tr>
<td>100</td>
<td>100,000</td>
<td>40 minutes</td>
<td>Fast</td>
</tr>
</tbody>
</table>

If you want to make the process faster, you can configure more concurrent runs in your job configuration. You can easily adjust the job configuration based on your requirements, but keep in mind that there is an AWS Glue service quota limit. For more information, see [AWS Glue endpoints and quotas](https://aws.amazon.com/gluendpoints/).

### Shell script output
The following example shows the output of the shell script from the Run the AWS Glue job from the command line story in this pattern.

```bash
user@MUC-1234567890 MINGW64 ~
$ # define parameters
NUMBER_OF_FILES=10000000;
PARALLELIZATION=50;
# initialize
_SB=0;

# generate commands
for i in $(seq 1 $PARALLELIZATION);
do
echo aws glue start-job-run --job-name create_small_files --arguments """"'""""{""""--START_RANGE":"'""""$(((NUMBER_OF_FILES/PARALLELIZATION) (i-1) + SB))""""'",""""--END_RANGE":"'""""$(((NUMBER_OF_FILES/PARALLELIZATION) (i)))""""'""""'";
_SB=1;
done
aws glue start-job-run --job-name create_small_files --arguments '{""""--START_RANGE":"'""""0""""'",""""--END_RANGE":"'""""200000""""'""""}
aws glue start-job-run --job-name create_small_files --arguments '{""""--START_RANGE":"'""""200001""""'",""""--END_RANGE":"'""""400000""""'""""}
aws glue start-job-run --job-name create_small_files --arguments '{""""--START_RANGE":"'""""400001""""'",""""--END_RANGE":"'""""600000""""'""""}
aws glue start-job-run --job-name create_small_files --arguments '{""""--START_RANGE":"'""""600001""""'",""""--END_RANGE":"'""""800000""""'""""}
aws glue start-job-run --job-name create_small_files --arguments '{""""--START_RANGE":"'""""800001""""'",""""--END_RANGE":"'""""1000000""""'""""}
aws glue start-job-run --job-name create_small_files --arguments '{""""--START_RANGE":"'""""1000001""""'",""""--END_RANGE":"'""""1200000""""'""""}
aws glue start-job-run --job-name create_small_files --arguments '{""""--START_RANGE":"'""""1200001""""'",""""--END_RANGE":"'""""1400000""""'""""}
aws glue start-job-run --job-name create_small_files --arguments '{""""--START_RANGE":"'""""1400001""""'",""""--END_RANGE":"'""""1600000""""'""""}
aws glue start-job-run --job-name create_small_files --arguments '{""""--START_RANGE":"'""""1600001""""'",""""--END_RANGE":"'""""1800000""""'""""}
aws glue start-job-run --job-name create_small_files --arguments '{""""--START_RANGE":"'""""1800001""""'",""""--END_RANGE":"'""""2000000""""'""""}

FAQ

How many concurrent runs or parallel jobs should I use?

The number of concurrent runs and parallel jobs depend on your time requirement and desired number of test files. We recommend that you check the size of the files that you’re creating. First, check how much time an AWS Glue job takes to generate your desired number of files. Then, use the right number of concurrent runs to meet your goals. For example, if you assume that 100,000 files takes 40 minutes to
complete the run but your target time is 30 minutes, then you must increase the concurrency setting for your AWS Glue job.

*What type of content can I create using this pattern?*

You can create any type of content, such as text files with different delimiters (for example, PIPE, JSON, or CSV). This pattern uses Boto3 to write to a file and then saves the file in an S3 bucket.

*What level of IAM permission do I need in the S3 bucket?*

You must have an identity-based policy that allows *Write* access to objects in your S3 bucket. For more information, see [Amazon S3: Allows read and write access to objects in an S3 bucket](https://aws.amazon.com/documentation/s3/) in the Amazon S3 documentation.
Launch a Spark job in a transient EMR cluster using a Lambda function

Created by Dhrubajyoti Mukherjee (AWS)

<table>
<thead>
<tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern uses the Amazon EMR RunJobFlow API action to launch a transient cluster to run a Spark job from a Lambda function. A transient EMR cluster is designed to terminate as soon as the job is complete or if any error occurs. A transient cluster provides cost savings because it runs only during the computation time, and it provides scalability and flexibility in a cloud environment.

The transient EMR cluster is launched using the Boto3 API and the Python programming language in a Lambda function. The Lambda function, which is written in Python, provides the added flexibility of initiating the cluster when it is needed.

To demonstrate a sample batch computation and output, this pattern will launch a Spark job in an EMR cluster from a Lambda function and run a batch computation against the example sales data of a fictional company. The output of the Spark job will be a comma-separated values (CSV) file in Amazon Simple Storage Service (Amazon S3). The input data file, Spark jar file, a code snippet, and an AWS CloudFormation template for a virtual private cloud (VPC) and AWS Identity and Access Management (IAM) roles to run the computation are provided as an attachment.

Prerequisites and limitations

Prerequisites

- An active AWS account

Limitations

- Only one Spark job can be initiated from the code at a time.

Product versions

- Tested on Amazon EMR 6.0.0

Architecture

Target technology stack

- Amazon EMR
Target architecture

Automation and scale

To automate the Spark-EMR batch computation, you can use either of the following options.

- Implement an Amazon EventBridge rule that can initiate the Lambda function in a cron schedule. For more information, see Tutorial: Schedule AWS Lambda functions using EventBridge.
- Configure Amazon S3 event notifications to initiate the Lambda function on file arrival.
- Pass the input parameters to the AWS Lambda function through the event body and Lambda environment variables.

Tools

AWS services

- Amazon EMR is a managed cluster platform that simplifies running big data frameworks on AWS to process and analyze large amounts of data.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

- Apache Spark is a multiple-language analytics engine for large-scale data processing.
## Epics

### Create the Amazon EMR and Lambda IAM roles and the VPC

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the IAM roles and the VPC.</td>
<td>If you already have the AWS Lambda and Amazon EMR IAM roles and a VPC, you can skip this step. To run the code, both the EMR cluster and the Lambda function require IAM roles. The EMR cluster also requires a VPC with a public subnet or a private subnet with a NAT gateway. To automatically create all the IAM roles and a VPC, deploy the attached AWS CloudFormation template as is, or you can create the roles and the VPC manually as specified in the Additional information section.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>
| Note the AWS CloudFormation template output keys. | After the CloudFormation template has successfully deployed, navigate to the Outputs tab in the AWS CloudFormation console. Note the five output keys:  
  - S3Bucket  
  - LambdaExecutionRole  
  - ServiceRole  
  - JobFlowRole  
  - Ec2SubnetId  
  
  You will use the values from these keys when you create the Lambda function.                                                                                                                                     | Cloud architect |

### Upload the Spark .jar file

)

IAM roles and VPC creation

To launch the EMR cluster in a Lambda function, a VPC and IAM roles are needed. You can set up the VPC and IAM roles by using the AWS CloudFormation template in the Attachments section of this pattern, or you can manually create them by using the following links.

The following IAM roles are required to run Lambda and Amazon EMR.

**Lambda execution role**

A Lambda function's execution role grants it permission to access AWS services and resources.

**Service role for Amazon EMR**

The Amazon EMR role defines the allowable actions for Amazon EMR when provisioning resources and performing service-level tasks that are not performed in the context of an Amazon Elastic Compute Cloud (Amazon EC2) instance running within a cluster. For example, the service role is used to provision EC2 instances when a cluster launches.

**Service role for EC2 instances**

The service role for cluster EC2 instances (also called the EC2 instance profile for Amazon EMR) is a special type of service role that is assigned to every EC2 instance in an Amazon EMR cluster when the instance launches. Application processes that run on top of Apache Hadoop assume this role for permissions to interact with other AWS services.

**VPC and subnet creation**

You can create a VPC from the VPC console.

Migrate Apache Cassandra workloads to Amazon Keyspaces using AWS Glue

Created by Nikolai Kolesnikov (AWS), Karthiga Priya Chandran (AWS), and Samir Patel (AWS)

Environment: PoC or pilot  Source: Cassandra  Target: Amazon Keyspaces

R Type: Relocate  Workload: Open-source; All other workloads  Technologies: Analytics; Migration; Serverless; Big data

AWS services: AWS Glue; Amazon Keyspaces

Summary

This pattern shows you how to migrate your existing Apache Cassandra workloads to Amazon Keyspaces (for Apache Cassandra) by using AWS Glue. You can use extract, transform, and load (ETL) jobs in AWS Glue to minimize the replication lag of migrating your workloads down to a matter of minutes. You also learn how to use an Amazon Simple Storage Service (Amazon S3) bucket to store data required for the migration, including Apache Parquet files, configuration files, and scripts. This pattern assumes that your Cassandra workloads are hosted on Amazon Elastic Compute Cloud (Amazon EC2) instances in a virtual private network (VPC).

Prerequisites and limitations

Prerequisites

- Cassandra cluster with a source table
- Target table in Amazon Keyspaces to replicate the workload
- S3 bucket to store intermediate Parquet files that contain incremental data changes
- S3 bucket to store job configuration files and scripts

Limitations

AWS Glue requires some time to provision Data Processing Units (DPUs) for the Cassandra workloads. The replication lag between the Cassandra cluster and the target keyspace and table in Amazon Keyspaces is likely to last for only a matter of minutes.

Architecture

Source technology stack

- Apache Cassandra
- DataStax
- ScyllaDB

Target technology stack
Migration architecture

The following diagram shows an example architecture where a Cassandra cluster is hosted on Amazon EC2 instances and spread across three Availability Zones. The Cassandra nodes are hosted in private subnets. The AWS Glue ETL jobs are hosted on Amazon Virtual Private Cloud (Amazon VPC).

The diagram shows the following workflow:

1. An AWS Glue job reads the job configuration and scripts in an S3 bucket.
2. The AWS Glue job connects through port 9042 to read data from the Cassandra cluster.
3. The AWS Glue job connects through port 9142 to write data to Amazon Keyspaces.

Tools

AWS services and tools

- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- **AWS Glue** is a fully managed ETL service that helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- **AWS Glue Studio** is a graphical interface that makes it easy to create, run, and monitor ETL jobs in AWS Glue.
- **Amazon Keyspaces Console** is a scalable, highly available, and managed database service that’s compatible with Apache Cassandra.

Code

The code for this pattern is available in the GitHub [Amazon Keyspaces (for Apache Cassandra) Examples](https://github.com/aws-samples/amazon-keysspaces-for-cassandra-softstate-pattern-realization) and [Migration to Amazon Keyspaces from Apache Cassandra](https://github.com/aws-samples/migration-from-cassandra-to-amazon-keyspaces) repositories.
## Epics

### Prepare the migration environment

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a target keyspace and table. | Create a **keyspace and table** in Amazon Keyspaces.  
**Note:** For more information on write capacity, see *Write unit calculations* in the *Additional information* section of this pattern.  
You can also create a keyspace by using the [Cassandra Query Language (CQL)](https://docs.datastax.com/en/cassandra/3.1/cql/). For more information, see *Create a keyspace using CQL* in the *Additional information* section of this pattern.  
**Note:** After you create the table, consider switching the table to **on-demand capacity mode** to avoid unnecessary charges.  
To update to throughput mode, run the following script:  
```
ALTER TABLE target_keyspace.target_table 
    WITH CUSTOM_PROPERTIES = { 'capacity_mode': { 'throughput_mode': 'PAY_PER_REQUEST' } }
``` | App owner, AWS administrator, DBA, App developer |
| Create a network connection for AWS Glue. | To create a new **AWS Glue connection** that connects the Cassandra cluster to the keyspace and table that you created earlier, use the following script:  
```
aws glue create-connection --connection-input '{  
    "Name": "conn-cassandra-custom",  
    "Description": "Connection to Cassandra cluster",  
    "ConnectionType": "NETWORK",  
    "ConnectionProperties": {  
        "JDBC_ENFORCE_SSL": "false"  
    },  
    "PhysicalConnectionRequirements": {  
        "SubnetId": "subnet-ee1111d1EXAMPLE",  
        "VpcId": "vpc-ee1111d1EXAMPLE",  
        "SecurityGroupIds": ["sg-ee1111d1EXAMPLE", "sg-ee2222d1EXAMPLE"]  
    }  
}'
``` | AWS administrator, Data engineer |
<table>
<thead>

<tbody>
<tr>
<td>Create an AWS Glue job to export the Cassandra workload to S3 in Parquet format.</td>
<td>Create an AWS Glue job based on the CassandraToS3.scala example from the GitHub amazon-keyspaces-examples repository. The example reads from Cassandra and writes the table to the S3 bucket.</td>
<td>App developer, App owner, Migration engineer</td>
</tr>
<tr>
<td>Create an AWS Glue job to import the incremental workload to Amazon Keyspaces.</td>
<td>Create an AWS Glue job based on the S3toKeyspaces.scala example from the GitHub amazon-keyspaces-examples repository.</td>
<td>App developer, App owner, Migration engineer</td>
</tr>
</tbody>
</table>

### Additional information

#### Migration considerations

You can use AWS Glue to migrate your Cassandra workload to Amazon Keyspaces, while keeping your Cassandra source databases completely functional during the migration process. After the replication is complete, you can choose to cut over your applications to Amazon Keyspaces with minimal replication lag (less than minutes) between the Cassandra cluster and Amazon Keyspaces. To maintain data consistency, you can also use a similar pipeline to replicate the data back to the Cassandra cluster from Amazon Keyspaces.
Write unit calculations

As an example, consider that you intend to write 500,000,000 with the row size 1 KiB during one hour. The total number of Amazon Keyspaces write units (WCUs) that you require is based on this calculation:

\[
\text{(number of rows/60 mins 60s) 1 WCU per row} = \frac{500,000,000}{(60 \times 60) \times 1} = 69,444 \text{ WCUs required}
\]

69,444 WCUs per second is the rate for 1 hour, but you could add some cushion for overhead. For example, \(69,444 \times 1.10 = 76,388\) WCUs has 10 percent overhead.

Create a keyspace using CQL

To create a keyspace by using CQL, run the following commands:

```sql
CREATE KEYSPACE target_keyspace WITH replication = {'class': 'SingleRegionStrategy'}
CREATE TABLE target_keyspace.target_table (userid uuid, level text, gameid int, description text, nickname text, zip text, email text, updatetime text, PRIMARY KEY (userid, level, gameid) ) WITH default_time_to_live = 0 AND CUSTOM_PROPERTIES = {'capacity_mode': { 'throughput_mode': 'PROVISIONED', 'write_capacity_units': 76388, 'read_capacity_units': 3612 }} AND CLUSTERING ORDER BY (level ASC, gameid ASC)
```
Migrate Oracle Business Intelligence 12c to the AWS Cloud from on-premises servers

Summary

This pattern shows how to migrate Oracle Business Intelligence Enterprise Edition 12c from on-premises servers to the AWS Cloud by using AWS CloudFormation. It also describes how you can use other AWS services to implement Oracle BI 12c components that deliver high availability, security, flexibility, and the ability to dynamically scale.

For a list of best practices related to migrating Oracle BI 12c to the AWS Cloud, see the Additional information section of this pattern.

Note: It’s a best practice to run multiple test migrations before transferring your existing Oracle BI 12c data to the cloud. These tests help you fine tune your migration approach, identify and fix potential issues, and estimate downtime requirements more accurately.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Secure network connectivity between your on-premises servers and AWS through either AWS Virtual Private Network (AWS VPN) services or AWS Direct Connect
- Software licenses for your Oracle operating system, Oracle BI 12c, Oracle Database, Oracle WebLogic Server, and Oracle HTTP Server

Limitations

For information about storage size limits, see the Amazon Relational Database Service (Amazon RDS) for Oracle documentation.

Product versions

- Oracle Business Intelligence Enterprise Edition 12c
• Oracle WebLogic Server 12c
• Oracle HTTP Server 12c
• Oracle Database 12c (or newer)
• Oracle Java SE 8

Architecture

The following diagram shows an example architecture for running Oracle BI 12c components in the AWS Cloud:
This diagram shows the following architecture:

1. Amazon Route 53 provides domain name service (DNS) configuration.
2. Elastic Load Balancing (ELB) distributes network traffic to improve the scalability and availability of the Oracle BI 12c components across multiple Availability Zones.
3. Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling groups host the Oracle HTTP Servers, Weblogic Admin server, and managed BI servers across multiple Availability Zones.
4. Amazon Relational Database Service (Amazon RDS) for Oracle database store BI Server metadata across multiple Availability Zones.
5. Amazon Elastic File System (Amazon EFS) is mounted to every Oracle BI 12c component for shared file storage.

**Technology stack**

- Amazon Elastic Block Store (Amazon EBS)
- Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon Elastic File System (Amazon EFS)
- Amazon RDS for Oracle
- AWS Certificate Manager (ACM)
- Elastic Load Balancing (ELB)
- Oracle BI 12c
- Oracle WebLogic Server 12c
- Oracle HTTP Server (OHS)

**Tools**

- [AWS CloudFormation](https://aws.amazon.com/cloudformation/) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [AWS Certificate Manager (ACM)](https://aws.amazon.com/acm/) helps you create, store, and renew public and private SSL/TLS X.509 certificates and keys that protect your AWS websites and applications.
- [AWS Database Migration Service (AWS DMS)](https://aws.amazon.com/dms/) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [Amazon Elastic Compute Cloud (Amazon EC2)](https://aws.amazon.com/ec2/) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need, and quickly scale them up or down.
- [Amazon EC2 Auto Scaling](https://aws.amazon.com/autoscaling/ec2/) helps you maintain application availability and allows you to automatically add or remove Amazon EC2 instances according to conditions you define.
- Elastic Load Balancing distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.
- [Amazon Relational Database Service (Amazon RDS)](https://aws.amazon.com/rds/) helps you set up, operate, and scale a relational database in the AWS Cloud.
- [Amazon Simple Storage Service (Amazon S3)](https://aws.amazon.com/s3/) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Amazon Virtual Private Cloud (Amazon VPC)](https://aws.amazon.com/vpc/) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- [Oracle Data Pump](https://www.oracle.com/database/data-pump.html) helps you move data and metadata from one database to another at high speeds.

</tr>
</tbody>
</table>
| Install Oracle Fusion Middleware 12c and Oracle BI 12c. | 1. Starting with one Amazon EC2 instance, install Oracle Fusion Middleware 12c infrastructure and OBIEE 12c. For more information, see the following sections of the Oracle Fusion Middleware Enterprise Deployment Guide for Oracle Business Intelligence:  
   - Starting the infrastructure installer on BIHOST1 | Migration Architect, Oracle BI Architect |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| 1. Install Oracle Business Intelligence in preparation for an enterprise deployment. | • Installing Oracle Business Intelligence in preparation for an enterprise deployment  
   **Note:** Use Amazon EFS to host directories that will be shared among Oracle BI 12c cluster nodes.  
   2. Apply any required patches to the installation.  
   3. Create AMIs of the instances and save copies for future use. | Migration Architect, Oracle BI Architect |
| 2. Configure your Oracle WebLogic Server domain for Oracle BI 12c. | Configure your Oracle BI 12c domain as a non-clustered deployment.  
   For more information, see Configuring the BI Domain in the Oracle Fusion Middleware Enterprise Deployment Guide for Oracle Business Intelligence. | Migration Architect, Oracle BI Architect |
| 3. Perform horizontal scale out of the Oracle BI 12c. | Horizontally scale out the single node to the desired number of nodes.  
   For more information, see Scaling out Oracle Business Intelligence in the Oracle Fusion Middleware Enterprise Deployment Guide for Oracle Business Intelligence. | Migration Architect, Oracle BI Architect |
| 4. Install Oracle HTTP Server 12c. | 1. Install Oracle HTTP Server 12c on the Oracle web tier Amazon EC2 instances. For instructions see Install Oracle HTTP Server 12c in Install and configure Oracle HTTP Server for Oracle Access Management 12c.  
   2. Apply any required patches to the installation.  
   3. Create AMIs of the instances and save copies for future use. | Migration Architect, Oracle BI Architect |
| 5. Configure load balancers for SSL termination. | 1. Create or import SSL certificates in ACM.  
   2. Associate the SSL certificates with ELB. | Cloud Infrastructure Architect, Migration Architect |
### Migrate business intelligence metadata artifacts to AWS.

1. Export Oracle Business Intelligence Application Archive (BAR) files from the on-premises Oracle BI 12c installation. To export the BAR files, use the WebLogic Scripting Tool (WLST) to run the `exportServiceInstance` command.

2. Import the on-premises BAR files into the AWS Oracle BI 12c installation. To import the BAR files, run the `importServiceInstance` WLST command.

### Skills required
- Migration Architect, Oracle BI Architect

### Perform post-migration tasks.

After importing the BAR files, do the following:
- Configure any additional JDBC data sources.
- Install drivers for other data sources like PostgreSQL, or Amazon Redshift.
- Configure Oracle LDAP, SSL, single sign-on (SSO), and WebLogic security store.
- Configure AWS Identity and Access Management (IAM) policies.
- Activate usage tracking.
- Set up integrations to other systems.
- Migrate any custom scripts.

### Skills required
- Migration Architect, Oracle BI Architect

### Test the new environment

Additional information

The following is a list of best practices related to migrating Oracle BI 12c to the AWS Cloud.

Repository databases

It’s a best practice to host Oracle BI 12c database schemas on an Amazon RDS for Oracle instance. This instance type provides cost-efficient and resizable capacity while automating administration tasks, such as hardware provisioning, database setup, patching, and backups.

For more information, see Using the Oracle Repository Creation Utility on RDS for Oracle in the Amazon RDS User Guide.

Web and application tiers

Memory optimized Amazon EC2 instances are often well suited for Oracle BI 12c servers. Whatever instance type you choose, make sure that the instances that you provision meet your system’s memory usage requirements. Also, make sure that you configure a sufficient WebLogic Java Virtual Machine (JVM) heap size based on your Amazon EC2 instance’s available memory.

Local storage

I/O plays an important part in the overall performance of your Oracle BI 12c application. Amazon Elastic Block Store (Amazon EBS) offers different storage classes that are optimized for different workload patterns. Make sure that you choose an Amazon EBS volume type that fits your use case.

For more information about EBS volume types, see Amazon EBS features in the Amazon EBS documentation.

Shared storage

A clustered Oracle BI 12c domain requires shared storage for the following resources:

- Configuration files
- Oracle BI 12c singleton data directory (SDD)
- Oracle global cache
- Oracle BI Scheduler scripts
- Oracle WebLogic Server binaries

You can meet this shared storage requirement by using Amazon EFS, which provides a scalable, fully managed elastic Network File System (NFS) file system.

Fine tuning shared storage performance

Amazon EFS has two throughput modes: Provisioned and Bursting. The service also has two performance modes: General Purpose and Max I/O.

To fine tune performance, start by testing your workloads in the General Purpose performance mode and Provisioned throughput mode. Doing these tests will help you determine if those baseline modes are sufficient to meet your desired service levels.

For more information, see Amazon EFS performance in the Amazon EFS User Guide.

Availability and disaster recovery

It's a best practice to deploy Oracle BI 12c components across multiple Availability Zones to protect those resources in the event of an Availability Zone failure. The following is a list of availability and disaster recovery best practices for specific Oracle BI 12c resources hosted in the AWS Cloud:
• **Oracle BI 12c repository databases**: Deploy a multi-AZ Amazon RDS database instance to your Oracle BI 12crepository database. In a multi-AZ deployment, Amazon RDS automatically provisions and maintains a synchronous standby replica in a different AZ. Running an Oracle BI 12c repository database instance across Availability Zones can enhance availability during planned system maintenance and help protect your databases against instance and Availability Zone failures.

• **Oracle BI 12c Managed Servers**: To achieve fault tolerance, it’s a best practice to deploy Oracle BI 12c system components on Managed Servers in an Amazon EC2 Auto Scaling Group configured to span multiple Availability Zones. Auto Scaling replaces faulty instances based on Amazon EC2 health checks. In the event of an Availability Zone failure, Oracle HTTP Servers continue to direct traffic to Managed Servers in the functioning Availability Zone. Then, Auto Scaling launches instances to keep up with your host count requirements. Activating HTTP session state replication is recommended to help make sure that there’s a smooth failover of the existing sessions to the functioning Managed Servers.

• **Oracle BI 12c Administration Servers**: To make sure that your Administration Server has high availability, host it in an Amazon EC2 Auto Scaling group configured to span multiple Availability Zones. Then, set the minimum and maximum size of the group set to 1. If an Availability Zone failure occurs, Amazon EC2 Auto Scaling starts up a replacement Administration Server in an alternate Availability Zone. To recover any failed underlying hosts within the same Availability Zone, you can activate Amazon EC2 Auto Recovery.

• **Oracle Web Tier servers**: It’s a best practice to associate your Oracle HTTP Server with your Oracle WebLogic Server domain. For high availability, deploy your Oracle HTTP Server in an Amazon EC2 Auto Scaling group configured to span multiple Availability Zones. Then, place the server behind an ELB elastic load balancer. To provide additional protection against host failure, you can activate Amazon EC2 Auto Recovery.

### Scalability

The elasticity of the AWS Cloud helps you scale applications either horizontally or vertically in response to workload requirements.

#### Vertical scaling

To vertically scale your application, you can change the size and type of the Amazon EC2 instances that are running your Oracle BI 12c components. You don’t need to over-provision instances at the start of your deployment and incur unnecessary cost.

#### Horizontal scaling

Amazon EC2 Auto Scaling helps you horizontally scale your application by automatically adding or removing Managed Servers based on workload requirements.

**Note:** Horizontal scaling with Amazon EC2 Auto Scaling requires scripting skills and thorough testing to implement.

### Backup and recovery

The following is a list of backup and recovery best practices for specific Oracle BI 12c resources hosted in the AWS Cloud:

• **Oracle Business Intelligence metadata repositories**: Amazon RDS automatically creates and saves backups of your database instances. These backups are retained for a period of time that you specify. Make sure that you configure your Amazon RDS backup duration and retention settings based on your data protection requirements. For more information, see Amazon RDS backup and restore.

• **Managed Servers, Administration Servers, and Web Tier servers**: Make sure that you configure Amazon EBS snapshots based on your data protection and retention requirements.

• **Shared storage**: You can manage backup and recovery for files stored in Amazon EFS by using AWS Backup. The AWS Backup service can also be deployed to centrally manage backup and recovery of
other services, including Amazon EC2, Amazon EBS, and Amazon RDS. For more information, see What is AWS Backup? in the AWS Backup Developer Guide.

Security and compliance

The following is a list of security best practices and AWS services that can help you protect your Oracle BI 12c applications in the AWS Cloud:

- **Encryption at rest**: Amazon RDS, Amazon EFS, and Amazon EBS all support industry standard encryption algorithms. You can use AWS Key Management Service (AWS KMS) to create and manage cryptographic keys and control their use across AWS services and in your applications. You can also configure Oracle Transparent Data Encryption (TDE) on the Amazon RDS for Oracle database instance that’s hosting your Oracle BI 12c repository database.

- **Encryption in transit**: It’s a best practice to activate either SSL or TLS protocols to protect data in transit between the various layers of your Oracle BI 12c installation. You can use AWS Certificate Manager (ACM) to provision, manage, and deploy public and private SSL and TLS certificates for your Oracle BI 12c resources.

- **Network security**: Make sure that you deploy your Oracle BI 12c resources in an Amazon VPC that has the appropriate access controls configured for your use case. Configure your security groups to filter inbound and outbound traffic from the Amazon EC2 instances that are running your installation. Also, make sure that you configure Network Access Control Lists (NACLs) that allow or deny traffic based on defined rules.

- **Monitoring and logging**: You can use AWS CloudTrail to track API calls to your AWS infrastructure, including your Oracle BI 12c resources. This functionality is useful when tracking changes to infrastructure or when conducting a security analysis. You can also use Amazon CloudWatch to view operational data that can provide you with actionable insight into the performance and health of your Oracle BI 12c application. You can configure alarms and take automated actions based on those alarms, too. Amazon RDS provides additional monitoring tools, including Enhanced Monitoring and Performance Insights.
Migrate an on-premises Apache Kafka cluster to Amazon MSK by using MirrorMaker

Created by Han Zhang (AWS) and Tanner Pratt (AWS)

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: On-premises or self-managed Apache Kafka cluster</th>
<th>Target: Amazon Managed Streaming for Apache Kafka (Amazon MSK)</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Replatform</td>
<td>Workload: Open-source; All other workloads</td>
<td>Technologies: Analytics; Big data; Migration</td>
</tr>
<tr>
<td>AWS services: Amazon MSK</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

This pattern provides guidance for migrating an on-premises, self-managed, or hosted Apache Kafka cluster to Amazon Managed Streaming for Apache Kafka (Amazon MSK). You can also use this pattern to migrate from one Amazon MSK cluster to another.

Apache Kafka includes the MirrorMaker feature, which replicates data between two Kafka clusters. MirrorMaker consists of a collection of consumers, which are part of a consumer group. The consumers read data from the topics in the source cluster and then pass this data to producers, which write the data to the target cluster.

The Amazon MSK documentation contains a high-level overview of the process to use MirrorMaker version 1.0 to migrate on-premises Kafka clusters to Amazon MSK. This pattern supplements this information by offering comprehensive, step-by-step instructions for using MirrorMaker version 2.0.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- A Kafka source cluster that is one of the following:
  - In an on-premises data center
  - Self-managed in the cloud
  - Hosted through a partner

**Limitations**

- To use MirrorMaker version 2.0, the source cluster must be operating Apache Kafka version 2.4.0 or later. For earlier versions, see the instructions in the Amazon MSK documentation in order to use MirrorMaker version 1.0.

**Product versions**

- MirrorMaker version 2.0
- Apache Kafka version 2.4.0 or later. For more information about the versions of Apache Kafka that Amazon MSK supports, see Supported Apache Kafka versions.
# Architecture

## Source technology stack

- On-premises or self-managed Kafka cluster

## Target technology stack

- Amazon MSK cluster

## Target architecture

The diagram shows the following process:

1. MirrorMaker reads the data from the topics and consumer groups in the source Kafka cluster.
2. MirrorMaker replicates the data and consumer information to the target Amazon MSK cluster.

## Tools

### AWS services

- **Amazon Elastic Compute Cloud (Amazon EC2)** provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- **Amazon Managed Streaming for Apache Kafka (Amazon MSK)** is a fully managed service that helps you build and run applications that use Apache Kafka to process streaming data.
- **Amazon Virtual Private Cloud (Amazon VPC)** helps you launch AWS resources into a virtual network that you’ve defined. This virtual network resembles a traditional network that you’d operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
Other tools

- **Apache Kafka** is an open-source event streaming platform. In this pattern, you use the **MirrorMaker** feature of Kafka to perform the cross-cluster migration.

Best practices

You can run MirrorMaker on in either the source or target environments, but it's recommended that you run it as close as possible to the target cluster. For more information, see **Best Practice: Consume from Remote, Produce to Local** in the Apache Kafka documentation.

Epics

Create the VPC and target Amazon MSK cluster

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a VPC.             | 1. Create a VPC in the target AWS account. For instructions, see [Create a VPC](#).  
2. Create three private subnets in different Availability Zones in the new VPC. For instructions, see [Create a subnet](#). Using different Availability Zones provides high availability and fault tolerance.  
**Note:** If you are using a public internet connection to migrate the Kafka cluster, create public subnets and enable public access to the Amazon MSK cluster. | AWS systems administrator, DevOps engineer, Cloud administrator |
| Create the Amazon MSK cluster. | Create an Amazon MSK cluster. For instructions, see [Creating a cluster using the AWS Management Console](#) or [Creating a cluster using the AWS CLI](#). Configure the cluster to use the VPC and subnets that you created previously. | AWS systems administrator, DevOps engineer, Cloud administrator |

Set up MirrorMaker

<td>When the consumer applications are successfully consuming on the target cluster, stop the producers on the source cluster.</td>
<td>App developer</td>
</tr>
<tr>
<td>Start the producers on the target cluster.</td>
<td>Alter the producer's configuration bootstrap servers, and point to the target cluster. Wait for MirrorMaker to finish mirroring all data from source cluster before starting the producers.</td>
<td>App developer</td>
</tr>
<tr>
<td>Stop MirrorMaker.</td>
<td>After producers have moved to the target cluster, stop MirrorMaker.</td>
<td>AWS systems administrator, Cloud administrator, DevOps engineer</td>
</tr>
</tbody>
</table>

**Related resources**

**AWS resources**

- [Migrating clusters using MirrorMaker](Amazon MSK documentation) (Amazon MSK documentation)
- [Amazon MSK migration labs](AWS workshop studio) (AWS workshop studio)

**Other resources**

- [MirrorMaker 2.0](Apache Kafka Improvement Proposals) (Apache Kafka Improvement Proposals)
- [Geo-Replication: Cross-Cluster Data Mirroring](Apache Kafka documentation) (Apache Kafka documentation)

**Additional information**

This pattern runs MirrorMaker 2.0 as a dedicated MirrorMaker cluster on Amazon EC2. This option is acceptable for development environments. Although it is not discussed in this pattern, you can also run MirrorMaker 2.0 in a Kafka Connect cluster. This deployment option uses a framework within the Kafka ecosystem that improves scaling and maintenance. You deploy the connector into a Kafka Connect cluster with the associated configuration to run the application. The connector can run in **standalone mode** for development or testing or in **distributed mode** for production. For more information, see [Running MirrorMaker in a Connect cluster](Apache Kafka documentation) (Apache Kafka documentation). For more information about other MirrorMaker 2.0 deployment options, see [Walkthrough: Running MirrorMaker 2.0](Kafka documentation) (Kafka documentation).
Migrate an ELK Stack to Elastic Cloud on AWS

Created by Battulga Purevragchaa (AWS), uday reddy, and Antony Prasad Thevaraj (AWS)

<table>
<thead>
<tr>

AWS services: Amazon EC2; Amazon EC2 Auto Scaling; Elastic Load Balancing (ELB); Amazon S3; Amazon Route 53

Summary

Elastic has provided services for many years, with their users and customers typically managing Elastic themselves on premises. Elastic Cloud, the managed Elasticsearch service, provides a way to consume the Elastic Stack (ELK Stack) and solutions for enterprise search, observability, and security. You can access Elastic solutions with apps such as Logs, Metrics, APM (application performance monitoring), and SIEM (security information and event management). You can use integrated features such as machine learning, index lifecycle management, Kibana Lens (for drag-and-drop visualizations).

When you move from self-managed Elasticsearch to Elastic Cloud, the Elasticsearch service takes care of the following:

• Provisioning and managing the underlying infrastructure
• Creating and managing Elasticsearch clusters
• Scaling clusters up and down
• Upgrades, patching, and taking snapshots

This gives you more time to focus on solving other challenges.

This pattern defines how to migrate on-premises Elasticsearch 7.13 to Elasticsearch on Elastic Cloud on Amazon Web Services (AWS). Other versions might require slight modifications to the processes described in this pattern. For more information, contact your Elastic representative.

Prerequisites and limitations

Prerequisites

• An active AWS account with access to Amazon Simple Storage Service (Amazon S3) for snapshots
• A secure, sufficiently high-bandwidth private link for copying snapshot data files to Amazon S3
• Amazon S3 Transfer Acceleration
• Elastic Snapshot policies to ensure that data ingestion is archived regularly, either to a sufficiently large local data store or to remote storage (Amazon S3)

You must understand how large your snapshots and the lifecycle policies for accompanying indexes are on premises before initiating your migration. For more information, contact Elastic.
Roles and skills

The migration process also requires the roles and expertise described in the following table.

<table>
<thead>
<tr>
<th>Role</th>
<th>Expertise</th>
<th>Responsibilities</th>
</tr>
</thead>
<tbody>
<tr>
<td>App support</td>
<td>Familiarity with Elastic Cloud and Elastic on premises</td>
<td>All Elastic related tasks</td>
</tr>
<tr>
<td>Systems administrator or DBA</td>
<td>In-depth knowledge of the on-premises Elastic environment and its configuration</td>
<td>The ability to provision storage, install and use the AWS Command Line Interface (AWS CLI), and identify all data sources feeding Elastic on premises</td>
</tr>
<tr>
<td>Network administrator</td>
<td>Knowledge of on-premises to AWS network connectivity, security, and performance</td>
<td>Establishment of network links from on premises to Amazon S3, with an understanding of connectivity bandwidth</td>
</tr>
</tbody>
</table>

Limitations

- Elasticsearch on Elastic Cloud is available only in [supported AWS Regions (September 2021)](https://aws.amazon.com/regions/).

Product versions

- Elasticsearch 7.13

Architecture

Source technology stack

On-premises Elasticsearch 7.13 or later:

- Cluster snapshots
- Index snapshots
- [ Beats](https://www.elastic.com/products/beats) configuration

Source technology architecture

The following diagram shows a typical on-premises architecture with different ingestion methods, node types, and Kibana. The different node types reflect the Elasticsearch cluster, authentication, and visualization roles.
1. Ingestion from Beats to Logstash
2. Ingestion from Beats to Apache Kafka messaging queue
3. Ingestion from Filebeat to Logstash
4. Ingestion from Apache Kafka messaging queue to Logstash
5. Ingestion from Logstash to an Elasticsearch cluster
6. Elasticsearch cluster
7. Authentication and notification node
8. Kibana and blob nodes

**Target technology stack**

Elastic Cloud is deployed to your software as a service (SaaS) account in multiple AWS Regions with cross-cluster replication.

- Cluster snapshots
- Index snapshots
- Beats configurations
- Elastic Cloud
- Network Load Balancer
- Amazon Route 53
- Amazon S3

**Target architecture**
The managed Elastic Cloud infrastructure is:

- Highly available, being present in multiple Availability Zones and multiple AWS Regions.
- Region failure tolerant because data (indexes and snapshots) is replicated using Elastic Cloud cross-cluster replication (CCR)
- Archival, because snapshots are archived in Amazon S3
- Network partition tolerant through a combination of Network Load Balancers and Route 53
- Data ingestion originating from (but not limited to) Elastic APM, Beats, Logstash

High-level migration steps

Elastic has developed its own prescriptive methodology for migrating on-premises Elastic Cluster to Elastic Cloud. The Elastic methodology is directly aligned and complementary to the AWS migration guidance and best practices, including Well-Architected Framework and AWS Migration Acceleration Program (MAP). Typically, the three AWS migration phases are the following:

- Assess
- Mobilize
- Migrate and modernize

Elastic follows similar migration phases with complementary terminology:

- Initiate
- Plan
- Implement
- Deliver
- Close
Elastic uses the Elastic Implementation Methodology to facilitate the delivery of project outcomes. This is inclusive by design to ensure that the Elastic, consulting teams, and customer teams work together with clarity to jointly deliver intended outcomes.

The Elastic methodology combines traditional waterfall phasing with Scrum within the implementation phase. Configurations of technical requirements are delivered iteratively in a collaborative manner while minimizing risk.

---

### Tools

#### AWS services

- **Amazon Route 53** – Amazon Route 53 is a highly available and scalable Domain Name System (DNS) web service. You can use Route 53 to perform three main functions in any combination: domain registration, DNS routing, and health checking.

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web. This pattern uses an S3 bucket and Amazon S3 Transfer Acceleration.

- **Elastic Load Balancing** – Elastic Load Balancing automatically distributes your incoming traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in one or more Availability Zones.

#### Other tools

- **Beats** – Beats ship data from Logstash or Elasticsearch

- **Elastic Cloud** – Elastic Cloud is a managed service for hosting Elasticsearch.

- **Elasticsearch** – Elasticsearch is a search and analytics engine that uses the Elastic Stack to centrally store your data for search and analytics that scale. This pattern also uses snapshot creation and cross-cluster replication.

- **Logstash** – Logstash is a server-side data processing pipeline that ingests data from multiple sources, transforms it, and then sends it to your data storage.
## Epics

### Prepare the migration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identify servers running the on-premises Elastic solution.</td>
<td>Confirm that Elastic migration is supported.</td>
<td>App owner</td>
</tr>
<tr>
<td>Understand the on-premises server configuration.</td>
<td>To understand the server configuration needed to drive workloads successfully on premises, find the server hardware footprint, network configuration, and storage characteristics that are currently in use</td>
<td>App Support</td>
</tr>
<tr>
<td>Gather user and app account information.</td>
<td>Identify the user names and app names that are used by the on-premises Elastic environment.</td>
<td>Systems administrator, App support</td>
</tr>
<tr>
<td>Document Beats and data shipper configuration.</td>
<td>To document the configurations, look at existing data sources and sinks. For more information, see the Elastic documentation.</td>
<td>App support</td>
</tr>
<tr>
<td>Determine the velocity and volume of data.</td>
<td>Establish a baseline for how much data the cluster is handling.</td>
<td>Systems administrator, App support</td>
</tr>
<tr>
<td>Document RPO and RTO scenarios.</td>
<td>Document recovery point objective (RPO) and recovery time objective (RTO) scenarios in terms of outages and service level agreements (SLAs).</td>
<td>App owner, Systems administrator, App support</td>
</tr>
<tr>
<td>Determine the optimal snapshot lifecycle settings.</td>
<td>Define how often data needs to be secured by using Elastic snapshots during and after the migration.</td>
<td>App owner, Systems administrator, App support</td>
</tr>
<tr>
<td>Define post-migration performance expectations.</td>
<td>Generate metrics on current and expected screen refresh, query runtimes, and user interface behaviors.</td>
<td>Systems administrator, App support</td>
</tr>
<tr>
<td>Document internet access transport, bandwidth, and availability requirements.</td>
<td>Ascertain speed, latency, and resiliency of internet connections for copying snapshots to Amazon S3.</td>
<td>Network administrator</td>
</tr>
<tr>
<td>Document current costs of on-premises runtime for Elastic.</td>
<td>Ensure that the sizing of the AWS targeted environment is designed to be both high performing and cost effective.</td>
<td>DBA, Systems administrator, App support</td>
</tr>
</tbody>
</table>
## Identify the authentication and authorization needs.

**Description:** The Elastic Stack security features provide built-in realms such as Lightweight Directory Access Protocol (LDAP), Security Assertion Markup Language (SAML), and OpenID Connect (OIDC).

**Skills required:** DBA, Systems administrator, App support

## Understand the specific regulatory requirements based on the geographic location.

**Description:** Ensure that data is exported and encrypted according to your requirements and to any relevant national requirements.

**Skills required:** DBA, Systems administrator, App support

## Implement the migration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prepare the staging area on Amazon S3.</td>
<td>To receive snapshots on Amazon S3, create an S3 bucket and a temporary AWS Identity and Access Management (IAM) role with full access to your newly created bucket. For more information, see Creating a role to delegate permissions to an IAM user. Use the AWS Security Token Service to request temporary security credentials. Keep the access key ID, secret access key, and session token secured. Enable Amazon S3 Transfer Acceleration on the bucket.</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>
| Install AWS CLI and the Amazon S3 plugin on premises. | On each Elasticsearch node, run the following command.  

```bash
sudo bin/elasticsearch-plugin install repository-s3
```

Then reboot the node. | AWS administrator |
| Configure Amazon S3 client access. | Add the keys created previously by running the following commands.  

```bash
elasticsearch-keystore add s3.client.default.access_key
```

```bash
elasticsearch-keystore add s3.client.default.secret_key
``` | AWS administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register a snapshot repository for Elastic data</td>
<td>Use the Kibana Dev Tools to tell the on-premises local cluster which remote S3 bucket to write to.</td>
<td>AWS administrator</td>
</tr>
<tr>
<td>Configure snapshot policy.</td>
<td>To configure snapshot lifecycle management, on the Kibana Policies tab, choose SLM policy, and define which times, data streams, or indexes should be included, and what names to use. Configure a policy that takes frequent snapshots. Snapshots are incremental and make efficient use of storage. Match your readiness assessment decision. A policy can also specify a retention policy and automatically delete snapshots when they are no longer needed.</td>
<td>App support</td>
</tr>
<tr>
<td>Verify that snapshots work.</td>
<td>In Kibana Dev Tools, run the following command.</td>
<td>AWS administrator, App support,</td>
</tr>
<tr>
<td>Deploy a new cluster on Elastic Cloud.</td>
<td>Log in to Elastic, and choose a cluster for “observability, search or security” derived from your business findings in the readiness assessment.</td>
<td>AWS administrator, App support</td>
</tr>
<tr>
<td>Set up cluster key store access.</td>
<td>The new cluster needs access to the S3 bucket that will store the snapshots. On the Elasticsearch Service Console, choose Security, and enter the access and secret IAM keys that you created earlier.</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>
### Configure the Elastic Cloud hosted cluster to access Amazon S3.

Set up new cluster access to the previously created snapshot repository in Amazon S3. Using Kibana, do the following:

1. Choose **Stack Management, Snapshot Settings, RegisterRepo**.
2. In the **Alias** field, enter the name of the repository.
3. For **S3 Client name**, choose **secondary**.
4. Add the S3 bucket that you created earlier to the repository.
5. Choose **Compress snapshot**.
6. For the **Encryption** settings, keep the default values.

**Skills required**: AWS administrator, App Support

### Verify the new Amazon S3 repository.

Ensure that you can access your new repository hosted in the Elastic Cloud cluster.

**Skills required**: AWS administrator

### Initialize the Elasticsearch service cluster.

On the Elasticsearch Service Console, initialize the Elasticsearch service cluster from the S3 snapshot.

Run the following commands as POST.

```
*/_close?
expand_wildcards=all

/_snapshot/<your-repo-name>/
<your-snapshot-name>/
_restore

*/_open?expand_wildcards=all
```

**Skills required**: App Support

### Complete the migration

Verify that the snapshot restore was successful.

Using Kibana Dev Tools, run the following command.

```
GET _cat/indices
```
Redeploy ingestion services.

Connect the endpoints for Beats and Logstash to the new Elasticsearch service endpoint.

App support

Test the cluster environment and clean up

Validate the cluster environment.

After the on-premises Elastic cluster environment is migrated to AWS, you can connect to it and use your own user acceptance testing (UAT) tools to validate the new environment.

App support

Clean-up the resources.

After you validate that the cluster migrated successfully, remove the S3 bucket and the IAM role used for the migration.

Migrate data to the AWS Cloud by using Starburst

*Created by Antony Prasad Thevaraj (AWS), Shaun Van Staden (Starburst), and Suresh Veeragoni (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technologies:</td>
<td>Analytics; Data lakes; Databases</td>
</tr>
<tr>
<td>Workload:</td>
<td>All other workloads</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon EKS</td>
</tr>
</tbody>
</table>

**Summary**

Starburst helps accelerate your data migration journey to Amazon Web Services (AWS) by providing an enterprise query engine that brings existing data sources together in a single access point. You can run analytics across multiple data sources to get valuable insights, before finalizing any migration plans. Without disrupting business-as-usual analytics, you can migrate the data by using the Starburst engine or a dedicated extract, transform, and load (ETL) application.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- A virtual private cloud (VPC)
- An Amazon Elastic Kubernetes Service (Amazon EKS) cluster
- An Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling group
- A list of current system workloads that need to be migrated
- Network connectivity from AWS to your on-premises environment

**Architecture**

**Reference architecture**

The following high-level architecture diagram shows the typical deployment of Starburst Enterprise in the AWS Cloud:

1. The Starburst Enterprise cluster runs inside your AWS account.
2. A user authenticates by using Lightweight Directory Access Protocol (LDAP) or Open Authorization (OAuth) and interacts directly with the Starburst cluster.
3. Starburst can connect to several AWS data sources, such as AWS Glue, Amazon Simple Storage Service (Amazon S3), Amazon Relational Database Service (Amazon RDS), and Amazon Redshift. Starburst provides federated query capabilities across data sources in the AWS Cloud, on premises, or in other cloud environments.
4. You launch Starburst Enterprise in an Amazon EKS cluster by using Helm charts.
5. Starburst Enterprise uses Amazon EC2 Auto Scaling groups and Amazon EC2 Spot Instances to optimize infrastructure.
6. Starburst Enterprise connects directly to your existing on-premises data sources to read data real-time. In addition, if you have an existing Starburst Enterprise deployment in this environment, you can directly connect your new Starburst cluster in the AWS Cloud to this existing cluster.
Please note the following:

- Starburst is not a data virtualization platform. It is a SQL-based massively parallel processing (MPP) query engine that forms the basis of an overall data mesh strategy for analytics.
- When Starburst is deployed as part of a migration, it has direct connectivity to the existing on-premises infrastructure.
- Starburst provides several built-in enterprise and open-source connectors that facilitate connectivity to a variety of legacy systems. For a full list of connectors and their capabilities, see Connectors in the Starburst Enterprise user guide.
- Starburst can query data in real-time from on-premises data sources. This prevents interruptions of regular business operations while data is being migrated.
If you are migrating from an existing on-premises Starburst Enterprise deployment, you can use a special connector, Starburst Stargate, to connect your Starburst Enterprise cluster in AWS directly to your on-premises cluster. This provides additional performance benefits when business users and data analysts are federating queries from the AWS Cloud to your on-premises environment.

High-level process overview

You can accelerate data migration projects by using Starburst because Starburst enables insights across all of your data, prior to migrating it. The following image shows the typical process for migrating data by using Starburst.

Roles

The following roles are typically required to complete a migration using Starburst:

- **Cloud administrator** – Responsible for making cloud resources available to run the Starburst Enterprise application
- **Starburst administrator** – Responsible for installing, configuring, managing, and supporting the Starburst application
- **Data engineer** – Responsible for:
  - Migrating the legacy data to the cloud
  - Building semantic views to support analytics
- **Solution or system owner** – Responsible for the overall solution implementation
Tools

AWS services

- **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud.
- **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service for running Kubernetes on AWS without needing to stand up or maintain your own Kubernetes control plane. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.

Other tools

- **Helm** – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- **Starburst Enterprise** – Starburst Enterprise is a SQL-based massively parallel processing (MPP) query engine that forms the basis of an overall data mesh strategy for analytics.
- **Starburst Stargate** – Starburst Stargate links catalogs and data sources in one Starburst Enterprise environment, such as a cluster in an on-premises data center, to the catalogs and data sources in another Starburst Enterprise environment, such as a cluster in the AWS Cloud.

Optimize the ETL ingestion of input file size on AWS

*Created by Apoorva Patrikar (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technologies:</td>
<td>Analytics; Data lakes</td>
</tr>
<tr>
<td>Workload:</td>
<td>Open-source</td>
</tr>
<tr>
<td>AWS services:</td>
<td>AWS Glue; Amazon S3</td>
</tr>
</tbody>
</table>

**Summary**

This pattern shows you how to optimize the ingestion step of the extract, transform, and load (ETL) process for big data and Apache Spark workloads on AWS Glue by optimizing file size before processing your data. Use this pattern to prevent or resolve the *small files problem*. That is, when a large number of small files slows down data processing due to the aggregate size of the files. For example, hundreds of files that are only a few hundred kilobytes each can significantly slow down data processing speeds for your AWS Glue jobs. This is because AWS Glue must perform internal list functions on Amazon Simple Storage Service (Amazon S3) and YARN (Yet Another Resource Negotiator) must store a large amount of metadata. To improve data processing speeds, you can use grouping to enable your ETL tasks to read a group of input files into a single in-memory partition. The partition automatically groups smaller files together. Alternatively, you can use custom code to add batch logic to your existing files.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- One or more AWS glue jobs
- One or more big data or Apache Spark workloads
- An S3 bucket

**Architecture**

The following pattern shows how data in different formats is processed by an AWS Glue job and then stored in an S3 bucket to get visibility into performance.
The diagram shows the following workflow:

1. An AWS Glue job converts small files in CSV, JSON, and Parquet format to dynamic frames. **Note:** The size of the input file has the most significant impact on the performance of the AWS Glue job.
2. The AWS Glue job performs internal list functions in an S3 bucket.

**Tools**

- **AWS Glue** is a fully managed ETL service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
## Epics

Use grouping to optimize ETL ingestion

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify the group size.</td>
<td>If you have more than 50,000 files, grouping is done by default. However, you can also use grouping for less than 50,000 files by specifying the group size in the connectionOptions parameter. The connectionOptions parameter is in the create_dynamic_frame.from_options method.</td>
<td>Data engineer</td>
</tr>
</tbody>
</table>
| Write the grouping code.    | Use the create_dynamic_frame method to create a dynamic frame. For example:  

```python
S3bucket_node1 = glueContext.create_dynamic_frame.from_options(
    format_options={"multiline": False},
    connection_type="s3",
    format="json",
    connection_options={
        "paths": ["s3://bucket/prefix/file.json"],
        "recurse": True,
        "groupFiles": 'inPartition',
        "groupSize": 1048576
    },
    transformation_ctx="S3bucket_node1"
)

**Note:** Use groupFiles to group files in an Amazon S3 partition group. Use groupSize to set the target size of the group to be read in memory. Specify groupSize in bytes (1048576 = 1 MB). | Data engineer     |
| Add the code to the workflow. | Add the grouping code to your job workflow in AWS Glue.                                                                                           | Data engineer     |
Use custom logic to optimize ETL ingestion

<table>
<thead>
<tr>
<th>Task</th>

Additional information

**Determining file size**

There is no straightforward way to determine if a file size is too big or too small. The impact of file size on processing performance depends on the configuration of your cluster. In core Hadoop, we recommend that you use files that are 128 MB or 256 MB to make the most of the block size.

For most text file workloads on AWS Glue, we recommended a file size between 100 MB and 1 GB for a 5-10 DPU cluster. To figure out the best size of input files, monitor the preprocessing section of your AWS Glue job, and then check the CPU utilization and memory utilization of the job.

**Additional considerations**

If performance in the early ETL stages is a bottleneck, consider grouping or merging the data files before processing. If you have complete control on the file generation process, it can be even more efficient to aggregate data points on the source system itself before the raw data is sent to AWS.
Orchestrate an ETL pipeline with validation, transformation, and partitioning using AWS Step Functions

**Summary**

This pattern describes how to build a serverless extract, transform, and load (ETL) pipeline to validate, transform, compress, and partition a large CSV dataset for performance and cost optimization. The pipeline is orchestrated by AWS Step Functions and includes error handling, automated retry, and user notification features.

When a CSV file is uploaded to an Amazon Simple Storage Service (Amazon S3) bucket source folder, the ETL pipeline starts to run. The pipeline validates the content and the schema of the source CSV file, transforms the CSV file to a compressed Apache Parquet format, partitions the dataset by year, month, and day, and stores it in a separate folder for analytics tools to process.

The code that automates this pattern is available on GitHub, in the ETL Pipeline with AWS Step Functions repository.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account.
- AWS Command Line Interface (AWS CLI) installed and configured with your AWS account, so that you can create AWS resources by deploying an AWS CloudFormation stack. AWS CLI version 2 is recommended. For installation instructions, see [Installing, updating, and uninstalling the AWS CLI version 2](https://docs.aws.amazon.com/cli/latest/userguide/cli-uptodate.html) in the AWS CLI documentation. For AWS CLI configuration instructions, see [Configuration and credential file settings](https://docs.aws.amazon.com/cli/latest/userguide/cli-uptodate.html#configuration) in the AWS CLI documentation.
- An Amazon S3 bucket.
- A CSV dataset with the correct schema. (The code repository included with this pattern provides a sample CSV file with the correct schema and data type that you can use.)
- A web browser that is supported for use with the AWS Management Console. (See the [list of supported browsers](https://aws.amazon.com/browsers)).
- AWS Glue console access.
- AWS Step Functions console access.

**Limitations**

- In AWS Step Functions, the maximum limit for keeping history logs is 90 days. For more information, see [Quotas](https://docs.aws.amazon.com/stepfunctions/latest/concepts/quota_info.html) and [Quotas for standard workflows](https://docs.aws.amazon.com/stepfunctions/latest/concepts/concurrency.html) in the AWS Step Functions documentation.
**Product versions**

- Python 3 for AWS Lambda
- AWS Glue version 2.0

**Architecture**

The workflow illustrated in the diagram consists of these high-level steps:

1. The user uploads a CSV file into the source folder in Amazon S3.
2. An Amazon S3 notification event initiates an AWS Lambda function that starts the Step Functions state machine.
3. The Lambda function validates the schema and data type of the raw CSV file.
4. Depending on the validation results:
   a. If validation of the source file succeeds, the file moves to the stage folder for further processing.
   b. If validation fails, the file moves to the error folder, and an error notification is sent through Amazon Simple Notification Service (Amazon SNS).
5. An AWS Glue crawler creates the schema of the raw file from the stage folder in Amazon S3.
6. An AWS Glue job transforms, compresses, and partitions the raw file into Parquet format.
7. The AWS Glue job also moves the file to the transform folder in Amazon S3.
8. The AWS Glue crawler creates the schema from the transformed file. The resulting schema can be used by any analytics job. You can also use Amazon Athena to run ad-hoc queries.
9. If the pipeline completes without errors, the schema file is moved to the archive folder. If any errors are encountered, the file is moved to the error folder instead.
10. Amazon SNS sends a notification that indicates success or failure based on the pipeline completion status.

All the AWS resources used in this pattern are serverless. There are no servers to manage.

**Tools**

**AWS services**

- **AWS Glue** – AWS Glue is a fully managed ETL service that makes it easy for customers to prepare and load their data for analytics.
• **AWS Step Functions** – AWS Step Functions is a serverless orchestration service that lets you combine AWS Lambda functions and other AWS services to build business-critical applications. Through the AWS Step Functions graphical console, you see your application’s workflow as a series of event-driven steps.

• **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service that offers industry-leading scalability, data availability, security, and performance.

• **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a highly available, durable, secure, fully managed pub/sub messaging service that enables you to decouple microservices, distributed systems, and serverless applications.

• **AWS Lambda** – AWS Lambda is a compute service that lets you run code without provisioning or managing servers. AWS Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.

**Code**

The code for this pattern is available on GitHub, in the [ETL Pipeline with AWS Step Functions](https://github.com/aws-samples/ETL-Pipeline-with-AWS-Step-Functions) repository. The code repository contains the following files and folders:

- **template.yml** – AWS CloudFormation template for creating the ETL pipeline with AWS Step Functions.
- **parameter.json** – Contains all parameters and parameter values. You update this file to change parameter values, as described in the Epics section.
- **myLayer/python** folder – Contains Python packages needed to create the required AWS Lambda layer for this project.
- **lambda** folder – Contains the following Lambda functions:
  - **move_file.py** – Moves the source dataset to the archive, transform, or error folder.
  - **check_crawler.py** – Checks the status of the AWS Glue crawler as many times as configured by the `RETRYLIMIT` environment variable before it sends a failure message.
  - **start_crawler.py** – Starts the AWS Glue crawler.
  - **start_step_function.py** – Starts AWS Step Functions.
  - **start_codebuild.py** – Starts the AWS CodeBuild project.
  - **validation.py** – Validates the input raw dataset.
  - **s3object.py** – Creates the required directory structure inside the S3 bucket.
  - **notification.py** – Sends success or error notifications at the end of the pipeline.

To use the sample code, follow the instructions in the Epics section.

**Epics**

**Prepare the source files**

<td></td>
</tr>
</tbody>
</table>
### Task

**Upload the source code to the S3 bucket.**

Before you deploy the CloudFormation template that automates the ETL pipeline, you must package the source files for the CloudFormation template and upload them to an S3 bucket. To do this, run the following AWS CLI command with your preconfigured profile:

```bash
aws cloudformation package --template-file template.yml --s3.bucket <bucket_name> --output-template-file packaged.template --profile <profile_name>
```

Where:

- `<bucket_name>` is the name of an existing S3 bucket in the AWS Region where you want to deploy the stack. This bucket is used to store the source code package for the CloudFormation template.
- `<profile_name>` is a valid AWS CLI profile that you preconfigured when you set up AWS CLI.

### Skills required

Developer

---

### Task

**Create the stack**

**Deploy the CloudFormation template.**

To deploy the CloudFormation template, run the following AWS CLI command:

```bash
aws cloudformation deploy --stack-name <stack_name> --template-file packaged.template --parameter-overrides file://parameter.json --capabilities CAPABILITY_IAM --profile <profile_name>
```

Where:

- `<stack_name>` is a unique identifier for the CloudFormation stack.

### Skills required

Developer
## Task Description

- `<profile-name>` is your preconfigured AWS CLI profile.

### Check progress.

On the [AWS CloudFormation console](https://console.aws.amazon.com/cloudformation), check the progress of stack development. When the status is `CREATE_COMPLETE`, the stack has been deployed successfully.

### Note the AWS Glue database name.

The Outputs tab for the stack displays the name of the AWS Glue database. The key name is `GlueDBOutput`.

---

### Test the pipeline

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Start the ETL pipeline.** | 1. Navigate to the source folder (`source`, or the folder name you set in the `parameter.json` file) inside the S3 bucket.  
2. Upload a sample CSV file to this folder. (The code repository provides a sample file called `Sample_Bank_Transaction_Raw_Dataset.csv` that you can use.) Uploading the file will start the ETL pipeline through Step Functions.  
3. On the [Step Functions console](https://console.aws.amazon.com/stepfunctions), check the ETL pipeline status. | Developer |
| **Check for the partitioned dataset.** | When the ETL pipeline completes, verify that the partitioned dataset is available in the Amazon S3 transform folder (`transform`, or the folder name you set in the `parameter.json` file). | Developer |
| **Check for the partitioned AWS Glue database.** | 1. On the [AWS Glue console](https://console.aws.amazon.com/glue), select the AWS Glue database created by the stack (this is the database that you noted in the previous epic).  
2. Verify that the partitioned table is available in the AWS Glue Data Catalog. | Developer |
### Task Description Skills required

Run queries. (Optional) Use Amazon Athena to run ad-hoc queries on the partitioned and transformed database. For instructions, see Running SQL Queries Using Amazon Athena in the AWS documentation. Database analyst

The following diagram shows the AWS Step Functions workflow for a successful ETL pipeline, from the Step Functions Inspector panel.
The following diagram shows the AWS Step Functions workflow for an ETL pipeline that fails because of an input validation error, from the Step Functions Inspector panel.
Perform advanced analytics using Amazon Redshift ML

Created by Po Hong (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technologies:</td>
<td>Analytics; Machine learning &amp; AI</td>
</tr>
<tr>
<td>Workload:</td>
<td>All other workloads</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon Redshift; Amazon SageMaker</td>
</tr>
</tbody>
</table>

Summary

On the Amazon Web Services (AWS) Cloud, you can use Amazon Redshift machine learning (Amazon Redshift ML) to perform ML analytics on data stored in either an Amazon Redshift cluster or on Amazon Simple Storage Service (Amazon S3). Amazon Redshift ML supports supervised learning, which is typically used for advanced analytics. Use cases for Amazon Redshift ML include revenue forecasting, credit card fraud detection, and customer lifetime value (CLV) or customer churn predictions.

Amazon Redshift ML makes it easy for database users to create, train, and deploy ML models by using standard SQL commands. Amazon Redshift ML uses Amazon SageMaker Autopilot to automatically train and tune the best ML models for classification or regression based on your data, while you retain control and visibility.

All interactions between Amazon Redshift, Amazon S3, and Amazon SageMaker are abstracted away and automated. After the ML model is trained and deployed, it becomes available as a user-defined function (UDF) in Amazon Redshift and can be used in SQL queries.

This pattern complements the Create, train, and deploy ML models in Amazon Redshift using SQL with Amazon Redshift ML from the AWS Blog, and the Build, train, and deploy an ML model with Amazon SageMaker tutorial from the Getting Started Resource Center.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Existing data in an Amazon Redshift table

Skills

- Familiarity with terms and concepts used by Amazon Redshift ML, including machine learning, training, and prediction. For more information about this, see Training ML models in the Amazon Machine Learning (Amazon ML) documentation.
- Experience with Amazon Redshift user setup, access management, and standard SQL syntax. For more information about this, see Getting started with Amazon Redshift in the Amazon Redshift documentation.
- Knowledge and experience with Amazon S3 and AWS Identity and Access Management (IAM).
- Experience running commands in AWS Command Line Interface (AWS CLI) is also beneficial but not required.
**Limitations**

- The Amazon Redshift cluster and S3 bucket must be located in the same AWS Region.
- This pattern's approach only supports supervised learning models such as regression, binary classification, and multiclass classification.

**Architecture**

The following steps explain how Amazon Redshift ML works with SageMaker to build, train, and deploy an ML model:

1. Amazon Redshift exports training data to an S3 bucket.
2. SageMaker Autopilot automatically preprocesses the training data.
3. After the CREATE MODEL statement is invoked, Amazon Redshift ML uses SageMaker for training.
4. SageMaker Autopilot searches for and recommends the ML algorithm and optimal hyper-parameters that optimize the evaluation metrics.
5. Amazon Redshift ML registers the output ML model as a SQL function in the Amazon Redshift cluster.
6. The ML model's function can be used in a SQL statement.

**Technology stack**

- Amazon Redshift
- SageMaker
- Amazon S3

**Tools**

- **Amazon Redshift** – Amazon Redshift is an enterprise-level, petabyte scale, fully managed data warehousing service.
- **Amazon Redshift ML** – Amazon Redshift machine learning (Amazon Redshift ML) is a robust, cloud-based service that makes it easy for analysts and data scientists of all skill levels to use ML technology.
• **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.
• **Amazon SageMaker** – SageMaker is a fully managed ML service.
• **Amazon SageMaker Autopilot** – SageMaker Autopilot is a feature-set that automates key tasks of an automatic machine learning (AutoML) process.

**Code**

You can create a supervised ML model in Amazon Redshift by using the following code:

```
"CREATE MODEL customer_churn_auto_model
FROM (SELECT state,
    account_length,
    area_code,
    total_charge/account_length AS average_daily_spend,
    cust_serv_calls/account_length AS average_daily_cases,
    churn
    FROM customer_activity
    WHERE record_date < '2020-01-01'
    )
TARGET churn
FUNCTION ml_fn_customer_churn_auto
IAM_ROLE 'arn:aws:iam::XXXXXXXXXXXX:role/Redshift-ML'
SETTINGS (S3_BUCKET 'your-bucket');"
```

**Note**: The SELECT state can refer to Amazon Redshift regular tables, Amazon Redshift Spectrum external tables, or both.

Access, query, and join Amazon DynamoDB tables using Athena

Created by Moinul Al-Mamun

| Environment: Production | Technologies: Analytics; Databases; Serverless; Big data | AWS services: Amazon Athena; Amazon DynamoDB; AWS Lambda; Amazon S3 |

Summary

This pattern shows you how to set up a connection between Amazon Athena and Amazon DynamoDB by using the Amazon Athena DynamoDB connector. The connector uses an AWS Lambda function to query the data in DynamoDB. You don't need to write any code to set up the connection. After the connection is established, you can quickly access and analyze DynamoDB tables by using Athena Federated Query to run SQL commands from Athena. You can also join one or more DynamoDB tables to each other or to other data sources, such as Amazon Redshift or Amazon Aurora.

Prerequisites and limitations

Prerequisites

- An active AWS account with permissions to manage DynamoDB tables, Athena Data sources, Lambda, and AWS Identity and Access Management (IAM) roles
- An Amazon Simple Storage Service (Amazon S3) bucket where Athena can store query results
- An S3 bucket where the Athena DynamoDB Connector can save the data in the short term
- An AWS Region that supports Athena engine version 2
- IAM permissions to access Athena and the required S3 buckets
- Amazon Athena DynamoDB Connector, installed

Limitations

There is a cost for querying DynamoDB tables. Table sizes exceeding a few gigabytes (GBs) can incur a high cost. We recommend that you consider cost before performing any full table SCAN operation. For more information, see Amazon DynamoDB pricing. To reduce costs and achieve high performance, we recommend that you always use LIMIT in your query (for example, SELECT * FROM table1 LIMIT 10). Also, before you perform a JOIN or GROUP BY query in a production environment, consider the size of your tables. If your tables are too large, consider alternative options such as migrating the table to Amazon S3.

Architecture

The following diagram shows how a user can run a SQL query on a DynamoDB table from Athena.
The diagram shows the following workflow:

1. To query a DynamoDB table, a user runs a SQL query from Athena.
2. Athena initiates a Lambda function.
3. The Lambda function queries the requested data in the DynamoDB table.
4. DynamoDB returns the requested data to the Lambda function. Then, the function transfers the query results to the user through Athena.
5. The Lambda function stores data in the S3 bucket.

**Technology stack**

- Amazon Athena
- Amazon DynamoDB
- Amazon S3
- AWS Lambda

**Tools**

- **Amazon Athena** is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- **Amazon Athena DynamoDB Connector** is an AWS tool that enables Athena to connect with DynamoDB and access your tables by using SQL queries.
- **Amazon DynamoDB** is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
## Epics

### Create sample DynamoDB tables

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create the first sample table. | 1. Sign in to the AWS Management Console and open the [DynamoDB console](https://aws.amazon.com/dynamodb/).  
2. Choose [Create table](https://aws.amazon.com/dynamodb/).  
3. For [Table name](https://aws.amazon.com/dynamodb/), enter dydbtable1.  
4. For [Partition key](https://aws.amazon.com/dynamodb/), enter PK1.  
5. For [Sort key](https://aws.amazon.com/dynamodb/), enter SK1.  
6. In the [Table settings](https://aws.amazon.com/dynamodb/) section, choose [Customize settings](https://aws.amazon.com/dynamodb/).  
7. In the [Table class](https://aws.amazon.com/dynamodb/) section, choose [DynamoDB Standard](https://aws.amazon.com/dynamodb/).  
8. In the [Read/write capacity settings](https://aws.amazon.com/dynamodb/) section, for [Capacity mode](https://aws.amazon.com/dynamodb/), choose [On-demand](https://aws.amazon.com/dynamodb/).  
9. In the [Encryption at rest](https://aws.amazon.com/dynamodb/) section, choose [Owned by Amazon DynamoDB](https://aws.amazon.com/dynamodb/).  
10. Choose [Create table](https://aws.amazon.com/dynamodb/). | Developer |

Insert sample data into the first table.  
1. Open the [DynamoDB console](https://aws.amazon.com/dynamodb/).  
2. In the navigation pane, choose [Table](https://aws.amazon.com/dynamodb/), and then choose your table in the [Name](https://aws.amazon.com/dynamodb/) column.  
3. Choose [Actions](https://aws.amazon.com/dynamodb/), and then choose [Create item](https://aws.amazon.com/dynamodb/).  
4. Choose [JSON view](https://aws.amazon.com/dynamodb/).  
5. In the title bar of the [Attributes](https://aws.amazon.com/dynamodb/) editor, turn off [View DynamoDB JSON](https://aws.amazon.com/dynamodb/).  
6. In the [Attributes](https://aws.amazon.com/dynamodb/) editor, enter the following sample data one by one:

```json
{
    "PK1": "1234",
    "SK1": "info",
    "Salary": "5000"
}
```

```json
{
    "PK1": "1235",
    "SK1": "info",
    "Salary": "5200"
}
```
Create the second sample table.

1. Open the [DynamoDB console](https://aws.amazon.com/dynamodb/).
2. Choose [Create table](https://aws.amazon.com/documentation/dynamodb/Quickstart/).
3. For **Table name**, enter **dydbtable2**.
4. For **Partition key**, enter **PK2**.
5. For **Sort key**, enter **SK2**.
6. In the **Table settings** section, choose **Customize settings**.
7. In the **Table class** section, choose **DynamoDB Standard**.
8. In the **Read/write capacity settings** section, for **Capacity mode**, choose **On-demand**.
9. In the **Encryption at rest** section, choose **Owned by Amazon DynamoDB**.
10. Choose [Create table](https://aws.amazon.com/dynamodb/).

Insert sample data into the second table.

1. Open the [DynamoDB console](https://aws.amazon.com/dynamodb/).
2. In the navigation pane, choose **Table**, and then choose your table in the **Name** column.
3. Choose **Actions**, and then choose **Create item**.
4. In the title bar of the **Attributes** editor, turn off **View DynamoDB JSON**.
5. In the **Attributes** editor, enter the following sample data one by one:

```json
{
  "PK2": "1234",
  "SK2": "bonus",
  "Bonus": "500"
}
```

```json
{
  "PK2": "1235",
  "SK2": "bonus",
  "Bonus": "1000"
}
```
## Create a data source in Athena for DynamoDB

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set up the data source connector.</td>
<td>Create a data source for DynamoDB, and then create a Lambda function to connect to that data source.</td>
<td>Developer</td>
</tr>
</tbody>
</table>

1. Sign in to the AWS Management Console and open the [Athena console](https://aws.amazon.com/athena/).
2. In the navigation pane, choose **Data sources**, and then choose **Create data source**.
3. Choose the **Amazon DynamoDB** data source, and then choose **Next**.
4. In the **Data source details** section, for **Data source name**, enter **testDynamoDB**.
5. In the **Connection details** section, select a Lambda function that's already deployed or choose **Create Lambda function** if you don't have a Lambda function to use for this pattern. **Note:** For more information on creating a Lambda function, see [Getting started with Lambda](https://docs.aws.amazon.com/lambda/latest/dg/) in the Lambda Developer Guide.
6. (Optional) If you choose **Create Lambda function**, then you must configure the AWS CloudFormation template that's included by the Java application before deploying that stack. The template includes ApplicationName, SpillBucket, AthenaCatalogName, and other application settings. **Note:** After you deploy this Java-based application, the stack creates a Lambda function that enables Athena to communicate with DynamoDB. This makes your tables accessible through SQL commands.
7. Deploy your Lambda function.
### Access DynamoDB tables from Athena

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Query the DynamoDB tables. | 1. Sign in to the AWS Management Console and open the **Athena console**.  
2. In the navigation pane, choose **Data sources**, and then choose **Create data source**.  
3. In the navigation pane, choose **Query editor**.  
4. On the **Editor** tab, in the **Data** section, for **Data source**, choose your data source for **Data source**.  
5. For **Database**, choose your database.  
6. For **Query 1**, enter the following query: `SELECT * FROM dydbtable1 t1;`                                                                                                                                                                                                                       | Developer       |
7. Choose Run, and then verify the output in the table.
8. For Query 2, enter the following query: `SELECT * FROM dydbtable2 t2;`
9. Choose Run, and then verify the output in the table.

Join the two DynamoDB tables. DynamoDB is a NoSQL data store and doesn't support the SQL join operation. Consequently, you must perform a join operation on two DynamoDB tables:

1. Choose the plus icon to create another query.
2. For Query 3, enter the following query:

```
SELECT pk1, salary, bonus
FROM dydbtable1 t1
JOIN dydbtable2 t2 ON t1.pk1 = t2.pk2;
```

### Related resources

- [Amazon Athena DynamoDB Connector](AWS Labs)
- Query any data source with Amazon Athena's new federated query (AWS Big Data Blog)
- Athena engine version reference (Athena User Guide)
- Simplify Amazon DynamoDB data extraction and analysis by using AWS Glue and Amazon Athena (AWS Database Blog)

### Additional information

If you run a query in Athena with `spill_bucket` in the `{bucket_name}/folder_name/` format, then you can receive the following error message:

```
"GENERIC_USER_ERROR: Encountered an exception[java.lang.RuntimeException] from your LambdaFunction[arn:aws:lambda:us-east-1:xxxxxx:function:testdynamodb] executed in context[retrieving meta-data] with message[You do NOT own the spill bucket with the name: s3://test-bucket-dynamodbconnector/athena_dynamodb_spill_data/] This query ran against the "default" database, unless qualified by the query. Please post the error message on our forum or contact customer support with Query Id: [query-id]"
```

To resolve this error, update the Lambda function's environment variable `spill_bucket` to `{bucket_name_only}`, and then update the following Lambda IAM policy for bucket write access:

```json
{
    "Action": [
```
Alternatively, you can remove the Athena data source connector that you created earlier, and recreate it by using only `{bucket_name}` for `spill_bucket`. 
Set up language-specific sorting for Amazon Redshift query results using a scalar Python UDF

Created by Ethan Stark (AWS)

| Environment: Production | Technologies: Analytics | AWS services: Amazon Redshift |

Summary

This pattern provides steps and sample code for using a scalar Python UDF (user-defined function) to set up case insensitive linguistic sorting for Amazon Redshift query results. It’s necessary to use a scalar Python UDF because Amazon Redshift returns results based on binary UTF-8 ordering and doesn't support language-specific sorting. A Python UDF is non-SQL processing code that's based on a Python 2.7 program and runs in a data warehouse. You can run Python UDF code with a SQL statement in a single query. For more information, see the [Introduction to Python UDFs in Amazon Redshift](https://aws.amazon.com/blogs/big-data/introduction-to-python-udfs-in-amazon-redshift/) AWS Big Data Blog post.

The sample data in this pattern is based on the Turkish alphabet for demonstration purposes. The scalar Python UDF in this pattern is built to make the default query results of Amazon Redshift conform to the linguistic ordering of characters in the Turkish language. For more information, see [Turkish language example](#) in the Additional information section of this pattern. You can modify the scalar Python UDF in this pattern for other languages.

Prerequisites and limitations

Prerequisites

- Amazon Redshift cluster with a database, schema, and tables
- Amazon Redshift user with CREATE TABLE and CREATE FUNCTION permissions
- Python 2.7 or later

Limitations

The linguistic sorting used by the queries in this pattern is case insensitive.

Architecture

Technology stack

- Amazon Redshift
- Python UDF

Tools

AWS services

- Amazon Redshift is a managed petabyte-scale data warehouse service in the AWS Cloud. Amazon Redshift is integrated with your data lake, which enables you to use your data to acquire new insights for your business and customers.
Other tools

- **Python (UDFs) user-defined functions** are functions that you can write in Python and then call in SQL statements.

## Epics

**Develop code to sort query results in linguistic order**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a table for your sample data. | To create a table in Amazon Redshift and insert your sample data into the table, use the following SQL statements:  
```sql
CREATE TABLE my_table 
(first_name varchar(30));
INSERT INTO my_table 
(first_name) VALUES 
('ali'), ('Ali'), ('ırmak'), ('IRMAK'), ('irem'), ('IREM'), ('oğuz'), ('OGUZ'), ('ömer'), ('ÖMER'), ('sedat'), ('SEDAT'), ('şule'),
```

**Note:** The first names in the sample data include special characters from the Turkish alphabet. For more information about Turkish language considerations for this example, see **Turkish language example** in the **Additional information** section of this pattern.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Check the default sorting of the sample data. | To see the default sorting of your sample data in Amazon Redshift, run the following query:  
```sql
SELECT first_name FROM my_table ORDER BY first_name;
```

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Check the default sorting of the sample data. | To see the default sorting of your sample data in Amazon Redshift, run the following query:  
```sql
SELECT first_name FROM my_table ORDER BY first_name;
```

Data engineer
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The query returns the list of first names from the table that you created earlier:</td>
<td></td>
</tr>
</tbody>
</table>
|      | _first_name_  
Ali  
IRMAK  
OĞUZ  
SEDAT  
alı  
iREM  
oğuz  
sedat  
ÖMER  
ömer  
İREM  
ırmak  
ŞULE  
şule | |
|      | The query results aren't in the correct order because the default binary UTF-8 ordering doesn't accommodate the linguistic ordering of the Turkish special characters. | |
Create a scalar Python UDF.

To create a scalar Python UDF, use the following SQL code:

```sql
CREATE OR REPLACE FUNCTION collate_sort (value varchar) 
RETURNS varchar IMMUTABLE 
AS $$
def sort_str(val):
    import string
    dictionary = {
        'I': 'ı',  
        'ı': 'ı',  
        'İ': 'ı',  
        'Ş': 's~', 
        'ş': 's~', 
        'Ğ': 'g~', 
        'ğ': 'g~', 
        'Ü': 'ü~', 
        'ü': 'ü~', 
        'Ö': 'ö~', 
        'ö': 'ö~', 
        'Ç': 'ç~', 
        'ç': 'ç~'
    }
    for key, value in dictionary.items():
        val = val.replace(key, value)
    return val.lower()
return sort_str(value)
$$ LANGUAGE plpythonu;
```

Skills required: Data engineer

143
Query the sample data.  

To query the sample data by using the Python UDF, run the following SQL query:

```
SELECT first_name FROM my_table ORDER BY collate_order(first_name);
```

The query now returns the sample data in Turkish linguistic order:

```
first_name  
--------------
  ali  
  Ali  
  ırmak  
   IRMAK  
  irem  
   İREM  
  oğuz  
  OĞUZ  
  ömer  
   Ömer  
  sedat  
   SEDAT  
  şule  
   ŞULE  
```

**Related resources**

- [ORDER BY clause](Amazon Redshift documentation)
- [Creating a scalar Python UDF](Amazon Redshift documentation)

**Additional information**

**Turkish language example**

Amazon Redshift returns query results based on binary UTF-8 sort ordering, not language-specific sort ordering. This means that if you query an Amazon Redshift table containing Turkish characters, then the query results aren’t sorted according to the linguistic ordering of the Turkish language. The Turkish language contains six special characters (ç, ı, ã, ö, ş, and ü) that don’t appear in the Latin alphabet. These special characters are placed at the end of a sorted result set based on binary UTF-8 ordering, as the following table shows.

<table>
<thead>
<tr>
<th>Binary UTF-8 ordering</th>
<th>Turkish linguistic ordering</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>a</td>
</tr>
<tr>
<td>b</td>
<td>b</td>
</tr>
<tr>
<td>c</td>
<td>c</td>
</tr>
</tbody>
</table>
As the table above illustrates, special character ç is between c and d in Turkish linguistic ordering, but appears after z in binary UTF-8 ordering. The scalar Python UDF in this pattern uses the following character replacement dictionary to replace the Turkish special characters with corresponding Latin-equivalent characters.

<table>
<thead>
<tr>
<th>Turkish special character</th>
<th>Latin-equivalent character</th>
</tr>
</thead>
<tbody>
<tr>
<td>ç</td>
<td>c~</td>
</tr>
</tbody>
</table>
Note: A tilde (~) character is appended to the end of the Latin characters that replace their corresponding Turkish special characters.

**Modify a scalar Python UDF function**

To modify the scalar Python UDF function from this pattern so that the function accepts a locate parameter and supports a multiple transaction dictionary, use the following SQL code:

```sql
CREATE OR REPLACE FUNCTION collate_sort (value varchar, locale varchar)
RETURNS varchar
IMMUTABLE
AS
$$
def sort_str(val):
    import string
    # Turkish Dictionary
    if locale == 'tr-TR':
        dictionary = {
          'I': 'ı',
          'ı': 'h~',
          'İ': 'i',
          'Ş': 's~',
          'ş': 's~',
          'Ğ': 'g~',
          'ğ': 'g~',
          'Ü': 'u~',
          'ü': 'u~',
          'Ö': 'o~',
          'ö': 'o~',
          'Ç': 'c~',
          'ç': 'c~'
        }
        # German Dictionary
        if locale == 'de-DE':
            dictionary = {
              ....
              ....
            }
        for key, value in dictionary.items():
            val = val.replace(key, value)
    return val.lower()
return sort_str(value)
$$ LANGUAGE plpythonu;
```

The following example code shows how to query the modified Python UDF:

```sql
SELECT first_name FROM my_table ORDER BY collate_order(first_name, 'tr-TR');
```
Subscribe a Lambda function to event notifications from S3 buckets in different AWS Regions

Created by Suresh Konathala (AWS) and Arindom Sarkar (AWS)

| Environment: | Production | Technologies: | Analytics | AWS services: | AWS Lambda; Amazon S3; Amazon SNS; Amazon SQS |

**Summary**

Amazon Simple Storage Service (Amazon S3) Event Notifications publishes notifications for certain events in your S3 bucket (for example, object created events, object removal events, or restore object events). You can use an AWS Lambda function to process these notifications according to your application’s requirements. However, the Lambda function can’t directly subscribe to notifications from S3 buckets that are hosted in different AWS Regions.

This pattern’s approach deploys a fanout scenario to process Amazon S3 notifications from cross-Region S3 buckets by using an Amazon Simple Notification Service (Amazon SNS) topic for each Region. These Regional SNS topics send the Amazon S3 event notifications to an Amazon Simple Queue Service (Amazon SQS) queue in a central Region that also contains your Lambda function. The Lambda function subscribes to this SQS queue and processes the event notifications according to your organization’s requirements.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account.
- Existing S3 buckets in multiple Regions, including a central Region to host the Amazon SQS queue and Lambda function.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information about this, see [Installing, updating, and uninstalling the AWS CLI](https://docs.aws.amazon.com/cli/latest/userguide/installing.html) in the AWS CLI documentation.
- Familiarity with the fanout scenario in Amazon SNS. For more information about this, see [Common Amazon SNS scenarios](https://docs.aws.amazon.com/sns/latest/dg/cross-region-sns-scenarios.html) in the Amazon SNS documentation.

**Architecture**

The following diagram shows the architecture for this pattern’s approach.
The diagram shows the following workflow:

1. Amazon S3 sends event notifications about S3 buckets (for example, object created, object removed, or object restored) to an SNS topic in the same Region.
2. The SNS topic publishes the event to an SQS queue in the central Region.
3. The SQS queue is configured as the event source for your Lambda function and buffers the event messages for the Lambda function.
4. The Lambda function polls the SQS queue for messages and processes the Amazon S3 event notifications according to your application’s requirements.

**Technology stack**

- Lambda
- Amazon SNS
- Amazon SQS
- Amazon S3

**Tools**

- **AWS CLI** – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.
- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
• **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

• **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

• **Amazon SQS** – Amazon Simple Queue Service (Amazon SQS) offers a secure, durable, and available hosted queue that lets you integrate and decouple distributed software systems and components. Amazon SQS supports both standard and FIFO queues.

## Epics

### Create the SQS queue and Lambda function in your central Region

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an SQS queue with a Lambda trigger.    | Sign in to the AWS Management Console and use the instructions from the tutorial [Using Lambda with Amazon SQS](https://docs.aws.amazon.com/lambda/latest/dg/sqs-lambda.html) in the AWS Lambda documentation to create the following resources in your central Region:  
  • A Lambda execution role  
  • A Lambda function to process the Amazon S3 events  
  • An SQS queue  
  **Note:** Make sure that you configure the SQS queue as the event source for your Lambda function.                                                                 | AWS DevOps, Cloud architect           |

### Create an SNS topic and set up event notifications for the S3 buckets in each required Region

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an SNS topic to receive Amazon S3 event notifications. | Create an SNS topic in a Region that you want to receive Amazon S3 event notifications from. For more information about this, see [Creating an SNS topic](https://docs.aws.amazon.com/sns/latest/dg/topic-arn.html) in the Amazon SNS documentation.  
  **Important:** Make sure that you record your SNS topic’s Amazon Resource Name (ARN).                                                                 | AWS DevOps, Cloud architect           |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subscribe the SNS topic to the central SQS queue.</td>
<td>Subscribe your SNS topic to the SQS queue hosted by your central Region. For more information about this, see <a href="https://docs.aws.amazon.com/sns/latest/dg/sns-topic-subscription.html">Subscribing to an SNS topic</a> in the Amazon SNS documentation.</td>
<td>AWS DevOps, Cloud architect</td>
</tr>
</tbody>
</table>
| Update the SNS topic's access policy. | 1. Open the Amazon SNS console, choose **Topics**, and then choose the SNS topic that you created earlier.  
2. Choose **Edit** and then expand the **Access policy - optional** section.  
3. Attach the following access policy to your SNS topic to allow `sns:publish` permission for Amazon S3 and then choose **Save**.  

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "0",
      "Effect": "Allow",
      "Principal": {
        "Service": "s3.amazonaws.com"
      },
      "Action": "sns:Publish",
      "Resource": "arn:aws:sns:us-west-2::s3Events-SNSTopic-us-west-2"
    }
  ]
}
``` | AWS DevOps, Cloud architect |
| Set up notifications for each S3 bucket in the Region. | Set up event notifications for each S3 bucket in the Region. For more information about this, see [Enabling and configuring event notifications using the Amazon S3 console](https://docs.aws.amazon.com/AmazonS3/latest/userguide/set-up-notifications.html) in the Amazon S3 documentation.  

**Note:** In the **Destination** section, choose **SNS topic** and specify the ARN of the SNS topic that you created earlier. | AWS DevOps, Cloud architect |
Repeat this epic for all required Regions.

**Important**: Repeat the tasks in this epic for each Region that you want to receive Amazon S3 event notifications from, including your central Region.

**Skills required**

AWS DevOps, Cloud architect

Three AWS Glue ETL job types for converting data to Apache Parquet

Created by Adnan Alvee (AWS), Karthikeyan Ramachandran, and Nith Govindasivan (AWS)

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Technologies: Analytics</th>
<th>Workload: All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services: AWS Glue</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary of using AWS Glue jobs to convert data to Apache Parquet

On the Amazon Web Services (AWS) Cloud, AWS Glue is a fully managed extract, transform, and load (ETL) service. AWS Glue makes it cost-effective to categorize your data, clean it, enrich it, and move it reliably between various data stores and data streams.

This pattern provides different job types in AWS Glue and uses three different scripts to demonstrate authoring ETL jobs.

You can use AWS Glue to write ETL jobs in a Python shell environment. You can also create both batch and streaming ETL jobs by using Python (PySpark) or Scala in a managed Apache Spark environment. To get you started with authoring ETL jobs, this pattern focuses on batch ETL jobs using Python shell, PySpark, and Scala. Python shell jobs are meant for workloads requiring lesser compute power. The managed Apache Spark environment is meant for workloads requiring high compute power.

Apache Parquet is built to support efficient compression and encoding schemes. It can speed up your analytics workloads because it stores data in a columnar fashion. Converting data to Parquet can save you storage space, cost, and time in the longer run. To learn more about Parquet, see the blog post [Apache Parquet: How to be a hero with the open-source columnar data format](#).

Prerequisites and limitations for using AWS Glue jobs to convert data to Apache Parquet

Prerequisites

- AWS Identity and Access Management (IAM) role (If you don't have a role, see the Additional information section.)

Architecture for using AWS Glue jobs to convert data to Apache Parquet

Target technology stack

- AWS Glue
- Amazon Simple Storage Service (Amazon S3)
- Apache Parquet
Automation and scale

- **AWS Glue workflows** support full automation of an ETL pipeline.
- You can change the number of data processing units (DPUs), or worker types, to scale horizontally and vertically.

**Tools for using AWS Glue jobs to convert data to Apache Parquet**

**AWS services**

- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **AWS Glue** is a fully managed ETL service for categorizing, cleaning, enriching, and moving your data between various data stores and data streams.

**Other tools**

- **Apache Parquet** is an open-source column-oriented data file format designed for storage and retrieval.

**Configuration**

Use the following settings for configuring the compute power of AWS Glue ETL. To reduce costs, use the minimal settings when you run the workload that is provided in this pattern.

- **Python shell** – You can use 1 DPU to utilize 16 GB of memory or 0.0625 DPU to utilize 1 GB of memory. This pattern uses 0.0625 DPU, which is the default in the AWS Glue console.
- **Python or Scala for Spark** – If you choose the Spark-related job types in the console, AWS Glue by default uses 10 workers and the G.1X worker type. This pattern uses two workers, which is the minimum number allowed, with the standard worker type, which is sufficient and cost effective.

The following table displays the different AWS Glue worker types for the Apache Spark environment. Because a Python shell job does not use the Apache Spark environment to run Python, it is not included in the table.

<table>
<thead>
<tr>
<th></th>
<th>Standard</th>
<th>G.1X</th>
<th>G.2X</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>vCPU</strong></td>
<td>4</td>
<td>4</td>
<td>8</td>
</tr>
<tr>
<td><strong>Memory</strong></td>
<td>16 GB</td>
<td>16 GB</td>
<td>32 GB</td>
</tr>
<tr>
<td><strong>Disk space</strong></td>
<td>50 GB</td>
<td>64 GB</td>
<td>128 GB</td>
</tr>
<tr>
<td><strong>Executor per worker</strong></td>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

**Code**

For the code that is used in this pattern, including the IAM role and parameter configuration, see the *Additional information* section.
Epics for using AWS Glue jobs to convert data to Apache Parquet

Upload the data

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Upload the data into a new or existing S3 bucket.</td>
<td>Create or use an existing S3 bucket in your account. Upload the sample_data.csv file from the Attachments section, and note the S3 bucket and prefix location.</td>
<td>General AWS</td>
</tr>
</tbody>
</table>

Create and run the AWS Glue job

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the AWS Glue job.</td>
<td>Under the ETL section of the AWS Glue console, add an AWS Glue job. Select the appropriate job type, AWS Glue version, and the corresponding DPU/Worker type and number of workers. For details, see the Configuration section.</td>
<td>Developer, cloud or data</td>
</tr>
<tr>
<td>Change the input and output locations.</td>
<td>Copy the code corresponding to your AWS Glue job, and change the input and output location that you noted in the Upload the data epic.</td>
<td>Developer, cloud or data</td>
</tr>
<tr>
<td>Configure the parameters.</td>
<td>You can use the snippets provided in the Additional information section to set parameters for your ETL job. AWS Glue uses four argument names internally: • --conf • --debug • --mode • --JOB_NAME The --JOB_NAME parameter must be explicitly entered on the AWS Glue console. Choose Jobs, Edit Job, Security configuration, script libraries, and job parameters (optional). Enter --JOB_NAME</td>
<td>Developer, cloud or data</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>as the key and provide a value. You can also use the AWS Command Line Interface (AWS CLI) or the AWS Glue API to set this parameter. The --JOB_NAME parameter is used by Spark and is not needed in a Python shell environment job. You must add -- before every parameter name; otherwise, the code will not work. For example, for the code snippets, the location parameters must be invoked by --input_loc and --output_loc.</td>
<td>Developer, cloud or data</td>
<td></td>
</tr>
</tbody>
</table>

Run the ETL job.  
Run your job and check the output. Note how much space was reduced from the original file.

Additional information for using AWS Glue jobs to convert data to Apache Parquet

IAM role

When you create the AWS Glue jobs, you can use either an existing IAM role that has the permissions shown in the following code snippet or a new role.

To create a new role, use the following YAML code.

```
# (c) 2022 Amazon Web Services, Inc. or its affiliates. All Rights Reserved. This AWS Content is provided subject to the terms of the AWS Customer Agreement available at https://aws.amazon.com/agreement/ or other written agreement between Customer and Amazon Web Services, Inc.
```
AWS Prescriptive Guidance Patterns
Additional information

AWSTemplateFormatVersion: "2010-09-09"

Description: This template will setup IAM role for AWS Glue service.

Resources:

    Name: !Join [ ":", [ !Ref "AWS::StackName", rGlueRole ] ]

AWS Glue Python Shell

The Python code uses the Pandas and PyArrow libraries to convert data to Parquet. The Pandas library is already available. The PyArrow library is downloaded when you run the pattern, because it is a one-time run. You can use wheel files to convert PyArrow to a library and provide the file as a library package. For more information about packaging wheel files, see Providing your own Python library.

AWS Glue Python shell parameters

```python
from awsglue.utils import getResolvedOptions
args = getResolvedOptions(sys.argv, ["input_loc", "output_loc"])
```

AWS Glue Python shell code

```python
from io import BytesIO
import pandas as pd
import boto3
import os
import io
import site
from importlib import reload
```
from setuptools.command import easy_install
install_path = os.environ['GLUE_INSTALLATION']
easy_install.main(["--install-dir", install_path, "pyarrow"])
reload(site)
import pyarrow

input_loc = "bucket-name/prefix/sample_data.csv"
output_loc = "bucket-name/prefix/"

input_bucket = input_loc.split('/', 1)[0]
object_key = input_loc.split('/', 1)[1]

output_loc_bucket = output_loc.split('/', 1)[0]
output_loc_prefix = output_loc.split('/', 1)[1]

s3 = boto3.client('s3')
obj = s3.get_object(Bucket=input_bucket, Key=object_key)
df = pd.read_csv(io.BytesIO(obj['Body'].read()))

parquet_buffer = BytesIO()
s3_resource = boto3.resource('s3')
df.to_parquet(parquet_buffer, index=False)
s3_resource.Object(output_loc_bucket, output_loc_prefix + 'data' + '.parquet').put(Body=parquet_buffer.getvalue())

AWS Glue Spark job with Python

To use an AWS Glue Spark job type with Python, choose Spark as the job type. Choose Spark 3.1, Python 3 with improved job startup time (Glue Version 3.0) as the AWS Glue version.

AWS Glue Python parameters

from awsglue.utils import getResolvedOptions
args = getResolvedOptions(sys.argv, ["JOB_NAME", "input_loc", "output_loc"])

AWS Glue Spark job with Python code

import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.transforms import *
from awsglue.dynamicframe import DynamicFrame
from awsglue.utils import getResolvedOptions
from awsglue.job import Job

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)

input_loc = "bucket-name/prefix/sample_data.csv"
output_loc = "bucket-name/prefix/"

inputDyf = glueContext.create_dynamic_frame_from_options(
    connection_type = "s3",
    connection_options = {
        "bucket": input_loc,
        "format": "csv",
    },
    transformation_ctx = "inputDyf"
)
For a large number of compressed big files (for example, 1,000 files that are each about 3 MB), use the `compressionType` parameter with the `recurse` parameter to read all the files that are available within the prefix, as shown in the following code.

```python
input_loc = "bucket-name/prefix/"
output_loc = "bucket-name/prefix/"

inputDyf = glueContext.create_dynamic_frame_from_options(
    connection_type = "s3",
    connection_options = {
        "paths": [input_loc],
        "compressionType" : "gzip",
        "recurse" : "True",
    },
    format = "csv",
    format_options={"withHeader": True,"separator": ","}
)
```

For a large number of compressed small files (for example, 1,000 files that are each about 133 KB), use the `groupFiles` parameter, along with both the `compressionType` and the `recurse` parameters. The `groupFiles` parameter groups small files into multiple big files, and the `groupSize` parameter controls the grouping to the specified size in bytes (for example, 1 MB). The following code snippet provides an example of using these parameters within the code.

```python
input_loc = "bucket-name/prefix/"
output_loc = "bucket-name/prefix/"

inputDyf = glueContext.create_dynamic_frame_from_options(
    connection_type = "s3",
    connection_options = {
        "paths": [input_loc],
        "compressionType" : "gzip",
        "recurse" : "True",
        "groupFiles" : "inPartition",
        "groupSize" : "1048576",
    },
    format = "csv",
    format_options={"withHeader": True,"separator": ","}
)
```

Without any change in the worker nodes, these settings enable the AWS Glue job to read multiple files (large or small, with or without compression) and write them to the target in Parquet format.

**AWS Glue Spark job with Scala**

To use an AWS Glue Spark job type with Scala, choose Spark as the job type and Language as Scala. Choose Spark 3.1, Scala 2 with improved job startup time (Glue Version 3.0) as the AWS Glue version. To save on storage space, the following AWS Glue with Scala sample also uses the applyMapping feature to convert data types.

**AWS Glue Scala parameters**

Summary

Security is an integral part of database operations on the Amazon Web Services (AWS) Cloud. Your organization should ensure that it monitors database user activities and connections to detect potential security incidents and risks. This pattern helps you monitor your databases for security and troubleshooting purposes, which is a process known as database auditing.

This pattern provides a SQL script that automates the creation of an Amazon Athena table and views for a reporting dashboard in Amazon QuickSight that helps you audit Amazon Redshift logs. This ensures that users responsible for monitoring database activities have convenient access to data security features.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing Amazon Redshift cluster. For more information about this, see Create an Amazon Redshift cluster in the Amazon Redshift documentation.
- Access to an existing Athena workgroup. For more information, see How workgroups work in the Amazon Athena documentation.
- An existing Amazon Simple Storage Service (Amazon S3) source bucket with the required AWS Identity and Access Management (IAM) permissions. For more information, see Bucket permissions for Amazon Redshift audit logging from Database audit logging in the Amazon Redshift documentation.

Architecture
Technology stack

- Athena
- Amazon Redshift
- Amazon S3
- QuickSight

Tools

- Amazon Athena – Athena is an interactive query service that makes it easy to analyze data in Amazon S3 using standard SQL.
- Amazon QuickSight – QuickSight is a scalable, serverless, embeddable, machine learning-powered business intelligence (BI) service.
- Amazon Redshift – Amazon Redshift is an enterprise-level, petabyte scale, fully managed data warehousing service.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

Epics

Configure the Amazon Redshift cluster

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Enable audit logging for the Amazon Redshift cluster. | 1. Sign in to the AWS Management Console, open the Amazon Redshift console, choose CLUSTERS, and then choose the cluster that you want to enable logging for.  
2. Choose the Properties tab and then enable auditing by following the instructions from Configuring auditing using the console in the Amazon Redshift documentation. | DBA, Data engineer |
| Enable logging in the Amazon Redshift cluster parameter group. | You can enable auditing of connection logs, user logs, and user activity logs at the same time by using the AWS Management Console, the Amazon Redshift API reference, or AWS Command Line Interface (AWS CLI).  
For auditing of user activity logs, you must enable the enable_user_activity_logging database parameter. If you only enable the audit logging feature but not the | DBA, Data engineer |
Configure S3 bucket permissions for Amazon Redshift cluster logging.

When you enable logging, Amazon Redshift collects logging information and uploads it to log files stored in an S3 bucket. You can use an existing S3 bucket or create a new bucket.

**Important:** Make sure that Amazon Redshift has the required IAM permissions to access the S3 bucket. For more information about this, see [Bucket permissions for Amazon Redshift audit logging](https://docs.aws.amazon.com/redshift/latest/guides/auditlog-permissions.html) from [Database audit logging](https://docs.aws.amazon.com/redshift/latest/guides/database-permissions.html) in the Amazon Redshift documentation.

Visualize IAM credential reports for all AWS accounts using Amazon QuickSight

Created by Parag Nagwekar (AWS) and Arun Chandapillai (AWS)

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: Production</th>
<th>Technologies: Analytics; Advisory; Management &amp; governance; Security, identity, compliance</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Get Organizational wide visibility of your IAM Credential Reports</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Workload: All other workloads</th>
<th>AWS services: Amazon Athena; AWS CloudFormation; Amazon EventBridge; AWS Identity and Access Management; Amazon QuickSight</th>
</tr>
</thead>
</table>

Summary

You can use AWS Identity and Access Management (IAM) credential reports to help you meet the security, auditing, and compliance requirements of your organization. Credential reports provide a list of all the users in your AWS accounts and show the status of their credentials, such as passwords, access keys, and multi-factor authentication (MFA) devices. You can use credential reports for multiple AWS accounts managed by AWS Organizations.

This pattern includes steps and code to help you create and share IAM credential reports for all the AWS accounts in your organization by using Amazon QuickSight dashboards. You can share the dashboards with stakeholders in your organization. The reports can help your organization achieve the following targeted business outcomes:

- Identify security incidents related to IAM users
- Track real-time migration of IAM users to single sign-on (SSO) authentication
- Track AWS Regions accessed by IAM users
- Stay compliant
- Share information with other stakeholders

Prerequisites and limitations

Prerequisites

- An active AWS account
- An organization with member accounts
- An IAM role with permissions to access accounts in Organizations
- AWS Command Line Interface (AWS CLI) version 2, installed and configured
- A subscription to Amazon QuickSight Enterprise edition
Architecture

Technology stack

- Amazon Athena
- Amazon EventBridge
- Amazon QuickSight
- Amazon Simple Storage Service (Amazon S3)
- AWS Glue
- AWS Identity and Access Management (IAM)
- AWS Lambda
- AWS Organizations

Target architecture

The following diagram shows an architecture for setting up a workflow that captures IAM credential report data from multiple AWS accounts.

1. EventBridge invokes a Lambda function daily.
2. The Lambda function assumes an IAM role in every AWS account across the organization. Then, the function creates the IAM credentials report and stores the report data in a centralized S3 bucket. You must enable encryption and deactivate public access on the S3 bucket.
3. An AWS Glue crawler crawls the S3 bucket daily and updates the Athena table accordingly.
4. QuickSight imports and analyzes the data from the credential report and builds a dashboard that can be visualized by and shared with stakeholders.

Tools

AWS services

- Amazon Athena is an interactive query service that makes it easy to analyze data in Amazon S3 by using standard SQL.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
Amazon QuickSight is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data in a single dashboard.

AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

Code

The code for this pattern is available in the GitHub getiamcredsreport-allaccounts-org repository. You can use the code from this repository to create IAM credential reports across AWS accounts in Organizations and store them in a central location.

Epics

Set up the infrastructure

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set up Amazon QuickSight</td>
<td>1. Activate the Amazon QuickSight Enterprise edition in your AWS account. For more information, see Managing user access inside Amazon QuickSight in the QuickSight documentation. 2. To grant dashboard permissions, get the Amazon Resource Name (ARN) of the QuickSight users.</td>
<td>AWS administrator, AWS DevOps, Cloud administrator, Cloud architect</td>
</tr>
<tr>
<td>Enterprise edition.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Integrate Amazon QuickSight</td>
<td>You must authorize QuickSight to use Amazon S3 and Athena before you deploy the AWS CloudFormation stack.</td>
<td>AWS administrator, AWS DevOps, Cloud administrator, Cloud architect</td>
</tr>
<tr>
<td>with Amazon S3 and Athena.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Deploy the infrastructure

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clone the GitHub repository.</td>
<td>1. Clone the GitHub getiamcredsreport-allaccounts-org repository to your local machine by running the following command: git clone <a href="https://github.com/aws-samples/getiamcredsreport-allaccounts-org">https://github.com/aws-samples/getiamcredsreport-allaccounts-org</a></td>
<td>AWS administrator</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------</td>
</tr>
</tbody>
</table>
| Deploy the infrastructure. | 1. Sign in to the AWS Management Console and open the [CloudFormation console](https://aws.amazon.com/cloudformation/).  
2. In the navigation pane, choose Create stack, and then choose With new resources (standard).  
3. On the Identify resources page, choose Next.  
4. On the Specify template page, for Template source, select Upload a template file.  
5. Choose Choose file, select the Cloudformation-createcredrepo.yaml file from your cloned GitHub repository, and then choose Next.  
6. In Parameters, update IAMRoleName with your IAM role. This should be the IAM role that you want Lambda to assume in every account of the organization. This role creates the credential report. **Note:** The role doesn’t have to be present in all accounts at this step of stack creation.  
7. In Parameters, update S3BucketName with the name of the S3 bucket where Lambda can store the credentials for all accounts.  
8. For Stack name, enter your stack name.  
9. Choose Submit.  
10. Note the Lambda function’s role name. | AWS administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an IAM permission policy. | Create an IAM policy for every AWS account across your organization with the following permissions:  
```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:GenerateCredentialReport",
        "iam:GetCredentialReport"
      ],
      "Resource": "*"
    }
  ]
}
``` | AWS DevOps, Cloud administrator, Cloud architect, Data engineer |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an IAM role with a trust policy. | 1. Create an IAM role for the AWS accounts and attach the permission policy that you created in the previous step.  
2. Attach the following trust policy to the IAM role:  

```json  
{  
  "Version":"2012-10-17",  
  "Statement": [  
    {  
      "Effect":"Allow",  
      "Principal": {  
        "AWS": [  
          "arn:aws:iam::<MasterAccountID>:role/<LambdaRole>"  
        ]  
      },  
      "Action": "sts:AssumeRole"  
    }  
  ]  
}  
```

**Important**: Replace `arn:aws:iam::<MasterAccountID>:role/<LambdaRole>` with the ARN of the Lambda role that you noted previously.  

**Note**: Organizations typically use automation to create IAM roles for their AWS accounts. We recommend that you use this automation, if available. Alternatively, you can use the `CreateRoleForOrg.py` script from the code repository. The script requires an existing administrative role or any other IAM role that has permission to create an IAM policy and role in every AWS account. | Cloud administrator, Cloud architect, AWS administrator |
Configure Amazon QuickSight to visualize the data.

1. **Sign in to QuickSight** with your credentials.
2. **Create a dataset** by using Athena (using the `iamcredsreportdb` database and “cfn_iamcredsreport” table), and then automatically refresh the dataset.
3. **Create an analysis in QuickSight.**
4. **Create a QuickSight dashboard.**

**Skills required:** AWS DevOps, Cloud administrator, Cloud architect, Data engineer

### Additional information

#### Additional considerations

Consider the following:

- After you use CloudFormation to deploy the infrastructure, you can wait to get the reports created in Amazon S3 and analyzed by Athena until Lambda and AWS Glue run as per their schedules. Alternatively, you can run Lambda manually to get the reports in Amazon S3, and then run the AWS Glue crawler to get the Athena table that's created from the data.

- QuickSight is a powerful tool for analyzing and visualizing data based on your business requirements. You can use **parameters** in QuickSight to control widget data based on data fields that you choose. Also, you can use a QuickSight analysis to create parameters (for example, Account, Date, and User fields such as `partition_0`, `partition_1`, and `user` respectively) from your dataset to add controls for the parameters for Account, Date, and User.

- To build your own QuickSight dashboards, see [QuickSight Workshops](https://aws.amazon.com/models) from the AWS Workshop Studio website.

- To see sample QuickSight dashboards, see the GitHub [getiamcredsreport-allaccounts-org](https://github.com/getiamcredsreport-allaccounts-org) code repository.

#### Targeted business outcomes

You can use this pattern to achieve the following targeted business outcomes:

- **Identify security incidents related to IAM users** – Investigate every user across every AWS account in your organization by using a single pane of glass. You can track the trend of an IAM user's most recently accessed individual AWS Regions and the services they used.

- **Track real-time migration of IAM users to SSO authentication** – By using SSO, users can sign in once with a single credential and access multiple AWS accounts and applications. If you’re planning to migrate your IAM users to SSO, this pattern can help you transition to SSO and track all IAM user credential usage (such as access to the AWS Management Console or usage of access keys) across all AWS accounts.

- **Track AWS Regions accessed by IAM users** – You can control IAM user access to Regions for various purposes, such as data sovereignty and cost control. You can also track use of Regions by any IAM user.

- **Stay compliant** – By following the principle of least privilege, you can grant only the specific IAM permissions that are required to perform a specific task. Also, you can track access to AWS services, the AWS Management Console, and long-term credentials usage.
• **Share information with other stakeholders** – You can share curated dashboards with other stakeholders, without granting them access to IAM credential reports or AWS accounts.
More patterns

- Automate data ingestion from AWS Data Exchange into Amazon S3 (p. 483)
- Automatically extract content from PDF files using Amazon Textract (p. 1376)
- Build a data pipeline to ingest, transform, and analyze Google Analytics data using the AWS DataOps Development Kit (p. 487)
- Configure cross-account access to a shared AWS Glue Data Catalog using Amazon Athena (p. 493)
- Cost-effectively ingest IoT data directly into Amazon S3 using AWS IoT Greengrass (p. 507)
- Create detailed cost and usage reports for Amazon EMR clusters by using AWS Cost Explorer (p. 477)
- Create detailed cost and usage reports for Amazon RDS and Amazon Aurora (p. 619)
- Create detailed cost and usage reports for AWS Glue jobs by using AWS Cost Explorer (p. 473)
- Deploy and manage a serverless data lake on the AWS Cloud by using infrastructure as code (p. 502)
- Embed an Amazon QuickSight dashboard in a local Angular application (p. 3492)
- Ensure an Amazon Redshift cluster is encrypted upon creation (p. 3166)
- Ensure encryption for Amazon EMR data at rest is enabled at launch (p. 3157)
- Extract and query AWS IoT SiteWise metadata attributes in a data lake (p. 1346)
- Give SageMaker notebook instances temporary access to a CodeCommit repository in another AWS account (p. 1030)
- Identify and alert when Amazon Kinesis Data Firehose resources are not encrypted with an AWS KMS key (p. 1606)
- Migrate a self-hosted MongoDB environment to MongoDB Atlas on the AWS Cloud (p. 2458)

| AWS services: | Amazon EC2 Auto Scaling; Amazon EFS; Elastic Load Balancing (ELB); Amazon RDS |

Summary

When you migrate your PeopleSoft workloads to AWS, resiliency is an important objective. It ensures that your PeopleSoft application is always highly available and able to recover from failures quickly.

This pattern provides an architecture for your PeopleSoft applications on AWS to ensure high availability (HA) at the network, application, and database tiers. It uses an Amazon Relational Database Service (Amazon RDS) for Oracle or Amazon RDS for SQL Server database for the database tier. This architecture also includes AWS services such as Amazon Route 53, Amazon Elastic Compute Cloud (Amazon EC2) Linux instances, Amazon Elastic Block Storage (Amazon EBS), Amazon Elastic File System (Amazon EFS), and an Application Load Balancer, and is scalable.

Oracle PeopleSoft provides a suite of tools and applications for workforce management and other business operations.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A PeopleSoft environment with the necessary licenses for setting it up on AWS
- A virtual private cloud (VPC) set up in your AWS account with the following resources:
  - At least two Availability Zones
  - One public subnet and three private subnets in each Availability Zone
  - A NAT gateway and an internet gateway
  - Route tables for each subnet to route the traffic
  - Network access control lists (network ACLs) and security groups defined to help ensure the security of the PeopleSoft application in accordance with your organization's standards

Limitations

- This pattern provides a high availability (HA) solution. It doesn't support disaster recovery (DR) scenarios. In the rare occurrence that the entire AWS Region for the HA implementation goes down, the application will become unavailable.

Product versions
• PeopleSoft applications running PeopleTools 8.52 and later

**Architecture**

**Target architecture**

Downtime or outage of your PeopleSoft production application impacts the availability of the application and causes major disruptions to your business.

We recommend that you design your PeopleSoft production application so that it is always highly available. You can achieve this by eliminating single points of failure, adding reliable crossover or failover points, and detecting failures. The following diagram illustrates an HA architecture for PeopleSoft on AWS.

This architecture deployment uses Amazon RDS for Oracle as the PeopleSoft database, and EC2 instances that are running on Red Hat Enterprise Linux (RHEL). You can also use Amazon RDS for SQL Server as the Peoplesoft database.

This architecture contains the following components:

- **Amazon Route 53** is used as the Domain Name Server (DNS) for routing requests from the internet to the PeopleSoft application.
**AWS Prescriptive Guidance Patterns**

**Architecture**

- **AWS WAF** helps you protect against common web exploits and bots that can affect availability, compromise security, or consume excessive resources. **AWS Shield Advanced** (not illustrated) provides much broader protection.
- An **Application Load Balancer** load-balances HTTP and HTTPS traffic with advanced request routing targeted at the web servers.
- The web servers, application servers, process scheduler servers, and Elasticsearch servers that support the PeopleSoft application run in multiple Availability Zones and use **Amazon EC2 Auto Scaling**.
- The database used by the PeopleSoft application runs on **Amazon RDS** in a Multi-AZ configuration.
- The file share used by the PeopleSoft application is configured on **Amazon EFS** and is used to access files across instances.
- **Amazon Machine Images (AMIs)** are used by Amazon EC2 Auto Scaling to ensure that PeopleSoft components are cloned quickly when needed.
- The **NAT gateways** connect instances in a private subnet to services outside your VPC, and ensure that external services cannot initiate a connection with those instances.
- The **internet gateway** is a horizontally scaled, redundant, and highly available VPC component that allows communication between your VPC and the internet.
- The bastion hosts in the public subnet provide access to the servers in the private subnet from an external network, such as the internet or on-premises network. The bastion hosts provide controlled and secure access to the servers in the private subnets.

**Architecture details**

The PeopleSoft database is housed in an Amazon RDS for Oracle (or Amazon RDS for SQL Server) database in a Multi-AZ configuration. The **Amazon RDS Multi-AZ feature** replicates database updates across two Availability Zones to increase durability and availability. Amazon RDS automatically fails over to the standby database for planned maintenance and unplanned disruptions.

The PeopleSoft web and middle tier are installed on EC2 instances. These instances are spread across multiple Availability Zones and tied by an **Auto Scaling group**. This ensures that these components are always highly available. A minimum number of required instances are maintained to ensure that the application is always available and can scale when required.

We recommend that you use a current generation EC2 instance type for the OEM EC2 instances. Current generation instance types, such as instances built on the AWS Nitro System, support hardware virtual machines (HVMs). The HVM AMIs are required to take advantage of enhanced networking, and they also offer increased security. The EC2 instances that are part of each Auto Scaling group use their own AMI when replacing or scaling up instances. We recommend that you select EC2 instance types based on the load you want your PeopleSoft application to handle and the minimum values recommended by Oracle for your PeopleSoft application and PeopleTools release. For more information about hardware and software requirements, see the Oracle support website.

The PeopleSoft web and middle tier share an Amazon EFS mount to share reports, data files, and (if needed) the PS_HOME directory. Amazon EFS is configured with mount targets in each Availability Zone for performance and cost reasons.

An Application Load Balancer is provisioned to support the traffic that accesses the PeopleSoft application and load-balances the traffic among the web servers across different Availability Zones. An Application Load Balancer is a network device that provides HA in at least two Availability Zones. The web servers distribute the traffic to different application servers by using a load balancing configuration. Load balancing among the web server and application server ensures that load is distributed evenly across the instances, and helps avoid bottlenecks and service disruptions due to overloaded instances.

Amazon Route 53 is used as the DNS service to route traffic to the Application Load Balancer from the internet. Route 53 is a highly available and scalable DNS web service.

**HA details**
• Databases: The Multi-AZ feature of Amazon RDS operates two databases in multiple Availability Zones with synchronous replication. This creates a highly available environment with automatic failover. Amazon RDS has failover event detection and initiates automated failover when these events occur. You can also initiate manual failover through the Amazon RDS API. For a detailed explanation, see the blog post Amazon RDS Under The Hood: Multi-AZ. The failover is seamless and the application automatically reconnects to the database when it happens. However, any process scheduler jobs during the failover generate errors and have to be resubmitted.

• PeopleSoft application servers: The application servers are spread across multiple Availability Zones and have an Auto Scaling group defined for them. If an instance fails, the Auto Scaling group immediately replaces it with a healthy instance that's cloned from the AMI of the application server template. Specifically, jolt pooling is enabled, so when an application server instance goes down, the sessions automatically fail over to another application server, and the Auto Scaling group automatically spins up another instance, brings up the application server, and registers it in the Amazon EFS mount. The newly created application server is automatically added to the web servers by using the PSSTRSETUP.SH script in the web servers. This ensures that the application server is always highly available and recovers from failure quickly.

• Process schedulers: The process schedulers servers are spread across multiple Availability Zones and have an Auto Scaling group defined for them. If an instance fails, the Auto Scaling group immediately replaces it with a healthy instance that's cloned from the AMI of the process scheduler server template. Specifically, when a process scheduler instance goes down, the Auto Scaling group automatically spins up another instance and brings up the process scheduler. Any jobs that were running when the instance failed must be resubmitted. This ensures that the process scheduler is always highly available and recovers from failure quickly.

• Elasticsearch servers: The Elasticsearch servers have an Auto Scaling group defined for them. If an instance fails, the Auto Scaling group immediately replaces it with a healthy instance that's cloned from the AMI of the Elasticsearch server template. Specifically, when an Elasticsearch instance goes down, the Application Load Balancer that serves requests to it detects the failure and stops sending traffic to it. The Auto Scaling group automatically spins up another instance and brings up the Elasticsearch instance. When the Elasticsearch instance is back up, the Application Load Balancer detects that it's healthy and starts sending requests to it again. This ensures that the Elasticsearch server is always highly available and recovers from failure quickly.

• Web servers: The web servers have an Auto Scaling group defined for them. If an instance fails, the Auto Scaling group immediately replaces it with a healthy instance that's cloned from the AMI of the web server template. Specifically, when a web server instance goes down, the Application Load Balancer that serves requests to it detects the failure and stops sending traffic to it. The Auto Scaling group automatically spins up another instance and brings up the web server instance. When the web server instance is back up, the Application Load Balancer detects that it's healthy and starts sending requests to it again. This ensures that the web server is always highly available and recovers from failure quickly.

Tools

AWS services

• Application Load Balancers distribute incoming application traffic across multiple targets, such as EC2 instances, in multiple Availability Zones.

• Amazon Elastic Block Store (Amazon EBS) provides block-level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances.

• Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

• Amazon Elastic File System (Amazon EFS) helps you create and configure shared file systems in the AWS Cloud.

• Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.
• Amazon Route 53 is a highly available and scalable DNS web service.

Best practices

Operational best practices

• When you run PeopleSoft on AWS, use Route 53 to route the traffic from the internet and locally. Use the failover option to reroute traffic to the disaster recovery (DR) site if the primary DB instance isn’t available.

• Always use an Application Load Balancer in front of the PeopleSoft environment. This ensures that traffic is load-balanced to the web servers in a secure fashion.

• In the Application Load Balancer target group settings, make sure that stickiness is turned on with a load balancer generated cookie.

  Note: You might need to use an application-based cookie if you use external single sign-on (SSO). This ensures that connections are consistent across the web servers and application servers.

• For a PeopleSoft production application, the Application Load Balancer idle timeout must match what is set in the web profile you use. This prevents user sessions from expiring at the load balancer layer.

• For a PeopleSoft production application, set the application server recycle count to a value that minimizes memory leaks.

• If you’re using an Amazon RDS database for your PeopleSoft production application, as described in this pattern, run it in Multi-AZ format for high availability.

• If your database is running on an EC2 instance for your PeopleSoft production application, make sure that a standby database is running on another Availability Zone for high availability.

• For DR, make sure that your Amazon RDS database or EC2 instance has a standby configured in a separate AWS Region from the production database. This ensures that in event of a disaster in the Region, you can switch the application over to another Region.

• For DR, use Amazon Elastic Disaster Recovery to set up application-level components in a separate Region from production components. This ensures that in the event of a disaster in the Region, you can switch the application over to another Region.

• Use Amazon EFS (for moderate I/O requirements) or Amazon FSx (for high I/O requirements) to store your PeopleSoft reports, attachments, and data files. This ensures that the content is stored in one central location and can be accessed from anywhere within the infrastructure.

• Use Amazon CloudWatch (basic and detailed) to monitor the AWS Cloud resources that your PeopleSoft application is using in near real time. This ensures that you are alerted of issues instantly and can address them quickly before they affect the availability of the environment.

• If you’re using an Amazon RDS database as the PeopleSoft database, use Enhanced Monitoring. This feature provides access to over 50 metrics, including CPU, memory, file system I/O, and disk I/O.

• Use AWS CloudTrail to monitor API calls on the AWS resources that your PeopleSoft application is using. This helps you perform security analysis, resource change tracking, and compliance auditing.

Security best practices

• To protect your PeopleSoft application from common exploits such as SQL injection or cross-site scripting (XSS), use AWS WAF. Consider using AWS Shield Advanced for tailored detection and mitigation services.

• Add a rule to the Application Load Balancer to redirect traffic from HTTP to HTTPS automatically to help secure your PeopleSoft application.

• Set up a separate security group for the Application Load Balancer. This security group should allow only HTTPS/HTTP inbound traffic and no outbound traffic. This ensures that only intended traffic is allowed and helps secure your application.
• Use private subnets for the application servers, web servers, and database, and use NAT gateways for outbound internet traffic. This ensures that the servers that support the application aren’t reachable publicly, while providing public access only to the servers that need it.

• Use different VPCs to run your PeopleSoft production and non-production environments. Use AWS Transit Gateway, VPC peering, network ACLs, and security groups to control the traffic flow between the VPCs and, if necessary, your on-premises data center.

• Follow the principle of least privilege. Grant access to the AWS resources used by the PeopleSoft application only to users who absolutely need it. Grant only the minimum privileges required to perform a task. For more information, see the security pillar of the AWS Well-Architected Framework.

• Wherever possible, use AWS Systems Manager to access the EC2 instances that the PeopleSoft application uses.

Reliability best practices

• When you use an Application Load Balancer, register a single target for each enabled Availability Zone. This makes the load balancer most effective.

• We recommend that you have three distinct URLs for each PeopleSoft production environment: one URL to access the application, one to serve the integration broker, and one to view reports. If possible, each URL should have its own dedicated web servers and application servers. This design helps make your PeopleSoft application more secure, because each URL has a distinct functionality and controlled access. It also minimizes the scope of impact if the underlying services fail.

• We recommend that you configure health checks on the load balancer target groups for your PeopleSoft application. The health checks should be performed on the web servers instead of the EC2 instances running those servers. This ensures that if the web server crashes or the EC2 instance that hosts the web server goes down, the Application Load Balancer reflects that information accurately.

• For a PeopleSoft production application, we recommend that you spread the web servers across at least three Availability Zones. This ensures that the PeopleSoft application is always highly available even if one of the Availability Zones goes down.

• For a PeopleSoft production application, enable jolt pooling (joltPooling=true). This ensures that your application fails over to another application server if a server is down for patching purposes or because of a VM failure.

• For a PeopleSoft production application, set DynamicConfigReload to 1. This setting is supported in PeopleTools version 8.52 and later. It adds new application servers to the web server dynamically, without restarting the servers.

• To minimize downtime when you apply PeopleTools patches, use the blue/green deployment method for your Auto Scaling group launch configurations for the web and application servers. For more information, see the Overview of deployment options on AWS whitepaper.

• Use AWS Backup to back up your PeopleSoft application on AWS. AWS Backup is a cost-effective, fully managed, policy-based service that simplifies data protection at scale.

Performance best practices

• Terminate the SSL at the Application Load Balancer for optimal performance of the PeopleSoft environment, unless your business requires encrypted traffic throughout the environment.

• Create interface VPC endpoints for AWS services like such as Amazon Simple Notification Service (Amazon SNS) and CloudWatch so that traffic is always internal. This is cost-effective and helps keep your application secure.

Cost optimization best practices

• Tag all the resources used by your PeopleSoft environment, and enable cost allocation tags. These tags help you view and manage your resource costs.
• For a PeopleSoft production application, set up Auto Scaling groups for the web servers and the application servers. This maintains a minimal number of web and application servers to support your application. You can use Auto Scaling group policies to scale the the servers up and down as required.

• Use billing alarms to get alerts when costs exceed a budget threshold that you specify.

Sustainability best practices

• Use infrastructure as code (IaC) to maintain your PeopleSoft environments. This helps you build consistent environments and maintain change control.

Epics

Migrate your PeopleSoft database to Amazon RDS

<table>
<thead>
<tr>
<th>Task</th>

Build a video processing pipeline by using Amazon Kinesis Video Streams and AWS Fargate

Summary

This pattern demonstrates how to use Amazon Kinesis Video Streams and AWS Fargate to extract frames from a video stream and store them as image files for further processing in Amazon Simple Storage Service (Amazon S3).

The pattern provides a sample application in the form of a Java Maven project. This application defines the AWS infrastructure by using the AWS Cloud Development Kit (AWS CDK). Both the frame processing logic and the infrastructure definitions are written in the Java programming language. You can use this sample application as a basis for developing your own real-time video processing pipeline or to build the video preprocessing step of a machine learning pipeline.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Java SE Development Kit (JDK) 11, installed
- Apache Maven, installed
- AWS Cloud Development Kit (AWS CDK), installed
- AWS Command Line Interface (AWS CLI) version 2, installed
- Docker (required for building Docker images to use in AWS Fargate task definitions), installed

Limitations

This pattern is intended as a proof of concept, or as a basis for further development. It should not be used in its current form in production deployments.

Product versions

- This pattern was tested with the AWS CDK version 1.77.0 (see AWS CDK versions)
- JDK 11
- AWS CLI version 2

Architecture

Target technology stack

- Amazon Kinesis Video Streams
- AWS Fargate task
• Amazon Simple Queue Service (Amazon SQS) queue
• Amazon S3 bucket

Target architecture

The user creates a Kinesis video stream, uploads a video, and sends a JSON message that contains details about the input Kinesis video stream and the output S3 bucket to an SQS queue. AWS Fargate, which is running the main application in a container, pulls the message from the SQS queue and starts extracting frames. Each frame is saved in an image file and stored in the target S3 bucket.

Automation and scale

The sample application can scale both horizontally and vertically within a single AWS Region. Horizontal scaling can be achieved by increasing the number of deployed AWS Fargate tasks that read from the SQS queue. Vertical scaling can be achieved by increasing the number of frame-splitting and image-publishing threads in the application. These settings are passed as environment variables to the application in the definition of the QueueProcessingFargateService resource in the AWS CDK. Due to the nature of AWS CDK stack deployment, you can deploy this application in multiple AWS Regions and accounts with no additional effort.

Tools

Tools

• AWS CDK is a software development framework for defining your cloud infrastructure and resources by using programming languages such as TypeScript, JavaScript, Python, Java, and C#/Net.
• Amazon Kinesis Video Streams is a fully managed AWS service that you can use to stream live video from devices to the AWS Cloud, or build applications for real-time video processing or batch-oriented video analytics.
• AWS Fargate is a serverless compute engine for containers. Fargate removes the need to provision and manage servers, and lets you focus on developing your applications.
• Amazon S3 is an object storage service that offers scalability, data availability, security, and performance.
• Amazon SQS is a fully managed message queuing service that enables you to decouple and scale microservices, distributed systems, and serverless applications.
Code

- A .zip file of the sample application project (frame-splitter-code.zip) is attached.

Epics

Deploy the infrastructure

### Additional information

#### Choosing an IDE

We recommend that you use your favorite Java IDE to build and explore this project.

#### Cleaning up

After you finish running this example, remove all deployed resources to avoid incurring additional AWS infrastructure costs.

To remove the infrastructure and the video stream, use these two commands in the AWS CLI:

```
cdk destroy --profile "$AWS_PROFILE_NAME" --all
```

```
aws kinesisvideo --profile "$AWS_PROFILE_NAME" delete-stream --stream-arn "$STREAM_ARN"
```

Alternatively, you can remove the resources manually by using the AWS CloudFormation console to remove the AWS CloudFormation stack, and the Kinesis console to remove the Kinesis video stream. Note that `cdk destroy` doesn't remove the output S3 bucket or the images in Amazon Elastic Container Registry (Amazon ECR) repositories (`aws cdk/assets`). You have to remove them manually.

Summary

This pattern describes how to copy data from an Amazon Simple Storage Service (Amazon S3) bucket in an Amazon Web Services (AWS) account and AWS Region to an S3 bucket in another account and Region.

The pattern uses a source account and a destination account in different Regions. You attach a bucket policy to your source S3 bucket that grants the destination account access through AWS Identity and Access Management (IAM). You then create an IAM policy in your destination account that allows a user to perform PutObject and GetObject actions on the source S3 bucket. Finally, you run copy and sync commands to transfer data from the source S3 bucket to the destination S3 bucket.

Accounts own the objects that they upload to S3 buckets. If you copy objects across accounts and Regions, you grant the destination account ownership of the copied objects. You can change the ownership of an object by changing its access control list (ACL) to bucket-owner-full-control. However, we recommend that you grant programmatic cross-account permissions to the destination account because ACLs can be difficult to manage for multiple objects.

Prerequisites and limitations

- Two active AWS accounts in different AWS Regions.
- An existing S3 bucket in the source account.
- If your source or destination Amazon S3 bucket has default encryption enabled, you must modify the AWS Key Management Service (AWS KMS) key permissions. For more information, see the AWS re:Post article on this topic.
- Familiarity with cross-account permissions.

Architecture
Tools

- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command line shell.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Best practices

- **Security best practices in IAM** (IAM documentation)
- **Applying least-privilege permissions** (IAM documentation)

Epics

Create IAM user and roles

</tr>
</tbody>
</table>

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "s3:ListBucket",
            "s3:GetObject"
         ],
         "Resource": [
            "arn:aws:s3:::awsexamplesourcebucket",
            "arn:aws:s3:::awsexamplesourcebucket/*"
         ]
      },
      {
         "Effect": "Allow",
         "Action": [
            "s3:ListBucket",
            "s3:PutObject",
            "s3:PutObjectAcl",
            "s3:PutObjectTagging",
            "s3:GetObjectTagging",
            "s3:GetObjectVersion",
            "s3:GetObjectVersionTagging"
         ],
         "Resource": [
            "arn:aws:s3:::awsexampledestinationbucket",
            "arn:aws:s3:::awsexampledestinationbucket/*"
         ]
      }
   ]
}
```
### Task: Create an IAM role.

Create an IAM role named `S3MigrationRole` by using the following trust policy, and then attach the previously created `S3MigrationPolicy`. For detailed steps, see [Creating a role to delegate permissions to an IAM user](https://docs.aws.amazon.com/IAM/latest/userguide/creating-a-role.html) in the IAM documentation.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "AWS": "arn:aws:iam::<destination_account>:user/<user_name>",
            "Action": "sts:AssumeRole",
            "Condition": {}
         }
      }
   ]
}
```

**Note:** Modify the Amazon Resource Name (ARN) of the destination IAM role in the trust policy according to your use case.

This trust policy allows the newly created IAM user to assume `S3MigrationRole`.

### Task: Create and attach the S3 bucket policy in the source account

Create and attach an S3 bucket policy.

Sign in to the AWS Management Console for your source account and open the Amazon S3 console. Choose your source S3 bucket and then choose...
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Permissions.** Under **Bucket policy**, choose **Edit** and then paste the following bucket policy. Choose **Save**. | {  
"Version": "2012-10-17",
"Statement": [
  
  "Sid":
  "DelegateS3Access",
  "Effect":
  "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::<destination_account>:role/<RoleName>"},
  "Action": [
    "s3:ListBucket","s3:GetObject"],
  "Resource": [
    "arn:aws:s3:::awsexamplesourcebucket/*",
    "arn:aws:s3:::awsexamplesourcebucket"
  ]
]  
} | Cloud administrator |
| Note: Make sure that you include the AWS account ID for the destination account and configure the bucket policy template according to your requirements. This resource-based policy allows the destination role S3MigrationRole to access S3 objects in the source account. | Configure the destination S3 bucket | |
| **Task** | **Description** | **Skills required** |
| Create a destination S3 bucket. | Sign in to the AWS Management Console for your destination account, open the Amazon S3 console, and then choose **Create bucket**. Create an S3 bucket according to your requirements. For more information, see **Creating a bucket** in the Amazon S3 documentation. | Cloud administrator |
# Copy data to the destination S3 bucket

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure AWS CLI with the newly created user credentials.          | 1. Install the latest release of the AWS CLI. For instructions, see [Installing or updating the latest version of the AWS CLI](https://docs.aws.amazon.com/cli/latest/userguide/installing.html) in the AWS CLI documentation.  
2. Run `$ aws configure` and update CLI with the AWS access key of the user you created. For more information, see [Configuration and credential file settings](https://docs.aws.amazon.com/cli/latest/userguide/cli-configure-file.html) in the AWS CLI documentation. | AWS DevOps               |
| Assume the S3 migration role.                                       | 1. Use the AWS CLI to assume S3MigrationRole:  
```bash
aws sts assume-role --role-arn "arn:aws:iam::<destination_account>:role/S3MigrationRole" --role-session-name AWSCLI-Session
```
This command outputs several pieces of information. Inside the credentials block you need the AccessKeyId, SecretAccessKey, and SessionToken. This example uses the environment variables RoleAccessKeyId, RoleSecretKey, and RoleSessionToken. Note that the timestamp of the expiration field is in the UTC time zone. The timestamp indicates when the temporary credentials of the IAM role expire. If the temporary credentials expire, you must call the sts:AssumeRole API again.  
2. Create three environment variables to assume the IAM role. These environment variables are filled out with the following output:  
```bash
export AWS_ACCESS_KEY_ID=RoleAccessKeyId
```
| AWS administrator                                                   | AWS administrator                                                   | AWS administrator                                                   |
### AWS Prescriptive Guidance Patterns

#### Troubleshooting

**Task**

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>export AWS_SECRET_ACCESS_KEY=RoleSecretKey export AWS_SESSION_TOKEN=RoleSessionToken</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>

3. Verify that you assumed the IAM role by running the following command:

```bash/aws sts get-caller-identity```

For more information, see the [AWS Knowledge Center](https://aws.amazon.com/documentation/knowledge-center/).

### Copy and synchronize data from the source S3 bucket to the destination S3 bucket.

When you have assumed the role S3MigrationRole you can copy the data using the copy (cp) or synchronize (sync) command.

**Copy** (see the [AWS CLI Command Reference](https://docs.aws.amazon.com/cli/latest/reference/s3/cp.html) for details):

```bash
```

**Synchronize** (see the [AWS CLI Command Reference](https://docs.aws.amazon.com/cli/latest/reference/s3/sync.html) for details):

```bash
```

Successfully import an S3 bucket as an AWS CloudFormation stack

Created by Ram Kandaswamy (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Technologies:</th>
<th>Cloud-native; Storage &amp; backup</th>
<th>AWS services:</th>
<th>Amazon S3; AWS CloudFormation</th>
</tr>
</thead>
</table>

Summary

If you use Amazon Web Services (AWS) resources, such as Amazon Simple Storage Service (Amazon S3) buckets, and want to use an infrastructure as code (IaC) approach, then you can import your resources into AWS CloudFormation and manage them as a stack.

This pattern provides steps to successfully import an S3 bucket as an AWS CloudFormation stack. By using this pattern's approach, you can avoid possible errors that might occur if you import your S3 bucket in a single action.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing S3 bucket and S3 bucket policy. For more information about this, see What S3 bucket policy should I use to comply with the AWS Config rule s3-bucket-ssl-requests-only in the AWS Knowledge Center.
- An existing AWS Key Management Service (AWS KMS) key and its alias. For more information about this, see Working with aliases in the AWS KMS documentation.
- The sample CloudFormation-template-S3-bucket AWS CloudFormation template (attached), downloaded to your local computer.

Architecture
The diagram shows the following workflow:

1. The user creates a JSON or YAML-formatted AWS CloudFormation template.
2. The template creates an AWS CloudFormation stack to import the S3 bucket.
3. The AWS CloudFormation stack manages the S3 bucket that you specified in the template.

**Technology stack**

- AWS CloudFormation
- AWS Identity and Access Management (IAM)
- AWS KMS
- Amazon S3

**Tools**

- **AWS CloudFormation** – AWS CloudFormation helps you to create and provision AWS infrastructure deployments predictably and repeatedly.
- **AWS Identity and Access Management (IAM)** – IAM is a web service for securely controlling access to AWS services.
- **AWS KMS** – AWS Key Management Service (AWS KMS) is an encryption and key management service scaled for the cloud.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the Internet.

**Epics**

**Import an S3 bucket with CMK-based encryption as an AWS CloudFormation stack**

| AWS administrator |

**Note:** This S3 bucket policy has a deny statement that restricts API calls that are not secure.

#### Update the key policy.

1. On the AWS CloudFormation console, choose **Stacks**, choose the name of the stack that you created earlier, choose the **Template** pane, and then choose **View in Designer**.
2. Modify the template's KMS resource to include the key policy that allows administrators to administer the CMK.
3. Choose **Create stack**, choose **Next**, and then complete the wizard according to your requirements.

For more information about this, see [Using key policies in AWS KMS](https://docs.aws.amazon.com/kms/latest/developerguide/key-policies.html) and [Allowing key administrators to administer the CMK](https://docs.aws.amazon.com/kms/latest/developerguide/key-policies.html) in the AWS KMS documentation.

| AWS services: | Amazon EC2; Amazon EC2 Auto Scaling; AWS EC2 Container Registry; Amazon EFS; Amazon RDS; Amazon VPC; Amazon ECS; Elastic Load Balancing (ELB); AWS Lambda |

**Summary**

This pattern describes how to privately host a Docker container application on Amazon Elastic Container Service (Amazon ECS) behind a Network Load Balancer, and access the application by using AWS PrivateLink. You can then use a private network to securely access services on the Amazon Web Services (AWS) Cloud. Amazon Relational Database Service (Amazon RDS) hosts the relational database for the application running on Amazon ECS with high availability (HA). Amazon Elastic File System (Amazon EFS) is used if the application requires persistent storage.

The Amazon ECS service running the Docker applications, with a Network Load Balancer at the front end, can be associated with a virtual private cloud (VPC) endpoint for access through AWS PrivateLink. This VPC endpoint service can then be shared with other VPCs by using their VPC endpoints.

You can also use AWS Fargate instead of an Amazon EC2 Auto Scaling group. For more information, see [Access container applications privately on Amazon ECS by using AWS Fargate, AWS PrivateLink, and a Network Load Balancer](#).

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- [AWS Command Line Interface (AWS CLI) version 2](#), installed and configured on Linux, macOS, or Windows
- [Docker](#), installed and configured on Linux, macOS, or Windows
- An application running on Docker

**Architecture**
AWS Prescriptive Guidance Patterns
Architecture
Technology stack

- Amazon CloudWatch
- Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon EC2 Auto Scaling
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon ECS
- Amazon RDS
- Amazon Simple Storage Service (Amazon S3)
- AWS Lambda
- AWS PrivateLink
- AWS Secrets Manager
- Application Load Balancer
- Network Load Balancer
- VPC

Automation and scale

- You can use AWS CloudFormation to create this pattern by using Infrastructure as Code.

Tools

- **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud.
- **Amazon EC2 Auto Scaling** – Amazon EC2 Auto Scaling helps you ensure that you have the correct number of Amazon EC2 instances available to handle the load for your application.
- **Amazon ECS** – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast, container management service that makes it easy to run, stop, and manage containers on a cluster.
- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is a managed AWS container image registry service that is secure, scalable, and reliable.
- **Amazon EFS** – Amazon Elastic File System (Amazon EFS) provides a simple, scalable, fully managed elastic NFS file system for use with AWS Cloud services and on-premises resources.
- **AWS Lambda** – Lambda is a compute service for running code without provisioning or managing servers.
- **Amazon RDS** – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers.
- **AWS Secrets Manager** – Secrets Manager helps you replace hardcoded credentials in your code, including passwords, by providing an API call to Secrets Manager to retrieve the secret programmatically.
- **Amazon VPC** – Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined.
- **Elastic Load Balancing** – Elastic Load Balancing distributes incoming application or network traffic across multiple targets, such as Amazon EC2 instances, containers, and IP addresses, in multiple Availability Zones.
- **Docker** – Docker helps developers to pack, ship, and run any application as a lightweight, portable, and self-sufficient container.
## Create networking components

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a VPC.         | 1. Sign in to the AWS Management Console and open the Amazon VPC console. Choose [Create VPC](https://aws.amazon.com), and choose **VPC and more**.  
2. Enter a name for your VPC, and choose an appropriate CIDR block range.  
3. Specify two Availability Zones, two public subnets, four private subnets. Two private subnets are for Amazon ECS tasks, and two private subnets are for Amazon RDS databases.  
4. Specify one NAT gateway for each Availability Zone.  
5. Choose [Create VPC](https://aws.amazon.com). | Cloud administrator           |

## Create the load balancers

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a Network Load Balancer. | 1. Open the Amazon EC2 console and choose the AWS Region that contains your VPC.  
2. Under **Load balancing**, choose **Load balancers**, and choose **Create load balancer**.  
3. Choose **Network Load Balancer**, and choose **Create**.  
4. On the **Configure load balancer** page, configure your Network Load Balancer and listener. **Important:** Make sure you choose your Network Load Balancer's scheme as **Internal**.  
5. Choose the applicable security settings, configure a security group and a target group. Choose **Instance** or **IP** as the **Target type** in the **Configure routing** section. | Cloud administrator           |
### AWS Prescriptive Guidance Patterns

### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Create an Application Load Balancer.** | Make sure you do not register a target.  
6. When you have configured all the settings, choose **Next: Review**, and then choose **Create.** | **Cloud administrator** |
| **Create an Amazon EFS file system.** | 1. On the Amazon EC2 console, choose the same Region that contains your VPC.  
2. Under **Load balancing**, choose **Load balancers**, and choose **Create load balancer.**  
3. Choose **Application Load Balancer**, and choose **Create.**  
4. Configure your Application Load Balancer and its listener. **Important:** Make sure you choose your Application Load Balancer's scheme as **Internal**.  
5. Choose the applicable security settings, configure a security group and a target group. Choose **Instance** or **IP** as the **Target type** in the **Configure routing** section. Make sure you do not register a target.  
6. When you have configured all the settings, choose **Next: Review**, and then choose **Create.** | **Cloud administrator** |

### Create an Amazon EFS file system

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Create an Amazon EFS file system.** | 1. Open the Amazon EFS console, and choose **Create file system.**  
2. In the **Create file system** dialog box, enter a name for your file system, and choose your VPC.  
3. Choose **Create** to create the file system.  
4. Set up and configure your Amazon EFS file system. | **Cloud administrator** |
<p>| <strong>Mount targets for the subnets.</strong> | 1. Return to the Amazon EFS console, and choose <strong>File</strong> | <strong>Cloud administrator</strong> |</p>
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>systems. The File systems page shows the Amazon EFS file systems in your account.</td>
<td>Cloud administrator</td>
<td></td>
</tr>
<tr>
<td>2. Choose the file system that you created, and choose Manage to display the Availability Zones. To add a mount target, choose Add mount target, and add the four private subnets that you created.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Verify that the subnets are mounted as targets.</td>
<td>1. On the Amazon EFS console, choose File systems.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td></td>
<td>2. Choose Network to display the list of existing mount targets. Make sure that these include the four subnets that you created.</td>
<td></td>
</tr>
</tbody>
</table>

### Create an S3 bucket

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>

</thead>
<tbody>
<tr>
<td>Create an AWS KMS key to encrypt the Secrets Manager secret.</td>
<td>Open the AWS Key Management Service (AWS KMS) console and create a KMS key.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td>Create a Secrets Manager secret to store the Amazon RDS password.</td>
<td>1. Open the AWS Secrets Manager console, and create a new secret by choosing Store a new secret.</td>
<td>Cloud Administrator</td>
</tr>
<tr>
<td></td>
<td>2. Choose the KMS key that you created, and store your new secret.</td>
<td></td>
</tr>
</tbody>
</table>
## Create an Amazon RDS instance

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a DB subnet group.                 | 1. Open the Amazon RDS console and choose **Subnet groups**.  
2. Choose **Create DB subnet group**, and enter a name and description for your DB subnet group.  
3. Choose the VPC that you created earlier, and choose the Availability Zones and subnets. Then choose **Create**. | Cloud administrator        |
| Create an Amazon RDS instance.            | Create and configure an Amazon RDS instance within the private subnets. Make sure that **Multi-AZ** is turned on for HA.                                                                                      | Cloud administrator        |
| Load data to the Amazon RDS instance.     | Load the relational data required by your application into your Amazon RDS instance. This process will vary depending on your application's needs, as well as how your database schema is defined and designed. | Cloud administrator, DBA   |

## Create the Amazon ECS components

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an ECS cluster.                    | 1. Open the Amazon ECS console, and choose **Clusters**.  
2. Choose **Create clusters**, and set up an ECS cluster according to your required specifications.                                                                                                         | Cloud administrator        |
| Create the Docker images.                 | Create the Docker images by following the instructions in the **Related resources** section.                                                                                                                                 | Cloud administrator        |
| Create Amazon ECR repositories.           | 1. On the Amazon ECR console, choose **Repositories**.  
2. Choose **Create repository**, and enter a unique name for your repository.  
3. Configure the repository according to your specifications, including AWS KMS encryption if required.                                                                                         | Cloud administrator, DevOps engineer |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authenticate your Docker client for the Amazon ECR repository.</td>
<td>To authenticate your Docker client for the Amazon ECR repository, run the “aws ecr get-login-password” command in the AWS CLI.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>
| Push the Docker images to the Amazon ECR repository.                 | 1. Identify the Docker image you want to push, and run the docker images command in the AWS CLI.  
|                                                                     | 2. Tag your image with the Amazon ECR registry, repository, and optional image tag name combination.  
|                                                                     | 3. Push the Docker image by running the docker push command.  
|                                                                     | 4. Repeat these steps for all required images. | Cloud administrator   |
| Create an Amazon ECS task definition.                                | A task definition is required to run Docker containers in Amazon ECS.  
|                                                                     | 1. Return to the Amazon ECS console, choose Task definitions, and then choose Create new task definition.  
|                                                                     | 2. On the Select compatibilities page, select the launch type that your task should use, and choose Next step. | Cloud administrator   |
|                                                                     | For help with setting up your task definition, see “Creating a task definition” in the Related resources section. Important: Make sure you provide the Docker images that you pushed to Amazon ECR. |                       |
| Create an Amazon ECS service.                                        | Create an Amazon ECS service by using the ECS cluster you created earlier. Make sure you choose Amazon EC2 as the launch type, and choose the task definition created in the previous step, as well as the target group of the Application Load Balancer. | Cloud administrator   |
# Create an Amazon EC2 Auto Scaling group

Summary

This pattern describes how to privately host a Docker container application on the Amazon Web Services (AWS) Cloud by using Amazon Elastic Container Service (Amazon ECS) with an AWS Fargate launch type, behind a Network Load Balancer, and access the application by using AWS PrivateLink. Amazon Relational Database Service (Amazon RDS) hosts the relational database for the application running on Amazon ECS with high availability (HA). You can use Amazon Elastic File System (Amazon EFS) if the application requires persistent storage.

This pattern uses a Fargate launch type for the Amazon ECS service running the Docker applications, with a Network Load Balancer at the front end. It can then be associated with a virtual private cloud (VPC) endpoint for access through AWS PrivateLink. This VPC endpoint service can then be shared with other VPCs by using their VPC endpoints.

You can use Fargate with Amazon ECS to run containers without having to manage servers or clusters of Amazon Elastic Compute Cloud (Amazon EC2) instances. You can also use an Amazon EC2 Auto Scaling group instead of Fargate. For more information, see Access container applications privately on Amazon ECS by using AWS PrivateLink and a Network Load Balancer.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2, installed and configured on Linux, macOS, or Windows
- Docker, installed and configured on Linux, macOS, or Windows
- An application running on Docker

Architecture
Technology stack

- Amazon CloudWatch
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon ECS
- Amazon EFS
- Amazon RDS
- Amazon Simple Storage Service (Amazon S3)
- AWS Fargate
- AWS Lambda
- AWS PrivateLink
- AWS Secrets Manager
- Application Load Balancer
- Network Load Balancer
- VPC

Automation and scale

- You can use AWS CloudFormation to create this pattern by using Infrastructure as Code.

Tools

- **Amazon ECS** – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast, container management service that makes it easy to run, stop, and manage containers on a cluster.
- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is a managed AWS container image registry service that is secure, scalable, and reliable.
- **Amazon EFS** – Amazon Elastic File System (Amazon EFS) provides a simple, scalable, fully managed NFS file system for use with AWS Cloud services and on-premises resources.
- **AWS Fargate** – AWS Fargate is a technology that you can use with Amazon ECS to run containers without having to manage servers or clusters of Amazon EC2 instances.
- **AWS Lambda** – Lambda is a compute service that lets you run code without provisioning or managing servers.
- **Amazon RDS** – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers.
- **AWS Secrets Manager** – Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- **Amazon VPC** – Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined.
- **Elastic Load Balancing** – Elastic Load Balancing (ELB) distributes incoming application or network traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in multiple Availability Zones.
- **Docker** – Docker helps developers to easily pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to privately host a Docker container application on Amazon Elastic Kubernetes Service (Amazon EKS) behind a Network Load Balancer, and access the application by using AWS PrivateLink. You can then use a private network to securely access services on the Amazon Web Services (AWS) Cloud.

The Amazon EKS cluster running the Docker applications, with a Network Load Balancer at the front end, can be associated with a virtual private cloud (VPC) endpoint for access through AWS PrivateLink. This VPC endpoint service can then be shared with other VPCs by using their VPC endpoints.

The setup described by this pattern is a secure way to share application access among VPCs and AWS accounts. It requires no special connectivity or routing configurations, because the connection between the consumer and provider accounts is on the global AWS backbone and doesn’t traverse the public internet.

Prerequisites and limitations

Prerequisites

- Docker, installed and configured on Linux, macOS, or Windows.
- An application running on Docker.
- An active AWS account.
- AWS Command Line Interface (AWS CLI) version 2, installed and configured on Linux, macOS, or Windows.
- An existing Amazon EKS cluster with tagged private subnets and configured to host applications. For more information, see Subnet tagging in the Amazon EKS documentation.
- Kubecti, installed and configured to access resources on your Amazon EKS cluster. For more information, see Installing kubectl in the Amazon EKS documentation.
Technology stack

- Amazon EKS
- AWS PrivateLink
- Network Load Balancer

Automation and scale

- Kubernetes manifests can be tracked and managed on a Git-based repository (for example, on AWS CodeCommit), and deployed by using continuous integration and continuous delivery (CI/CD) in AWS CodePipeline.
- You can use AWS CloudFormation to create this pattern by using infrastructure as code (IaC).

Tools

- **AWS CLI** – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.
- **Elastic Load Balancing** – Elastic Load Balancing distributes incoming application or network traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses, in one or more Availability Zones.
- **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.
- **Amazon VPC** – Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you’ve defined.
- **Kubectl** – Kubectl is a command line utility for running commands against Kubernetes clusters.

Activate mTLS in AWS App Mesh using AWS Private CA on Amazon EKS

Created by Omar Kahil (AWS), Emmanuel Saliu (AWS), and Muhammad Shahzad (AWS)

| Environment: | PoC or pilot | Technologies: | Containers & microservices | AWS services: | AWS App Mesh; Amazon EKS; AWS Certificate Manager (ACM) |

Summary

This pattern shows how to implement Mutual Transport Layer Security (mTLS) on Amazon Web Services (AWS) using certificates from AWS Private Certificate Authority (AWS Private CA) in AWS App Mesh. It uses the Envoy secret discovery service (SDS) API through the Secure Production Identity Framework for Everyone (SPIFFE). SPIFFE is a Cloud Native Computing Foundation (CNCF) open-source project with wide community support that provides fine-grained and dynamic workload identity management. To implement SPIFFE standards, use the SPIRE SPIFFE runtime environment.

Using mTLS in App Mesh offers two-way peer authentication, because it adds a layer of security over TLS and allows services in the mesh to verify the client that’s making the connection. The client in the client-server relationship also provides an X.509 certificate during the session negotiation process. The server uses this certificate to identify and authenticate the client. This helps to verify if the certificate is issued by a trusted certificate authority (CA) and if the certificate is a valid one.

Prerequisites and limitations

Prerequisites

- An Amazon Elastic Kubernetes Service (Amazon EKS) cluster with self-managed or managed node groups
- App Mesh controller deployed on the cluster with SDS activated
- A private certificate from AWS Certificate Manager (ACM) that is issued by AWS Private CA

Limitations

- SPIRE cannot be installed on AWS Fargate because the SPIRE Agent must be run as a Kubernetes DaemonSet.

Product versions

- AWS App Mesh Controller chart 1.3.0 or later

Architecture

The following diagram shows the EKS cluster with App Mesh in the VPC. The SPIRE server in one worker node communicates with the SPIRE Agents in other worker nodes, and with AWS Private CA. Envoy is used for mTLS communication between the SPIRE Agent worker nodes.
The diagram illustrates the following steps:

1. Certificate is issued.
2. Request cert signing and certificate.

**Tools**

**AWS services**

- **AWS Private CA** – AWS Private Certificate Authority (AWS Private CA) enables creation of private certificate authority (CA) hierarchies, including root and subordinate CAs, without the investment and maintenance costs of operating an on-premises CA.

- **AWS App Mesh** – AWS App Mesh is a service mesh that makes it easier to monitor and control services. App Mesh standardizes how your services communicate, giving you consistent visibility and network traffic controls for every service in an application.

- **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.

**Other tools**

- **Helm** – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster. This pattern uses Helm to deploy AWS App Mesh Controller.

- **AWS App Mesh Controller chart** – AWS App Mesh Controller chart is used by this pattern to enable AWS App Mesh on Amazon EKS.

Summary

Backing up your PostgreSQL databases is an important task and can typically be completed with the `pg_dump` utility, which uses the COPY command by default to create a schema and data dump of a PostgreSQL database. However, this process can become repetitive if you require regular backups for multiple PostgreSQL databases. If your PostgreSQL databases are hosted in the cloud, you can also take advantage of the automated backup feature provided by Amazon Relational Database Service (Amazon RDS) for PostgreSQL as well. This pattern describes how to automate regular backups for Amazon RDS for PostgreSQL DB instances using the `pg_dump` utility.

Note: The instructions assume that you're using Amazon RDS. However, you can also use this approach for PostgreSQL databases that are hosted outside Amazon RDS. To take backups, the AWS Lambda function must be able to access your databases.

A time-based Amazon CloudWatch Events event initiates a Lambda function that searches for specific backup tags applied to the metadata of the PostgreSQL DB instances on Amazon RDS. If the PostgreSQL DB instances have the `b kp:AutomatedDBDump = Active` tag and other required backup tags, the Lambda function submits individual jobs for each database backup to AWS Batch.

AWS Batch processes these jobs and uploads the backup data to an Amazon Simple Storage Service (Amazon S3) bucket. This pattern uses a Dockerfile and an entrypoint.sh file to build a Docker container image that is used to make backups in the AWS Batch job. After the backup process is complete, AWS Batch records the backup details to an inventory table on Amazon DynamoDB. As an additional safeguard, a CloudWatch Events event initiates an Amazon Simple Notification Service (Amazon SNS) notification if a job fails in AWS Batch.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing managed or unmanaged compute environment. For more information, see [Managed and unmanaged compute environments](#) in the AWS Batch documentation.
- [AWS Command Line Interface (CLI) version 2 Docker image](#), installed and configured.
- Existing Amazon RDS for PostgreSQL DB instances.
- An existing S3 bucket.
- [Docker](#), installed and configured on Linux, macOS, or Windows.
• Familiarity with coding in Lambda.

## Architecture

### Technology stack

- Amazon CloudWatch Events
- Amazon DynamoDB
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon RDS
- Amazon SNS
- Amazon S3
- AWS Batch
- AWS Key Management Service (AWS KMS)
- AWS Lambda
- AWS Secrets Manager
- Docker

### Tools

- **Amazon CloudWatch Events** – CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- **Amazon DynamoDB** – DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is a managed AWS container image registry service that is secure, scalable, and reliable.
- **Amazon RDS** – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.
• **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers.
• **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.
• **AWS Batch** – AWS Batch helps you run batch computing workloads on the AWS Cloud.
• **AWS KMS** – AWS Key Management Service (AWS KMS) is a managed service that makes it easy for you to create and control the encryption keys used to encrypt your data.
• **AWS Lambda** – Lambda is a compute service that helps you run code without provisioning or managing servers.
• **AWS Secrets Manager** – Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
• **Docker** – Docker helps developers easily pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

Your PostgreSQL DB instances on Amazon RDS must have tags applied to their metadata. The Lambda function searches for tags to identify DB instances that should be backed up, and the following tags are typically used.

<table>
<thead>
<tr>
<th>Tag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bkp:AutomatedDBDump = Active</td>
<td>Identifies an Amazon RDS DB instance as a candidate for backups.</td>
</tr>
<tr>
<td>bkp:AutomatedBackupSecret = &lt;secret_name&gt;</td>
<td>Identifies the Secrets Manager secret that contains the Amazon RDS login credentials.</td>
</tr>
<tr>
<td>bkp:AutomatedDBDumpS3Bucket = &lt;s3_bucket_name&gt;</td>
<td>Identifies the S3 bucket to send backups to.</td>
</tr>
<tr>
<td>bkp:AutomatedDBDumpFrequency</td>
<td>Identify the frequency and times when databases should be backed up.</td>
</tr>
<tr>
<td>bkp:AutomatedDBDumpTime</td>
<td></td>
</tr>
<tr>
<td>bkp:pgdumpcommand = &lt;pgdump_command&gt;</td>
<td>Identifies the databases for which the backups need to be taken.</td>
</tr>
</tbody>
</table>

Automate deployment of Node Termination Handler in Amazon EKS by using a CI/CD pipeline

Created by Sandip Gangapadhyay (AWS), John Vargas (AWS), Pragtideep Singh (AWS), Sandeep Gawande (AWS), and Viyoma Sachdeva (AWS)

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: Production</th>
<th>Technologies: Containers &amp; microservices; DevOps</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Deploy NTH to EKS</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

AWS services: AWS CodePipeline; Amazon EKS; AWS CodeBuild

Summary

On the Amazon Web Services (AWS) Cloud, you can use AWS Node Termination Handler, an open-source project, to handle Amazon Elastic Compute Cloud (Amazon EC2) instance shutdown within Kubernetes gracefully. AWS Node Termination Handler helps to ensure that the Kubernetes control plane responds appropriately to events that can cause your EC2 instance to become unavailable. Such events include the following:

- EC2 instance scheduled maintenance
- Amazon EC2 Spot Instance interruptions
- Auto Scaling group scale in
- Auto Scaling group rebalancing across Availability Zones
- EC2 instance termination through the API or the AWS Management Console

If an event isn't handled, your application code might not stop gracefully. It also might take longer to recover full availability, or it might accidentally schedule work to nodes that are going down. The `aws-node-termination-handler` (NTH) can operate in two different modes: Instance Metadata Service (IMDS) or Queue Processor. For more information about the two modes, see the Readme file.

This pattern automates the deployment of NTH by using Queue Processor through a continuous integration and continuous delivery (CI/CD) pipeline.

Note: If you're using EKS managed node groups, you don't need the `aws-node-termination-handler`.

Prerequisites and limitations

**Prerequisites**

- An active AWS account.
- A web browser that is supported for use with the AWS Management Console. See the list of supported browsers.
- AWS Cloud Development Kit (AWS CDK) installed.
- kubectl, the Kubernetes command line tool, installed.
• eksctl, the AWS Command Line Interface (AWS CLI) for Amazon Elastic Kubernetes Service (Amazon EKS), installed.
• A running EKS cluster with version 1.20 or later.
• A self-managed node group attached to the EKS cluster. To create an Amazon EKS cluster with a self-managed node group, run the following command.

```
eksctl create cluster --managed=false --region <region> --name <cluster_name>
```

For more information on eksctl, see the eksctl documentation.
• AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. For more information, see Creating an IAM OIDC provider for your cluster.

Limitations
• You must use an AWS Region that supports the Amazon EKS service.

Product versions
• Kubernetes version 1.20 or later
• eksctl version 0.107.0 or later
• AWS CDK version 2.27.0 or later

Architecture

Target technology stack
• A virtual private cloud (VPC)
• An EKS cluster
• Amazon Simple Queue Service (Amazon SQS)
• IAM
• Kubernetes

Target architecture
The following diagram shows the high-level view of the end-to-end steps when the node termination is started.
The workflow shown in the diagram consists of the following high-level steps:

1. The automatic scaling EC2 instance terminate event is sent to the SQS queue.
2. The NTH Pod monitors for new messages in the SQS queue.
3. The NTH Pod receives the new message and does the following:
   - Cords the node so that new pod does not run on the node.
   - Drains the node, so that the existing pod is evacuated
   - Sends a lifecycle hook signal to the Auto Scaling group so that the node can be terminated.

**Automation and scale**

- Code is managed and deployed by AWS CDK, backed by AWS CloudFormation nested stacks.
- The Amazon EKS control plane runs across multiple Availability Zones to ensure high availability.
- For automatic scaling, Amazon EKS supports the Kubernetes Cluster Autoscaler and Karpenter.

</table>

**The npm registry isn’t set correctly.**

During the installation of this solution, the script installs npm install to download all the required packages. If, during the installation, you see a message that says "Cannot find module," the npm registry might not be set correctly. To see the current registry setting, run the following command.

```
npm config get registry
```

To set the registry with `https://registry.npmjs.org/`, run the following command.

```
npm config set registry https://registry.npmjs.org
```

**Delay SQS message delivery.**

As part of your troubleshooting, if you want to delay the SQS message delivery to NTH Pod, you can adjust the SQS delivery delay parameter. For more information, see [Amazon SQS delay queues](https://docs.aws.amazon.com/sqs/latest/dg/sqs-delay-queue.html).
Related resources

- AWS Node Termination Handler source code
- EC2 workshop
- AWS CodePipeline
- Amazon Elastic Kubernetes Service (Amazon EKS)
- AWS Cloud Development Kit
- AWS CloudFormation

Additional information

1. Find the NTH Pod name.

```bash
kubectl get pods -n kube-system |grep aws-node-termination-handler
aws-node-termination-handler-65445555-kbqc7 1/1 Running 0 26m
```

2. Check the logs. An example log looks like the following. It shows that the node has been cordoned and drained before sending the Auto Scaling group lifecycle hook completion signal.

```bash
kubectl -n kube-system logs aws-node-termination-handler-65445555-kbqc7
022/07/17 20:20:43 INF Adding new event to the event store
  event="["AutoScalingGroupName":"eksctl-my-cluster-target-nodegroup-ng-10d99c89-NodeGroup-ZME36IGAP701", "Description":"ASG Lifecycle Termination event received. Instance will be interrupted at 2022-07-17 20:20:42.702 UTC", "EndTime":"0001-01-01T00:00:00Z", "EventID":"asg-lifecycle-term-33383831316538382d353564362d343332362d613931552d3834306661566334333564", "InProgress":false,"InstanceID":"i-0409f2a9d3085b80e","NodeLabels":null,"NodeName":"ip-192-168-75-60.us-east-2.compute.internal","NodeProcessed":false,"Pods":null,"ProviderID":"aws:///us-east-2c/i-0409f2a9d3085b80e","StartTime":"2022-07-17T20:20:42.702Z","State":""]"

Automatically build and deploy a Java application to Amazon EKS using a CI/CD pipeline

Summary

This pattern describes how to create a continuous integration and continuous delivery (CI/CD) pipeline that automatically builds and deploys a Java application with recommended DevSecOps practices to an Amazon Elastic Kubernetes Service (Amazon EKS) cluster on the Amazon Web Services (AWS) Cloud. This pattern uses a greeting application developed with a Spring Boot Java framework and that uses Apache Maven.

You can use this pattern’s approach to build the code for a Java application, package the application artifacts as a Docker image, security scan the image, and upload the image as a workload container on Amazon EKS. This pattern’s approach is useful if you want to migrate from a tightly coupled monolithic architecture to a microservices architecture. The approach also helps you to monitor and manage the entire lifecycle of a Java application, which ensures a higher level of automation and helps avoid errors or bugs.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) version 2, installed and configured. For more information about this, see Installing, updating, and uninstalling the AWS CLI version 2 in the AWS CLI documentation.
- AWS CLI version 2 must be configured with the same IAM role that creates the Amazon EKS cluster because only that role is authorized to add other IAM roles to the `aws-auth` ConfigMap. For information and steps to configure AWS CLI, see Configuration basics in the AWS CLI documentation.
- AWS Identity and Access Management (IAM) roles and permissions with full access to AWS CloudFormation. For more information about this, see Controlling access with IAM in the AWS CloudFormation documentation.
- An existing Amazon EKS cluster, with details of the IAM role name and IAM role Amazon Resource Name (ARN) of worker nodes in the EKS cluster.
- Kubernetes Cluster Autoscaler, installed and configured in your Amazon EKS cluster. For more information, see Cluster Autoscaler in the Amazon EKS documentation.
- Access to code in the GitHub repository.
Important note

AWS Security Hub is enabled as part of the AWS CloudFormation templates that are in the code. By default, after Security Hub is enabled, it comes with a 30-day free trial, after which there is a cost associated with this AWS service. For more information about pricing, see [AWS Security Hub pricing](#).

Product versions

- Helm version 3.4.2 or later
- Apache Maven version 3.6.3 or later
- BridgeCrew Checkov version 2.2 or later
- Aqua Security Trivy version 0.37 or later

Architecture

Technology stack

- AWS CodeBuild
- AWS CodeCommit
- Amazon CodeGuru
- AWS CodePipeline
- Amazon Elastic Container Registry
- Amazon Elastic Kubernetes Service
- Amazon EventBridge
- AWS Security Hub
- Amazon Simple Notification Service (Amazon SNS)

Target architecture

The diagram shows the following workflow:

1. The developer updates the Java application code in the base branch of the CodeCommit repository, which creates a pull request (PR).
2. As soon as the PR is submitted, Amazon CodeGuru Reviewer automatically reviews the code, analyzes it based on best practices for Java, and gives recommendations to the developer.
3. After the PR is merged to the base branch, an Amazon EventBridge event is created.
4. The EventBridge event initiates the CodePipeline pipeline, which starts.
5. CodePipeline runs the CodeSecurity Scan stage (continuous security).
6. CodeBuild starts the security scan process in which the Dockerfile and Kubernetes deployment Helm files are scanned using Checkov, and application source code is scanned based on incremental code changes. The application source code scan is performed by the CodeGuru Reviewer Command Line Interface (CLI) wrapper..
7. If the security scan stage is successful, the Build stage (continuous integration) is initiated.
8. In the Build stage, CodeBuild builds the artifact, packages the artifact to a Docker image, scans the image for security vulnerabilities by using Aqua Security Trivy, and stores the image in Amazon ECR.
9. The vulnerabilities detected from step 8 are uploaded to Security Hub for further analysis by developers or engineers. Security Hub provides an overview and recommendations for remediating the vulnerabilities.
10. Email notifications of various phases within the CodePipeline pipeline are sent through Amazon SNS.
11. After the continuous integration phases are complete, CodePipeline enters the Deploy stage (continuous delivery).
12. The Docker image is deployed to Amazon EKS as a container workload (pod) by using Helm charts.
13. The application pod is configured with Amazon CodeGuru Profiler Agent which will send the profiling data of the application (CPU, heap usage, and latency) to Amazon CodeGuru Profiler, which helps developers to understand the behavior of the application.

**Tools**

**AWS services**

- **AWS CloudFormation** helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- **AWS CodeBuild** is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- **AWS CodeCommit** is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- **Amazon CodeGuru Profiler** collects runtime performance data from your live applications, and provides recommendations that can help you fine-tune your application performance.
- **Amazon CodeGuru Reviewer** uses program analysis and machine learning to detect potential defects that are difficult for developers to find and offers suggestions for improving your Java and Python code.
- **AWS CodePipeline** helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- **Amazon Elastic Container Registry (Amazon ECR)** is a managed container image registry service that's secure, scalable, and reliable.
- **Amazon Elastic Kubernetes Service (Amazon EKS)** helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- **Amazon EventBridge** is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- **AWS Security Hub** provides a comprehensive view of your security state in AWS. It also helps you check your AWS environment against security industry standards and best practices.
- **Amazon Simple Notification Service (Amazon SNS)** helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
• **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

**Other services**

• **Helm** is an open-source package manager for Kubernetes.
• **Apache Maven** is a software project management and comprehension tool.
• **BridgeCrew Checkov** is a static code analysis tool for scanning infrastructure as code (IaC) files for misconfigurations that might lead to security or compliance problems.
• **Aqua Security Trivy** is a comprehensive scanner for vulnerabilities in container images, file systems, and Git repositories, in addition to configuration issues.

**Code**

The code for this pattern is available in the GitHub [aws-codepipeline-devsecops-amazoneks](https://github.com/aws-samples/aws-codepipeline-devsecops-amazoneks) repository.

**Best practices**

• The principle of least privilege has been followed for IAM entities across all the phases of this solution. If you want to extend the solution with additional AWS services or third-party tools, we recommend following the principle of least privilege.
• If you have multiple Java applications, we recommend creating separate CI/CD pipelines for each application.
• If you have a monolith application, we recommend breaking the application into microservices as much as possible. Microservices are more flexible, they make it easier to deploy applications as containers, and they provide better visibility into the overall build and deployment of the application.

**Epics**

**Set up the environment**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clone the GitHub repository.</td>
<td>To clone the repository, run the following command.</td>
<td>App developer, DevOps engineer</td>
</tr>
</tbody>
</table>
| Create an S3 bucket and upload the code. | 1. Sign in to the AWS Management Console, open the Amazon S3 console, and then create an S3 bucket in the AWS Region where you plan to deploy this solution. For more information, see [Creating a bucket](https://docs.aws.amazon.com/s3/latest/userguide/creating-a-bucket.html) in the Amazon S3 documentation.  
2. In the S3 bucket, create a folder named code. | AWS DevOps, DevOps engineer, Cloud administrator, DevOps |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.</td>
<td>Navigate to where you cloned the repository. To create compressed version of the entire code with the .zip extension (<code>cicdstack.zip</code>) and validate the .zip file, run the following commands in order. <strong>Note:</strong> If the <code>python</code> command fails and states that Python was not found, use <code>python3</code> instead.</td>
<td></td>
</tr>
</tbody>
</table>
|      | `cd aws-codepipeline-devsecops-amazoneks`  
|      | `python -m zipfile -c cicdstack.zip *`  
<p>|      | <code>python -m zipfile -t cicdstack.zip</code>  |
| 4.   | Upload the <code>cicdstack.zip</code> file to the code folder that you previously created in the S3 bucket. |</p>
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an AWS CloudFormation stack. | 1. Open the AWS CloudFormation console and choose **Create stack**.  
2. In **Specify template**, choose **Upload a template file**, upload the `cf_templates/codecommit_ecr.yaml` file, and then choose **Next**.  
3. In **Specify stack details**, enter the stack name, and then provide the following input parameter values:  
   - **CodeCommitRepositoryBranchName**: The branch-name where your code will be residing (the default is `main`)  
   - **CodeCommitRepositoryName**: The name of the CodeCommit repo to be created.  
   - **CodeCommitRepositoryS3Bucket**: The name of the S3 bucket where you created the code folder  
   - **CodeCommitRepositoryS3BucketObjKey**: `code/cicdstack.zip`  
   - **ECRRepositoryName**: The name of the Amazon ECR repo to be created  
4. Choose **Next**, use the default settings for the **Configure stack options**, and then choose **Next**.  
5. In the **Review** section, verify the template and stack details, and then choose **Create stack**. The stack is then created, including the CodeCommit and Amazon ECR repositories.  
6. Note the names of the CodeCommit and Amazon ECR repositories, which will be required for the Java CI/CD pipeline setup. | AWS DevOps, DevOps |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Validate the CloudFormation stack deployment. | 1. Under **Stacks** on the CloudFormation console, verify the status of CloudFormation stack that you deployed. The status of the stack should be **CREATE COMPLETE**.  
2. Additionally, from the console, validate that CodeCommit and Amazon ECR have been provisioned and are ready. | DevOps engineer |
| Delete the S3 bucket. | Empty and delete the S3 bucket that you created earlier. For more information, see Deleting a bucket in the Amazon S3 documentation. | AWS DevOps, DevOps |

**Configure the Helm charts**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure the Helm charts of your Java application. | 1. In the location where you cloned the GitHub repository, navigate to the folder `helm_charts/aws-proserve-java-greeting`. In this folder, the `dev.yaml` file contains information about Kubernetes resources configuration that you can modify for your container deployments to Amazon EKS. Update the Docker repository parameter by providing your AWS account ID, AWS Region, and Amazon ECR repository name.  
```
image:
  repository: <account-id>.dkr.ecr.<region>.amazonaws.com/<app-ecr-repo-name>
```
2. The Java pod's service type is set to **LoadBalancer**.  
```
service:
  type: LoadBalancer
  port: 80
  targetPort: 8080
  path: /hello
  initialDelaySeconds: 60
``` | DevOps |
To use a different service (for example, NodePort), you can change the parameters. For more information, see the Kubernetes documentation.

3. You can activate the Kubernetes Horizontal Pod Autoscaler by changing the autoscaling parameter to enabled: true.

```yaml
autoscaling:
  enabled: true
  minReplicas: 1
  maxReplicas: 100

# targetCPUUtilizationPercentage: 80
# targetMemoryUtilizationPercentage: 80
```

You can turn on different features for the Kubernetes workloads by changing the values in the values.<ENV>.yaml file, where <ENV> is your development, production, UAT, or QA environment.
### Validate Helm charts for syntax errors.

**Task**

1. From the terminal, verify that Helm v3 is installed in your local workstation by running the following command.

   `helm --version`

   If Helm v3 isn't installed, [install it](#).

2. In the terminal, navigate to the Helm charts directory (`helm_charts/aws-proserve-java-greeting`), and run the following command.

   `helm lint . -f values.dev.yaml`

   This will check the Helm charts for any syntax errors.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Validate Helm charts for syntax errors. | 1. From the terminal, verify that Helm v3 is installed in your local workstation by running the following command.

   2. In the terminal, navigate to the Helm charts directory (`helm_charts/aws-proserve-java-greeting`), and run the following command.  

   `helm lint . -f values.dev.yaml`

   This will check the Helm charts for any syntax errors. | DevOps engineer |

### Set up the Java CI/CD pipeline

**Task**

1. Open the AWS CloudFormation console, and choose Create stack.
2. In Specify template, choose Upload a template file, upload the `cf_templates/build_deployment.yaml` template, and then choose Next.
3. In Specify stack details, specify the Stack name, and then provide the following values for the input parameters:  
   - **CodeBranchName**: Branch name of CodeCommit repo, where your code resides  
   - **EKSClusterName**: Name of your EKS cluster (not the EKSCluster ID)  
   - **EKSCodeBuildAppName**: Name of the app Helm chart (`aws-proserve-java-greeting`)  

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create the CI/CD pipeline. | 1. Open the AWS CloudFormation console, and choose Create stack.  

   2. In Specify template, choose Upload a template file, upload the `cf_templates/build_deployment.yaml` template, and then choose Next.  

   3. In Specify stack details, specify the Stack name, and then provide the following values for the input parameters:  

      - **CodeBranchName**: Branch name of CodeCommit repo, where your code resides  
      - **EKSClusterName**: Name of your EKS cluster (not the EKSCluster ID)  
      - **EKSCodeBuildAppName**: Name of the app Helm chart (`aws-proserve-java-greeting`) | AWS DevOps |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>• EKSWorkerNodeRoleARN:</td>
<td>ARN of the Amazon EKS worker nodes IAM role</td>
<td></td>
</tr>
<tr>
<td>• EKSWorkerNodeRoleName:</td>
<td>Name of the IAM role assigned to the Amazon EKS worker nodes</td>
<td></td>
</tr>
<tr>
<td>• EcrDockerRepository:</td>
<td>Name of Amazon ECR repo where the Docker images of your code will be stored</td>
<td></td>
</tr>
<tr>
<td>• EmailRecipient:</td>
<td>Email address where build notifications need to be sent</td>
<td></td>
</tr>
<tr>
<td>• EnvType:</td>
<td>Environment (for example, dev, test, or prod)</td>
<td></td>
</tr>
<tr>
<td>• SourceRepoName:</td>
<td>Name of the CodeCommit repo, where your code resides</td>
<td></td>
</tr>
</tbody>
</table>

4. Choose Next. Use the default settings in Configure stack options, and then choose Next.

5. In the Review section, verify the AWS CloudFormation template and stack details, and then choose Next.

6. Choose Create stack.

7. During the CloudFormation stack deployment, the owner of the email address that you provided in the parameters will receive a message to subscribe to an SNS topic. To subscribe to Amazon SNS, the owner must choose the link in the message.

8. After the stack is created, open the Outputs tab of the stack, and then record the ARN value for the EksCodeBuildkubeRoleARN output key. This IAM ARN value will be required later for providing the CodeBuild IAM role with permissions to deploy workloads in the Amazon EKS cluster.
### Activate integration between Security Hub and Aqua Security

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Turn on Aqua Security</td>
<td>This step is required for uploading the Docker image vulnerability findings reported by Trivy to Security Hub. Because AWS CloudFormation doesn't support Security Hub integrations, this process must be done manually.</td>
<td>AWS administrator, DevOps engineer</td>

</tbody>
</table>
| integration.                  | 1. Open the **AWS Security Hub** console, and navigate to **Integrations**.  
3. Choose **Accept findings**. |                                    |

### Configure CodeBuild to run Helm or kubectl commands

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Allow CodeBuild to run Helm or kubectl commands in the Amazon EKS cluster. | For CodeBuild to be authenticated to use Helm or kubectl commands with the EKS cluster, you must add the IAM roles to the aws-auth ConfigMap. In this case, add the ARN of IAM role EksCodeBuildkubeRoleARN, which is the IAM role created for the CodeBuild service to access the EKS cluster and deploy workloads on it. This is a one-time activity.  
**Important:** The following procedure must be completed before the deployment approval stage in CodePipeline.  
1. Open the `cf_templates/kube_aws_auth_configmap_patch.sh` shell script in your Amazon Linux or macOS environment.  
2. Authenticate to the Amazon EKS cluster by running the following command. | DevOps           |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>aws eks --region &lt;aws-region&gt; update-kubeconfig --name &lt;eks-cluster-name&gt;</strong></td>
<td>3. Run the shell script by using the following command, replacing <code>&lt;roleARN-eks-codebuild-kubectl&gt;</code> with the ARN value of <code>EksCodeBuildkubeRoleARN</code> that you recorded earlier.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>bash cf_templates/kube_aws_auth_configmap_patch.sh &lt;roleARN-eks-codebuild-kubectl&gt;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The aws_auth ConfigMap is configured, and access is granted.</td>
</tr>
</tbody>
</table>

**Validate the CI/CD pipeline**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Verify that the CI/CD pipeline automatically initiates.</strong></td>
<td>1. The CodeSecurity Scan stage in the pipeline will usually fail if Checkov detects vulnerabilities in the Dockerfile or Helm charts. However, the purpose of this example is to establish a process of identifying potential security vulnerabilities rather than fixing it through the CI/CD pipeline, typically a DevSecOps process. In the file <code>buildspec/buildspec_secscan.yaml</code>, the checkov command uses the <code>--soft-fail</code> flag to avoid pipeline failure.</td>
<td>DevOps</td>
</tr>
</tbody>
</table>
|  | | - echo -e "
  Running Dockerfile Scan"
  - checkov -f code/app/Dockerfile --framework dockerfile --soft-fail --summary-position bottom |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
|      | - echo -e "\n Running Scan of Helm Chart files" | - checkov
|      | - cp -pv helm_charts/ $EKS_CODEBUILD_APP_NAME/ values.dev.yaml helm_charts/ $EKS_CODEBUILD_APP_NAME/ values.yaml | - AWS_REGION=
|      | - checkov -d helm_charts/ $EKS_CODEBUILD_APP_NAME --framework helm --soft-fail --summary-position bottom - rm -rfv helm_charts/ $EKS_CODEBUILD_APP_NAME/ values.yaml | $AWS_DEFAULT_REGION
|      | - AWS_ACCOUNT_ID= $AWS_DEFAULT_REGION AWS_ACCOUNT_ID= $AWS_ACCOUNT_ID trivy -d image --no-progress --ignore-unfixed --exit-code 0 --severity HIGH,CRITICAL --format | $AWS_DEFAULT_REGION

For the pipeline to fail when vulnerabilities are reported for the Dockerfile and Helm charts, the `--soft-fail` option must be removed from the `checkov` command. Developers or engineers can then fix the vulnerabilities and commit the changes to the CodeCommit source code repository.

2. Similar to CodeSecurity Scan, the Build stage uses Aqua Security Trivy for identifying HIGH and CRITICAL Docker image vulnerabilities before pushing the application to Amazon ECR. In this example, we are not making pipeline fail for Docker image vulnerabilities. In the file `buildspec/buildspec.yml`, the `trivy` command includes the flag `--exit-code` with a value 0, which is why pipeline doesn't fail when HIGH or CRITICAL Docker image vulnerabilities are reported.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>template --template &quot;@securityhub/asff.tpl&quot; -o securityhub/report.asff $AWS_ACCOUNT_ID.dkr.ecr.$AWS_DEFAULT_REGION.amazonaws.com/$IMAGE_REPO_NAME: $CODEBUILD_RESOLVED_SOURCE_VERSION</td>
<td></td>
</tr>
</tbody>
</table>

For the pipeline to fail when HIGH, CRITICAL vulnerabilities are reported, change the value of --exit-code to 1.

Developers or engineers can then fix the vulnerabilities and commit the changes to the CodeCommit source code repository.

For more information about starting the pipeline by using CodePipeline, see Start a pipeline in CodePipeline, Start a pipeline manually, and Start a pipeline on a schedule in the AWS CodePipeline documentation.
## Task

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Approve the deployment. | 1. After the build phase is complete, there is a deployment approval gate. The reviewer or a release manager should inspect the build and, if all requirements are met, approve it. This is the recommended approach for teams that use continuous delivery for application deployment.  
2. After approval, the pipeline initiates the Deploy stage.  
3. After the Deploy stage is successful, the CodeBuild log for this stage provides the URL of the application. Use the URL to validate the readiness of the application. | DevOps |

| Validate application profiling. | After the deployment is complete and the application pod is deployed in Amazon EKS, the Amazon CodeGuru Profiler agent configured in the application will try to send profiling data of the application (CPU, heap summary, latency, and bottlenecks) to Amazon CodeGuru Profiler.  
For the initial deployment of an application, Amazon CodeGuru Profiler takes about 15 minutes to visualize the profiling data. | AWS DevOps |

## Related resources

- [AWS CodePipeline documentation](#)
- [Scanning images with Trivy in an AWS CodePipeline](blog post)
- [Improving your Java applications using Amazon CodeGuru Profiler](blog post)
- [AWS Security Finding Format (ASFF) syntax](#)
- [Amazon EventBridge event patterns](#)
- [Helm upgrade](#)

## Additional information

CodeGuru Profiler should not be confused with the AWS X-Ray service in terms of functionality. CodeGuru Profiler is preferred for identifying the most expensive lines of codes, which might cause
bottlenecks or security issues, and fix them before they become a potential risk. AWS X-Ray service is for application performance monitoring.

In this pattern, event rules are associated with the default event bus. If needed, you can extend the pattern to use a custom event bus.

This pattern uses CodeGuru Reviewer as a static application security testing (SAST) tool for application code. You can also use this pipeline for other tools, such as SonarQube or Checkmarx. The corresponding scan setup instructions of any of these tools can be added in buildspec/buildspec_secscan.yaml, replacing the scan instructions of CodeGuru.
Create an Amazon ECS task definition and mount a file system on EC2 instances using Amazon EFS

Created by Durga Prasad Cheepuri (AWS)

| **Environment:** PoC or pilot | **Technologies:** Containers & microservices; Cloud-native; Management & governance; Storage & backup; Websites & web apps | **AWS services:** Amazon ECS; Amazon EFS |

Summary

This pattern provides code samples and steps to create an Amazon Elastic Container Service (Amazon ECS) task definition that runs on Amazon Elastic Compute Cloud (Amazon EC2) instances in the Amazon Web Services (AWS) Cloud, while using Amazon Elastic File System (Amazon EFS) to mount a file system on those EC2 instances. Amazon ECS tasks that use Amazon EFS automatically mount the file systems that you specify in the task definition and make these file systems available to the task’s containers across all Availability Zones in an AWS Region.

To meet your persistent storage and shared storage requirements, you can use Amazon ECS and Amazon EFS together. For example, you can use Amazon EFS to store persistent user data and application data for your applications with active and standby ECS container pairs running in different Availability Zones for high availability. You can also use Amazon EFS to store shared data that can be accessed in parallel by ECS containers and distributed job workloads.

To use Amazon EFS with Amazon ECS, you can add one or more volume definitions to a task definition. A volume definition includes an Amazon EFS file system ID, access point ID, and a configuration for AWS Identity and Access Management (IAM) authorization or Transport Layer Security (TLS) encryption in transit. You can use container definitions within task definitions to specify the task definition volumes that get mounted when the container runs. When a task that uses an Amazon EFS file system runs, Amazon ECS ensures that the file system is mounted and available to the containers that need access to it.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A virtual private cloud (VPC) with a virtual private network (VPN) endpoint or a router
- (Recommended) Amazon ECS container agent 1.38.0 or later for compatibility with Amazon EFS access points and IAM authorization features (For more information, see the AWS blog post New for Amazon EFS – IAM Authorization and Access Points.)

Limitations

- Amazon ECS container agent versions earlier than 1.35.0 don’t support Amazon EFS file systems for tasks that use the EC2 launch type.
Architecture

The following diagram shows an example of an application that uses Amazon ECS to create a task definition and mount an Amazon EFS file system on EC2 instances in ECS containers.

The diagram shows the following workflow:

1. Create an Amazon EFS file system.
2. Create a task definition with a container.
3. Configure the container instances to mount the Amazon EFS file system. The task definition references the volume mounts, so the container instance can use the Amazon EFS file system. ECS tasks have access to the same Amazon EFS file system, regardless of which container instance those tasks are created on.
4. Create an Amazon ECS service with three instances of the task definition.

Technology stack

- Amazon EC2
- Amazon ECS
- Amazon EFS

Tools

- **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
- **Amazon ECS** – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for
more control over your infrastructure, you can run your tasks and services on a cluster of EC2 instances that you manage.

- **Amazon EFS** – Amazon Elastic File System (Amazon EFS) provides a simple, scalable, fully managed elastic NFS file system for use with AWS Cloud services and on-premises resources.
- **AWS CLI** – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.

Deploy Java microservices on Amazon ECS using AWS Fargate

*Created by Vijay Thompson (AWS) and Sandeep Bondugula (AWS)*

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: Containers</th>
<th>Target: Amazon ECS</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: N/A</td>
<td>Technologies: Containers &amp; microservices; Websites &amp; web apps</td>
<td>AWS services: Amazon ECS</td>
</tr>
</tbody>
</table>

**Summary**

This pattern provides guidance for deploying containerized Java microservices on Amazon Elastic Container Service (Amazon ECS) by using AWS Fargate. The pattern doesn't use Amazon Elastic Container Registry (Amazon ECR) for container management; instead, Docker images are pulled in from a Docker hub.

**Prerequisites and limitations**

**Prerequisites**

- An existing Java microservices application on a Docker hub
- A public Docker repository
- An active AWS account
- Familiarity with AWS services, including Amazon ECS and Fargate
- Docker, Java, and Spring Boot framework
- Amazon Relational Database Service (Amazon RDS) up and running (optional)
- A virtual private cloud (VPC) if the application requires Amazon RDS (optional)

**Architecture**

**Source technology stack**

- Java microservices (for example, implemented in Spring Boot) and deployed on Docker

**Source architecture**
Target technology stack

- An Amazon ECS cluster that hosts each microservice by using Fargate
- A VPC network to host the Amazon ECS cluster and associated security groups
- A cluster/task definition for each microservice that spins up containers by using Fargate

Target architecture

Tools

- Amazon ECS eliminates the need to install and operate your own container orchestration software, manage and scale a cluster of virtual machines, or schedule containers on those virtual machines.
• **AWS Fargate** helps you run containers without needing to manage servers or Amazon Elastic Compute Cloud (Amazon EC2) instances. It's used in conjunction with Amazon Elastic Container Service (Amazon ECS).

• **Docker** is a software platform that allows you to build, test, and deploy applications quickly. Docker packages software into standardized units called **containers** that have everything the software needs to run, including libraries, system tools, code, and runtime.

### Docker code

The following Dockerfile specifies the Java Development Kit (JDK) version that is used, where the Java archive (JAR) file exists, the port number that is exposed, and the entry point for the application.

```bash
FROM openjdk:11
ADD target/Spring-docker.jar Spring-docker.jar
EXPOSE 8080
ENTRYPOINT ["java","-jar","Spring-docker.jar"]
```

</tbody>
</table>

**R Type:** N/A

**Technologies:** Containers & microservices; Websites & web apps

**AWS services:** Amazon ECS

### Summary

This pattern guides you through the steps for deploying Java microservices as containerized applications in Amazon Elastic Container Service (Amazon ECS). The pattern also uses Amazon Elastic Container Registry (Amazon ECR) to manage your container, and AWS Fargate to run your container.

### Prerequisites and limitations

**Prerequisites**

- An existing Java microservices application running on premises on Docker
- An active AWS account
- Familiarity with Amazon ECR, Amazon ECS, AWS Fargate, and AWS Command Line Interface (AWS CLI)
- Familiarity with Java and Docker software

**Product versions**

- AWS CLI version 1.7 or later

### Architecture

**Source technology stack**

- Java microservices (for example, developed using Spring Boot) and deployed on premises
- Docker

**Source architecture**
**Target technology stack**
- Amazon ECR
- Amazon ECS
- AWS Fargate

**Target architecture**
Tools

Tools

- **Amazon ECR** - Amazon Elastic Container Registry (Amazon ECR) is a fully managed registry that makes it easy for developers to store, manage, and deploy Docker container images. Amazon ECR is integrated with Amazon ECS to simplify your development-to-production workflow. Amazon ECR hosts your images in a highly available and scalable architecture so you can reliably deploy containers for your applications. Integration with AWS Identity and Access Management (IAM) provides resource-level control of each repository.

- **Amazon ECS** - Amazon Elastic Container Service (Amazon ECS) is a highly scalable, high-performance container orchestration service that supports Docker containers and allows you to easily run and scale containerized applications on AWS. Amazon ECS eliminates the need for you to install and operate your own container orchestration software, manage and scale a cluster of virtual machines, or schedule containers on those virtual machines.

- **AWS Fargate** - AWS Fargate is a compute engine for Amazon ECS that allows you to run containers without having to manage servers or clusters. With AWS Fargate, you no longer have to provision, configure, and scale clusters of virtual machines to run containers. This removes the need to choose server types, decide when to scale your clusters, or optimize cluster packing.

- **Docker** - Docker is a platform that lets you build, test, and deliver applications in packages called containers.

Code

The following DockerFile specifies the Java Development Kit (JDK) version that is used, where the Java archive (JAR) file exists, the port number that is exposed, and the entry point for the application.

```
FROM openjdk:8
ADD target/Spring-docker.jar Spring-docker.jar
EXPOSE 8080
ENTRYPOINT ["java","-jar","Spring-docker.jar"]
```

<tr>
<td>Create a service.</td>
<td>Inside the cluster, choose Create service.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Choose the launch type.</td>
<td>Choose Fargate as the launch type.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Choose task definition, revision, and platform version.</td>
<td>Choose the task that you want to run, followed by the revision of the task definition and the platform version.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Select the cluster.</td>
<td>Select the cluster in which to create your service from the dropdown list.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Provide a service name.</td>
<td>Provide a unique name for the service that you are creating.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Specify the number of tasks.</td>
<td>Configure the number of tasks that should run when the service launches. If you’re launching with two or more tasks, a load balancer is required to balance the tasks. The minimum number of tasks to be configured is One.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Set the minimum and maximum healthy percentages.</td>
<td>Configure the minimum and maximum healthy percentages for the application, or accept the default option that is provided.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Configure deployment settings.</td>
<td>Choose the deployment type based on your requirements. You can choose a rolling update or a blue/green deployment.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Configure the cluster VPC, subnets, and security groups.</td>
<td>Configure the cluster VPC, the subnets on which you want to deploy the application, and the security groups (HTTP, HTTPS, and port 8080) for providing access to inbound/outbound connections.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Configure public IP settings.</td>
<td>Enable or disable the public IP, depending on whether you want to use a public IP address for Fargate tasks.</td>
<td>Developer, System Admin</td>
</tr>
</tbody>
</table>
### Task: Configure load balancing.
- Configure the load balancer, if you're launching the service with more than one task. You must create a load balancer and its target group before you launch the service.
- **Skills required:** Developer, System Admin

### Task: Configure automatic scaling.
- Configure your service to use Amazon ECS Service Auto Scaling to adjust the desired number of tasks up or down, depending on your requirements.
- **Skills required:** Developer, System Admin

### Task: Review settings and create the service.
- Review your service settings, and then choose Create service.
- **Skills required:** Developer, System Admin

### Cut over

### Task: Test your application.
- Test the application by using the public DNS that's created when the task is deployed. If the application has a load balancer, test the application by using it and then cut over.
- **Skills required:** Developer, System Admin

Summary

This pattern outlines steps for deploying a containerized Java microservices architecture on Amazon Elastic Container Service (Amazon ECS) to make it easier to scale and faster to develop your applications. This helps enable innovation and accelerates time-to-market for new features.

The pattern also uses Amazon Elastic Container Registry (Amazon ECR) to store and manage the Docker-based containers, and an AWS CloudFormation template with a Python script to automate the setup of your infrastructure. The pattern is based on the post Deploying Java Microservices on Amazon Elastic Container Service, which is published on the AWS Compute blog.

Microservices provide an architectural and organizational approach to software development, where software is composed of small, independent services that communicate over well-defined application programming interfaces (APIs). Small, self-contained teams own these services.

Amazon ECS is a highly scalable, high-performance container orchestration service. It supports Docker containers and enables you to run and scale containerized applications on AWS quickly. With Amazon ECS, you no longer have to install and operate your container orchestration software, manage and scale a cluster of virtual machines (VMs), or schedule containers on those VMs.

With simple API calls, you can launch and stop Docker-enabled applications, query the complete state of your request, and access many natural features, such as AWS Identity and Access Management (IAM) roles, security groups, load balancers, Amazon CloudWatch Events, AWS CloudFormation templates, and AWS CloudTrail logs.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Java microservices source code, with Java Development Kit version 1.7 or later
- An access key and secret access key for a user in the account
- AWS Command Line Interface (AWS CLI)
- Java, AWS Software Development Kit (SDK) for Python (Boto3), and Docker software
- Familiarity with the use of the preceding technologies
- Familiarity with AWS services such as Amazon ECS, AWS CloudFormation, and Elastic Load Balancing
Architecture

Source technology stack

- Microservices implemented in Java and deployed on Apache Tomcat in an on-premises environment

Target technology stack

- The Application Load Balancer that inspects the client request. Based on routing rules, the load balancer directs the request to an instance and port from the target group that matches the state.
- A target group for each microservice. The target groups are used by the corresponding services to register available container instances. Each target group has a path, so when you call the way for a particular microservice, it maps to the correct target group. This enables you to use one Application Load Balancer to serve all the microservices, accessed by the path. For example, https://owner/* would map and direct to the Owner microservice.
- An Amazon ECS cluster that hosts the containers for each microservice.
- An Amazon Virtual Private Cloud (Amazon VPC) network for hosting the Amazon ECS cluster and associated security groups.
- An Amazon Elastic Container Registry (Amazon ECR) repository for each microservice.
- A service or task definition for each microservice, which spins up containers on the instances of the Amazon ECS cluster.

Target architecture
Tools

- **Amazon ECS** – Amazon ECS lets you launch and stop container-based applications with simple API calls, enables you to get the state of your cluster from a centralized service, and gives you access to many familiar Amazon Elastic Compute Cloud (Amazon EC2) features.

- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is a fully managed registry that makes it easy for developers to store, manage, and deploy Docker container images. Amazon ECR is integrated with Amazon ECS to simplify your development-to-production workflow. Amazon ECR
hosts your images in a highly available and scalable architecture so you can reliably deploy containers for your applications. Integration with AWS Identity and Access Management (IAM) provides resource-level control of each repository.

**Epics**

*Create an AWS CloudFormation template to set up an Amazon ECS cluster to host the Java microservices*

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provision an Amazon EC2 Linux instance, install Docker, and create a Docker file for each microservice.</td>
<td>Use the Dockerfile for the image to push, build the image, and tag it for your new repository. Do the same for each microservice. Push the newly tagged images to the repository.</td>
<td>Ops</td>
</tr>
<tr>
<td>Set up Docker images on Amazon ECR.</td>
<td>Create an AWS CloudFormation template to provision the virtual private cloud (VPC), Amazon ECS cluster, and Amazon Relational Database Service (Amazon RDS).</td>
<td>Ops</td>
</tr>
</tbody>
</table>

**Provision AWS services**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the AWS infrastructure by using the CloudFormation template you created earlier.</td>
<td>Use the Python script at <a href="https://github.com/awslabs/amazon-ecs-java-microservices/blob/master/2_ECS_Java_Spring_PetClinic_Microservices/setup.py">https://github.com/awslabs/amazon-ecs-java-microservices/blob/master/2_ECS_Java_Spring_PetClinic_Microservices/setup.py</a> to invoke the AWS CloudFormation template you created earlier. This template creates the AWS infrastructure you need for the target environment.</td>
<td>Ops</td>
</tr>
<tr>
<td>Create Amazon ECR repositories, tasks, services, the Application Load Balancer, and target groups.</td>
<td>The Python script reads the outputs of the AWS CloudFormation template and uses BOTO3 API calls to create Amazon ECR repositories, tasks, services, the Application Load Balancer, and target groups.</td>
<td>Ops</td>
</tr>
</tbody>

Deploy Kubernetes resources and packages using Amazon EKS and a Helm chart repository in Amazon S3

*Created by Sagar Panigrahi (AWS)*

| Environment: | PoC or pilot |
| Technologes: | Containers & microservices; DevOps |
| AWS services: | Amazon EKS |

**Summary**

This pattern helps you to manage Kubernetes applications efficiently, regardless of their complexity. The pattern integrates Helm into your existing continuous integration and continuous delivery (CI/CD) pipelines to deploy applications into a Kubernetes cluster. Helm is a Kubernetes package manager that helps you manage Kubernetes applications. Helm charts help to define, install, and upgrade complex Kubernetes applications. Charts can be versioned and stored in Helm repositories, which improves mean time to restore (MTTR) during outages.

This pattern uses Amazon Elastic Kubernetes Service (Amazon EKS) for the Kubernetes cluster. It uses Amazon Simple Storage Service (Amazon S3) as a Helm chart repository, so that the charts can be centrally managed and accessed by developers across the organization.

**Prerequisites and limitations**

**Prerequisites**

- An active Amazon Web Services (AWS) account with a virtual private cloud (VPC)
- An Amazon EKS cluster
- Worker nodes set up within the Amazon EKS cluster and ready to take workloads
- Kubectl for configuring the Amazon EKS kubeconfig file for the target cluster in the client machine
- AWS Identity and Access Management (IAM) access to create the S3 bucket
- IAM (programmatic or role) access to Amazon S3 from the client machine
- Source code management and a CI/CD pipeline

**Limitations**

- There is no support at this time for upgrading, deleting, or managing custom resource definitions (CRDs).
- If you are using a resource that refers to a CRD, the CRD must be installed separately (outside of the chart).

**Product versions**

- Helm v3.6.3
Architecture

Target technology stack

- Amazon EKS
- Amazon VPC
- Amazon S3
- Source code management
- Helm
- Kubectl

Target architecture

Automation and scale

- AWS CloudFormation can be used to automate the infrastructure creation. One option is to use the Modular and Scalable Amazon EKS Architecture Quick Start.
- Helm is to be incorporated into your existing CI/CD automation tool to automate the packaging and versioning of Helm charts (out of scope for this pattern).
- GitVersion or Jenkins build numbers can be used to automate the versioning of charts.

Tools

Tools

- Amazon EKS – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service for running Kubernetes on AWS without needing to stand up or maintain your own Kubernetes control plane. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.
- **Helm** – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- **Kubectl** – Kubectl is a command line utility for running commands against Kubernetes clusters.

### Code
The example code is attached.

<tr>
<td></td>
<td><code>helm s3 push ./my-nginx-0.1.0.tgz my-helm-charts</code></td>
<td></td>
</tr>
<tr>
<td>Search for the Helm chart.</td>
<td>To confirm that the chart appears both locally and in the Helm repository in Amazon S3, run the following command.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td><code>helm search repo my-nginx</code></td>
<td></td>
</tr>
</tbody>
</table>
Modify, version, and package a chart

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modify and package the chart.</td>
<td>In values.yaml, set the replicaCount value to 1. Then package the chart by running helm package ./my-nginx/, this time changing the version in Chart.yaml to 0.1.1. The versioning is ideally updated through automation using tools such as GitVersion or Jenkins build numbers in a CI/CD pipeline. Automating the version number is out of scope for this pattern.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Push the new version to the Helm repository in Amazon S3.</td>
<td>To push the new package with version of 0.1.1 to the my-helm-charts Helm repository in Amazon S3, run the following command.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

```
helm s3 push ./my-nginx-0.1.1.tgz my-helm-charts
```

Search for and install a chart from the Amazon S3 Helm repository

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search for all versions of the my-nginx chart.</td>
<td>To view all the available versions of a chart, run the following command with the --versions flag.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Install a chart from the Amazon S3 Helm repository.</td>
<td>The search results from the previous task show the multiple versions of the my-nginx chart. To install the new version (0.1.1) from the Amazon S3 Helm repository, use the following command.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

```
helm search repo my-nginx --versions
```

Without the flag, Helm by default displays the latest uploaded version of a chart.

Deploy Lambda functions with container images

Created by Ram Kandaswamy (AWS)

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Technologies: Containers &amp; microservices; Cloud-native; Software development &amp; testing; Serverless</th>
<th>Workload: All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>AWS EC2 Container Registry; AWS Lambda</td>
<td></td>
</tr>
</tbody>
</table>

Summary

AWS Lambda supports containers images as a deployment model. This pattern shows how to deploy Lambda functions through container images.

Lambda is a serverless, event-driven compute service that you can use to run code for virtually any type of application or backend service without provisioning or managing servers. With container image support for Lambda functions, you get the benefits of up to 10 GB of storage for your application artifact and the ability to use familiar container image development tools.

The example in this pattern uses Python as the underlying programming language, but you can use other languages, such as Java, Node.js, or Go. The pattern uses AWS CodeCommit as the source, but you could also use GitHub, Bitbucket, or Amazon Simple Storage Service (Amazon S3).

Prerequisites and limitations

Prerequisites

- Amazon Elastic Container Registry (Amazon ECR) activated
- Application code
- Docker images with the runtime interface client

Limitations

- Maximum image size supported is 10 GB.
- Maximum runtime for a Lambda based container deployment is 15 minutes.

Architecture

Target technology stack

- AWS CodeBuild
- AWS CodeCommit
- Docker image
- Amazon ECR
• AWS Identity and Access Management (IAM)
• AWS Lambda
• Amazon CloudWatch Logs

Target architecture

1. You create a repository and commit the application code using CodeCommit.
2. The CodeBuild project is created, using CodeCommit as the source provider.
3. The CodeBuild run creates the Docker image.
4. CodeBuild publishes the image to Amazon ECR.
5. You create the Lambda function using the image in Amazon ECR.

Automation and scale

This pattern can be automated by using AWS CloudFormation, AWS Cloud Development Kit (AWS CDK), or API operations from an SDK. Lambda can automatically scale based on the number of requests, and you can tune it by using the concurrency parameters. For more information, see the Lambda documentation.

Tools

AWS services

• AWS CloudFormation Designer provides an integrated JSON and YAML editor that helps you view and edit CloudFormation templates.
• AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
• AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
• AWS CodeStar is a cloud-based service for creating, managing, and working with software development projects on AWS. For this pattern, you can use AWS CodeStar or another development environment.
• **Amazon Elastic Container Registry (Amazon ECR)** is a managed container image registry service that’s secure, scalable, and reliable.

• **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

**Other tools**

• **Docker** is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.

## Epics

### Create a project in CodeBuild

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a CodeCommit repository.</td>
<td>Create a CodeCommit repository that will contain the Dockerfile, the buildspec.yaml file, and the application source code.</td>
<td>Developer</td>
</tr>
<tr>
<td>Create a CodeBuild project.</td>
<td>On the CodeBuild console, create a new project that uses the CodeCommit repo and the buildspec.yaml file. You will use the CodeBuild project to create the image. Confirm that privileged mode is enabled. To build Docker images, this is necessary. Otherwise, the image will not build successfully. Provide values for project name and description. For the source provider, choose CodeCommit.</td>
<td>Developer</td>
</tr>
<tr>
<td>Edit the Dockerfile.</td>
<td>The Dockerfile should be located in the top-level directory where you're developing the application. The Python code should be in the src folder. When you create the image, use the official Lambda supported images. Otherwise, a bootstrap error will occur, making the packing process more difficult. For details, see the Additional information section.</td>
<td>Developer</td>
</tr>
<tr>
<td>Create a repo in Amazon ECR.</td>
<td>Create a container repository in Amazon ECR. In the following example command, the name</td>
<td>AWS administrator, Developer</td>
</tr>
</tbody>
</table>
Create the Lambda function to run the image

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the Lambda function.</td>
<td>On the Lambda console, choose Create function, and then choose Container image. Enter the function name and the URI for the image that is in the Amazon ECR repository, and then choose Create function.</td>
<td>App developer</td>
</tr>
<tr>
<td>Test the Lambda function.</td>
<td>To invoke and test the function, choose Test.</td>
<td>App developer</td>
</tr>
</tbody>
</table>

Troubleshooting

<table>
<thead>
<tr>
<th>Issue</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Build is not succeeding.</td>
<td>1. Check if the privileged mode is turned on for the CodeBuild project.</td>
</tr>
</tbody>
</table>
2. Ensure that the Docker related commands have the necessary permissions. Trying adding sudo to the commands.

3. Verify that the IAM role associated with CodeBuild has a policy with appropriate actions to interact with Amazon ECR, Amazon S3, and CloudWatch logs.

Additional information

Edit the Dockerfile

The following code shows the commands that you edit in the Dockerfile.

```bash
FROM public.ecr.aws/lambda/python:3.9
# Copy function code
COPY app.py ${LAMBDA_TASK_ROOT}
COPY requirements.txt ${LAMBDA_TASK_ROOT}
# install dependencies
RUN pip3 install --user -r requirements.txt
# Set the CMD to your handler (could also be done as a parameter override outside of the Dockerfile)
CMD ["app.handler"]
```

The FROM command value corresponds to the Python 3.8 base image that is using the Lambda function in the public Amazon ECR image repository.

The COPY `src/server.py` `{LAMBDA_TASK_ROOT}` command copies the code to the task root directory, which the Lambda function will use. This command uses the environment variable so we don’t have to worry about the actual path. The function to be run is passed as an argument to the CMD `[ "server.lambda_handler" ]` command.

The COPY `requirements.txt` command captures the dependencies necessary for the code.

The RUN `pip install --user -r requirements.txt` command installs the dependencies to the local user directory.

To build your image, run the following command.

```bash
docker build -t <image name> .
```

Add the image in Amazon ECR
In the following code, replace `aws_account_id` with the account number, and replace `us-east-1` if you are using a different Region. The `buildspec` file uses the CodeBuild build number to uniquely identify image versions as a tag value. You can change this to fit your requirements.

**The `buildspec` custom code**

```plaintext
phases:
  install:
    runtime-versions:
      python: 3.9
  pre_build:
    commands:
      - python3 --version
      - pip3 install --upgrade pip
      - pip3 install --upgrade awscli
      - sudo docker info
  build:
    commands:
      - echo Build started on `date`
      - ls
      - cd app
      - docker build -t cf-demo:$CODEBUILD_BUILD_NUMBER .
      - docker ls
  post_build:
    commands:
      - echo Build completed on `date`
      - echo Pushing the Docker image...
      - aws ecr get-login-password --region us-east-1 | docker login --username AWS --password-stdin aws_account_id.dkr.ecr.us-east-1.amazonaws.com
      - docker tag cf-demo:$CODEBUILD_BUILD_NUMBER aws_account_id.dkr.ecr.us-east-1.amazonaws.com/cf-demo:$CODEBUILD_BUILD_NUMBER
      - docker push aws_account_id.dkr.ecr.us-east-1.amazonaws.com/cf-demo:$CODEBUILD_BUILD_NUMBER
```
Deploy a sample Java microservice on Amazon EKS and expose the microservice using an Application Load Balancer

Summary

This pattern describes how to deploy a sample Java microservice as a containerized application on Amazon Elastic Kubernetes Service (Amazon EKS) by using the eksctl command line utility and Amazon Elastic Container Registry (Amazon ECR). You can use an Application Load Balancer to load balance the application traffic.

Prerequisites and limitations

Prerequisites

- An active AWS account
- The AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows
- A running Docker daemon
- The eksctl command line utility, installed and configured on macOS, Linux, or Windows (For more information, see Getting started with Amazon EKS – eksctl in the Amazon EKS documentation.)
- The kubectl command line utility, installed and configured on macOS, Linux, or Windows (For more information, see Installing or updating kubectl in the Amazon EKS documentation.)

Limitations

- This pattern doesn't cover the installation of an SSL certificate for the Application Load Balancer.

Architecture

Target technology stack

- Amazon ECR
- Amazon EKS
- Elastic Load Balancing

Target architecture
The following diagram shows an architecture for containerizing a Java microservice on Amazon EKS.

### Tools

- **Amazon Elastic Container Registry (Amazon ECR)** is a managed container image registry service that’s secure, scalable, and reliable.
- **Amazon Elastic Kubernetes Service (Amazon EKS)** helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- **Elastic Load Balancing** automatically distributes your incoming traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses, in one or more Availability Zones.
- **eksctl** helps you create clusters on Amazon EKS.
- **kubectl** makes it possible to run commands against Kubernetes clusters.
- **Docker** helps you build, test, and deliver applications in packages called containers.

### Epics

**Create an Amazon EKS cluster by using eksctl**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an Amazon EKS cluster.</td>
<td>To create an Amazon EKS cluster that uses two t2.small Amazon EC2 instances as nodes, run the following command:</td>
<td>Developer, System Admin</td>
</tr>
</tbody>
</table>
## Create an Amazon EKS cluster

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>eksctl create cluster --name &lt;your-cluster-name&gt; --version &lt;version-number&gt; --nodes=1 --node-type=t2.small</td>
<td><strong>Note:</strong> The process can take between 15 to 20 minutes. After the cluster is created, the appropriate Kubernetes configuration is added to your kubeconfig file. You can use the kubeconfig file with kubectl to deploy the application in later steps.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Verify the Amazon EKS cluster.</td>
<td>To verify that the cluster is created and that you can connect to it, run the kubectl get nodes command.</td>
<td></td>
</tr>
</tbody>
</table>

## Create an Amazon ECR repository and push the Docker image.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an Amazon ECR repository.</td>
<td>Follow the instructions from Creating a private repository in the Amazon ECR documentation.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Create a POM XML file.</td>
<td>Create a pom.xml file based on the Example POM file code in the Additional information (p. 327) section of this pattern.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Create a source file.</td>
<td>Create a source file called HelloWorld.java in the src/main/java/eksExample path based on the following example:</td>
<td></td>
</tr>
</tbody>
</table>

```java
package eksExample;
import static spark.Spark.get;
public class HelloWorld {
    public static void main(String[] args) {
        get("/", (req, res) -> {
            return "Hello World!";
        });
    }
}
```

Be sure to use the following directory structure:
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Create a Dockerfile.</strong></td>
<td>Create a Dockerfile based on the Example Dockerfile code in the Additional information (p. 327) section of this pattern.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td><strong>Build and push the Docker image.</strong></td>
<td>In the directory where you want your Dockerfile to build, tag, and push the image to Amazon ECR, run the following commands:</td>
<td></td>
</tr>
</tbody>
</table>
| | ```
aws ecr get-login-password
--region <region>
``` | |
| | ```
docker login --username <username> --password-stdin
```
```<account_number>.dkr.ecr.<region>.amazonaws.com
```docker buildx build --platform linux/amd64 -t
```hello-world-java:v1 .
docker tag hello-world-java:v1
```<account_number>.dkr.ecr.<region>.amazonaws.com/
```<repository_name>:v1
docker push
```<account_number>.dkr.ecr.<region>.amazonaws.com/
```<repository_name>:v1
``` | |
| **Note:** | Modify the AWS Region, account number, and repository details in the preceding commands. Be sure to note the image URL for later use. | |
| **Important:** | A macOS system with an M1 chip has a problem building an image that's compatible with Amazon EKS running on an AMD64 platform. To resolve this issue, use `docker buildx` to build a Docker image that works on Amazon EKS. | |
## Deploy the Java microservices

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a deployment file.</td>
<td>Create a YAML file called <code>deployment.yaml</code> based on the Example deployment file code in the Additional information (p. 327) section of this pattern.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Note: Use the image URL that you copied earlier as the path of the image file for the Amazon ECR repository.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Deploy the Java microservices on the Amazon EKS cluster.</td>
<td>To create a deployment in your Amazon EKS cluster, run the <code>kubectl apply -f deployment.yaml</code> command.</td>
<td>Developer, System Admin</td>
</tr>
</tbody>
</table>
| Verify the status of the pods.                                       | 1. To verify the status of the pods, run the `kubectl get pods` command.  
2. Wait for the status to change to Ready.                                                                                  | Developer, System Admin  |
| Create a service.                                                    | 1. Create a file called `service.yaml` based on the Example service file code in the Additional information (p. 327) section of this pattern.                                                             | Developer, System Admin  |
| 2. Run the `kubectl apply -f service.yaml` command.                  |                                                                                                                                                                                                              |                          |
| Install the AWS Load Balancer Controller add-on.                    | Follow the instructions from Installing the AWS Load Balancer Controller add-on in the Amazon EKS documentation.                                                                                              | Developer, System Admin  |
| Note: You must have the add-on installed to create an Application Load Balancer or Network Load Balancer for a Kubernetes service. |                                                                                                                                                                                                              |                          |
| Create an ingress resource.                                          | Create a YAML file called `ingress.yaml` based on the Example ingress resource file code in the Additional information (p. 327) section of this pattern.                                                        | Developer, System Admin  |
| Create an Application Load Balancer.                                 | To deploy the ingress resource and create an Application Load Balancer, run the `kubectl` command.                                                                                                          | Developer, System Admin  |
Test the application

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Test and verify the application.               | 1. To get the load balancer's DNS name from the ADDRESS field, run the `kubectl get ingress.networking.k8s.io/java-microservice-ingress` command.  
|                                               | 2. On an EC2 instance in the same VPC as your Amazon EKS nodes, run the `curl -v <DNS address from previous command>` command. | Developer, System Admin  |

Deploy a clustered application to Amazon ECS by using AWS Copilot

Created by Jean-Baptiste Guillois (AWS), Mathew George (AWS), and Thomas Scott (AWS)

<table>

</table>

AWS services: Amazon ECS; AWS Fargate; Amazon ECR

Summary

This pattern shows how to deploy containers in an Amazon Elastic Container Service (Amazon ECS) cluster in two ways—by using the Amazon Web Services (AWS) Management Console, and by using AWS Copilot—to demonstrate how AWS Copilot simplifies deployment tasks.

Amazon ECS is a highly scalable, fast container management service that makes it easy to run, stop, and manage containers on a cluster. Your containers are defined in a task definition that you use to run individual tasks or tasks within a service. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of Amazon Elastic Compute Cloud (Amazon EC2) instances that you manage.

The AWS Copilot command line interface (CLI) commands simplify building, releasing, and operating production-ready containerized applications on Amazon ECS from a local development environment. The AWS Copilot CLI aligns with developer workflows that support modern application best practices: from using infrastructure as code to creating a continuous integration and continuous delivery (CI/CD) pipeline provisioned on behalf of a user. You can use the AWS Copilot CLI as part of your everyday development and testing cycle as an alternative to the AWS Management Console.

Prerequisites and limitations

Prerequisites

• An active AWS account
• AWS Command Line Interface (AWS CLI) locally installed and configured to use your AWS account (see the installation instructions and the configuration instructions in the AWS CLI documentation)
• AWS Copilot locally installed (see the installation instructions in the Amazon ECS documentation)
• Docker installed on your local machine (see the Docker documentation)

Limitations

• Docker enforces pull limits of 100 container images per 6 hours per IP address on the free plan.

Architecture

Target technology stack
• AWS environment set up with a virtual private cloud (VPC), public and private subnets, and security groups
• Amazon ECS cluster
• Amazon ECS service and task definition
• Amazon Elastic Container Registry (Amazon ECR)
• Amazon DynamoDB
• Application Load Balancer
• AWS Fargate
• Amazon Identity and Access Management (IAM)
• Amazon CloudWatch
• AWS CloudTrail

**Target architecture**

When you deploy the sample application for this pattern, multiple tasks are created and deployed in separate Availability Zones. Each task stores data in Amazon DynamoDB. When you access the webpage for a task, you can view the data from all other tasks.

**Tools**

**AWS services**

- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable. Amazon ECR supports private repositories with resource-based permissions using IAM.
**Epics**

**Amazon ECS** – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of Amazon Elastic Compute Cloud (Amazon EC2) instances that you manage.

**AWS Copilot** – AWS Copilot provides a command line interface that helps you launch and manage containerized applications on AWS, including pushing to a registry, creating a task definition, and creating a cluster.

**AWS Fargate** – AWS Fargate is a serverless, pay-as-you-go compute engine that lets you focus on building applications without managing servers. AWS Fargate is compatible with both Amazon ECS and Amazon Elastic Kubernetes Service (Amazon EKS). When you run your Amazon ECS tasks and services with the Fargate launch type or a Fargate capacity provider, you package your application in containers, specify the CPU and memory requirements, define networking and IAM policies, and launch the application. Each Fargate task has its own isolation boundary and doesn't share the underlying kernel, CPU resources, memory resources, or elastic network interface with another task.

**Amazon DynamoDB** – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.

**Elastic Load Balancing (ELB)** – Elastic Load Balancing automatically distributes your incoming traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in one or more Availability Zones. It monitors the health of its registered targets, and routes traffic only to the healthy targets. Elastic Load Balancing scales your load balancer as your incoming traffic changes over time. It can automatically scale to the vast majority of workloads.

**Tools**

- **Docker Command Line Interface**
- **AWS Command Line Interface (AWS CLI)**
- **AWS Copilot command line interface**

**Code**

The code for the sample application used in this pattern is available on GitHub, in the Cluster Sample Application repository. Follow the instructions in the next section to use the sample files.

### Epics

**Deploy the application stack - option 1 (AWS Management Console)**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clone the GitHub repository.</td>
<td>Clone the sample code repository by using the command:</td>
<td>App developer, AWS DevOps</td>
</tr>
<tr>
<td></td>
<td><code>git clone https://github.com/aws-samples/cluster-sample-app cluster-sample-app &amp;&amp; cd cluster-sample-app</code></td>
<td></td>
</tr>
<tr>
<td>Create your Amazon ECR repository.</td>
<td>1. Sign in to the AWS Management Console and open the Amazon</td>
<td>App developer, AWS DevOps</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
</tbody>
</table>
2. Choose **Create repository**.  
3. For the repository name, enter **cluster-sample-app**.  
4. For all other settings, keep the default values.  
5. Choose **Create repository**.  
   
For more information, see [Creating a private repository](https://docs.aws.amazon.com/eks/latest/userguide/cluster-management-private-repositories.html) in the Amazon ECR documentation. | **Build, tag, and push your Docker image to your Amazon ECR repository.**  
1. Select the repository you just created and choose **View push commands**.  
2. Copy the commands that are displayed and run them locally to build, tag, and push your docker image. These commands will be similar to the following.  
   
   To authenticate your Docker client to the registry:  
   ```bash  
   aws ecr get-login-password --region <YOUR_AWS_REGION>  
   | docker login --username AWS --password-stdin  
   <YOUR_AWS_ACCOUNT>.dkr.ecr.<YOUR_AWS_REGION>.amazonaws.com  
   ```  
   
   To build your Docker image:  
   ```bash  
   docker build -t cluster-sample-app .  
   ```  
   
   To tag your Docker image:  
   ```bash  
   docker tag cluster-sample-app:latest  
   <YOUR_AWS_ACCOUNT>.dkr.ecr.<YOUR_AWS_REGION>.amazonaws.com/cluster-sample-app:latest  
   ```  
   
   To push the Docker image to your repository:  
   ```bash  
   docker push <YOUR_AWS_ACCOUNT>.dkr.ecr.<YOUR_AWS_REGION>.amazonaws.com/cluster-sample-app:latest  
   ```  
| **App developer, AWS DevOps** |
### Task

**Deploy the application stack.**

2. Choose **Create stack**.
3. In the **Prepare template** section, choose **Template is ready**.
4. In the **Specify template** section, choose **Upload a template file**.
5. Choose the local file `cluster-sample-app-stack.yml` that you cloned from the GitHub repository as the CloudFormation template, and then choose **Next**.
6. Enter a name for your stack, and then choose **Next**.
7. Keep all default options, and then choose **Next**.
8. Review all options, acknowledge the creation of IAM resources, and then choose **Create stack**.
9. When your application stack has been deployed, choose the **Output** tab, copy the URL, and open it in your browser to access the application.

For more information about deploying CloudFormation templates, see [Creating a stack](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/creating-a-stack.html) in the AWS CloudFormation documentation.

Deploy a gRPC-based application on an Amazon EKS cluster and access it with an Application Load Balancer

Summary

This pattern describes how to host a gRPC-based application on an Amazon Elastic Kubernetes Service (Amazon EKS) cluster and securely access it through an Application Load Balancer.

**gRPC** is an open-source remote procedure call (RPC) framework that can run in any environment. You can use it for microservice integrations and client-server communications. For more information about gRPC, see Application Load Balancer support for end-to-end HTTP/2 and gRPC on the Amazon Web Services (AWS) Blog.

This patterns shows you how to host a gRPC-based application that runs as Kubernetes pods on Amazon EKS. The gRPC client connects to an Application Load Balancer through the HTTP/2 protocol with a Secure Sockets Layer/Transport Layer Security (SSL/TLS) encrypted connection. The Application Load Balancer forwards traffic to the gRPC application that runs on Amazon EKS pods. The number of gRPC pods can be automatically scaled based on traffic by using the Kubernetes Horizontal Pod Autoscaler. The Application Load Balancer's target group performs health checks on the Amazon EKS nodes, evaluates if the target is healthy, and only forwards traffic to healthy nodes.

Prerequisites and limitations

**Prerequisites**

- **Docker**, installed and configured on Linux, macOS, or Windows.
- An active AWS account.
- **AWS Command Line Interface (AWS CLI) version 2**, installed and configured on Linux, macOS, or Windows.
- An existing Amazon EKS cluster with tagged private subnets, public subnets, and configured to host applications. For more information, see Subnet tagging in the Amazon EKS documentation.
- **kubectl**, installed and configured to access resources on your Amazon EKS cluster. For more information, see Installing kubectl in the Amazon EKS documentation.
- **gRPCurl**, installed and configured.
- **AWS Load Balancer Controller**, provisioned in the Amazon EKS cluster.
- An existing Domain Name System (DNS) host name with a valid SSL or SSL/TLS certificate. You can obtain a certificate for your domain by using AWS Certificate Manager (ACM) or uploading an existing certificate to ACM. For more information about these two options, see Requesting a public certificate and Importing certificates into AWS Certificate Manager in the ACM documentation.
The following diagram shows a workflow where SSL/TLS traffic is received from a gRPC client that offloads to an Application Load Balancer. Traffic is forwarded in plaintext to the gRPC server because it comes from a virtual private cloud (VPC).
Tools

- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- **Elastic Load Balancing** distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.
- **Amazon Elastic Container Registry (Amazon ECR)** is a managed container image registry service that's secure, scalable, and reliable.
- **Amazon Elastic Kubernetes Service (Amazon EKS)** helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- **kubectl** is a command line utility for running commands against Kubernetes clusters.
- **AWS Load Balancer Controller** helps you manage AWS Elastic Load Balancers for a Kubernetes cluster.
- **gRPCurl** is a command line tool that helps you interact with gRPC services.

Epics

Build and push the gRPC server's Docker image to Amazon ECR

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an Amazon ECR repository. | Sign in to the AWS Management Console, open the Amazon ECR console, and then create an Amazon ECR repository. For more information about this, see [Creating a repository](https://docs.aws.amazon.com/AmazonECR/latest/ug/repo-creating-repository.html) in the Amazon ECR documentation. Make sure that you record the Amazon ECR repository's URL. You can also create an Amazon ECR repository with AWS CLI by running the following command:  
```bash
aws ecr create-repository --repository-name helloworld-grpc
```
| Cloud administrator          |
| Build the Docker image.      | Download the helloworld_grpc_alb file (attached) and open the directory. From the root of the directory contents, make sure that the Dockerfile exists and then run the following command to build the Docker image:  
```bash
docker build -t <amazon_ecr_repository_url>:<Tag> .
```
| DevOps engineer               |
### Push the Docker image to Amazon ECR.

Run the following command to log in to the Amazon ECR repository:

```
aws ecr get-login-password
--region us-east-1
--no-cli-auto-prompt
| docker login
--username AWS
--password-stdin
0123456789.dkr.ecr.us-east-1.amazonaws.com
```

Push the Docker image to the Amazon ECR repository by running the following command:

```
docker push <your_aws_account_id>.dkr.ecr.us-east-1.amazonaws.com/helloworld-grpc:1.0
```

**Important:** Make sure that you replace `<your_aws_account_id>` with your AWS account ID.

### Deploy the Kubernetes manifests to the Amazon EKS cluster

Modify the values in the Kubernetes manifest file.

Modify the grpc-sample.yaml Kubernetes manifest file in the Kubernetes directory according to your requirements. You must modify the annotations and host name in the ingress resource. For a sample ingress resource, see the **Additional information** section. For more information about ingress annotations, see [Ingress annotations](#) in the Kubernetes documentation.

In the Kubernetes deployment resource, change the deployment resource's image to the uniform resource identifier (URI) for the Amazon ECR repository that you pushed the Docker image to. For a sample deployment resource, see the **Additional information** section.

---

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Push the Docker image to Amazon ECR.</td>
<td>Run the following command to log in to the Amazon ECR repository:</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td>Push the Docker image to the Amazon ECR repository by running the following command:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Important:</strong> Make sure that you replace <code>&lt;your_aws_account_id&gt;</code> with your AWS account ID.</td>
<td></td>
</tr>
<tr>
<td>Modify the values in the Kubernetes manifest file.</td>
<td>Modify the grpc-sample.yaml Kubernetes manifest file in the Kubernetes directory according to your requirements. You must modify the annotations and host name in the ingress resource. For a sample ingress resource, see the <strong>Additional information</strong> section. For more information about ingress annotations, see <a href="#">Ingress annotations</a> in the Kubernetes documentation. In the Kubernetes deployment resource, change the deployment resource's image to the uniform resource identifier (URI) for the Amazon ECR repository that you pushed the Docker image to. For a sample deployment resource, see the <strong>Additional information</strong> section.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>
Deploy the Kubernetes manifest file. Deploy the grpc-sample.yaml file to the Amazon EKS cluster by running the following kubectl command:

```
kubectl apply -f ./kubernetes/grpc-sample.yaml
```

Skills required: DevOps engineer

Create the DNS record for the Application Load Balancer's FQDN

Record the FQDN for the Application Load Balancer. Run the following kubectl command to describe the Kubernetes ingress resource that manages the Application Load Balancer:

```
kubectl get ingress -n grpcserver
```

A sample output is provided in the Additional information section. In the output, the HOSTS field displays the DNS host name that the SSL certificates were created for. Record the Application Load Balancer's fully qualified domain name (FQDN) from the Address field.

Create a DNS record pointing to the Application Load Balancer's FQDN. If your DNS provider is Amazon Route 53, you can create an alias record that points to the Application Load Balancer's FQDN. For more information about this, see Choosing between alias and non-alias records in the Route 53 documentation.

Skills required: DevOps engineer

Test the solution

Test the gRPC server. Use gRPCurl to test the endpoint by running the following command:

```
```

Skills required: DevOps engineer

AWS services: Amazon EKS; AWS Fargate

Summary

Containers are becoming an essential part of cloud native application development. Kubernetes provides an efficient way to manage and orchestrate containers. Amazon Elastic Kubernetes Service (Amazon EKS) is a fully-managed, certified Kubernetes conformant service for building, securing, operating, and maintaining Kubernetes clusters on Amazon Web Services (AWS). It supports running pods on AWS Fargate to provide on-demand, right-sized compute capacity.

It's important for developers and administrators to know debugging options when running containerized workloads. This pattern walks you through deploying and debugging containers on Amazon EKS with AWS Fargate. It includes creating, deploying, accessing, debugging, and cleaning up the Amazon EKS workloads.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Identity and Access Management (IAM) role configured with sufficient permissions to create and interact with Amazon EKS, IAM roles, and service linked roles
- AWS Command Line Interface (AWS CLI) installed on the local machine
- eksctl
- kubectl
- Helm

Limitations

- This pattern provides developers with useful debugging practices for development environments. It does not state best practices for production environments.
- If you are running Windows, use your operating system–specific commands for setting the environment variables.

Product versions used

- AWS CLI version 2
- kubectl version within one minor version difference of the Amazon EKS control plane that you’re using
- eksctl latest version
AWS Prescriptive Guidance Patterns
Architecture

- **Helm v3**

**Architecture**

**Technology stack**

- Application Load Balancer
- Amazon EKS
- AWS Fargate

**Target architecture**

All resources shown in the diagram are provisioned by using `eksctl` and `kubectl` commands issued from a local machine. Private clusters must be run from an instance that is inside the private VPC.

The target architecture consists of an EKS cluster using the Fargate launch type. This provides on-demand, right-sized compute capacity without the need to specify server types. The EKS cluster has a control plane, which is used to manage the cluster nodes and workloads. The pods are provisioned into private VPC subnets spanning multiple Availability Zones. The Amazon ECR Public Gallery is referenced to retrieve and deploy an NGINX web server image to the cluster's pods.

The diagram shows how to access the Amazon EKS control plane using by `kubectl` commands and how to access the application by using the Application Load Balancer.

1. A local machine outside the AWS Cloud sends commands to the Kubernetes control plane inside an Amazon EKS managed VPC.
2. Amazon EKS schedules pods based on the selectors in the Fargate profile.
3. The local machine opens the Application Load Balancer URL in the browser.
4. The Application Load Balancer divides traffic between the Kubernetes pods in Fargate cluster nodes deployed in private subnets spanning multiple Availability Zones.
Tools

AWS services

- **Amazon Elastic Container Registry (Amazon ECR)** is a managed container image registry service that's secure, scalable, and reliable.
- **Amazon Elastic Kubernetes Service (Amazon EKS)** helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes. This pattern also uses the eksctl command-line tool to work with Kubernetes clusters on Amazon EKS.
- **AWS Fargate** helps you run containers without needing to manage servers or Amazon Elastic Compute Cloud (Amazon EC2) instances. It's used in conjunction with Amazon Elastic Container Service (Amazon ECS).
- **Elastic Load Balancing (ELB)** distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones. This pattern uses the **AWS Load Balancer Controller** controlling component to create the Application Load Balancer when a **Kubernetes ingress** is provisioned. The Application Load Balancer distributes incoming traffic among multiple targets.

Other tools

- **Helm** is an open-source package manager for Kubernetes. In this pattern, Helm is used to install the AWS Load Balancer Controller.
- **Kubernetes** is an open-source system for automating deployment, scaling, and management of containerized applications.
- **NGINX** is a high-performance web and reverse proxy server.

Epics

Create an EKS cluster

<td></td>
</tr>
<tr>
<td></td>
<td>[ &quot;vpc-&lt;YOUR-VPC-ID&gt;&quot; ]</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Copy the VPC ID and export it as an environment variable.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>export VPC_ID=&quot;vpc-&lt;YOUR-VPC-ID&gt;&quot;</code></td>
<td></td>
</tr>
<tr>
<td>Configure IAM for the cluster service account.</td>
<td>Use the AWS_REGION and CLUSTER_NAME from the earlier epic to create an IAM Open ID Connect provider for the cluster.</td>
<td>App developer, AWS DevOps, AWS systems administrator</td>
</tr>
<tr>
<td></td>
<td><code>eksctl utils associate-iam-oidc-provider ...</code></td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td></td>
<td><code>--region $AWS_REGION \</code>&lt;br&gt;<code>--cluster $CLUSTER_NAME \</code>&lt;br&gt;<code>--approve</code></td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Download and create the IAM policy.</td>
<td>Download the IAM policy for the AWS Load Balancer Controller that allows it to make calls to AWS APIs on your behalf.</td>
<td>App developer, AWS DevOps, AWS systems administrator</td>
</tr>
</tbody>
</table>

```bash
```

Create the policy in your AWS account by using the AWS CLI.

```bash
aws iam create-policy \
  --policy-name AWSLoadBalancerControllerIAMPolicy \
  --policy-document file://iam-policy.json
```

You should see the following output.

```json
{
  "Policy": {
    "PolicyName": "AWSLoadBalancerControllerIAMPolicy",
    "PolicyId": "<YOUR_POLICY_ID>",
    "Arn": "arn:aws:iam::<YOUR-ACCOUNT-ID>:policy/AWSLoadBalancerControllerIAMPolicy",
    "Path": "/",
    "DefaultVersionId": "v1",
    "AttachmentCount": 0,
    "PermissionsBoundaryUsageCount": 0,
    "IsAttachable": true,
    "CreateDate": "<YOUR-DATE>",
    "UpdateDate": "<YOUR-DATE>
  }
}
```

Save the Amazon Resource Name (ARN) of the policy as $POLICY_ARN.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>export POLICY_ARN=&quot;arn:aws:iam::&lt;YOUR-ACCOUNT-ID&gt;:policy/AWSLoadBalancerControllerIAMPolicy&quot;</code></td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Create an IAM service account</td>
<td>Create an IAM service account named <code>aws-load-balancer-controller</code> in the <code>kube-system</code> namespace. Use the <code>CLUSTER_NAME</code>, <code>AWS_REGION</code>, and <code>POLICY_ARN</code> that you previously configured.</td>
</tr>
</tbody>
</table>

```
eksctl create iamserviceaccount \
--cluster=$CLUSTER_NAME \
--region=$AWS_REGION \
--attach-policy-arn= $POLICY_ARN \
--namespace=kube-system \
--name=aws-load-balancer-controller \
--override-existing-serviceaccounts \
--approve
```

Verify the creation.

```
eksctl get iamserviceaccount \
--cluster $CLUSTER_NAME \
--name aws-load-balancer-controller \
--namespace kube-system \
--output yaml
```

The output should be the following.

```yaml
- metadata:
  name: aws-load-balancer-controller
  namespace: kube-system
  status:
    roleARN:
      arn:aws:iam::<YOUR-ACCOUNT-ID>:role/eksctl-my-fargate-addon-iamserviceaccount-kube-Role1::<YOUR-ROLE-ID>
    wellKnownPolicies:
      autoScaler: false
      awsLoadBalancerController: false
      certManager: false
      ebsCSIController: false
      efsCSIController: false
      externalDNS: false
      imageBuilder: false
```
<table>

<td>ingress.networking.k8s.io/nginx-ingress created</td>
<td></td>
</tr>
</tbody>
</table>
### Get the load balancer URL

**Description**
To retrieve the ingress information, use the following command.

```
kubectl get ingress nginx-ingress
```

**Skills required**
App developer, AWS DevOps, AWS systems administrator

**Output**
The output should be the following.

<table>
<thead>
<tr>
<th>NAME</th>
<th>CLASS</th>
<th>HOSTS</th>
<th>ADDRESS</th>
</tr>
</thead>
<tbody>
<tr>
<td>nginx-ingress</td>
<td>&lt;none&gt;</td>
<td>*</td>
<td>k8s-default-nginxing-xxx.us-east-1.elb.amazonaws.com</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>80 80s</td>
</tr>
</tbody>
</table>

Copy the ADDRESS (for example, k8s-default-nginxing-xxx.us-east-1.elb.amazonaws.com) from the output, and paste it into your browser to access the index.html file.

### Debug running containers

**Task**
Select a pod.

**Description**
List all pods, and copy the desired pod's name.

```
kubectl get pods
```

**Skills required**
App developer, AWS DevOps, AWS systems administrator

**Output**
The output should be the following.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>nginx-deployment-xxxx-aaa</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>55m</td>
</tr>
<tr>
<td>nginx-deployment-xxxx-bbb</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>55m</td>
</tr>
<tr>
<td>nginx-deployment-xxxx-ccc</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>55m</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
<td></td>
<td></td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
<td></td>
<td></td>
</tr>
<tr>
<td>nginx-deployment-xxxx-ddd</td>
<td>1/1     Running   0 42m</td>
<td><strong>POD_NAME</strong> variable or set it as an environment variable. Otherwise, omit this parameter to look up all resources.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Access the logs.</td>
<td>Get the logs from the pod that you want to debug.</td>
<td>App developer, AWS systems administrator, AWS DevOps</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Forward the NGINX port.</td>
<td>Use port-forwarding to map the pod's port for accessing the NGINX web server to a port on your local machine.</td>
<td>App developer, AWS DevOps, AWS systems administrator</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This command lists the existing pods and additional information.

Access the logs.

```bash
export POD_NAME="nginx-deployment-<YOUR-POD-NAME>"
kubectl logs $POD_NAME
```

Forward the NGINX port.

```bash
kubectl port-forward deployment/nginx-deployment 8080:80
```

In your browser, open the following URL.

```
http://localhost:8080
```

The port-forward command provides access to the index.html file without making it publicly available over a load balancer. This is useful for accessing the running application while debugging it. You can stop the port-forwarding by pressing the keyboard command **Ctrl+C**.
<table>

AWS services: AWS Elastic Beanstalk

Summary

On the Amazon Web Services (AWS) Cloud, AWS Elastic Beanstalk supports Docker as an available platform, so that containers can run with the created environment. This pattern shows how to deploy containers using the Elastic Beanstalk service. The deployment of this pattern will use the web server environment based on the Docker platform.

To use Elastic Beanstalk for deploying and scaling web applications and services, you upload your code and the deployment is automatically handled. Capacity provisioning, load balancing, automatic scaling, and application health monitoring are also included. When you use Elastic Beanstalk, you can take full control over the AWS resources that it creates on your behalf. There is no additional charge for Elastic Beanstalk. You pay only for the AWS resources that are used to store and run your applications.

This pattern includes instructions for deployment using the AWS Elastic Beanstalk Command Line Interface (EB CLI) and the AWS Management Console.

Use cases

Use cases for Elastic Beanstalk include the following:

- Deploy a prototype environment to demo a frontend application. (This pattern uses a Dockerfile as the example.)
- Deploy an API to handle API requests for a given domain.
- Deploy an orchestration solution using Docker-Compose (docker-compose.yml is not used as the practical example in this pattern).

Prerequisites and limitations

Prerequisites

- An AWS account
- AWS EB CLI locally installed
- Docker installed on a local machine

Limitations

- There is a Docker pull limit of 100 pulls per 6 hours per IP address on the free plan.
Architecture

Target technology stack

- Amazon Elastic Compute Cloud (Amazon EC2) instances
- Security group
- Application Load Balancer
- Auto Scaling group

Target architecture

Automation and scale

AWS Elastic Beanstalk can automatically scale based on the number of requests made. AWS resources created for an environment include one Application Load Balancer, an Auto Scaling group, and one or more Amazon EC2 instances.

The load balancer sits in front of the Amazon EC2 instances, which are part of the Auto Scaling group. Amazon EC2 Auto Scaling automatically starts additional Amazon EC2 instances to accommodate increasing load on your application. If the load on your application decreases, Amazon EC2 Auto Scaling stops instances, but it keeps at least one instance running.

Automatic scaling triggers

The Auto Scaling group in your Elastic Beanstalk environment uses two Amazon CloudWatch alarms to initiate scaling operations. The default triggers scale when the average outbound network traffic from
AWS Prescriptive Guidance Patterns

Tools

AWS services

- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- **AWS EB Command Line Interface (EB CLI)** is a command-line client that you can use to create, configure, and manage Elastic Beanstalk environments.
- **Elastic Load Balancing** distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.

Other services

- **Docker** packages software into standardized units called containers that include libraries, system tools, code, and runtime.

Code

The code for this pattern is available in the GitHub [Cluster Sample Application](https://github.com/aws-samples/cluster-sample-app) repository.

Additional information

Advantages of using Elastic Beanstalk

- Automatic infrastructure provisioning
- Automatic management of the underlying platform
- Automatic patching and updates to support the application
- Automatic scaling of the application
- Ability to customize the number of nodes
- Ability to access the infrastructure components if needed
- Ease of deployment over other container deployment solutions
Generate a static outbound IP address using a Lambda function, Amazon VPC, and a serverless architecture

Created by Thomas Scott (AWS)

<table>

Summary of generating a static outbound IP address using Lambda and Amazon VPC

This pattern describes how to generate a static outbound IP address in the Amazon Web Services (AWS) Cloud by using a serverless architecture. Your organization can benefit from this approach if it wants to send files to a separate business entity by using Secure File Transfer Protocol (SFTP). This means that the business entity must have access to an IP address that allows files through its firewall.

The pattern’s approach helps you create an AWS Lambda function that uses an Elastic IP address as the outbound IP address. By following the steps in this pattern, you can create a Lambda function and a virtual private cloud (VPC) that routes outbound traffic through an internet gateway with a static IP address. To use the static IP address, you attach the Lambda function to the VPC and its subnets.

Prerequisites and limitations for generating a static outbound IP address using Lambda and Amazon VPC

Prerequisites

- An active AWS account.
- AWS Identity and Access Management (IAM) permissions to create and deploy a Lambda function, and to create a VPC and its subnets. For more information about this, see Execution role and user permissions in the AWS Lambda documentation.
- If you plan to use infrastructure as code (IaC) to implement this pattern’s approach, you need an integrated development environment (IDE) such as AWS Cloud9. For more information about this, see What is AWS Cloud9? in the AWS Cloud9 documentation.

Architecture for generating a static outbound IP address using Lambda and Amazon VPC

The following diagram shows the serverless architecture for this pattern.
The diagram shows the following workflow:

1. Outbound traffic leaves NAT gateway 1 in Public subnet 1.
2. Outbound traffic leaves NAT gateway 2 in Public subnet 2.
3. The Lambda function can run in Private subnet 1 or Private subnet 2.
4. Private subnet 1 and Private subnet 2 route traffic to the NAT gateways in the public subnets.
5. The NAT gateways send outbound traffic to the internet gateway from the public subnets.
6. Outbound data is transferred from the internet gateway to the external server.

Technology stack

- Lambda
- Amazon Virtual Private Cloud (Amazon VPC)

Automation and scale

You can ensure high availability (HA) by using two public and two private subnets in different Availability Zones. Even if one Availability Zone becomes unavailable, the pattern's solution continues to work.

Tools for generating a static outbound IP address using Lambda and Amazon VPC

- AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- Amazon VPC – Amazon Virtual Private Cloud (Amazon VPC) provisions a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you've defined. This
virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Epics for generating a static outbound IP address using Lambda and Amazon VPC

Create a new VPC

<table>
<thead>
<tr>

<td>AWS administrator</td>
</tr>
</tbody>
</table>

Create two public subnets

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the first public subnet.</td>
<td>1. On the Amazon VPC console, choose Subnets and then choose Create Subnet. 2. For Name tag, enter public-one. 3. For VPC, choose Lambda VPC. 4. Choose an Availability Zone and record it. 5. For IPv4 CIDR block, enter 10.0.0.0/28 and then choose Create subnet.</td>
<td>AWS administrator</td>
</tr>
<tr>
<td>Create the second public subnet.</td>
<td>1. On the Amazon VPC console, choose Subnets and then choose Create Subnet. 2. For Name tag, enter public-two. 3. For VPC, choose Lambda VPC. 4. Choose an Availability Zone and record it. <strong>Important:</strong> You cannot use the Availability Zone that contains the public-one subnet.</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>
### Create two private subnets

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the first private subnet.</td>
<td>1. On the Amazon VPC console, choose <strong>Subnets</strong> and then choose <strong>Create Subnet</strong>. 2. For <strong>Name tag</strong>, enter <code>private-one</code>. 3. For <strong>VPC</strong>, choose Lambda VPC. 4. Choose the Availability Zone that contains the public-one subnet that you created earlier. 5. For <strong>IPv4 CIDR block</strong>, enter <code>10.0.0.32/28</code> and then choose <strong>Create subnet</strong>.</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the second private subnet.</td>
<td>1. On the Amazon VPC console, choose <strong>Subnets</strong> and then choose <strong>Create Subnet</strong>. 2. For <strong>Name tag</strong>, enter <code>private-two</code>. 3. For <strong>VPC</strong>, choose Lambda VPC. 4. Choose the same Availability Zone that contains the public-two subnet that you created earlier. 5. For <strong>IPv4 CIDR block</strong>, enter <code>10.0.0.64/28</code> and then choose <strong>Create subnet</strong>.</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>

### Create two Elastic IP addresses for your NAT gateways

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the first Elastic IP address.</td>
<td>1. On the Amazon VPC console, choose <strong>Elastic IPs</strong> and then choose <strong>Allocate new address</strong>. 2. Choose <strong>Allocate</strong> and record the <strong>Allocation ID</strong> for your newly created Elastic IP address.</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>
## Create the second Elastic IP address.

1. On the Amazon VPC console, choose **Elastic IPs** and then choose **Allocate new address**.
2. Choose **Allocate** and record the **Allocation ID** for this second Elastic IP address.

**Note:** This Elastic IP address is used for your second NAT gateway.

## Create an internet gateway

1. On the Amazon VPC console, choose **Internet Gateways** and then choose **Create internet gateway**.
2. Enter `Lambda internet gateway` as the name and then choose **Create internet gateway**. Make sure that you record the internet gateway ID.

## Attach the internet gateway to the VPC.

Select the internet gateway that you just created, and then choose **Actions, Attach to VPC**.

## Create two NAT gateways

1. On the Amazon VPC console, choose **NAT Gateways** and then choose **Create NAT Gateway**.
2. Enter `nat-one` as the NAT gateway name.
3. Choose `public-one` as the subnet to create the NAT gateway in.
4. For **Connectivity type**, choose **Public**.

**Note:** This Elastic IP address is used for your first NAT gateway.
### AWS Prescriptive Guidance Patterns

#### Epics

<table>
<thead>
<tr>

Install SSM Agent on Amazon EKS worker nodes by using Kubernetes DaemonSet

Created by Mahendra Siddappa (AWS)

| Environment: | PoC or pilot | Technologies: | Containers & microservices; DevOps; Infrastructure | AWS services: | Amazon EKS; AWS Systems Manager |

Summary

Note, September 2021: The latest Amazon EKS optimized AMIs install SSM Agent automatically. For more information, see the release notes for the June 2021 AMIs.

In Amazon Elastic Kubernetes Service (Amazon EKS), because of security guidelines, worker nodes don't have Secure Shell (SSH) key pairs attached to them. This pattern shows how you can use the Kubernetes DaemonSet resource type to install AWS Systems Manager Agent (SSM Agent) on all worker nodes, instead of installing it manually or replacing the Amazon Machine Image (AMI) for the nodes. DaemonSet uses a cron job on the worker node to schedule the installation of SSM Agent. You can also use this pattern to install other packages on worker nodes.

When you're troubleshooting issues in the cluster, installing SSM Agent on demand enables you to establish an SSH session with the worker node, to collect logs or to look into instance configuration, without SSH key pairs.

Prerequisites and limitations

Prerequisites

- An existing Amazon EKS cluster with Amazon Elastic Compute Cloud (Amazon EC2) worker nodes.
- Container instances should have the required permissions to communicate with the SSM service. The AWS Identity and Access Management (IAM) managed role AmazonSSMManagedInstanceCore provides the required permissions for SSM Agent to run on EC2 instances. For more information, see the AWS Systems Manager documentation.

Limitations

- This pattern isn't applicable to AWS Fargate, because DaemonSets aren't supported on the Fargate platform.
- This pattern applies only to Linux-based worker nodes.
- The DaemonSet pods run in privileged mode. If the Amazon EKS cluster has a webhook that blocks pods in privileged mode, the SSM Agent will not be installed.

Architecture

The following diagram illustrates the architecture for this pattern.
Tools

**Tools**

- **kubectl** is a command-line utility that is used to interact with an Amazon EKS cluster. This pattern uses kubectl to deploy a DaemonSet on the Amazon EKS cluster, which will install SSM Agent on all worker nodes.
- **Amazon EKS** makes it easy for you to run Kubernetes on AWS without having to install, operate, and maintain your own Kubernetes control plane or nodes. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.
- **AWS Systems Manager Session Manager** lets you manage your EC2 instances, on-premises instances, and virtual machines (VMs) through an interactive, one-click, browser-based shell or through the AWS Command Line Interface (AWS CLI).

**Code**

Use the following code to create a DaemonSet configuration file that will install SSM Agent on the Amazon EKS cluster. Follow the instructions in the [Epics (p. 381)](#) section.

```yaml
cat << EOF > ssm_daemonset.yaml
apiVersion: apps/v1
kind: DaemonSet
metadata:
  labels:
    k8s-app: ssm-installer
    name: ssm-installer
    namespace: kube-system
spec:

Install the SSM Agent and CloudWatch agent on Amazon EKS worker nodes using preBootstrapCommands

Summary

This pattern provides code samples and steps to install the AWS Systems Manager Agent (SSM Agent) and Amazon CloudWatch agent on Amazon Elastic Kubernetes Service (Amazon EKS) worker nodes in the Amazon Web Services (AWS) Cloud during Amazon EKS cluster creation. You can install the SSM Agent and CloudWatch agent by using the preBootstrapCommands property from the eksctl config file schema (Weaveworks documentation). Then, you can use the SSM Agent to connect to your worker nodes without using an Amazon Elastic Compute Cloud (Amazon EC2) key pair. Additionally, you can use the CloudWatch agent to monitor memory and disk utilization on your Amazon EKS worker nodes.

Prerequisites and limitations

Prerequisites

- An active AWS account
- The eksctl command line utility, installed and configured on macOS, Linux, or Windows
- The kubectl command line utility, installed and configured on macOS, Linux, or Windows

Limitations

- We recommend that you avoid adding long-running scripts to the preBootstrapCommands property, because this delays the node from joining the Amazon EKS cluster during scaling activities. We recommend that you create a custom Amazon Machine Image (AMI) instead.
- This pattern applies to Amazon EC2 Linux instances only.

Architecture

Technology stack

- Amazon CloudWatch
- Amazon Elastic Kubernetes Service (Amazon EKS)
- AWS Systems Manager Parameter Store

Target architecture
The following diagram shows an example of a user connecting to Amazon EKS worker nodes using SSM Agent which was installed using the `preBootstrapCommands`.

The diagram shows the following workflow:

1. The user creates an Amazon EKS cluster by using the `eksctl` configuration file with the `preBootstrapCommands` property, which installs the SSM Agent and CloudWatch agent.
2. Any new instances that join the cluster later due to scaling activities get created with the pre-installed SSM Agent and CloudWatch agent.
3. The user connects to Amazon EC2 by using the SSM Agent and then monitors memory and disk utilization by using the CloudWatch agent.

**Tools**

- **Amazon CloudWatch** helps you monitor the metrics of your AWS resources and the applications that you run on AWS in real time.
- **Amazon Elastic Kubernetes Service (Amazon EKS)** helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- **AWS Systems Manager Parameter Store** provides secure, hierarchical storage for configuration data management and secrets management.
- **AWS Systems Manager Session Manager** helps you manage your EC2 instances, on-premises instances, and virtual machines through an interactive, one-click, browser-based shell or through the AWS Command Line Interface (AWS CLI).
- **eksctl** is a command-line utility for creating and managing Kubernetes clusters on Amazon EKS.
- **kubectl** is a command-line utility for communicating with the cluster API server.

Additional information

Example CloudWatch agent configuration file

In the following example, the CloudWatch agent is configured to monitor disk and memory utilization on Amazon Linux instances:

```json
{
    "agent": {
        "metrics_collection_interval": 60,
        "run_as_user": "cwagent"
    },
    "metrics": {
        "append_dimensions": {
            "AutoScalingGroupName": "${aws:AutoScalingGroupName}",
            "ImageId": "${aws:ImageId}",
            "InstanceId": "${aws:InstanceId}",
            "InstanceType": "${aws:InstanceType}"
        },
        "metrics_collected": {
            "disk": [
                "measurement": [
                    "used_percent"
                ],
                "metrics_collection_interval": 60,
                "resources": [
                    "*
                ]
            ],
            "mem": {
                "measurement": [
                    "mem_used_percent"
                ],
                "metrics_collection_interval": 60
            }
        }
    }
}
Example eksctl configuration file

```yaml
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig
metadata:
  name: test
  region: us-east-2
  version: "1.24"
managedNodeGroups:
  - name: test
    minSize: 2
    maxSize: 4
    desiredCapacity: 2
    volumeSize: 20
    instanceType: t3.medium
    preBootstrapCommands:
      - sudo yum install amazon-ssm-agent -y
      - sudo systemctl enable amazon-ssm-agent
      - sudo systemctl start amazon-ssm-agent
      - sudo yum install amazon-cloudwatch-agent -y
      - sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2 -s -c ssm:AmazonCloudwatch-linux
    iam:
      attachPolicyARNs:
        - arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy
        - arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy
        - arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly
        - arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
        - arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

Additional code details

- In the last line of the `preBootstrapCommands` property, `AmazonCloudwatch-linux` is the name of the parameter created in AWS System Manager Parameter Store. You must include `AmazonCloudwatch-linux` in Parameter Store in the same AWS Region where you created the Amazon EKS cluster. You can also specify a file path, but we recommend using Systems Manager for easier automation and reusability.
- If you use `preBootstrapCommands` in the `eksctl` configuration file, you see two launch templates in the AWS Management Console. The first launch template includes the commands specified in `preBootstrapCommands`. The second template includes the commands specified in `preBootstrapCommands` and default Amazon EKS user data. This data is required to get the nodes to join the cluster. The node group’s Auto Scaling group uses this user data to spin up new instances.
- If you use the `iam` attribute in the `eksctl` configuration file, you must list the default Amazon EKS policies with any additional policies required in your attached AWS Identity and Access Management (IAM) policies. In the code snippet from the 'Create the eksctl configuration file and cluster' step, `CloudWatchAgentServerPolicy` and `AmazonSSMManagedInstanceCore` are additional policies added to make sure that the CloudWatch agent and SSM Agent work as expected. The `AmazonEKSWorkerNodePolicy`, `AmazonEKS_CNI_Policy`, `AmazonEC2ContainerRegistryReadOnly` policies are mandatory policies required for the Amazon EKS cluster to function correctly.
Optimize AWS App2Container generated Docker images

Created by Varun Sharma (AWS)

| Environment: | PoC or pilot | Technologies: | Containers & microservices; Modernization; DevOps | AWS services: | Amazon ECS |

Summary

AWS App2Container is a command line tool that helps transform existing applications running on premises or on virtual machines into containers, without needing code changes.

Based on application type, App2Container takes a conservative approach to identify dependencies. For process mode, all non-system files on the application server are included in the container image. In such cases, a fairly large image might be generated.

This pattern provides an approach for optimizing the container images generated by App2Container. It is applicable for all Java applications discovered by App2Container in process mode. The workflow defined in the pattern is designed to be run on the application server.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A Java application running on an application server on a Linux server
- App2Container installed and set up, with all prerequisites met, on the Linux server

Architecture

Source technology stack

- A Java application running on a Linux server

Target technology stack

- A Docker image generated by App2Container

Target architecture flow
1. Discover the applications that are running on the application server, and analyze the applications.
2. Containerize the applications.
3. Evaluate the size of the Docker image. If the image is too large, continue to step 4.
4. Use the shell script (attached) to identify large files.
5. Update the appExcludedFiles and appSpecificFiles lists in the analysis.json file.

Tools

AWS App2Container – AWS App2Container (A2C) is a command line tool to help you lift and shift applications that run in your on-premises data center or on virtual machines, so that they run in containers that are managed by Amazon Elastic Container Service (Amazon ECS) or Amazon Elastic Kubernetes Service (Amazon EKS).

Code

The optimizeImage.sh shell script and an example analysis.json file are attached.

The optimizeImage.sh file is a utility script for reviewing the contents of the App2Container generated file, ContainerFiles.tar. The review identifies files or subdirectories that are large and can be excluded. The script is a wrapper for the following tar command.

```
tar -Ptvf <path>\;tr -s ' '\;cut -d ' ' -f3,6\;awk '\$2 ~/<filetype>$/\;awk '\$2 ~/^<toplevel>/\;cut -f1-<depth> -d'/\;awk '{ if ($1<= <size>) arr[$2]+=$1 } END { for (key in arr) if(<verbose>) printf("%-50s\t%-50s\n", key, arr[key]) else printf("%s,", key) }\}'\;sort -k2 -nr
```
In the `tar` command, the script uses the following values:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>path</code></td>
<td>The path to <code>ContainerFiles.tar</code></td>
</tr>
<tr>
<td><code>filetype</code></td>
<td>The file type to match</td>
</tr>
<tr>
<td><code>toplevel</code></td>
<td>The top-level directory to match</td>
</tr>
<tr>
<td><code>depth</code></td>
<td>The depth of the absolute path</td>
</tr>
<tr>
<td><code>size</code></td>
<td>The size for each file</td>
</tr>
</tbody>
</table>

The script does the following:

1. It uses `tar -Ptvf` to list the files without extracting them.
2. It filters the files by file type, starting with the top-level directory.
3. Based on the depth, it generates the absolute path as an index.
4. Based on the index and stores, it provides the total size of the subdirectory.
5. It prints the size of the subdirectory.

You can also replace the values manually in the `tar` command.

<td>AWS DevOps</td>
</tr>
</tbody>
</table>

```bash
./optimizeImage.sh -p /{workspace}/{java-app-id}/Artifacts/ContainerFiles.tar -d 0 -t / -v
```

This is the total size of the tar file after optimization.

```bash
./optimizeImage.sh -p /{workspace}/{java-app-id}/Artifacts/ContainerFiles.tar -d 1 -t / -s 1000000 -v
```

- var: 554144711
- usr: 2097300819
- tmp: 18579660
- root: 43645397
- opt: 222320534
- home: 65212518
- etc: 11357677
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Identify large subdirectories under the / directory. | For each major subdirectory that is listed in the previous command, identify the sizes of its subdirectories. Use `-d` to increase the depth and `-t` to indicate the top-level directory. For example, use `/var` as the top-level directory. Under `/var`, identify all the large subdirectories and their sizes. 

```
./optimizeImage.sh -p /{workspace}/{java-app-id}/Artifacts/ContainerFiles.tar -d 2 -t /var -s 1000000 -v
```

Repeat this process for each subdirectory listed in the previous step (for example, `/usr`, `/tmp`, `/opt`, and `/home`). | AWS DevOps |
| Analyze the large folder in each subdirectory under the / directory. | For each subdirectory that is listed in the previous step, identify any folders that are required to run the application. For example, using the subdirectories from the previous step, list all the subdirectories in the `/var` directory and their sizes. Identify any subdirectories that are needed by the application. 

```
/var/tmp
  237285851
/var/lib
  24489984
/var/cache
  237285851
```

To exclude subdirectories that are not needed by the application, in the `analysis.json` file, add those subdirectories to the `appExcludedFiles` section under `containerParameters`. An example `analysis.json` file is attached. | AWS DevOps |
### Identify files that are needed from the appExcludes list.

**Task:** Identify files that are needed from the appExcludes list.

**Description:** For each subdirectory that is added to appExcludes list, identify any files in that subdirectory that are required by the application. In the analysis.json file, add the specific files or subdirectories in the appSpecificFiles section under containerParameters.

For example, if the /usr/lib directory is added to the exclude list, but /usr/lib/jvm is needed by the application, add /usr/lib/jvm to the appSpecificFiles section.

**Skills required:** AWS DevOps

### Extract and containerize the application again

#### Containerize the analyzed application.

**Task:** Containerize the analyzed application.

**Description:** To containerize the application, run the following command.

```bash
sudo app2container containerize --application-id <application-id>
```

The command generates the Docker image along with a tar bundle in the workspace location.

**Skills required:** AWS DevOps

#### Identify the Artifacts tar file size.

**Task:** Identify the Artifacts tar file size.

**Description:** Identify the ContainerFiles.tar file in `{workspace}/{java-app-id}/Artifacts`, where `workspace` is the App2Container workspace and `java-app-id` is the application ID.

```bash
./optimizeImage.sh -p /{workspace}/{java-app-id}/Artifacts/ContainerFiles.tar -d 0 -t / -v
```

This is the total size of the tar file after optimization.

**Skills required:** AWS DevOps

#### Run the Docker image.

**Task:** Run the Docker image.

**Description:** To verify that the image starts without errors, run the

**Skills required:** AWS DevOps
**Task**

Docker image locally using the following commands.

To identify the `imageId` of the container, use `docker images |grep java-app-id`.

To run the container, use `docker run -d <image id>`.

Place Kubernetes Pods on Amazon EKS by using node affinity, taints, and tolerations

Created by Hitesh Parikh (AWS) and Raghu Bhamidimarri (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technologies:</td>
<td>Containers &amp; microservices</td>
</tr>
<tr>
<td>Workload:</td>
<td>Open-source</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon EKS</td>
</tr>
</tbody>
</table>

Summary

This pattern demonstrates the use of Kubernetes node affinity, node taints, and Pod tolerations to intentionally schedule application Pods on specific worker nodes in an Amazon Elastic Kubernetes Service (Amazon EKS) cluster on the Amazon Web Services (AWS) Cloud.

A taint is a node property that enables nodes to reject a set of pods. A toleration is a Pod property that enables the Kubernetes scheduler to schedule Pods on nodes that have matching taints.

However, tolerations alone can't prevent a scheduler from placing a Pod on a worker node that doesn't have any taints. For example, a compute intensive Pod with a toleration can unintentionally get scheduled on a general-purpose untainted node. In that scenario, the node affinity property of a Pod instructs the scheduler to place the Pod on a node that meets the node selection criteria specified in the node affinity.

Taints, tolerations, and node affinity together instruct the scheduler to schedule Pods consistently on the nodes with matching taints and the node labels that match the node affinity node-selection criteria specified on the Pod.

This pattern provides an example Kubernetes deployment manifest file, and the steps to create an EKS cluster, deploy an application, and validate Pod placement.

Prerequisites and limitations

Prerequisites

- An AWS account with credentials configured to create resources on your AWS account
- AWS Command Line Interface (AWS CLI)
- eksctl
- kubectl
- Docker installed (for the operating system being used), and the engine started (for information about Docker licensing requirements, see the Docker site)
- Java version 11 or later
- A Java microservice running on your favorite integrated development environment (IDE); for example, AWS Cloud9, IntelliJ IDEA Community Edition or Eclipse (if you don't have a Java microservice, see the Deploy a sample Java microservice on Amazon EKS pattern and Microservices with Spring for help with creating the microservice)

Limitations
This pattern doesn’t provide the Java code, and it assumes that you are already familiar with Java. To create a basic Java microservice, see Deploy a sample Java microservice on Amazon EKS.

The steps in this article create AWS resources that can accrue cost. Make sure that you clean up the AWS resources after you have completed the steps to implement and validate the pattern.

Architecture

Target technology stack

- Amazon EKS
- Java
- Docker
- Amazon Elastic Container Registry (Amazon ECR)

Target architecture

The solution architecture diagram shows Amazon EKS with two Pods (Deployment 1 and Deployment 2) and two node groups (ng1 and ng2) with two nodes each. The Pods and nodes have the following properties.

<table>
<thead>
<tr>
<th></th>
<th>Deployment 1 Pod</th>
<th>Deployment 2 Pod</th>
<th>Node group 1 (ng1)</th>
<th>Node group 2 (ng2)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Tolerance</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>key:</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>classified_workload, value: true, effect: NoSchedule</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>key:</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>machine_learning_workload, value: true, effect: NoSchedule</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Node affinity</strong></td>
<td>key:</td>
<td>None</td>
<td>nodeGroups.name = ng1</td>
<td></td>
</tr>
<tr>
<td>key:</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>alpha.eksctl.io/nodegroup-name = ng1;</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Taint</strong></td>
<td></td>
<td></td>
<td>key:</td>
<td></td>
</tr>
<tr>
<td>key:</td>
<td></td>
<td></td>
<td>classified_workload, value: true, effect: NoSchedule</td>
<td></td>
</tr>
<tr>
<td>key:</td>
<td></td>
<td></td>
<td>machine_learning_workload, value: true, effect: NoSchedule</td>
<td></td>
</tr>
</tbody>
</table>

396
1. The Deployment 1 Pod has tolerations and node affinity defined, which instructs the Kubernetes scheduler to place the deployment Pods on the Node group 1 (ng1) nodes.

2. Node group 2 (ng2) doesn't have a node label that matches the node affinity node selector expression for Deployment 1, so the Pods will not be scheduled on ng2 nodes.

3. The Deployment 2 Pod doesn't have any tolerations or node affinity defined in the deployment manifest. The scheduler will reject scheduling Deployment 2 Pods on Node group 1 because of the taints on the nodes.

4. The Deployment 2 Pods will be placed on Node group 2 instead, because the nodes don't have any taints.

This pattern demonstrates that by using taints and tolerations, combined with node affinity, you can control placement of Pods on specific sets of worker nodes.

**Tools**

**AWS services**

- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

- **Amazon Elastic Container Registry (Amazon ECR)** is a managed container image registry service that's secure, scalable, and reliable.

- **Amazon Elastic Kubernetes Service (Amazon EKS)** helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.

- **eksctl** is AWS equivalent of kubectl and helps with creating EKS.

**Other tools**

- **Docker** is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.

- **kubectl** is a command-line interface that helps you run commands against Kubernetes clusters.

<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
</tbody>
</table>
| Check the deployment. | 1. To check if the pods are READY, run the following command.  
   ```bash
   kubectl get pods -o wide
   ```
   If the POD is ready, the output should look similar to the following, with the STATUS as Running.  
   |   NAME        | READY |
   |             | STATUS | RESTARTS  |
   | <pod_name>  | 1/1    | 0         |
   | Running     |      |           |
   | 12d         |      |           |
   | 192.168.18.50 |      |           |
   | ip-192-168-20-110.us-west-1.compute.internal |      |           |
   | <none>       |      |           |
   | <none>       |      |           |
   |
   Note the name of the Pod and the name of the node. You can skip the next step.  
   2. (Optional) To get additional details about the Pod and check the tolerations on the Pod, run the following command.  
   ```bash
   kubectl describe pod <pod_name>
   ```
   An example of the output is in the Additional information (p. 405) section.  
   3. To validate that the Pod placement on the node is correct, run the following command.  
   ```bash
   kubectl describe node <node name> | grep -A 1 "Taints"
   ```
   Confirm that the taint on the node matches toleration, and the label on the node matches the node affinity defined in deployment.yaml. | App developer, DevOps engineer, AWS DevOps |

```
## AWS Prescriptive Guidance Patterns

### Troubleshooting

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Deploy the second deployment .yaml file, and validate Pod placement | 1. Run the following command.  
```  
kubectl apply -f deploy_no_taint.yaml  
```  
2. After the deployment is successful, run the same commands that you ran previously to check the Pod placement in a node group with no taint.  
```  
kubectl describe node <node_name> | grep "Taints"  
```  
The output should be the following.  
Taints: <none>  
This completes the testing. | App developer, AWS DevOps, DevOps engineer |

### Clean up resources

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clean up the resources.</td>
<td>To avoid incurring AWS charges for resources that are left running, use the following command.</td>
<td>AWS DevOps, App developer</td>
</tr>
</tbody>
</table>

```  
eksctl delete cluster --name <Name of the cluster> --region <region-code>  
```  

### Troubleshooting

<table>
<thead>
<tr>
<th>Issue</th>
<th>Solution</th>
</tr>
</thead>
</table>
| Some of these commands might not run if your system uses arm64 architecture (especially if you are running this on an M1 Mac). The following line might error out. | If you have errors when running the Dockerfile, replace the FROM line with the following line.  
```  
FROM adoptopenjdk/openjdk11:jdk-11.0.14.1_1-alpine  
```  
```  
FROM bellsoft/liberica-openjdk-alpine-musl:17  
```

Replicate filtered Amazon ECR container images across accounts or Regions

Summary

Amazon Elastic Container Registry (Amazon ECR) can replicate all container images in an image repository across Amazon Web Services (AWS) Regions and AWS accounts natively, by using the cross-Region and cross-account replication features. (For more information, see the AWS blog post Cross region replication in Amazon ECR has landed.) However, there is no way to filter the images that are copied across AWS Regions or accounts based on any criteria.

This pattern describes how to replicate container images that are stored in Amazon ECR across AWS accounts and Regions, based on image tag patterns. The pattern uses Amazon CloudWatch Events to listen for push events for images that have a predefined, custom tag. A push event starts an AWS CodeBuild project and passes the image details to it. The CodeBuild project copies the images from the source Amazon ECR registry to the destination registry based on the details provided.

This pattern copies images that have specific tags across accounts. For example, you can use this pattern to copy only production-ready, secure images to the production AWS account. In the development account, after images are thoroughly tested, you can add a predefined tag to the secure images and use the steps in this pattern to copy the marked images to the production account.

Prerequisites and limitations

Prerequisites

- An active AWS account for source and destination Amazon ECR registries
- Administrative permissions for the tools used in this pattern
- Docker installed on your local machine for testing
- AWS Command Line Interface (AWS CLI), for authenticating into Amazon ECR

Limitations

- This pattern watches the push events of the source registry in only one AWS Region. You can deploy this pattern to other Regions to watch registries in those Regions.
- In this pattern, one Amazon CloudWatch Events rule listens for a single image tag pattern. If you want to check for multiple patterns, you can add events to listen for additional image tag patterns.

Architecture

Target architecture
Automation and scale

This pattern can be automated with an infrastructure as code (IaC) script and deployed at scale. To use AWS CloudFormation templates to deploy this pattern, download the attachment and follow the instructions in the Additional information (p. 417) section.

You can point multiple Amazon CloudWatch Events events (with different custom event patterns) to the same AWS CodeBuild project to replicate multiple image tag patterns, but you will need to update the secondary validation in the buildspec.yaml file (which is included in the attachment and in the Tools (p. 408) section) as follows to support multiple patterns.

```bash
... if [[ ${IMAGE_TAG} != release-* ]]; then
...
```

Tools

Amazon services

- **IAM** – AWS Identity and Access Management (IAM) enables you to manage access to AWS services and resources securely. In this pattern, you would need to create the cross-account IAM role that AWS CodeBuild will assume when pushing container images to the destination registry.

- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is a fully managed container registry that makes it easy to store, manage, share, and deploy your container images and artifacts anywhere. Image push actions to the source registry send system event details to the event bus that is picked up by Amazon CloudWatch Events.

- **AWS CodeBuild** – AWS CodeBuild is a fully managed continuous integration service that provides compute power to perform jobs such as compiling source code, running tests, and producing artifacts that are ready to be deployed. This pattern uses AWS CodeBuild to perform the copy action from the source Amazon ECR registry to the destination registry.

- **CloudWatch Events** – Amazon CloudWatch Events delivers a stream of system events that describe changes in AWS resources. This pattern uses rules to match Amazon ECR push actions with a specific image tag pattern.
Tools

- **Docker CLI** – Docker is a tool that makes it easier to create and manage containers. Containers pack an application and all its dependencies into one unit or package that can easily be deployed on any platform that supports the container runtime.

Code

You can implement this pattern in two ways:

- Automated setup: Deploy the two AWS CloudFormation templates provided in the attachment. For instructions, see the Additional information (p. 417) section.
- Manual setup: Follow the steps in the Epics (p. 410) section.

Sample buildspec.yaml

If you’re using the CloudFormation templates that are provided with this pattern, the buildspec.yaml file is included in the CodeBuild resources.

```yaml
version: 0.2
env:
  shell: bash
phases:
  install:
    commands:
      - export CURRENT_ACCOUNT=$(echo ${CODEBUILD_BUILD_ARN} | cut -d':' -f5)
      - export CURRENT_ECR_REGISTRY=${CURRENT_ACCOUNT}.dkr.ecr.
          ${AWS_REGION}.amazonaws.com
      - export DESTINATION_ECR_REGISTRY=${DESTINATION_ACCOUNT}.dkr.ecr.
          ${DESTINATION_REGION}.amazonaws.com
  pre_build:
    on-failure: ABORT
    commands:
      - echo "Validating Image Tag ${IMAGE_TAG}"
      - if [[ ${IMAGE_TAG} != release-* ]]; then
          aws codebuild stop-build --id ${CODEBUILD_BUILD_ID}
          sleep 60
          exit 1
        fi
      - aws ecr get-login-password --region ${AWS_REGION} | docker login -u AWS --
          password-stdin ${CURRENT_ECR_REGISTRY}
      - docker pull ${CURRENT_ECR_REGISTRY}/${REPO_NAME}:${IMAGE_TAG}
  build:
    commands:
      - echo "Assume cross-account role"
      - CREDENTIALS=$(aws sts assume-role --role-arn ${CROSS_ACCOUNT_ROLE_ARN} --role-
          session-name Rolesession)
      - export AWS_DEFAULT_REGION=${DESTINATION_REGION}
      - export AWS_ACCESS_KEY_ID=$(echo $CREDENTIALS | jq -r '.Credentials.AccessKeyId')
      - export AWS_SECRET_ACCESS_KEY=$(echo $CREDENTIALS | jq -r '.Credentials.SecretAccessKey')
      - export AWS_SESSION_TOKEN=$(echo $CREDENTIALS | jq -r '.Credentials.SessionToken')
      - echo "Logging into cross-account registry"
      - aws ecr get-login-password --region ${DESTINATION_REGION} | docker login -u AWS
          --password-stdin ${DESTINATION_ECR_REGISTRY}
      - echo "Check if Destination Repository exists, else create"
      - aws ecr describe-repositories --repository-names ${REPO_NAME} --region
          ${DESTINATION_REGION}
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a CloudWatch Events role.</td>
<td>In the source AWS account, create an IAM role for Amazon CloudWatch Events to assume. The role should have permissions to start an AWS CodeBuild project.</td>
<td>AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect, DevOps engineer</td>
</tr>
</tbody>
</table>

To create the role by using the AWS CLI, follow the instructions in the IAM documentation.

Example trust policy (trustpolicy.json):

```json
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {"Service": "events.amazonaws.com"},
    "Action": 
    "sts:AssumeRole"
  }
}
```

Example permission policy (permissionpolicy.json):

```json
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "codebuild:StartBuild",
    "Resource": "<CodeBuild Project ARN>"
  }
}
```

| Create a CodeBuild role. | Create an IAM role for AWS CodeBuild to assume, by following the instructions in the IAM documentation. The role should have the following permissions: | AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect, DevOps engineer |

```bash
|| aws ecr create-repository --repository-name ${REPO_NAME} --region ${DESTINATION_REGION} 
- echo "retag image and push to destination"
- docker tag ${CURRENT_ECR_REGISTRY}/${REPO_NAME}:${IMAGE_TAG} ${DESTINATION_ECR_REGISTRY}/${REPO_NAME}:${IMAGE_TAG} 
- docker push ${DESTINATION_ECR_REGISTRY}/${REPO_NAME}:${IMAGE_TAG} 
```
<table>
<thead>
<tr>
<th>Task</th>

<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td>Create a cross-account role.</td>
<td>In the destination AWS account, create an IAM role for the AWS CodeBuild role for the source account to assume. The cross-account role should allow container images to create a new repository and upload container images to Amazon ECR. To create the IAM role by using the AWS CLI, follow the instructions in the IAM documentation. To allow the AWS CodeBuild project from the previous step, use the following trust policy:</td>
<td>AWS administrator, AWS DevOps, Cloud administrator, Cloud architect, DevOps engineer, AWS systems administrator</td>
</tr>
</tbody>
</table>

```json
{  
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {
      "AWS": "<ARN of source codebuild role>"
    },
    "Action": "sts:AssumeRole"
  }
}
```

To allow the AWS CodeBuild project from the previous step to save images in the destination registry, use the following permission policy:

```json
{  
  "Version": "2012-10-17",
  "Statement": [
    {  
      "Action": [  
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchCheckLayerAvailability",
        "ecr:PutImage",
        "ecr:InitiateLayerUpload",
        "ecr:UploadLayerPart",
        "ecr:CompleteLayerUpload",
        "ecr:GetRepositoryPolicy",
```
Create the CodeBuild project

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a CodeBuild project. | Create a AWS CodeBuild project in the source account by following the instructions in the AWS CodeBuild documentation. The project should be in the same Region as the source registry. Configure the project as follows:  
  - Environment type: LINUX CONTAINER  
  - Service role: CodeBuild Role  
  - Privileged mode: true  
  - Environment image: aws/codebuild/standard:x.x (use the latest image available)  
  - Environment variables:  
    - CROSS_ACCOUNT_ROLE_ARN: The Amazon Resource Name (ARN) of the cross-account role  
    - DESTINATION_REGION: The name of the cross-account Region  
    - DESTINATION_ACCOUNT: The number of the destination account  
  - Build specifications: Use the buildspec.yaml file listed in the Tools (p. 408) section.                                                                 | AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect, DevOps engineer                                                                                                                                                                           |
Create the event

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an events rule.| Because the pattern uses the content filtering feature, you need to create the event by using Amazon EventBridge. Create the event and target by following the instructions in the EventBridge documentation, with a few modifications:  
  - For **Define pattern**, choose Event Pattern, and then choose Custom pattern.  
  - Copy the following custom events pattern sample code into the text box provided:  
    ```json
    {
      "source": ["aws.ecr"],
      "detail-type": ["ECR Image Action"],
      "detail": {
        "action-type": ["PUSH"],
        "result": ["SUCCESS"],
        "image-tag": [
          { "prefix": "release-"}
        ]
      }
    }
    ```  
  - For **Select targets**, choose the AWS CodeBuild project, and paste the ARN for the AWS CodeBuild project that you created in the previous epic.  
  - For **Configure Input**, choose Input Transformer.  
    - In the **Input Path** text box, paste:  
      ```json
      {"IMAGE_TAG":"$.detail.image-tag","REPO_NAME":"$.detail.repository-name"}
      ```  
    - In the **Input Template** text box, paste:  
      ```json
      {"environmentVariablesOverride": [ {
        "name": "IMAGE_TAG",
        "value":<IMAGE_TAG>},
        {"name": "REPO_NAME",
        "value":<REPO_NAME>}]}
      ```  
  - Choose **Use existing role**, and choose the name of the CloudWatch Events role you | AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect, DevOps engineer |

</tbody>
</table>

### Related resources

- [Getting started with CodeBuild](#)
- [Getting started with Amazon EventBridge](#)
- [Content-based filtering in Amazon EventBridge event patterns](#)
- [Delegate access across AWS accounts using IAM roles](#)
Additional information

To automatically deploy the resources for this pattern, follow these steps:

1. Download the attachment and extract the two CloudFormation templates: `part-1-copy-tagged-images.yaml` and `part-2-destination-account-role.yaml`.
2. Log in to the AWS CloudFormation console, and deploy `part-1-copy-tagged-images.yaml` in the same AWS account and Region as the source Amazon ECR registries. Update the parameters as needed. The template deploys the following resources:
   - Amazon CloudWatch Events IAM role
   - AWS CodeBuild project IAM role
   - AWS CodeBuild project
   - AWS CloudWatch Events rule
3. Take note of the value of `SourceRoleName` in the Outputs tab. You will need this value in the next step.
4. Deploy the second CloudFormation template, `part-2-destination-account-role.yaml`, in the AWS account that you want to copy the Amazon ECR container images to. Update the parameters as needed. For the `SourceRoleName` parameter, specify the value from step 3. This template deploys the cross-account IAM role.
5. Validate image replication and exclusion, as described in the last step of the Epics (p. 410) section.

Rotate database credentials without restarting containers

Summary

On the Amazon Web Services (AWS) Cloud, you can use AWS Secrets Manager to rotate, manage, and retrieve database credentials throughout their lifecycle. Users and applications retrieve secrets with a call to the Secrets Manager API, removing the need to hardcode sensitive information in plaintext.

If you’re using containers for microservice workloads, you can securely store credentials in AWS Secrets Manager. To separate out configuration from code, these credentials are commonly injected into the container. However, it’s important to rotate your credentials periodically and automatically. It’s also important to support the ability to refresh credentials after revocation. At the same time, applications require the ability to rotate credentials while reducing any potential downstream availability impact.

This pattern describes how to rotate your secrets that are secured with AWS Secrets Manager within your containers without requiring your containers to restart. In addition, this pattern reduces the number of credential lookups to Secrets Manager by using the Secrets Manager client-side caching component. When you use the client-side caching component to refresh the credentials within the application, the container doesn’t need to be restarted to fetch a rotated credential.

This approach works for Amazon Elastic Kubernetes Service (Amazon EKS) and Amazon Elastic Container Service (Amazon ECS).

Two scenarios are covered. In the single-user scenario, the database credential is refreshed on secret rotation by detecting the expired credential. The credential cache is instructed to refresh the secret, and then the application re-establishes the database connection. The client-side caching component caches the credential within the application and helps avoid reaching out to Secrets Manager for each credential lookup. The credential is rotated within the application without the need to force the credential refresh by restarting the container.

The second scenario rotates the secret by alternating between two users. Having two active users reduces the potential for downtime, because one user’s credentials are always active. Two-user credential rotation is helpful when you have a large deployment with clusters in which there might be a small propagation delay of credential updates.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An application running in a container in Amazon EKS or Amazon ECS.
• Credentials stored in Secrets Manager, with rotation enabled.
• A second set of credentials stored in Secrets Manager, if deploying the two-user solution. Code examples can be found in the GitHub repo aws-secrets-manager-rotation-lambdas.
• An Amazon Aurora database.

Limitations
• This example is targeted for Python applications. For Java applications, you can use the Java client-side caching component or the JDBC client-side caching library for Secrets Manager.

Architecture

Target architecture

Scenario 1 – Rotation of a credential for a single user

In the first scenario, a single database credential is periodically rotated by Secrets Manager. The application container runs in Fargate. When the first database connection is established, the application container fetches the database credential for Aurora. The Secrets Manager caching component then caches the credential for future connection establishment. When rotation period has elapsed, the credential expires and the database returns an authentication error. The application then fetches the rotated credential, invalidates the cache, and updates the credential cache via the Secrets Manager client-side caching component.

In this scenario, there might be a minimal disruption while the credential is being rotated and stale connections are using the outdated credential. This concern can be addressed by using the two-user scenario.

Scenario 2 – Rotation of credentials for two users
In the second scenario, two database user credentials (Alice's and Bob's) are periodically rotated by Secrets Manager. The application container runs in a Fargate cluster. When the first database connection is established, the application container fetches the Aurora database credential for the first user (Alice). The Secrets Manager caching component then caches the credential for future connection establishment. Although there are two users and credentials, one only active credential is managed by Secrets Manager. In this case, the caching component periodically expires and fetches the latest credential. If the Secrets Manager rotation period is longer than the cache timeout, the caching component picks up the rotated credential for the second user (Bob). For example, if the cache expiration is measured in minutes and the rotation period is measured in days, the caching component fetches the new credential as part of its periodic cache refresh. In this way, the downtime is minimized because each user's credential is active for one Secrets Manager rotation.

**Automation and scale**

You can use [AWS CloudFormation](https://aws.amazon.com/cloudformation/) to deploy this pattern by using infrastructure as code. This builds and creates the application container, creates the Fargate task, deploys the container into Fargate, and sets up and configure Secrets Manager with Aurora. For step-by-step deployment instructions, see the [readme](https://aws.amazon.com/) file.

**Tools**

- **AWS Secrets Manager** enables the replacement of hardcoded credentials, including passwords, with an API call to Secrets Manager to retrieve the secret. Because Secrets Manager can automatically rotate the secret according to a schedule, you can replace long-term secrets with short-term ones, reducing the risk of compromise.
- **Docker** helps developers to pack, ship, and run any application as a lightweight, portable, and self-sufficient container.
This pattern uses the Python client-side caching component for Secrets Manager to retrieve the authentication credentials when establishing the database connection. The client-side caching component helps avoid reaching out to Secrets Manager each time.

Now, when the rotation period elapses, the cached credential will be expired, and connecting to the database will result in an authentication error. For MySQL, the authentication error code is 1045. This example uses Amazon Aurora for MySQL, though you could use another engine such as PostgreSQL. Upon the authentication error, the database connection exception handling code catches the error. It then informs the Secrets Manager client-side caching component to refresh the secret, then to reauthenticate and re-establish the database connection. If you are using PostgreSQL or another engine, you must look up the corresponding authentication error code.

The container application can now update the database password with the rotated password without restarting the container.

Place the following code in your application code that handles database connections. This example uses Django, and it subclasses the database backend with a database wrapper for connections. If you are using a different programming language or database connection library, see your database connection library to review how to subclass database connection retrieval.

```python
def get_new_connection(self, conn_params):
    try:
        logger.info("get connection")
        databasecredentials.get_conn_params_from_secrets_manager(conn_params)
        conn = super(DatabaseWrapper, self).get_new_connection(conn_params)
        return conn
    except MySQLdb.OperationalError as e:
        error_code=e.args[0]
        if error_code!=1045:
            raise e

        logger.info("Authentication error. Going to refresh secret and try again.")
        databasecredentials.refresh_now()
        databasecredentials.get_conn_params_from_secrets_manager(conn_params)
        conn=super(DatabaseWrapper, self).get_new_connection(conn_params)
        logger.info("Successfully refreshed secret and established new database connection.")
        return conn
```

Run Amazon ECS tasks on Amazon WorkSpaces with Amazon ECS Anywhere

Summary

Amazon Elastic Container Service (Amazon ECS) Anywhere supports the deployment of Amazon ECS tasks in any environment, including Amazon Web Services (AWS) managed infrastructure and customer managed infrastructure. You can do this while using a fully AWS managed control plane that’s running in the cloud and always up to date.

Enterprises often use Amazon WorkSpaces for developing container-based applications. This has required Amazon Elastic Compute Cloud (Amazon EC2) or AWS Fargate with an Amazon ECS cluster to test and run ECS tasks. Now, by using Amazon ECS Anywhere, you can add Amazon WorkSpaces as external instances directly to an ECS cluster, and you can run your tasks directly. This reduces your development time, because you can test your container with an ECS cluster locally on Amazon WorkSpaces. You can also save the cost of using EC2 or Fargate instances for testing your container applications.

This pattern showcases how to deploy ECS tasks on Amazon WorkSpaces with Amazon ECS Anywhere. It sets up the ECS cluster and uses AWS Directory Service Simple AD to launch the WorkSpaces. Then the example ECS task launches NGINX in the WorkSpaces.

Prerequisites and limitations

- An active AWS account
- AWS Command Line Interface (AWS CLI)
- AWS credentials configured on your machine

Architecture

Target technology stack

- A virtual private cloud (VPC)
- An Amazon ECS cluster
- Amazon WorkSpaces
- AWS Directory Service with Simple AD

Target architecture
The architecture includes the following services and resources:

- An ECS cluster with public and private subnets in a custom VPC
- Simple AD in the VPC to provide user access to Amazon WorkSpaces
- Amazon WorkSpaces provisioned in the VPC using Simple AD
- AWS Systems Manager activated for adding Amazon WorkSpaces as managed instances
- Using Amazon ECS and AWS Systems Manager Agent (SSM Agent), Amazon WorkSpaces added to Systems Manager and the ECS cluster
- An example ECS task to run in the WorkSpaces in the ECS cluster

**Tools**

- **AWS Directory Service Simple Active Directory (Simple AD)** is a standalone managed directory powered by a Samba 4 Active Directory Compatible Server. Simple AD provides a subset of the features offered by AWS Managed Microsoft AD, including the ability to manage users and to securely connect to Amazon EC2 instances.
- **Amazon Elastic Container Service (Amazon ECS)** is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- **AWS Systems Manager** helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.
- **Amazon WorkSpaces** helps you provision virtual, cloud-based Microsoft Windows or Amazon Linux desktops for your users, known as WorkSpaces. WorkSpaces eliminates the need to procure and deploy hardware or install complex software.

Run an ASP.NET Core web API Docker container on an Amazon EC2 Linux instance

Created by Vijai Anand Ramalingam (AWS) and Sreelaxmi Pai (AWS)

<table>

</tr>
</tbody>
</table>

Summary

This pattern is for people who are starting to containerize their applications on the Amazon Web Services (AWS) Cloud. When you begin to containerize apps on cloud, usually there are no container orchestrating platforms set up. This pattern helps you quickly set up infrastructure on AWS to test your containerized applications without needing an elaborate container orchestrating infrastructure.

The first step in the modernization journey is to transform the application. If it's a legacy .NET Framework application, you must first change the runtime to ASP.NET Core. Then do the following:

- Create the Docker container image
- Run the Docker container using the built image
- Validate the application before deploying it on any container orchestration platform, such as Amazon Elastic Container Service (Amazon ECS) or Amazon Elastic Kubernetes Service (Amazon EKS).

This pattern covers the build, run, and validate aspects of modern application development on an Amazon Elastic Compute Cloud (Amazon EC2) Linux instance.

Prerequisites and limitations

Prerequisites

- An active [Amazon Web Services (AWS) account](https://aws.amazon.com)
- An [AWS Identity and Access Management (IAM) role](https://docs.aws.amazon.com/IAM/latest/UserGuide/index.html) with sufficient access to create AWS resources for this pattern
- [Visual Studio Community 2022](https://visualstudio.microsoft.com/downloads/) or later downloaded and installed
- A .NET Framework project modernized to ASP.NET Core
- A GitHub repository

Product versions

- Visual Studio Community 2022 or later
Architecture

Target architecture

This pattern uses an AWS CloudFormation template to create the highly available architecture shown in the following diagram. An Amazon EC2 Linux instance is launched in a private subnet. AWS Systems Manager Session Manager is used to access the private Amazon EC2 Linux instance and to test the API running in the Docker container.

1. Access to the Linux instance through Session Manager

Tools

AWS services

- AWS Command Line Interface – AWS Command Line Interface (AWS CLI) is an open source tool for interacting with AWS services through commands in your command line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console.
- AWS Management Console – The AWS Management Console is a web application that comprises and refers to a broad collection of service consoles for managing AWS resources. When you first sign in, you see the console home page. The home page provides access to each service console and offers a single place to access the information you need to perform your AWS related tasks.
- AWS Systems Manager Session Manager – Session Manager is a fully managed AWS Systems Manager capability. With Session Manager, you can manage your Amazon Elastic Compute Cloud (Amazon EC2) instances. Session Manager provides secure and auditable node management without the need to open inbound ports, maintain bastion hosts, or manage SSH keys.

Other tools

- Visual Studio 2022 – Visual Studio 2022 is an integrated development environment (IDE).
- Docker – Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.

### Build and run the Docker container.

**Description:** To build the Docker image and run the container inside the Amazon EC2 Linux instance, do the following:

1. To create the Docker image, run the following command.
   
   ```bash
docker build -t aspnetcorewebapiimage -f Dockerfile .
   ```

2. To view all the Docker images, run the following command.
   
   ```bash
docker images
   ```

3. To create and run the container, run the following command.
   
   ```bash
docker run -d -p 80:80 --name aspnetcorewebapicontainer aspnetcorewebapiimage
   ```

**Skills required:** App developer, AWS administrator, AWS DevOps

### Test the web API

**Description:** To test the web API, run the following command.

```bash
curl -X GET "http://localhost/WeatherForecast" -H "accept: text/plain"
```

**Note:** You can get the curl commands for each endpoint from Swagger when you are running it locally.

### Clean up resources

**Description:** Delete the stack to remove all the resources. This ensures

**Skills required:** AWS administrator, AWS DevOps

Run message-driven workloads at scale by using AWS Fargate

Created by Stan Zubarev (AWS)

Environment: PoC or pilot  Technologies: Containers & microservices; Messaging & communications; Databases  AWS services: AWS Fargate; Amazon SQS; Amazon DynamoDB

Summary

This pattern shows how to run message-driven workloads at scale in the AWS Cloud by using containers and AWS Fargate.

Using containers to process data can be helpful when the amount of data an application processes exceeds the limitations of function-based serverless compute services. For example, if an application requires more compute capacity or processing time than what AWS Lambda offers, using Fargate can improve performance.

The following example setup uses the AWS Cloud Development Kit (AWS CDK) in TypeScript to configure and deploy the following resources in the AWS Cloud:

- A Fargate service
- An Amazon Simple Queue Service (Amazon SQS) queue
- An Amazon DynamoDB table.
- An Amazon CloudWatch dashboard

The Fargate service receives and processes messages from the Amazon SQS queue, then stores them in the Amazon DynamoDB table. You can monitor how many Amazon SQS messages are processed and how many DynamoDB items are created by Fargate by using the CloudWatch dashboard.

Note: You can also use this pattern's example code to build more complex data processing workloads in event-driven serverless architectures. For more information, see Run event-driven and scheduled workloads at scale with AWS Fargate.

Prerequisites and limitations

Prerequisites

- An active AWS account
- The latest version of the AWS Command Line Interface (AWS CLI), installed and configured on your local machine
- Git, installed and configured on your local machine
- The AWS CDK, installed and configured on your local machine
- Go, installed and configured on your local machine
- Docker, installed and configured on your local machine
Architecture

Target technology stack

- Amazon SQS
- AWS Fargate
- Amazon DynamoDB

Target architecture

The following diagram shows an example workflow for running message-driven workloads at scale in the AWS Cloud by using Fargate:

The diagram shows the following workflow:

1. The Fargate service uses Amazon SQS long polling to receive messages from an Amazon SQS queue.
2. The Fargate service then processes the Amazon SQS messages and stores them in a DynamoDB table.

Automation and scale

To automate scaling your Fargate task count, you can configure Amazon Elastic Container Service (Amazon ECS) Service Auto Scaling. It's a best practice to configure the scaling policy based on the number of visible messages in your application's Amazon SQS queue.

For more information, see Scaling based on Amazon SQS in the Amazon EC2 Auto Scaling User Guide.

Tools

AWS services

- **AWS Fargate** helps you run containers without needing to manage servers or Amazon Elastic Compute Cloud (Amazon EC2) instances. It's used in conjunction with Amazon Elastic Container Service (Amazon ECS).
• **Amazon Simple Queue Service (Amazon SQS)** provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.

• **Amazon DynamoDB** is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

• **Amazon CloudWatch** helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.

**Code**

The code for this pattern is available in the GitHub [sqs-fargate-ddb-cdk-go](https://github.com/aws-samples/sqs-fargate-ddb-cdk-go) repository.

**Epics**

Create and deploy the resources by using the AWS CDK

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Clone the GitHub repository. | Clone the GitHub [sqs-fargate-ddb-cdk-go](https://github.com/aws-samples/sqs-fargate-ddb-cdk-go) repository to your local machine by running the following command:  
`git clone https://github.com/aws-samples/sqs-fargate-ddb-cdk-go.git` | App developer |
| Verify that the AWS CLI is configured to the correct AWS account and that the AWS CDK has the required permissions. | To check if your AWS CLI configuration settings are correct, you can run the following Amazon Simple Storage Service (Amazon S3) `ls` command:  
`aws s3 ls`  
This procedure also requires the AWS CDK to have permissions to provision infrastructure within your AWS account. To grant the required permissions, you must create named AWS profile in AWS CLI and export it as an `AWS_PROFILE` environment variable.  
**Note:** If you haven't used the AWS CDK in your AWS account before, you must first provision the required AWS CDK resources. For more information, see [Bootstrapping](https://docs.aws.amazon.com/cdk/v2/en/userguide/management-console-bootstapguide.html) in the [AWS CDK v2 Developer Guide](https://docs.aws.amazon.com/cdk/v2/en/userguide/). | App developer |
### Deploy the AWS CDK stack to your AWS account.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| 1. **Build a container image** by running the following AWS CLI command:  
   ```bash
docker build -t go-fargate .
```
| **App developer** | |
| 2. **Open the AWS CDK directory** by running the following command:  
   ```bash
cd cdk
```
| 3. **Install the required npm modules** by running the following command:  
   ```bash
npm i
```
| 4. **Deploy the AWS CDK pattern** to your AWS account by running the following command:  
   ```bash
cdk deploy --profile ${AWS_PROFILE}
```
| **App developer** | |

### Test the setup

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Send a test message to the Amazon SQS queue.**  

For instructions, see [Sending messages to a queue (console)](https://docs.aws.amazon.com/sqs/latest/userguide/sqs-console.html) in the *Amazon SQS Developer Guide*.  

**Test Amazon SQS message example**  
```json
{
   "message": "Hello, Fargate"
}
```
| **App developer** | |
| **Verify that the test message appears in the Fargate service's CloudWatch logs.**  

Follow the instructions in [Viewing CloudWatch Logs](https://docs.aws.amazon.com/ecs/latest/userguide/viewing-cloudwatch-logs.html) in the *Amazon ECS Developer Guide*. Make sure that you review the logs for the `go-fargate-service` log group in the `go-service-cluster` ECS cluster.
| **App developer** | |
| **Verify that the test message appears in the DynamoDB table.**  

1. Open the [DynamoDB console](https://console.aws.amazon.com/dynamodb/).  
2. In the left navigation pane, choose Tables. Then, select

```json
{
   "message": "Hello, Fargate"
}
```
<table>
<thead>
<tr>
<th>Task</th>

Run stateful workloads with persistent data storage by using Amazon EFS on Amazon EKS with AWS Fargate

*Created by Ricardo Morais (AWS) and Lucio Pereira (AWS)*

**Summary**

This pattern provides guidance for enabling Amazon Elastic File System (Amazon EFS) as a storage device for containers that are running on Amazon Elastic Kubernetes Service (Amazon EKS), using AWS Fargate to provision your compute resources.

The setup described in this pattern follows security best practices and provides security at rest and security in transit by default. To encrypt your Amazon EFS file system, it uses an AWS Key Management Service (AWS KMS) key, but you can also specify a key alias that dispatches the process of creating a KMS key.

You can follow the steps in this pattern to create a namespace and Fargate profile for a proof-of-concept (PoC) application, install the Amazon EFS Container Storage Interface (CSI) driver that is used to integrate the Kubernetes cluster with Amazon EFS, configure the storage class, and deploy the PoC application. These steps result in an Amazon EFS file system that is shared among multiple Kubernetes workloads, running over Fargate. The pattern is accompanied by scripts that automate these steps.

You can use this pattern whenever you want to ensure data persistence in your containerized applications, and avoid data loss in scale-in or scale-out operations. For example:

- DevOps tools – A common scenario is to use Jenkins as a continuous integration and continuous delivery (CI/CD) tool. In this case, you can use Amazon EFS as a shared file system to store configurations among different instances of the CI/CD tool or to store a cache (for example, an Apache Maven repository) for pipeline stages among different instances of the CI/CD tool.

- Web servers – A common scenario is to use Apache as an HTTP web server. You can use Amazon EFS as a shared file system to store static files that are shared among different instances of the web server. In this example scenario, modifications are applied directly to the file system instead of static files being baked into a Docker image.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- An existing Amazon EKS cluster with Kubernetes version 1.17 or later
- Cluster administration permissions
• Context configured to point to the desired Amazon EKS cluster

Limitations

• You have to create the Amazon EFS file system before you can use the CSI driver to mount it inside a container as a persistent volume. Currently, the CSI driver doesn't provision the Amazon EFS file system automatically.

• There are some limitations to consider when you're using Amazon EKS with Fargate. For example, daemonsets and privileged containers aren't supported. For more information, see AWS Fargate considerations in the Amazon EKS documentation.

• The code provided with this pattern supports workstations that are running Linux or macOS.

Product versions

• AWS Command Line Interface (AWS CLI) version 2 or later
• Amazon EFS CSI driver version 1.0 or later
• eksctl version 0.24.0 or later
• jq version 1.6 or later
• kubectl version 1.17 or later
• Kubernetes version 1.17 or later

Architecture
The target architecture includes the following services and components, and follows AWS Well-Architected Framework best practices:

- Amazon EFS, which provides a simple, scalable, fully managed elastic NFS file system. This is used as a shared file system among all replications of the PoC application that are running in pods, which are distributed in the private subnets of the chosen Amazon EKS cluster.

- An Amazon EFS mount target for each private subnet. This provides redundancy per Availability Zone within the virtual private cloud (VPC) of the cluster.

- Amazon EKS, which runs the Kubernetes workloads. You must provision an Amazon EKS cluster before you use this pattern, as described in the Prerequisites section.

- AWS KMS, which provides encryption at rest for the content that's stored in the Amazon EFS file system.
• Fargate, which manages the compute resources for the containers so that you can focus on business requirements instead of infrastructure burden. The Fargate profile is created for all private subnets. It provides redundancy per Availability Zone within the virtual private cloud (VPC) of the cluster.
• Kubernetes pods, for validating that content can be shared, consumed, and written by different instances of an application.

**Tools**

**AWS CLI** – AWS Command Line Interface (AWS CLI) is an open-source tool that you can use to interact with AWS services from the command line.

**eksctl** – eksctl is a command-line utility for creating and managing Kubernetes clusters on Amazon EKS.

**kubectl** – kubectl is a command-line utility for communicating with the cluster API server.

**jq** – jq is a command-line tool for parsing JSON.

**AWS services**

• **Amazon EFS** – Amazon Elastic File System (Amazon EFS) manages file storage in the AWS Cloud. In this pattern, it provides a simple, scalable, fully managed, and shared file system for use with Amazon EKS.

• **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or operate your own clusters.

• **AWS Fargate** – AWS Fargate is a serverless compute engine for Amazon EKS. It creates and manages compute resources for your Kubernetes applications.

• **AWS KMS** – AWS Key Management Service (AWS KMS) is an encryption and key management service that helps you protect your application data.

**Code**

The code for this pattern is provided in a GitHub repo. The scripts are organized by epic, in the folders epic01 through epic06, corresponding to the order in the following section. For information about how to use the scripts to automate the epics in this pattern, see the Additional information section.

**Epics**

Create a Kubernetes namespace and a linked Fargate profile

<table>

</tbody>
</table>

Create a custom Fargate profile. Create a custom Fargate profile that is linked to the namespace you created. Kubernetes user with granted permissions |
Create an Amazon EFS file system

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generate an unique token.</td>
<td>Amazon EFS requires a creation token to ensure idempotent operation (calling the operation with the same creation token has no effect). To meet this requirement, you must generate an unique token through an available technique. For example, you can generate an universally unique identifier (UUID) to use as a creation token. After you create a token, you can run a script to automate the remaining steps in this epic; see the Additional information section.</td>
<td>System administrator</td>
</tr>
<tr>
<td>Create a KMS key.</td>
<td>(Optional) Create a unique, symmetric AWS KMS key in your AWS account and AWS Region. This key is used for file system encryption, so that the pattern can use a KMS key for handling encryption at rest. If it is not specified, an AWS managed key is used.</td>
<td>System administrator</td>
</tr>
<tr>
<td>Create an Amazon EFS file system.</td>
<td>Create the file system for receiving the data files that are read and written by the application workloads. You can create an encrypted or non-encrypted file system. (As a best practice, the code for this pattern creates an encrypted system to enable encryption at rest by default.)</td>
<td>System administrator</td>
</tr>
<tr>
<td>Create a security group.</td>
<td>Create a security group to allow the Amazon EKS cluster to access the Amazon EFS file system.</td>
<td>System administrator</td>
</tr>
</tbody>
</table>
| Update the inbound rule for the security group. | Update the inbound rules of the security group to allow incoming traffic for the following settings:  
  • TCP protocol: port 2049  
  • Source: CIDR block ranges for the private subnets in the VPC that contains the Kubernetes cluster | System administrator    |

GitHub tutorials and examples

• Static provisioning
• Encryption in transit
• Accessing the file system from multiple pods
• Consuming Amazon EFS in StatefulSets
• Mounting subpaths
• Using Amazon EFS access points

Required tools

• Installing the AWS CLI version 2
• Installing eksctl
• Installing kubectl
• Installing jq

Additional information

The scripts that automate the epics and stories for this pattern are included in a GitHub repo and described in the following sections.

Creating a Kubernetes namespace and a linked Fargate profile

Run the following script to implement these two steps:

```
./scripts/epic01/create-k8s-ns-and-linked-fargate-profile.sh \
- c "MY_CLUSTER_NAME"
```

where MY_CLUSTER_NAME is the name of your Amazon EKS cluster.

Creating an Amazon EFS file system

Use the create-efs.sh script to create an encrypted or non-encrypted Amazon EFS file system, after you generate a unique token for Amazon EFS.

*With encryption at rest, without a KMS key:*

```
./scripts/epic02/create-efs.sh \
- c "MY_CLUSTER_NAME" \ 
- t "MY_EFS_CREATION_TOKEN"
```

where MY_CLUSTER_NAME is the name of your Amazon EKS cluster and MY_EFS_CREATION_TOKEN is a unique creation token for the file system.

*With encryption at rest, with a KMS key:*
Additional information

```bash
./scripts/epic02/create-efs.sh \
  -c "MY_CLUSTER_NAME" \
  -t "MY_EFS_CREATION_TOKEN" \
  -k "MY_KMS_KEY_ALIAS"
```

where `MY_CLUSTER_NAME` is the name of your Amazon EKS cluster, `MY_EFS_CREATION_TOKEN` is a unique creation token for the file system, and `MY_KMS_KEY_ALIAS` is the alias for the KMS key.

**Without encryption:**

```bash
./scripts/epic02/create-efs.sh -d \
  -c "MY_CLUSTER_NAME" \
  -t "MY_EFS_CREATION_TOKEN"
```

where `MY_CLUSTER_NAME` is the name of your Amazon EKS cluster, `MY_EFS_CREATION_TOKEN` is a unique creation token for the file system, and `--d` disables encryption at rest.

**Installing Amazon EFS components into the Kubernetes cluster**

Run the following script to deploy the Amazon EFS CSI driver and the storage class into the cluster:

```bash
./scripts/epic03/create-k8s-efs-csi-sc.sh
```

This script uses the `kubectl` utility, so make sure that the context has been configured to point to the desired Amazon EKS cluster.

**Installing the PoC application**

Run the `deploy-poc-app.sh` script to deploy the persistent volume, the persistent volume claim, and the two workloads.

**With encryption in transit:**

```bash
./scripts/epic04/deploy-poc-app.sh \
  -t "MY_EFS_CREATION_TOKEN"
```

where `MY_EFS_CREATION_TOKEN` is the unique creation token for the file system.

**Without encryption in transit:**

```bash
./scripts/epic04/deploy-poc-app.sh -d \
  -t "MY_EFS_CREATION_TOKEN"
```

where `MY_EFS_CREATION_TOKEN` is the unique creation token for the file system, and `--d` disables encryption in transit.

**Validating file system persistence, durability, and shareability**

To validate that workload 1 is writing to `/data/out1.txt`:

```bash
kubectl exec -ti poc-app1 -n poc-efs-eks-fargate -- tail -f /data/out1.txt
```

The results will be similar to the following:

```
...  
Thu Sep  3 15:25:07 UTC 2020 - PoC APP 1
```
To validate that workload 2 is writing to /data/out2.txt:

```
kubectl exec -ti poc-app2 -n poc-efs-eks-fargate -- tail -f /data/out2.txt
```

The results will be similar to the following:

```
...  
Thu Sep 3 15:26:48 UTC 2020 - PoC APP 2  
Thu Sep 3 15:26:53 UTC 2020 - PoC APP 2  
Thu Sep 3 15:26:58 UTC 2020 - PoC APP 2  
...  
```

To validate that workload 1 can read the file written by workload 2:

```
kubectl exec -ti poc-app1 -n poc-efs-eks-fargate -- tail -n 3 /data/out2.txt
```

The results will be similar to the following:

```
...  
Thu Sep 3 15:26:48 UTC 2020 - PoC APP 2  
Thu Sep 3 15:26:53 UTC 2020 - PoC APP 2  
Thu Sep 3 15:26:58 UTC 2020 - PoC APP 2  
...  
```

To validate that workload 2 can read the file written by workload 1:

```
kubectl exec -ti poc-app2 -n poc-efs-eks-fargate -- tail -n 3 /data/out1.txt
```

The results will be similar to the following:

```
...  
Thu Sep 3 15:29:22 UTC 2020 - PoC APP 1  
Thu Sep 3 15:29:27 UTC 2020 - PoC APP 1  
Thu Sep 3 15:29:32 UTC 2020 - PoC APP 1  
...  
```

To validate that files are retained after you remove application components:

```
./scripts/epic05/validate-efs-content.sh  
   -t "MY_EFS_CREATION_TOKEN"
```

where MY_EFS_CREATION_TOKEN is the unique creation token for the file system.

The results will be similar to the following:

```
pod/poc-app-validation created  
Waiting for pod get Running state...  
Waiting for pod get Running state...  
Waiting for pod get Running state...  
Results from execution of 'find /data' on validation process pod:  
/data  
/data/out2.txt
```
Cleaning up resources

Run the clean-up-resources.sh script to remove all resources after you have finished using the PoC application.

**With encryption at rest, with a KMS key:**

```
./scripts/epic06/clean-up-resources.sh \
   -c "MY_CLUSTER_NAME" \
   -t "MY_EFS_CREATION_TOKEN" \
   -k "MY_KMS_KEY_ALIAS"
```

where `MY_CLUSTER_NAME` is the name of your Amazon EKS cluster, `MY_EFS_CREATION_TOKEN` is the creation token for the file system, and `MY_KMS_KEY_ALIAS` is the alias for the KMS key.

**Without encryption at rest:**

```
./scripts/epic06/clean-up-resources.sh \
   -c "MY_CLUSTER_NAME" \
   -t "MY_EFS_CREATION_TOKEN"
```

where `MY_CLUSTER_NAME` is the name of your Amazon EKS cluster and `MY_EFS_CREATION_TOKEN` is the creation token for the file system.

## Summary

Historically, there were two ways to move data into Splunk: a push or a pull architecture. A **pull architecture** offers delivery data guarantees through retries, but it requires dedicated resources in Splunk that poll data. Pull architectures usually are not real time because of the polling. A **push architecture** in typically has lower latency, is more scalable, and reduces operational complexity and costs. However, it doesn’t guarantee delivery and typically requires agents.

Splunk integration with Amazon Kinesis Data Firehose delivers real-time streaming data to Splunk through an HTTP event collector (HEC). This integration provides the advantages of both push and pull architectures—it guarantees data delivery through retries, is near real-time, and is low latency and low complexity. The HEC quickly and efficiently sends data over HTTP or HTTPS directly to Splunk. HECs are token-based, which eliminates the need to hardcode credentials in an application or in supporting files.

In an AWS Firewall Manager policy, you can configure logging for all of the AWS WAF web ACL traffic in all of your accounts, and you can then use a Kinesis Data Firehose delivery stream to send that log data to Splunk for monitoring, visualization, and analysis. This solution provides the following benefits:

- Central management and logging for AWS WAF web ACL traffic in all of your accounts
- Splunk integration with a single AWS account
- Scalability
- Near real-time delivery of log data
- Cost optimization through the use of a serverless solution, so you don’t have to pay for unused resources.

## Prerequisites and limitations

### Prerequisites

- An active AWS account that is part of an organization in AWS Organizations.
- You must have the following permissions to enable logging with Kinesis Data Firehose:
  - `iam:CreateServiceLinkedRole`
  - `firehose:ListDeliveryStreams`
  - `wafv2:PutLoggingConfiguration`
- AWS WAF and its web ACLs must be configured. For instructions, see [Getting started with AWS WAF](#).
AWS Prescriptive Guidance Patterns
Architecture

- AWS Firewall Manager must be setup. For instructions, see [AWS Firewall Manager prerequisites](#).
- The Firewall Manager security policies for AWS WAF must be configured. For instructions, see [Getting started with AWS Firewall Manager AWS WAF policies](#).
- Splunk must be setup with a public HTTP endpoint that can be reached by AWS Kinesis Data Firehose.

Limitations

- The AWS accounts must be managed in a single organization in AWS Organizations.
- The web ACL must be in the same Region as the delivery stream. If you are capturing logs for Amazon CloudFront, create the Firehose delivery stream in US East (N. Virginia) Region, `us-east-1`.
- The Splunk add-on for Amazon Kinesis Data Firehose is available for paid Splunk Cloud deployments, distributed Splunk Enterprise deployments, and single-instance Splunk Enterprise deployments. This add-on is not supported for free trial Splunk Cloud deployments.

Architecture

Target technology stack

- Firewall Manager
- Kinesis Data Firehose
- Amazon S3
- AWS WAF
- Splunk

Target architecture

The following image shows how you can use Firewall Manager to centrally log all AWS WAF data and send it to Splunk through Kinesis Data Firehose.

1. The AWS WAF web ACLs send firewall log data to Firewall Manager.
2. Firewall Manager sends the log data to Kinesis Data Firehose.
3. The Kinesis Data Firehose delivery stream forwards the log data to Splunk and to an S3 bucket. The S3 bucket acts as a backup in the event of an error with the Firehose delivery stream.

Automation and scale

This solution is designed to scale and accommodate all AWS WAF web ALCs within the organization. You can configure all web ACLs to use the same Amazon Kinesis Data Firehose instance. However, if you want to set up and use multiple Kinesis Data Firehose instances, you can.

Tools

AWS services

- **AWS Firewall Manager** is a security management service that helps you to centrally configure and manage firewall rules across your accounts and applications in AWS Organizations.
- **Amazon Kinesis Data Firehose** helps you deliver real-time streaming data to other AWS services, custom HTTP endpoints, and HTTP endpoints owned by supported third-party service providers, such as Splunk.
- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **AWS WAF** is a web application firewall that helps you monitor HTTP and HTTPS requests that are forwarded to your protected web application resources.

Other tools

- **Splunk** helps you monitor, visualize, and analyze log data.

Epics

Configure Splunk

<table>

### Application Firewall Add-on for Splunk

1. Install and configure the Splunk add-on for Kinesis Data Firehose. As part of the installation and configuration, if necessary for your Splunk platform, you set up an HTTP Event Collector and prepare the infrastructure to send the log data to your indexers. See the instructions that correspond to your Splunk deployment:
   - Splunk Cloud deployment (Splunk documentation)
   - Distributed Splunk Enterprise deployment (Splunk documentation)
   - Single-instance Splunk Enterprise deployment (Splunk documentation)

   **Important:** Stop this procedure after you have installed and configured the Splunk add-on. Do not proceed with the instructions for configuring Amazon Kinesis Data Firehose to send data to the Splunk platform.

2. Make note of the HTTP event collector token and the HTTP endpoint. You need this value later, when you configure the delivery stream.

Serve static content in an Amazon S3 bucket through a VPC by using Amazon CloudFront

Created by Angel Emmanuel Hernandez Cebrian

| Environment: | PoC or pilot | Technologies: | Content delivery; Security, identity, compliance; Serverless; Web hosting; Networking | AWS services: | Amazon CloudFront; Elastic Load Balancing (ELB); AWS Lambda |

Summary

When you serve static content that is hosted on Amazon Web Services (AWS), the recommended approach is to use an Amazon Simple Storage Service (S3) bucket as the origin and use Amazon CloudFront to distribute the content. There are two primary benefits of this solution. The first is the convenience of caching static content at edge locations. The second is that you can define web access control lists (web ACLs) for the CloudFront distribution, which helps you secure requests to the content with minimal configuration and administrative overhead.

However, there is a common architectural limitation to the standard, recommended approach. In some environments, you want virtual firewall appliances deployed in a virtual private cloud (VPC) to inspect all content, including static content. The standard approach doesn't route traffic through the VPC for inspection. This pattern provides an alternative architectural solution. You still use a CloudFront distribution to serve static content in an S3 bucket, but the traffic is routed through the VPC by using an Application Load Balancer. An AWS Lambda function then retrieves and returns the content from the S3 bucket.

Prerequisites and limitations

Prerequisites

• An active AWS account.
• Static website content hosted in an S3 bucket.

Limitations

• The resources in this pattern must be in a single AWS Region, but they can be provisioned in different AWS accounts.
• Limits apply to the maximum request and response size that the Lambda function can receive and send, respectively. For more information, see Limits in Lambda functions as targets (Elastic Load Balancing documentation).
• It's important to find a good balance between performance, scalability, security, and cost-effectiveness when using this approach. Despite the high scalability of Lambda, if the number of concurrent Lambda invocations exceeds the maximum quota, some requests are throttled. For more information, see Lambda quotas (Lambda documentation). You also need to consider pricing when using Lambda. To minimize Lambda invocations, make sure that you properly define the cache for the CloudFront distribution. For more information, see Optimizing caching and availability (CloudFront documentation).
Architecture

Target technology stack

- CloudFront
- Amazon Virtual Private Cloud (Amazon VPC)
- Application Load Balancer
- Lambda
- Amazon S3

Target architecture

The following image shows the suggested architecture when you need to use CloudFront to serve static content from an S3 bucket through a VPC.

1. The client requests the URL of CloudFront distribution to get a particular website file in the S3 bucket.
2. CloudFront sends the request to AWS WAF. AWS WAF filters the request by using the web ACLs applied to the CloudFront distribution. If the request is determined to be valid, the flow continues. If the request is determined to be invalid, the client receives a 403 error.
3. CloudFront checks its internal cache. If there is a valid key matching the incoming request, the associated value is sent back to the client as a response. If not, the flow continues.
4. CloudFront forwards the request to the URL of the specified Application Load Balancer.
5. The Application Load Balancer has a listener associated with a target group based on a Lambda function. The Application Load Balancer invokes the Lambda function.
6. The Lambda function connects to the S3 bucket, perform a `GetObject` operation on it, and returns the content as a response.
Automation and scale

To automate the deployment of static content using this approach, create CI/CD pipelines to update the Amazon S3 buckets that host websites.

The Lambda function scales automatically to handle the concurrent requests, within the quotas and limitations of the service. For more information, see Lambda function scaling and Lambda quotas (Lambda documentation). For the other AWS services and features, such as CloudFront and the Application Load Balancer, AWS scales these automatically.

Tools

- **Amazon CloudFront** speeds up distribution of your web content by delivering it through a worldwide network of data centers, which lowers latency and improves performance.
- **Elastic Load Balancing (ELB)** distributes incoming application or network traffic across multiple targets. In this pattern, you use an Application Load Balancer provisioned through Elastic Load Balancing to direct traffic to the Lambda function.
- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **Amazon Virtual Private Cloud (Amazon VPC)** helps you launch AWS resources into a virtual network that you’ve defined. This virtual network resembles a traditional network that you’d operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Epics

Use CloudFront to serve static content from Amazon S3 through a VPC

<table>

<td><code>aws lambda update-function-code \ --function-name \ --zip-file fileb://lambda-alb-s3-website.zip</code></td>
<td></td>
</tr>
<tr>
<td>Create an Application Load Balancer.</td>
<td>Create an internet-facing Application Load Balancer that points to the Lambda function. For instructions, see Create a target group for the Lambda function (Elastic Load Balancing documentation). For a high-availability configuration, create the Application Load Balancer and attach it to private subnets in different Availability Zones.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>
### Task
Create a CloudFront distribution.

### Description
Create a CloudFront distribution that points to the Application Load Balancer you created.

2. Choose Create Distribution.
3. On the first page of the Create Distribution Wizard, in the Web section, choose Get Started.
4. Specify settings for your distribution. For more information, see Values that you specify when you create or update a distribution. Note the following:
   a. Set the Application Load Balancer as the origin.
   b. In Distribution settings, choose existing web ACLs that you want to apply through AWS WAF. For more information, see AWS WAF web ACL.
5. Save your changes.
6. After CloudFront creates your distribution, the value of the Status column for your distribution changes from InProgress to Deployed. If you chose to enable the distribution, it will be ready to process requests after the status switches to Deployed.

Additional information

Code

The following example Lambda function is written in Node.js. This Lambda function acts as a web server that performs a GetObject operation to an S3 bucket that contains the website resources.

```javascript
/**
 * This is an AWS Lambda function created for demonstration purposes.
 * It retrieves static assets from a defined Amazon S3 bucket.
 * To make the content available through a URL, use an Application Load Balancer with a Lambda integration.
 * Set the S3_BUCKET environment variable in the Lambda function definition.
 */

var AWS = require('aws-sdk');
exports.handler = function(event, context, callback) {
  var bucket = process.env.S3_BUCKET;
  var key = event.path.replace('/', '');
  if (key == '') {
    key = 'index.html';
  }

  // Fetch from S3
  var s3 = new AWS.S3();
  return s3.getObject({Bucket: bucket, Key: key},
    function(err, data) {
      if (err) {
        return err;
      }

      var isBase64Encoded = false;
      var encoding = 'utf8';

      if (data.ContentType.indexOf('image/') > -1) {
        isBase64Encoded = true;
        encoding = 'base64'
      }

      var resp = {
        statusCode: 200,
        headers: {
          'Content-Type': data.ContentType,
        },
        body: new Buffer(data.Body).toString(encoding),
        isBase64Encoded: isBase64Encoded
      };
    });
```
callback(null, resp);
);

Summary

This pattern shows how to track the usage costs of Amazon EMR clusters by configuring user-defined cost allocation tags. You can use these tags to create detailed cost and usage reports in AWS Cost Explorer for clusters across multiple dimensions. For example, you can track usage costs at the team, project, or cost center level.

Prerequisites and limitations

Prerequisites

- An active AWS account
- One or more EMR clusters that have user-defined tags activated

Architecture

Target technology stack

- Amazon EMR
- AWS Cost Explorer

Target architecture

The following diagram shows how you can apply tags to track usage costs for specific Amazon EMR clusters.
The diagram shows the following workflow:

1. A data engineer or AWS administrator creates user-defined cost allocation tags for the Amazon EMR clusters.
2. An AWS administrator activates the tags.
3. The tags report metadata to AWS Cost Explorer.

**Tools**

**Tools**

- **Amazon EMR** is a managed cluster platform that simplifies running big data frameworks on AWS to process and analyze large amounts of data.
- **AWS Cost Explorer** helps you view and analyze your AWS costs and usage.

Automate data ingestion from AWS Data Exchange into Amazon S3

Summary

This pattern provides an AWS CloudFormation template that enables you to automatically ingest data from AWS Data Exchange into your data lake in Amazon Simple Storage Service (Amazon S3).

AWS Data Exchange is a service that makes it easy to securely exchange file-based data sets in the AWS Cloud. AWS Data Exchange data sets are subscription-based. As a subscriber, you can also access data set revisions as providers publish new data.

The AWS CloudFormation template creates an Amazon CloudWatch Events event and an AWS Lambda function. The event watches for any updates to the data set you have subscribed to. If there is an update, CloudWatch initiates a Lambda function, which copies the data over to the S3 bucket you specify. When the data has been copied successfully, Lambda sends you an Amazon Simple Notification Service (Amazon SNS) notification.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Subscription to a data set in AWS Data Exchange

Limitations

- The AWS CloudFormation template must be deployed separately for each subscribed data set in AWS Data Exchange.

Architecture

Target technology stack

- AWS Lambda
- Amazon S3
- AWS Data Exchange
- Amazon CloudWatch
- Amazon SNS
Target architecture

Automation and scale

You can use the AWS CloudFormation template multiple times for the data sets you want to ingest into the data lake.

Tools

- **AWS Data Exchange** – A service that makes it easy for AWS customers to securely exchange file-based data sets in the AWS Cloud. As a subscriber, you can find and subscribe to hundreds of products from qualified data providers. Then, you can quickly download the data set or copy it to Amazon S3 for use across a variety of AWS analytics and machine learning services. Anyone with an AWS account can be an AWS Data Exchange subscriber.

- **AWS Lambda** – A compute service that lets you run code without provisioning or managing servers. AWS Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time you consume; there is no charge when your code isn't running. With AWS Lambda, you can run code for virtually any type of application or backend service with zero administration. AWS Lambda runs your code on a high-availability compute infrastructure and manages all the compute resources, including server and operating system maintenance, capacity provisioning and automatic scaling, code monitoring, and logging.

- **Amazon S3** – Storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.

- **Amazon CloudWatch Events** – Delivers a near real-time stream of system events that describe changes in AWS resources. Using simple rules that you can quickly set up, you can match events and route them to one or more target functions or streams. CloudWatch Events becomes aware of operational changes as they occur. It responds to these operational changes and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information. You can also use CloudWatch Events to schedule automated actions that self-initiate at certain times using **cron** or **rate** expressions.

- **Amazon SNS** – A web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud. Amazon SNS provides topics (communication channels) for high-throughput, push-based, many-to-many messaging. Using Amazon SNS topics, publishers can
distribute messages to a large number of subscribers for parallel processing, including Amazon Simple Queue Service (Amazon SQS) queues, AWS Lambda functions, and HTTP/S webhooks. You can also use Amazon SNS to send notifications to end users using mobile push, SMS, and email.

<td>Data lakes; Analytics; DevOps; Infrastructure</td>
</tr>
</tbody>
</table>

| Workload: Open-source | AWS services: Amazon AppFlow; Amazon Athena; AWS CDK; AWS Lambda; Amazon S3 |

Summary

This pattern describes how to build a data pipeline to ingest, transform, and analyze Google Analytics data by using the AWS DataOps Development Kit (DDK) and other AWS services. The AWS DDK is an open-source development framework that helps you build data workflows and modern data architecture on AWS. One of the main objectives of the AWS DDK is to save you the time and effort that's typically devoted to labor-intensive data pipeline tasks, such as orchestrating pipelines, building infrastructure, and creating the DevOps behind that infrastructure. You can offload these labor-intensive tasks to AWS DDK so that you can focus on writing code and other high-value activities.

Prerequisites and limitations

Prerequisites

• An active AWS account
• An Amazon AppFlow connector for Google Analytics, configured
• Python and pip (Python's package manager)
• Git, installed and configured
• AWS Command Line Interface (AWS CLI), installed and configured
• AWS Cloud Development Kit (AWS CDK), installed

Product versions

• Python 3.7 or later
• pip 9.0.3 or later

Architecture

Technology stack
• Amazon AppFlow
• Amazon Athena
• Amazon CloudWatch
• Amazon EventBridge
• Amazon Simple Storage Service (Amazon S3)
• Amazon Simple Queue Service (Amazon SQS)
• AWS DataOps Development Kit (DDK)
• AWS Lambda

Target architecture

The following diagram shows the event-driven process that ingests, transforms, and analyzes Google Analytics data.

1. An Amazon CloudWatch scheduled event rule invokes Amazon AppFlow.
2. Amazon AppFlow ingests Google Analytics data into an S3 bucket.
3. After the data is ingested by the S3 bucket, event notifications in EventBridge are generated, captured by a CloudWatch Events rule, and then put into an Amazon SQS queue.
4. A Lambda function consumes events from the Amazon SQS queue, reads the respective S3 objects, transforms the objects to Apache Parquet format, writes the transformed objects to the S3 bucket, and then creates or updates the AWS Glue Data Catalog table definition.
5. An Athena query runs against the table.

Tools

AWS tools

• **Amazon AppFlow** is a fully-managed integration service that enables you to securely exchange data between software as a service (SaaS) applications.
• **Amazon Athena** is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
• **Amazon CloudWatch** helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
• **Amazon EventBridge** is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
• **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

• **Amazon Simple Queue Service (Amazon SQS)** provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.

• **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

• **AWS Cloud Development Kit (CDK)** is a framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.

• **AWS DataOps Development Kit (DDK)** is an open-source development framework to help you build data workflows and modern data architecture on AWS.

**Code**

The code for this pattern is available in the GitHub [AWS DataOps Development Kit (DDK)](https://github.com/aws-samples/aws-ddk-examples) and [Analyzing Google Analytics data with Amazon AppFlow, Amazon Athena, and AWS DataOps Development Kit](https://github.com/aws-samples/analytics-with-appflow-athena-ddk) repositories.

</table>
| Deployment fails during the creation of an AWS::AppFlow::Flow resource and you receive the following error: Connector Profile with name ga-connection does not exist | Confirm that you created an Amazon AppFlow connector for Google Analytics and named it ga-connection.  
For instructions, see Google Analytics in the Amazon AppFlow documentation. |

Related resources

- **AWS DataOps Development Kit (DDK)** (GitHub)
- **AWS DDK Examples** (GitHub)
AWS DDK data pipelines are composed of one or many stages. In the following code examples, you use AppFlowIngestionStage to ingest data from Google Analytics, SqsToLambdaStage to handle data transformation, and AthenaSQLStage to run the Athena query.

First, the data transformation and ingestion stages are created, as the following code example shows:

```python
appflow_stage = AppFlowIngestionStage(
    self,
    id="appflow-stage",
    flow_name=flow.flow_name,
)
sqs_lambda_stage = SqsToLambdaStage(
    self,
    id="lambda-stage",
    lambda_function_props={
        "code": Code.from_asset("./ddk_app/lambda_handlers"),
        "handler": "handler.lambda_handler",
        "layers": [
            LambdaVersion.from_layer_version_arn(
                self,
                id="layer",
                layer_version_arn=f"arn:aws:lambda:
                {self.region}:336392948345:layer:AWSDataWrangler-Python39:1",
            )
        ],
        "runtime": Runtime.PYTHON_3_9,
    },
)
# Grant lambda function S3 read & write permissions
bucket.grant_read_write(sqs_lambda_stage.function)
# Grant Glue database & table permissions
sqs_lambda_stage.function.add_to_role_policy(
    self._get_glue_db_iam_policy(database_name=database.database_name)
)
athena_stage = AthenaSQLStage(
    self,
    id="athena-sql",
    query_string=[
        "SELECT year, month, day, device, count(user_count) as cnt "
        f"FROM {database.database_name}.ga_sample "
        "GROUP BY year, month, day, device "
        "ORDER BY cnt DESC "
        "LIMIT 10;",
    ],
    output_location=Location(
        bucket_name=bucket.bucket_name, object_key="query-results/
    ),
    additional_role_policy_statements=[
        self._get_glue_db_iam_policy(database_name=database.database_name)
    ],
)
```

Next, the DataPipeline construct is used to "wire" the stages together by using EventBridge rules, as the following code example shows:

```python
(DataPipeline(self, id="ingestion-pipeline")
    .add_stage(
```

491
stage=appflow_stage,
override_rule=Rule(
    self,
    "schedule-rule",
    schedule=Schedule.rate(Duration.hours(1)),
    targets=appflow_stage.targets,
),
).
.add_stage(
    stage=sqs_lambda_stage,
    # By default, AppFlowIngestionStage stage emits an event after the flow run
    # finishes successfully
    # Override rule below changes that behavior to call the stage when data
    # lands in the bucket instead
    override_rule=Rule(
        self,
        "s3-object-created-rule",
        event_pattern=EventPattern(
            source=["aws.s3"],
            detail={
                "bucket": [{"name": [bucket.bucket_name]},
                "object": [{"key": [{"prefix": "ga-data"}]}],
            },
            detail_type=["Object Created"],
        ),
        targets=sqs_lambda_stage.targets,
        ),
).add_stage(stage=athena_stage)
)

For more code examples, see the GitHub Analyzing Google Analytics data with Amazon AppFlow, Amazon Athena, and AWS DataOps Development Kit repository.
Configure cross-account access to a shared AWS Glue Data Catalog using Amazon Athena

Created by Denis Avdonin (AWS)

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Technologies: Data lakes; Analytics; Big data</th>
<th>Workload: All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AWS services:</strong></td>
<td>Amazon Athena; AWS Glue</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern provides step-by-step instructions, including AWS Identity and Access Management (IAM) policy samples, to configure cross-account sharing of a dataset stored in an Amazon Simple Storage Service (Amazon S3) bucket by using the AWS Glue Data Catalog. You can store the dataset in an S3 bucket. The metadata is collected by an AWS Glue crawler and put into the AWS Glue Data Catalog. The S3 bucket and the AWS Glue Data Catalog reside in an AWS account referred to as the *data account*. You can provide access to IAM principals in another AWS account referred to as the *consumer account*. Users can query the data in the consumer account by using the Amazon Athena serverless query engine.

Prerequisites and limitations

Prerequisites

- Two active **AWS accounts**
- An **S3 bucket** in one of the AWS accounts
- **Athena engine version 2**
- AWS Command Line Interface (AWS CLI), **installed** and **configured** (or **AWS CloudShell** for running AWS CLI commands)

Product versions

This pattern works with **Athena engine version 2** and **Athena engine version 3** only. We recommend that you upgrade to Athena engine version 3. If you can’t upgrade from Athena engine version 1 to Athena engine version 3, then follow the approach from [Cross-account AWS Glue Data Catalog access with Amazon Athena](https://aws.amazon.com/blogs/big-data/) in the AWS Big Data Blog.

Architecture

Target technology stack

- Amazon Athena
- Amazon Simple Storage Service (Amazon S3)
- AWS Glue
- AWS Identity and Access Management (IAM)
- AWS Key Management Service (AWS KMS)
The following diagram shows an architecture that uses IAM permissions to share data in an S3 bucket in one AWS account (data account) with another AWS account (consumer account) through the AWS Glue Data Catalog.

The diagram shows the following workflow:

1. The S3 bucket policy in the data account grants permissions to an IAM role in the consumer account and to the AWS Glue crawler service role in the data account.
2. The AWS KMS key policy in the data account grants permissions to the IAM role in the consumer account and to the AWS Glue crawler service role in the data account.
3. The AWS Glue crawler in the data account discovers the schema of the data that's stored in the S3 bucket.
4. The resource policy of the AWS Glue Data Catalog in the data account grants access to the IAM role in the consumer account.
5. A user creates a named catalog reference in the consumer account by using an AWS CLI command.
6. An IAM policy grants an IAM role in the consumer account access to resources in the data account. The IAM role's trust policy allows IAM users in the consumer account to assume the IAM role.
7. A user in the consumer account assumes the IAM role and accesses objects in the data catalog by using SQL queries.
8. The Athena serverless engine runs the SQL queries.

**Note:** You can grant access directly to IAM users and even to all principals in the consumer account, but IAM best practices recommend granting permissions to an IAM role and assuming the role by the IAM users or by using identity federation.

**Tools**

- **Amazon Athena** is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **AWS Glue** is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to protect your data.

    }
  ]
} | |
| (If required) Grant the crawler access to the data encryption key. | If the S3 bucket is encrypted by an AWS KMS key, grant kms:Decrypt permission on the key to the crawler's service role by attaching the following policy to it: | Cloud administrator |
| | ```json
{
  "Effect": "Allow",
  "Action": "kms:Decrypt",
  "Resource": "arn:aws:kms:<region>:<data account id>:key/<key id>"
} | |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Grant the IAM role in the consumer account and the crawler access to the data catalog.** | 1. Sign in to the AWS Management Console and open the [AWS Glue console](https://aws.amazon.com/glue/).  
2. In the navigation pane, under **Data Catalog**, choose **Settings**.  
3. In the **Permissions** section, add the following statement, and then choose **Save**.  

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "AWS": [
               "arn:aws:iam::<consumer account id>:role/<role name>",
               "arn:aws:iam::<data account id>:role/service-role/AWSGlueServiceRole-data-bucket-crawler"
            ],
            "arn:aws:iam::<data account id>:role/service-role/AWSGlueServiceRole-data-bucket-crawler"
         },
         "Action": "glue:*",
         "Resource": [
            "arn:aws:glue:<region>:<data account id>:catalog",
            "arn:aws:glue:<region>:<data account id>:database/**",
            "arn:aws:glue:<region>:<data account id>:table/**"
         ]
      }
   ]
}
```

This policy allows all AWS Glue actions on all databases and tables in the data account. You can customize the policy to grant only required permissions to the consumer principals. For example, you can provide read-only access to specific tables or views in a database. | Cloud administrator |
Access data from the consumer account

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a named reference for the data catalog. | To create a named data catalog reference, use CloudShell or a locally installed AWS CLI to run the following command:  
```
aws athena create-data-catalog --name <shared catalog name> --type GLUE --parameters catalog-id=<data account id>
```

| Grant the IAM role in the consumer account access to the data. | Attach the following policy to the IAM role in the consumer account to grant the role cross-account access to the data:  
```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:GetObject",
      "Resource": "arn:aws:s3:::data-bucket/*"
    },
    {
      "Effect": "Allow",
      "Action": "s3:ListBucket",
      "Resource": "arn:aws:s3:::data-bucket"
    },
    {
      "Effect": "Allow",
      "Action": "glue:*",
      "Resource": [
        "arn:aws:glue:<region>:<data account id>:catalog",
        "arn:aws:glue:<region>:<data account id>:database/*",
        "arn:aws:glue:<region>:<data account id>:table/*"
      ]
    }
  ]
}``` | Cloud administrator |

</thead>
<tbody>
<tr>
<td>Access the data.</td>
<td>Query data using Athena. For example, open the Athena query editor and run the following query:</td>
<td>Data consumer</td>
</tr>
</tbody>
</table>
|                      | ```sql
SELECT *
FROM <shared catalog name>.<database name>.<table name>
```                                                           |                 |
|                      | Instead of using a named catalog reference, you can also refer to the catalog by its Amazon Resource Name (ARN). |
| Note: If you use a dynamic catalog reference in a query or view, surround the reference with escaped double quotation marks (\"). For example: |                 |
|                      | ```sql
SELECT *
FROM "glue:arn:aws:glue:<region>:<data account id>:catalog "<database name>.<table name>
```                                                      |                 |
|                      | For more information, see [Cross-account access to AWS Glue data catalogs](https://docs.aws.amazon.com/athena/latest/ug/glue-catalogs.html) in the Amazon Athena User Guide. |                 |

### Related resources

- [Cross-account access to AWS Glue data catalogs](https://docs.aws.amazon.com/athena/latest/ug/glue-catalogs.html) (Athena documentation)
- [Cross-account AWS Glue Data Catalog access with Amazon Athena](https://aws.amazon.com/blogs/big-data/cross-account-access-with-aws-glue-data-catalogs/) (AWS Big Data Blog)

### Additional information

#### Using Lake Formation as an alternative for cross-account sharing

You can also use AWS Lake Formation to share access to AWS Glue catalog objects across accounts. Lake Formation provides fine-grained access control at the column and row level, tag-based access control, governed tables for ACID transactions, and other functionality. Although Lake Formation is well-integrated with Athena, it does require additional configuration compared to this pattern's IAM-only approach. We recommend that you consider the decision to use Lake Formation or IAM-only access controls within the wider context of your overall solution architecture. Considerations include what other services are involved and how they integrate with both approaches.
Deploy and manage a serverless data lake on the AWS Cloud by using infrastructure as code

Created by Kirankumar Chandrashekar (AWS) and Abdel Jaidi (AWS)

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Technologies: Data lakes; Analytics; Serverless; DevOps</th>
<th>Workload: All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AWS services:</strong> Amazon S3; Amazon SQS; AWS CloudFormation; AWS Glue; Amazon CloudWatch; AWS Lambda; AWS Step Functions; Amazon DynamoDB</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary of using IaC to deploy and manage a serverless data lake

This pattern describes how to use **serverless computing** and **infrastructure as code** (IaC) to implement and administer a data lake on the Amazon Web Services (AWS) Cloud. This pattern is based on the **serverless data lake framework (SDLF)** workshop developed by AWS.

SDLF is a collection of reusable resources that accelerate the delivery of enterprise data lakes on the AWS Cloud and helps with faster deployment to production. It is used to implement the foundational structure of a data lake by following best practices.

SDLF implements a continuous integration / continuous deployment (CI/CD) process throughout the code and infrastructure deployment by using AWS services such as AWS CodePipeline, AWS CodeBuild, and AWS CodeCommit.

This pattern uses multiple AWS serverless services to simplify data lake management. These include Amazon Simple Storage Service (Amazon S3) and Amazon DynamoDB for storage, AWS Lambda and AWS Glue for computing, and Amazon CloudWatch Events, Amazon Simple Queue Service (Amazon SQS), and AWS Step Functions for orchestration.

AWS CloudFormation and AWS code services act as the IaC layer to provide reproducible and fast deployments with easy operations and administration.

Prerequisites and limitations for using IaC to deploy and manage a serverless data lake

**Prerequisites**

- An active AWS account.
- **AWS Command Line Interface (AWS CLI)**, installed and configured.
- A Git client, installed and configured.
- The **SDLF workshop**, open in a web browser window and ready to use.
Architecture for using IaC to deploy and manage a serverless data lake

The architecture diagram illustrates an event-driven process with the following steps.

1. After a file is added to the raw data S3 bucket, an Amazon S3 event notification is placed in an SQS queue. Each notification is delivered as a JSON file, which contains metadata such as the S3 bucket name, object key, or timestamp.

2. This notification is consumed by a Lambda function that routes the event to the correct extraction, transformation, and loading (ETL) process based on the metadata. The Lambda function can also use contextual configurations stored in an Amazon DynamoDB table. This step enables decoupling and scaling to multiple applications in the data lake.

3. The event is routed to the first Lambda function in the ETL process, which transforms and moves data from the raw data area to the staging area for the data lake. The first step is to update the comprehensive catalog. This is a DynamoDB table that contains all the file metadata of the data lake. Each row in this table holds operational metadata about a single object stored in Amazon S3. A synchronous call is made to a Lambda function that performs a light transformation, which is a computationally inexpensive operation (such as converting a file from one format to another), on the S3 object. Because a new object has been added to the staging S3 bucket, the comprehensive catalog is updated and a message is sent to the SQS queue waiting for the next phase in the ETL.
4. A CloudWatch Events rule triggers a Lambda function every 5 minutes. This function checks if messages were delivered to the SQS queue from the previous ETL phase. If a message was delivered, the Lambda function begins the second function from AWS Step Functions in the ETL process.

5. A heavy transformation is then applied on a batch of files. This heavy transformation is a computationally expensive operation, such as a synchronous call to an AWS Glue job, AWS Fargate task, Amazon EMR step, or Amazon SageMaker notebook. Table metadata is extracted from the output files by using an AWS Glue crawler, which updates the AWS Glue catalog. File metadata is also added to the comprehensive catalog table in DynamoDB. Finally, a data quality step leveraging Deequ is also run.

Technology stack

- Amazon CloudWatch Events
- AWS CloudFormation
- AWS CodePipeline
- AWS CodeBuild
- AWS CodeCommit
- Amazon DynamoDB
- AWS Glue
- AWS Lambda
- Amazon S3
- Amazon SQS
- AWS Step Functions

Tools for using IaC to deploy and manage a serverless data lake

- Amazon CloudWatch Events – CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- AWS CloudFormation – CloudFormation helps create and provision AWS infrastructure deployments predictably and repeatedly.
- AWS CodeBuild – CodeBuild is a fully managed build service that compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- AWS CodeCommit – CodeCommit is a version control service hosted by AWS that you can use to privately store and manage assets (such as source code and binary files).
- AWS CodePipeline – CodePipeline is a continuous delivery service that you can use to model, visualize, and automate the steps required to release your software changes continuously.
- Amazon DynamoDB – DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with scalability.
- AWS Glue – AWS Glue is a fully managed ETL service that makes it easier to prepare and load data for analytics.
- AWS Lambda – Lambda supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service. Amazon S3 can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
• **AWS Step Functions** - AWS Step Functions is a serverless function orchestrator that makes it easy to sequence AWS Lambda functions and multiple AWS services into business-critical applications.

• **Amazon SQS** – Amazon Simple Queue Service (Amazon SQS) is a fully managed message queuing service that helps you decouple and scale microservices, distributed systems, and serverless applications.

• **Deequ** – Deequ is a tool that helps you compute data quality metrics for large datasets, define and verify data quality constraints, and stay informed about changes in the data distribution.

### Code

The source code and resources for the SDLF are available in the [AWS Labs GitHub repository](https://github.com/aws-labs/cloudformation-templates).

### Epics for using IaC to deploy and manage a serverless data lake

Cost-effectively ingest IoT data directly into Amazon S3 using AWS IoT Greengrass

Created by Sebastian Viviani (AWS) and Rizwan Syed (AWS)

Environment: PoC or pilot
Technologies: Data lakes; Analytics; IoT
Workload: Open-source

AWS services: AWS IoT Greengrass; Amazon S3; Amazon Athena

Summary

This pattern shows you how to cost-effectively ingest Internet of Things (IoT) data directly into an Amazon Simple Storage Service (Amazon S3) bucket by using an AWS IoT Greengrass Version 2 device. The device runs a custom component that reads the IoT data and saves the data in persistent storage (that is, a local disk or volume). Then, the device compresses the IoT data into an Apache Parquet file and uploads the data periodically to an S3 bucket.

The amount and speed of IoT data that you ingest is limited only by your edge hardware capabilities and network bandwidth. You can use Amazon Athena to cost-effectively analyze your ingested data. Athena supports compressed Apache Parquet files and data visualization by using Amazon Managed Grafana.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An edge gateway that runs on AWS IoT Greengrass Version 2 and collects data from sensors (The data sources and the data collection process are beyond the scope of this pattern, but you can use nearly any type of sensor data. This pattern uses a local MQTT broker with sensors or gateways that publish data locally.)
- AWS IoT Greengrass component, roles, and SDK dependencies
- A stream manager component to upload the data to the S3 bucket
- AWS SDK for Java, AWS SDK for JavaScript, or AWS SDK for Python (Boto3) to run the APIs

Limitations

- The data in this pattern isn't uploaded in real time to the S3 bucket. There is a delay period, and you can configure the delay period. Data is buffered temporarily in the edge device and then uploaded once the period expires.
- The SDK is available only in Java, Node.js, and Python.

Architecture

Target technology stack
Tools

- **Amazon S3**
- **AWS IoT Greengrass**
- **MQTT broker**
- **Stream manager component**

**Target architecture**

The following diagram shows an architecture designed to ingest IoT sensor data and store that data in an S3 bucket.

The diagram shows the following workflow:

1. Multiple sensors (for example, temperature and valve) updates are published to a local MQTT broker.
2. The Parquet file compressor that's subscribed to these sensors updates topics and receives these updates.
3. The Parquet file compressor stores the updates locally.
4. After the period lapses, the stored files are compressed into Parquet files and passed on to the stream manager to get uploaded to the specified S3 bucket.
5. The stream manager uploads the Parquet files to the S3 bucket.

**Note:** The stream manager (StreamManager) is a managed component. For examples of how to export data to Amazon S3, see Stream manager in the AWS IoT Greengrass documentation. You can use a local MQTT broker as a component or another broker like Eclipse Mosquitto.

**Tools**

**AWS tools**

- **Amazon Athena** is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **AWS IoT Greengrass** is an open source IoT edge runtime and cloud service that helps you build, deploy, and manage IoT applications on your devices.
Other tools

- **Apache Parquet** is an open-source column-oriented data file format designed for storage and retrieval.
- **MQTT** (Message Queuing Telemetry Transport) is a lightweight messaging protocol that's designed for constrained devices.

**Best practices**

**Use the right partition format for uploaded data**

There are no specific requirements for the root prefix names in the S3 bucket (for example, "myAwesomeDataSet/" or "dataFromSource"), but we recommend that you use a meaningful partition and prefix so that it's easy to understand the purpose of the dataset.

We also recommend that you use the right partitioning in Amazon S3 so that the queries run optimally on the dataset. In the following example, the data is partitioned in HIVE format so that the amount of data scanned by each Athena query is optimized. This improves performance and reduces cost.

`s3://<ingestionBucket>/<rootPrefix>/year=YY/month=MM/day=DD/HHMM_<suffix>.parquet`

<td></td>
<td>• Add the component to the CI/CD pipeline (if one exists). Be sure to copy the artifact from the artifact repository to the AWS IoT Greengrass artifact bucket. Then, create or update</td>
<td></td>
</tr>
</tbody>
</table>
### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
|      | your AWS IoT Greengrass component.  
|      | • Add the MQTT broker as a component or add it manually later. **Note:** This decision affects the authentication scheme that you can use with the broker. Manually adding a broker decouples the broker from AWS IoT Greengrass and enables any supported authentication scheme of the broker. The AWS provided broker components have predefined authentication schemes. For more information, see [MQTT 3.1.1 broker (Moquette)](https://github.com/mqtt/moquette) and [MQTT 5 broker (EMQX)](https://www.emqx.com/). | **App developer** |
| Add the component to the AWS IoT Greengrass Version 2 core device | **Update the MQTT client.** The sample code doesn't use authentication because the component connects locally to the broker. If your scenario differs, update the MQTT client section as needed. Additionally, do the following:  
|      | 1. Update the MQTT topics in the subscription.  
|      | 2. Update the MQTT message parser as needed as messages from each source may differ. | |
|      | **Update the deployment of the core device.** If the deployment of the AWS IoT Greengrass Version 2 core device already exists, [revise the deployment](https://docs.aws.amazon.com/greengrass/latest/developer-guide/developer-guide-how-to-update-a-deployment.html). If the deployment doesn’t exist, [create a new deployment](https://docs.aws.amazon.com/greengrass/latest/developer-guide/developer-guide-create-deployment.html).  
|      | To give the component the correct name, [update the log manager configuration](https://docs.aws.amazon.com/greengrass/latest/developer-guide/developer-guide-how-to-update-log-manager.html) for the new component (if needed) based on the following: | **App developer** |
Finally, complete the revision of the deployment for your AWS IoT Greengrass core device.

### Verify data ingestion into the S3 bucket

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Check the logs for the AWS IoT Greengrass volume. | Check for the following:  
- The MQTT client is successfully connected to the local MQTT broker.  
- The MQTT client is subscribed to the correct topics.  
- Sensor update messages are coming to the broker on the MQTT topics.  
- Parquet compression happens at every periodic interval. | App developer |
| Check the S3 bucket. | Verify if the data is being uploaded to the S3 bucket. You can see the files being uploaded at every period. | App developer |
**AWS Prescriptive Guidance Patterns**

**Troubleshooting**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>You can also verify if the data is uploaded to the S3 bucket by querying the data in the next section.</td>
<td></td>
</tr>
</tbody>
</table>

### Set up querying from Athena

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a database and table. | 1. Create an AWS Glue database (if needed).  
2. Create a table in AWS Glue manually or by running a crawler in AWS Glue. | App developer         |
| Grant Athena access to the data. | 1. Update permissions to allow Athena to access the S3 bucket. For more information, see Fine-grained access to databases and tables in the AWS Glue Data Catalog in the Athena documentation.  
2. Query the table in your database. | App developer         |

### Troubleshooting

<table>
<thead>
<tr>
<th>Issue</th>
<th>Solution</th>
</tr>
</thead>
</table>
| MQTT client fails to connect       | • Validate the permissions on the MQTT broker. If you have an MQTT broker from AWS, see MQTT 3.1.1 broker (Moquette) and MQTT 5 broker (EMQX).  
• Validate the credentials on the MQTT client. If you have an MQTT broker from AWS, see MQTT 3.1.1 broker (Moquette) and MQTT 5 broker (EMQX). |
| MQTT client fails to subscribe     | Validate the permissions on the MQTT broker. If you have an MQTT broker from AWS, see MQTT 3.1.1 broker (Moquette) and MQTT 5 broker (EMQX).                                                                 |
| Parquet files don’t get created    | • Verify that the MQTT topics are correct.  
• Verify that the MQTT messages from the sensors are in the correct format.                                                                                                                                  |
| Objects are not uploaded to the S3 bucket | • Verify that you have internet connectivity and endpoint connectivity.  
• Verify that the resource policy for your S3 bucket is correct.                                                                                                                                                |
Issue | Solution
--- | ---
 | • Verify the permissions for the AWS IoT Greengrass Version 2 core device role.

**Additional information**

**Cost analysis**

The following cost analysis scenario demonstrates how the data ingestion approach covered in this pattern can impact data ingestion costs in the AWS Cloud. The pricing examples in this scenario are based on prices at the time of publication. Prices are subject to change. Additionally, your costs may vary depending on your AWS Region, AWS service quotas, and other factors related to your cloud environment.

**Input signal set**

This analysis uses the following set of input signals as the basis for comparing IoT ingestion costs with other available alternatives.

<table>
<thead>
<tr>
<th>Number of signals</th>
<th>Frequency</th>
<th>Data per signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>125</td>
<td>25 Hz</td>
<td>8 bytes</td>
</tr>
</tbody>
</table>

In this scenario, the system receives 125 signals. Each signal is 8 bytes and occurs every 40 milliseconds (25 Hz). These signals could come individually or grouped in a common payload. You have the option to split and pack these signals based on your needs. You can also determine the latency. Latency consists of the time period for receiving, accumulating, and ingesting the data.

For comparison purposes, the ingestion operation for this scenario is based in the us-east-1 AWS Region. The cost comparison applies to AWS services only. Other costs, like hardware or connectivity, are not factored into the analysis.

**Cost comparisons**

The following table shows the monthly cost in US dollars (USD) for each ingestion method.

<table>
<thead>
<tr>
<th>Method</th>
<th>Monthly cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS IoT SiteWise*</td>
<td>331.77 USD</td>
</tr>
</tbody>
</table>
AWS IoT SiteWise Edge with data processing pack (keeping all data at the edge) | 200 USD
---|---
AWS IoT Core and Amazon S3 rules for accessing raw data | 84.54 USD
Parquet file compression at the edge and uploading to Amazon S3 | 0.5 USD

*Data must be downsampled to comply with service quotas. This means there is some data loss with this method.*

**Alternative methods**

This section shows the equivalent costs for the following alternative methods:

- **AWS IoT SiteWise** – Each signal must be uploaded in an individual message. Therefore, the total number of messages per month is \(125 \times 25 \times 3600 \times 24 \times 30\), or 8.1 billion messages per month. However, AWS IoT SiteWise can handle only 10 data points per second per property. Assuming the data is downsampled to 10 Hz, the number of messages per month is reduced to \(125 \times 10 \times 3600 \times 24 \times 30\), or 3.24 billion. If you use the publisher component that packs measurements in groups of 10 (at 1 USD per million messages), then you get a monthly cost of 324 USD per month. Assuming that each message is 8 bytes (1 Kb/125), that's 25.92 Gb of data storage. This adds a monthly cost of 7.77 USD per month. The total cost for the first month is 331.77 USD and increases by 7.77 USD every month.

- **AWS IoT SiteWise Edge with data processing pack, including all models and signals fully processed at the edge (that is, no cloud ingestion)** – You can use the data processing pack as an alternative to reduce costs and to configure all the models that get calculated at the edge. This can work just for storage and visualization, even if no real calculation is performed. In this case, it's necessary to use powerful hardware for the edge gateway. There is a fixed cost of 200 USD per month.

- **Direct ingestion to AWS IoT Core by MQTT and an IoT rule to store the raw data in Amazon S3** – Assuming all the signals are published in a common payload, the total number of messages published to AWS IoT Core is \(25 \times 3600 \times 24 \times 30\), or 64.8 million per month. At 1 USD per million messages, that's a monthly cost of 64.8 USD per month. At 0.15 USD per million rule activations and with one rule per message, that adds a monthly cost of 19.44 USD per month. At a cost of 0.023 USD per Gb of storage in Amazon S3, that adds another 1.5 USD per month (increasing every month to reflect the new data). The total cost for the first month is 84.54 USD and increases by 1.5 USD every month.

- **Compressing data at the edge in a Parquet file and uploading to Amazon S3 (proposed method)** – The compression ratio depends on the type of data. With the same industrial data tested for MQTT, the total output data for a full month is 1.2 Gb. This costs 0.03 USD per month. Compression ratios (using random data) described in other benchmarks are on the order of 66 percent (closer to a worst-case scenario). The total data is 21 Gb and costs 0.5 USD per month.

**Parquet file generator**

The following code example shows the structure of a Parquet file generator that's written in Python. The code example is for illustration purposes only and won't work if pasted into your environment.

```python
import queue
import paho.mqtt.client as mqtt
import pandas as pd

#queue for decoupling the MQTT thread
messageQueue = queue.Queue()

client = mqtt.Client()
streammanager = StreamManagerClient()

def feederListener(topic, message):
```

515
payload = {
    "topic" : topic,
    "payload" : message,
}
messageQueue.put_nowait(payload)

def on_connect(client_instance, userdata, flags, rc):
    client.subscribe("#", qos=0)

def on_message(client, userdata, message):
    feederListener(topic=str(message.topic), message=str(message.payload.decode("utf-8")))

filename = "tempfile.parquet"
streamname = "mystream"
destination_bucket = "mybucket"
keyname="mykey"
period= 60
client.on_connect = on_connect
client.on_message = on_message
streammanager.create_message_stream(
    MessageStreamDefinition(name=streamname,
                            strategy_on_full=StrategyOnFull.OverwriteOldestData)
)}

while True:
    try:
        message = messageQueue.get(timeout=myArgs.mqtt_timeout)
    except (queue.Empty):
        logger.warning("MQTT message reception timed out")

    currentTimestamp = getCurrentTime()
    if currentTimestamp >= nextUploadTimestamp:
        df = pd.DataFrame.from_dict(accumulator)
        df.to_parquet(filename)
        s3_export_task_definition = S3ExportTaskDefinition(input_url=filename,
                                                            bucket=destination_bucket, key=key_name)
        streammanager.append_message(streamname,
                                      Util.validate_and_serialize_to_json_bytes(s3_export_task_definition))
        accumulator = {}
        nextUploadTimestamp += period
    else:
        accumulator.append(message)
Migrate Hadoop data to Amazon S3 by using WANdisco LiveData Migrator

Summary

This pattern describes the process for migrating Apache Hadoop data from a Hadoop Distributed File System (HDFS) to Amazon Simple Storage Service (Amazon S3). It uses WANdisco LiveData Migrator to automate the data migration process.

Prerequisites and limitations

Prerequisites

- Hadoop cluster edge node where LiveData Migrator will be installed. The node should meet the following requirements:
  - Minimum specification: 4 CPUs, 16 GB RAM, 100 GB storage.
  - 2 Gbps minimum network.
  - Port 8081 accessible on your edge node to access the WANdisco UI.
  - Java 1.8 64-bit.
  - Hadoop client libraries installed on the edge node.
  - Ability to authenticate as the HDFS superuser (for example, “hdfs”).
  - If Kerberos is enabled on your Hadoop cluster, a valid keytab that contains a suitable principal for the HDFS superuser must be available on the edge node.
  - See the release notes for a list of supported operating systems.
- An active AWS account with access to an S3 bucket.
- An AWS Direct Connect link established between your on-premises Hadoop cluster (specifically the edge node) and AWS.

Product versions

- LiveData Migrator 1.8.6
- WANdisco UI (OneUI) 5.8.0

Architecture

Source technology stack
- On-premises Hadoop cluster

**Target technology stack**

- Amazon S3

**Architecture**

The following diagram shows the LiveData Migrator solution architecture.

The workflow consists of four primary components for data migration from on-premises HDFS to Amazon S3.

- **LiveData Migrator** – Automates the migration of data from HDFS to Amazon S3, and resides on an edge node of the Hadoop cluster.
- **HDFS** – A distributed file system that provides high-throughput access to application data.
- **Amazon S3** – An object storage service that offers scalability, data availability, security, and performance.
- **AWS Direct Connect** – A service that establishes a dedicated network connection from your on-premises data centers to AWS.

**Automation and scale**

You will typically create multiple migrations so that you can select specific content from your source file system by path or directory. You can also migrate data to multiple, independent file systems at the same time by defining multiple migration resources.

**Epics**

**Configure Amazon S3 storage in your AWS account**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sign in to your AWS account</td>
<td>Sign in to the AWS Management Console and open the Amazon S3 console at <a href="https://console.aws.amazon.com/s3/">https://console.aws.amazon.com/s3/</a>.</td>
<td>AWS experience</td>
</tr>
</tbody>
</table>
**Create an S3 bucket.**  
If you don’t already have an existing S3 bucket to use as the target storage, choose the “Create bucket” option on the Amazon S3 console, and specify a bucket name, AWS Region, and bucket settings for block public access. AWS and WANdisco recommend that you enable the block public access options for the S3 bucket, and set up the bucket access and user permission policies to meet your organization’s requirements. An AWS example is provided at https://docs.aws.amazon.com/AmazonS3/latest/dev/example-walkthroughs-managing-access-example1.html.

**Skills required:** AWS experience

### Install LiveData Migrator

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Download the LiveData Migrator installer.</td>
<td>Download the LiveData Migrator installer and upload it to the Hadoop edge node. You can download a free trial of LiveData Migrator at <a href="https://www2.wandisco.com/ldm-trial">https://www2.wandisco.com/ldm-trial</a>. You can also obtain access to LiveData Migrator from AWS Marketplace, at <a href="https://aws.amazon.com/marketplace/pp/B07B8SZND9">https://aws.amazon.com/marketplace/pp/B07B8SZND9</a>.</td>
<td>Hadoop administrator, Application owner</td>
</tr>
<tr>
<td>Install LiveData Migrator.</td>
<td>Use the downloaded installer and install LiveData Migrator as the HDFS superuser on an edge node in your Hadoop cluster. See the “Additional information” section for the installation commands.</td>
<td>Hadoop administrator, Application owner</td>
</tr>
<tr>
<td>Check the status of LiveData Migrator and other services.</td>
<td>Check the status of LiveData Migrator, Hive migrator, and WANdisco UI by using the commands provided in the &quot;Additional information&quot; section.</td>
<td>Hadoop administrator, Application owner</td>
</tr>
</tbody>
</table>
## Configure storage through the WANdisco UI

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register your LiveData Migrator account.</td>
<td>Log in to the WANdisco UI through a web browser on port 8081 (on the Hadoop edge node) and provide your details for registration. For example, if you are running LiveData Migrator on a host named myldmhost.example.com, the URL would be: <a href="http://myldmhost.example.com:8081">http://myldmhost.example.com:8081</a></td>
<td>Application owner</td>
</tr>
<tr>
<td>Configure your source HDFS storage.</td>
<td>Provide the configuration details needed for your source HDFS storage. This will include the &quot;fs.defaultFS&quot; value and a user-defined storage name. If Kerberos is enabled, provide the principal and keytab location for LiveData Migrator to use. If NameNode HA is enabled on the cluster, provide a path to the core-site.xml and hdfs-site.xml files on the edge node.</td>
<td>Hadoop administrator, Application owner</td>
</tr>
<tr>
<td>Configure your target Amazon S3 storage.</td>
<td>Add your target storage as the S3a type. Provide the user-defined storage name and the S3 bucket name. Enter &quot;org.apache.hadoop.fs.s3a.SimpleAWSCredentialsProvider&quot; for the Credentials Provider option, and provide the AWS access and secret keys for the S3 bucket. Additional S3a properties will also be needed. For details, see the &quot;S3a Properties&quot; section in the LiveData Migrator documentation at <a href="https://docs.wandisco.com/live-data-migrator/docs/command-reference/#filesystem-add-s3a">https://docs.wandisco.com/live-data-migrator/docs/command-reference/#filesystem-add-s3a</a>.</td>
<td>AWS, Application owner</td>
</tr>
</tbody>
</table>

## Prepare for the migration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add exclusions (if needed).</td>
<td>If you want to exclude specific datasets from migration, add exclusions for the source HDFS storage. These exclusions can be based on file size, file names</td>
<td>Hadoop administrator, Application owner</td>
</tr>
</tbody>
</table>
### Create and start the migration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create and configure the migration.</td>
<td>Create a migration in the dashboard of the WANdisco UI. Choose your source (HDFS) and target (the S3 bucket). Add new exclusions that you have defined in the previous step. Select either the &quot;Overwrite&quot; or the &quot;Skip if Size Match&quot; option. Create the migration when all fields are complete.</td>
<td>Hadoop administrator, Application owner</td>
</tr>
<tr>
<td>Start the migration.</td>
<td>On the dashboard, select the migration you created. Click to start the migration. You can also start a migration automatically by choosing the auto-start option when you create the migration.</td>
<td>Application owner</td>
</tr>
</tbody>
</table>

### Manage bandwidth (optional)

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set a network bandwidth limit between the source and target.</td>
<td>In the Storages list on the dashboard, select your source storage and select &quot;Bandwidth Management&quot; in the Grouping list. Clear the unlimited option, and define the maximum bandwidth limit and unit. Choose &quot;Apply.&quot;</td>
<td>Application owner, Networking</td>
</tr>
</tbody>
</table>

### Monitor and manage migrations

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>View migration information using the WANdisco UI.</td>
<td>Use the WANdisco UI to view license, bandwidth, storage and migration information. The UI also provides a notification system so you can receive notifications about errors,</td>
<td>Hadoop administrator, Application owner</td>
</tr>
</tbody>

### Additional information

**Installing LiveData Migrator**

You can use the following commands to install LiveData Migrator, assuming that the installer is inside your working directory:

```
su - hdfs
chmod +x livedata-migrator.sh && sudo ./livedata-migrator.sh
```

**Checking the status of LiveData Migrator and other services after installation**

Use the following commands to check the status of LiveData Migrator, Hive migrator, and WANdisco UI:

```
service livedata-migrator status
service hivemigrator status
service livedata-ui status
```

Access on-premises Microsoft SQL Server tables from Microsoft SQL Server on Amazon EC2 using linked servers

Summary

This pattern describes how to access on-premises Microsoft SQL Server database tables running on Microsoft Windows, from Microsoft SQL Server databases running or hosted on Amazon Elastic Compute Cloud (Amazon EC2) Windows or Linux instances by using linked servers.

Prerequisites and limitations

**Prerequisites**

- An active AWS account
- Amazon EC2 with Microsoft SQL Server running on Amazon Linux AMI (Amazon Machine Image)
- AWS Direct Connect between the on-premises Microsoft SQL Server (Windows) server and the Windows or Linux EC2 instance

**Product versions**

- SQL Server 2016 or later

Architecture

**Source technology stack**

- On-premises Microsoft SQL Server database running on Windows
- Amazon EC2 with Microsoft SQL Server running on Windows AMI or Linux AMI

**Target technology stack**

- Amazon EC2 with Microsoft SQL Server running on Amazon Linux AMI
- Amazon EC2 with Microsoft SQL Server running on Windows AMI

**Source and target database architecture**
Tools

- **Microsoft SQL Server Management Studio (SSMS)** is an integrated environment for managing a SQL Server infrastructure. It provides a user interface and a group of tools with rich script editors that interact with SQL Server.

Related resources

- Release notes for SQL Server on Linux

Additional information

Using stored procedures to create linked servers

SSMS doesn't support the creation of linked servers for Linux SQL Server, so you have to use these stored procedures to create them:
EXEC master.sys.sp_addlinkedserver @server= N'SQLLIN' , @srvproduct= N'SQL Server'
EXEC master.dbo.sp_addlinkededsrvlogin
    @rmtsrvname=N'SQLLIN',@useself=N'False',@locallogin=NULL,@rmtuser=N'username',@rmtpassword='Test123$'

Note 1: Enter the sign-in credentials that you created earlier in Windows SQL Server in the stored
procedure master.dbo.sp_addlinkededsrvlogin.

Note 2: @server name SQLLIN and host file entry name 172.12.12.4 SQLLIN should be the same.

You can use this process to create linked servers for the following scenarios:

- Linux SQL Server to Windows SQL Server through a linked server (as specified in this pattern)
- Windows SQL Server to Linux SQL Server through a linked server
- Linux SQL Server to another Linux SQL Server through a linked server
Add HA to Oracle PeopleSoft on Amazon RDS Custom by using a read replica

Summary

To run the Oracle PeopleSoft enterprise resource planning (ERP) solution on Amazon Web Services (AWS), you can use Amazon Relational Database Service (Amazon RDS) or Amazon RDS Custom for Oracle, which supports legacy, custom, and packaged applications that require access to the underlying operating system and database environment. For key factors to consider when planning a migration, see Oracle database migration strategies in AWS Prescriptive Guidance.

As of this writing, RDS Custom for Oracle doesn't support the Multi-AZ option, which is available for Amazon RDS for Oracle as an HA solution using storage replication. Instead, this pattern achieves HA by using a standby database that creates and maintains a physical copy of the primary database. The pattern focuses on the steps to run a PeopleSoft application database on Amazon RDS Custom with HA by using Oracle Data Guard to set up a read replica.

This pattern also changes the read replica to read-only mode. Having your read replica in read-only mode provides additional benefits:

- Offloading read-only workloads from the primary database
- Enabling automatic repair of corrupted blocks by retrieving healthy blocks from the standby database using the Oracle Active Data Guard feature
- Using the Far Sync capability to keep the remote standby database in sync without the performance overhead associated with long-distance redo log transmission.

Using a replica in read-only mode requires the Oracle Active Data Guard option, which comes at an extra cost because it is a separately licensed feature of Oracle Database Enterprise Edition.

Prerequisites and limitations

Prerequisites

- An existing PeopleSoft application on Amazon RDS Custom. If you don’t have an application, see the pattern Migrate Oracle PeopleSoft to Amazon RDS Custom.
- A single PeopleSoft application tier. However, you can adapt this pattern to work with multiple application tiers.
- Amazon RDS Custom configured with at least 8 GB of swap space.
- An Oracle Active Data Guard database license for converting the read replica into read-only mode and using it for offloading reporting tasks to the standby. For more information, see the Oracle Technology Commercial Price List.
Limitations

- General limitations and unsupported configurations for RDS Custom for Oracle
- Limitations associated with Amazon RDS Custom for Oracle read replicas

Product versions

- For Oracle Database versions supported by Amazon RDS Custom, see RDS Custom for Oracle.
- For Oracle Database instance classes supported by Amazon RDS Custom, see DB instance class support for RDS Custom for Oracle.

Architecture

Target technology stack

- Amazon RDS Custom for Oracle
- AWS Secrets Manager
- Oracle Active Data Guard
- Oracle PeopleSoft application

Target architecture

The following diagram shows an Amazon RDS Custom DB instance and an Amazon RDS Custom read replica. The read replica uses Oracle Active Data Guard to replicate to another Availability Zone. You can also use the read replica to offload read traffic on the primary database and for reporting purposes.

For a representative architecture using Oracle PeopleSoft on AWS, see Set up a highly available PeopleSoft architecture on AWS.
Tools

AWS services

- **Amazon RDS Custom for Oracle** is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment.

- **AWS Secrets Manager** helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically. In this pattern, you retrieve the database user passwords from Secrets Manager for RDS_DATAGUARD with the secret name `do-not-delete-rds-custom-+<<RDS Resource ID>>+-dg`.

Other Tools

- **Oracle Data Guard** helps you create, maintain, manage, and monitor standby databases.

Best practices

To work toward a zero data loss (RPO=0) objective, use the Max Availability Data Guard protection mode, with the redo transport `SYNC+NOAFFIRM` setting for better performance. For more information about selecting the database protection mode, see the **Additional information** section.

Epics

Create the read replica

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the read replica.</td>
<td>To create a read replica of the Amazon RDS Custom DB instance, follow the instructions in the <a href="https://docs.aws.amazon.com/AmazonRDS%E9%B3%85Manual/RDS-Database-User-Guide.html">Amazon RDS documentation</a> and use the Amazon RDS Custom DB instance that you created (see the <strong>Prerequisites</strong> section) as the source database. By default, the Amazon RDS Custom read replica is created as a physical standby and is in the mounted state. This is intentional to ensure compliance with the Oracle Active Data Guard license. This pattern includes code for setting up a multitenant container database (CDB) or a non-CDB instance.</td>
<td>DBA</td>

<tr>
<td>Access the Data Guard broker configuration on the primary database.</td>
<td>In this example, the Amazon RDS Custom read replica is RDS_CUSTOM_ORCL_D for the Non-CDB instance and RDS_CUSTOM_RDSCDB_B for the CDB instance. The databases for Non-CDB are orcl_a (primary) and orcl_d (standby). The database names for CDB are rdscdb_a (primary) and rdscdb_b (standby). You can connect to the RDS Custom read replica directly or through the primary database. You can find the net service name for your database in the tnsnames.ora file located in the $ORACLE_HOME/network/admin directory. RDS Custom for Oracle automatically populates these entries for your primary database and your read replicas. The password for the RDS_DATAGUARD user is stored in AWS Secrets Manager, with secret name do-not-delete-rds-custom-+&lt;&lt;RDS Resource ID&gt;&gt;+-dg. For more information on how to connect to an RDS Custom instance using the SSH (Secure Shell) key retrieved from Secrets Manager, see Connecting to your RDS Custom DB instance using SSH. To access the Oracle Data Guard broker configuration through the Data Guard command line (dgmgrl), use the following code.</td>

## Additional information

### Select your database protection mode

Oracle Data Guard provides three protection modes to configure your Data Guard environment based on your availability, protection, and performance requirements. The following table summarizes these three modes.

<table>
<thead>
<tr>
<th>Protection mode</th>
<th>Redo transport setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>MAXIMUM PERFORMANCE</strong></td>
<td>ASYNC</td>
<td>For transactions happening on the primary database, redo data is asynchronously transmitted and written to the standby database redo log. Therefore, the performance impact is minimal. MaxPerformance can't provide RPO=0 because of asynchronous log shipping.</td>
</tr>
<tr>
<td><strong>MAXIMUM PROTECTION</strong></td>
<td>SYNC+AFFIRM</td>
<td>For transactions on the primary database, redo data is synchronously transmitted and written to the standby database redo log on disk before the transaction is acknowledged. If the standby database becomes unavailable, the primary database shuts itself down to ensure transactions are protected.</td>
</tr>
<tr>
<td><strong>MAXIMUM AVAILABILITY</strong></td>
<td>SYNC+AFFIRM</td>
<td>This is similar to MaxProtection mode, except when no acknowledgement is received from the standby database. In that case, it operates as if it were in MaxPerformance mode to preserve the primary database availability until it's able to write its redo stream to a synchronized standby database again.</td>
</tr>
<tr>
<td></td>
<td>SYNC+NOAFFIRM</td>
<td>For transactions on the primary database, redo is synchronously transmitted to the standby database, and the primary waits only for acknowledgement that the redo has been received on the standby, not that it has been written to the standby disk. This mode, which is also known as FastSync, can provide a</td>
</tr>
</tbody>
</table>
Read replicas in RDS Custom for Oracle are created with maximum performance protection mode, which is also the default protection mode for Oracle Data Guard. The maximum performance mode provides the lowest performance impact on the primary database, which can help you meet the recovery point objective (RPO) requirement measured in seconds.

To work to achieve a zero data loss (RPO=0) objective, you can customize the Oracle Data Guard protection mode to MaxAvailability with the SYNC+NOAFFIRM setting for redo transport for better performance. Because commits on the primary database are acknowledged only after the corresponding redo vectors are successfully transmitted to the standby database, the network latency between the primary instance and replica can be crucial for commit-sensitive workloads. We recommend performing load testing for your workload to assess the performance impact when the read replica is customized to run in MaxAvailability mode.

Deploying the read replica in the same Availability Zone as the primary database provides lower network latency compared with deploying the read replica in a different Availability Zone. However, deploying the primary and read replicas in the same Availability Zone might not meet your HA requirements because, in the unlikely event of Availability Zone unavailability, both the primary instance and read replica instance are impacted.
Assess query performance for migrating SQL Server databases to MongoDB Atlas on AWS

Created by Battulga Purevragchaa (AWS), Krishnakumar Sathyanarayana (PeerIslands US Inc), and Babu Srinivasan (MongoDB)

Summary

This pattern provides guidance for loading MongoDB with near real-world data and assessing MongoDB query performance that is as close to the production scenario as possible. The assessment provides input to help you plan your migration to MongoDB from a relational database. The pattern uses PeerIslands Test Data Generator and Performance Analyzer to test query performance.

This pattern is particularly useful for Microsoft SQL Server migration to MongoDB, because performing schema transformations and loading data from current SQL Server instances to MongoDB can be very complex. Instead, you can load near real-world data into MongoDB, understand MongoDB performance, and fine-tune the schema design before you start the actual migration.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Familiarity with MongoDB Atlas
- Target MongoDB schema
- Typical query patterns

Limitations

- Data load times and performance will be limited by the MongoDB cluster instance size. We recommend that you choose instances that are recommended for production use to understand real-world performance.
- PeerIslands Test Data Generator and Performance Analyzer currently supports only online data loads and queries. Offline batch processing (for example, loading data into MongoDB by using Spark connectors) isn't yet supported.
- PeerIslands Test Data Generator and Performance Analyzer supports field relations within a collection. It doesn't support relationships across collections.

Product editions

- This pattern supports both MongoDB Atlas and MongoDB Enterprise Advanced.
Architecture

Target technology stack

- MongoDB Atlas or MongoDB Enterprise Advanced

Architecture

PeerIslands Test Data Generator and Performance Analyzer is built by using Java and Angular, and stores its generated data on Amazon Elastic Block Store (Amazon EBS). The tool consists of two workflows: test data generation and performance testing.

- In test data generation, you create a template, which is the JSON representation of the data model that has to be generated. After you create the template, you can generate the data in a target collection, as defined by the load generation configuration.
In performance testing, you create a profile. A profile is a multi-stage testing scenario where you can configure create, read, update, and delete (CRUD) operations, aggregation pipelines, the weightage for each operation, and the duration of each stage. After you create the profile, you can run performance testing on the target database based on the configuration.

PeerIslands Test Data Generator and Performance Analyzer stores its data on Amazon EBS, so you can connect Amazon EBS to MongoDB by using any MongoDB-supported connection mechanism, including peering, allow lists, and private endpoints. By default, the tool doesn’t include operational components; however, it can be configured with Amazon Managed Service for Prometheus, Amazon Managed Grafana, Amazon CloudWatch, and AWS Secrets Manager if required.

Tools

- PeerIslands Test Data Generator and Performance Analyzer includes two components. The Test Data Generator component helps you generate highly customer-specific, real-world data based on your MongoDB schema. The tool is fully UI-driven with a rich data library and can be used to quickly generate billions of records on MongoDB. The tool also provides capabilities to implement relationships between fields in the MongoDB schema. The Performance Analyzer component helps you generate highly customer-specific queries and aggregations, and perform realistic performance testing on MongoDB. You can use the Performance Analyzer to test MongoDB performance with rich load profiles and parameterized queries for your specific use case.

Automate the replication of Amazon RDS instances across AWS accounts

Created by Parag Nagwekar (AWS) and Arun Chandapillai (AWS)

<table>

</table>

Summary

This pattern shows you how to automate the process of replicating, tracking, and rolling back your Amazon Relational Database Service (Amazon RDS) DB instances across different AWS accounts by using AWS Step Functions and AWS Lambda. You can use this automation to perform large-scale replication of RDS DB instances without any performance impact or operational overhead—regardless of the size of your organization. You can also use this pattern to help your organization comply with mandatory data governance strategies or compliance requirements that call for your data to be replicated and redundant across different AWS accounts and AWS Regions. Cross-account replication of Amazon RDS data at scale is an inefficient and error-prone manual process that can be costly and time-consuming, but the automation in this pattern can help you achieve cross-account replication safely, effectively, and efficiently.

Prerequisites and limitations

Prerequisites

- Two AWS accounts
- An RDS DB instance, up and running in the source AWS account
- A subnet group for the RDS DB instance in the destination AWS account
- An AWS Key Management Service (AWS KMS) key created in the source AWS account and shared with the destination account (For more information about policy details, see the Additional information section of this pattern.)
- An AWS KMS key in the destination AWS account to encrypt the database in the destination account

Product versions

- Python 3.9 (using AWS Lambda)
- PostgreSQL 11.3, 13.x, and 14.x

Architecture

Technology stack

- Amazon Relational Database Service (Amazon RDS)
- Amazon Simple Notification Service (Amazon SNS)
- AWS Key Management Service (AWS KMS)
- AWS Lambda
- AWS Secrets Manager
- AWS Step Functions

Target architecture

The following diagram shows an architecture for using Step Functions to orchestrate scheduled, on-demand replication of RDS DB instances from a source account (account A) to a destination account (account B).

In the source account (account A in the diagram), the Step Functions state machine performs the following:

1. Creates a snapshot from the RDS DB instance in account A.
2. Copies and encrypts the snapshot with an AWS KMS key from account A. To ensure encryption in transit, the snapshot is encrypted whether or not the DB instance is encrypted.
3. Shares the DB snapshot with account B by giving account B access to the snapshot.
4. Pushes a notification to the SNS topic, and then the SNS topic invokes the Lambda function in account B.

In the destination account (account B in the diagram), the Lambda function runs the Step Functions state machine to orchestrate the following:

1. Copies the shared snapshot from account A to account B, while using the AWS KMS key from account A to decrypt the data first and then encrypt the data by using the AWS KMS key in account B.
2. Reads the secret from Secrets Manager to capture the name of the current DB instance.
3. Restores the DB instance from the snapshot with a new name and default AWS KMS key for Amazon RDS.
4. Reads the endpoint of the new database and updates the secret in Secrets Manager with the new database endpoint, and then tags the previous DB instance so that it can be deleted later.
5. Keeps the latest N instances of the databases and deletes all the other instances.

Tools

AWS tools

- **Amazon Relational Database Service (Amazon RDS)** helps you set up, operate, and scale a relational database in the AWS Cloud.
- **Amazon Simple Notification Service (Amazon SNS)** helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- **AWS CloudFormation** helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- **AWS Key Management Service (AWS KMS)** helps you create and control cryptographic keys to help protect your data.
- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- **AWS SDK for Python (Boto3)** is a software development kit that helps you integrate your Python application, library, or script with AWS services.
- **AWS Secrets Manager** helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- **AWS Step Functions** is a serverless orchestration service that helps you combine Lambda functions and other AWS services to build business-critical applications.

Code

The code for this pattern is available in the GitHub [Crossaccount RDS Replication](https://github.com/aws-samples/crossaccount-rds-replication) repository.

Epics

Automate the replication of RDS DB instances across AWS accounts with a single click

<table>
<thead>
<tr>

| Deploy the CloudFormation stack in the source account. | 1. Sign in to the AWS Management Console for the source account (account A) and open the CloudFormation console.  
2. In the navigation pane, choose Stacks.  
3. Choose Create stack, and then choose With existing resources (import resources).  
4. On the Identify resources page, choose Next.  
5. On the Specify template page, select Upload a template. | Cloud administrator, Cloud architect |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.</td>
<td>Choose <strong>Choose file</strong>, select the Cloudformation-SourceAccountRDS.yaml file from the GitHub <a href="https://github.com">Crossaccount RDS Replication</a> repository, and then choose <strong>Next</strong>.</td>
<td></td>
</tr>
<tr>
<td>7.</td>
<td>For <strong>Stack name</strong>, enter a name for your stack.</td>
<td></td>
</tr>
</tbody>
</table>
| 8. | In the **Parameters** section, specify the parameters that are defined in the stack template:  
• For **DestinationAccountNumber**, enter the account number for your destination RDS DB instance.  
• For **KeyName**, enter your AWS KMS key.  
• For **ScheduleExpression**, enter a **cron expression** (the default is 12:00 am daily).  
• For **SourceDBIdentifier**, enter the name of the source database.  
• For **SourceDBSnapshotName**, enter the name of the snapshot or accept the default. |  |
<p>| 9. | Choose <strong>Next</strong>. |  |
| 10. | On the <strong>Configure stack options</strong> page, leave the default values, and then choose <strong>Next</strong>. |  |
| 11. | Review your stack configuration, and then choose <strong>Submit</strong>. |  |
| 12. | Choose the <strong>Resources</strong> tab for your stack, and then note the Amazon Resource Name (ARN) of the SNS topic. |  |</p>
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Deploy the CloudFormation stack in the destination account. | 1. Sign in to the AWS Management Console for the destination account (account B) and open the [CloudFormation console](https://aws.amazon.com).  
2. In the navigation pane, choose **Stacks**.  
3. Choose **Create stack**, and then choose **With existing resources (import resources)**.  
4. On the **Identify resources** page, choose **Next**.  
5. On the **Specify template** page, select **Upload a template**.  
6. Choose **file**, select the Cloudformation-DestinationAccountRDS.yaml file from the GitHub [Crossaccount RDS Replication](https://github.com/aws-samples/crossaccount-rds-replication) repository, and then choose **Next**.  
7. For **Stack name**, enter a name for your stack.  
8. In the **Parameters** section, specify the parameters that are defined in the stack template:  
   • For **DatabaseName**, enter a name for your database.  
   • For **Engine**, enter the database engine type that matches the source database.  
   • For **DBInstanceClass**, enter the preferred database instance type or accept the default.  
   • For **Subnetgroups**, enter the existing VPC subnet group. For instructions about creating a subnet group, see [Step 2: Create a DB subnet group](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Concepts.DBSubnetGroups.html) in the Amazon RDS User Guide.  
   • For **SecretName**, enter the path and secret name, or accept the default.  
   • For **SGID**, enter the security group ID of your destination cluster. | Cloud architect, DevOps engineer, Cloud administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Sign in to the AWS Management Console and open the Amazon RDS console.</td>
<td>Cloud administrator, Cloud architect, DevOps engineer</td>
</tr>
<tr>
<td>2.</td>
<td>In the navigation pane, choose Databases, and then verify that the new RDS DB instance appears under the new cluster.</td>
<td></td>
</tr>
<tr>
<td>9.</td>
<td>Choose Next.</td>
<td></td>
</tr>
<tr>
<td>10.</td>
<td>On the Configure stack options page, leave the default values, and then choose Next.</td>

Automatically back up SAP HANA databases using Systems Manager and EventBridge

*Created by Ambarish Satarkar (AWS) and Gaurav Rath*

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: Production</th>
<th>Technologies: Databases; Storage &amp; backup</th>
</tr>
</thead>
<tbody>
<tr>
<td>HDB_Backup_SSM_Document</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

| Workload: SAP | AWS services: Amazon EC2; Amazon EventBridge; Amazon S3; AWS Systems Manager |

**Summary**

This pattern describes how to automate SAP HANA database backups using AWS Systems Manager, Amazon EventBridge, Amazon Simple Storage Service (Amazon S3), and AWS Backint Agent for SAP HANA.

This pattern provides a shell script-based approach using the BACKUP DATA command and removes the need to maintain scripts and job configurations for each operating system (OS) instance across numerous systems.

**Prerequisites and limitations**

**Prerequisites**

- An existing SAP HANA instance with a supported release in running state on a managed Amazon Elastic Compute Cloud (Amazon EC2) instance that is configured for Systems Manager
- Systems Manager Agent (SSM Agent) 2.3.274.0 or later installed
- An S3 bucket that doesn't have public access enabled
- An hdbuserstore key named SYSTEM
- An AWS Identity and Access Management (IAM) role for the Automation runbook to run on schedule
- AmazonSSMManagedInstanceCore and ssm:StartAutomationExecution policies are attached to Systems Manager Automation service role.

**Limitations**

- AWS Backint Agent for SAP HANA doesn't support deduplication.
- AWS Backint Agent for SAP HANA doesn't support data compression.

**Product versions**

AWS Backint Agent is supported on the following operating systems:

- SUSE Linux Enterprise Server
- SUSE Linux Enterprise Server for SAP
- Red Hat Enterprise Linux for SAP
AWS Backint Agent supports the following databases:

- SAP HANA 1.0 SP12 (single node and multiple nodes)
- SAP HANA 2.0 and later (single node and multiple nodes)

## Architecture

### Target Technology Stack

- AWS Backint Agent
- Amazon S3
- AWS Systems Manager
- Amazon EventBridge
- SAP HANA

### Target Architecture

The following diagram shows the installation scripts that install AWS Backint Agent, the S3 bucket, and Systems Manager and EventBridge, which use a Command document to schedule regular backups.

![Diagram of installation process]

### Automation and Scale

- Multiple AWS Backint Agents can be installed by using a Systems Manager Automation runbook.
- Each run of the Systems Manager runbook can scale to \( n \) number of SAP HANA instances, based on target selection.
- EventBridge can automate SAP HANA backups.

### Tools

- **AWS Backint Agent for SAP HANA** is a standalone application that integrates with your existing workflows to back up your SAP HANA database to an S3 bucket that you specify in the configuration file. AWS Backint Agent supports full, incremental, and differential backups of SAP HANA databases. It runs on an SAP HANA database server, where backups and catalogs are transferred from the SAP HANA database to the AWS Backint Agent.
- **Amazon EventBridge** is a serverless event bus service that you can use to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your...
applications, software as a service (SaaS) applications, and AWS services to targets such as AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other accounts.

- **Amazon Simple Storage Service (Amazon S3)** is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- **AWS Systems Manager** helps you to view and control your infrastructure on AWS. Using the Systems Manager console, you can view operational data from multiple AWS services and automate operational tasks across your AWS resources.

### Code

The code for this pattern is available in the [aws-backint-automated-backup](https://github.com/aws-backint-automated-backup) GitHub repository.

### Epics

#### Create an hdbuserstore key SYSTEM

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an hdbuserstore key. | 1. Navigate to `/usr/sap/<SID>/HDB<InstNo>/exe`.  
|                          | 2. Run the following command, with XX as the SAP HANA database instance number. | AWS administrator, SAP HANA Administrator |
|                          | `hdbuserstore -i set SYSTEM <hostname>:3XX13@SYSTEMDB SYSTEM`                 |                                  |
|                          | For example, for an SAP HANA host saphanadb with instance number 00, run the following command. |                                  |
|                          | `hdbuserstore -i set SYSTEM saphanadb:30013@SYSTEMDB SYSTEM`                 |                                  |

#### Install AWS Backint Agent

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Install AWS Backint Agent.</td>
<td>Follow the instructions in <a href="https://docs.aws.amazon.com/awssimpleserversvc/latest/userguide/install-simpleserversvc-sap-hana.html">Install and configure AWS Backint Agent for SAP HANA</a> in the AWS Backint Agent documentation.</td>
<td>AWS administrator, SAP HANA administrator</td>
</tr>
</tbody>
</table>
### Create the Systems Manager Command document

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create the Systems Manager Command document. | 1. Sign in to the AWS Management Console and open the AWS Systems Manager Console.  
2. Choose Documents, and choose Owned by me.  
3. Confirm that you are in the same AWS Region as your SAP HANA database.  
4. Choose Create document, Command or session to create your document.  
5. Use a unique and descriptive name, with no spaces (for example, SAP HANA-Backup).  
6. Make sure that Document type is set to Command document.  
7. Under the Content header, there is some sample code. Make sure that you choose the JSON code type, and replace the code with the code from the HDB_Backup_SSM_Document.json file from the GitHub repository.  
8. Choose Create document.  
9. Check your document in the Owned by me section. | AWS administrator, SAP HANA administrator |

### Schedule backups on a regular frequency

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Schedule regular backups using Amazon EventBridge. | 1. Open the Amazon EventBridge console, choose Rules, and choose Create rule.  
2. On the Define rule detail screen, enter a unique name and description for your rule, and use the default event bus.  
3. Under Rule type, choose Schedule, and choose Next.  
4. On then Define schedule screen, choose the | AWS administrator, SAP HANA administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.</td>
<td>On the Select targets screen, for Target type, choose AWS service. Under Select a target, choose Systems Manager Run Command.</td>
<td></td>
</tr>
<tr>
<td>6.</td>
<td>Choose the document that you created earlier.</td>
<td></td>
</tr>
<tr>
<td>7.</td>
<td>Under Target key and Target value, provide the instance ID. You can use tag names and tag values to add multiple instances.</td>
<td></td>
</tr>
<tr>
<td>8.</td>
<td>Under Configure automation parameters, choose Constant for incremental or differential backups. If you want full backup, choose No Parameters.</td>
<td></td>
</tr>
<tr>
<td>9.</td>
<td>Choose whether to create a new role or to use an existing role. If you use an existing role, make sure that it has the policies required to invoke the target.</td>
<td></td>
</tr>
<tr>
<td>10.</td>
<td>Keep the default additional settings, and choose Next.</td>
<td></td>
</tr>
<tr>
<td>11.</td>
<td>The Configure tags screen is optional. Choose next.</td>
<td></td>
</tr>
<tr>
<td>12.</td>
<td>On the Review and create screen, review the rule settings, and choose Create. The rule should be successfully created.</td>
<td></td>
</tr>
</tbody>
</table>

You can verify backup success from the S3 bucket path.

`s3://<your_bucket_name>/<target_folder>/<SID>/usr/sap/<SID>/SYS/global/hdb/backint/DB_<SID>/`

You can also verify backups from the SAP HANA backup catalog.

Block public access to Amazon RDS by using Cloud Custodian

Created by abhay kumar (AWS) and Dwarika Patra (AWS)

<table>
<thead>

</tr>
</tbody>
</table>

**Summary**

Many organizations run their workloads and services on multiple cloud vendors. In these hybrid cloud environments, the cloud infrastructure needs strict cloud governance, in addition to the security provided by the individual cloud providers. A cloud database such as Amazon Relational Database Service (Amazon RDS) is one important service that must be monitored for any access and permission vulnerabilities. Although you can restrict access to the Amazon RDS database by configuring a security group, you can add a second layer of protection to prohibit actions such as public access. Ensuring public access is blocked will help you with General Data Protection Regulation (GDPR), Health Insurance Portability and Accountability Act (HIPAA), National Institute of Standards and Technology (NIST), and Payment Card Industry Data Security Standard (PCI DSS) compliance.

Cloud Custodian is an open-source rules engine that you can use to enforce access restrictions for Amazon Web Services (AWS) resources such as Amazon RDS. With Cloud Custodian, you can set rules that validate the environment against defined security and compliance standards. You can use Cloud Custodian to manage your cloud environments by helping to ensure compliance with security policies, tag policies, and garbage collection of unused resources and cost management. With Cloud Custodian, you can use a single interface for implementing governance in a hybrid cloud environment. For example, you could use the Cloud Custodian interface to interact with AWS and Microsoft Azure, reducing the effort of working with mechanisms such as AWS Config, AWS security groups, and Azure policies.

This pattern provides instructions for using Cloud Custodian on AWS to enforce restriction of public accessibility on Amazon RDS instances.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- A key pair
- AWS Lambda installed

**Architecture**

**Target technology stack**

- Amazon RDS
- AWS CloudTrail
• AWS Lambda
• Cloud Custodian

**Target architecture**

The following diagram shows Cloud Custodian deploying the policy to Lambda, AWS CloudTrail initiating the `CreateDBInstance` event, and the Lambda function setting `PubliclyAccessible` to false on Amazon RDS.

**Tools**

**AWS services**

• **AWS CloudTrail** helps you audit the governance, compliance, and operational risk of your AWS account.

• **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command line shell.

• **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

• **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

• **Amazon Relational Database Service (Amazon RDS)** helps you set up, operate, and scale a relational database in the AWS Cloud.

**Other tools**

• **Cloud Custodian** unifies the tools and scripts that many organizations use to manage their public cloud accounts into one open source tool. It uses a stateless rules engine for policy definition and enforcement, with metrics, structured outputs, and detailed reporting for cloud infrastructure. It integrates tightly with a serverless runtime to provide real-time remediation and response with low operational overhead.
## Epics

### Set up AWS CLI

```
Security Hub integration

Cloud Custodian can be integrated with AWS Security Hub to send security findings and attempt remediation actions. For more information, see Announcing Cloud Custodian Integration with AWS Security Hub.
Configure read-only routing in an Always On availability group in SQL Server on AWS

Created by Subhani Shaik (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>Databases; Infrastructure</th>
<th>Workload:</th>
<th>Microsoft</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>AWS Managed Microsoft AD; Amazon EC2</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern covers how to use the standby secondary replica in SQL Server Always On by offloading the read-only workloads from the primary replica to the secondary replica.

Database mirroring has one-to-one mapping. You can't read the secondary database directly, so you must create snapshots. The Always On availability group feature was introduced in Microsoft SQL Server 2012. In later versions, major functionalities have been introduced, including read-only routing. In Always On availability groups, you can read the data directly from the secondary replica by changing the replica mode to read-only.

The Always On availability groups solution supports high availability (HA), disaster recovery (DR), and an alternative to database mirroring. Always On availability groups work at the database level and maximize the availability of a set of user databases.

SQL Server uses the read-only routing mechanism to redirect the incoming read-only connections to the secondary read replica. To achieve this, you should add the following parameters and values in the connection string:

- ApplicationIntent=ReadOnly
- Initial Catalog=<database name>

Prerequisites and limitations

Prerequisites

- An active AWS account with a virtual private cloud (VPC), two Availability Zones, private subnets, and a security group
- Two Amazon Elastic Compute Cloud (Amazon EC2) machines with SQL Server 2019 Enterprise Edition Amazon Machine Image with Windows Server Failover Clustering (WSFC) configured at the instance level and an Always On availability group configured at the SQL Server level between the primary node (WSFCNODE1) and the secondary node (WSFCNODE2), which are part of the AWS Directory Service for Microsoft Active Directory directory named tagechtta1k.com
- One or more nodes configured to accept read-only in the secondary replica
- A listener named SQLAG1 for the Always On availability group
- SQL Server Database Engine running with the same service account on two nodes
- SQL Server Management Studio (SSMS)
- A test database named test
Product Versions

- SQL Server 2014 and later

Architecture

Target technology stack

- Amazon EC2
- AWS Managed Microsoft AD
- Amazon FSx

Target architecture

The following diagram shows how the Always On availability group (AG) listener redirects queries that contain the ApplicationIntent parameter in the connection to the appropriate secondary node.
1. A request is sent to the Always On availability group listener.
2. If the connection string does not have the ApplicationIntent parameter, the request is sent to the primary instance.
3. If the connection string contains ApplicationIntent=ReadOnly, the request is sent to the secondary instance with read-only routing configuration, which is WSFC with an Always On availability group.

**Tools**

**AWS services**

- [AWS Directory Service for Microsoft Active Directory](https://aws.amazon.com/directoryservice/microsoft-ads/) enables your directory-aware workloads and AWS resources to use Microsoft Active Directory in the AWS Cloud.
- [Amazon Elastic Compute Cloud (Amazon EC2)](https://aws.amazon.com/ec2/) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Amazon FSx](https://aws.amazon.com/fsx/) provides file systems that support industry-standard connectivity protocols and offer high availability and replication across AWS Regions.

**Other services**

- SQL Server Management Studio (SSMS) is a tool for connecting, managing, and administering the SQL Server instances.
- `sqlcmd` is a command-line utility.

**Best practices**

For more information about Always On availability groups, see the [SQL Server documentation](https://docs.microsoft.com/en-us/sql-server/relational-databases/redundancy/availability-groups/always-on-availability-groups/).

</tr>
</tbody>
</table>

**Test the read-only routing**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Connect by using the ApplicationIntent parameter. | 1. From SSMS, connect to the Always On availability group listener name with ApplicationIntent=ReadOnly;Initial Catalog=test.  
2. The connection is established with the secondary replica. To test this, run the following command to show the connected server name.  
```sql
SELECT SERVERPROPERTY('ComputernamePhysicalNetBios')
```
The output will show the current secondary replica name (WSFCNODE2). | DBA |
| Perform a failover. | 1. From SSMS, connect to the Always On availability group listener name.  
2. Verify that the primary and secondary database are in sync, with no data loss.  
3. Perform a failover so that the current primary replica becomes the secondary replica, and the secondary replica becomes the primary replica.  
4. From SSMS, connect to the Always On availability group listener name with ApplicationIntent=ReadOnly;Initial Catalog=test.  
5. The connection is established with the secondary replica. To test this, show the connected | DBA |
Connect by using the sqlcmd command-line utility

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Connect by using sqlcmd.  | To connect from sqlcmd, run the Step 5 code from the Additional information section at the command prompt. After you are connected, run the following command to show the connected server name.  

```sql
SELECT SERVERPROPERTY('ComputernamePhysicalNetBios')
```

The output will display the current secondary replica name (WSFCNODE1). | DBA              |

Troubleshooting

<table>
<thead>
<tr>
<th>Issue</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creating the listener fails with the message 'The WSFC cluster could not bring the Network Name resource online'.</td>
<td>For information, see the Microsoft blog post [Create Listener Fails with Message 'The WSFC cluster could not bring the Network Name resource online'].</td>
</tr>
</tbody>
</table>

Related resources

- Configure read-only routing for an Always On availability group
- Troubleshoot Always On Availability Groups Configuration (SQL Server)
Additional information

Step 1. Update the replicas to read-only

ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE1' WITH (SECONDARY_ROLE (ALLOW_CONNECTIONS = READ_ONLY))
GO
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE2' WITH (SECONDARY_ROLE (ALLOW_CONNECTIONS = READ_ONLY))
GO

Step 2. Create the routing URL

ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE1' WITH (SECONDARY_ROLE (READ_ONLY_ROUTING_URL = N'TCP://WSFCNode1.tagechtalk.com:1433'))
GO
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE2' WITH (SECONDARY_ROLE (READ_ONLY_ROUTING_URL = N'TCP://WSFCNode2.tagechtalk.com:1433'))
GO

Step 3. Create the routing list

ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE1' WITH (PRIMARY_ROLE(READ_ONLY_ROUTING_LIST=('WSFCNODE2','WSFCNODE1')));
GO
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE2' WITH (PRIMARY_ROLE (READ_ONLY_ROUTING_LIST=('WSFCNODE1','WSFCNODE2')));
GO

Step 4. Validate the routing list

SELECT AVSrc.replica_server_name AS PrimaryReplica, AGRepl.replica_server_name AS ReadOnlyReplica, AGRepl.read_only_routing_url AS RoutingURL, AGL.routing_priority AS RoutingPriority FROM sys.availability_read_only_routing_lists AGL INNER JOIN sys.availability_replicas AVSrc ON AGL.replica_id = AVSrc.replica_id INNER JOIN sys.availability_replicas AGRepl ON AGL.read_only_replica_id = AGRepl.replica_id INNER JOIN sys.availability_groups AV ON AV.group_id = AVSrc.group_id ORDER BY PrimaryReplica

Step 5. SQL Command Utility

sqlcmd -S SQLAG1,1433 -E -d test -K ReadOnly
Connect by using an SSH tunnel in pgAdmin

Created by Jeevan Shetty (AWS) and Bhanu Ganesh Gudivada (AWS)

<table>

<tr>
<td>AWS services:</td>
<td>Amazon RDS; Amazon Aurora</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

For security reasons, it's always good to place databases in a private subnet. Queries against the database can be run by connecting through an Amazon Elastic Compute Cloud (Amazon EC2) bastion host in a public subnet on the Amazon Web Services (AWS) Cloud. This requires installing software, such as pgAdmin or DBeaver, which are commonly used by developers or database administrators, on the Amazon EC2 host.

Running pgAdmin on a Linux server and accessing it through a web browser requires the installation of additional dependencies, permissions setup, and configuration.

As an alternate solution, developers or database administrators can connect to a PostgreSQL database by using pgAdmin to enable an SSH tunnel from their local system. In this approach, pgAdmin uses the Amazon EC2 host in the public subnet as an intermediary host before connecting to the database. The diagram in the Architecture section shows the setup.

Note: Ensure that the security group attached to the PostgreSQL database allows connection on port 5432 from the Amazon EC2 host.

Prerequisites and limitations

Prerequisites

- An existing AWS account
- A virtual private cloud (VPC) with a public subnet and a private subnet
- An EC2 instance with a security group attached
- An Amazon Aurora PostgreSQL-Compatible Edition database with a security group attached
- A Secure Shell (SSH) key pair for setting up the tunnel

Product versions

- pgAdmin version 6.2+
- Amazon Aurora PostgreSQL-Compatible Edition version 12.7+

Architecture

Target technology stack

- Amazon EC2
- Amazon Aurora PostgreSQL-Compatible
Target architecture

The following diagram shows using pgAdmin with an SSH tunnel to connect through an internet gateway to the EC2 instance, which connects to the database.

Tools

AWS services

• Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.

• Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

Other services

• pgAdmin is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

Epics

Create the connection

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a server.</td>
<td>In pgAdmin, choose Create, and then choose Server. For additional help with setting up pgAdmin to register a server, configure a connection, and connect through SSH tunneling by using the Server Dialog, see the links in the Related resources section.</td>
<td>DBA</td>
</tr>
<tr>
<td>Provide a name for the server.</td>
<td>On the General tab, enter a name.</td>
<td>DBA</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
</tbody>
</table>
| Enter the database details. | On the **Connection** tab, enter values for the following:  
  - Host name/address  
  - Port  
  - Maintenance database  
  - Username  
  - Password | DBA |
| Enter the Amazon EC2 server details. | On the **SSH Tunnel** tab, provide the details of the Amazon EC2 instance that is in the public subnet.  
  - Set **Use SSH tunneling** to **Yes** to specify that pgAdmin should use an SSH tunnel when connecting to the specified server.  
  - In the **Tunnel host** field, specify the name or IP address of the SSH host (for example, 10.x.x.x).  
  - In the **Tunnel port** field, specify the port of the SSH host (for example, 22).  
  - In the **Username** field, specify the name of a user with login privileges for the SSH host (for example, ec2-user).  
  - Specify the type of authentication as **Identity file** so that pgAdmin will use a private key file when connecting.  
  - Include the location of the Privacy Enhanced Mail (PEM) file in the **Identity file** field. The .pem file is the Amazon EC2 key pair. | DBA |
| Save and connect. | Choose **Save** to complete the setup and connect to the Aurora PostgreSQL-Compatible database by using the SSH tunnel. | DBA |

**Convert JSON Oracle queries into PostgreSQL database SQL**

*Created by Pinesh Singal (AWS) and Lokesh Gurram (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>Databases: Relational</th>
<th>Target: Amazon RDS PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>
<td>Re-architect</td>
<td>Workload:</td>
<td>Oracle</td>
<td>Technologies: Databases; Migration</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon Aurora;</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

This migration process for moving from on-premises to the Amazon Web Services (AWS) Cloud uses the AWS Schema Conversion Tool (AWS SCT) to convert the code from an Oracle database into a PostgreSQL database. Most of the code is automatically converted by AWS SCT. However, JSON-related Oracle queries are not automatically converted.

Starting from Oracle 12.2 version, Oracle Database supports various JSON functions that help in converting JSON-based data into ROW-based data. However, AWS SCT doesn't automatically convert JSON-based data into language that is supported by PostgreSQL.

This migration pattern primarily focuses on manually converting the JSON-related Oracle queries with functions such as `JSON_OBJECT`, `JSON_ARRAYAGG`, and `JSON_TABLE` from an Oracle database to a PostgreSQL database.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- An on-premises Oracle database instance (up and running)
- An Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition database instance (up and running)

**Limitations**

- JSON-related queries require a fixed KEY and VALUE format. Not using that format returns the wrong result.
- If any change in JSON structure adds new KEY and VALUE pairs in the result section, the corresponding procedure or function must be changed in the SQL query.
- Some JSON-related functions are supported in earlier versions of Oracle and PostgreSQL but with fewer capabilities.

**Product versions**
• Oracle Database version 12.2 and later
• Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible version 9.5 and later
• AWS SCT latest version (tested using version 1.0.664)

Architecture

Source technology stack

• An Oracle database instance with version 19c

Target technology stack

• An Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database instance with version 13

Target architecture

1. Use AWS SCT with the JSON function code to convert the source code from Oracle to PostgreSQL.
2. The conversion produces PostgreSQL-supported migrated .sql files.
3. Manually convert the non-converted Oracle JSON function codes to PostgreSQL JSON function codes.
4. Run the .sql files on the target Aurora PostgreSQL-Compatible DB instance.

Tools

AWS services

• **Amazon Aurora** is a fully managed relational database engine that's built for the cloud and compatible with MySQL and PostgreSQL.
• **Amazon Relational Database Service (Amazon RDS) for PostgreSQL** helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
• **AWS Schema Conversion Tool (AWS SCT)** supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database.
Other services

- **Oracle SQL Developer** is an integrated development environment that simplifies the development and management of Oracle databases in both traditional and cloud-based deployments.
- pgAdmin or DBeaver. **pgAdmin** is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects. **DBeaver** is a universal database tool.

Best practices

Oracle query has type CAST as the default when using the JSON_TABLE function. A best practice is to use CAST in PostgreSQL too, using double greater-than characters (>>).

For more information, see Postgres_SQL_Read_JSON in the Additional information section.

To convert JSON code from the Oracle database to PostgreSQL database, use the following scripts, in order.

1. **Oracle_Table_Creation_Insert_Script**

```sql
create table aws_test_table(id number,created_on date default sysdate,modified_on
date,json_doc clob);

REM INSERTING into EXPORT_TABLE
SET DEFINE OFF;
Insert into aws_test_table (ID,CREATED_ON,MODIFIED_ON,json_doc)
values (1,to_date('02-AUG-2022 12:30:14','DD-MON-YYYY HH24:MI:SS'),to_date('02-AUG-2022
12:30:14','DD-MON-YYYY HH24:MI:SS'),TO_CLOB(q'[{
"metadata" : {
"upperLastNameFirstName" : "ABC XYZ",
"upperEmailAddress" : "abc@gmail.com",
"profileType" : "P"
},
"data" : {
"onlineContactId" : "032323323",
"displayName" : "Abc, Xyz",
"firstName" : "Xyz",
"lastName" : "Abc",
"emailAddress" : "abc@gmail.com",
"productRegistrationStatus" : "Not registered",
"positionId" : "0100",
"arrayPattern" : " -'",
"a"]')
|| TO_CLOB(q'[<count" : {
"companyId" : "SMGE",
"businessUnitId" : 7,
"accountNumber" : 42000,
"parentAccountNumber" : 32000,
"firstName" : "john",
"lastName" : "doe",
"street1" : "retOdertcaShr ",
"city" : "new york",
"postalcode" : "XY ABC",
"country" : "United States"
},
"products" : [
{ "appUserGuid" : "i0acc445000001823fbad478e2eab8a0",
"id" : "00000000046",
}
)
|| TO_CLOB(q'[ "name" : "ProView",
"domain" : "EREADER",
"registrationStatus" : false,
"status" : "11"
]
})
|| TO_CLOB(q'["metadata" : {
"upperLastNameFirstName" : "PQR XYZ",
"upperEmailAddress" : "pqr@gmail.com",
"profileType" : "P"
},
"data" : {
```
```
"onlineContactId" : "54534343",
"displayName" : "Xyz, pqr",
"firstName" : "pqr",
"lastName" : "Xyz",
"emailAddress" : "pqr@gmail.com",
"productRegistrationStatus" : "Not registered",
"positionId" : "0090",
"arrayPattern" : " -",
"account" : {
  "companyId" : "CARS",
  "busin"
}
] TO_CLOB(q'
[essUnitId" : 6,
"accountNumber" : 42001,
"firstName" : "terry",
"lastName" : "whitlock",
"street1" : "UO 123",

    "name" : "ProView eLooseleaf",
  }
] TO_CLOB(q'
[ "domain" : "EREADER",
  "registrationStatus" : false,
  "status" : "11"
]
}
]'))

commit;

2. Postgres_Table_Creation_Insert_Script

create table aws_test_pg_table(id int,created_on date ,modified_on date,json_doc text);
insert into aws_test_pg_table(id,created_on,modified_on,json_doc)
values(1,now(),now(),'{
  "metadata" : {
    "upperLastNameFirstName" : "ABC XYZ",
    "upperEmailAddress" : "abc@gmail.com",
    "profileType" : "P"
  },
  "data" : {
    "onlineContactId" : "032323323",
    "displayName" : "Abc, Xyz",
    "firstName" : "Xyz",
    "lastName" : "Abc",
    "emailAddress" : "abc@gmail.com",
    "productRegistrationStatus" : "Not registered",
    "positionId" : "0100",
    "arrayPattern" : " -",
    "account" : {
      "companyId" : "SMGE",
      "businessUnitId" : 7,
      "accountNumber" : 42000,
      "parentAccountNumber" : 32000,
      "firstName" : "john",
      "lastName" : "doe",
      "street1" : "retOdertcaShr",
    }
  }
});
commit;
3. Oracle_SQL_Read_JSON

The following code blocks show how to convert Oracle JSON data into row format.

Example query and syntax
SELECT JSON_OBJECT(
    'accountCounts' VALUE JSON_ARRAYAGG(
        JSON_OBJECT(
            'businessUnitId' VALUE business_unit_id,
            'parentAccountNumber' VALUE parent_account_number,
            'accountNumber' VALUE account_number,
            'totalOnlineContactsCount' VALUE online_contacts_count,
            'countByPosition' VALUE JSON_OBJECT(
                'taxProfessionalCount' VALUE tax_count,
                'attorneyCount' VALUE attorney_count,
                'nonAttorneyCount' VALUE non_attorney_count,
                'clerkCount' VALUE clerk_count
            )
        )
    )
) FROM
(SELECT
    tab_data.business_unit_id,
    tab_data.parent_account_number,
    tab_data.account_number,
    SUM(1) online_contacts_count,
    SUM(CASE WHEN tab_data.position_id = '0095' THEN 1 ELSE 0 END) tax_count,
    SUM(CASE WHEN tab_data.position_id = '0100' THEN 1 ELSE 0 END) attorney_count,
    SUM(CASE WHEN tab_data.position_id = '0090' THEN 1 ELSE 0 END) non_attorney_count,
    SUM(CASE WHEN tab_data.position_id = '0050' THEN 1 ELSE 0 END) clerk_count
FROM aws_test_table scco,
JSON_TABLE ( json_doc, '$' ERROR ON ERROR
    COLUMNS (
        parent_account_number NUMBER PATH '$.data.account.parentAccountNumber',
        account_number NUMBER PATH '$.data.account.accountNumber',
        business_unit_id NUMBER PATH '$.data.account.businessUnitId',
        position_id VARCHAR2 ( 4 ) PATH '$.data.positionId'
    )
) AS tab_data
INNER JOIN JSON_TABLE ( '{
    "accounts": [{
        "accountNumber": 42000,
        "parentAccountNumber": 32000,
        "businessUnitId": 7
    }, {
        "accountNumber": 42001,
        "parentAccountNumber": 32001,
        "businessUnitId": 6
    }]
}', '$.accounts[*]' ERROR ON ERROR
COLUMNS ( parent_account_number PATH '$.parentAccountNumber',
    account_number PATH '$.accountNumber',
    business_unit_id PATH '$.businessUnitId' )
) AS static_data
ON ( static_data.parent_account_number = tab_data.parent_account_number
    AND static_data.account_number = tab_data.account_number
    AND static_data.business_unit_id = tab_data.business_unit_id )
GROUP BY
    tab_data.business_unit_id,
    tab_data.parent_account_number,
    tab_data.account_number
);

The JSON document stores the data as collections. Each collection can have KEY and VALUE pairs. Every VALUE can have nested KEY and VALUE pairs. The following table provides information about reading the specific VALUE from the JSON document.

<table>
<thead>
<tr>
<th>KEY</th>
<th>HIERARCHY or PATH to be used</th>
<th>VALUE to get the VALUE</th>
</tr>
</thead>
</table>

593
In the previous table, the KEY profileType is a VALUE of the metadata KEY. The KEY positionId is a VALUE of the data KEY. The KEY accountNumber is a VALUE of the account KEY, and the account KEY is a VALUE of the data KEY.

Example JSON document

```json
{
  "metadata": {
    "upperLastNameFirstName": "ABC XYZ",
    "upperEmailAddress": "abc@gmail.com",
    "profileType": "P"
  },
  "data": {
    "onlineContactId": "032323323",
    "displayName": "Abc, Xyz",
    "firstName": "Xyz",
    "lastName": "Abc",
    "emailAddress": "abc@gmail.com",
    "productRegistrationStatus": "Not registered",
    "positionId": "0100",
    "arrayPattern": "-",
    "account": {
      "companyId": "SMGE",
      "businessUnitId": 7,
      "parentAccountNumber": 32000,
      "firstName": "john",
      "lastName": "doe",
      "street1": "retOdertcaShr",
      "city": "new york",
      "postalcode": "XY ABC",
      "country": "United States"
    },
    "products": [
      {
        "appUserGuid": "i0acc4450000001823fbad478e2eab8a0",
        "id": "000000000046",
        "name": "ProView",
        "domain": "EREADER",
        "registrationStatus": false,
        "status": "11"
      }
    ]
  }
}
```

SQL query that is used to get the selected fields from the JSON document

```sql
SELECT parent_account_number, account_number, business_unit_id, position_id FROM aws_test_table AWS, JSON_TABLE (json_doc, '$' ERROR ON ERROR COLUMNS(
  parent_account_number NUMBER PATH '$.data.account.parentAccountNumber',
  account_number NUMBER PATH '$.data.account.accountNumber',
  business_unit_id NUMBER PATH '$.data.account.businessUnitId',
  position_id NUMBER PATH '$.data.positionId'
))
```
position_id VARCHAR2 ( 4 ) PATH '$.data.positionId'
)) as sc

In the previous query, JSON_TABLE is a built-in function in Oracle that converts the JSON data into row format. The JSON_TABLE function expects parameters in JSON format.

Every item in COLUMNS has a predefined PATH, and there an appropriate VALUE for a given KEY is returned in row format.

**Result from the previous query**

<table>
<thead>
<tr>
<th>PARENT_ACCOUNT_NUMBER</th>
<th>ACCOUNT_NUMBER</th>
<th>BUSINESS_UNIT_ID</th>
<th>POSITION_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>32000</td>
<td>42000</td>
<td>7</td>
<td>0100</td>
</tr>
<tr>
<td>32001</td>
<td>42001</td>
<td>6</td>
<td>0090</td>
</tr>
</tbody>
</table>

### 4. Postgres_SQL_Read_JSON

**Example query and syntax**

```
select *
from (select (json_doc::json->'data')->'account')->'parentAccountNumber')::INTEGER as parentAccountNumber,
(json_doc::json->'data')->'account')->'accountNumber')::INTEGER as accountNumber,
(json_doc::json->'data')->'account')->'businessUnitId')::INTEGER as businessUnitId,
(json_doc::json->'data')->'positionId')::VARCHAR as positionId
from aws_test_pg_table) d ;
```

In Oracle, PATH is used to identify the specific KEY and VALUE. However, PostgreSQL uses a HIERARCHY model for reading KEY and VALUE from JSON. The same JSON data mentioned under Oracle_SQL_Read_JSON is used in the following examples.

**SQL query with type CAST not allowed**

(If you force type CAST, the query fails with a syntax error.)

```
select *
from (select (json_doc::json->'data')->'account')->'parentAccountNumber' as parentAccountNumber,
(json_doc::json->'data')->'account')->'accountNumber' as accountNumber,
(json_doc::json->'data')->'account')->'businessUnitId' as businessUnitId,
(json_doc::json->'data')->'positionId' as positionId
from aws_test_pg_table) d ;
```

Using a single greater-than operator (>) will return the VALUE defined for that KEY. For example, KEY: positionId, and VALUE: "0100".

Type CAST is not allowed when you use the single greater-than operator (>).

**SQL query with type CAST allowed**

```
select *
from (select (json_doc::json->'data')->'account')->'parentAccountNumber' as parentAccountNumber,
(json_doc::json->'data')->'account')->'accountNumber' as accountNumber,
(json_doc::json->'data')->'account')->'businessUnitId' as businessUnitId,
(json_doc::json->'data')->'positionId' as positionId
from aws_test_pg_table) d ;
```
select (json_doc::json->'data'->>'account'->>'parentAccountNumber')::INTEGER as parentAccountNumber, (json_doc::json->'data'->>'account'->>'accountNumber')::INTEGER as accountNumber, (json_doc::json->'data'->>'account'->>'businessUnitId')::INTEGER as businessUnitId, (json_doc::json->'data'->>'positionId')::varchar as positionId from aws_test_pg_table) d ;

To use type CAST, you must use the double greater-than operator. If you use the single greater-than operator, the query returns the VALUE defined (for example, KEY: positionId, and VALUE: "0100"). Using the double greater-than operator (>>) will return the actual value defined for that KEY (for example, KEY: positionId, and VALUE: 0100, without double quotation marks).

In the preceding case, parentAccountNumber is type CAST to INT, accountNumber is type CAST to INT, businessUnitId is type CAST to INT, and positionId is type CAST to VARCHAR.

The following tables show query results that explain role of the single greater-than operator (>) and the double greater-than operator (>>).

In the first table, the query uses the single greater-than operator (>). Each column is in JSON type and can't be converted into another data type.

<table>
<thead>
<tr>
<th>parentAccountNumber</th>
<th>accountNumber</th>
<th>businessUnitId</th>
<th>positionId</th>
</tr>
</thead>
<tbody>
<tr>
<td>2003565430</td>
<td>2003564830</td>
<td>7</td>
<td>&quot;0100&quot;</td>
</tr>
<tr>
<td>2005284042</td>
<td>2005284042</td>
<td>6</td>
<td>&quot;0090&quot;</td>
</tr>
<tr>
<td>2000272719</td>
<td>2000272719</td>
<td>1</td>
<td>&quot;0100&quot;</td>
</tr>
</tbody>
</table>

In the second table, the query uses the double greater-than operator (>>). Each column supports type CAST based on the column value. For example, INTEGER in this context.

<table>
<thead>
<tr>
<th>parentAccountNumber</th>
<th>accountNumber</th>
<th>businessUnitId</th>
<th>positionId</th>
</tr>
</thead>
<tbody>
<tr>
<td>2003565430</td>
<td>2003564830</td>
<td>7</td>
<td>0100</td>
</tr>
<tr>
<td>2005284042</td>
<td>2005284042</td>
<td>6</td>
<td>0090</td>
</tr>
<tr>
<td>2000272719</td>
<td>2000272719</td>
<td>1</td>
<td>0100</td>
</tr>
</tbody>
</table>

5. Oracle_SQL_JSON_Aggregation_Join

Example query

```sql
SELECT
  JSON_OBJECT('accountCounts' VALUE JSON_ARRAYAGG(
    JSON_OBJECT('businessUnitId' VALUE business_unit_id,
    'parentAccountNumber' VALUE parent_account_number,
    'accountNumber' VALUE account_number,
    'totalOnlineContactsCount' VALUE online_contacts_count,
    'countByPosition' VALUE
      JSON_OBJECT('taxProfessionalCount' VALUE tax_count,
      'attorneyCount' VALUE attorney_count,
      'nonAttorneyCount' VALUE non_attorney_count,
    ))
  ))
```
To convert the row-level data into JSON format, Oracle has built-in functions such as JSON_OBJECT, JSON_ARRAY, JSON_OBJECTAGG, and JSON_ARRAYAGG.

- **JSON_OBJECT** accepts two parameters: KEY and VALUE. The KEY parameter should be hardcoded or static in nature. The VALUE parameter is derived from table output.
- **JSON_ARRAYAGG** accepts **JSON_OBJECT** as a parameter. This helps in grouping the set of **JSON_OBJECT** elements as a list. For example, if you have a **JSON_OBJECT** element that has multiple records (multiple KEY and VALUE pairs in the dataset), **JSON_ARRAYAGG** appends the dataset and creates a list. According to the Data Structure language, LIST is a group of elements. In this context, LIST is a group of **JSON_OBJECT** elements.

The following example shows one **JSON_OBJECT** element.

```json
{

}
```
This next example shows two JSON_OBJECT elements, with LIST indicated by square braces ([ ]).

```
[
  {
    "taxProfessionalCount": 0,
    "attorneyCount": 0,
    "nonAttorneyCount": 1,
    "clerkCount": 0
  },
  {
    "taxProfessionalCount": 2,
    "attorneyCount": 1,
    "nonAttorneyCount": 3,
    "clerkCount": 4
  }
]
```

Example SQL query

```
SELECT JSON_OBJECT('accountCounts' VALUE JSON_ARRAYAGG(
  JSON_OBJECT(
    'businessUnitId' VALUE business_unit_id,
    'parentAccountNumber' VALUE parent_account_number,
    'accountNumber' VALUE account_number,
    'totalOnlineContactsCount' VALUE online_contacts_count,
    'countByPosition' VALUE JSON_OBJECT(
      'taxProfessionalCount' VALUE tax_count,
      'attorneyCount' VALUE attorney_count,
      'nonAttorneyCount' VALUE non_attorney_count,
      'clerkCount' VALUE clerk_count
    )
  )
)
FROM (SELECT tab_data.business_unit_id,
    tab_data.parent_account_number,
    tab_data.account_number,
    SUM(1) online_contacts_count,
    SUM(CASE WHEN tab_data.position_id = '0095' THEN 1 ELSE 0 END) tax_count,
    SUM(CASE WHEN tab_data.position_id = '0100' THEN 1 ELSE 0 END) attorney_count,
    SUM(CASE WHEN tab_data.position_id = '0090' THEN 1 ELSE 0 END) non_attorney_count,
    SUM(CASE WHEN tab_data.position_id = '0050' THEN 1 ELSE 0 END) clerk_count
FROM aws_test_table scco, JSON_TABLE (json_doc, '$' ERROR ON ERROR
```
```
COLUMNS (  
  parent_account_number NUMBER PATH '$.data.account.parentAccountNumber',  
  account_number NUMBER PATH '$.data.account.accountNumber',  
  business_unit_id NUMBER PATH '$.data.account.businessUnitId',  
  position_id VARCHAR2 ( 4 ) PATH '$.data.positionId'  
) AS tab_data
INNER JOIN JSON_TABLE ( '{  
  "accounts": [{  
    "accountNumber": 42000,  
    "parentAccountNumber": 32000,  
    "businessUnitId": 7  
  }, {  
    "accountNumber": 42001,  
    "parentAccountNumber": 32001,  
    "businessUnitId": 6  
  }]  
}', '$.accounts[*]' ERROR ON ERROR  
COLUMNS (  
  parent_account_number PATH '$.parentAccountNumber',  
  account_number PATH '$.accountNumber',  
  business_unit_id PATH '$.businessUnitId'  
) static_data ON ( static_data.parent_account_number =  
  tab_data.parent_account_number  
  AND static_data.account_number = tab_data.account_number  
  AND static_data.business_unit_id = tab_data.business_unit_id )  
GROUP BY  
  tab_data.business_unit_id,  
  tab_data.parent_account_number,  
  tab_data.account_number  
);

Example output from the previous SQL query

```
{
  "accountCounts": [
    {
      "businessUnitId": 6,
      "parentAccountNumber": 32001,
      "accountNumber": 42001,
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 0,
        "nonAttorneyCount": 1,
        "clerkCount": 0
      }
    },
    {
      "businessUnitId": 7,
      "parentAccountNumber": 32000,
      "accountNumber": 42000,
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 1,
        "nonAttorneyCount": 0,
        "clerkCount": 0
      }
    }
  ]
}
```

6. Postgres_SQL_JSON_Aggregation_Join
The PostgreSQL built-in functions JSON_BUILD_OBJECT and JSON_AGG convert the ROW-level data into JSON format. PostgreSQL JSON_BUILD_OBJECT and JSON_AGG are equivalent to Oracle JSON_OBJECT and JSON_ARRAYAGG.

Example query

```sql
select
JSON_BUILD_OBJECT ('accountCounts',
  JSON_AGG(
    JSON_BUILD_OBJECT ('businessUnitId',businessUnitId,
                      'parentAccountNumber',parentAccountNumber,
                      'accountNumber',accountNumber,
                      'totalOnlineContactsCount',online_contacts_count,
                      'countByPosition',
                      JSON_BUILD_OBJECT ('taxProfessionalCount',tax_professional_count,
                                         'attorneyCount',attorney_count,
                                         'nonAttorneyCount',non_attorney_count,
                                         'clerkCount',clerk_count)
    )
  )
)
from (with tab as (select *
                  from (select (json_doc::json->'data'->>'parentAccountNumber')::INTEGER as parentAccountNumber,
                          (json_doc::json->'data'->>'accountNumber')::INTEGER as accountNumber,
                          (json_doc::json->'data'->>'businessUnitId')::INTEGER as businessUnitId,
                          (json_doc::json->'data'->>'positionId')::varchar as positionId
                   from aws_test_pg_table) a ),
    tab1 as (select (json_array_elements(b.jc -> 'accounts') ->> 'accountNumber')::integer accountNumber,
                (json_array_elements(b.jc -> 'accounts') ->> 'businessUnitId')::integer businessUnitId,
                (json_array_elements(b.jc -> 'accounts') ->> 'parentAccountNumber')::integer parentAccountNumber
          from (select '{
              "accounts": [
                "accountNumber": 42001,
                "parentAccountNumber": 32001,
                "businessUnitId": 6
              ],
              {"accountNumber": 42000,
                "parentAccountNumber": 32000,
                "businessUnitId": 7
              }
              }'::json as jc) b)
    select
    tab.businessUnitId::text,
    tab.parentAccountNumber::text,
    tab.accountNumber::text,
    SUM(1) online_contacts_count,
    SUM(CASE WHEN tab.positionId::text = '0095' THEN 1 ELSE 0 END) tax_professional_count,
    SUM(CASE WHEN tab.positionId::text = '0100' THEN 1 ELSE 0 END) attorney_count,
    SUM(CASE WHEN tab.positionId::text = '0090' THEN 1 ELSE 0 END) non_attorney_count,
    SUM(CASE WHEN tab.positionId::text = '0050' THEN 1 ELSE 0 END) clerk_count
  from tab1,tab
  where tab.parentAccountNumber::INTEGER=tab1.parentAccountNumber::INTEGER
  and tab.accountNumber::INTEGER=tab1.accountNumber::INTEGER
  and tab.businessUnitId::INTEGER=tab1.businessUnitId::INTEGER
  GROUP BY tab.businessUnitId::text,
          tab.parentAccountNumber::text,
          tab.accountNumber::text,
          tab.businessUnitId::text,
          tab.parentAccountNumber::text
```
Example output from the preceding query

Output from Oracle and PostgreSQL is exactly the same.

```
{
  "accountCounts": [
    {
      "businessUnitId": 6,
      "parentAccountNumber": 32001,
      "accountNumber": 42001,
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 0,
        "nonAttorneyCount": 1,
        "clerkCount": 0
      }
    },
    {
      "businessUnitId": 7,
      "parentAccountNumber": 32000,
      "accountNumber": 42000,
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 1,
        "nonAttorneyCount": 0,
        "clerkCount": 0
      }
    }
  ]
}
```

7. Oracle_procedure_with_JSON_Query

This code converts the Oracle procedure into a PostgreSQL function that has JSON SQL queries. It shows how the query transposes JSON into rows and the reverse.

```sql
CREATE OR REPLACE PROCEDURE p_json_test(p_in_accounts_json IN varchar2,
p_out_accounts_json OUT varchar2)
IS
BEGIN
  /*
   * p_in_accounts_json parameter should have following format:
     {
      "accounts": [{
        "accountNumber": 42000,
        "parentAccountNumber": 32000,
        "businessUnitId": 7
      }, {
        "accountNumber": 42001,
        "parentAccountNumber": 32001,
        "businessUnitId": 6
      }]
   */
  SELECT JSON_OBJECT(
    'accountCounts' VALUE JSON_ARRAYAGG(
      JSON_OBJECT(
        'businessUnitId' VALUE business_unit_id,
        'accountNumber' VALUE account_number,
        'parentAccountNumber' VALUE parent_account_number
      )))
FROM
```
'parentAccountNumber' VALUE parent_account_number,
'accountNumber' VALUE account_number,
'totalOnlineContactsCount' VALUE online_contacts_count,
'countByPosition' VALUE
JSON_OBJECT(
    'taxProfessionalCount' VALUE tax_count,
    'attorneyCount' VALUE attorney_count,
    'nonAttorneyCount' VALUE non_attorney_count,
    'clerkCount' VALUE clerk_count
) ) ) )

into p_out_accounts_json
FROM
(SELECT
    tab_data.business_unit_id,
    tab_data.parent_account_number,
    tab_data.account_number,
    SUM(1) online_contacts_count,
    SUM(CASE WHEN tab_data.position_id = '0095' THEN 1 ELSE 0 END) tax_count,
    SUM(CASE WHEN tab_data.position_id = '0100' THEN 1 ELSE 0 END) attorney_count,
    SUM(CASE WHEN tab_data.position_id = '0090' THEN 1 ELSE 0 END) non_attorney_count,
    SUM(CASE WHEN tab_data.position_id = '0050' THEN 1 ELSE 0 END) clerk_count
FROM aws_test_table scco,
     JSON_TABLE ( json_doc, '$' ERROR ON ERROR
       COLUMNS (           parent_account_number NUMBER PATH '$.data.account.parentAccountNumber',
                         account_number NUMBER PATH '$.data.account.accountNumber',
                         business_unit_id NUMBER PATH '$.data.account.businessUnitId',
                         position_id VARCHAR2 (4) PATH '$.data.positionId'
          ) AS tab_data
     ) INNER JOIN
     JSON_TABLE ( p_in_accounts_json, '$.accounts[*]' ERROR ON ERROR
       COLUMNS (           parent_account_number PATH '$.parentAccountNumber',
                         account_number PATH '$.accountNumber',
                         business_unit_id PATH '$.businessUnitId'
          ) ) static_data
ON ( static_data.parent_account_number = tab_data.parent_account_number
     AND static_data.account_number = tab_data.account_number
     AND static_data.business_unit_id = tab_data.business_unit_id )
GROUP BY
    tab_data.business_unit_id,
    tab_data.parent_account_number,
    tab_data.account_number
);

EXCEPTION
WHEN OTHERS THEN
    raise_application_error(-20001,'Error while running the JSON query');
END;
/

Running the procedure

The following code block explains how you can run the previously created Oracle procedure with example JSON input to the procedure. It also gives you the result or output from this procedure.

```
set serveroutput on;
declare
    v_out varchar2(30000);
v_in varchar2(30000):= ' {
    "accounts": [ [ 
        "accountNumber": 42000,
        "parentAccountNumber": 32000,
        "businessUnitId": {'
```
AWS Prescriptive Guidance Patterns
Additional information

Procedure output

```
{
  "accountCounts": [
    {
      "businessUnitId": 6,
      "parentAccountNumber": 32001,
      "accountNumber": 42001,
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 0,
        "nonAttorneyCount": 1,
        "clerkCount": 0
      }
    },
    {
      "businessUnitId": 7,
      "parentAccountNumber": 32000,
      "accountNumber": 42000,
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 1,
        "nonAttorneyCount": 0,
        "clerkCount": 0
      }
    }
  ]
}
```

8. Postgres_function_with_JSON_Query

Example function

```sql
CREATE OR REPLACE FUNCTION f_pg_json_test(p_in_accounts_json text)
RETURNS text
LANGUAGE plpgsql
AS $$
DECLARE
  v_out_accounts_json text;
BEGIN
  v_out_accounts_json := JSON_BUILD_OBJECT ('accountCounts',
    JSON_AGG (JSON_BUILD_OBJECT ('businessUnitId',businessUnitId
      ,'parentAccountNumber',parentAccountNumber
      ,'accountNumber',accountNumber
      ,'totalOnlineContactsCount',online_contacts_count,
      'countByPosition',
      JSON_BUILD_OBJECT (}
'"taxProfessionalCount",tax_professional_count
,'"attorneyCount",attorney_count
,'"nonAttorneyCount",non_attorney_count
,'"clerkCount",clerk_count
)))))
INTO v_out_accouts_json
FROM (WITH tab AS (SELECT * FROM (SELECT (json_doc::json->'data'->'account'->>'parentAccountNumber')::INTEGER AS parentAccountNumber,
(json_doc::json->'data'->'account'->>'accountNumber')::INTEGER AS accountNumber,
(json_doc::json->'data'->'account'->>'businessUnitId')::INTEGER AS businessUnitId,
(json_doc::json->'data'->'positionId')::varchar AS positionId
FROM aws_test_pg_table) a ),
tab1 AS ( SELECT
(json_array_elements(b.jc -> 'accounts') ->> 'accountNumber')::integer accountNumber,
(json_array_elements(b.jc -> 'accounts') ->> 'businessUnitId')::integer businessUnitId,
(json_array_elements(b.jc -> 'accounts') ->> 'parentAccountNumber')::integer parentAccountNumber
FROM (SELECT p_in_accounts_json::json AS jc) b)
SELECT
(tab.businessUnitId::text,
tab.parentAccountNumber::text,
tab.accountNumber::text,
SUM(1) online_contacts_count,
SUM(CASE WHEN tab.positionId::text = '0095' THEN 1 ELSE 0 END) tax_professional_count,
SUM(CASE WHEN tab.positionId::text = '0100' THEN 1 ELSE 0 END) attorney_count,
SUM(CASE WHEN tab.positionId::text = '0090' THEN 1 ELSE 0 END) non_attorney_count,
SUM(CASE WHEN tab.positionId::text = '0050' THEN 1 ELSE 0 END) clerk_count
FROM tab1,tab
WHERE tab.parentAccountNumber::INTEGER=tab1.parentAccountNumber::INTEGER
AND tab.accountNumber::INTEGER=tab1.accountNumber::INTEGER
AND tab.businessUnitId::INTEGER=tab1.businessUnitId::INTEGER
GROUP BY tab.businessUnitId::text,
tab.parentAccountNumber::text,
tab.accountNumber::text) a;
RETURN v_out_accouts_json;
END;
$$;

Running the function

```sql
select f_pg_json_test('{
  "accounts": [
    { "accountNumber": 42001, "parentAccountNumber": 32001, "businessUnitId": 6 },
    { "accountNumber": 42000, "parentAccountNumber": 32000, "businessUnitId": 7 }
  ]
}')
```

Function output
The following output is similar to the Oracle procedure output. The difference is that this output is in Text format.

```json
{
```
"accountCounts": [
  {
    "businessUnitId": "6",
    "parentAccountNumber": "32001",
    "accountNumber": "42001",
    "totalOnlineContactsCount": 1,
    "countByPosition": {
      "taxProfessionalCount": 0,
      "attorneyCount": 0,
      "nonAttorneyCount": 1,
      "clerkCount": 0
    }
  },
  {
    "businessUnitId": "7",
    "parentAccountNumber": "32000",
    "accountNumber": "42000",
    "totalOnlineContactsCount": 1,
    "countByPosition": {
      "taxProfessionalCount": 0,
      "attorneyCount": 1,
      "nonAttorneyCount": 0,
      "clerkCount": 0
    }
  }
]
Copy Amazon DynamoDB tables across accounts using a custom implementation

Environment: Production Source: Amazon DynamoDB Target: Amazon DynamoDB
R Type: N/A Workload: All other workloads Technologies: Databases
AWS services: Amazon DynamoDB

Summary

When working with Amazon DynamoDB on Amazon Web Services (AWS), a common use case is to copy or sync DynamoDB tables in development, testing, or staging environments with the table data that are in the production environment. As a standard practice, each environment uses a different AWS account.

DynamoDB now supports cross-account backup using AWS Backup. For information about associated storage costs when using AWS Backup, see AWS Backup pricing. When you use AWS Backup to copy across accounts, the source and target accounts must be part of an AWS Organizations organization. There are other solutions for cross-account backup and restore using AWS services such as AWS Data Pipeline or AWS Glue. Using those solutions, however, increases the application footprint, because there are more AWS services to deploy and maintain.

You can also use Amazon DynamoDB Streams to capture table changes in the source account. Then you can initiate an AWS Lambda function, and make the corresponding changes in the target table in the target account. But that solution applies to use cases in which source and target tables must always be kept in sync. It might not apply to development, testing, and staging environments where data are updated frequently.

This pattern provides steps to implement a custom solution to copy a Amazon DynamoDB table from one account to another. This pattern can be implemented using common programming languages such as C#, Java, and Python. We recommend using a language that is supported by an AWS SDK.

Prerequisites and limitations

Prerequisites

- Two active AWS accounts
- DynamoDB tables in both the accounts
- Knowledge of AWS Identity and Access Management (IAM) roles and policies
- Knowledge of how to access Amazon DynamoDB tables using any common programming language, such as C#, Java, or Python

Limitations

This pattern applies to DynamoDB tables that are around 2 GB or smaller. With additional logic to handle connection or session interruptions, throttling, and failures and retries, it can be used for larger tables.
The DynamoDB scan operation, which reads items from the source table, can fetch only up to 1 MB of data in a single call. For larger tables, greater than 2 GB, this limitation can increase the total time to perform a full table copy.

**Architecture**

![Diagram of architecture](image)

**Automation and scale**

This pattern applies to DynamoDB tables that are smaller in size, around 2 GB.

To apply this pattern for larger tables, address the following issues:

- During the table copy operation, two active sessions are maintained, using different security tokens. If the table copy operation takes longer than the token expiration times, you must put in place logic to refresh the security tokens.
- If enough read capacity units (RCUs) and write capacity units (WCUs) are not provisioned, reads or writes on the source or target table might get throttled. Be sure to catch and handle these exceptions.
- Handle any other failures or exceptions and put a retry mechanism in place to retry or continue from where the copy operation failed.

**Tools**

- **Amazon DynamoDB** – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
- The additional tools required will differ based on the programming language that you choose for the implementation. For example, if you use C#, you will need Microsoft Visual Studio and the following NuGet packages:
  - AWSSDK
  - AWSSDK.DynamoDBv2

**Code**

The following Python code snippet deletes and recreates a DynamoDB table using the Boto3 library.
Do not use the AWS_ACCESS_KEY_ID and AWS_SECRET_ACCESS_KEY of an IAM user because these are long-term credentials, which should be avoided for programmatic access to AWS services. For more information about temporary credentials, see the Best practices section.

The AWS_ACCESS_KEY_ID, AWS_SECRET_ACCESS_KEY, and TEMPORARY_SESSION_TOKEN used in the following code snippet are temporary credentials fetched from AWS Security Token Service (AWS STS).

```python
import boto3
import sys
import json

#args = input-parameters = GLOBAL_SEC_INDEXES_JSON_COLLECTION, ATTRIBUTES_JSON_COLLECTION, TARGET_DYNAMODB_NAME, TARGET_REGION, ...

#Input param: GLOBAL_SEC_INDEXES_JSON_COLLECTION
#[{"IndexName":"Test-index","KeySchema":[{"AttributeName":"AppId","KeyType":"HASH"},
{"AttributeName":"AppType","KeyType":"RANGE"}],"Projection":
{"ProjectionType":"INCLUDE","NonKeyAttributes":[]}]}

#Input param: ATTRIBUTES_JSON_COLLECTION
#[{"AttributeName":"PK","AttributeType":"S"},{"AttributeName":"SK","AttributeType":"S"},
{"AttributeName":"AppId","AttributeType":"S"},
{"AttributeName":"AppType","AttributeType":"N"}]

region = args['TARGET_REGION']
target_ddb_name = args['TARGET_DYNAMODB_NAME']

# Drop and create target DynamoDB table

dynamodb_client = boto3.Session(
    aws_access_key_id=args['AWS_ACCESS_KEY_ID'],
    aws_secret_access_key=args['AWS_SECRET_ACCESS_KEY'],
    aws_session_token=args['TEMPORARY_SESSION_TOKEN'],
).client('dynamodb')

table = dynamodb_client.create_table(
    TableName=target_ddb_name,
    KeySchema=[
        {'AttributeName': 'PK',
         'KeyType': 'HASH' # Partition key
        },
        {'AttributeName': 'SK',
         'KeyType': 'RANGE' # Sort key
        }
    ],
    # Drop and create target DynamoDB table

dynamodb_client = boto3.Session(
    aws_access_key_id=args['AWS_ACCESS_KEY_ID'],
    aws_secret_access_key=args['AWS_SECRET_ACCESS_KEY'],
    aws_session_token=args['TEMPORARY_SESSION_TOKEN'],
).client('dynamodb')

table = dynamodb_client.create_table(
    TableName=target_ddb_name,
    KeySchema=[
        {'AttributeName': 'PK',
         'KeyType': 'HASH' # Partition key
        },
        {'AttributeName': 'SK',
         'KeyType': 'RANGE' # Sort key
        }
    ],
```

608
Best practices

Temporary credentials

As a security best practice, while accessing AWS services programmatically, avoid using the AWS_ACCESS_KEY_ID and AWS_SECRET_ACCESS_KEY of an IAM user because these are long-term credentials. Always try to use temporary credentials to access AWS services programmatically.

As an example, a developer hardcodes the AWS_ACCESS_KEY_ID and AWS_SECRET_ACCESS_KEY of an IAM user in the application during development but fails to remove the hardcoded values before pushing changes to code repository. These exposed credentials can be used by unintended or malicious users, which can have serious implications (especially if the exposed credentials have admin privileges). These exposed credentials should be deactivated or deleted immediately by using the IAM console or AWS Command Line Interface (AWS CLI).

To get temporary credentials for programmatic access to AWS services, use AWS STS. Temporary credentials are valid only for the specified time (from 15 minutes up to 36 hours). The maximum allowed duration of temporary credentials varies depending on such factors as role settings and role chaining. For more information about AWS STS, see the documentation.

**Additional information**

This pattern was implemented using C# to copy a DynamoDB table with 200,000 items (average item size of 5 KB and table size of 250 MB). The target DynamoDB table was set up with provisioned capacity of 4000 RCU and 4000 WCU.

The complete table copy operation (from source account to target account), including dropping and recreating the table, took 5 minutes. Total capacity units consumed: 30,000 RCU and approximately 400,000 WCU.

For more information on DynamoDB capacity modes, see [Read/Write capacity mode](#) in the AWS documentation.

Copy Amazon DynamoDB tables across accounts using AWS Backup

Created by Ramkumar Ramanujam (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>Databases; Migration</th>
<th>AWS services:</th>
<th>Amazon DynamoDB; AWS Backup</th>
</tr>
</thead>
</table>

Summary

When working with Amazon DynamoDB on Amazon Web Services (AWS), a common use case is to copy or sync DynamoDB tables in development, testing, or staging environments with the table data that is in the production environment. As a standard practice, each environment uses a different AWS account.

AWS Backup supports cross-Region and cross-account backup and restore of data for DynamoDB, Amazon Simple Storage Service (Amazon S3), and other AWS services. This pattern provides the steps for using AWS Backup cross-account backup and restore to copy DynamoDB tables between AWS accounts.

Prerequisites and limitations

Prerequisites
- Two active AWS accounts that belong to the same AWS Organizations organization
- DynamoDB tables in both the accounts.
- AWS Identity and Access Management (IAM) permissions to create and use AWS backup vaults

Limitations
- Source and target AWS accounts should be part of the same AWS Organizations organization.

Architecture

Target technology stack
- AWS Backup
- Amazon DynamoDB

Target architecture
1. Create the DynamoDB table backup in the AWS Backup backup vault in the source account.
2. Copy the backup to the backup vault in the target account.
3. Restore the DynamoDB table in the target account using the backup from the target account backup vault.

**Automation and scale**

You can use AWS Backup to schedule backups to run at specific intervals.

**Tools**

- **AWS Backup** – AWS Backup is a fully-managed service for centralizing and automating data protection across AWS services, in the cloud, and on premises. Using this service, you can configure backup policies and monitor activity for your AWS resources in one place. It allows you to automate and consolidate backup tasks that were previously performed service-by-service, and removes the need to create custom scripts and manual processes.
- **Amazon DynamoDB** – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
## Epics

### Turn on AWS Backup features in the source and target accounts

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Turn on advanced features for DynamoDB and cross-account backup. | In both the source and the target AWS accounts, do the following:  
1. On the AWS Management Console, open the AWS Backup console.  
2. Choose Settings.  
3. Under Advanced features for Amazon DynamoDB backups, confirm that Advanced features is enabled, or choose Enable.  
4. Under Cross-account management, for Cross-account backup, choose Enable. | AWS DevOps, Migration engineer |

### Create backup vaults in the source and target accounts

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create backup vaults. | In both the source and the target AWS accounts, do the following:  
1. On the AWS Backup console, choose Backup vaults.  
2. Choose Create Backup vault.  
3. Copy the Amazon Resource Name (ARN) of the backup vault and save it. The ARNs of both the source and the target backup vaults will be required when you copying the DynamoDB table backup between the source account and the target account. | AWS DevOps, Migration engineer |
Perform backup and restore using backup vaults

Create detailed cost and usage reports for Amazon RDS and Amazon Aurora

Created by Lakshmanan Lakshmanan (AWS) and Sudarshan Narasimhan

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Technologies: Databases; Cost management; Analytics</th>
<th>AWS services: Amazon Athena; Amazon Aurora; Amazon RDS; AWS Billing and Cost Management</th>
</tr>
</thead>
</table>

Summary

This pattern shows how to track usage costs for Amazon Relational Database Service (Amazon RDS) or Amazon Aurora clusters by configuring user-defined cost allocation tags. You can use these tags to create detailed cost and usage reports in AWS Cost Explorer for clusters across multiple dimensions. For example, you can track usage costs at the team, project, or cost center level, and then analyze the data in Amazon Athena.

Prerequisites and limitations

**Prerequisites**

- An active AWS account
- One or more Amazon RDS or Amazon Aurora instances

**Limitations**

For tagging restrictions, see the AWS Billing User Guide.

Architecture

**Target technology stack**

- Amazon RDS or Amazon Aurora
- AWS Cost and Usage Report
- AWS Cost Explorer
- Amazon Athena

**Workflow and architecture**

The tagging and analysis workflow consists of these steps:

1. A data engineer, database administrator, or AWS administrator creates user-defined cost allocation tags for the Amazon RDS or Aurora clusters.
2. An AWS administrator activates the tags.
3. The tags report metadata to AWS Cost Explorer.
4. A data engineer, database administrator, or AWS administrator creates a monthly cost allocation report.
5. A data engineer, database administrator, or AWS administrator analyzes the monthly cost allocation report by using Amazon Athena.

The following diagram shows how to apply tags to track usage costs for Amazon RDS or Aurora instances.

The following architecture diagram shows how the cost allocation report is integrated with Amazon Athena for analysis.

The monthly cost allocation report is stored in an Amazon S3 bucket that you specify. When you set up Athena with the AWS CloudFormation template, as described in the Epics section, the template provisions several additional resources, including an AWS Glue crawler, an AWS Glue database, an
Amazon Simple Notification System (Amazon SNS) event, AWS Lambda functions, and AWS Identity and Access Management (IAM) roles for the Lambda functions. As new cost data files arrive in the S3 bucket, event notifications are used to forward these files to a Lambda function for processing. The Lambda function initiates an AWS Glue crawler job to create or update the table in the AWS Glue Data Catalog. This table is then used to query data in Athena.

**Tools**

- **Amazon Athena** is an interactive query service that makes it easy to analyze data in Amazon S3 using standard SQL.
- **Amazon Aurora** is a fully managed relational database engine that’s built for the cloud and compatible with MySQL and PostgreSQL.
- **Amazon Relational Database Service (Amazon RDS)** helps you set up, operate, and scale a relational database in the AWS Cloud.
- **AWS CloudFormation** is an infrastructure as code (IaC) service that allows you to easily model, provision, and manage AWS and third-party resources.
- **AWS Cost Explorer** helps you view and analyze your AWS costs and usage.

### Analyze cost and usage report data

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Analyze the cost and usage report data. | 1. Set up and use Athena to analyze the report data. For instructions, see [Querying Cost and Usage Reports using Amazon Athena](https://aws.amazon.com/about-aws/whats-new/guides/cost-usage-reporting/athena/) in the AWS Cost and Usage Reports User Guide. We recommend that you use the [AWS CloudFormation template provided by Athena](https://aws.amazon.com/cloudformation/templates/).  
2. Run Athena queries. For example, you can use the following SQL query to check the status of the data refresh.  
```sql
select status from cost_and_usage_data_status
```
For more information, see [Running Amazon Athena queries](https://aws.amazon.com/about-aws/whats-new/guides/cost-usage-reporting/athena/) in the AWS Cost and Usage Reports User Guide.  
**Note:** When you run your SQL query, make sure that the correct database is selected from the dropdown list. | App owner, AWS administrator, DBA, General AWS, Data engineer |

Emulate Oracle RAC workloads using custom endpoints in Aurora PostgreSQL

Created by HariKrishna Boorgadda (AWS)

<table>
<thead>
<tr>
<th>Environment</th>
<th>Source: Databases: Relational</th>
<th>Target: Aurora PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Replatform</td>
<td>Workload: Oracle</td>
<td>Technologies: Databases; Migration</td>
</tr>
<tr>
<td>AWS services:</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Amazon Aurora; Amazon CloudWatch</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to emulate services in an Oracle Real Application Clusters (Oracle RAC) workload by using Amazon Aurora PostgreSQL-Compatible Edition with custom endpoints that distribute workloads across instances within a single cluster. The pattern shows you how to create custom endpoints for Amazon Aurora databases. Custom endpoints enable you to distribute and load balance workloads across different sets of DB instances in your Aurora cluster.

In an Oracle RAC environment, services can span one or more instances and facilitate workload balancing based on transaction performance. Service features include end-to-end unattended recovery, rolling changes by workload, and full location transparency. You can use this pattern to emulate some of these features. For example, you can emulate the ability to route connections for reporting applications.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A PostgreSQL JDBC driver
- An Aurora PostgreSQL-Compatible database
- An Oracle RAC database migrated to an Aurora PostgreSQL-Compatible database

Limitations

- For limitations that apply to custom endpoints, see Specifying properties for custom endpoints in the Amazon RDS documentation.

Architecture

Source technology stack

- A three-node Oracle RAC database

Target technology stack

624
• An Aurora PostgreSQL-Compatible database with two read replicas

Source architecture

The following diagram shows the architecture of a three-node Oracle RAC database.

Target architecture

The following diagram shows the architecture of an Aurora PostgreSQL-Compatible database with two read replicas. Three different applications/services are using custom endpoints, which serve different application users and redirect the traffic and load between primary and read replicas.
Tools

- **Amazon Aurora PostgreSQL-Compatible Edition** is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- **Amazon CloudWatch** helps you monitor the metrics of your AWS resources and the applications that you run on AWS in real time.
- **Amazon Relational Database Service (Amazon RDS) for PostgreSQL** helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

Enable encrypted connections for PostgreSQL DB instances in Amazon RDS

Created by Rohit Kapoor (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>Databases; Networking; Security, identity, compliance</th>
<th>Workload: Open-source</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>Amazon RDS; Amazon Aurora</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

Amazon Relational Database Service (Amazon RDS) supports SSL encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your Amazon RDS for PostgreSQL DB instances. By default, Amazon RDS for PostgreSQL uses SSL/TLS and expects all clients to connect by using SSL/TLS encryption. Amazon RDS for PostgreSQL supports TLS versions 1.2 and 1.3.

This pattern describes how you can enable encrypted connections for an Amazon RDS for PostgreSQL DB instance. You can use the same process to enable encrypted connections for Amazon Aurora PostgreSQL-Compatible Edition.

Prerequisites and limitations

- An active AWS account
- An Amazon RDS for PostgreSQL DB instance
- An SSL bundle

Architecture
Tools

- **pgAdmin** is an open-source administration and development platform for PostgreSQL. You can use pgAdmin on Linux, Unix, macOS, and Windows to manage your database objects in PostgreSQL 10 and later.
- **PostgreSQL editors** provide a more user-friendly interface to help you create, develop, and run queries, and to edit code according to your requirements.

Best practices

- Monitor unsecure database connections.
- Audit database access rights.
- Make sure that backups and snapshots are encrypted at rest.
- Monitor database access.
- Avoid unrestricted access groups.
- Enhance your notifications with Amazon GuardDuty.
- Monitor policy adherence regularly.

Epics

**Download a trusted certificate and import it into your trust store**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Load a trusted certificate</td>
<td>To add certificates to the Trusted Root Certification Authorities store for your computer, follow these steps.</td>
<td>DevOps engineer, Migration engineer, DBA</td>
</tr>
</tbody>
</table>
### Force SSL connections

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a parameter group and set the rds.force_ssl parameter.</td>
<td>If the PostgreSQL DB instance has a custom parameter group, edit the parameter group and change <code>rds.force_ssl</code> to <code>1</code>. If the DB instance uses the default parameter group that doesn't have <code>rds.force_ssl</code> enabled, create a new parameter group. You can modify the new parameter group by using the Amazon RDS API or manually as in the following instructions. To create a new parameter group:</td>
<td>DevOps engineer, Migration engineer, DBA</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td>1.</td>
<td>Sign in to the AWS Management console and open the Amazon RDS console for the AWS Region that hosts the DB instance.</td>
<td></td>
</tr>
<tr>
<td>2.</td>
<td>In the navigation pane, choose Parameter groups.</td>
<td></td>
</tr>
<tr>
<td>3.</td>
<td>Choose Create parameter group, and set the following values:</td>
<td></td>
</tr>
<tr>
<td>4.</td>
<td>Choose the parameter group that you created.</td>
<td></td>
</tr>
<tr>
<td>5.</td>
<td>From Parameter group actions, choose Edit.</td>
<td></td>
</tr>
<tr>
<td>6.</td>
<td>Find rds.force_ssl and change its setting to 1.</td>
<td></td>
</tr>
<tr>
<td>7.</td>
<td>Choose Save changes.</td>
<td></td>
</tr>
</tbody>
</table>

To associate the parameter group with your PostgreSQL DB instance:

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>On the Amazon RDS console, in the navigation pane, choose Databases, and then choose the PostgreSQL DB instance.</td>
<td></td>
</tr>
<tr>
<td>2.</td>
<td>Choose Modify.</td>
<td></td>
</tr>
<tr>
<td>3.</td>
<td>Under Additional configuration, choose the new parameter group, and then choose Continue.</td>
<td></td>
</tr>
<tr>
<td>4.</td>
<td>Under Schedule modifications, choose Apply immediately.</td>
<td></td>
</tr>
<tr>
<td>5.</td>
<td>Choose Modify DB instance.</td>
<td></td>
</tr>
</tbody>
</table>
### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Force SSL connections.</td>
<td>Connect to the Amazon RDS for PostgreSQL DB instance. Connection attempts that don’t use SSL are rejected with an error message. For more information, see the Amazon RDS documentation.</td>

Encrypt an existing Amazon RDS for PostgreSQL DB instance

Created by Piyush Goyal (AWS), Shobana Raghu (AWS), and Yaser Raja (AWS)

| Environment: Production | Technologies: Databases; Security, identity, compliance | AWS services: Amazon RDS; AWS KMS; AWS DMS |

Summary

This pattern explains how to encrypt an existing Amazon Relational Database Service (Amazon RDS) for PostgreSQL DB instance in the Amazon Web Services (AWS) Cloud with minimal downtime. This process works for Amazon RDS for MySQL DB instances as well.

You can enable encryption for an Amazon RDS DB instance when you create it, but not after it's created. However, you can add encryption to an unencrypted DB instance by creating a snapshot of your DB instance, and then creating an encrypted copy of that snapshot. You can then restore a DB instance from the encrypted snapshot to get an encrypted copy of your original DB instance. If your project allows for downtime (at least for write transactions) during this activity, this is all you need to do. When the new, encrypted copy of the DB instance becomes available, you can point your applications to the new database. However, if your project doesn't allow for significant downtime for this activity, you need an alternate approach that helps minimize the downtime. This pattern uses the AWS Database Migration Service (AWS DMS) to migrate and continuously replicate the data so that the cutover to the new, encrypted database can be done with minimal downtime.

Amazon RDS encrypted DB instances use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon RDS DB instances. After your data is encrypted, Amazon RDS handles authentication of access and decryption of your data transparently, with minimal impact on performance. You don't need to modify your database client applications to use encryption.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An unencrypted Amazon RDS for PostgreSQL DB instance
- Experience working with (creating, modifying, or stopping) AWS DMS tasks (see Working with AWS DMS tasks in the AWS DMS documentation)
- Familiarity with AWS Key Management Service (AWS KMS) for encrypting databases (see the AWS KMS documentation)

Limitations

- You can enable encryption for an Amazon RDS DB instance only when you create it, not after the DB instance is created.
- Data in unlogged tables will not be restored using snapshots. For more information, review Best practices for working with PostgreSQL.
- You can't have an encrypted read replica of an unencrypted DB instance or an unencrypted read replica of an encrypted DB instance.
• You can't restore an unencrypted backup or snapshot to an encrypted DB instance.
• AWS DMS does not automatically transfers the Sequences therefore additional steps are required to handle this.

For more information, see Limitations of Amazon RDS encrypted DB instances in the Amazon RDS documentation.

Architecture

Source architecture
• Unencrypted RDS DB instance

Target architecture
• Encrypted RDS DB instance
  • The destination RDS DB instance is created by restoring the DB snapshot copy of the source RDS DB instance.
  • An AWS KMS key is used for encryption while restoring the snapshot.
  • An AWS DMS replication task is used to migrate the data.
Tools used to enable encryption:

- AWS KMS key for encryption – When you create an encrypted DB instance, you can choose a customer managed key or the AWS managed key for Amazon RDS to encrypt your DB instance. If you don’t specify the key identifier for a customer managed key, Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for Amazon RDS for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region. For more information about using KMS keys for Amazon RDS encryption, see Encrypting Amazon RDS Resources.

Tools used for ongoing replication:
AWS Prescriptive Guidance Patterns
Epics

- AWS DMS – You can use AWS Database Migration Service (AWS DMS) to replicate changes from the source DB to the target DB. It is important to keep the source and target DB in sync to keep downtime to a minimum. For information about setting up AWS DMS and creating tasks, see the AWS DMS documentation.

Epics

Create a snapshot of the source DB instance and encrypt it

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>

Checking the encryption for the source PostgreSQL DB instance:

Additional notes for this pattern:

- Enable replication on PostgreSQL by setting the rds.logical_replication parameter to 1.

Important note: Replication slots retain the write ahead log (WAL) files until the files are externally consumed—for example, by pg_recvlogical; by extract, transform, and load (ETL) jobs; or by AWS DMS. When you set the rds.logical_replication parameter value to 1, AWS DMS sets the
wal_level, max_wal_senders, max_replication_slots, and max_connections parameters. If logical replication slots are present but there is no consumer for the WAL files retained by the replication slot, you might see an increase in the transaction log disk usage and a constant decrease in free storage space. For more information and steps to resolve this issue, see the article [How can I identify what is causing the "No space left on device" or "DiskFull" error on Amazon RDS for PostgreSQL?](https://aws.amazon.com/support/knowledge-center/how-can-i-identify-what-is-causing-the-no-space-left-on-device-or-diskfull-error-on-amazon-rds-for-postgresql/) in the AWS Support Knowledge Center.

- Any schema changes that you make to the source DB instance after you create the DB snapshot will not be present on the target DB instance.
- After you create an encrypted DB instance, you can’t change the KMS key used by that DB instance. Be sure to determine your KMS key requirements before you create your encrypted DB instance.
- You must disable triggers and foreign keys on the target DB instance before you run the AWS DMS task. You can re-enable these when the task is complete.
Enforce automatic tagging of Amazon RDS databases at launch

Summary

Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the Amazon Web Services (AWS) Cloud. It provides cost-efficient, resizable capacity for an industry-standard relational database and manages common database administration tasks.

You can use tagging to categorize your AWS resources in different ways. Relational database tagging is useful when you have many resources in your account and you want to quickly identify a specific resource based on the tags. You can use Amazon RDS tags to add custom metadata to your RDS DB instances. A tag consists of a user-defined key and value. We recommend that you create a consistent set of tags to meet your organization's requirements.

This pattern provides an AWS CloudFormation template to help you monitor and tag RDS DB instances. The template creates an Amazon CloudWatch Events event that watches for the AWS CloudTrail CreateDBInstance event. (CloudTrail captures API calls for Amazon RDS as events.) When it detects this event, it calls an AWS Lambda function that automatically applies tag keys and values that you define. The template also sends out a notification that the instance has been tagged, by using Amazon Simple Notification Service (Amazon SNS).

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An Amazon Simple Storage Service (Amazon S3) bucket to upload the Lambda code.
- An email address where you would like to receive tagging notifications.

Limitations

- The solution supports CloudTrail CreateDBInstance events. It does not create notifications for any other events.

Architecture

Workflow architecture
Tools

AWS services

- **AWS CloudTrail** – AWS CloudTrail is an AWS service that helps you with governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail.
- **Amazon CloudWatch Events** – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources. CloudWatch Events becomes aware of operational changes as they occur and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information.
- **AWS Lambda** – AWS Lambda is a compute service that supports running code without needing to provision or manage servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume — there is no charge when your code is not running.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud.

Code

This pattern includes an attachment with two files:

- `index.zip` is a compressed file that includes the Lambda code for this pattern.
- `rds.yaml` is a CloudFormation template that deploys the Lambda code.

See the Epics section for information about how to use these files.

Epics

Deploy the Lambda code

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Upload the code to an S3 bucket.</td>
<td>Create a new S3 bucket or use an existing S3 bucket to upload the attached <code>index.zip</code> file (Lambda code). This bucket must be public.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>
### Deploy the CloudFormation template.

- **Description:** Open the Cloudformation console in the same AWS Region as the S3 bucket, and deploy the `rds.yaml` file that's provided in the attachment. In the next epic, provide values for the template parameters.

- **Skills required:** Cloud architect

### Complete the parameters in the CloudFormation template

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>

Estimate the cost of a DynamoDB table for on-demand capacity

Summary

Amazon DynamoDB is a NoSQL transactional database that provides single-digit millisecond latency even at petabytes scale. This Amazon Web Services (AWS) serverless offering is getting popular because of its consistent performance and scalability. You do not need to provision underlying infrastructure. Your single table can grow up to petabytes.

With on-demand capacity mode, you pay per request for the data reads and writes that your application performs on the tables. AWS charges are based on the accumulated read request units (RRUs) and write request units (WRUs) in a month. DynamoDB monitors the size of your table continuously throughout the month to determine your storage charges. It supports continuous backup with point-in-time-recovery (PITR). DynamoDB monitors the size of your PITR-enabled tables continuously throughout the month to determine your backup charges.

To estimate the DynamoDB cost for a project, it's important to calculate how much RRU, WRU, and storage will be consumed at different stages of your product lifecycle. For a rough cost estimation, you can use AWS Pricing Calculator, but you must provide an approximate number of RRUs, WRUs, and storage requirements for your table. These can be difficult to estimate at the beginning of the project. AWS Pricing Calculator doesn't consider data growth rate or item size, and it doesn't consider the number of reads and writes for the base table and global secondary indexes (GSIs) separately. To use AWS Pricing Calculator, you must estimate all those aspects to assume ballpark figures for WRU, RRU, and storage size to obtain your cost estimation.

This pattern provides a mechanism and a re-usable Microsoft Excel template to estimate basic DynamoDB cost factors, such as write, read, storage, backup and recovery cost, for on-demand capacity mode. It is more granular than AWS Pricing Calculator, and it considers base table and GSIs requirements independently. It also considers the monthly item data growth rate and forecasts costs for three years.

Prerequisites and limitations

Prerequisites

- Basic knowledge of DynamoDB and DynamoDB data model design
- Basic knowledge of DynamoDB pricing, WRU, RRU, storage, and backup and recovery (for more information, see Pricing for On-Demand Capacity)
- Knowledge of your data, data model, and item size in DynamoDB
- Knowledge of DynamoDB GSIs

Limitations
• The template provides you with an approximate calculation, but it isn't appropriate for all configurations. To get a more accurate estimate, you must measure the individual item size for each item in the base table and GSIs.
• For a more accurate estimate, you must consider the expected number of writes (insert, update, and delete) and reads for each item in an average month.
• This pattern supports estimating only write, read, storage, and backup and recovery costs for next few years based on fixed data growth assumptions.

**Tools**

**AWS services**

• Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

**Other tools**

• AWS Pricing Calculator is a web-based planning tool that you can use to create estimates for your AWS use cases.

**Best practices**

To help keep costs low, consider the following DynamoDB design best practices.

• **Partition key design** – Use a high-cardinality partition key to distribute load evenly.
• **Adjacency list design pattern** – Use this design pattern for managing one-to-many and many-to-many relationships.
• **Sparse index** – Use sparse index for your GSIs. When you create a GSI, you specify a partition key and optionally a sort key. Only items in the base table that contain a corresponding GSI partition key appear in the sparse index. This helps to keep GSIs smaller.
• **Index overloading** – Use the same GSI for indexing various types of items.
• **GSI write sharding** – Shard wisely to distribute data across the partitions for efficient and faster queries.
• **Large items** – Store only metadata inside the table, save the blob in Amazon S3, and keep the reference in DynamoDB. Break large items into multiple items, and efficiently index by using sort keys.

For more design best practices, see the Amazon DynamoDB Developer Guide.

**Epics**

**Extract item information from your DynamoDB data model**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Get item size.| 1. Check how many different types of item you are going to store in your table.  
2. To calculate the size of each item in kilobytes, add the | Data engineer     |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Calculate item size     | Key and Value size of each attribute.  
3. Calculate item size for a base table and for each GSI.                                                                                                                                             |                          |
| Estimate the write cost | To estimate write cost in on-demand capacity mode, first you have to measure how many WRUs will be consumed in a month. For that, you need to consider the following factors:  
• Number of create, update, and delete operations for each item in a month.  
• Number of available GSIs. Consider each index independently.  
  • Average size of an index item  
  • Number of synchronization times on an index  
• How many new things (for example, components or products) will be added in the table each month? The number of added things could be different every month, but you can assume an average growth rate based on your business cases.  
For more information, see the Additional information section. | Data engineer             |
| Estimate the read cost  | To estimate read cost in on-demand mode, first you have to measure how many RRRUs will be consumed in a month. For that, you need to consider the following factors:  
• Number of available GSIs. Consider each index independently.  
  • Average size of an index item  
  • Average number of reads per product per month.  
• Number of total available things (components or products) in the DynamoDB table. | Data engineer, App developer |
Estimate the storage size and cost.

First, estimate the average monthly storage requirement based on your item size in the table. Then calculate storage cost by multiplying storage size by the per GB storage price for your AWS Region.

If you already entered data for estimating the write cost, you don't need to enter it again for calculating storage size. Otherwise, to estimate storage size, you need to consider the following factors:

- Number of data items in a module (product) based on your table design.
- Average item size in kilobytes.
- Number of available GSIs. Consider each index independently.
- Average size of an index item
- How many new products will be added in the table each month? The number of new products could be different every month, but you can assume an average growth rate based on your business cases. This example uses an average of 10 million new products each month.

Data engineer

Enter the item and object information in the Excel template

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Download the Excel template from the Attachments section, and adjust it for your use case table.</td>
<td>1. Download the Excel template. 2. Adjust the business module and GSIs, based on your table design.</td>
<td>Data engineer</td>
</tr>
<tr>
<td>Enter information in the Excel template.</td>
<td>1. Update item information in the sheet. Update data only in orange cells. 2. Adjust the object numbers: How much could be added into the table each month?</td>
<td>Data engineer</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td>3.</td>
<td>Update the WRU and RRU prices per million for your AWS Region.</td>
<td></td>
</tr>
<tr>
<td>4.</td>
<td>Update the storage and backup prices per GB-month for your AWS Region.</td>
<td></td>
</tr>
<tr>
<td>5.</td>
<td>Update the recovery price per GB for your AWS Region.</td>
<td></td>
</tr>
</tbody>
</table>

In the template, there are three items, or entities: information, metadata, and relationship. There are two GSIs. For your use case, if you need more items, create new rows. If you need more GSIs, copy an existing GSI block, and paste to create as many GSI blocks as you need. Then adjust the SUM and TOTAL column calculations.

**Guides and patterns**
- Modeling data with Amazon DynamoDB
- Estimate storage costs for an Amazon DynamoDB table

### Additional information

**Write cost calculation example**

The DynamoDB data model design shows three items for a product, and an average item size of 4 KB. When you add a new product into the DynamoDB base table, it consumes the number of items * (item size/1 KB write unit) = 3 * (4/1) = 12 WRU. In this example, for writing 1 KB, the product consumes 1 WRU.

**Read cost calculation example**

To get the RRU estimation, consider the average of how many times each item will be read in a month. For example, the Information item will be read, on average, 10 times in a month, and the metadata item will be read two times, and the relationship item will be read five times. In the example template, total...
RRU for all components = number of new components created each month * RRU per component per month = 10 million * 17 RRU = 170 million RRU each month.

Every month, new things (components or products) will be added, and the total number of products will grow over time. So, RRU requirements will also grow over time.

- For the first month RRU, consumption will be 170 million.
- For the second month, RRU consumption will be 2 * 170 million = 340 million.
- For the third month RRU consumption will be 3 * 170 million = 510 million.

The following graph shows monthly RRU consumption and cost forecasting.

![MONTHLY RRU COST FORECASTING](image)

Note that prices within the graph are for illustration only. To create accurate forecasts for your use case, check the AWS pricing page, and use those prices in the Excel sheet.

Storage, backup, and recovery cost calculation examples

DynamoDB storage, backup, and restore all are connected with each other. Backup is directly connected with storage, and recovery is directly connected with backup size. As the table size increases, corresponding storage, backup, and restore costs will increase proportionally.

**Storage size and cost**

Storage cost will increase over time based on your data growth rate. For example, assume that the average size of a component or product in the base table and GSIs is 11 KB, and 10 million new products will be added every month into your database table. In that case, your DynamoDB table size will grow (11 KB * 10 million)/1024/1024 = 105 GB per month. At the first month, your table storage size will be 105 GB, at second month it will be 105 + 105 = 210 GBs, and so on.

- For the first month, storage cost will be 105 GB * storage price per GB for your AWS Region.
- For the second month, storage cost will be 210 GB * storage price per GB for your Region.
- For the third month, storage cost will be 315 GB * storage price per GB for your Region.

For storage size and cost for next three years, see the Storage size and forecasting section.
**Backup cost**

Backup cost will increase over time based on your data growth rate. When you turn on continuous backup with point-in-time-recovery (PITR), continuous backup charges are based on average storage GB-Month. In a calendar month, the average backup size would be the same as your table storage size, although the actual size could be a bit different. As new products will be added every month, the total storage size and the backup size will grow over time. For example, for the first month, the average backup size of 105 GB could grow to 210 GB for the second month.

- For the first month, backup cost will be 105 GB-month * continuous backup price per GB for your AWS Region.
- For the second month, backup cost will be 210 GB-month * continuous backup price per GB for your Region.
- For the third month, backup cost will be 315 GB-month * continuous backup price per GB for your Region.
- and, so on

Backup cost is included in the graph in the *Storage size and cost forecasting* section.

**Recovery cost**

When you are taking continuous backup with PITR enabled, recovery operation charges are based on the size of the restore. Each time that you restore, you pay based on gigabytes of restored data. If your table size is large and you perform restore multiple times in a month, it will be costly.

To estimate restore cost, this example assumes that you perform a PITR recovery one time each month at the end of the month. The example uses the monthly average backup size as the restore data size for that month. For the first month, the average backup size is 105 GB, and for the recovery at end of the month, the restore data size would be 105 GB. For the second month, it would be 210 GBs, and so on.

Recovery cost will increase over time based on your data growth rate.

- For the first month, recovery cost will be 105 GB * restore price per GB for your AWS Region.
- For the second month, recovery cost will be 210 GB * restore price per GB for your Region.
- For the third month, recovery cost will be 315 GB * restore price per GB for your Region.

For more information, see the Storage, backup and recovery tab in the Excel template and the graph in the following section.

**Storage size and cost forecasting**

In the template, actual billable storage size is calculated by subtracting the free tier 25 GB per month for the Standard table class. In the sheet, you will get a forecasting graph broken out into monthly values.

The following example chart forecasts monthly storage size in GB, billable storage cost, on-demand backup cost, and recovery cost for next 36 calendar months. All costs are in USD. From the graph, it's clear that storage, backup, and recovery costs increase proportionally to increases in storage size.
Note that prices used in the graph are for illustration purposes only. To create accurate prices for your use case, check the AWS pricing page, and use those prices in the Excel template.

Summary

Amazon DynamoDB is a NoSQL transactional database that provides single-digit millisecond latency even at petabytes scale. This Amazon Web Services (AWS) serverless offering is getting popular because of its consistent performance and scalability. You do not need to provision storage. Your single table can grow up to petabytes.

DynamoDB monitors the size of your table continuously throughout the month to determine your storage charges. AWS then charges you for the average size of storage in gigabytes. The more that your table grows over time, the more that your storage cost will grow. To calculate storage cost, you can use AWS Pricing Calculator, but you need to provide the approximate size of your table, including global secondary indexes (GSIs), which is really difficult to estimate at the beginning of the project. Also, AWS Pricing Calculator does not consider the data growth rate.

This pattern provides a mechanism and a reusable Microsoft Excel template to calculate DynamoDB storage size and cost. It considers the storage requirements for the base table and the GSIs independently. It calculates storage size by considering the size of your individual items and data growth rate over time.

To get an estimate, insert two pieces of information into the template:

- The individual item size in kilobytes for the base table and GSIs
- How many new objects or products could be added to the table, on average, in a month, (for example, 10 million)

The template will generate a storage and cost forecasting graph for the next three years, which is shown in the following example.
Prerequisites and limitations

Prerequisites

- Basic knowledge of DynamoDB, and DynamoDB storage and pricing
- Knowledge of your data, data model, and item size in DynamoDB
- Knowledge of DynamoDB global secondary indexes (GSIs)

Limitations

- The template provides you with an approximate calculation, but it isn’t appropriate for all configurations. To get a more accurate estimate, you must measure the individual item size for each item in the base table and GSIs.
- This pattern supports estimating only storage size and cost for the next few years based on fixed data growth assumptions.

Tools

AWS services

- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

Other tools

- AWS Pricing Calculator is a web-based planning tool that you can use to create estimates for your AWS use cases.

</tr>
</tbody>
</table>

Related resources

- Amazon DynamoDB On-Demand pricing
- AWS Pricing Calculator for DynamoDB

Additional information

Note that the attached template forecasts only storage size and cost for Standard storage table class. Based on the forecast for storage costs, and considering individual item size and product or object growth rate, you can estimate the following:
• Data export cost
• Backup and recovery cost
• Data storage requirements.

**Amazon DynamoDB data storage cost**

DynamoDB monitors the size of your tables continuously to determine your storage charges. DynamoDB measures the size of your billable data by adding the raw byte size of your data plus a per-item storage overhead that depends on the features you have enabled. For more information, see the DynamoDB Developer Guide.

The price for data storage depends on your table class. The first 25 GB stored each month is free if you’re using the DynamoDB Standard table class. For more information about storage costs for Standard table class and Standard-Infrequent Access table class in different AWS Regions, see Pricing for On-Demand Capacity.

Estimate the Amazon RDS engine size for an Oracle database by using AWR reports

Created by Abhishek Verma (AWS) and Eduardo Valentim (AWS)

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Source: Oracle Database</th>
<th>Target: Amazon RDS or Amazon Aurora</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Re-architect</td>
<td>Workload: Oracle</td>
<td>Technologies: Databases; Migration</td>
</tr>
<tr>
<td>AWS services: Amazon RDS; Amazon Aurora</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

When you migrate an Oracle database to Amazon Relational Database Service (Amazon RDS) or Amazon Aurora, computing the CPU, memory, and disk I/O for the target database is a key requirement. You can estimate the required capacity of the target database by analyzing the Oracle Automatic Workload Repository (AWR) reports. This pattern explains how to use AWR reports to estimate these values.

The source Oracle database could be on premises or hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance, or it could be an Amazon RDS for Oracle DB instance. The target database could be any Amazon RDS or Aurora database.

Note: Capacity estimates will be more precise if your target database engine is Oracle. For other Amazon RDS databases, the engine size can vary due to differences in database architecture.

We recommend that you run the performance test before you migrate your Oracle database.

Prerequisites and limitations

Prerequisites

- An Oracle Database Enterprise Edition license and Oracle Diagnostics Pack license in order to download AWR reports.

Product versions

- All Oracle Database editions for versions 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c,19c.
- This pattern doesn't cover Oracle Engineered Systems or Oracle Cloud Infrastructure (OCI).

Architecture

Source technology stack

One of the following:
AWS Prescriptive Guidance Patterns
Tools

- An on-premises Oracle database
- An Oracle database on an EC2 instance
- An Amazon RDS for Oracle DB instance

Target technology stack

- Any Amazon RDS or Amazon Aurora database

Target architecture

For information about the full migration process, see the pattern [Migrate an Oracle database to Aurora PostgreSQL using AWS DMS and AWS SCT](#).

Automation and scale

If you have multiple Oracle databases to migrate and you want to use additional performance metrics, you can automate the process by following the steps described in the blog post [Right-size Amazon RDS instances at scale based on Oracle performance metrics](#).

Tools

- **Oracle Automatic Workload Repository (AWR)** is a repository that's built into Oracle databases. It periodically gathers and stores system activity and workload data, which is then analyzed by Automatic Database Diagnostic Monitor (ADDM). AWR takes snapshots of system performance data periodically (by default, every 60 minutes) and stores the information (by default, up to 8 days). You can use AWR views and reports to analyze this data.

Best practices

- To calculate resource requirements for your target database, you can use a single AWR report, multiple AWR reports, or dynamic AWR views. We recommend that you use multiple AWR reports during the peak load period to estimate the resources required to handle those peak loads. In addition, dynamic views provide more data points that help you calculate resource requirements more precisely.
- You should estimate IOPS only for the database that you plan to migrate, not for other databases and processes that use the disk.
- To calculate how much I/O is being used by the database, don’t use the information in the Load Profile section of the AWR report. Use the I/O Profile section instead, if it's available, or skip to the Instance Activity Stats section and look at the total values for physical read and write operations.
- When you estimate CPU utilization, we recommend that you use the database metrics method instead of operating system (OS) statistics, because it's based on the CPU used only by databases. (OS statistics also include CPU usage by other processes.) You should also check CPU-related recommendations in the ADDM report to improve performance after migration.
- Consider I/O throughput limits—Amazon Elastic Block Store (Amazon EBS) throughput and network throughput—for the specific instance size when you’re determining the right instance type.
- Run the performance test before migration to validate the engine size.

<td>DBA</td>
</tr>
<tr>
<td>Generate the snapshot.</td>
<td>If the AWR snapshot interval isn't granular enough to capture the spike of the peak workload, you can generate the AWR report manually. To generate the manual AWR snapshot, use the following query.</td>
<td>DBA</td>
</tr>
<tr>
<td>Check recent snapshots.</td>
<td>To check recent AWR snapshots, use the following query.</td>
<td>DBA</td>
</tr>
</tbody>
</table>

**SQL**

```sql
SQL> SELECT snap_interval,retention
       FROM dba_hist_wr_control;
```

```sql
SQL> EXEC dbms_workload_repository.create_snapshot;
```

```sql
SQL> SELECT snap_id,
       TO_CHAR(begin_interval_time,'dd/MON/yy hh24:mi') Begin_Interval,
       TO_CHAR(end_interval_time,'dd/MON/yy hh24:mi') End_Interval
       FROM dba_hist_snapshot
       ORDER BY 1;
```

### Estimate disk I/O requirements

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Choose a method.</td>
<td>IOPS is the standard measure of input and output operations per second on a storage device, and includes both read and write operations. If you are migrating an on-premises database to AWS, you</td>
<td>DBA</td>
</tr>
</tbody>
</table>

**SQL**

```sql
SQL> SELECT snap_id,
       TO_CHAR(begin_interval_time,'dd/MON/yy hh24:mi') Begin_Interval,
       TO_CHAR(end_interval_time,'dd/MON/yy hh24:mi') End_Interval
       FROM dba_hist_snapshot
       ORDER BY 1;
```
need to determine the peak disk I/O used by the database. You can use the following methods to estimate disk I/O for your target database:

- Load Profile section of the AWR report
- Instance Activity Stats section of the AWR report (use this section for Oracle Database 12c or later)
- I/O Profile section of the AWR report (use this section for Oracle Database versions before 12c)
- AWR views

The following steps describe these four methods.
Option 1: Use the load profile.

The following table shows an example of the Load Profile section of the AWR report.

**Important:** For more accurate information, we recommend that you use option 2 (I/O profiles) or option 3 (instance activity statistics) instead of the load profile.

<table>
<thead>
<tr>
<th></th>
<th>Per Second</th>

<td></td>
</tr>
<tr>
<td></td>
<td>Rollbacks 0.2</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Transactions</td>
<td></td>
</tr>
</tbody>
</table>

Based on this information, you can calculate IOPs and throughput as follows:

\[
IOPS = \text{Read I/O requests: + Write I/O requests} = 3,586.8 + 574.7 = 4134.5
\]

\[
\text{Throughput} = \text{Physical read (blocks) + Physical write (blocks)} = 13,575.1 + 3,467.3 = 17,042.4
\]

Because the block size in Oracle is 8 KB, you can calculate total throughput as follows:

\[
\text{Total throughput in MB is} = 17042.4 \times 8 / 1024 / 1024 = 133.2 \text{ MB}
\]

**Warning:** Don't use the load profile to estimate the instance size. It isn't as precise as instance activity statistics or I/O profiles.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option 2: Use instance activity statistics.</td>
<td>If you're using an Oracle Database version before 12c, you can use the Instance Activity Stats section of the AWR report to estimate IOPS and throughput. The following table shows an example of this section.</td>
<td>DBA</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Total per Second</th>
<th>per Trans</th>
</tr>
</thead>
<tbody>
<tr>
<td>physical read total IO requests</td>
<td>2,547,333,217</td>
<td>3,610.28</td>
</tr>
<tr>
<td>physical read total bytes</td>
<td>80,776,296,124,928</td>
<td>114,482,426.26</td>
</tr>
<tr>
<td>physical write total IO requests</td>
<td>534,198,208</td>
<td>757.11</td>
</tr>
<tr>
<td>physical write total bytes</td>
<td>25,517,678,849,024</td>
<td>36,165,631.84</td>
</tr>
</tbody>
</table>

Based on this information, you can calculate total IOPS and throughput as follows:

Total IOPS = 3,610.28 + 757.11 = 4367

Total Mbps = \( \frac{114,482,426.26 + 36,165,631.84}{1024 / 1024} = 143 \text{ Mbps} \)
### Task
Option 3: Use I/O profiles.

### Description
In Oracle Database 12c, the AWR report includes an I/O Profiles section that presents all the information in a single table and provides more accurate data about database performance. The following table shows an example of this section.

<table>
<thead>
<tr>
<th></th>
<th>Read+Write per Second</th>
<th>Read per Second</th>
<th>Write per Second</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Total Requests:</strong></td>
<td>4,367.4</td>
<td>3,610.3</td>
<td>757.1</td>
</tr>
<tr>
<td><strong>Database Requests:</strong></td>
<td>4,161.5</td>
<td>3,586.8</td>
<td>574.7</td>
</tr>
<tr>
<td><strong>Optimized Requests:</strong></td>
<td>0.0</td>
<td>0.0</td>
<td>0.0</td>
</tr>
<tr>
<td><strong>Redo Requests:</strong></td>
<td>179.3</td>
<td>2.8</td>
<td>176.6</td>
</tr>
<tr>
<td><strong>Total (MB):</strong></td>
<td>143.7</td>
<td>109.2</td>
<td>34.5</td>
</tr>
<tr>
<td><strong>Database (MB):</strong></td>
<td>133.1</td>
<td>106.1</td>
<td>27.1</td>
</tr>
<tr>
<td><strong>Optimized Total (MB):</strong></td>
<td>0.0</td>
<td>0.0</td>
<td>0.0</td>
</tr>
<tr>
<td><strong>Redo (MB):</strong></td>
<td>7.6</td>
<td>2.7</td>
<td>4.9</td>
</tr>
<tr>
<td><strong>Database (blocks):</strong></td>
<td>7,042.4</td>
<td>5,375.3</td>
<td>13,467.3</td>
</tr>
<tr>
<td><strong>Via Buffer Cache (blocks):</strong></td>
<td>5,898.5</td>
<td>5,360.9</td>
<td>537.6</td>
</tr>
<tr>
<td><strong>Direct (blocks):</strong></td>
<td>11,143.9</td>
<td>121.2</td>
<td>2,929.7</td>
</tr>
</tbody>
</table>

This table provides the following values for throughput and total IOPS:

**DBA**
### Throughput

- **Throughput** = 143 MBPS (from the fifth row, labeled Total, second column)

### IOPS

- **IOPS** = 4,367.4 (from the first row, labeled Total Requests, second column)

#### Option 4: Use AWR views.

You can see the same IOPS and throughput information by using AWR views. To get this information, use the following query:

```sql
break on report compute sum of Value on report
select METRIC_NAME,avg(AVERAGE) as "Value"
from dba_hist_sysmetric_summary
where METRIC_NAME in ('Physical Read Total IO Requests Per Sec','Physical Write Total IO Requests Per Sec')
group by metric_name;
```

### Estimate CPU requirements

#### Choose a method.

You can estimate the CPU required for the target database in three ways:

- By using the actual available cores of the processor
- By using the utilized cores based on OS statistics
- By using the utilized cores based on database statistics

If you’re looking at utilized cores, we recommend that you use the database metrics method instead of OS statistics, because it’s based on the CPU used only by the databases that you’re planning to migrate. (OS statistics also include CPU usage by other processes.) You should also check CPU-
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>related recommendations in the ADDM report to improve performance after migration. You can also estimate requirements based on CPU generation. If you are using different CPU generations, you can estimate the required CPU of the target database by following the instructions in the whitepaper Demystifying the Number of vCPUs for Optimal Workload Performance.</td>
<td></td>
</tr>
</tbody>
</table>
Option 1: Estimate requirements based on available cores.

In AWR reports:
- CPUs refer to logical and virtual CPUs.
- Cores are the number of processors in a physical CPU chipset.
- A socket is a physical device that connects a chip to a board. Multi-core processors have sockets with several CPU cores.

You can estimate available cores in two ways:
- By using OS commands
- By using the AWR report

To estimate available cores by using OS commands

Use the following command to count the cores in the processor.

```bash
$ cat /proc/cpuinfo | grep "cpu cores" | uniq
cpu cores : 4
```

Use the following command to count the sockets in the processor.

```bash
grep "physical id" /proc/cpuinfo | sort -u
physical id : 0
physical id : 1
```

**Note:** We don't recommend using OS commands such as `nmon` and `sar` to extract CPU utilization. This is because those calculations include CPU utilization by other processes and might not reflect the actual CPU that is used by the database.

Skills required: DBA
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>To estimate available cores by using the AWR report</strong></td>
<td>You can also derive CPU utilization from the first section of the AWR report. Here's an excerpt from the report.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>DB Name</strong></td>
<td><strong>DB Id</strong></td>
</tr>
<tr>
<td></td>
<td>XXXX</td>
<td>&lt;DB_ID&gt;</td>
</tr>
<tr>
<td></td>
<td><strong>Host Name</strong></td>
<td><strong>Platform</strong></td>
</tr>
<tr>
<td></td>
<td>&lt;host_name&gt;</td>
<td>Linux x86 64-bit</td>
</tr>
</tbody>
</table>

In this example, the CPUs count is 80, which indicates that these are logical (virtual) CPUs. You can also see that this configuration has two sockets, one physical processor on each socket (for a total of two physical processors), and 40 cores for each physical processor or socket.
### Task
Option 2: Estimate CPU utilization by using OS statistics.

### Description
You can check the OS CPU usage statistics either directly in the OS (using `sar` or another host OS utility) or by reviewing the IDLE/(IDLE+BUSY) values from the Operating System Statistics section of the AWR report. You can see the seconds of CPU consumed directly from `v$sosstat`. The AWR and Statspack reports also show this data in the Operating System Statistics section.

If there are multiple databases on the same box, they all have the same `v$sosstat` values for `BUSY_TIME`.

If there are no other major CPU consumers in the system, use the following formula to calculate the percentage of CPU utilization:

\[
\text{Utilization} = \frac{\text{Busy time}}{\text{Total time}}
\]

\[
\text{Busy time} = \text{requirements} = v \\
\text{C} = \text{Total time (Busy + Idle)}
\]

\[
\text{C} = \text{capacity} = v \\
\text{Utilization} = \frac{\text{BUSY\_TIME}}{\text{(BUSY\_TIME + IDLE\_TIME)}}
\]

\[
= \frac{-1,305,569,937}{1,305,569,937 + 4,312,718,839} \\
= 23\% \text{ utilized}
\]
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option 3: Estimate CPU utilization by using database metrics.</td>
<td>If multiple databases are running in the system, you can use the database metrics that appears at the beginning of the report.</td>
<td>DBA</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Snap Id</th>
<th>Snap Time</th>
<th>Session</th>
<th>Cursors/Session</th>
</tr>
</thead>
<tbody>
<tr>
<td>Begin Snap:</td>
<td>1846628-1226</td>
<td>Sep-20 09:00:42</td>
<td>35.8</td>
<td></td>
</tr>
<tr>
<td>End Snap:</td>
<td>185446-1876</td>
<td>Oct-20 13:00:20</td>
<td>41.1</td>
<td></td>
</tr>
<tr>
<td>Elapsed:</td>
<td>11,759.64 (mins)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DB Time:</td>
<td>312,625.40 (mins)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

To get CPU utilization metrics, use this formula:

\[
\text{Database CPU usage} \% \text{ of CPU power available} = \frac{\text{CPU time}}{\text{NUM\_CPUS} \times \text{elapsed time}}
\]

where CPU usage is described by CPU time and represents the time spent on CPU, not the time waiting for CPU. This calculation results in:

\[
= \frac{312,625.40}{11,759.64/80} = 33\% \text{ of CPU is being used}
\]

\[
\text{Number of cores} (33\%) \times 80 = 26.4 \text{ cores}
\]

\[
\text{Total cores} = 26.4 \times (120\%) = 31.68 \text{ cores}
\]

You can use the greater of these two values to calculate the CPU utilization of the Amazon RDS or Aurora DB instance.

**Note:** On IBM AIX, the calculated utilization doesn't match the values from the operating system or the database. These
## Estimate memory requirements

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Estimate memory requirements by using memory statistics.</td>
<td>You can use the AWR report to calculate the memory of the source database and match it in the target database. You should also check the performance of the existing database and reduce your memory requirements to save costs, or increase your requirements to improve performance. That requires a detailed analysis of the AWR response time and the service-level agreement (SLA) of the application. Use the sum of Oracle system global area (SGA) and program global area (PGA) usage as the estimated memory utilization for Oracle. Add an extra 20 percent for the OS to determine a target memory size requirement. For Oracle RAC, use the sum of the estimated memory utilization on all RAC nodes and reduce the total memory, because it's stored on common blocks.</td>
<td>DBA</td>
</tr>
</tbody>
</table>
|                                               | 1. Check for the metrics in the Instance Efficiency Percentage table. The table uses the following terms:  
  • *Buffer Hit %* is the percentage of times a particular block was found in the buffer cache instead of performing a physical I/O. For better performance, target 100 percent.  
  • *Buffer Nowait %* should be close to 100 percent.  
  • *Latch Hit %* should be close to 100 percent.  
  • *% Non-Parse CPU* is the percentage of CPU time spent in non-parsing. |                  |

Determine the DB instance type of the target database

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Determine the DB instance type based on disk I/O, CPU, and memory estimates. | Based on the estimates in the previous steps, the capacity of the target Amazon RDS or Aurora database should be:  
  - 68 cores of CPU  
  - 143 MBPS of throughput  
  - 4367 IOPS for disk I/O  
  - 464 GB of memory  

In the target Amazon RDS or Aurora database, you can map these values to the db.r5.16xlarge instance type, which has a capacity of 32 cores, 512 GB of RAM, and 13,600 Mbps of throughput. For more information, see the AWS blog post [Right-size Amazon](https://aws.amazon.com/blogs/database/right-size-amazon-rds/) | DBA |

Summary

Amazon Relational Database Service (Amazon RDS) for SQL Server doesn’t support loading data onto other DB engine linked servers on the Amazon Web Services (AWS) Cloud. Instead, you can use AWS Database Migration Service (AWS DMS) to export Amazon RDS for SQL Server tables to an Amazon Simple Storage Service (Amazon S3) bucket, where the data is available to other DB engines.

AWS DMS helps you migrate databases to AWS quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from the most widely used commercial and open-source databases.

This pattern uses AWS Secrets Manager while configuring the AWS DMS endpoints. Secrets Manager helps you protect secrets needed to access your applications, services, and IT resources. You can use the service to rotate, manage, and retrieve database credentials, API keys, and other secrets throughout their lifecycle. Users and applications retrieve secrets with a call to Secrets Manager, reducing the need to hardcode sensitive information. Secrets Manager offers secret rotation with built-in integration for Amazon RDS, Amazon Redshift, and Amazon DocumentDB. Also, the service is extensible to other types of secrets, including API keys and OAuth tokens. With Secrets Manager, you can control access to secrets by using fine-grained permissions and audit secret rotation centrally for resources in the AWS Cloud, third-party services, and on premises.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An S3 bucket
- A virtual private cloud (VPC)
- A DB subnet
- Amazon RDS for SQL Server
- An AWS Identity and Access Management (IAM) role with access (list, get, and put objects) to the S3 bucket on behalf of the Amazon RDS instance.
- Secrets Manager to store the RDS instance credentials.
Architecture

Technology stack

- Amazon RDS for SQL Server
- AWS DMS
- Amazon S3
- AWS Secrets Manager

Target architecture

The following diagram shows the architecture for importing data from the Amazon RDS instance to the S3 bucket with the help of AWS DMS.

1. The AWS DMS migration task connecting to the source Amazon RDS instance through the source endpoint
2. Copying data from the source Amazon RDS instance
3. The AWS DMS migration task connecting to the target S3 bucket through the target endpoint
4. Exporting copied data to the S3 bucket in comma-separated values (CSV) format

Tools

AWS services

- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
• **Amazon Relational Database Service (Amazon RDS)** helps you set up, operate, and scale a relational database in the AWS Cloud.

• **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

• **AWS Secrets Manager** helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.

**Other services**

• **Microsoft SQL Server Management Studio (SSMS)** is a tool for managing SQL Server, including accessing, configuring, and administering SQL Server components.

Additional information

To create the database and table, and to load the example data, use the following code.

```
--Step1: Database creation in RDS SQL Server
CREATE DATABASE [Test_DB]
ON PRIMARY
( NAME = N'Test_DB', FILENAME = N'D:\rdsdbdata\DATA\Test_DB.mdf' , SIZE = 5120KB ,
FILEGROWTH = 10%)
LOG ON
( NAME = N'Test_DB_log', FILENAME = N'D:\rdsdbdata\DATA\Test_DB_log.ldf' , SIZE = 1024KB ,
FILEGROWTH = 10%)
GO

--Step2: Create Table
USE Test_DB
GO
Create Table Test_Table(ID int, Company Varchar(30), Location Varchar(20))
```
-- Step 3: Load sample data.
USE Test_DB
GO
Insert into Test_Table values(1,'AnyCompany','India')
Insert into Test_Table values(2,'AnyCompany','USA')
Insert into Test_Table values(3,'AnyCompany','UK')
Insert into Test_Table values(4,'AnyCompany','Hyderabad')
Insert into Test_Table values(5,'AnyCompany','Banglore')
Handle anonymous blocks in Dynamic SQL statements in Aurora PostgreSQL

*Created by anuradha chintha (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>Database Relational</th>
<th>Target:</th>
<th>PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>
<td>Re-architect</td>

<td>Technologies:</td>
<td>Databases; Migration</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon Aurora; Amazon RDS</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

This pattern shows you how to avoid the error that you get when handling anonymous blocks in Dynamic SQL statements. You receive an error message when you use the AWS Schema Conversion Tool to convert an Oracle database to an Aurora PostgreSQL-Compatible Edition database. To avoid the error, you must know the value of an `OUT` bind variable, but you can't know the value of an `OUT` bind variable until after you run the SQL statement. The error results from the AWS Schema Conversion Tool (AWS SCT) not understanding the logic inside the Dynamic SQL statement. AWS SCT can't convert the dynamic SQL statement in PL/SQL code (that is, functions, procedures, and packages).

**Prerequisites and limitations**

**Prerequisites**

- Active AWS account
- [Aurora PostgreSQL database (DB) instance](#)
- [Amazon Relational Database Service (Amazon RDS) for Oracle DB instance](#)
- [PostgreSQL interactive terminal (psql)](#)
- SQL *Plus*
- AWS_ORACLE_EXT schema (part of the [AWS SCT extension pack](#)) in your target database
- Latest version of [AWS Schema Conversion Tool (AWS SCT)](#) and its required drivers

**Architecture**

**Source technology stack**

- On-premises Oracle Database 10g and later version

**Target technology stack**

- Amazon Aurora PostgreSQL
- Amazon RDS for PostgreSQL
- AWS Schema Conversion Tool (AWS SCT)
Migration architecture

The following diagram shows how to use AWS SCT and Oracle OUT bind variables to scan your application code for embedded SQL statements and convert the code to a compatible format that an Aurora database can use.

The diagram shows the following workflow:
1. Generate an AWS SCT report for the source database by using Aurora PostgreSQL as the target database.
2. Identify the anonymous block in the Dynamic SQL code block (for which AWS SCT raised the error).
3. Convert the code block manually and deploy the code on a target database.

Tools

AWS services

- **Amazon Aurora PostgreSQL-Compatible Edition** is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- **Amazon Relational Database Service (Amazon RDS) for Oracle** helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.
- **AWS Schema Conversion Tool (AWS SCT)** helps you make heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects to a format compatible with the target database.

Other tools

- **pgAdmin** enables you to connect to and interact with your database server.
• Oracle SQL Developer is an integrated development environment that you can use to develop and manage databases in Oracle Database. You can use either SQL*Plus or Oracle SQL Developer for this pattern.

Epics

Configure the Oracle source database

<table>
<thead>
<tr>

<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an Oracle instance on Amazon RDS or Amazon EC2.</td>
<td>To create an Oracle DB instance on Amazon RDS, see Creating an Oracle DB instance and connecting to a database on an Oracle DB instance in the Amazon RDS documentation. To create an Oracle DB instance on Amazon Elastic Compute Cloud (Amazon EC2), see Amazon EC2 for Oracle in the AWS Prescriptive Guidance documentation.</td>
<td>DBA</td>
</tr>
<tr>
<td>Create a database schema and objects for migration.</td>
<td>You can use Amazon Cloud Directory to create a database schema. For more information, see Create a Schema in the Cloud Directory documentation.</td>
<td>DBA</td>
</tr>
<tr>
<td>Configure inbound and outbound security groups.</td>
<td>To create and configure security groups, see Controlling access with security groups in the Amazon RDS documentation.</td>
<td>DBA</td>
</tr>
<tr>
<td>Confirm that the database is running.</td>
<td>To check the status of your database, see Viewing Amazon RDS events in the Amazon RDS documentation.</td>
<td>DBA</td>
</tr>
</tbody>
</table>

Configure the target Aurora PostgreSQL database

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an Aurora PostgreSQL instance in Amazon RDS.</td>
<td>To create an Aurora PostgreSQL instance, see Creating a DB cluster and connecting to a database on an Aurora PostgreSQL DB cluster in the Amazon RDS documentation.</td>
<td>DBA</td>
</tr>
<tr>
<td>Configure an inbound and outbound security group.</td>
<td>To create and configure security groups, see Provide access to the DB cluster in the VPC by creating</td>
<td>DBA</td>
</tr>
</tbody>
</table>
Confim that the Aurora PostgreSQL database is running. To check the status of your database, see Viewing Amazon RDS events in the Aurora documentation.

Set up AWS SCT

Connect AWS SCT to the source database. To connect AWS SCT to your source database, see Connecting to PostgreSQL as a source in the AWS SCT documentation.

Connect AWS SCT to the target database. To connect AWS SCT to your target database, see the What is the AWS Schema Conversion Tool? in the AWS Schema Conversion Tool User Guide.

Convert the database schema in AWS SCT and save the automated converted code as a SQL file. To save AWS SCT converted files, see Saving and applying your converted schema in AWS SCT in the AWS Schema Conversion Tool User Guide.

Migrate the code

Get the SQL file for manual conversion. In the AWS SCT converted file, pull the SQL file that requires manual conversion.

Update the script. Manually update the SQL file.

Additional information

The following example code shows how to configure the Oracle source database:

```sql
CREATE or replace PROCEDURE calc_stats_new1 (```
The following example code shows how to configure the target Aurora PostgreSQL database:

```sql
w integer,
  x integer
RETURNS integer
AS
$BODY$
DECLARE
begin
return w + x ;
end;
$BODY$
LANGUAGE  plpgsql;

CREATE OR REPLACE FUNCTION test_pg.init()
RETURNS void
AS
$BODY$
BEGIN
if aws_oracle_ext.is_package_initialized
  ('test_pg') then
  return;
end if;
perform aws_oracle_ext.set_package_initialized
  ('test_pg');
PERFORM aws_oracle_ext.set_package_variable('test_pg', 'v_output', NULL::INTEGER);
PERFORM aws_oracle_ext.set_package_variable('test_pg', 'v_status', NULL::text);
END;
$BODY$
LANGUAGE  plpgsql;

DO $$
declare
v_sql text;
v_output_loc int;
a integer :=1;
b integer :=2;
BEGIN
```

```sql```
perform test_pg.init();
--raise notice 'v_sql %', v_sql;
execute 'do $a$ declare v_output_l int; begin select * from test_pg.calc_stats_new1(''||a'||',''||b'||') into v_output_l;
PERFORM aws_oracle_ext.set_package_variable(''test_pg'', ''v_output'', v_output_l) ; end;
$a$;
v_output_loc := aws_oracle_ext.get_package_variable('test_pg', 'v_output');
raise notice 'v_output_loc %', v_output_loc;
END ;
$$
Handle overloaded Oracle functions in Aurora PostgreSQL-Compatible

Summary

The code you migrate from an on-premises Oracle database to Amazon Aurora PostgreSQL-Compatible Edition might include overloaded functions. These functions have the same definition—that is, the same function name and the same number and data type of input (IN) parameters—but the data type or the number of output (OUT) parameters might differ.

These parameter mismatches can cause problems in PostgreSQL, because it’s difficult to determine which function to run. This pattern illustrates how to handle overloaded functions when you migrate your database code to Aurora PostgreSQL-Compatible.

Prerequisites and limitations

Prerequisites

• An Oracle database instance as your source database
• An Aurora PostgreSQL-Compatible DB instance as your target database (see instructions in the Aurora documentation)

Product versions

• Oracle Database 9i or later
• Oracle SQL Developer version 18.4.0.376
• pgAdmin 4 client
• Aurora PostgreSQL-Compatible version 11 or later (see Identifying versions of Amazon Aurora PostgreSQL in the Aurora documentation)

Tools

AWS services

• Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.

Other tools
**Oracle SQL Developer** is a free, integrated development environment for working with SQL in Oracle databases in both traditional and cloud deployments.

**pgAdmin** is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

## Epics

### Create a simple function

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a function in PostgreSQL that has one input parameter and one output parameter.</td>
<td>The following example illustrates a function named <code>test_overloading</code> in Aurora PostgreSQL-Compatible. This function has two parameters: one input text parameter and one output text parameter.</td>
<td>Data engineer, Aurora PostgreSQL-Compatible</td>
</tr>
<tr>
<td>Run the function in PostgreSQL.</td>
<td>Run the function that you created in the previous step.</td>
<td>Data engineer, Aurora PostgreSQL-Compatible</td>
</tr>
</tbody>
</table>

```sql
CREATE OR REPLACE FUNCTION public.test_overloading(
  str1 text,
  OUT str2 text)
LANGUAGE 'plpgsql'
COST 100
VOLATILE
AS $BODY$
DECLARE
  str2 := 'Success';
  RETURN ;
EXCEPTION
  WHEN others THEN
    RETURN ;
END;
$BODY$;
```

```sql
select public.test_overloading('Test');
```

It should display the following output.

```
Success
```
Overload the function

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use the same function name to create an overloaded function in PostgreSQL.</td>
<td>Create an overloaded function in Aurora PostgreSQL-Compatible that uses the same function name as your previous function. The following example is also named test_overloading, but it has three parameters: one input text parameter, one output text parameter, and one output integer parameter.</td>
<td>Data engineer, Aurora PostgreSQL-Compatible</td>
</tr>
</tbody>
</table>

```sql
CREATE OR REPLACE FUNCTION public.test_overloading(
    str1 text,
    OUT str2 text,
    OUT num1 integer)
LANGUAGE 'plpgsql'
COST 100
VOLATILE
AS $BODY$
DECLARE
    str3 text;
BEGIN
    str2 := 'Success';
    num1 := 100;
    RETURN;
EXCEPTION
    WHEN others THEN
    RETURN;
END;
$BODY$
```

Run the function in PostgreSQL. | When you run this function, it fails with the following error message. | Data engineer, Aurora PostgreSQL-Compatible |

```sql
ERROR: cannot change return type of existing function
HINT: Use DROP FUNCTION test_overloading(text) first.
```

This happens because Aurora PostgreSQL-Compatible doesn't support function overloading directly. It can't identify which function to run, because the number of output parameters is different in the second version.
### Apply the workaround

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add INOUT to the first output parameter.</td>
<td>As a workaround, modify the function code by representing the first output parameter as INOUT.</td>
<td>Data engineer, Aurora PostgreSQL-Compatible</td>
</tr>
</tbody>
</table>

```sql
CREATE OR REPLACE FUNCTION public.test_overloading(
    str1 text,
    INOUT str2 text,
    OUT num1 integer)
LANGUAGE 'plpgsql'
COST 100
VOLATILE
AS $BODY$
DECLARE
    str3 text;
BEGIN
    str2 := 'Success';
    num1 := 100;
    RETURN ;
EXCEPTION
    WHEN others THEN
        RETURN ;
END;
$BODY$;
```

Run the revised function.

Run the function that you updated by using the following query. You pass a null value as the second argument of this function, because you declared this parameter as INOUT to avoid the error.

```sql
select public.test_overloading('Test', null);
```

The function is now created successfully.

Success, 100

Help enforce DynamoDB tagging

Created by Mansi Suratwala (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Technologies: Cloud-native; Security, identity, compliance; Databases</th>
<th>Workload: All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>Amazon CloudWatch; Amazon DynamoDB; AWS Lambda; Amazon SNS</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern sets up automatic notifications when a predefined Amazon DynamoDB tag is missing or removed from a DynamoDB resource on the Amazon Web Services (AWS) Cloud.

DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with scalability. DynamoDB lets you offload the administrative burdens of operating and scaling a distributed database. When you use DynamoDB, you don't have to worry about hardware provisioning, setup and configuration, replication, software patching, or cluster scaling.

The pattern uses an AWS CloudFormation template, which creates an Amazon CloudWatch Events event and an AWS Lambda function. The event watches for any new or existing DynamoDB tagging information by using AWS CloudTrail. If a predefined tag is missing or removed, CloudWatch triggers a Lambda function, which sends you an Amazon Simple Notification Service (Amazon SNS) notification informing you of the violation.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon Simple Storage Service (Amazon S3) bucket for the Lambda .zip file that contains the Python script for running the Lambda function

Limitations

- The solution works only when the TagResource or UntagResource CloudTrail events occur. It does not create notifications for any other events.

Architecture

Target technology stack

- Amazon DynamoDB
- AWS CloudTrail
- Amazon CloudWatch
- AWS Lambda
- Amazon S3
Tools

- **Amazon DynamoDB** – DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with scalability.
- **AWS CloudTrail** – CloudTrail is an AWS service that helps you with governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail.
- **Amazon CloudWatch Events** – Amazon CloudWatch Events delivers a near-real time stream of system events that describe changes in AWS resources.
- **AWS Lambda** – Lambda is a compute service that supports running code without needing to provision or manage servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud.

**Code**

- A .zip file of the project is available as an attachment.

Implement cross-Region disaster recovery with AWS DMS and Amazon Aurora

Created by Mark Hudson (AWS)

Environment: Production  Technologies: Databases  AWS services: AWS DMS; Amazon RDS; Amazon Aurora

Summary

Natural or human-induced disasters can occur at any time and can impact the availability of services and workloads running in a given Amazon Web Services (AWS) Region. To mitigate the risks, you must develop a disaster recovery (DR) plan that incorporates the built-in cross-Region capabilities of AWS services. For AWS services that do not inherently provide cross-Region functionality, the DR plan must also provide a solution to handle their failover across AWS Regions.

This pattern guides you through a disaster recovery setup involving two Amazon Aurora MySQL-Compatible Edition database clusters in a single Region. To meet DR requirements, the database clusters are configured to use the Amazon Aurora global database feature, with a single database spanning multiple AWS Regions. An AWS Database Migration Service (AWS DMS) task replicates data between the clusters in the local Region. AWS DMS, however, currently doesn’t support cross-Region tasks. This pattern includes the steps required to work around that limitation and independently configure AWS DMS in both Regions.

Prerequisites and limitations

Prerequisites

- Selected primary and secondary AWS Regions that support Amazon Aurora global databases.
- Two independent Amazon Aurora MySQL-Compatible Edition database clusters in a single account in the primary Region.
- Database instance class db.r5 or higher (recommended).
- An AWS DMS task in the primary Region performing ongoing replication between the existing database clusters.
- DR Region resources in place to meet requirements for creating database instances. For more information, see Working with a DB instance in a VPC.

Limitations

- For the full list of Amazon Aurora global database limitations, see Limitations of Amazon Aurora global databases.

Product versions

- Amazon Aurora MySQL-Compatible Edition 5.7 or 8.0. For more information, see Amazon Aurora versions.
Architecture

Target technology stack

- Amazon Aurora MySQL-Compatible Edition global database cluster
- AWS DMS

Target architecture

Automation and scale

You can use AWS CloudFormation to create the prerequisite infrastructure in the secondary Region, such as the virtual private cloud (VPC), subnets, and parameter groups. You can also use AWS CloudFormation to create the secondary clusters in the DR Region and add them to the global database. If you used CloudFormation templates to create the database clusters in the primary Region, you can update or augment them with an additional template to create the global database resource. For more information, see Creating an Amazon Aurora DB cluster with two DB instances and Creating a global database cluster for Aurora MySQL.

Finally, you can create the AWS DMS tasks in the primary and secondary Regions using CloudFormation after failover and failback events occur. For more information, see AWS::DMS::ReplicationTask.

Tools

- Amazon Aurora - Amazon Aurora is a fully managed relational database engine that’s compatible with MySQL and PostgreSQL. This pattern uses Amazon Aurora MySQL-Compatible Edition.
- Amazon Aurora global databases - Amazon Aurora global databases are designed for globally distributed applications. A single Amazon Aurora global database can span multiple AWS Regions. It replicates your data with no impact on database performance. It also enables fast local reads with low latency in each Region, and it provides disaster recovery from Region-wide outages.
- AWS DMS - AWS Database Migration Service (AWS DMS) provides one-time migration or on-going replication. An on-going replication task keeps your source and target databases in sync. After it is set up, the on-going replication task continuously applies source changes to the target with minimal
latency. All AWS DMS features, such as data validation and transformations, are available for any replication task.

## Epics

### Prepare the existing database clusters in the primary Region

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Modify the database cluster parameter group. | In the existing database cluster parameter group, activate row-level binary logging by setting the binlog_format parameter to a value of **row**.  
AWS DMS requires row-level binary logging for MYSQL-compatible databases when performing ongoing replication or change data capture (CDC). For more information, see [Using an AWS managed MySQL-compatible database as a source for AWS DMS](#). | AWS administrator    |
| Update the database binary log retention period. | Using a MySQL client installed on your end-user device or an Amazon Elastic Compute Cloud (Amazon EC2) instance, run the following stored procedure provided by Amazon Relational Database Service (Amazon RDS) on the main database cluster's writer node, where XX is the number of hours to retain the logs.  
```sql  
call mysql.rds_set_configuration('binlog retention hours', XX)  
```
Confirm the setting by running the following command.  
```sql  
call mysql.rds_show_configuration;  
```
MySQL-compatible databases managed by AWS purge the binary logs as soon as possible. Therefore, the retention period must be long enough to ensure that the logs are not purged before the AWS DMS task runs. A value of 24 hours is usually | DBA      |
Update the existing AWS DMS task in the primary Region

- [Working with Amazon Aurora MySQL](#)
• Working with an AWS DMS replication instance
• Working with AWS DMS endpoints
• Working with AWS DMS tasks
• What is AWS CloudFormation?

Additional information

Amazon Aurora global databases are used in this example for DR because they provide an effective recovery time objective (RTO) of 1 second and a recovery point objective (RPO) of less than 1 minute, both lower than traditional replicated solutions and ideal for DR scenarios.

Amazon Aurora global databases offer many other advantages, including the following:

• Global reads with local latency – Global consumers can access information in a local Region, with local latency.
• Scalable secondary Amazon Aurora DB clusters – Secondary clusters can be scaled independently, adding up to 16 read-only replicas.
• Fast replication from primary to secondary Amazon Aurora DB clusters – Replication has little performance impact on the primary cluster. It occurs at the storage layer, with typical cross-Region replication latencies of less than 1 second.

This pattern also uses AWS DMS for replication. Amazon Aurora databases provide the ability to create read replicas, which can simplify the replication process and the DR setup. However, AWS DMS is often used to replicate when data transformations are required or when the target database requires additional indexes that the source database does not have.
Migrate Oracle functions and procedures that have more than 100 arguments to PostgreSQL

Created by Srinivas Potlachervoo (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>Oracle</th>
<th>Target:</th>
<th>PostgreSQL</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>AWS services:</td>
<td>Amazon RDS; Amazon Aurora</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern shows how to migrate Oracle Database functions and procedures that have more than 100 arguments to PostgreSQL. For example, you can use this pattern to migrate Oracle functions and procedures to one of the following PostgreSQL-compatible AWS database services:

- Amazon Relational Database Service (Amazon RDS) for PostgreSQL
- Amazon Aurora PostgreSQL-Compatible Edition

PostgreSQL doesn’t support functions or procedures that have more than 100 arguments. As a workaround, you can define a new data type that has type fields that match the source function’s arguments. Then, you can create and run a PL/pgSQL function that uses the custom data type as an argument.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon RDS Oracle database (DB) instance
- An Amazon RDS for PostgreSQL DB instance or an Aurora PostgreSQL-Compatible DB instance

Product versions

- Amazon RDS Oracle DB instance versions 10.2 and later
- Amazon RDS PostgreSQL DB instance versions 9.4 and later, or Aurora PostgreSQL-Compatible DB instance versions 9.4 and later
- Oracle SQL Developer version 18 and later
- pgAdmin version 4 and later

Architecture

Source technology stack

- Amazon RDS Oracle DB instance versions 10.2 and later
Target technology stack

- Amazon RDS PostgreSQL DB instance versions 9.4 and later, or Aurora PostgreSQL-Compatible DB instance versions 9.4 and later

Tools

AWS services

- Amazon Relational Database Service (Amazon RDS) for PostgreSQL helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.

Other services

- Oracle SQL Developer is an integrated development environment that simplifies the development and management of Oracle databases in both traditional and cloud-based deployments.
- pgAdmin is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

Best practices

Make sure that the data type that you create matches the type fields that are included in the source Oracle function or procedure.

Epics

Migrate Amazon RDS for Oracle DB instances to other accounts that use AMS

Created by Pinesh Singal (AWS)

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: Databases: Relational</th>
<th>Target: Amazon RDS for Oracle on AWS Managed Services</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Rehost</td>
<td>Workload: Oracle</td>
<td>Technologies: Databases; Migration; Storage &amp; backup</td>
</tr>
<tr>
<td>AWS services: Amazon RDS; AWS Managed Services</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern shows you how to migrate an Amazon Relational Database Service (Amazon RDS) for Oracle DB instance from one AWS account to another AWS account. The pattern applies to scenarios where the source AWS account doesn't use AWS Managed Services (AMS) but the target account does use AMS. You can complete the migration by using a request for change (RFC) in AMS instead of using the AWS Management Console to perform database operations. This approach provides minimal downtime for a multi-terabyte Oracle source database with a high number of transactions. For example, the downtime for a 400–900 GB database could last for approximately two or three hours. Database migration time is directly proportionate to the size of the Amazon RDS for Oracle DB instance.

Important: This pattern requires you to take a database snapshot of the Amazon RDS for Oracle DB instance in a source account, copy the snapshot to a target account that’s using AMS, and then create a new DB instance from that snapshot by raising RFCs.

Prerequisites and limitations

Prerequisites

- An active AWS account for the source account
- An active AWS account that uses AMS for the target account
- Amazon RDS for Oracle DB instance, up and running

Limitations

- The same properties or configurations for the DB instances in the source account are copied over to a new target DB instance on AMS.
- The RFC method that’s used in this migration approach has limited features to support Amazon RDS for Oracle. You can access the full features of Amazon RDS for Oracle by using an AWS CloudFormation template to perform the database migration.
- You can experience an application outage for several hours because the migration must be completed during scheduled downtime. During downtime, you stop the DB instance in the source account, and then you go live to a new DB instance in the target account.
- This migration approach doesn't apply to the migration of a DB instance from one AWS Region to another Region within the same AWS account.
Product versions

- Oracle Database Standard Edition 2 (SE2) 12.1.0.2.v2 instance and later on Amazon RDS for Oracle
- Amazon RDS for Oracle 11g is no longer supported (For more information, see Amazon RDS for Oracle in the Amazon RDS documentation.)

Architecture

Source technology stack

- Oracle Database SE2 12.1.0.2.v2 instance on Amazon RDS for Oracle
- Amazon RDS subnet group
- Amazon RDS option group (if needed)
- Amazon RDS parameter group (if needed)
- Amazon Virtual Private Cloud (Amazon VPC) security group
- AWS Key Management Service (AWS KMS) with AWS managed keys or customer managed keys
- AWS Identity and Access Management (IAM) role (if needed)

Target technology stack

- Oracle Database SE2 12.1.0.2.v2 instance on Amazon RDS for Oracle
- Amazon RDS subnet group
- Amazon RDS option group (if needed)
- Amazon RDS parameter group (if needed)
- Amazon VPC security group
- AWS Managed Services (AMS)
- AWS KMS with AWS managed keys and customer managed keys
- IAM role (if needed)

Source and target migration architecture

The following diagram shows the migration of an Amazon RDS for Oracle DB instance in one AWS account to an Amazon RDS for Oracle DB instance in another AWS account that uses AMS.

The diagram shows the following workflow:
1. Take a database snapshot of the Amazon RDS for Oracle DB instance in the source account.
2. Copy the snapshot to AMS in the target account.
3. Create a new Amazon RDS for Oracle DB instance from the snapshot in the target account.

**Automation and scale**

You can automate and scale the migration by using CloudFormation templates and [creating RFCs in AMS](#). CloudFormation enables you to use all the features of Amazon RDS for Oracle, including the ability to configure and restore the DB instance when you create an Amazon RDS for Oracle DB instance from a snapshot.

**Tools**

- [Amazon Relational Database Service (Amazon RDS) for Oracle](#) helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.
- [AWS Key Management Service (AWS KMS)](#) helps you create and control cryptographic keys to help protect your data.
- [AWS Managed Services (AMS)](#) helps you operate your AWS infrastructure more efficiently and securely.

**Epics**

### Additional information

#### Roll back the migration

If you want to roll back the migration, complete the following steps:

1. Raise a manual RFC (Update Other) from the target account to delete the database stack created in the target account.
2. Update the application configuration to point to the Amazon RDS for Oracle DB instance in the source account.
3. Start the Amazon RDS for Oracle DB instance in the source account.
Migrate Oracle OUT bind variables to a PostgreSQL database

*Created by Bikash Chandra Rout (AWS) and Vinay Paladi (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source: Database Relational</th>
<th>Target: RDS/Aurora Postgresql</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>
<td>Replatform</td>
<td>Workload: Oracle</td>
<td>Technologies: Databases; Migration</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon Aurora; Amazon RDS; AWS SCT</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

This pattern shows how to migrate Oracle Database OUT bind variables to either one of the following PostgreSQL-compatible AWS database services:

- Amazon Relational Database Service (Amazon RDS) for PostgreSQL
- Amazon Aurora PostgreSQL-Compatible Edition

PostgreSQL doesn’t support OUT bind variables. To get the same functionality in your Python statements, you can create a custom PL/pgSQL function that uses the GET and SET package variables instead. To apply these variables, the example wrapper function script that’s provided in this pattern uses an [AWS Schema Conversion Tool (AWS SCT) extension pack](https://aws.amazon.com/sct/).

**Note:** If the Oracle EXECUTE IMMEDIATE statement is a SELECT statement that can return one row at most, it’s a best practice to do the following:

- Put OUT bind variables (defines) in the INTO clause
- Put IN bind variables in the USING clause

For more information, see [EXECUTE IMMEDIATE statement](https://docs.oracle.com/database/121/MPG/execute.htm) in the Oracle documentation.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- An Oracle Database 10g (or newer) source database in an on-premises data center
- An [Amazon RDS for PostgreSQL DB instance](https://aws.amazon.com/rds/postgresql/) or an [Aurora PostgreSQL-Compatible DB instance](https://aws.amazon.com/aurora/)

**Architecture**

**Source technology stack**

- On-premises Oracle Database 10g (or newer) database
**Tools**

- **Amazon Aurora PostgreSQL-Compatible Edition** is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- **Amazon Relational Database Service (Amazon RDS) for PostgreSQL** helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- **AWS Schema Conversion Tool (AWS SCT)** supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format compatible with the target database.
- **pgAdmin** is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.
Epics

Migrate Oracle OUT bind variables by using a custom PL/pgSQL function and AWS SCT

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add the example wrapper function script from this pattern to the target database's main schema.</td>
<td>Copy the example PL/pgSQL wrapper function script from the Additional information section of this pattern. Then, add the function to the target database's main schema. For more information, see CREATE FUNCTION in the PostgreSQL documentation.</td>
<td>Migration engineer</td>
</tr>
</tbody>
</table>
| Connect to your PostgreSQL-compatible AWS database. | After you've created your DB instance, you can use any standard SQL client application to connect to a database in your DB cluster. For example, you can use pgAdmin to connect to your DB instance. For more information, see either of the following:  
  - Connecting to an Amazon RDS DB instance in the Amazon RDS User Guide  
  - Connecting to an Amazon Aurora DB cluster in the Amazon Aurora User Guide | Migration engineer |
| (Optional) Update the search path in the target database's main schema so that includes the Test_pg schema. | To improve performance, you can update the PostgreSQL search_path variable so that it includes the Test_pg schema name. If you include the schema name in the search path, you don't need to specify the name whenever you call the PL/pgSQL function. For more information, see section 5.9.3 The Schema Search Path in the PostgreSQL documentation. | Migration engineer |

### Additional information

#### Example PL/pgSQL function

```sql
/* Oracle */
CREATE or replace PROCEDURE test_pg.calc_stats_new1 (
    a NUMBER,
    b NUMBER,
    result out NUMBER
)
IS
BEGIN
    result:=a+b;
END;
/

/* Testing */
set serveroutput on
DECLARE
    a NUMBER := 4;
    b NUMBER := 7;
    plsql_block VARCHAR2(100);
    output number;
BEGIN
    plsql_block := 'BEGIN test_pg.calc_stats_new1(:a, :b,:output); END;';
    EXECUTE IMMEDIATE plsql_block USING a, b, output;  -- calc_stats(a, a, b, a)
    DBMS_OUTPUT.PUT_LINE('output:'||output);
END;
output:11

PL/SQL procedure successfully completed.

--Postgres--

/* Example : 1 */
CREATE OR REPLACE FUNCTION test_pg.calc_stats_new1(
    w integer,
    x integer
)
RETURNS integer
AS
    $BODY$
    begin
        return w + x;
    end;
$BODY$
LANGUAGE 'plpgsql';

CREATE OR REPLACE FUNCTION aws_oracle_ext.set_package_variable(  package_name name,
    variable_name name,
    variable_value anyelement
)
RETURNS void
LANGUAGE 'plpgsql';
```
```sql

        raise notice 'v_status %',v_status;
    END ;
$$ ;

Migrate SAP HANA to AWS using SAP HSR with the same hostname

Summary

SAP HANA migrations to Amazon Web Services (AWS) can be performed using multiple options, including backup and restore, export and import, and SAP HANA System Replication (HSR). The selection of a particular option depends on the network connectivity between source and target SAP HANA databases, the size of the source database, downtime considerations, and other factors.

The SAP HSR option for migrating SAP HANA workloads to AWS works well when there is a stable network between the source and target systems and the entire database (SAP HANA DB replication snapshot) can be completely replicated within 1 day, as stipulated by SAP for network throughput requirements for SAP HSR. The downtime requirements with this approach are limited to performing the takeover on the target AWS environment, SAP HANA DB backup, and post-migration tasks.

SAP HSR supports the use of different hostnames (hostnames mapped to different IP addresses) for replication traffic between the primary, or source, and secondary, or target, systems. You can do this by defining those specific sets of hostnames under the [system_replication_hostname_resolution] section in global.ini. In this section, all hosts of the primary and the secondary sites must be defined on each host. For detailed configuration steps, see the SAP documentation.

One key takeaway from this setup is that the hostnames in the primary system must be different from the hostnames in the secondary system. Otherwise, the following errors can be observed.

• "each site must have a unique set of logical hostnames"
• "remoteHost does not match with any host of the source site. All hosts of source and target site must be able to resolve all hostnames of both sites correctly"

However, the number of post-migration steps can be reduced by using the same SAP HANA DB hostname on the target AWS environment.

This pattern provides a workaround for using the same hostname on source and target environments when using the SAP HSR option. With this pattern, you can use the SAP HANA Hostname Rename option. You assign a temporary hostname to the target SAP HANA DB to facilitate hostname uniqueness for SAP HSR. After the migration completes the takeover milestone on the target SAP HANA environment, you can revert the target system hostname back to the hostname of the source system.
Prerequisites and limitations

Prerequisites

- An active AWS account.
- A virtual private cloud (VPC) with a virtual private network (VPN) endpoint or a router.
- AWS Client VPN or AWS Direct Connect configured to transfer files from the source to the target.
- SAP HANA databases in both the source and the target environment. The target SAP HANA DB patch level should be equal to or higher than the source SAP HANA DB patch level, within the same SAP HANA Platform edition. For example, replication cannot be set up between HANA 1.0 and HANA 2.0 systems. For more information, see question 15 in SAP Note: 1999880 – FAQ: SAP HANA System Replication.
- SAP application servers in the target environment.
- Amazon Elastic Block Store (Amazon EBS) volumes in the target environment.

Limitations

The following list of SAP documents covers known issues that are related to this workaround, including constraints regarding SAP HANA dynamic tiering and scale-out migrations:

- 2956397 – Renaming of SAP HANA Database System failed
- 2222694 – When trying to rename the HANA system, the following error appears “Source files are not owned by the original sidadm user (uid = xxxx)”
- 2607227 – hdblcm: register_rename_system: Renaming SAP HANA instance failed
- 2630562 – HANA Hostname Rename failed and HANA does not start up
- 2935639 – sr_register is not using the hostname that is specified under system_replication_hostname_resolution in the global.ini section
- 2710211 – Error: source system and target system have overlapping logical hostnames
- 2693441 – Failed to rename an SAP HANA System due to error
- 2519672 – HANA Primary and Secondary has different system PKI SSFS data and key or unable to check
- 2457129 – SAP HANA System Host Rename is not Permitted when Dynamic Tiering is Part of Landscape
- 2473002 – Using HANA System Replication to migrate scale out system (There are no restrictions provided by SAP in using this hostname rename approach for scale-out SAP HANA systems. However, the procedure must be repeated on each individual host. Other scale-out migration limitations also apply to this approach.)

Product versions

- This solution applies to SAP HANA DB platform edition 1.0 and 2.0.

Architecture

Source setup

An SAP HANA database is installed on the source environment. All the SAP application server connections and DB interfaces use the same hostname for client connections. The following diagram shows the example source hostname hdbhost and its corresponding IP address.
Target setup

The AWS Cloud target environment uses the same hostname to run an SAP HANA database. The target environment on AWS includes the following:

- SAP HANA database
- SAP application servers
- EBS volumes
Intermediate configuration

In the following diagram, the hostname on the AWS target environment is temporarily renamed as temp-host so that the hostnames on the source and target are unique. After the migration completes the takeover milestone on the target environment, the target system virtual hostname is renamed using the original name, hdbhost.

The intermediate configuration includes one of the following options:

- AWS Client VPN with a Client VPN endpoint
- AWS Direct Connect connecting to a router
SAP application servers on the AWS target environment can be installed either before replication setup or after the takeover. However, installing the application servers before replication setup can help with reduction of downtime during installation, configuration of high availability, and backups.

**Tools**

**AWS services**

- **AWS Client VPN** – AWS Client VPN is a managed client-based VPN service that enables you to securely access AWS resources and resources in your on-premises network.

- **AWS Direct Connect** – AWS Direct Connect links your internal network to an AWS Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services, bypassing internet service providers in your network path.

- **Amazon EBS** – Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with EC2 instances. EBS volumes behave like raw, unformatted block devices. You can mount these volumes as devices on your instances.

**Other tools**

- **SAP application servers** – SAP application servers provide programmers with a way to express business logic. The SAP application server performs the data processing based on the business logic. The actual data is stored in a database, which is a separate component.

- **SAP HANA cockpit** and **SAP HANA Studio** – Both SAP HANA cockpit and SAP HANA Studio provide an administrative interface to the SAP HANA database. In SAP HANA Studio, the SAP HANA Administration console is the system view that provides relevant content for SAP HANA database administration.

- **SAP HANA System Replication** – SAP HANA System Replication (SAP HSR) is the standard procedure provided by SAP for replicating SAP HANA databases. The required executables for SAP HSR are part of the SAP HANA server kernel itself.

SAP HANA Database System renamed
Migrate SQL Server to AWS using distributed availability groups

Created by Praveen Marthala (AWS)

| Source: SQL Server On-Premises | Target: SQL Server on EC2 | R Type: Rehost |
| Environment: PoC or pilot | Technologies: Databases; Migration | Workload: Microsoft |
| AWS services: Amazon EC2 |

Summary

Microsoft SQL Server Always On availability groups provide a high availability (HA) and disaster recovery (DR) solution for SQL Server. An availability group consists of a primary replica that accepts read/write traffic, and up to eight secondary replicas that accept read traffic. An availability group is configured on a Windows Server Failover Cluster (WSFC) with two or more nodes.

Microsoft SQL Server Always On distributed availability groups provide a solution to configure two separate availability groups between two independent WSFCs. The availability groups that are part of the distributed availability group don't have to be in the same data center. One availability group can be on premises, and the other availability group can be on the Amazon Web Services (AWS) Cloud on Amazon Elastic Compute Cloud (Amazon EC2) instances in a different domain.

This pattern outlines steps for using a distributed availability group to migrate on-premises SQL Server databases that are part of an existing availability group to SQL Server with availability groups set up on Amazon EC2. By following this pattern, you can migrate the databases to the AWS Cloud with minimal downtime during cutover. The databases are highly available on AWS immediately after the cutover. You can also use this pattern to change the underlying operating system from on-premises to AWS while keeping the same version of SQL Server.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Direct Connect or AWS Site-to-Site VPN
- The same version of SQL Server installed on-premises and on the two nodes on AWS

Product versions

- SQL Server version 2016 and later
- SQL Server Enterprise Edition

Architecture

Source technology stack
• Microsoft SQL Server database with Always On availability groups on premises

**Target technology stack**

• Microsoft SQL Server database with Always On availability groups on Amazon EC2 on the AWS Cloud

**Migration architecture**

**Terminology**

• WSFC 1 – WSFC on premises
• WSFC 2 – WSFC on the AWS Cloud
• AG 1 – First availability group, which is in WSFC 1
• AG 2 – Second availability group, which is in WSFC 2
• SQL Server primary replica – Node in AG 1 that is considered the global primary for all writes
• SQL Server forwarder – Node in AG 2 that receives data asynchronously from the SQL Server primary replica
• SQL Server secondary replica – Nodes in AG 1 or AG 2 that receive data synchronously from the primary replica or the forwarder

**Tools**

• **AWS Direct Connect** – AWS Direct Connect links your internal network to an AWS Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services, bypassing internet service providers in your network path.
• **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
• **AWS Site-to-Site VPN** – AWS Site-to-Site VPN supports creating a site-to-site virtual private network (VPN). You can configure the VPN to pass traffic between instances that you launch on AWS and your own remote network.

<tr>
<td>GROUP with the DISTRIBUTED option.</td>
<td>1. Use LISTENER_URL endpoint addresses for AG 1 and AG 2.&lt;br&gt;2. For AVAILABILITY-MODE, use ASYNCHRONOUS_COMMIT to avoid network latency, if any. This will not impact the performance of the database.&lt;br&gt;3. For FAILOVER_MODE, use MANUAL. It is the only availability mode that works with distributed availability groups.&lt;br&gt;4. To restore the databases manually on AG 2 and have more control on larger databases, use MANUAL for SEEDING_MODE.</td>
<td>DBA, Developer</td>
</tr>
<tr>
<td>Create the distributed availability group on AG 2.</td>
<td>To create the distributed availability group on AG 2, use ALTER AVAILABILITY GROUP with the DISTRIBUTED option.&lt;br&gt;1. Use LISTENER_URL endpoint addresses for AG 1 and AG 2.&lt;br&gt;2. For AVAILABILITY-MODE, use ASYNCHRONOUS_COMMIT to avoid network latency, if any. This will not impact the performance of the database.&lt;br&gt;3. For FAILOVER_MODE, use MANUAL. It is the only availability mode that works with distributed availability groups.&lt;br&gt;4. To restore the databases manually on AG 2 and have more control on larger databases, use MANUAL for SEEDING_MODE.</td>
<td>DBA, Developer</td>
</tr>
</tbody>
</table>

The distributed availability group is created between AG 1 and AG 2.

The databases in AG 2 are not yet configured to take part in the data flow from AG 1 to AG 2.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add databases to the forwarder and secondary replica on AG 2.</td>
<td>Add the databases to the distributed availability group by using <code>ALTER DATABASE</code> with the <code>SET HADR AVAILABILITY GROUP</code> option in both the forwarder and the secondary replica on AG 2. This starts asynchronous data flow between databases on AG 1 and AG 2. The global primary takes writes, sends data synchronously to the secondary replica on AG 1, and sends data asynchronously to the forwarder on AG 2. The forwarder on AG 2 sends data synchronously to the secondary replica on AG 2.</td>
<td>DBA, Developer</td>
</tr>
</tbody>
</table>

Monitor asynchronous data flow between AG 1 and AG 2

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>

</tr>
</thead>
<tbody>
<tr>
<td>Use DMVs and SQL Server logs.</td>
<td>Monitor the status of the data flow between two availability groups by using dynamic management views (DMVs) and SQL Server logs. DMVs that are of interest for monitoring include <code>sys.dm_hadr_availability_replica_states</code> and <code>sys.dm_hadr_automatic_seeding</code>. For the status of forwarder synchronization, monitor the <code>synchronized state</code> in the SQL Server log on the forwarder.</td>
<td>DBA, Developer</td>
</tr>
</tbody>
</table>

Perform cutover activities for final migration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stop all traffic to the primary replica.</td>
<td>Stop incoming traffic to the primary replica in AG 1 so that no write activity occurs on the databases and the databases are ready for migration.</td>
<td>App owner, Developer</td>
</tr>
</tbody>
</table>
### Change the availability mode of the distributed availability group on AG 1.

**On the primary replica, set the availability mode of the distributed availability group to synchronous.**

After you change the availability mode to synchronous, the data are sent synchronously from the primary replica in AG 1 to the forwarder in AG 2.

**Skills required:** DBA, Developer

### Check the LSNs in both availability groups.

**Check the last Log Sequence Numbers (LSNs) in both AG 1 and AG 2.** Because no writes are happening in the primary replica in AG 1, the data are synchronized, and last LSNs for both availability groups should match.

**Skills required:** DBA, Developer

### Update AG 1 to the secondary role.

**When you update AG 1 to the secondary role, AG 1 loses the primary replica role and doesn’t accept writes, and the data flow between two availability groups stops.**

**Skills required:** DBA, Developer

### Fail over to the second availability group

**Task** | **Description** | **Skills required**
---|---|---
Manually fail over to AG 2. | On the forwarder in AG 2, alter the distributed availability group to allow data loss. Because you already checked and confirmed that the last LSNs on AG 1 and AG 2 match, data loss is not a concern. When you allow data loss on the forwarder in AG 2, the roles of AG 1 and AG 2 change:
- AG 2 becomes the availability group with the primary replica and secondary replica.
- AG 1 becomes the availability group with the forwarder and secondary replica. | DBA, Developer

Change the availability mode of the distributed availability group on AG 2. | On the primary replica in AG 2, change the availability mode to asynchronous. | DBA, Developer
### Task

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>This changes the data movement from AG 2 to AG 1, from synchronous to asynchronous. This step is required to avoid network latency between AG 2 and AG 1, if any, and will not impact the performance of the database.</td>
<td></td>
</tr>
</tbody>
</table>

**Start sending traffic to the new primary replica.**

- Update the connection string to use the listener URL endpoint on AG 2 for sending traffic to the databases.
- AG 2 now accepts writes and sends data to the forwarder in AG 1, along with sending data to its own secondary replica in AG 2. Data moves asynchronously from AG 2 to AG 1.

**Skills required:** App owner, Developer

### Perform post-cutover activities

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drop the distributed availability group on AG 2.</td>
<td>Monitor the migration for the planned amount of time. Then drop the distributed availability group on AG 2 to remove distributed availability group setup between AG 2 and AG 1. This removes the distributed availability group configuration, and data flow from AG 2 to AG 1 stops. At this point, AG 2 is highly available on AWS, with a primary replica that takes writes and a secondary replica in the same availability group.</td>
<td>DBA, Developer</td>
</tr>
</tbody>
</table>

| Decommission the on-premises servers. | Decommission the on-premises servers in WSFC 1 that are part of AG 1. | Systems administrator, SysOps administrator |

Migrate from Oracle to a PostgreSQL database by using a standby database

Summary

This pattern shows how to migrate an Oracle database to a PostgreSQL database by using a standby Oracle database and Oracle Cloud Infrastructure (OCI) GoldenGate. The source Oracle database can be on premises or AWS Cloud based and can be migrated to either of the following PostgreSQL-compatible AWS database services:

- Amazon Relational Database Service (Amazon RDS) for PostgreSQL
- Amazon Aurora PostgreSQL-Compatible Edition

It's a best practice to use this setup when adding processes to a production server during a migration isn't desirable. For example, using a standby database can be helpful when migrating a busy transactional database.

By using Oracle Active Data Guard (ADG) mode, you can configure the Oracle GoldenGate Extract process to connect to a standby database. The Extract process then uses production logs that are transferred from the source Oracle database to the standby database as the data source. To get the data and metadata needed for the migration, Oracle GoldenGate connects to the standby database rather than the source database. No access to the production server is needed during migration.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Oracle GoldenGate license
- An Oracle Database 10g (or newer) source database in either an on-premises data center or hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance
- An Oracle Active Data Guard standby database
- Java Database Connectivity (JDBC) driver to connect to the PostgreSQL database
- Schema and tables created with the AWS Schema Conversion Tool (AWS SCT) on the target PostgreSQL database

Limitations

- Oracle GoldenGate is used only to replicate existing table data (initial load) and ongoing changes (change data capture or CDC)
Product versions

- Oracle GoldenGate 12.2.0.1.1 or newer versions
- Oracle GoldenGate 12.2.0.1.1 for PostgreSQL or newer versions

Architecture

Source technology stack

- On-premises or AWS Cloud-based Oracle Database 10g (or newer) database

Target technology stack

- An Amazon RDS for PostgreSQL DB instance or an Aurora PostgreSQL-Compatible DB instance

Target architecture

The following diagram shows an example workflow for migrating an Oracle database to a PostgreSQL-compatible AWS database by using a standby database and Oracle GoldenGate:

The diagram shows the following workflow:

1. The Oracle GoldenGate Extract process runs against the source database to extract data. Then, the GoldenGate Replicat process delivers the extracted data to the Oracle Active Data Guard standby database.

2. The GoldenGate Extract process runs against the standby database to extract data. Then, the GoldenGate Replicat process delivers the extracted data to the target PostgreSQL-compatible AWS database.
Tools

- **Amazon Aurora PostgreSQL-Compatible Edition** is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- **Amazon Relational Database Service (Amazon RDS) for PostgreSQL** helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- **Oracle GoldenGate** helps you design, run, orchestrate, and monitor your data replication and stream data processing solutions in the Oracle Cloud Infrastructure.

Epics

Migrate from Oracle 8i or 9i to Amazon RDS for Oracle using SharePlex and AWS DMS

Summary

This pattern describes how to migrate an on-premises Oracle 8i or 9i database to an Amazon Relational Database Service (Amazon RDS) for Oracle database. You can use this pattern to complete your migration with reduced downtime by using Quest SharePlex for synchronous replication.

You must use an intermediate Oracle database instance for your migration because AWS Database Migration Service (AWS DMS) doesn't support Oracle 8i or 9i as a source environment. You can use SharePlex 7.6.3 to replicate from previous Oracle database versions to later Oracle database versions. The intermediate Oracle database instance is compatible as a target for SharePlex 7.6.3 and supported as a source for AWS DMS or newer releases of SharePlex. This support enables onward replication of data to the Amazon RDS for Oracle target environment.

Consider that several deprecated data types and features can impact a migration from Oracle 8i or 9i to the latest version of Oracle Database. To mitigate this impact, this pattern uses Oracle 11.2.0.4 as an intermediate database version to help optimize the schema code prior to migrating to the Amazon RDS for Oracle target environment.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Oracle 8i or 9i database in an on-premises environment
- Oracle Database 12c Release 2 (12CR2) for staging on Amazon Elastic Compute Cloud (Amazon EC2)
- Quest SharePlex 7.6.3 (commercial grade)

Limitations

- RDS for Oracle limitations

Product versions

- Oracle 8i or 9i for the source database
- Oracle 12CR2 for the staging database (must match the Amazon RDS for Oracle version)
- Oracle 12CR2 or later for the target database (Amazon RDS for Oracle)
Architecture

Source technology stack

- Oracle 8i or 9i database
- SharePlex

Target technology stack

- Amazon RDS for Oracle

Migration architecture

The following diagram shows how to migrate an Oracle 8i or 9i database from an on-premises environment to an Amazon RDS for Oracle DB instance in the AWS Cloud.

The diagram shows the following workflow:

1. Enable the Oracle source database with archive log mode, force logging, and supplemental logging.
2. Restore the Oracle staging database from the Oracle source database by using Recovery Manager (RMAN) point-in-time recovery and FLASHBACK_SCN.
3. Configure SharePlex to read redo logs from the Oracle source database by using FLASHBACK_SCN (used in RMAN).
4. Start SharePlex replication to synchronize data from the Oracle source database to the Oracle staging database.
5. Restore the Amazon RDS for Oracle target database by using EXPDP and IMPDP with FLASHBACK_SCN.
6. Configure AWS DMS and its source tasks as the Oracle staging database and Amazon RDS for Oracle as the target database by using FLASHBACK_SCN (used in EXPDP).
7. Start AWS DMS tasks to synchronize data from the Oracle staging database to the Oracle target database.
Tools

- **Amazon Relational Database Service (Amazon RDS)** helps you set up, operate, and scale a relational database in the AWS Cloud.
- **AWS Database Migration Service (AWS DMS)** helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- **Quest SharePlex** is an Oracle-to-Oracle data replication tool for moving data with minimal downtime and no data loss.
- **Recovery Manager (RMAN)** is an Oracle Database client that performs backup and recovery tasks on your databases. It greatly simplifies backing up, restoring, and recovering database files.
- **Data Pump Export** helps you upload data and metadata into a set of operating system files called a dump file set. The dump file set can be imported only by the **Data Pump Import** utility or **DBMS_DATAPUMP** package.

Monitor Amazon Aurora for instances without encryption

Summary

This pattern provides an Amazon Web Services (AWS) CloudFormation template that you can deploy to set up automatic notifications when an Amazon Aurora instance is created without encryption turned on.

Aurora is a fully managed relational database engine that's compatible with MySQL and PostgreSQL. With some workloads, Aurora can deliver up to five times the throughput of MySQL and up to three times the throughput of PostgreSQL without requiring changes to most of your existing applications.

The CloudFormation template creates an Amazon CloudWatch Events event and an AWS Lambda function. The event uses AWS CloudTrail to monitor for any Aurora instance creation or a point in time restoration of an existing instance. The Cloudwatch Events event initiates the Lambda function, which checks whether encryption is enabled. If encryption is not turned on, the Lambda function sends an Amazon Simple Notification Service (Amazon SNS) notification informing you of the violation.

Prerequisites and limitations

Prerequisites

• An active AWS account

Limitations

• This service control works with Amazon Aurora instances only. It does not support other Amazon Relational Database Service (Amazon RDS) instances.
• The CloudFormation template must be deployed for CreateDBInstance and RestoreDBClusterToPointInTime only.

Product versions

• PostgreSQL versions that are supported in Amazon Aurora
• MySQL versions that are supported in Amazon Aurora

Architecture

Target technology stack
AWS Prescriptive Guidance Patterns

Tools

- Amazon Aurora
- AWS CloudTrail
- Amazon CloudWatch
- AWS Lambda
- Amazon Simple Storage Service (Amazon S3)
- Amazon SNS

Target architecture

Automation and scale

You can use the CloudFormation template multiple times for different Regions and accounts. You need to run it only once in each Region or account.

Tools

- Amazon Aurora — Amazon Aurora is a fully managed relational database engine that’s compatible with MySQL and PostgreSQL.
- AWS CloudTrail — AWS CloudTrail helps you manage governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, a role, or an AWS service are recorded as events in CloudTrail.
- Amazon CloudWatch Events — Amazon CloudWatch Events delivers a near-real-time stream of system events that describe changes in AWS resources.
- AWS Lambda — AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- Amazon S3 — Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that you can use for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- Amazon SNS — Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery using Lambda, HTTP, email, mobile push notifications, and mobile text messages (SMS).

Monitor Oracle GoldenGate logs by using Amazon CloudWatch

*Created by Chithra Krishnamurthy (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Technologies:</th>
<th>Databases</th>
<th>Workload:</th>
<th>Oracle</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>Amazon CloudWatch; Amazon SNS</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

Oracle GoldenGate provides real-time replication between Amazon Relational Database Service (Amazon RDS) for Oracle databases, or between Oracle databases hosted on Amazon Elastic Compute Cloud (Amazon EC2). It supports both unidirectional and bidirectional replication.

When you use GoldenGate for replication, monitoring is critical to verify that the GoldenGate process is up and running, to make sure that the source and target databases are in sync.

This pattern explains the steps to implement Amazon CloudWatch monitoring for a GoldenGate error log, and how to set alarms to send notifications for specific events such as STOP or ABEND so you can take appropriate actions to resume replication quickly.

**Prerequisites and limitations**

**Prerequisites**

- GoldenGate installed and configured on an EC2 instance, so you can set up CloudWatch monitoring on those EC2 instances. If you want to monitor GoldenGate across AWS Regions for bidirectional replication, you must install the CloudWatch agent in each EC2 instance where the GoldenGate process is running.

**Limitations**

- This pattern explains how to monitor the GoldenGate process by using CloudWatch. CloudWatch doesn't monitor replication lag or data synchronization issues during replication. You must run separate SQL queries to monitor replication lag or data-related errors, as explained in the [GoldenGate documentation](#).

**Product versions**

- This document is based on the implementation of Oracle GoldenGate 19.1.0.0.4 for Oracle on Linux x86-64. However, this solution is applicable to all major versions of GoldenGate.

**Architecture**

**Target technology stack**

- GoldenGate binaries for Oracle installed on an EC2 instance
- Amazon CloudWatch
Tools

AWS services

- **Amazon CloudWatch** is a monitoring service that is used in this pattern to monitor GoldenGate error logs.
- **Amazon SNS** is a message notification service that is used in this pattern to send email notifications.

Other tools

- **Oracle GoldenGate** is a data replication tool that you can use for Amazon RDS for Oracle databases or Oracle databases that are hosted on Amazon EC2.

High-level implementation steps

1. Create an AWS Identity and Access Management (IAM) role for the CloudWatch agent.
2. Attach the IAM role to the EC2 instance where GoldenGate error logs are generated.
3. Install the CloudWatch agent on the EC2 instance.
4. Configure the CloudWatch agent configuration files: `awscli.conf` and `awslogs.conf`.
5. Start the CloudWatch agent.
6. Create metric filters in the log group.
7. Set up Amazon SNS.
8. Create an alarm for the metric filters. Amazon SNS sends email alerts when those filters capture events.

For detailed instructions, see the next section.

Epics

Step 1. Create an IAM role for the CloudWatch agent

| Edit the agent configuration files.  | 1. Run the following command.  
```bash
sudo su -
```
| 2. Edit this file to update the AWS Region as necessary.  
```bash
cat /etc/awslogs/conf
[plugins]
cwlogs = cwlogs
[default]
region = us-east-1
```
| 3. Edit the /etc/awslogs/awslogs.conf file to update the file name, log group name, and the date/time format. You must specify the date/time to match the date format in ggserror.log; otherwise, the log stream |
### AWS Prescriptive Guidance Patterns

#### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>won’t flow into CloudWatch. For example:</td>
<td><code>datetime_format = %Y-%m-%dT%H:%M:%S%z</code></td>
<td>AWSCloudWatch</td>
</tr>
<tr>
<td></td>
<td><code>file = /u03/oracle/oragg/ggserr.log</code></td>
<td>AWS general</td>
</tr>
<tr>
<td></td>
<td><code>log_group_name = goldengate_monitor</code></td>
<td></td>
</tr>
<tr>
<td>Start the CloudWatch agent.</td>
<td>To start the agent, use the following command.</td>
<td>AWS general</td>
</tr>
<tr>
<td></td>
<td><code>$ sudo service awslogsd start</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>After you start the agent, you can view the log group in the CloudWatch console. The log stream will have the contents of the file.</td>
<td></td>
</tr>
</tbody>
</table>

### Step 6. Create metric filters for the log group

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create metric filters for the keywords ABEND and STOPPED.</td>
<td>When you create metric filters for the log group, whenever the filters are identified in the error log, it starts an alarm and sends an email notification based on the Amazon SNS configuration.</td>
<td>CloudWatch</td>
</tr>
<tr>
<td></td>
<td>To create metric filters:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1. Open the CloudWatch console at <a href="https://console.aws.amazon.com/cloudwatch/">https://console.aws.amazon.com/cloudwatch/</a></td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. Choose the name of the log group.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. Choose Actions, and then choose Create metric filter.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4. For the Filter pattern, specify a pattern such as ABEND.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>5. Choose Next, and then enter a name for your metric filter.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>6. Under Metric details, for Metric namespace, enter a name for the CloudWatch namespace where the metric will be published. If the</td>
<td></td>
</tr>
</tbody>
</table>
### Step 7. Set up Amazon SNS

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an SNS topic.</td>
<td>In this step, you configure Amazon SNS to create alarms for the metric filters.</td>
<td>Amazon SNS</td>
</tr>
<tr>
<td></td>
<td>To create an SNS topic:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. In the Create topic box, enter a topic name such as goldengate-alert, and then choose Next step.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. For Type, choose Standard.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4. Scroll to the end of the form and choose Create topic. The console opens the new topic’s Details page.</td>
<td></td>
</tr>
<tr>
<td>Create a subscription.</td>
<td>To create a subscription to the topic:</td>
<td>Amazon SNS</td>
</tr>
<tr>
<td></td>
<td>1. In the left navigation pane, choose Subscriptions.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. On the Subscriptions page, choose Create subscription.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. On the Create subscription page, choose the Topic ARN</td>
<td></td>
</tr>
</tbody>
</table>
### Task Description

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.</td>
<td>Choose the topic that you created in the previous step.</td>
<td>CloudWatch</td>
</tr>
<tr>
<td>4.</td>
<td>For Protocol, choose Email.</td>
<td></td>
</tr>
<tr>
<td>5.</td>
<td>For Endpoint, enter an email address that can receive notifications.</td>
<td></td>
</tr>
<tr>
<td>7.</td>
<td>Choose Create subscription. The console opens the new subscription's Details page.</td>
<td></td>
</tr>
<tr>
<td>8.</td>
<td>Check your email inbox for a message from AWS Notifications, and then choose Confirm subscription in the email.</td>
<td></td>
</tr>
</tbody>
</table>

Amazon SNS opens your web browser and displays a subscription confirmation with your subscription ID.

---

### Step 8. Create an alarm to send notifications for the metric filters

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an alarm for the SNS topic.</td>
<td>To create an alarm based on a log group-metric filter:</td>
<td>CloudWatch</td>
</tr>
<tr>
<td>2.</td>
<td>From the navigation pane, choose Logs, and then choose Log groups.</td>
<td></td>
</tr>
<tr>
<td>3.</td>
<td>Choose the log group that includes your metric filter.</td>
<td></td>
</tr>
<tr>
<td>5.</td>
<td>In the Metric filters tab, select the check box for the metric filter that you want to base your alarm on.</td>
<td></td>
</tr>
<tr>
<td>6.</td>
<td>Choose Create alarm.</td>
<td></td>
</tr>
<tr>
<td>7.</td>
<td>For Conditions, specify the following in each section:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• For Threshold type, choose Static.</td>
<td></td>
</tr>
</tbody>
</table>
**Task** | **Description** | **Skills required**
---|---|---
• For Whenever `<metric-name>` is `. . .`, choose Greater.
• For than `. . .`, specify 0.
8. Choose Next.
9. Under Notification:
• For Alarm state trigger, choose In alarm.
• For Send notification to following SNS topic, choose Select an existing topic.
• In the email box, select the Amazon SNS topic that you created in the previous step.
10 Choose Next.
11 For Name and description, enter a name and description for your alarm.

**Note:** For the description, you can specify the instance name so that the notification email is descriptive.
12 For Preview and create, check that your configuration is correct, and then choose Create alarm.

After these steps, whenever these patterns are detected in the GoldenGate error log file (`ggserr.log`) that you are monitoring, you will get an email notification.

---

**Troubleshooting**

<table>
<thead>
<tr>
<th>Issue</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>The log stream from the GoldenGate error log doesn't flow into CloudWatch.</td>
<td>Check the <code>/etc/awslogs/awslogs.conf</code> file to verify the file name, log group name, and the date/time format. You must specify the date/time to match the date format in <code>ggserror.log</code>. Otherwise, the log stream won't flow into CloudWatch.</td>
</tr>
</tbody>
</table>

Replatform Oracle Database Enterprise Edition to Standard Edition 2 on Amazon RDS for Oracle

*Created by Lanre showunmi (AWS) and Tarun Chawla (AWS)*

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Source: on-premises</th>
<th>Target: Amazon RDS</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Replatform</td>
<td>Workload: Oracle</td>
<td>Technologies: Databases</td>
</tr>
<tr>
<td>AWS services: Amazon RDS</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

Oracle Database Enterprise Edition (EE) is a popular choice for running applications in many enterprises. In some cases, however, applications use few or no Oracle Database EE features, so there is a lack of justification for incurring huge licensing costs. You can achieve cost savings by downgrading such databases to Oracle Database Standard Edition 2 (SE2) when you migrate to Amazon RDS.

This pattern describes how to downgrade from Oracle Database EE to Oracle Database SE2 when migrating from on premises to Amazon RDS for Oracle. The steps presented in this pattern also apply if your EE Oracle database is already running on Amazon RDS or on an Amazon Elastic Compute Cloud (Amazon EC2) instance.

For more information, see the AWS Prescriptive Guidance guide on how to Evaluate downgrading Oracle databases to Standard Edition 2 on AWS.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- Oracle Database Enterprise Edition
- A client tool, such as Oracle SQL Developer or SQL*Plus, for connecting to and running SQL commands on Oracle database
- Database user for performing the assessment; for example, one of the following:
  - User with sufficient privileges for running AWS Schema Conversion Tool (AWS SCT) assessment
  - User with sufficient privileges to run SQL queries on Oracle database dictionary tables
- Database user for performing database migration; for example, one of the following:
  - User with sufficient privileges for running AWS Database Migration Service (AWS DMS)
  - User with sufficient privileges for performing Oracle Data Pump export and import
  - User with sufficient privileges for running Oracle GoldenGate

**Limitations**

- Amazon RDS for Oracle has a maximum database size. For more information, see Amazon RDS DB instance storage.

**Product versions**
The general logic described in this document applies to Oracle versions from 9i and later. For supported versions of self-managed and Amazon RDS for Oracle databases, see the AWS DMS documentation.

To identify feature usage in cases where AWS SCT is not supported, run SQL queries on the source database. To migrate from earlier versions of Oracle where AWS DMS and Oracle Data Pump are not supported, use Oracle Export and Import utilities.

For a current list of supported versions and editions, see Oracle on Amazon RDS in the AWS documentation. For details on pricing and supported instance classes, see Amazon RDS for Oracle pricing.

**Architecture**

**Source technology stack**
- Oracle Database Enterprise Edition running on premises or on Amazon EC2

**Target technology stack using native Oracle tools**
- Amazon RDS for Oracle running Oracle Database SE2

1. Export data by using Oracle Data Pump.
2. Copy dump files to Amazon RDS through a database link.
3. Import dump files to Amazon RDS by using Oracle Data Pump.

**Target technology stack using AWS DMS**
- Amazon RDS for Oracle running Oracle Database SE2
- AWS DMS
1. Export data by using Oracle Data Pump with FLASHBACK_SCN.
2. Copy dump files to Amazon RDS through a database link.
3. Import dump files to Amazon RDS by using Oracle Data Pump.
4. Use AWS DMS change data capture (CDC).

Tools

AWS services

- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud. This pattern uses Amazon RDS for Oracle.
- AWS SCT provides a project-based user interface to automatically assess, convert, and copy the database schema of your source Oracle database into a format compatible with Amazon RDS for Oracle. AWS SCT enables you to analyze potential cost savings that can be achieved by changing your license type from Enterprise to Standard Edition of Oracle. The License Evaluation and Cloud Support section of the AWS SCT report provides detailed information about Oracle features in use so you can make an informed decision while migrating to Amazon RDS for Oracle.

Other tools

- Native Oracle import and export utilities support moving Oracle data in and out of Oracle databases. Oracle offers two types of database import and export utilities: Original Export and Import (for earlier releases) and Oracle Data Pump Export and Import (available in Oracle Database 10g release 1 and later).
- Oracle GoldenGate offers real-time replication capabilities so that you can synchronize your target database after an initial load. This option can help reduce application downtime during go-live.
# Epics

## Make a pre-migration assessment

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Validate database requirements for your applications.</td>
<td>Ensure that your applications are certified to run on Oracle Database SE2. Check directly with the software vendor, developer, or application documentation.</td>
<td>App developer, DBA, App owner</td>
</tr>
</tbody>
</table>
| Investigate use of EE features directly in the database. | To determine EE feature use, do one of the following:  
- Generate an AWS SCT assessment report for your Oracle EE database. The report tells you which features from your current EE database should be removed if you want to change license types.  
- If you have an Oracle Support account, obtain and run the script options_packs_usage_statistics.sql in Support document 1317265.1 to generate a report of options and features that are being used on your Oracle database.  
- Query DBA_FEATURE_USAGE_STATISTICS to display details of all features that are in use. | App owner, DBA, App developer |
| Identify use of EE features for operational activities. | Database or application administrators sometimes rely on EE-only features for operational activities. Common examples include online maintenance activities (index rebuild, table move) and use of parallelism by batch jobs.  
These dependencies can be mitigated by modifying your operations where possible. Identify the use of these features and make a decision based on cost compared with benefits.  
Use the Comparing Oracle Database EE and SE2 features | App developer, DBA, App owner |
### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Review workload patterns of the EE Oracle database.** | Oracle Database SE2 automatically restricts usage to a maximum of 16 CPU threads at any time.  
If your Oracle EE database is licensed to use the Oracle Diagnostic Pack, use the Automatic Workload Repository (AWR) tool, or DBA_HIST_* views, to analyze database workload patterns to determine whether the maximum limit of 16 CPU threads will negatively impact service levels when you downgrade to SE2.  
Ensure that your assessment covers periods of peak activity, such as end of day, month, or year processing. | App owner, DBA, App developer |

### Prepare the target infrastructure on AWS

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Deploy and configure networking infrastructure.</strong></td>
<td>Create a virtual private cloud (VPC) and subnets, security groups, and network access control lists.</td>
<td>AWS administrator, Cloud architect, Network administrator, DevOps engineer</td>
</tr>
<tr>
<td><strong>Provision the Amazon RDS for Oracle SE2 database.</strong></td>
<td>Provision the target Amazon RDS for Oracle SE2 database to meet your applications’ performance, availability, and security requirements. We recommend Multi-AZ configuration for production workloads. However, to improve migration performance, you can defer enabling Multi-AZ until after data migration.</td>
<td>Cloud administrator, Cloud architect, DBA, DevOps engineer, AWS administrator</td>
</tr>
<tr>
<td><strong>Customize the Amazon RDS environment.</strong></td>
<td>Configure custom parameters and options, and enable additional monitoring. For more information, see Best practices for migrating to Amazon RDS for Oracle.</td>
<td>AWS administrator, AWS systems administrator, Cloud administrator, DBA, Cloud architect</td>
</tr>
</tbody>
</table>
## Perform the migration dry run and application testing

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Migrate the data (dry run). | Migrate data from the source Oracle EE database to the Amazon RDS for Oracle SE2 database instance using the approach best suited to your specific environment. Select a migration strategy based on factors such as size, complexity, and the available downtime window. Use one or a combination of the following:  
  - Native Oracle tools such as Oracle Data Pump (recommended), Oracle Import-Export utilities, and Oracle GoldenGate.  
  - AWS DMS, using the full load with continuous replication through CDC. |
|                             |                                                                                                                                                                                                                                                                                                                                          | DBA             |
| Validate the target database.| Perform post-migration validation of database storage and code objects. Review migration logs, and fix any identified issues. For more information, see the guide Migrating Oracle databases to the AWS Cloud.                                                                                          | DBA             |
| Test the applications.      | Application and database administrators should conduct functional, performance, and operational tests as appropriate. For more information, see Best practices for migrating to Amazon RDS for Oracle.  
  Lastly, obtain sign-offs on test-results from stakeholders.                                                                                                                                   | App developer, App owner, DBA, Migration engineer, Migration lead |

### Cut over

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Refresh data from Oracle Database EE.</td>
<td>Select a data refresh approach based on the application availability requirement. For more information, see the migration methods in Strategies</td>
<td>App owner, Cutover lead, DBA, Migration engineer, Migration lead</td>
</tr>
</tbody>
</table>
### Task

### Description

**for Migrating Oracle Databases to AWS.**

For example, you can achieve near-zero downtime by using tools such as Oracle GoldenGate or AWS DMS with ongoing replication. If the downtime window permits, you can perform the final data cutover using offline methods such as Oracle Data Pump or Original Export-Import utilities.

Point applications to the target database instance. Update connection parameters in applications and other clients to point to the Amazon RDS for Oracle SE2 database.

Perform post-migration activities.

Perform post data migration tasks such as enabling Multi-AZ, data validation, and other checks.

Perform post-cutover monitoring.

Use tools such as Amazon CloudWatch and Amazon RDS Performance Insights to monitor the Amazon RDS for Oracle SE2 database.

### Skills required

- App developer, App owner, Migration engineer, Migration lead, Cutover lead
- DBA, Migration engineer
- App developer, App owner, AWS administrator, DBA, Migration engineer

Replicate mainframe databases to AWS by using Precisely Connect

*Created by Lucio Pereira (AWS), Balaji Mohan (AWS), and Sayantan Giri (AWS)*

</table>

**Summary**

This pattern outlines steps for replicating data from mainframe databases to Amazon data stores in near real time by using Precisely Connect. It implements an event-based architecture with Amazon Managed Streaming for Apache Kafka (Amazon MSK) and custom database connectors in the cloud to improve scalability, resilience, and performance.

Precisely Connect is a replication tool that captures data from legacy mainframe systems and integrates it into cloud environments. Data is replicated from mainframes to AWS through change data capture (CDC) by using near real-time message flows with low-latency and high-throughput heterogeneous data pipelines.

This pattern also covers a disaster recovery strategy for resilient data pipelines with multi-Region data replication and failover routing.

**Prerequisites and limitations**

**Prerequisites**

- An existing mainframe database—for example, IBM DB2, IBM Information Management System (IMS), or Virtual Storage Access Method (VSAM)—that you want to replicate to the AWS Cloud
- An active [AWS account](https://aws.amazon.com)
- [AWS Direct Connect](https://aws.amazon.com/directconnect/) or [AWS Virtual Private Network (AWS VPN)](https://aws.amazon.com/vpn/) from your corporate environment to AWS
- A [virtual private cloud](https://aws.amazon.com/vpc/) with a subnet that is reachable by your legacy platform

**Architecture**

**Source technology stack**

A mainframe environment that includes at least one of the following databases:
AWS Prescriptive Guidance Patterns
Architecture

- IBM IMS database
- IBM DB2 database
- VSAM files

Target technology stack

- Amazon MSK
- Amazon Elastic Kubernetes Service (Amazon EKS) and Amazon EKS Anywhere
- Docker
- An AWS relational or NoSQL database such as the following:
  - Amazon DynamoDB
  - Amazon Relational Database Service (Amazon RDS) for Oracle, Amazon RDS for PostgreSQL, or Amazon Aurora
  - Amazon ElastiCache for Redis
  - Amazon Keyspaces (for Apache Cassandra)

Target architecture

*Replicating mainframe data to AWS databases*

The following diagram illustrates the replication of mainframe data to an AWS database such as DynamoDB, Amazon RDS, Amazon ElastiCache, or Amazon Keyspaces. The replication occurs in near real time by using Precisely Capture and Publisher in your on-premises mainframe environment, Precisely Dispatcher on Amazon EKS Anywhere in your on-premises distributed environment, and Precisely Apply Engine and database connectors in the AWS Cloud.
The diagram shows the following workflow:

1. Precisely Capture gets mainframe data from CDC logs and maintains the data in internal transient storage.
2. Precisely Publisher listens for changes in the internal data storage and sends CDC records to Precisely Dispatcher through a TCP/IP connection.
3. Precisely Dispatcher receives the CDC records from Publisher and sends them to Amazon MSK. Dispatcher creates Kafka keys based on the user configuration and multiple worker tasks to push data in parallel. Dispatcher sends an acknowledgment back to Publisher when records have been stored in Amazon MSK.
4. Amazon MSK holds the CDC records in the cloud environment. The partition size of topics depends on your transaction processing system (TPS) requirements for throughput. The Kafka key is mandatory for further transformation and transaction ordering.

5. The Precisely Apply Engine listens to the CDC records from Amazon MSK and transforms the data (for example, by filtering or mapping) based on target database requirements. You can add customized logic to the Precisely SQD scripts. (SQD is Precisely’s proprietary language.) The Precisely Apply Engine transforms each CDC record to Apache Avro or JSON format and distributes it to different topics based on your requirements.

6. The target Kafka topics hold CDC records in multiple topics based on the target database, and Kafka facilitates transaction ordering based on the defined Kafka key. The partition keys align with the corresponding partitions to support a sequential process.

7. Database connectors (customized Java applications) listen to the CDC records from Amazon MSK and store them in the target database.

8. You can select a target database based on your requirements. This pattern supports both NoSQL and relational databases.

Disaster recovery

Business continuity is key to your organization's success. The AWS Cloud provides capabilities for high availability (HA) and disaster recovery (DR), and supports your organization’s failover and fallback plans. This pattern follows an active/passive DR strategy and provides high-level guidance for implementing a DR strategy that meets your RTO and RPO requirements.

The following diagram illustrates the DR workflow.
The diagram shows the following:

1. A semi-automated failover is required if any failure happens in AWS Region 1. In the case of failure in Region 1, the system must initiate routing changes to connect Precisely Dispatcher to Region 2.
2. Amazon MSK replicates data through mirroring between Regions. For this reason, during failover, the Amazon MSK cluster in Region 2 has to be promoted as the primary leader.
3. The Precisely Apply Engine and database connectors are stateless applications that can work in any Region.
4. Database synchronization depends on the target database. For example, DynamoDB can use global tables, and ElastiCache can use global datastores.

**Low-latency and high-throughput processing through database connectors**

Database connectors are critical components in this pattern. Connectors follow a listener-based approach to collect data from Amazon MSK and send transactions to the database through high-throughput and low-latency processing for mission-critical applications (tiers 0 and 1). The following diagram illustrates this process.

This pattern supports the development of a customized application with single-threaded consumption through a multithreaded processing engine.

1. The connector main thread consumes CDC records from Amazon MSK and sends them to the thread pool for processing.
2. Threads from the thread pool process CDC records and send them to the target database.
3. If all threads are busy, the CDC records are kept on hold by the thread queue.
4. The main thread waits to get all the records cleared from the thread queue and commits offsets into Amazon MSK.
5. The child threads handle failures. If failures happen during processing, the failed messages are sent to the DLQ (dead letter queue) topic.
6. The child threads initiate conditional updates (see Condition expressions in the DynamoDB documentation), based on the mainframe timestamp, to avoid any duplication or out-of-order updates in the database.

784
For information about how to implement a Kafka consumer application with multi-threading capabilities, see the blog post [Multi-Threaded Message Consumption with the Apache Kafka Consumer](#) on the Confluent website.

## Tools

### AWS services

- **Amazon Managed Streaming for Apache Kafka (Amazon MSK)** is a fully managed service that helps you build and run applications that use Apache Kafka to process streaming data.
- **Amazon Elastic Kubernetes Service (Amazon EKS)** helps you run Kubernetes on AWS without having to install or maintain your own Kubernetes control plane or nodes.
- **Amazon EKS Anywhere** helps you deploy, use, and manage Kubernetes clusters that run in your own data centers.
- **Amazon DynamoDB** is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- **Amazon Relational Database Service (Amazon RDS)** helps you set up, operate, and scale a relational database in the AWS Cloud.
- **Amazon ElastiCache** helps you set up, manage, and scale distributed in-memory cache environments in the AWS Cloud.
- **Amazon Keyspaces (for Apache Cassandra)** is a managed database service that helps you migrate, run, and scale your Cassandra workloads in the AWS Cloud.

### Other tools

- **Precisely Connect** integrates data from legacy mainframe systems such as VSAM datasets or IBM mainframe databases into next-generation cloud and data platforms.

## Best practices

- Find the best combination of Kafka partitions and multi-threaded connectors to balance optimal performance and cost. Multiple Precisely Capture and Dispatcher instances can increase cost because of higher MIPS (million instructions per second) consumption.
- Avoid adding data manipulation and transformation logic to the database connectors. For this purpose, use the Precisely Apply Engine, which provides processing times in microseconds.
- Create periodic request or health check calls to the database (*heartbeats*) in database connectors to warm up the connection frequently and reduce latency.
- Implement thread pool validation logic to understand the pending tasks in the thread queue and wait for all threads to be completed before the next Kafka polling. This helps avoid data loss if a node, container, or process crashes.
- Expose latency metrics through health endpoints to enhance observability capabilities through dashboards and tracing mechanisms.

Schedule jobs for Amazon RDS for PostgreSQL and Aurora PostgreSQL by using Lambda and Secrets Manager

Created by Yaser Raja (AWS)

Summary

For on-premises databases and databases that are hosted on Amazon Elastic Compute Cloud (Amazon EC2) instances, database administrators often use the cron utility to schedule jobs.

For example, a job for data extraction or a job for data purging can easily be scheduled using cron. For these jobs, database credentials are typically either hard-coded or stored in a properties file. However, when you migrate to Amazon Relational Database Service (Amazon RDS) or Amazon Aurora PostgreSQL-Compatible Edition, you lose the ability to log in to the host instance to schedule cron jobs.

This pattern describes how to use AWS Lambda and AWS Secrets Manager to schedule jobs for Amazon RDS for PostgreSQL and Aurora PostgreSQL-Compatible databases after migration.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database

Limitations

- A job must complete within 15 minutes, which is the Lambda function timeout limit. For other limits, see the AWS Lambda documentation.
- Job code must be written in a language supported by Lambda.

Architecture

Source technology stack

This stack features jobs written in languages such as Bash, Python, and Java. Database credentials are stored in the properties file, and the job is scheduled using Linux cron.

Target technology stack
This stack has a Lambda function that uses the credentials stored in Secrets Manager to connect to the database and to perform the activity. The Lambda function is initiated at the scheduled interval by using Amazon CloudWatch Events.

Target architecture

Tools

- **AWS Lambda** is a compute service that lets you run code without provisioning or managing servers. AWS Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time you consume; there is no charge when your code is not running. With AWS Lambda, you can run code for virtually any type of application or backend service with zero administration. AWS Lambda runs your code on a high-availability compute infrastructure and manages all the compute resources, including server and operating system maintenance, capacity provisioning and automatic scaling, code monitoring, and logging. All you need to do is provide your code in one of the languages that AWS Lambda supports.

- **Amazon CloudWatch Events** delivers a near real-time stream of system events that describe changes in AWS resources. Using simple rules that you can quickly set up, you can match events and route them to one or more target functions or streams. CloudWatch Events becomes aware of operational changes as they occur. It responds to these operational changes and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information. You can also use CloudWatch Events to schedule automated actions that self-initiate at certain times using cron or rate expressions.

- **AWS Secrets Manager** helps you protect secrets for accessing your applications, services, and IT resources. You can easily rotate, manage, and retrieve database credentials, API keys, and other secrets throughout their lifecycle. Users and applications retrieve secrets by calling Secrets Manager APIs, which eliminates the need to hard-code sensitive information in plain text. Secrets Manager offers secret rotation with built-in integration for Amazon RDS, Amazon Redshift, and Amazon DocumentDB. The service is extensible to other types of secrets, including API keys and OAuth tokens. Secrets Manager enables you to control access to secrets using fine-grained permissions and to audit secret rotation centrally for resources in the AWS Cloud, third-party services, and on-premises.

Set up disaster recovery for SAP on IBM Db2 on AWS

Created by Ambarish Satarkar (AWS) and Debasis Sahoo (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technologies:</td>
<td>Databases; Operations</td>
</tr>
<tr>
<td>Workload:</td>
<td>SAP</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon EC2; AWS Elastic Disaster Recovery</td>
</tr>
</tbody>
</table>

Summary

This pattern outlines the steps to set up a disaster recovery (DR) system for SAP workloads with IBM Db2 as the database platform, running on the Amazon Web Services (AWS) Cloud. The objective is to provide a low-cost solution for providing business continuity in the event of an outage.

The pattern uses the pilot light approach. By implementing pilot light DR on AWS, you can reduce downtime and maintain business continuity. The pilot light approach focuses on setting up a minimal DR environment in AWS, including an SAP system and a standby Db2 database, that is synchronized with the production environment.

This solution is scalable. You can extend it to a full-scale disaster recovery environment as needed.

Prerequisites and limitations

Prerequisites

- An SAP instance running on an Amazon Elastic Compute Cloud (Amazon EC2) instance
- An IBM Db2 database
- An operating system that is supported by the SAP Product Availability Matrix (PAM)
- Different physical database hostnames for production and standby database hosts
- An Amazon Simple Storage Service (Amazon S3) bucket in each AWS Region with Cross-Region Replication (CRR) enabled

Product versions

- IBM Db2 Database version 11.5.7 or later

Architecture

Target technology stack

- Amazon EC2
- Amazon Simple Storage Service (Amazon S3)
- Amazon Virtual Private Cloud (VPC peering)
- Amazon Route 53
- IBM Db2 High Availability Disaster Recovery (HADR)
**Target architecture**

This architecture implements a DR solution for SAP workloads with Db2 as the database platform. The production database is deployed in AWS Region 1 and a standby database is deployed in a second Region. The standby database is referred to as the DR system. Db2 Database supports multiple standby databases (up to three). It uses Db2 HADR for setting up the DR database and automating log shipping between the production and standby databases.

In the event of a disaster that makes Region 1 unavailable, the standby database in the DR Region takes over the production database role. SAP application servers can be built in advance or by using AWS Elastic Disaster Recovery or an Amazon Machine Image (AMI) to meet the recovery time objective (RTO) requirements. This pattern uses an AMI.

Db2 HADR implements a production-standby setup, where production acts as the primary server, and all users are connected to it. All transactions are written to log files, which are transferred to the standby server by using TCP/IP. The standby server updates its local database by rolling forward the transferred log records, which helps to ensure that it is kept in sync with the production server.

VPC peering is used so that instances in the production Region and DR Region can communicate with each other. Amazon Route 53 routes end users to internet applications.

1. Create an AMI of the application server in Region 1 and copy the AMI to Region 2. Use the AMI to launch servers in Region 2 in the event of a disaster.
2. Set up Db2 HADR replication between the production database (in Region 1) and the standby database (in Region 2).
3. Change the EC2 instance type to match the production instance in the event of a disaster.
4. In Region 1, LOGARCHMETH1 is set to db2remote: S3 path.
5. In Region 2, LOGARCHMETH1 is set to db2remote: S3 path.
6. Cross-Region Replication is performed between the S3 buckets.

**Tools**

AWS services
• Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

• Amazon Route 53 is a highly available and scalable DNS web service.

• Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

• Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you’ve defined. This virtual network resembles a traditional network that you’d operate in your own data center, with the benefits of using the scalable infrastructure of AWS. This pattern uses VPC peering.

### Best practices

• The network plays a key role in deciding the HADR replication mode. For DR across AWS Regions, we recommend that you use Db2 HADR ASYNC or SUPERASYNC mode.

• For more information about replication modes for Db2 HADR, see the IBM documentation.

• You can use the AWS Management Console or the AWS Command Line Interface (AWS CLI) to create a new AMI of your existing SAP system. You can then use the AMI to recover your existing SAP system or to create a clone.

• AWS Systems Manager Automation can help with the common maintenance and deployment tasks of EC2 instances and other AWS resources.

• AWS provides multiple native services to monitor and manage your infrastructure and applications on AWS. Services such as Amazon CloudWatch and AWS CloudTrail can be used to monitor your underlying infrastructure and API operations, respectively. For more details, see SAP on AWS – IBM Db2 HADR with Pacemaker.

</tbody>
</table>

#### Set up the servers and replication

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the SAP and database servers.</td>
<td>1. To deploy the infrastructure for the DR Region, use an AWS CloudFormation script or</td>
<td>SAP Basis administrator</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td>1.</td>
<td>use an AMI of the production instance. As a part of the pilot light approach, you can use a smaller EC2 instance in the same family as the production instance. For example, if your production instance type is <code>r6i.12xlarge</code>, you can use the <code>r6i.xlarge</code> instance type for the DR build. However, make sure that you allocate the same storage capacity on the DR instance to restore the production database backup.</td>
<td></td>
</tr>
<tr>
<td>2.</td>
<td>Create Amazon Elastic File System (Amazon EFS) mount points for <code>/sapmnt/&lt;SID&gt;/</code>, and make sure that it is set to be replicated from the primary system.</td>
<td></td>
</tr>
<tr>
<td>3.</td>
<td>Take a FULL database backup (online or offline) from the production system. You will use this backup to build the DR database.</td>
<td></td>
</tr>
<tr>
<td>4.</td>
<td>In the DR system, use the SAP Software Provisioning Manager (SWPM) system copy method with <strong>Using system copy with backup/restore for HA/DR purposes</strong> to build the DR SAP system.</td>
<td></td>
</tr>
<tr>
<td>5.</td>
<td>When asked by SWPM, restore the database in DR with the backup that you took from the production. The DR database will be in the rollforward pending state.</td>
<td></td>
</tr>
</tbody>
</table>

The rollforward pending state is set by default after the full backup is restored. The rollforward pending state indicates that the database is in the process of being restored and that some changes might need to be applied. For more information, see the [IBM documentation](https://www.ibm.com).
Check the configuration.

1. To set up log archiving for HADR, both the production and DR databases must be able to retrieve logs automatically from all log archive locations. Verify that the LOGARCHMETH1 parameter in the DR database is set to the same location as in the production database. If the same location is not accessible because of Regional limitations, ensure that the DR system can automatically fetch logs from the primary system.

2. To enable TCP/IP ports for database replication enablement, modify /etc/services in the production and DR hosts by adding the following two entries. In the code, <SID> refers to the System ID (SID) of the Db2 database (for example, PR1).

   ```
   <SID>_HADR_1      55001/tcp       # DB2 HADR Port1
   <SID>_HADR_2      55002/tcp       # DB2 HADR Port2
   ```

   Confirm that both ports allow inbound and outbound traffic between both the primary and the standby.

3. Check /etc/hosts in the production and DR hosts to confirm that hostnames for both production and standby hosts are pointing to the correct IP addresses.

<thead>
<tr>
<th>Issue</th>
<th>Solution</th>
</tr>
</thead>
</table>
| Key log files and commands to troubleshoot HADR-related issues | • `db2 get db cfg | grep -i hadr`
• `db2pd -d sid -hadr`
• `Db2diag.log` (This file is generally located inside the `db2dump` directory, and the `db2dump` path is defined by the parameter `DIAGPATH`.) |
**Issue** | **Solution**
---|---
SAP note for troubleshooting HADR issues on Db2 UDB | Refer to SAP [Note 1154013 - DB6: DB problems in HADR environment](https://portal.sap.com). (You need SAP portal credentials to access this note.)

**Related resources**

- [Disaster recovery approaches for Db2 databases on AWS](https://aws.amazon.com/blogs/database/) (blog post)
- [SAP on AWS – IBM Db2 HADR with Pacemaker](https://help.sap.com/annotation/005ij0/)  
- [Step by Step Procedure to set up HADR replication between DB2 databases](https://www.ibm.com)  
- [Db2 HADR Wiki](https://www.ibm.com)

**Additional information**

Using this pattern, you can set up a disaster recovery system for an SAP system running on the Db2 database. In a disaster situation, business should be able to continue within your defined recovery time objective (RTO) and recovery point objective (RPO) requirements:

- **RTO** is the maximum acceptable delay between the interruption of service and restoration of service. This determines what is considered an acceptable time window when service is unavailable.
- **RPO** is the maximum acceptable amount of time since the last data recovery point. This determines what is considered an acceptable loss of data between the last recovery point and the interruption of service.

For FAQs related to HADR, see [SAP note #1612105 - DB6: FAQ on Db2 High Availability Disaster Recovery (HADR)](https://portal.sap.com). (You need SAP portal credentials to access this note.)
Set up an HA/DR architecture for Oracle E-Business Suite on Amazon RDS Custom with an active standby database

Created by Simon Cunningham (AWS) and Nitin Saxena

Environment: Production  Technologies: Databases; Infrastructure  Workload: Oracle
AWS services: Amazon RDS

Summary

This pattern describes how you can architect your Oracle E-Business solution on Amazon Relational Database Service (Amazon RDS) Custom for high availability (HA) and disaster recovery (DR) by setting up an Amazon RDS Custom read replica database in another Amazon Web Services (AWS) Availability Zone and converting it to an active standby database. The creation of the Amazon RDS Custom read replica is fully automated through the AWS Management Console.

This pattern doesn't discuss the steps for adding additional application tiers and shared file systems, which can also be part of an HA/DR architecture. For more information about those topics, see the following Oracle Support Notes: 1375769.1, 1375670.1, and 1383621.1 (section 5, Advanced Cloning Options). (Access requires an Oracle Support account.)

To migrate E-Business Suite system to a single-tier, Single-AZ architecture on Amazon Web Services (AWS), see the pattern Migrate Oracle E-Business Suite to Amazon RDS Custom.

Oracle E-Business Suite is an Enterprise Resource Planning (ERP) solution for automating enterprise-wide processes such as financials, human resources, supply chains, and manufacturing. It has a three-tier architecture: client, application, and database. Previously, you had to run your E-Business Suite database on a self-managed Amazon Elastic Compute Cloud (Amazon EC2) instance, but you can now benefit from Amazon RDS Custom.

Prerequisites and limitations

Prerequisites

- An existing E-Business Suite installation on Amazon RDS Custom; see the pattern Migrate Oracle E-Business Suite to Amazon RDS Custom
- If you want to change the read replica to read-only and use it to offload reporting to the standby, an Oracle Active Data Guard database license (see the Oracle Technology Commercial Price List)

Limitations

- Limitations and unsupported configurations for Oracle databases on Amazon RDS Custom
- Limitations associated with Amazon RDS Custom for Oracle read replicas

Product versions
For Oracle Database versions and instance classes supported by Amazon RDS Custom, see [Requirements and limitations for Amazon RDS Custom for Oracle](#).

**Architecture**

The following diagram illustrates a representative architecture for E-Business Suite on AWS that includes multiple Availability Zones and application tiers in an active/passive setup. The database uses an Amazon RDS Custom DB instance and Amazon RDS Custom read replica. The read replica uses Active Data Guard to replicate to another Availability Zone. You can also use the read replica to offload read traffic on the primary database and for reporting purposes.

For more information, see [Working with read replicas for Amazon RDS Custom for Oracle](#) in the Amazon RDS documentation.

The Amazon RDS Custom read replica is created by default as mounted. However, if you want to offload some of your read-only workloads to the standby database to reduce the load on your primary database, you can manually change the mode of mounted replicas to read-only by following the steps in the Epics (p. 813) section. A typical use case for this would be to run your reports from the standby database. Changing to read-only requires an active standby database license.

When you create a read replica on AWS, the system uses Oracle Data Guard broker under the covers. This configuration is automatically generated and set up in Maximum Performance mode as follows:

```
DGMGRL> show configuration
Configuration - rds_dg
 Protection Mode: MaxPerformance
 Members:
  vis_a - Primary database
  vis_b - Physical standby database
 Fast-Start Failover: DISABLED
 Configuration Status:
 SUCCESS  (status updated 58 seconds ago)
```
Tools

AWS services

- **Amazon RDS Custom for Oracle** is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. It automates database administration tasks and operations while making it possible for you, as a database administrator, to access and customize your database environment and operating system.

Other tools

- Oracle Data Guard is a tool that helps you create and manage Oracle standby databases. This pattern uses Oracle Data Guard to set up an active standby database on Amazon RDS Custom.

Set up data replication between Amazon RDS for MySQL and MySQL on Amazon EC2 using GTID

Created by Rajesh Madiwale (AWS)

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Technologies: Databases</th>
<th>Workload: Open-source</th>
</tr>
</thead>
</table>

Summary

This pattern describes how to set up data replication on the Amazon Web Services (AWS) Cloud between an Amazon Relational Database Service (Amazon RDS) for MySQL DB instance and a MySQL database on an Amazon Elastic Compute Cloud (Amazon EC2) instance by using MySQL native global transaction identifier (GTID) replication.

With GTIDs, transactions are identified and tracked when they are committed on the originating server and applied by replicas. You don't need to refer to log files when starting a new replica during failover.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon Linux instance deployed

Restrictions

- This setup requires an internal team to run the read-only queries.
- The source and target MySQL versions must be the same.
- Replication is set up in the same AWS Region and virtual private cloud (VPC).

Product versions

- Amazon RDS versions 5.7.23 and later, which are the versions that support GTID

Architecture

Source technology stack

- Amazon RDS for MySQL

Target technology stack

- MySQL on Amazon EC2

Target architecture
Tools

AWS services

- **Amazon Elastic Compute Cloud (Amazon EC2)** provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

- **Amazon Relational Database Service (Amazon RDS) for MySQL** helps you set up, operate, and scale a MySQL relational database in the AWS Cloud.

Other services

- **Global transaction identifiers (GTIDs)** are unique identifiers generated for committed MySQL transactions.

- **mysqldump** is a client utility for performing logical backups by producing SQL statements that can be run to reproduce the source database object definitions and table data.

- **mysql** is the command-line client for MySQL.
## Epics

### Create and prepare the Amazon RDS for MySQL DB instance

<td>CREATE USER 'repl'@'%' IDENTIFIED BY 'xxxx'; GRANT REPLICATION slave ON '.*' TO 'repl'@'%' ; FLUSH PRIVILEGES;</td>
<td></td>
</tr>
</tbody>
</table>
### Log in to MySQL on EC2
- **Task:** Log in to MySQL on the EC2 instance and create the database.
- **Description:** The database name should be the same as the database name in Amazon RDS for MySQL. In the following example, the database name is `replication`.
  ```sql
  create database replication;
  ```
- **Skills required:** DBA

### Edit the MySQL config file
- **Task:** Edit the MySQL config file, and restart the database.
- **Description:** Edit the `my.conf` file that is located in `/etc/` by adding the following parameters.
  ```
  server-id=3
  gtid_mode=ON
  enforce_gtid_consistency=ON
  replicate-ignore-db=mysql
  binlog-format=ROW
  log_bin=mysql-bin
  ```
- **Skills required:** DBA

  Then restart the `mysqld` service.
  ```
  systemctl mysqld restart
  ```

### Set up replication

<table>

Transition roles for an Oracle PeopleSoft application on Amazon RDS Custom for Oracle

Created by sampath kathirvel (AWS)

<table>
<thead>
<tr>

Summary

To run the Oracle PeopleSoft enterprise resource planning (ERP) solution on Amazon Web Services (AWS), you can use Amazon Relational Database Service (Amazon RDS) or Amazon RDS Custom for Oracle, which supports legacy, custom, and packaged applications that require access to the underlying operating system (OS) and database environment. For key factors to consider when planning a migration, see Oracle database migration strategies in AWS Prescriptive Guidance.

This pattern focuses on the steps to perform an Oracle Data Guard switchover, or role transition, for a PeopleSoft application database running on Amazon RDS Custom as the primary database with a read replica database. The pattern includes steps to configure fast-start failover (FSFO). During this process, the databases in the Oracle Data Guard configuration continue to function in their new roles. Typical use cases for Oracle Data Guard switchover are disaster recovery (DR) drills, scheduled maintenance activities on databases, and Standby-First Patch Apply rolling patches. For more information, see the blog post Reduce database patching downtime in Amazon RDS Custom.

Prerequisites and limitations

Prerequisites

- Completion of the Add HA to Oracle PeopleSoft on Amazon RDS Custom by using a read replica pattern.

Limitations

- Limitations and unsupported configurations for RDS Custom for Oracle
- Limitations associated with Amazon RDS Custom for Oracle read replicas

Product versions

- For Oracle Database versions supported by Amazon RDS Custom, see RDS Custom for Oracle.
- For Oracle Database instance classes supported by Amazon RDS Custom, see DB instance class support for RDS Custom for Oracle.

Architecture

Technology stack
• Amazon RDS Custom for Oracle

**Target architecture**

The following diagram shows an Amazon RDS Custom DB instance and an Amazon RDS Custom read replica. Oracle Data Guard provides role transition during failover for DR.

For a representative architecture using Oracle PeopleSoft on AWS, see [Set up a highly available PeopleSoft architecture on AWS.](#)

**Tools**

**AWS services**

- **Amazon RDS Custom for Oracle** is a managed database service for legacy, custom, and packaged applications that require access to the underlying OS and database environment.

- **AWS Secrets Manager** helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically. In this pattern, you retrieve the database user passwords from Secrets Manager for RDS_DATAGUARD with the secret name `do-not-delete-rds-custom-+<<RDS Resource ID>>+-dg`.

---

**Other services**

- **Oracle Data Guard** helps you create, maintain, manage, and monitor standby databases. This pattern uses Oracle Data Guard Maximum Performance for transitioning roles ([Oracle Data Guard switchover](#)).

---

**Best practices**

For your production deployment, we recommend launching the observer instance in a third Availability Zone, separate from the primary and read replica nodes.
## Epics

### Initiate role transition

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Pause database automation for both the primary and the replica.</strong></td>
<td>Although the RDS Custom automation framework doesn't interfere with the role transition process, it's a good practice to pause automation during Oracle Data Guard switchover. To pause and resume RDS Custom database automation, follow the instructions at <a href="#">Pausing and resuming RDS Custom automation</a>.</td>
<td>Cloud administrator, DBA</td>
</tr>
<tr>
<td><strong>Check the Oracle Data Guard status.</strong></td>
<td>To check the Oracle Data Guard status, log in to the primary database. This pattern includes code for using a multitenant container database (CDB) or a non-CDB instance. <strong>Non-CDB</strong></td>
<td>DBA</td>
</tr>

Configuration Status: SUCCESS (status updated 53 seconds ago)  
DGMGRL> | **Verify the instance role on the Amazon RDS console.**  
After you perform the role switch, the Amazon RDS console shows the new roles under the Replication section on the Connectivity & Security tab under Databases. It might take a few minutes for Replication state to update from empty to Replicating.  
**DBA** | **Reset the switchover.**  
Set the switchover back to the primary node.  
**DBA** |
| **Install and start the observer.**  
An observer process is a DGMGRL client component, typically running in a different machine from the primary and standby databases. The ORACLE HOME installation for the observer can be an Oracle Client Administrator installation, or you can install either Oracle Database Enterprise Edition or Personal Edition. For more information about observer installation for your database release, see Installing and Starting the Observer.  
**DBA** | **Configure FSFO** |

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure FastStartFailoverThreshold for the connection to DGMGRL.</td>
<td>The default value is 30 seconds in Oracle 19c, and the minimum value is 6 seconds. A lower value can potentially shorten the recovery time objective (RTO) during the failover. A higher value helps reduce the chance of unnecessary failover transient errors on the primary database. The RDS Custom for Oracle automation framework monitors database health and performs corrective actions every few seconds. Therefore, we recommend setting FastStartFailoverThreshold to a value higher than 10 seconds. The following example configures the threshold value at 35 seconds. <strong>Non-CBD or CDB</strong></td>
<td>DBA</td>
</tr>
<tr>
<td>FastStartFailoverTarget = 'rdscdb_a'</td>
<td>DGMGRL&gt; edit configuration set property FastStartFailoverThreshold=35; Property &quot;faststartfailoverthreshold&quot; updated</td>
<td></td>
</tr>
<tr>
<td>DGMGRL&gt; show configuration FastStartFailoverThreshold; FastStartFailoverThreshold = '35' DGMGRL&gt;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
## Task
Enable FSFO by connecting to DGMGRL from the primary or observer node.

## Description
If the database doesn't have Flashback Database enabled, the warning message ORA-16827 appears. The optional flashback database helps automatically reinstate failed primary databases to a point in time before failover if the FastStartFailoverAutoReinstate configuration property is set to TRUE (which is the default).

### Non-CDB

```sql
DGMGRL> enable fast_start failover;
Warning: ORA-16827: Flashback Database is disabled
Enabled in Zero Data Loss Mode.
DGMGRL> show configuration
Configuration - rds_dg
Protection Mode: MaxAvailability
Members:
orcl_a - Primary database
Warning: ORA-16819: fast-start failover observer not started
orcl_d - (*) Physical standby database
Warning: ORA-16819: fast-start failover observer not started
Fast-Start Failover: Enabled in Zero Data Loss Mode
Configuration Status: WARNING (status updated 29 seconds ago)
DGMGRL>
```

### CDB

```sql
DGMGRL> enable fast_start failover;
Warning: ORA-16827: Flashback Database is disabled
Enabled in Zero Data Loss Mode.
DGMGRL> show configuration;
Configuration - rds_dg
Protection Mode: MaxAvailability
Members:
rdscdb_a - Primary database
```

- Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server using linked servers (p. 2516)
- Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server using native backup and restore methods (p. 2521)
- Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS DMS (p. 1932)
- Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS SCT data extraction agents (p. 1936)
- Migrate an on-premises Microsoft SQL Server database to Microsoft SQL Server on Amazon EC2 running Linux (p. 2512)
- Migrate data from Microsoft Azure Blob to Amazon S3 by using Rclone (p. 2412)
- Migrate SQL Server to AWS using distributed availability groups (p. 738)
- Migrate Windows SSL certificates to an Application Load Balancer using ACM (p. 2372)
N/A

- Create an approval process for firewall requests during a rehost migration to AWS (p. 1995)
- Encrypt an existing Amazon RDS for PostgreSQL DB instance (p. 636)
- Estimate storage costs for an Amazon DynamoDB table (p. 655)
- Implement cross-Region disaster recovery with AWS DMS and Amazon Aurora (p. 701)
Open-source

- Connect by using an SSH tunnel in pgAdmin (p. 581)
- Create application users and roles in Aurora PostgreSQL-Compatible (p. 1747)
- Enable encrypted connections for PostgreSQL DB instances in Amazon RDS (p. 629)
- Migrate an on-premises MariaDB database to Amazon RDS for MariaDB using native tools (p. 2532)
- Migrate an on-premises MySQL database to Amazon EC2 (p. 2106)
- Migrate an on-premises MySQL database to Amazon RDS for MySQL (p. 2399)
- Migrate an on-premises MySQL database to Aurora MySQL (p. 1948)
- Migrate an on-premises PostgreSQL database to Aurora PostgreSQL (p. 2502)
- Migrate from IBM WebSphere Application Server to Apache Tomcat on Amazon EC2 with Auto Scaling (p. 2447)
- Migrate from Oracle 8i or 9i to Amazon RDS for Oracle using SharePlex and AWS DMS (p. 753)
- Migrate from Oracle GlassFish to AWS Elastic Beanstalk (p. 2076)
- Migrate from PostgreSQL on Amazon EC2 to Amazon RDS for PostgreSQL using pglogical (p. 2497)
- Migrate on-premises Java applications to AWS using AWS App2Container (p. 2547)
- Migrate on-premises MySQL databases to Aurora MySQL using Percona XtraBackup, Amazon EFS, and Amazon S3 (p. 2537)
- Migrate Oracle external tables to Amazon Aurora PostgreSQL-Compatible (p. 1791)
- Migrate Oracle functions and procedures that have more than 100 arguments to PostgreSQL (p. 711)
- Migrate Redis workloads to Redis Enterprise Cloud on AWS (p. 2347)
- Monitor Amazon Aurora for instances without encryption (p. 759)
- Restart the AWS Replication Agent automatically without disabling SELinux after rebooting a RHEL source server (p. 1732)
- Schedule jobs for Amazon RDS for PostgreSQL and Aurora PostgreSQL by using Lambda and Secrets Manager (p. 793)
- Set up data replication between Amazon RDS for MySQL and MySQL on Amazon EC2 using GTID (p. 817)
- Transport PostgreSQL databases between two Amazon RDS DB instances using pg_transport (p. 2182)
Oracle

- Add HA to Oracle PeopleSoft on Amazon RDS Custom by using a read replica (p. 531)
- Configure links between Oracle Database and Aurora PostgreSQL-Compatible (p. 2191)
- Convert JSON Oracle queries into PostgreSQL database SQL (p. 585)
- Convert VARCHAR2(1) data type for Oracle to Boolean data type for Amazon Aurora PostgreSQL (p. 1739)
- Emulate Oracle DR by using a PostgreSQL-compatible Aurora global database (p. 1756)
- Emulate Oracle RAC workloads using custom endpoints in Aurora PostgreSQL (p. 624)
- Estimate the Amazon RDS engine size for an Oracle database by using AWR reports (p. 659)
- Handle anonymous blocks in Dynamic SQL statements in Aurora PostgreSQL (p. 686)
- Handle overloaded Oracle functions in Aurora PostgreSQL-Compatible (p. 692)
- Incrementally migrate from Amazon RDS for Oracle to Amazon RDS for PostgreSQL using Oracle SQL Developer and AWS SCT (p. 1761)
- Load BLOB files into TEXT by using file encoding in Aurora PostgreSQL-Compatible (p. 1766)
- Migrate Amazon RDS for Oracle DB instances to other accounts that use AMS (p. 715)
- Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL with AWS SCT and AWS DMS using AWS CLI and AWS CloudFormation (p. 1776)
- Migrate an Amazon RDS for Oracle database to another AWS account and AWS Region using AWS DMS for ongoing replication (p. 2135)
- Migrate an Amazon RDS for Oracle DB instance to another VPC (p. 2149)
- Migrate an on-premises Oracle database to Amazon EC2 by using Oracle Data Pump (p. 2087)
- Migrate an on-premises Oracle database to Amazon OpenSearch Service using Logstash (p. 2476)
- Migrate an on-premises Oracle database to Amazon RDS for MySQL using AWS DMS and AWS SCT (p. 1886)
- Migrate an on-premises Oracle database to Amazon RDS for Oracle (p. 2481)
- Migrate an on-premises Oracle database to Amazon RDS for Oracle by using direct Oracle Data Pump Import over a database link (p. 2246)
- Migrate an on-premises Oracle database to Amazon RDS for Oracle using Oracle Data Pump (p. 2490)
- Migrate an on-premises Oracle database to Amazon RDS for PostgreSQL by using an Oracle bystander and AWS DMS (p. 1890)
- Migrate an on-premises Oracle database to Oracle on Amazon EC2 (p. 2081)
- Migrate an Oracle database from Amazon EC2 to Amazon RDS for MariaDB using AWS DMS and AWS SCT (p. 1879)
- Migrate an Oracle database from Amazon EC2 to Amazon RDS for Oracle using AWS DMS (p. 2471)
- Migrate an Oracle database to Amazon DynamoDB using AWS DMS (p. 1833)
- Migrate an Oracle database to Amazon RDS for Oracle by using Oracle GoldenGate flat file adapters (p. 2571)
- Migrate an Oracle Database to Amazon Redshift using AWS DMS and AWS SCT (p. 1903)
- Migrate an Oracle database to Aurora PostgreSQL using AWS DMS and AWS SCT (p. 1911)
- Migrate an Oracle partitioned table to PostgreSQL by using AWS DMS (p. 1837)
- Migrate an Oracle PeopleSoft database to AWS by using AWS DMS (p. 2384)
- Migrate data from an on-premises Oracle database to Aurora PostgreSQL (p. 1920)
- Migrate from Amazon RDS for Oracle to Amazon RDS for MySQL (p. 1840)
- Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using materialized views and AWS DMS (p. 1859)
- Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using SharePlex and AWS DMS (p. 1852)
- Migrate from Oracle Database to Amazon RDS for PostgreSQL by using Oracle GoldenGate (p. 1898)
- Migrate from Oracle on Amazon EC2 to Amazon RDS for MySQL using AWS DMS and AWS SCT (p. 1867)
- Migrate from Oracle to a PostgreSQL database by using a standby database (p. 746)
- Migrate from Oracle to Amazon DocumentDB using AWS DMS (p. 1874)
- Migrate from Oracle WebLogic to Apache Tomcat (TomEE) on Amazon ECS (p. 2464)
- Migrate function-based indexes from Oracle to PostgreSQL (p. 1808)
- Migrate legacy applications from Oracle Pro*C to ECPG (p. 1954)
- Migrate Oracle CLOB values to individual rows in PostgreSQL on AWS (p. 2241)
- Migrate Oracle Database error codes to an Amazon Aurora PostgreSQL-Compatible database (p. 2343)
- Migrate Oracle E-Business Suite to Amazon RDS Custom (p. 2256)
- Migrate Oracle native functions to PostgreSQL using extensions (p. 1812)
- Migrate Oracle OUT bind variables to a PostgreSQL database (p. 721)
- Migrate Oracle PeopleSoft to Amazon RDS Custom (p. 2317)
- Migrate Oracle ROWID functionality to PostgreSQL on AWS (p. 2335)
- Migrate Oracle SERIALLY_REUSABLE pragma packages into PostgreSQL (p. 1786)
- Migrate virtual generated columns from Oracle to PostgreSQL (p. 1966)
- Monitor Oracle GoldenGate logs by using Amazon CloudWatch (p. 763)
- Replatform Oracle Database Enterprise Edition to Standard Edition 2 on Amazon RDS for Oracle (p. 772)
- Set up an HA/DR architecture for Oracle E-Business Suite on Amazon RDS Custom with an active standby database (p. 811)
- Set up Oracle UTL_FILE functionality on Aurora PostgreSQL-Compatible (p. 1971)
- Transition roles for an Oracle PeopleSoft application on Amazon RDS Custom for Oracle (p. 822)
- Validate database objects after migrating from Oracle to Amazon Aurora PostgreSQL (p. 1982)
SAP

- Automatically back up SAP HANA databases using Systems Manager and EventBridge (p. 563)
- Migrate an on-premises SAP ASE database to Amazon EC2 (p. 2093)
- Migrate from SAP ASE to Amazon RDS for SQL Server using AWS DMS (p. 1927)
- Migrate SAP ASE on Amazon EC2 to Amazon Aurora PostgreSQL-Compatible using AWS SCT and AWS DMS (p. 2365)
- Migrate SAP HANA to AWS using SAP HSR with the same hostname (p. 727)
- Reduce homogeneous SAP migration cutover time by using Application Migration Service (p. 2112)
- Set up disaster recovery for SAP on IBM Db2 on AWS (p. 798)
More patterns

- Access, query, and join Amazon DynamoDB tables using Athena (p. 132)
- Allow EC2 instances write access to S3 buckets in AMS accounts (p. 3382)
- Authenticate Microsoft SQL Server on Amazon EC2 using AWS Directory Service (p. 2973)
- Automate backups for Amazon RDS for PostgreSQL DB instances by using AWS Batch (p. 253)
- Automatically archive items to Amazon S3 using DynamoDB TTL (p. 2634)
- Automatically remediate unencrypted Amazon RDS DB instances and clusters (p. 3006)
- Automatically stop and start an Amazon RDS DB instance using AWS Systems Manager Maintenance Windows (p. 1627)
- Build a loosely coupled architecture with microservices using DevOps practices and AWS Cloud9 (p. 902)
- Change Python and Perl applications to support database migration from Microsoft SQL Server to Amazon Aurora PostgreSQL-Compatible Edition (p. 2583)
- Configure cross-account access to Amazon DynamoDB (p. 919)
- Configure links between Oracle Database and Aurora PostgreSQL-Compatible (p. 2191)
- Convert and unpack EBCDIC data to ASCII on AWS by using Python (p. 1477)
- Convert the Teradata NORMALIZE temporal feature to Amazon Redshift SQL (p. 27)
- Convert the Teradata RESET WHEN feature to Amazon Redshift SQL (p. 33)
- Convert VARCHAR2(1) data type for Oracle to Boolean data type for Amazon Aurora PostgreSQL (p. 1739)
- Create application users and roles in Aurora PostgreSQL-Compatible (p. 1747)
- Create AWS CloudFormation templates for AWS DMS tasks using Microsoft Excel and Python (p. 1724)
- Deliver DynamoDB records to Amazon S3 using Kinesis Data Streams and Kinesis Data Firehose with AWS CDK (p. 3338)
- Deploy a Cassandra cluster on Amazon EC2 with private static IPs to avoid rebalancing (p. 1224)
- Emulate Oracle DR by using a PostgreSQL-compatible Aurora global database (p. 1756)
- Enable transparent data encryption in Amazon RDS for SQL Server (p. 3145)
- Export a Microsoft SQL Server database to Amazon S3 by using AWS DMS (p. 2215)
- Incrementally migrate from Amazon RDS for Oracle to Amazon RDS for PostgreSQL using Oracle SQL Developer and AWS SCT (p. 1761)
- Load BLOB files into TEXT by using file encoding in Aurora PostgreSQL-Compatible (p. 1766)
- Manage credentials using AWS Secrets Manager (p. 3217)
- Migrate a Microsoft SQL Server database from Amazon EC2 to Amazon DocumentDB by using AWS DMS (p. 1818)
- Migrate a Microsoft SQL Server database to Aurora MySQL by using AWS DMS and AWS SCT (p. 2525)
- Migrate a self-hosted MongoDB environment to MongoDB Atlas on the AWS Cloud (p. 2458)
- Migrate a Teradata database to Amazon Redshift using AWS SCT data extraction agents (p. 1940)
- Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL with AWS SCT and AWS DMS using AWS CLI and AWS CloudFormation (p. 1776)
- Migrate an Amazon RDS DB instance to another VPC or account (p. 2144)
- Migrate an Amazon RDS for Oracle database to another AWS account and AWS Region using AWS DMS for ongoing replication (p. 2135)
- Migrate an Amazon RDS for Oracle DB instance to another VPC (p. 2149)
- Migrate an Amazon Redshift cluster to an AWS Region in China (p. 2153)
- Migrate an on-premises MariaDB database to Amazon RDS for MariaDB using native tools (p. 2532)
- Migrate an on-premises Microsoft SQL Server database to Amazon EC2 (p. 2099)
• Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server (p. 2407)
• Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server using linked servers (p. 2516)
• Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server using native backup and restore methods (p. 2521)
• Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS DMS (p. 1932)
• Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS SCT data extraction agents (p. 1936)
• Migrate an on-premises Microsoft SQL Server database to Microsoft SQL Server on Amazon EC2 running Linux (p. 2512)
• Migrate an on-premises MySQL database to Amazon EC2 (p. 2106)
• Migrate an on-premises MySQL database to Amazon RDS for MySQL (p. 2399)
• Migrate an on-premises MySQL database to Aurora MySQL (p. 1948)
• Migrate an on-premises Oracle database to Amazon EC2 by using Oracle Data Pump (p. 2087)
• Migrate an on-premises Oracle database to Amazon OpenSearch Service using Logstash (p. 2476)
• Migrate an on-premises Oracle database to Amazon RDS for MySQL using AWS DMS and AWS SCT (p. 1886)
• Migrate an on-premises Oracle database to Amazon RDS for Oracle (p. 2481)
• Migrate an on-premises Oracle database to Amazon RDS for Oracle by using direct Oracle Data Pump import over a database link (p. 2246)
• Migrate an on-premises Oracle database to Amazon RDS for Oracle using Oracle Data Pump (p. 2490)
• Migrate an on-premises Oracle database to Amazon RDS for PostgreSQL by using an Oracle bystander and AWS DMS (p. 1890)
• Migrate an on-premises Oracle database to Oracle on Amazon EC2 (p. 2081)
• Migrate an on-premises PostgreSQL database to Aurora PostgreSQL (p. 2502)
• Migrate an on-premises SAP ASE database to Amazon EC2 (p. 2093)
• Migrate an on-premises ThoughtSpot Falcon database to Amazon Redshift (p. 1825)
• Migrate an on-premises Vertica database to Amazon Redshift using AWS SCT data extraction agents (p. 1944)
• Migrate an Oracle database from Amazon EC2 to Amazon RDS for MariaDB using AWS DMS and AWS SCT (p. 1879)
• Migrate an Oracle database from Amazon EC2 to Amazon RDS for Oracle using AWS DMS (p. 2471)
• Migrate an Oracle database to Amazon DynamoDB using AWS DMS (p. 1833)
• Migrate an Oracle database to Amazon RDS for Oracle by using Oracle GoldenGate flat file adapters (p. 2571)
• Migrate an Oracle Database to Amazon Redshift using AWS DMS and AWS SCT (p. 1903)
• Migrate an Oracle database to Aurora PostgreSQL using AWS DMS and AWS SCT (p. 1911)
• Migrate an Oracle partitioned table to PostgreSQL by using AWS DMS (p. 1837)
• Migrate an Oracle PeopleSoft database to AWS by using AWS DMS (p. 2384)
• Migrate data from an on-premises Oracle database to Aurora PostgreSQL (p. 1920)
• Migrate data to the AWS Cloud by using Starburst (p. 106)
• Migrate Db2 for LUW to Amazon EC2 by using log shipping to reduce outage time (p. 2006)
• Migrate Db2 for LUW to Amazon EC2 with high availability disaster recovery (p. 2017)
• Migrate from Amazon RDS for Oracle to Amazon RDS for MySQL (p. 1840)
• Migrate from Couchbase Server to Couchbase Capella on AWS (p. 2420)
• Migrate from IBM Db2 on Amazon EC2 to Aurora PostgreSQL-Compatible using AWS DMS and AWS SCT (p. 1846)
Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using materialized views and AWS DMS (p. 1859)
Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using SharePlex and AWS DMS (p. 1852)
Migrate from Oracle Database to Amazon RDS for PostgreSQL by using Oracle GoldenGate (p. 1898)
Migrate from Oracle on Amazon EC2 to Amazon RDS for MySQL using AWS DMS and AWS SCT (p. 1867)
Migrate from Oracle to Amazon DocumentDB using AWS DMS (p. 1874)
Migrate from PostgreSQL on Amazon EC2 to Amazon RDS for PostgreSQL using pglogical (p. 2497)
Migrate from SAP ASE to Amazon RDS for SQL Server using AWS DMS and AWS SCT (p. 1927)
Migrate function-based indexes from Oracle to PostgreSQL (p. 1808)
Migrate legacy applications from Oracle Pro*C to ECPG (p. 1954)
Migrate on-premises MySQL databases to Aurora MySQL using Percona XtraBackup, Amazon EFS, and Amazon S3 (p. 2537)
Migrate Oracle Business Intelligence 12c to the AWS Cloud from on-premises servers (p. 76)
Migrate Oracle CLOB values to individual rows in PostgreSQL on AWS (p. 2241)
Migrate Oracle Database error codes to an Amazon Aurora PostgreSQL-Compatible database (p. 2343)
Migrate Oracle E-Business Suite to Amazon RDS Custom (p. 2256)
Migrate Oracle external tables to Amazon Aurora PostgreSQL-Compatible (p. 1791)
Migrate Oracle native functions to PostgreSQL using extensions (p. 1812)
Migrate Oracle PeopleSoft to Amazon RDS Custom (p. 2317)
Migrate Oracle ROWID functionality to PostgreSQL on AWS (p. 2335)
Migrate Oracle SERIALY_REUSABLE pragma packages into PostgreSQL (p. 1786)
Migrate Redis workloads to Redis Enterprise Cloud on AWS (p. 2347)
Migrate SAP ASE on Amazon EC2 to Amazon Aurora PostgreSQL-Compatible using AWS SCT and AWS DMS (p. 2365)
Migrate virtual generated columns from Oracle to PostgreSQL (p. 1966)
Monitor Amazon ElastiCache clusters for at-rest encryption (p. 3226)
Monitor ElastiCache clusters for security groups (p. 3236)
Reduce homogeneous SAP migration cutover time by using Application Migration Service (p. 2112)
Rotate database credentials without restarting containers (p. 418)
Run message-driven workloads at scale by using AWS Fargate (p. 438)
Set up a highly available PeopleSoft architecture on AWS (p. 175)
Set up Oracle UTL_FILE functionality on Aurora PostgreSQL-Compatible (p. 1971)
Transfer large-scale Db2 z/OS data to Amazon S3 in CSV files (p. 1584)
Transport PostgreSQL databases between two Amazon RDS DB instances using pg_transport (p. 2182)
Use CloudEndure for disaster recovery of an on-premises database (p. 3446)
Validate database objects after migrating from Oracle to Amazon Aurora PostgreSQL (p. 1982)
Verify that new Amazon Redshift clusters launch in a VPC (p. 3320)
DevOps

Topics

- Install SAP systems automatically by using open-source tools (p. 856)
- Automate AWS Service Catalog portfolio and product deployment by using AWS CDK (p. 864)
- Automate event-driven backups from CodeCommit to Amazon S3 using CodeBuild and CloudWatch Events (p. 876)
- Automatically attach an AWS managed policy for Systems Manager to EC2 instance profiles using Cloud Custodian and AWS CDK (p. 882)
- Automatically build CI/CD pipelines and Amazon ECS clusters for microservices using AWS CDK (p. 893)
- Build a loosely coupled architecture with microservices using DevOps practices and AWS Cloud9 (p. 902)
- Build and test iOS apps with AWS CodeCommit, AWS CodePipeline, and AWS Device Farm (p. 910)
- Check AWS CDK applications or CloudFormation templates for best practices by using cdk-nag rule packs (p. 916)
- Configure cross-account access to Amazon DynamoDB (p. 919)
- Configure mutual TLS authentication for applications running on Amazon EKS (p. 934)
- Create a custom log parser for Amazon ECS using a Firelens log router (p. 942)
- Create a pipeline and AMI using CodePipeline and HashiCorp Packer (p. 948)
- Create a pipeline and deploy artifact updates to on-premises EC2 instances using CodePipeline (p. 953)
- Create dynamic CI pipelines for Java and Python projects automatically (p. 959)
- Deploy CloudWatch Synthetics canaries by using Terraform (p. 969)
- Deploy a CI/CD pipeline for Java microservices on Amazon ECS (p. 975)
- Use AWS CodeCommit and AWS CodePipeline to deploy a CI/CD pipeline in multiple AWS accounts (p. 982)
- Deploy a firewall using AWS Network Firewall and AWS Transit Gateway (p. 987)
- Deploy an AWS Glue job with an AWS CodePipeline CI/CD pipeline (p. 996)
- Deploy an Amazon EKS cluster from AWS Cloud9 using an EC2 instance profile (p. 1000)
- Deploy code in multiple AWS Regions using AWS CodePipeline, AWS CodeCommit, and AWS CodeBuild (p. 1008)
- Export AWS Backup reports from across an organization in AWS Organizations as a CSV file (p. 1016)
- Export tags for a list of Amazon EC2 instances to a CSV file (p. 1022)
- Generate an AWS CloudFormation template containing AWS Config managed rules using Troposphere (p. 1026)
- Give SageMaker notebook instances temporary access to a CodeCommit repository in another AWS account (p. 1030)
- Automatically detect changes and initiate different CodePipeline pipelines for a monorepo in CodeCommit (p. 1037)
- Integrate a Bitbucket repository with AWS Amplify using AWS CloudFormation (p. 1046)
- Launch a CodeBuild project across AWS accounts using Step Functions and a Lambda proxy function (p. 1052)
- Monitor Amazon ECR repositories for wildcard permissions using AWS CloudFormation and AWS Config (p. 1059)
- Perform custom actions from AWS CodeCommit events (p. 1063)
- Publish Amazon CloudWatch metrics to a CSV file (p. 1067)
- Run unit tests for Python ETL jobs in AWS Glue using the pytest framework (p. 1071)
- Set up a Helm v3 chart repository in Amazon S3 (p. 1079)
- Set up a CI/CD pipeline by using AWS CodePipeline and AWS CDK (p. 1086)
- Set up end-to-end encryption for applications on Amazon EKS using cert-manager and Let’s Encrypt (p. 1096)
- Subscribe multiple email endpoints to an SNS topic by using a custom resource (p. 1104)
- Use Serverspec for test-driven development of infrastructure code (p. 1108)
- Use third-party Git source repositories in AWS CodePipeline (p. 1114)
- Create a CI/CD pipeline to validate Terraform configurations by using AWS CodePipeline (p. 1120)
- More patterns (p. 1130)
Install SAP systems automatically by using open-source tools

Summary

This pattern shows how to automate SAP systems installation by using open-source tools to create the following resources:

- An SAP S/4HANA 1909 database
- An SAP ABAP Central Services (ASCS) instance
- An SAP Primary Application Server (PAS) instance

HashiCorp Terraform creates the SAP system’s infrastructure and Ansible configures the operating system (OS) and installs SAP applications. Jenkins runs the installation.

This setup turns SAP systems installation into a repeatable process, which can help increase deployment efficiency and quality.

**Note:** The example code provided in this pattern works for both high-availability (HA) systems and non-HA systems.

Prerequisites and limitations

**Prerequisites**

- An active AWS account
- An Amazon Simple Storage Service (Amazon S3) bucket that contains all of your SAP media files
- An AWS Identity and Access Management (IAM) principal with an [access key and secret key](#), and that has the following permissions:
  - **Read only permissions:** Amazon Route 53, AWS Key Management Service (AWS KMS)
  - **Read and write permissions:** Amazon S3, Amazon Elastic Compute Cloud (Amazon EC2), Amazon Elastic File System (Amazon EFS), IAM, Amazon CloudWatch, Amazon DynamoDB
- A Route 53 [private hosted zone](#)
- A subscription to the [Red Hat Enterprise Linux for SAP with HA and Update Services 8.2](#) Amazon Machine Image (AMI) in Amazon Marketplace
- An [AWS KMS customer managed key](#)
- A [Secure Shell (SSH) key pair](#)
- An [Amazon EC2 security group](#) that allows SSH connection on port 22 from the hostname where you install Jenkins (the hostname is most likely `localhost`)
• **Vagrant** by HashiCorp installed and configured
• **VirtualBox** by Oracle installed and configured
• Familiarity with Git, Terraform, Ansible, and Jenkins

**Limitations**

• Only SAP S/4HANA 1909 is fully tested for this specific scenario. The example Ansible code in this pattern requires modification if you use another version of SAP HANA.
• The example procedure in this pattern works for Mac OS and Linux operating systems. Some of the commands can be run only in Unix-based terminals. However, you can achieve a similar result by using different commands and a Windows OS.

**Product versions**

• SAP S/4HANA 1909
• Red Hat Enterprise Linux (RHEL) 8.2 or higher versions

**Architecture**

The following diagram shows an example workflow that uses open-source tools to automate SAP systems installation in an AWS account:

The diagram shows the following workflow:

1. Jenkins orchestrates running the SAP system installation by running Terraform and Ansible code.
2. Terraform code builds the SAP system's infrastructure.
3. Ansible code configures the OS and installs SAP applications.
4. An SAP S/4HANA 1909 database, an ASCS instance, and PAS instance that include all defined prerequisites are installed on an Amazon EC2 instance.
Note: The example setup in this pattern automatically creates an Amazon S3 bucket in your AWS account to store the Terraform state file.

Technology stack

- Terraform
- Ansible
- Jenkins
- An SAP S/4HANA 1909 database
- An SAP ASCS instance
- An SAP PAS instance
- Amazon EC2

Tools

AWS services

- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need, and quickly scale them up or down.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to protect your data.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Other tools

- HashiCorp Terraform is a command-line interface application that helps you use code to provision and manage cloud infrastructure and resources.
- Ansible is an open-source configuration as code (CaC) tool that helps automate applications, configurations, and IT infrastructure.
- Jenkins is an open-source automation server that enables developers to build, test, and deploy their software.

Code

The code for this pattern is available in the GitHub aws-install-sap-with-jenkins-ansible repository.

Wizard's folder hierarchy for S/4HANA in the Launch Wizard documentation.
Task | Description | Skills required
--- | --- | ---
Configure your AWS account. | 1. Verify that you have an IAM principal with an access key and secret key, and that has the following permissions:  
   - **Read only permissions:** Amazon Route 53, AWS Key Management Service (AWS KMS)  
   - **Read and write permissions:** Amazon S3, Amazon Elastic Compute Cloud (Amazon EC2), Amazon Elastic File System (Amazon EFS), IAM, Amazon CloudWatch, Amazon DynamoDB  
   2. Save the IAM principal's access key and secret key for reference later.  
   3. Create a Route 53 private hosted zone, if you don't have one already. Save the zone name (for example, sapteam.net) for reference later.  
   4. Subscribe to the Red Hat Enterprise Linux for SAP with HA and Update Services 8.2 AMI in Amazon Marketplace. Save the AMI ID (for example, ami-0000000) for reference later.  
   5. Create an AWS KMS customer managed key. Save the KMS key's Amazon Resource Name (ARN) for reference later.  
      **Note:** The following is an example AWS KMS customer managed key ARN: arn:aws:kms:us-east-1:123412341234:key/uuid  
   6. Create an SSH key pair. Save the key pair's name and .pem file for reference later.  
   7. Create an Amazon EC2 security group that allows SSH connection on port 22 from the hostname where you install Jenkins. Save | General AWS
### Build and run your SAP installation

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Start the Jenkins service.                | Open the Linux terminal. Then, navigate to the local folder that contains the cloned code repository folder and run the following command:  
  ```
  sudo vagrant up
  ```  
  **Note:** The Jenkins startup takes about 20 minutes. The command returns a **Service is up and running** message when successful. | DevOps engineer                      |
  2. Log in to Jenkins by using `admin` for the username and `my_secret_pass_from_vault` for the password. | DevOps engineer                      |
| Configure your SAP system installation parameters. | 1. In Jenkins, choose **Manage Jenkins**. Then, choose **Manage Credentials**. A list of credential variables that you can configure appears.  
  2. Configure all of the following credential variables:  
  - For **AWS_ACCOUNT_CREDENTIALS**, enter your IAM principal's access key ID and secret access key ID.  
  - For **AMI_ID**, enter the Red Hat Enterprise Linux for SAP with | AWS systems administrator, DevOps engineer |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| HA and Update Services 8.2 AMI's AMI ID.  | • For **KMS_KEYARN**, enter your AWS KMS customer managed key's ARN.  
• For **SSH_KEYPAIR NAME**, enter the name of your SSH key pair, without entering the .pem file type.  
• For **SSH_KEYPAIR_FILE**, enter the full name of your key pair's .pem file (for example, mykeypair.pem). Make sure that you also upload the key pairs' .pem file to Jenkins.  
• For **S3_ROOT_FOLDER_INSTALL_FILES**, enter the name of the Amazon S3 bucket—and folder, if applicable—(for example, s3://my-media-bucket/S4H1909) that contains your SAP media files.  
• For **PRIVATE_DNS_ZONE_NAME**, enter the name of your Route 53 private hosted zone (for example, myprivatecompanyurl.net).  
• For **VPC_ID**, enter the VPC ID (for example, vpc-12345) of the Amazon VPC that you’re creating the SAP resources in.  
• For **SUBNET_IDS**, enter two public subnet IDs if you’re working in a test environment (for future HA capabilities). If you’re working in a production environment, it’s a best practice to use two private subnets with a bastion host.  
• For **SECURITY_GROUP_ID**, enter the ID of the Amazon EC2 security group that allows SSH connection on port 22 from the hostname where you installed Jenkins. |                 |
| Note: You can configure the other nonrequired parameters as needed, based on your use case. For example, you can change |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                 |
the SAP system ID (SID) of the instances, default password, names, and tags for your SAP system. All of the required variables have **Required** at the beginning of their names.

Run you SAP system installation.

1. In Jenkins, choose **Jenkins Home**. Then, choose **SAP Hana+ASCS+PAS 3 Instances**.
2. Choose **Spin up and install**. Then, choose **Main**.
3. Choose **Build now**.

For information on the pipeline steps, see the **Understanding the pipeline steps** section of Automating SAP installation with open-source tools on the AWS Blog.

**Note**: If an error occurs, move your cursor over the red error box that appears and choose **Logs**. The logs for the pipeline step that errored out appear. Most errors occur because of incorrect parameter settings.

Automate AWS Service Catalog portfolio and product deployment by using AWS CDK

Created by Sandeep Gawande (AWS) and RAJNEESH TYAGI (AWS)

<table>
<thead>

<td>AWS services: AWS Service Catalog; AWS CDK</td>
<td></td>
</tr>
</tbody>
</table>

Summary

AWS Service Catalog helps you centrally manage catalogs of IT services, or products, that are approved for use in your organization's AWS environment. A collection of products is called a portfolio, and a portfolio also contains configuration information. With AWS Service Catalog, you can create a customized portfolio for each type of user in your organization and then grant access to the appropriate portfolio. Those users can then quickly deploy any product they need from within the portfolio.

If you have a complex networking infrastructure, such as multi-Region and multi-account architectures, it is recommended that you create and manage Service Catalog portfolios in a single, central account. This pattern describes how to use AWS Cloud Development Kit (AWS CDK) to automate creation of Service Catalog portfolios in a central account, grant end users access to them, and then, optionally, provision products in one or more target AWS accounts. This ready-to-use solution creates the Service Catalog portfolios in the source account. It also, optionally, provisions products in target accounts by using AWS CloudFormation stacks and helps you configure TagOptions for the products:

- **AWS CloudFormation StackSets** – You can use StackSets to launch Service Catalog products across multiple AWS Regions and accounts. In this solution, you have the option to automatically provision products when you deploy this solution. For more information, see Using AWS CloudFormation StackSets (Service Catalog documentation) and StackSets concepts (CloudFormation documentation).

- **TagOption library** – You can manage tags on provisioned products by using TagOption library. A TagOption is a key-value pair managed in AWS Service Catalog. It is not an AWS tag, but it serves as a template for creating an AWS tag based on the TagOption. For more information, see TagOption library (Service Catalog documentation).

Prerequisites and limitations

Prerequisites

- An active AWS account that you want to use as the source account for administering Service Catalog portfolios.
- If you are using this solution to provision products in one or more target accounts, the target account must already exist and be active.

Product versions
AWS Prescriptive Guidance Patterns
Architecture

- AWS CDK version 2.27.0

Architecture

Target technology stack

- Service Catalog portfolios in a centralized AWS account
- Service Catalog products deployed in target account

Target architecture

1. In the portfolio (or source) account, you update the config.json file with the AWS account, AWS Region, IAM role, portfolio, and product information for your use case.
2. You deploy the AWS CDK application.
3. The AWS CDK application assumes the deployment IAM role and creates the Service Catalog portfolios and products defined in the config.json file.

If you configured StackSets to deploy products in a target account, the process continues. If you didn’t configure StackSets to provision any products, then the process is complete.

4. The AWS CDK application assumes the StackSet administrator role and deploys the AWS CloudFormation stack set you defined in the config.json file.

5. In the target account, StackSets assumes the StackSet execution role and provisions the products.

Tools

AWS services

- **AWS Cloud Development Kit (AWS CDK)** is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- **AWS CDK Toolkit** is a command line cloud development kit that helps you interact with your AWS CDK app.
- **AWS CloudFormation** helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- **AWS Service Catalog** helps you centrally manage catalogs of IT services that are approved for AWS. End users can quickly deploy only the approved IT services they need, following the constraints set by your organization.

Code repository

The code for this pattern is available on GitHub, in the aws-cdk-servicecatalog-automation repository. The code repository contains the following files and folders:

- **cdk-servicecatalog-app** – This folder contains the AWS CDK application for this solution.
- **config** – This folder contains the config.json file and the CloudFormation template for deploying the products in the Service Catalog portfolio.
- **config/config.json** – This file contains all of the configuration information. You update this file to customize this solution for your use case.
- **config/templates** – This folder contains the CloudFormation templates for the Service Center products.
- **setup.sh** – This script deploys the solution.
- **uninstall.sh** – This script deletes the stack and all of the AWS resources created when deploying this solution.

To use the sample code, follow the instructions in the Epics (p. 867) section.

Best practices

- IAM roles used to deploy this solution should adhere to the principle of least-privilege (IAM documentation).
- Adhere to the Best practices for developing cloud applications with AWS CDK (AWS blog post).
- Adhere to the AWS CloudFormation best practices (CloudFormation documentation).
### Epics

**Set up your environment**

<table>

</tr>
</thead>
<tbody>
<tr>
<td>Verify the deployment.</td>
<td>Verify successful deployment by doing the following:</td>
<td>General AWS</td>
</tr>
<tr>
<td></td>
<td>1. Sign in to the AWS Management Console with credentials that can access one or more of the portfolios you defined in the config file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. In the navigation pane, under <strong>Provisioning</strong>, choose <strong>Products</strong>. Verify that you see a list of products that you specified for the portfolio.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4. Follow the instructions in <a href="https://docs.aws.amazon.com/servicecatalog/latest/adminguides/provisioningproduct.html">Launching a product</a> to launch one of the available products. Confirm that the available product versions and tags match the values you provided in the config file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>5. If you chose to automatically provision products in one or more target accounts by using StackSets, do the following:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>a. Sign in with credentials that give you permissions to view the provisioned products in one of the target accounts.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>b. In the Service Catalog console, in the navigation pane, under <strong>Provisioning</strong>, choose <strong>Provisioned products</strong>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>c. Confirm that the expected products appear in the list.</td>
<td></td>
</tr>
</tbody>
</table>
## (Optional) Update the portfolios and products.

If you want to use this solution to update the portfolios or products or to provision new products:

1. Make the required changes in the `config.json` file.
2. Add or modify any CloudFormation templates as needed in the `config/template` folder.
3. Redeploy the solution.

For example, you can add additional portfolios or provision more resources. The AWS CDK app implements only the changes. If there are no changes to previously deployed portfolios or products, the redeployment doesn't affect them.

### Clean up the solution

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| (Optional) Remove AWS resources deployed by this solution. | If you want to delete a provisioned product, follow the instructions in [Deleting provisioned products](https://docs.aws.amazon.com/servicecatalog/latest/adminguide/delete-provisioned-products.html) (Service Catalog documentation). If you want to delete all the resources created by this solution, enter the following command.  

```
sh uninstall.sh
```
| AWS DevOps, DevOps engineer, App developer |

Automate event-driven backups from CodeCommit to Amazon S3 using CodeBuild and CloudWatch Events

*Created by Kirankumar Chandrashekar (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technologies:</td>
<td>DevOps; Storage &amp; backup</td>
</tr>
<tr>
<td>Workload:</td>
<td>All other workloads</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon S3; Amazon CloudWatch; AWS CodeBuild; AWS CodeCommit</td>
</tr>
</tbody>
</table>

**Summary**

On the Amazon Web Services (AWS) Cloud, you can use AWS CodeCommit to host secure Git-based repositories. CodeCommit is a fully managed source control service. However, if a CodeCommit repository is accidentally deleted, its contents are also deleted and cannot be restored.

This pattern describes how to automatically back up a CodeCommit repository to an Amazon Simple Storage Service (Amazon S3) bucket after a change is made to the repository. If the CodeCommit repository is later deleted, this backup strategy provides you with a point-in-time recovery option.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account.
- An existing CodeCommit repository, with user access configured according to your requirements. For more information, see Setting up for AWS CodeCommit in the CodeCommit documentation.
- An S3 bucket for uploading the CodeCommit backups.

**Limitations**

- This pattern automatically backs up all of your CodeCommit repositories. If you want to back up individual CodeCommit repositories, you must modify the Amazon CloudWatch Events rule.

**Architecture**

The following diagram illustrates the workflow for this pattern.
The workflow consists of the following steps:

1. Code is pushed to a CodeCommit repository.
2. The CodeCommit repository notifies CloudWatch Events of a repository change (for example, a `git push` command).
3. CloudWatch Events invokes AWS CodeBuild and sends it the CodeCommit repository information.
4. CodeBuild clones the entire CodeCommit repository and packages it into a .zip file.
5. CodeBuild uploads the .zip file to an S3 bucket.

**Technology stack**
- CloudWatch Events
- CodeBuild
- CodeCommit
- Amazon S3

**Tools**
- [Amazon CloudWatch Events](https://aws.amazon.com/cloudwatch/): CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- [AWS CodeBuild](https://aws.amazon.com/codebuild/): CodeBuild is a fully managed continuous integration service that compiles source code, runs tests, and produces software packages that are ready to deploy.
- [AWS CodeCommit](https://aws.amazon.com/codecommit/): CodeCommit is a fully managed source control service that hosts secure Git-based repositories.
- [AWS Identity and Access Management (IAM)](https://aws.amazon.com/iam/): IAM is a web service that helps you securely control access to AWS resources.
- [Amazon S3](https://aws.amazon.com/s3/): Amazon Simple Storage Service (Amazon S3) is storage for the internet.
## Epics

### Create a CodeBuild project

<table>
<thead>
<tr>

Automatically attach an AWS managed policy for Systems Manager to EC2 instance profiles using Cloud Custodian and AWS CDK

*Created by Ali Asfour (AWS) and Aaron Lennon (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>DevOps; Software development &amp; testing; Management &amp; governance; Security, identity, compliance; Infrastructure</th>
<th>Workload: Open-source</th>

<tbody>
<tr>
<td>AWS services:</td>
<td>Amazon SNS; Amazon SQS; AWS CodeBuild; AWS CodePipeline; AWS Systems Manager; AWS CodeCommit</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

You can integrate Amazon Elastic Compute Cloud (Amazon EC2) instances with AWS Systems Manager to automate operational tasks and provide more visibility and control. To integrate with Systems Manager, EC2 instances must have an installed [AWS Systems Manager Agent (SSM Agent)](https://aws.amazon.com/samplecode) and an AmazonSSMManagedInstanceCore AWS Identity and Access Management (IAM) policy attached to their instance profiles.

However, if you want to ensure that all EC2 instance profiles have the AmazonSSMManagedInstanceCore policy attached, you can face challenges updating new EC2 instances that don't have instance profiles or EC2 instances that have an instance profile but don't have the AmazonSSMManagedInstanceCore policy. It can also be difficult to add this policy across multiple Amazon Web Services (AWS) accounts and AWS Regions.

This pattern helps solve these challenges by deploying three [Cloud Custodian](https://docs.aws.amazon.com/c Custodian policies in your AWS accounts:

- The first Cloud Custodian policy checks for existing EC2 instances that have an instance profile but don't have the AmazonSSMManagedInstanceCore policy. The AmazonSSMManagedInstanceCore policy is then attached.
- The second Cloud Custodian policy checks for existing EC2 instances without an instance profile and adds a default instance profile that has the AmazonSSMManagedInstanceCore policy attached.
- The third Cloud Custodian policy creates [AWS Lambda functions](https://aws.amazon.com/samplecode) in your accounts to monitor the creation of EC2 instances and instance profiles. This ensures that the AmazonSSMManagedInstanceCore policy is automatically attached when an EC2 instance is created.

This pattern uses AWS DevOps tools to achieve a continuous, at-scale deployment of the Cloud Custodian policies to a multi-account environment, without provisioning a separate compute environment.

**Prerequisites and limitations**

**Prerequisites**

AWS Prescriptive Guidance Patterns
Architecture

- Two or more active AWS accounts. One account is the security account and the others are member accounts.
- Permissions to provision AWS resources in the security account. This pattern uses administrator permissions, but you should grant permissions according to your organization's requirements and policies.
- Ability to assume an IAM role from the security account to member accounts and create the required IAM roles. For more information about this, see Delegate access across AWS accounts using IAM roles in the IAM documentation.
- AWS Command Line Interface (AWS CLI), installed and configured. For testing purposes, you can configure AWS CLI by using the aws configure command or setting environment variables. **Important:** This isn't recommended for production environments and we recommend that this account is only granted least privilege access. For more information about this, see Grant least privilege in the IAM documentation.
- The devops-cdk-cloudcustodian.zip file (attached), downloaded to your local computer.
- Familiarity with Python.
- The required tools (Node.js, AWS Cloud Development Kit (AWS CDK), and Git), installed and configured. You can use the install-prerequisites.sh file in the devops-cdk-cloudcustodian.zip file to install these tools. Make sure you run this file with root privileges.

**Limitations**

- Although this pattern can be used in a production environment, make sure that all IAM roles and policies meet your organization's requirements and policies.

**Package versions**

- Cloud Custodian version 0.9 or later
- TypeScript version 3.9.7 or later
- Node.js version 14.15.4 or later
- npm version 7.6.1 or later
- AWS CDK version 1.96.0 or later

**Architecture**
The diagram shows the following workflow:

1. Cloud Custodian policies are pushed to an AWS CodeCommit repository in the security account. An Amazon CloudWatch Events rule automatically initiates the AWS CodePipeline pipeline.
2. The pipeline fetches the most recent code from CodeCommit and sends it to the continuous integration part of the continuous integration and continuous delivery (CI/CD) pipeline handled by AWS CodeBuild.
3. CodeBuild performs the complete DevSecOps actions, including policy syntax validation on the Cloud Custodian policies, and runs these policies in \texttt{--dryrun} mode to check which resources are identified.
4. If there are no errors, the next task alerts an administrator to review the changes and approve the deployment into the member accounts.

**Technology stack**

- AWS CDK
- CodeBuild
- CodeCommit
- CodePipeline
- IAM
- Cloud Custodian

**Automation and scale**

The AWS CDK pipelines module provisions a CI/CD pipeline that uses CodePipeline to orchestrate the building and testing of source code with CodeBuild, in addition to the deployment of AWS resources with AWS CloudFormation stacks. You can use this pattern for all member accounts and Regions in your organization. You can also extend the Roles creation stack to deploy other IAM roles in your member accounts.
Tools

- **AWS Cloud Development Kit (AWS CDK)** is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- **AWS Command Line Interface (AWS CLI)** is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.
- **AWS CodeBuild** is a fully managed build service in the cloud.
- **AWS CodeCommit** is a version control service that you can use to privately store and manage assets.
- **AWS CodePipeline** is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software.
- **AWS Identity and Access Management** is a web service that helps you securely control access to AWS resources.
- **Cloud Custodian** is a tool that unifies the dozens of tools and scripts most organizations use for managing their public cloud accounts into one open-source tool.
- **Node.js** is a JavaScript runtime built on Google Chrome's V8 JavaScript engine.

Code

For a detailed list of modules, account functions, files, and deployment commands used in this pattern, see the README file in the devops-cdk-cloudcustodian.zip file (attached).

Epics

Set up the pipeline with AWS CDK

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Set up the CodeCommit repository. | 1. Unzip the devops-cdk-cloudcustodian.zip file (attached) in the working directory on your local computer.  
2. Sign in to the AWS Management Console for your security account, open the CodeCommit console, and then create a new devops-cdk-cloudcustodian repository.  
3. Change into the project directory and set up the CodeCommit repository as the origin, commit the changes, and then push them to the origin branch by running the following commands:  
   - `cd devops-cdk-cloudcustodian`  
   - `git init --initial-branch=main` | Developer |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
|     | • `git add .`  
    • `git commit -m 'initial commit'`  
    • `git remote add origin https://git-codecommit.us-east-1.amazonaws.com/v1/devops-cdk-cloudcustodian`  
    • `git push origin main`  
    
    For more information about this, see [Creating a CodeCommit repository](https://aws.amazon.com/documentation/codecommit/) in the AWS CodeCommit documentation. | Developer |
| Install the required tools. | Use the `install-prerequisites.sh` file to install all the required tools on Amazon Linux. This doesn’t include AWS CLI because it comes pre-installed.  
    
    For more information about this, see the [Prerequisites](https://docs.aws.amazon.com/cdk/latest/userguide/quick-start.html) section of [Getting started with the AWS CDK](https://docs.aws.amazon.com/cdk/latest/userguide/quick-start.html) in the AWS CDK documentation. | Developer |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Install the required AWS CDK packages.</td>
<td>1. Set up your virtual environment by running the following command in AWS CLI: <code>$ python3 -m venv .env</code>  &lt;br&gt;2. Activate your virtual environment by running the following command: <code>$ source .env/bin/activate</code>  &lt;br&gt;3. After the virtual environment is activated, install the required dependencies by running the following command: <code>$ pip install -r requirements.txt</code>  &lt;br&gt;4. To add additional dependencies (for example, other AWS CDK libraries), add them to the requirements.txt file, and then run the following command: <code>pip install -r requirements.txt</code></td>
<td>Developer</td>
</tr>
</tbody>
</table>

The following packages are required by AWS CDK and are included in the requirements.txt file:

- `aws-cdk.aws-cloudwatch`
- `aws-cdk.aws-codebuild`
- `aws-cdk.aws-codecommit`
- `aws-cdk.aws-codedeploy`
- `aws-cdk.aws-codepipeline`
- `aws-cdk.aws-codepipeline-actions`
- `aws-cdk.aws-events`
- `aws-cdk.aws-events-targets`
- `aws-cdk.aws-iam`
- `aws-cdk.aws-logs`
- `aws-cdk.aws-s3`
- `aws-cdk.aws-sns`
- `aws-cdk.aws-sns-subscriptions`
- `aws-cdk.aws-sqs`
- `aws-cdk.core`
## Configure your environment

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>

|      | - charge_code: xyz
|      | - type:prod
|      | - division:some division
|      | - partition:us
|      | - scope:pci ``` |
### Bootstrap the AWS accounts

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap the security account.</td>
<td>Bootstrap the deploy_account with the cloudcustodian_stack application by running the following command: <code>cdk bootstrap -a 'python3 cloudcustodian/cloudcustodian_stack.py</code></td>
<td>Developer</td>
</tr>
</tbody>
</table>
| Option 1 - Automatically bootstrap the member accounts. | If the cdk_bootstrap_member_accounts variable is set to `True` in the vars.py file, the accounts specified in the member_accounts variable are automatically bootstrapped by the pipeline.  
If required, you can update `*cdk_bootstrap_role*` with an IAM role that you can assume from the security account and that has the required permissions to bootstrap the AWS CDK.  
New accounts added to the member_accounts variable are automatically bootstrapped by the pipeline so that the required roles can be deployed. | Developer |
| Option 2 - Manually bootstrap the member accounts. | Although we don't recommend using this approach, you can set the value of cdk_bootstrap_member_accounts to `False` and perform this step manually by running the following command: ```$ cdk bootstrap -a 'python3 cloudcustodian/member_account_roles_stack.py' \ 
--trust {security_account_id} \ 
--context assume-role-credentials:writeIamRoleName={role_name}``` | Developer |
## Deploy the AWS CDK stacks

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the IAM roles in the member accounts.</td>
<td>Run the following command to deploy the <code>member_account_roles_stack</code> stack and create the IAM roles in the member accounts:</td>
<td>Developer</td>
</tr>
<tr>
<td>Deploy the Cloud Custodian pipeline stack.</td>
<td>Run the following command to create the Cloud Custodian <code>cloudcustodian_stack.py</code> pipeline that is deployed into the security account:</td>
<td>Developer</td>
</tr>
</tbody>
</table>

- `cdk deploy --all -a 'python3 cloudcustodian/member_account_roles_stack.py' --require-approval never`
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>cdk deploy -a 'python3 cloudcustodian/cloudcustodian_stack.py'</td>
<td></td>
</tr>
</tbody>
</table>

Automatically build CI/CD pipelines and Amazon ECS clusters for microservices using AWS CDK

Created by Varsha Raju (AWS)

| Environment: | PoC or pilot | Technologies: | DevOps; Containers & microservices; Modernization; Infrastructure | AWS services: | AWS CodeBuild; AWS CodeCommit; AWS CodePipeline; Amazon ECS; AWS CDK |

Summary

This pattern describes how to automatically create the continuous integration and continuous delivery (CI/CD) pipelines and underlying infrastructure for building and deploying microservices on Amazon Elastic Container Service (Amazon ECS). You can use this approach if you want to set up proof-of-concept CI/CD pipelines to show your organization the benefits of CI/CD, microservices, and DevOps. You can also use this approach to create initial CI/CD pipelines that you can then customize or change according to your organization’s requirements.

The pattern’s approach creates a production environment and non-production environment that each have a virtual private cloud (VPC) and an Amazon ECS cluster configured to run in two Availability Zones. These environments are shared by all your microservices and you then create a CI/CD pipeline for each microservice. These CI/CD pipelines pull changes from a source repository in AWS CodeCommit, automatically build the changes, and then deploy them into your production and non-production environments. When a pipeline successfully completes all of its stages, you can use URLs to access the microservice in the production and non-production environments.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account.
- An existing Amazon Simple Storage Service (Amazon S3) bucket that contains the starter-code.zip file (attached).
- AWS Cloud Development Kit (AWS CDK), installed and configured in your account. For more information about this, see Getting started with the AWS CDK in the AWS CDK documentation.
- Python 3 and pip, installed and configured. For more information about this, see the Python documentation.
- Familiarity with AWS CDK, AWS CodePipeline, AWS CodeBuild, CodeCommit, Amazon Elastic Container Registry (Amazon ECR), Amazon ECS, and AWS Fargate.
- Familiarity with Docker.
- An understanding of CI/CD and DevOps.

Limitations

- General AWS account limits apply. For more information about this, see AWS service quotas in the AWS General Reference documentation.

Product versions
The code was tested using Node.js version 16.13.0 and AWS CDK version 1.132.0.

Architecture

The diagram shows the following workflow:

1. An application developer commits code to a CodeCommit repository.
2. A pipeline is initiated.
3. CodeBuild builds and pushes the Docker image to an Amazon ECR repository.
4. CodePipeline deploys a new image to an existing Fargate service in a non-production Amazon ECS cluster.
5. Amazon ECS pulls the image from the Amazon ECR repository into a non-production Fargate service.
6. Testing is performed using a non-production URL.
7. The release manager approves the production deployment.
8. CodePipeline deploys the new image to an existing Fargate service in a production Amazon ECS cluster.
9. Amazon ECS pulls the image from the Amazon ECR repository into the production Fargate service.
10. Production users access your feature by using a production URL.

Technology stack

- AWS CDK
- CodeBuild
- CodeCommit
- CodePipeline
- Amazon ECR
- Amazon ECS
- Amazon VPC
**Automation and scale**

You can use this pattern’s approach to create pipelines for microservices deployed in a shared AWS CloudFormation stack. The automation can create more than one Amazon ECS cluster in each VPC and also create pipelines for microservices deployed in a shared Amazon ECS cluster. However, this requires that you provide new resource information as inputs to the pipeline stack.

**Tools**

- **AWS CDK** – AWS Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- **AWS CodeBuild** – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- **AWS CodeCommit** – AWS CodeCommit is a version control service that enables you to privately store and manage Git repositories in the AWS Cloud. CodeCommit eliminates the need for you to manage your own source control system or worry about scaling its infrastructure.
- **AWS CodePipeline** – AWS CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software. You can quickly model and configure the different stages of a software release process. CodePipeline automates the steps required to release your software changes continuously.
- **Amazon ECS** – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service that is used for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of Amazon Elastic Compute Cloud (Amazon EC2) instances that you manage.
- **Docker** – Docker helps developers to pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

**Code**

The code for this pattern is available in the cicdstarter.zip and starter-code.zip files (attached).

**Epics**

**Set up your environment**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set up the working directory for AWS CDK.</td>
<td>1. Create a directory named cicdproject on your local machine. 2. Download the cicdstarter.zip file (attached) into the cicdproject directory and unzip it. This creates a folder named cicdstarter. 3. Run the cd &lt;user-home&gt;/cicdproject/cicdstarter command. 4. Set up the Python virtual environment by running the</td>
<td>AWS DevOps, Cloud infrastructure</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td></td>
<td>python3 -m venv .venv command.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>5. Run the source ./.venv/bin/activate command.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>6. Configure your AWS environment by running the <code>aws configure</code> command or by using the following environment variables:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS_ACCESS_KEY_ID</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS_SECRET_ACCESS_KEY</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS_DEFAULT_REGION</td>
<td></td>
</tr>
</tbody>
</table>

Create the shared infrastructure

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the shared infrastructure.</td>
<td>1. In your working directory, run the <code>cd cicdvpcsecs</code> command.</td>
<td>AWS DevOps, Cloud infrastructure</td>
</tr>
<tr>
<td></td>
<td>2. Run the <code>pip3 install -r requirements.txt</code> command to install all required Python dependencies</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. Run the <code>cdk bootstrap</code> command to set the AWS environment for the AWS CDK.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4. Run the `cdk synth --context aws_account=&lt;aws_account_ID&gt; --context aws_region=&lt;aws-region&gt; command.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>5. Run the `cdk deploy --context aws_account=&lt;aws_account_ID&gt; --context aws_region=&lt;aws-region&gt; command.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>6. The AWS CloudFormation stack creates the following infrastructure:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• A non-production VPC named <code>cicd-vpc-ecs/cicd-vpc-nonprod</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• A production VPC named <code>cicd-vpc-ecs/cicd-vpc-prod</code></td>
<td></td>
</tr>
</tbody>
</table>
### Monitor the AWS CloudFormation stack.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1. Sign in to the AWS Management Console, open the AWS CloudFormation console, and then choose the cicd-vpc-ecs stack from the list. 2. In the stack details pane, choose the <strong>Events</strong> tab and monitor the progress of your stack creation.</td>
<td>AWS DevOps, Cloud infrastructure</td>
</tr>
</tbody>
</table>

### Test the AWS CloudFormation stack.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1. After the cicd-vpc-ecs AWS CloudFormation stack is created, ensure that the cicd-vpc-ecs/cicd-vpc-nonprod and cicd-vpc-ecs/cicd-vpc-prod VPCs are created. 2. Ensure that the cicd-ecs-nonprod and cicd-ecs-prod Amazon ECS clusters are created.</td>
<td>AWS DevOps, Cloud infrastructure</td>
</tr>
</tbody>
</table>

**Important:** Make sure that you record the IDs for the two VPCs and the security group IDs for the default security groups in both VPCs.

### Create a CI/CD pipeline for a microservice

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1. Name your microservice. For example, this pattern uses myservice1 as the microservice's name. 2. In your working directory run the <code>cd &lt;working-directory&gt;/cdkpipeline</code> command. 3. Run the <code>pip3 install -r requirements.txt</code> command.</td>
<td>AWS DevOps, Cloud infrastructure</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
</tbody>
</table>
| 4. Run the full `cdk synth` command that is available in the *Additional information* section of this pattern.  
5. Run the full `cdk deploy` command that is available in the *Additional information* section of this pattern. | Note: You can also provide the values for both commands by using the `cdk.json` file in the directory. | AWS DevOps, Cloud infrastructure |
<p>| Monitor the AWS CloudFormation stack. | Open the AWS CloudFormation console and monitor the progress of the <code>myservice1-cicd-stack</code> stack. Eventually, the status changes to <code>CREATE_COMPLETE</code>. | AWS DevOps, Cloud infrastructure |</p>
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Test the AWS CloudFormation stack.             | 1. On the AWS CodeCommit console, verify that a repository named myservice1 exists and contains the starter code.  
2. On the AWS CodeBuild console, verify that a build project named myservice1 exists.  
3. On the Amazon ECR console, verify that an Amazon ECR repository named myservice1 exists.  
4. On the Amazon ECS console, verify that a Fargate service named myservice1 exists in both a non-production and production Amazon ECS cluster.  
5. On the Amazon Elastic Compute Cloud (Amazon EC2) console, verify that the non-production and production Application Load Balancers are created. Record the DNS names of the ALBs.  
6. On the AWS CodePipeline console, verify that a pipeline named myservice1 exists. It must have Source, Build, Deploy-NonProd, and Deploy-Prod stages. The pipeline should also have an in progress status.  
7. Monitor the pipeline until all stages are complete.  
8. Manually approve it for production.  
9. In a browser window, enter the DNS names of the ALBs.  
10. The application should display Hello World in the non-production and production URLs. |                |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Use the pipeline.                         | 1. Open the CodeCommit repository that you created earlier and open the index.js file.  
2. Replace Hello World with Hello CI/CD.  
3. Save and commit the changes to the main branch.  
4. Verify that the pipeline initiates and that the change goes through the Build, Deploy-NonProd, and Deploy-Prod stages.  
5. Manually approve the production.  
6. Both production and non-production URLs should now display Hello CI/CD. | AWS DevOps, Cloud infrastructure |
| Repeat this epic for each microservice.   | Repeat the tasks in this epic to create a CI/CD pipeline for each of your microservices.                                                                                                                   | AWS DevOps, Cloud infrastructure |

Build a loosely coupled architecture with microservices using DevOps practices and AWS Cloud9

Created by Alexandre Nardi (AWS)

| Environment: PoC or pilot | Technologies: DevOps; Serverless; Websites & web apps; Databases | AWS services: AWS Cloud9; AWS CloudFormation; AWS CodePipeline; Amazon DynamoDB; AWS CodeCommit |

Summary

This pattern demonstrates how to develop a typical web application in a serverless architecture, for developers and development leads who are beginning to test DevOps practices on Amazon Web Services (AWS). It builds a sample application that creates a storefront and backend for browsing and purchasing books, and provides a microservice that can be developed independently. The pattern uses AWS Cloud9 as a development environment, an Amazon DynamoDB database as a data store, and AWS services such as AWS CodePipeline and AWS CodeBuild for continuous integration and continuous deployment (CI/CD) functionality.

The pattern guides you through the following development activities:

- Creating a standard AWS Cloud9 development environment
- Using AWS CloudFormation templates to create a web application and a microservice for books
- Using AWS Cloud9 to modify the front-end, commit changes, and test changes
- Creating and testing a CI/CD pipeline to the microservice
- Automating unit tests

The code for this pattern is provided in GitHub, in the AWS DevOps End-to-End Workshop repository.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Files from the AWS DevOps End-to-End Workshop downloaded to your computer

Important: Building this demo application in your AWS account creates and consumes AWS resources. You are responsible for the cost of the AWS services and resources used to create and run the application. After you finish your work, be sure to remove all resources to avoid ongoing charges. For cleanup instructions, see the Epics section.

Limitations

This walkthrough is intended for demonstration and development purposes only. To use it in a production environment, see Security best practices in the AWS Identity and Access Management (IAM)
documentation, and make the necessary changes to IAM roles, Amazon DynamoDB, and other services used. The web application is derived from the AWS Bookstore Demo App; for additional considerations, see the Known limitations section of the README file.

Architecture

The architecture of the bookstore application is illustrated in the Architecture section of the README file for the AWS Bookstore Demo App.

From a deployment perspective, the Bookstore Demo App uses a single CloudFormation template to deploy all services and objects in one stack. This pattern makes a few changes to demonstrate how a particular developer or team could work in a specific product (Books), and update it independently from the rest of the application. For this reason, the code for this pattern separates the AWS Lambda functions and related objects for the Books microservice into a second CloudFormation template, which creates a Books stack. That makes it possible to see the microservice being updated by using CI/CD practices. In the following diagram, the dashed border identifies the Books microservice.

Tools

Tools

- Jest framework for JavaScript testing
- Python 3.9

Code
The source code and templates for this pattern are available on GitHub, in the [AWS DevOps End-to-End Workshop](https://github.com/aws-ww-end-to-end-workshop) repository. Before you follow the steps in the Epics section, download all the files from the repository to your computer.

**Note:** The Epics section provides the high-level steps for this walkthrough, to give you general information about the process. To complete each step, see the [README file](https://github.com/aws-ww-end-to-end-workshop) in the AWS DevOps End-to-End Workshop repository for detailed instructions.

The [AWS DevOps End-to-End Workshop](https://github.com/aws-ww-end-to-end-workshop) repository extends the [AWS Bookstore Demo App](https://github.com/aws/bookstore-demos) repository and uses a modified version of the [AWS Cloud9 Bootstrapping](https://github.com/aws/aws-cloud9-bootstrapping) code to create the AWS Cloud9 IDE.

### Best practices

Using the Bookstore application is straightforward. Here are some recommended best practices:

- When you install the application, you can use a project name of your choice or use the default name (demobookstore) for convenience.
- After you have the application up and running, it's a good practice to shut down the Amazon Neptune database if you want to keep testing for another day, because the database instance could result in additional charges. However, be aware that the database will automatically be started after seven days.
- For code details, see the documentation for the [AWS Bookstore Demo App](https://github.com/aws/bookstore-demos) repository. It describes each microservice and table.
- For additional best practices, see the *Some challenges if you have time...* section of the [README file](https://github.com/aws-ww-end-to-end-workshop) in the AWS DevOps End-to-End Workshop repository. We recommend that you review the information to dive deep into additional features for security and to practice decoupling services.

### AWS Prescriptive Guidance Patterns

#### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>using <a href="https://aws.amazon.com/systems-manager/parameter-store/">AWS Systems Manager Parameter Store</a></td>
<td></td>
</tr>
</tbody>
</table>

Create a Cart microservice. Use the Books microservice as an example for taking shopping cart-related functions out of the `DemoBookstoreMainTemplate.yml` template and creating a Cart microservice.

#### Clean up

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
|      | Delete the S3 buckets. On the [Amazon S3 console](https://aws.amazon.aws.amazon.com/s3/), delete the following buckets that are associated with the sample web application:  
- Two buckets created for the AWS Bookstore Demo App. The buckets names start with the stack name you provided for AWS CloudFormation when you created the frontend; for example, `DemoBookStoreStack`.  
- One bucket for the build pipeline; for example, `demobookstore-books-service-pipeline-bucket-<YYYYMMDDHHMM>` | Developer |

Delete the stacks. On the [CloudFormation console](https://aws.amazon.aws.amazon.com/cloudformation/), delete the stacks associated with the sample web application:  
- DemoBooksServiceStack  
- DemoBookStoreStack

The removal could take more than 90 minutes. If the removal fails, delete them again, and also delete any manual resources (for example, the VPC or network interfaces) based on notifications.

Delete the IAM roles. On the [IAM console](https://aws.amazon.aws.amazon.com/iam/), delete the following roles:  
- `demobookstore-Cloudformation-role` | Developer |

- Creating a bucket (Amazon S3 documentation)

Additional information

For detailed, step-by-step instructions, see the README file in the AWS DevOps End-to-End Workshop GitHub repository.

**About the May 2023 update:** This pattern was updated to use newer versions of Node and Python. We updated many of the packages in the source code and removed Glyphicon because it's no longer free. We also removed all dependencies on the AWS Bookstore Demo App repository, so the two repositories can now evolve independently.
Build and test iOS apps with AWS CodeCommit, AWS CodePipeline, and AWS Device Farm

Created by Abdullahi Olaoye (AWS)

<table>
<thead>

AWS services: AWS CodeCommit; AWS CodePipeline; AWS Device Farm

Summary

This pattern outlines the steps for creating a continuous integration and continuous delivery (CI/CD) pipeline that uses AWS CodePipeline to build and test iOS applications on real devices on AWS. The pattern uses AWS CodeCommit to store the application code, the Jenkins open-source tool to build the iOS application, and AWS Device Farm to test the built application on real devices. These three phases are orchestrated together in a pipeline by using AWS CodePipeline.

This pattern is based on the post Building and testing iOS and iPadOS apps with AWS DevOps and mobile services on the AWS DevOps blog. For detailed instructions, see the blog post.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Apple developer account
- Build server (macOS)
- Xcode version 11.3 (installed and set up on the build server)
- AWS Command Line Interface (AWS CLI) installed and configured on the workstation
- Basic knowledge of Git

Limitations

- The application build server must be running macOS.
- The build server must have a public IP address, so CodePipeline can connect to it remotely to initiate builds.

Architecture

Source technology stack
• An on-premises iOS application build process that involves using a simulator or manual test on physical devices

**Target technology stack**

• An AWS CodeCommit repository for storing application source code
• A Jenkins server for application builds using Xcode
• An AWS Device Farm device pool for testing applications on real devices

**Target architecture**

When a user commits changes to the source repository, the pipeline (AWS CodePipeline) fetches the code from the source repository, initiates a Jenkins build, and passes the application code to Jenkins. After the build, the pipeline retrieves the build artifact and starts an AWS Device Farm job to test the application against a device pool.
Tools

- **AWS CodePipeline** – AWS CodePipeline is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates. CodePipeline automates the build, test, and deploy phases of your release process every time there is a code change, based on the release model you define.

- **AWS CodeCommit** – AWS CodeCommit is a fully managed source control service that hosts secure Git-based repositories. It makes it easy for teams to collaborate on code in a secure and highly scalable ecosystem. CodeCommit eliminates the need to operate your own source control system or worry about scaling its infrastructure.
• **AWS Device Farm** – AWS Device Farm is an application testing service that lets you improve the quality of your web and mobile apps by testing them across an extensive range of desktop browsers and real mobile devices, without having to provision and manage any testing infrastructure.

• **Jenkins** – Jenkins is an open-source automation server that enables developers to build, test, and deploy their software.

## Best practices

*Author remove these notes: Provide a list of guidelines and recommendations that can help users implement this pattern more effectively.>*

Check AWS CDK applications or CloudFormation templates for best practices by using cdk-nag rule packs

Created by Arun Donti

Environment: Production
Technologies: DevOps; Security, identity, compliance
Workload: Open-source

AWS services: AWS CDK

Summary

This pattern explains how you can use the cdk-nag utility to check AWS Cloud Development Kit (AWS CDK) applications for best practices by using a combination of rule packs. cdk-nag is an open-source project that was inspired by cfn_nag. It implements rules in evaluation packs such as AWS Solutions Library, Health Insurance Portability and Accountability Act (HIPAA), and National Institute of Standards and Technology (NIST) 800-53 by using AWS CDK Aspects. You can check your AWS CDK applications for best practices by using the rules in these packs, detect and remediate code based on best practices, and suppress the rules that you don’t want to use in your evaluations.

You can also use cdk-nag to check your AWS CloudFormation templates by using the cloudformation-include module.

For information about all available packs, see the Rules section of the cdk-nag repository. Evaluation packs are available for:

- AWS Solutions Library
- HIPAA security
- NIST 800-53 rev 4
- NIST 800-53 rev 5
- Payment Card Industry Data Security Standard (PCI DSS) 3.2.1

Prerequisites and limitations

Prerequisites

- An application that uses the AWS CDK

Tools

- AWS CDK – Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and you can launch and configure them...
together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

## Epics

### Integrate cdk-nag with your AWS CDK application

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Learn about cdk-nag.</td>
<td>Navigate to the cdk-nag GitHub repository and read through the documentation.</td>
<td>App developer</td>
</tr>
<tr>
<td>Install the cdk-nag package in your AWS CDK application.</td>
<td>To use cdk-nag in your AWS CDK application, you must install it first. cdk-nag is available to download from PyPI, npm, NuGet, and Apache Maven. For the latest information about available versions and download locations, see the Readme file in the repository.</td>
<td>App developer</td>
</tr>
<tr>
<td>Choose your NagPacks.</td>
<td>cdk-nag has different packs of rules called NagPacks. Each NagPack contains rules that conform to a specific standard. For example, the AWS Solutions NagPack contains general best practices, and the NIST 800-53 rev 5 NagPack can help with compliance. You can apply multiple NagPacks to your application, and you can add and remove packs as necessary. For a list of available packs, see the Readme file in the GitHub repository. For information about the individual rules in each pack, see the Rules section of the GitHub repository.</td>
<td>App developer</td>
</tr>
<tr>
<td>Integrate cdk-nag into your AWS CDK application.</td>
<td>You can integrate cdk-nag into your application on an applicationwide level, or integrate it into individual stages or stacks in your application. For example, to integrate the AWS Solutions and HIPAA security NagPacks into an AWS CDK v2 TypeScript application on an applicationwide level, you can use the following code:</td>
<td>App developer</td>
</tr>
</tbody>
</table>
### Task Description

```javascript
import { App, Aspects } from 'aws-cdk-lib';
import { CdkTestStack } from '../../lib/cdk-test-stack';
import { AwsSolutionsChecks, HIPAASecurityChecks } from 'cdk-nag';

const app = new App();
new CdkTestStack(app, 'CdkNagDemo');
// Simple rule informational messages
Aspects.of(app).add(new AwsSolutionsChecks());
// Additional explanations on the purpose of triggered rules
Aspects.of(app).add(new HIPAASecurityChecks({ verbose: true }));
```

Configure cross-account access to Amazon DynamoDB

Created by Shashi Dalmia (AWS) and Jay Enjamoori (AWS)

| Environment: Production | Technologies: DevOps; Databases; Security, identity, compliance | AWS services: Amazon DynamoDB; AWS Identity and Access Management; AWS Lambda |

**Summary**

This pattern explains the steps for configuring cross-account access to Amazon DynamoDB. Amazon Web Services (AWS) services can access DynamoDB tables that are in the same AWS account if the service has the appropriate AWS Identity and Access Management (IAM) permissions set up in the database. However, access from a different AWS account requires setting up IAM permissions and establishing a trust relationship between the two accounts.

This pattern provides steps and sample code to demonstrate how you can configure AWS Lambda functions in one account to read and write to a DynamoDB table in a different account.

**Prerequisites and limitations**

- Two active AWS accounts. This pattern refers to these accounts as Account A and Account B.
- AWS Command Line Interface (AWS CLI) installed and configured to access Account A, to create the DynamoDB database. The other steps in this pattern provide instructions for using the IAM, DynamoDB, and Lambda consoles. If you’re planning to use AWS CLI instead, configure it to access both accounts.

**Architecture**

In the following diagram, AWS Lambda, Amazon EC2, and DynamoDB are all in the same account. In this scenario, Lambda functions and Amazon Elastic Compute Cloud (Amazon EC2) instances can access DynamoDB.
If resources in a different AWS account try to access DynamoDB, they require setting up cross-account access and a trust relationship. For example, in the following diagram, to enable access between DynamoDB in Account A and the Lambda function in Account B, you must create a trust relationship between the accounts and grant appropriate access to the Lambda service and users, as described in the Epics (p. 922) section.
Tools

AWS services

- **Amazon DynamoDB** is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
- **AWS Lambda** is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
This pattern includes sample code in the Additional information (p. 931) section to illustrate how you can configure a Lambda function in Account B to write and read from the DynamoDB table in Account A. The code is provided for illustration and testing purposes only. If you're implementing this pattern in a production environment, use the code as a reference and customize it for your own environment.

This pattern illustrates cross-account access with Lambda and DynamoDB. You can use the same steps for other AWS services as well, but make sure that you grant and configure the appropriate permissions in both accounts. For example, if you want to grant access to an Amazon Relational Database Service (Amazon RDS) database in Account A, create a role for that database and bind it with a trust relationship. In Account B, if you want to use Amazon EC2 instead of AWS Lambda, create the respective IAM policy and role, and then attach them to the EC2 instance.

Epics

Create a DynamoDB table in Account A

</tr>
</tbody>
</table>
### Configure access to Account A from Account B

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Create a policy to access Account A.** | 1. Sign in to Account B at https://<account-ID-for-Account-B>.signin.aws.amazon.com/console.  
2. Open the IAM console at https://console.aws.amazon.com/iam/.  
3. In the navigation pane of the console, choose Policies, and then choose Create Policy.  
4. Choose the JSON tab.  
5. Type or paste the following JSON document:  

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
    }
  ]
}
``` | AWS DevOps |

Note the ARN for the role in Account A.

1. In the navigation pane of the IAM console, choose Roles.  
2. In the search box, enter **DynamoDB-FullAccess-For-Account-B** (or the role name you created in the previous story), and choose the role.  
3. In the summary page for the role, copy the Amazon Resource Name (ARN). You'll use the ARN when setting up the Lambda code in Account B.
<table>
<thead>
<tr>

</table>
| Create a Lambda function to read data from DynamoDB.                | 1. In the navigation pane of the Lambda console, choose **Functions**, and then choose **Create function**.  
2. For **Name**, enter `lambda_read_function`.  
3. For **Runtime**, choose **Python 3.8** or later.  
4. For **Permissions**, change default execution role, choose **Use an existing role**.  
5. For **Existing role**, choose **DynamoDB-FullAccess-in-Account-A**.  
6. Choose **Create function**.  
7. In the **Code** tab, paste the **Lambda read function** sample code provided in Additional information (p. 931) section in this pattern. Make sure to provide the correct role ARN (from the epic Create a role in Account A) for the RoleArn field, and change region_name to where the DynamoDB table is created in account A (from the epic Create a DynamoDB table in Account A). Failing to do this results in a ResourceNotFoundException error.  
8. To deploy the code, choose **Deploy**.  
9. Run the function by choosing **Test**. This prompts you to configure a test event. Create a new event with your preferred name, such as **MyTestEventForRead**, and save the configuration.  
10. Run the function again by choosing **Test**. This runs the code with the event name you provided.  
11. Check the output from the function. It should be similar to the output shown in the **Lambda read function** section of Additional information (p. 931). This output indicates that | AWS DevOps |

929
the function accessed the DynamoDB table in Account A and was able to read the data you added to the table.

For more information about creating Lambda functions, see the Lambda documentation.

## Clean up resources

### Task
Delete the resources you created.

### Description
If you’re running this pattern in a testing or proof of concept (PoC) environment, delete the resources you created to avoid incurring costs.

1. In Account B, delete the two Lambda functions and other resources you created to connect to DynamoDB.
2. In Account A, delete the DynamoDB table you created.
3. IAM policies do not cost anything, so you can keep them as is. However, for security, we recommend that you delete the following roles and policies you created for this pattern:
   - Account A: DynamoDB- Full-Access-for-Account-A role
   - Account B: DynamoDB- FullAccess-in-Account-A role
   - Account B: DynamoDB- FullAccess-Policy-in-Account-A policy

### Skills required

Configure mutual TLS authentication for applications running on Amazon EKS

Summary

Certificate-based mutual Transport Layer Security (TLS) is an optional TLS component that provides two-way peer authentication between servers and clients. With mutual TLS, clients must provide an X.509 certificate during the session negotiation process. The server uses this certificate to identify and authenticate the client.

Mutual TLS is a common requirement for Internet of Things (IoT) applications and can be used for business-to-business applications or standards such as Open Banking.

This pattern describes how to configure mutual TLS for applications running on an Amazon Elastic Kubernetes Service (Amazon EKS) cluster by using an NGINX ingress controller. You can enable built-in mutual TLS features for the NGINX ingress controller by annotating the ingress resource. For more information about mutual TLS annotations on NGINX controllers, see Client certificate authentication in the Kubernetes documentation.

Important: This pattern uses self-signed certificates. We recommend that you use this pattern only with test clusters, and not in production environments. If you want to use this pattern in a production environment, you can use AWS Private Certificate Authority (AWS Private CA) or your existing public key infrastructure (PKI) standard to issue private certificates.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account.
- An existing Amazon EKS cluster.
- AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows.
- The kubectl command line utility, installed and configured to access the Amazon EKS cluster. For more information about this, see Installing kubectl in the Amazon EKS documentation.
- An existing Domain Name System (DNS) name to test the application.

Limitations

- This pattern uses self-signed certificates. We recommend that you use this pattern only with test clusters, and not in production environments.

Architecture
Technology stack

- Amazon EKS
- Amazon Route 53
- Kubectl

Tools

- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- Amazon Route 53 is a highly available and scalable DNS web service.
- Kubectl is a command line utility that you use to interact with an Amazon EKS cluster.

Epics

Generate the self-signed certificates

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generate the CA key and certificate.</td>
<td>Generate the certificate authority (CA) key and certificate by running the following command.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td>openssl req -x509 -sha256 -newkey rsa:4096 -keyout ca.key -out ca.crt -days 356 -nodes -subj '/CN=Test Cert Authority'</td>
<td></td>
</tr>
</tbody>
</table>
### Generate the server key and certificate, and sign with the CA certificate.

Generate the server key and certificate, and sign with the CA certificate by running the following command.

```bash
openssl req -new -newkey rsa:4096 -keyout server.key -out server.csr -nodes -subj '/CN=<your_domain_name>' && openssl x509 -req -sha256 -days 365 -in server.csr -CA ca.crt -CAkey ca.key -set_serial 01 -out server.crt
```

**Important:** Make sure that you replace `<your_domain_name>` with your existing domain name.

### Generate the client key and certificate, and sign with the CA certificate.

Generate the client key and certificate, and sign with the CA certificate by running the following command.

```bash
openssl req -new -newkey rsa:4096 -keyout client.key -out client.csr -nodes -subj '/CN=Test' && openssl x509 -req -sha256 -days 365 -in client.csr -CA ca.crt -CAkey ca.key -set_serial 02 -out client.crt
```

### Deploy the NGINX ingress controller

#### Task

Deploy the NGINX ingress controller in your Amazon EKS cluster.

**Description**

Deploy the NGINX ingress controller by using the following command.

```bash
kubectl apply -f https://raw.githubusercontent.com/kubernetes/ingress-nginx/controller-v1.7.0/deploy/static/provider/aws/deploy.yaml
```

**Skills required**

DevOps engineer

#### Task

Verify that the NGINX ingress controller service is running.

**Description**

Verify that the NGINX ingress controller service is running by using the following command.

**Skills required**

DevOps engineer
## Create a namespace in the Amazon EKS cluster to test mutual TLS

<table>

</tbody>
</table>

Create the Kubernetes deployment and service in the `mtls` namespace by running the following command.

```
kubectl create -f mtls.yaml -n mtls
```

Verify that the Kubernetes deployment is created.

Run the following command to verify that the deployment is created and has one pod in available status.

```
kubectl get deploy -n mtls
```

Verify that the Kubernetes service is created.

Verify that the Kubernetes service is created by running the following command.

```
kubectl get service -n mtls
```

### Create a secret in the `mtls` namespace

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a secret for the ingress resource.</td>
<td>Run the following command to create a secret for the NGINX ingress controller by using the certificates that you created earlier.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td><code>kubectl create secret generic mtls-certs --from-file=tl.crt=server.crt --from-file=tl.key=server.key --from-file=ca.crt=ca.crt -n mtls</code></td>
<td>---</td>
</tr>
</tbody>
</table>
## Task

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Your secret has a server certificate for the client to identify the server and a CA certificate for the server to verify the client certificates.</td>
<td></td>
</tr>
</tbody>
</table>

### Create the ingress resource in the mtls namespace

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the ingress resource in the mtls namespace.</td>
<td>Create a file named ingress.yaml. Paste the following code into the file (replace <code>&lt;your_domain_name&gt;</code> with your existing domain name).</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

```yaml
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
  annotations:
    nginx.ingress.kubernetes.io/auth-tls-verify-client: "on"
    nginx.ingress.kubernetes.io/auth-tls-secret: mtls/mtls-certs
name: mtls-ingress
spec:
  ingressClassName: nginx
  rules:
  - host: "*.<your_domain_name>"
    http:
      paths:
      - path: /
        pathType: Prefix
        backend:
          service:
            name: mtls-service
            port:
              number: 5678
    tls:
      - hosts:
        - "*.<your_domain_name>"
        secretName: mtls-certs
```

Create the ingress resource in the mtls namespace by running the following command.

```bash
kubectl create -f ingress.yaml -n mtls
```
### Task: Verify that the ingress resource is created.

**Description:** Verify that the ingress resource is created by running the following command.

```
kubectl get ing -n mtls
```

**Important:** Make sure that the address of the ingress resource shows the load balancer created for the NGINX ingress controller.

**Skills required:** DevOps engineer

---

### Configure DNS to point the hostname to the load balancer

#### Task: Create CNAME record that points to the load balancer for the NGINX ingress controller.

**Description:** Sign in to the AWS Management Console, open the Amazon Route 53 console, and create a Canonical Name (CNAME) record that points `mtls.<your_domain_name>` to the load balancer for the NGINX ingress controller.

For more information, see [Creating records by using the Route 53 console](https://docs.aws.amazon.com/Route53/latest/DeveloperGuide/creating-records.html) in the Route 53 documentation.

**Skills required:** DevOps engineer

---

### Test the application

#### Task: Test mutual TLS setup without certificates.

**Description:** Run the following command.

```
curl -k https://mtls.<your_domain_name>
```

You should receive the "400 No required SSL certificate was sent" error response.

**Skills required:** DevOps engineer

#### Task: Test mutual TLS setup with certificates.

**Description:** Run the following command.

```
curl -k https://mtls.<your_domain_name>
```

**Skills required:** DevOps engineer
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>--cert client.crt --key client.key</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>You should receive the “mTLS is working” response.</td>
<td></td>
</tr>
</tbody>
</table>

Create a custom log parser for Amazon ECS using a Firelens log router

Created by Varun Sharma (AWS)

Environment: Production
Technologies: DevOps; Containers & microservices
Workload: All other workloads

AWS services: Amazon ECS

Summary

Firelens is a log router for Amazon Elastic Container Service (Amazon ECS) and AWS Fargate. You can use Firelens to route container logs from Amazon ECS to Amazon CloudWatch and other destinations (for example, Splunk or Sumo Logic). Firelens works with Fluentd or Fluent Bit as the logging agent, which means that you can use Amazon ECS task definition parameters to route logs.

By choosing to parse logs at the source level, you can analyze your logging data and perform queries to more efficiently and effectively respond to operational issues. Because different applications have different logging patterns, you need to use a custom parser that structures the logs and makes searching easier at your end destination.

This pattern uses a Firelens log router with a custom parser to push logs to CloudWatch from a sample Spring Boot application running on Amazon ECS. You can then use Amazon CloudWatch Logs Insights to filter the logs based on custom fields that are generated by the custom parser.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account.
- AWS Command Line Interface (AWS CLI), installed and configured on your local machine.
- Docker, installed and configured on your local machine.
- An existing Spring Boot-based containerized application on Amazon Elastic Container Registry (Amazon ECR).

Architecture
Technology stack

- CloudWatch
- Amazon ECR
- Amazon ECS
- Fargate
- Docker
- Fluent Bit

Tools

- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable.
- **Amazon ECS** – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service that makes it easy to run, stop, and manage containers on a cluster.
- **AWS Identity and Access Management (IAM)** – IAM is a web service for securely controlling access to AWS services.
- **AWS CLI** – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.
- **Docker** – Docker is an open platform for developing, shipping, and running applications.

Code

The following files are attached to this pattern:

- **customFluentBit.zip** – Contains the files to add the custom parsing and configurations.
- **firelens_policy.json** – Contains the policy document to create an IAM policy.
- **Task.json** – Contains a sample task definition for Amazon ECS.
## Epics

**Create a custom Fluent Bit image**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an Amazon ECR repository.</td>
<td>Sign in to the AWS Management Console, open the Amazon ECR console, and create a repository called fluentbit_custom. For more information about this, see <a href="https://docs.aws.amazon.com/AmazonECR/latest/userguide/creating-repository.html">Creating a repository</a> in the Amazon ECR documentation.</td>
<td>Systems administrator, Developer</td>
</tr>
</tbody>
</table>
| Unzip the customFluentBit.zip package. | 1. Download the customFluentBit.zip package (attached) to your local machine.  
2. Unzip to the customFluentBit directory by running the following command: `unzip -d customFluentBit.zip`  
3. The directory contains the following files that are required for adding the custom parsing and configurations:  
   - parsers/springboot_parser.conf  
     - Contains the parser directive and defines the regular expression (regex) pattern for the custom parser. You can add the regex pattern for your specific parser.  
   - conf/parse_springboot.conf  
     - Contains the filter and the service directive.  
   - The Dockerfile | |
| Create the custom Docker image. | 1. Change the directory to customFluentBit.  
2. Open the Amazon ECR console, choose the fluentbit_custom repository, and then choose **View push commands.**  
3. Upload your project. | Systems administrator, Developer |
### Set up the Amazon ECS cluster

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an Amazon ECS cluster.</td>
<td>Create an Amazon ECS cluster by following the instructions from the <em>Networking only template</em> section of <em>Creating a cluster</em> in the Amazon ECS documentation. <strong>Note:</strong> Make sure that you choose <em>Create VPC</em> to create a new virtual private cloud (VPC) for your Amazon ECS cluster.</td>
<td>Systems administrator, Developer</td>
</tr>
</tbody>
</table>

### Set up the Amazon ECS task

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set up the Amazon ECS task execution IAM role.</td>
<td>Create an Amazon ECS task execution IAM role by using the AmazonECSTaskExecutionRolePolicy managed policy. For more information about this, see <em>Amazon ECS task execution IAM role</em> in the Amazon ECS documentation. <strong>Note:</strong> Make sure that you record the IAM role's Amazon Resource Name (ARN).</td>
<td>Systems administrator, Developer</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach the IAM policy to the Amazon ECS task execution IAM role.</td>
<td>1. Create an IAM policy by using the <code>firelens_policy.json</code> (attached) policy document. For more information about this, see <em>Creating policies on the JSON tab</em> in the IAM documentation. 2. Attach this policy to the Amazon ECS task execution</td>
<td>Systems administrator, Developer</td>
</tr>
</tbody>
</table>
### Set up the Amazon ECS task definition.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>IAM role that you created earlier. For more information about this, see [Adding IAM policies (AWS CLI)] in the IAM documentation.</td>
<td></td>
</tr>
</tbody>
</table>

1. Update the following sections in the Task.json sample task definition (attached):
   - Update the `executionRoleArn` and `taskRoleArn` with the ARN of the task execution IAM role
   - Update the image in `containerDefinitions` with the custom Fluent Bit Docker image that you created earlier
   - Update the image in `containerDefinitions` with your application image's name

2. Open the Amazon ECS console, choose Task Definitions, choose Create new task definition, and then choose Fargate on the Select compatibilities page.

3. Choose Configure via Json, paste the updated Task.json file into the text area, and then choose Save.

4. Create the task definition.

For more information about this, see [Creating a task definition](#) in the Amazon ECS documentation.

### Run the Amazon ECS task

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Run the Amazon ECS task.</td>
<td>Systems administrator, Developer</td>
</tr>
</tbody>
</table>

On the Amazon ECS console, choose Clusters, choose the cluster that you created earlier, and then run the standalone task.

Create a pipeline and AMI using CodePipeline and HashiCorp Packer

Created by Akash Kumar (AWS)

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: DevOps</th>
<th>Target: Amazon Machine Images (AMI)</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Rehost</td>
<td>Workload: All other workloads</td>
<td>Technologies: DevOps; Modernization; Websites &amp; web apps</td>
</tr>
</tbody>
</table>

Summary

This pattern provides code samples and steps to create both a pipeline in the Amazon Web Services (AWS) Cloud by using AWS CodePipeline and an Amazon Machine Image (AMI) by using HashiCorp Packer. The pattern is based on the continuous integration practice, which automates the building and testing of code with a Git-based version control system. In this pattern, you create and clone a code repository by using AWS CodeCommit. Then, create a project and configure your source code by using AWS CodeBuild. Finally, create an AMI that gets committed to your repository.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon Linux AMI for launching Amazon Elastic Compute Cloud (Amazon EC2) instances
- HashiCorp Packer 0.12.3 or later
- Amazon CloudWatch Events (optional)
- Amazon CloudWatch Logs (optional)

Architecture

The following diagram shows an example of application code that automates the creation of an AMI by using this pattern's architecture.
The diagram shows the following workflow:

1. The developer commits code changes to a private CodeCommit Git repository. Then, CodePipeline uses CodeBuild to initiate the build and add new artifacts that are ready for deployment to the Amazon Simple Storage Service (Amazon S3) bucket.

2. CodeBuild uses Packer to bundle and package the AMI based on a JSON template. If enabled, CloudWatch Events can automatically start the pipeline when a change occurs in the source code.

**Technology stack**

- CodeBuild
- CodeCommit
- CodePipeline
- CloudWatch Events (optional)

**Tools**

- **AWS CodeBuild** – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.

- **AWS CodeCommit** – AWS CodeCommit is a version control service that enables you to privately store and manage Git repositories in the AWS Cloud. CodeCommit eliminates the need for you to manage your own source control system or worry about scaling its infrastructure.

- **AWS CodePipeline** – AWS CodePipeline is a continuous delivery service that you can use to model, visualize, and automate the steps required to release your software.

- **HashiCorp Packer** – HashiCorp Packer is an open-source tool for automating the creation of identical machine images from a single source configuration. Packer is lightweight, runs on every major operating system, and creates machine images for multiple platforms in parallel.

**Code**
This pattern includes the following attachments:

- `buildspec.yml` – This file uses CodeBuild to build and create an artifact for deployment.
- `amazon-linux_packer-template.json` – This file uses Packer to create an Amazon Linux AMI.

**Epics**

**Set up the code repository**

Create a pipeline and deploy artifact updates to on-premises EC2 instances using CodePipeline

Created by Akash Kumar (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>DevOps</th>
<th>Target:</th>
<th>Amazon EC2/On-Premises</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>
<td>Rehost</td>
<td>Technologies:</td>
<td>DevOps; Modernization; Websites &amp; web apps</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>AWS services:</td>
<td>AWS CodeBuild; AWS CodeCommit; AWS CodeDeploy; AWS CodePipeline</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern provides code samples and steps to create a pipeline in the Amazon Web Services (AWS) Cloud and deploy updated artifacts to on-premises Amazon Elastic Compute Cloud (Amazon EC2) instances in AWS CodePipeline. The pattern is based on the continuous integration practice. This practice automates the building and testing of code with a Git-based version control system. In this pattern, you create and clone a code repository by using AWS CodeCommit. Then, you create a project and configure your source code by using AWS CodeBuild. Finally, you create your application and configure its target environment for on-premises EC2 instances by using AWS CodeDeploy.

Prerequisites and limitations

Prerequisites

- An active AWS account
- User-defined tags to identify EC2 instances during deployment
- CodeDeploy agent, installed on EC2 instances
- Your required runtime software, installed on EC2 instances
- Amazon Corretto 8 for the Java Development Kit
- Apache Tomcat web server, installed
- Amazon CloudWatch Events (optional)
- A key pair to log in to the web server (optional)
- An Apache Maven application project for a web application

Architecture

The following diagram shows an example Java web application that’s deployed to on-premises EC2 instances by using this pattern's architecture.
The diagram shows the following workflow:

1. The developer commits code changes to a private CodeCommit Git repository.
2. CodePipeline uses CodeBuild to initiate the build and add new artifacts that are ready for deployment in the Amazon Simple Storage Service (Amazon S3) bucket.
3. CodePipeline uses the CodeDeploy agent to pre-install any dependencies required for the deployment artifact changes.
4. CodePipeline uses the CodeDeploy agent to deploy the artifacts from the S3 bucket to target EC2 instances. If enabled, CloudWatch Events can automatically start the pipeline when a change occurs in the source code.

**Technology stack**

- CodeBuild
- CodeCommit
- CodeDeploy
- CodePipeline
- CloudWatch Events (optional)

**Tools**

- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS CodeDeploy](#) automates deployments to Amazon Elastic Compute Cloud (Amazon EC2) or on-premises instances, AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
This pattern includes the following attachments:

- `buildspec.yml` – This file specifies the actions that CodeBuild requires to build and create an artifact for deployment.
- `appspec.yml` – This file specifies the actions that CodeDeploy requires to create an application and configure a target environment for on-premises EC2 instances.
- `install_dependencies.sh` – This file installs dependencies for the Apache Tomcat web server.
- `start_server.sh` – This file starts the Apache Tomcat web server.
- `stop_server.sh` – This file stops the Apache Tomcat web server.

## Epics

### Set up the code repository

Create dynamic CI pipelines for Java and Python projects automatically

*Created by Aromal Raj Jayarajan (AWS), Amarnath Reddy (AWS), MAHESH RAGHUNANDANAN (AWS), and Vijesh Vijayakumaran Nair (AWS)*

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: PoC or pilot</th>
<th>Technologies: DevOps; Infrastructure; Serverless; Cloud-native</th>

<td>AWS services: AWS CodeBuild; AWS CodePipeline; AWS Lambda; AWS Step Functions; AWS CodeCommit</td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

This pattern shows how to create dynamic continuous integration (CI) pipelines for Java and Python projects automatically by using AWS developer tools.

As technology stacks diversify and development activities increase, it can become difficult to create and maintain CI pipelines that are consistent across an organization. By automating the process in AWS Step Functions, you can make sure that your CI pipelines are consistent in their usage and approach.

To automate the creation of dynamic CI pipelines, this pattern uses the following variable inputs:

- Programming language (Java or Python only)
- Pipeline name
- Required pipeline stages

**Note:** Step Functions orchestrates pipeline creation by using multiple AWS services. For more information about the AWS services used in this solution, see the Tools section of this pattern.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- An Amazon S3 bucket in the same AWS Region that this solution is being deployed
- An AWS Identity and Access Management (IAM) principal that has the AWS CloudFormation permissions required to create the resources needed for this solution

**Limitations**

- This pattern supports Java and Python projects only.
- The IAM roles provisioned in this pattern follow the principle of least privilege. The IAM roles’ permissions must be updated based on the specific resources that your CI pipeline needs to create.
Architecture

Target technology stack

- AWS CloudFormation
- AWS CodeBuild
- AWS CodeCommit
- AWS CodePipeline
- IAM
- Amazon Simple Storage Service (Amazon S3)
- AWS Systems Manager
- AWS Step Functions
- AWS Lambda
- Amazon DynamoDB

Target architecture

The following diagram shows an example workflow for creating dynamic CI pipelines for Java and Python projects automatically by using AWS developer tools.

The diagram shows the following workflow:

1. An AWS user provides the input parameters for CI pipeline creation in JSON format. This input starts a Step Functions workflow (state machine) that creates a CI pipeline by using AWS developer tools.
2. A Lambda function reads a folder named input-reference, which is stored in an Amazon S3 bucket, and then generates a buildspec.yml file. This generated file defines the CI pipeline stages and is stored back in the same Amazon S3 bucket that stores the parameter references.
3. Step Functions checks the CI pipeline creation workflow’s dependencies for any changes, and updates the dependencies stack as needed.
4. Step Functions creates the CI pipeline resources in a CloudFormation stack, including a CodeCommit repository, CodeBuild project, and a CodePipeline pipeline.

5. The CloudFormation stack copies the sample source code for the selected technology stack (Java or Python) and the `buildspec.yml` file to the CodeCommit repository.

6. CI pipeline runtime details are stored in a DynamoDB table.

**Automation and scale**

- This pattern is for use in a single development environment only. Configuration changes are required for use across multiple development environments.
- To add support for more than one CloudFormation stack, you can create additional CloudFormation templates. For more information, see [Getting started with AWS CloudFormation](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/) in the CloudFormation documentation.

**Tools**

- **AWS Step Functions** is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- **AWS CodeBuild** is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- **AWS CodeCommit** is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- **AWS CodePipeline** helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- **AWS Key Management Service (AWS KMS)** helps you create and control cryptographic keys to help protect your data.
- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **AWS CloudFormation** helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- **Amazon DynamoDB** is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- **AWS Systems Manager Parameter Store** provides secure, hierarchical storage for configuration data management and secrets management.

**Code**

The code for this pattern is available in the GitHub [automated-ci-pipeline-creation](https://github.com/) repository. The repository contains the CloudFormation templates required to create the target architecture outlined in this pattern.
Best practices

- Don't enter credentials (secrets) such as tokens or passwords directly into CloudFormation templates or Step Functions action configurations. If you do, the information will be displayed in the DynamoDB logs. Instead, use AWS Secrets Manager to set up and store secrets. Then, reference the secrets stored in Secrets Manager within the CloudFormation templates and Step Functions action configurations as needed. For more information, see What is AWS Secrets Manager in the Secrets Manager documentation.

- Configure server-side encryption for CodePipeline artifacts stored in Amazon S3. For more information, see Configure server-side encryption for artifacts stored in Amazon S3 for CodePipeline in the CodePipeline documentation.

- Apply least-privilege permissions when configuring IAM roles. For more information, see Apply least-privilege permissions in the IAM documentation.

- Make sure that your Amazon S3 bucket is not publicly accessible. For more information, see Configuring block public access setting for your S3 buckets in the Amazon S3 documentation.

- Make sure that you activate versioning for your Amazon S3 bucket. For more information, see Using versioning in S3 buckets in the Amazon S3 documentation.

- Use IAM Access Analyzer when configuring IAM policies. The tool provides actionable recommendations to help you author secure and functional IAM policies. For more information, see Using AWS Identity and Access Management Access Analyzer in the IAM documentation.

- When possible, define specific access conditions when configuring IAM policies.

- Activate Amazon CloudWatch logging for monitoring and auditing purposes. For more information, see What is Amazon CloudWatch Logs? in the CloudWatch documentation.

Epics

</tbody>
</table>
## Upload the Solution Templates folder from the cloned GitHub repository to your Amazon S3 bucket.

Copy the contents from the cloned `Solution-Templates` folder and upload them into the Amazon S3 bucket that you created.

For more information, see [Uploading objects](#) in the Amazon S3 documentation.

**Note:** Make sure that you upload the contents of the `Solution-Templates` folder only. You can upload the files at the Amazon S3 bucket's root level only.

### Deploy the solution

**Task** | **Description** | **Skills required**
--- | --- | ---
Create a CloudFormation stack to deploy the solution by using the `template.yml` file in the cloned GitHub repository. | 1. Sign into the AWS Management Console and then open the AWS CloudFormation console. 2. Choose `Create stack`. A dropdown list appears. 3. In the dropdown list, select `With new resources (standard)`. The `Create stack` page opens. 4. In the `Specify template` section, select the checkbox next to `Upload a template file`. 5. Select `Choose file`. Then, navigate to the cloned GitHub repository's root folder and select the `template.yml` file. Then, choose `Open`. 6. Choose `Next`. The `Specify stack details` page opens. 7. In the `Parameters` section, specify the following parameters: | AWS administrator, AWS DevOps
### AWS Prescriptive Guidance Patterns

Deploy CloudWatch Synthetics canaries by using Terraform

Created by Dhrubajyoti Mukherjee (AWS) and Jean-Francois Landreau (AWS)

</thead>
<tbody>
<tr>
<td>Amazon CloudWatch; Amazon S3; Amazon SNS; Amazon VPC; AWS Identity and Access Management</td>
<td></td>
</tr>
</tbody>
</table>

Summary

It’s important to validate the health of a system from a customer perspective and confirm that customers are able to connect. This is more difficult when the customers don’t constantly call the endpoint. Amazon CloudWatch Synthetics supports the creation of canaries, which can test both public and private endpoints. By using canaries, you can know the status of a system even if it isn’t in use. These canaries are either Node.js Puppeteer scripts or Python Selenium scripts.

This pattern describes how to use HashiCorp Terraform to deploy canaries that test private endpoints. It embeds a Puppeteer script that tests whether a URL returns 200-OK. The Terraform script can then be integrated with the script that deploys the private endpoint. You can also modify the solution to monitor public endpoints.

Prerequisites and limitations

Prerequisites

• An active Amazon Web Services (AWS) account with a virtual private cloud (VPC) and private subnets
• The URL of the endpoint that can be reached from the private subnets
• Terraform installed in the deployment environment

Limitations

The current solution works for the following CloudWatch Synthetics runtime versions:

• syn-nodejs-puppeteer-3.4
• syn-nodejs-puppeteer-3.5
• syn-nodejs-puppeteer-3.6
• syn-nodejs-puppeteer-3.7

As new runtime versions are released, you might need to update the current solution. You will also need to modify the solution to keep up with security updates.
Product versions

- Terraform 1.3.0

Architecture

Amazon CloudWatch Synthetics is based on CloudWatch, Lambda, and Amazon Simple Storage Service (Amazon S3). Amazon CloudWatch offers a wizard to create the canaries and a dashboard that displays the status of the canary runs. The Lambda function runs the script. Amazon S3 stores the logs and screenshots from the canary runs.

This pattern simulates a private endpoint through an Amazon Elastic Compute Cloud (Amazon EC2) instance deployed in the targeted subnets. The Lambda function requires elastic network interfaces in the VPC where the private endpoint is deployed.

The diagram shows the following:

1. The Synthetics canary initiates the canary Lambda function.
2. The canary Lambda function connects to the elastic network interface.
3. The canary Lambda function monitors the status of the endpoint.
4. The Synthetics canary pushes run data to the S3 bucket and CloudWatch metrics.
5. A CloudWatch alarm is initiated based on the metrics.
6. The CloudWatch alarm initiates the Amazon Simple Notification Service (Amazon SNS) topic.

Tools

AWS services

- **Amazon CloudWatch** helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
• **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

• **Amazon Simple Notification Service (Amazon SNS)** helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.

• **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

• **Amazon Virtual Private Cloud (Amazon VPC)** helps you launch AWS resources into a virtual network that you’ve defined. This virtual network resembles a traditional network that you’d operate in your own data center, with the benefits of using the scalable infrastructure of AWS. This pattern uses VPC endpoints and elastic network interfaces.

**Other services**

• **HashiCorp Terraform** is an open-source infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources. This pattern uses Terraform to deploy the infrastructure.

• **Puppeteer** is a Node.js library. The CloudWatch Synthetics runtime uses the Puppeteer framework.

**Code**

The solution is available in the GitHub [cloud-watch-synthetics-canary-terraform](https://github.com/cloud-watch-synthetics-canary-terraform) repository. For more information, see the Additional information section.

**Epics**

**Implement the solution for monitoring a private URL**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gather requirements for monitoring the private URL.</td>
<td>Gather the full URL definition: domain, parameters, and headers. To communicate privately to Amazon S3 and Amazon CloudWatch, use VPC endpoints. Note how the VPC and subnets are accessible to the endpoint. Consider the frequency of canary runs.</td>
<td>Cloud architect, Network administrator</td>
</tr>
</tbody>
</table>
| Modify the existing solution to monitor the private URL. | Modify the `terraform.tfvars` file:  
  - name – The name of your canary.  
  - runtime_version – The runtime version of the canary. We recommend using `syn-nodejs-puppeteer-3.7`.  
  - take_screenshot – Whether a screenshot should be taken.  
  - api_hostname – The hostname of the endpoint that is monitored. | Cloud architect |
### Task Description

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>• api_path</td>
<td>The path of the endpoint that is monitored.</td>
<td></td>
</tr>
<tr>
<td>• vpc_id</td>
<td>The VPC ID that is used by the canary Lambda function.</td>
<td></td>
</tr>
<tr>
<td>• subnet_ids</td>
<td>The subnet IDs that are used by the canary Lambda function.</td>
<td></td>
</tr>
<tr>
<td>• frequency</td>
<td>The run frequency of the canary in minutes.</td>
<td></td>
</tr>
<tr>
<td>• alert_sns_topic</td>
<td>The SNS topic to which the CloudWatch alarm notification is sent.</td>
<td></td>
</tr>
</tbody>
</table>

### Deploy and operate the solution.

To deploy the solution, do the following:

1. From the `cloudwatch-synthetics-canary-terraform` directory in your development environment, initialize Terraform.

   ```bash
   terraform init
   ```

2. Plan and review the changes.

   ```bash
   terraform plan
   ```

3. Deploy the solution.

   ```bash
   terraform apply
   ```

### Troubleshooting

<table>
<thead>
<tr>
<th>Issue</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deletion of the provisioned resources gets stuck.</td>
<td>Manually delete the canary Lambda function, corresponding elastic network interface, and security group, in that order.</td>
</tr>
</tbody>
</table>

Additional information

Repository artifacts

The repository artifacts are in the following structure.

```

### README.md
### main.tf
### modules
#   ### canary
#   ### canary-infra
### terraform.tfvars
### tf.plan
### variable.tf
```

The main.tf file contains the core module, and it deploys two submodules:

- canary-infra deploys the infrastructure required for the canaries.
- canary deploys the canaries.

The input parameters for the solution are located in the terraform.tfvars file. You can use the following code example to create one canary.

```hcl
module "canary" {
  source = "./modules/canary"
  name   = var.name
  runtime_version = var.runtime_version
  take_screenshot = var.take_screenshot
  api_hostname = var.api_hostname
  api_path = var.api_path
  reports_bucket = module.canary_infra.reports_bucket
  role = module.canary_infra.role
  security_group_id = module.canary_infra.security_group_id
  subnet_ids = var.subnet_ids
  frequency = var.frequency
  alert_sns_topic = var.alert_sns_topic
}
```

The corresponding .var file follows.

```
name   = "my-canary"
runtime_version = "syn-nodejs-puppeteer-3.7"
take_screenshot = false
api_hostname = "mydomain.internal"
api_path = "/path?param=value"
vpc_id = "vpc_id"
subnet_ids = ["subnet_id1"]
frequency = 5
alert_sns_topic = "arn:aws:sns:eu-central-1:1111111111:yyyyy"
```

Cleaning up the solution

If you are testing this in a development environment, you can clean up the solution to avoid accruing costs.

1. On the AWS Management Console, navigate to the Amazon S3 console. Empty the Amazon S3 bucket that the solution created. Make sure to take a backup of the data, if required.
2. In your development environment, from the cloudwatch-synthetics-canary-terraform directory, run the destroy command.

```bash
terraform destroy
```
Deploy a CI/CD pipeline for Java microservices on Amazon ECS

Created by Vijay Thompson (AWS) and Sankar Sangubotla (AWS)

| Environment: PoC or pilot | Technologies: DevOps; Containers & microservices | AWS services: AWS CodeBuild; AWS EC2 Container Registry; Amazon ECS; AWS Fargate; AWS CodePipeline |

Summary

This pattern guides you through the steps for deploying a continuous integration and continuous delivery (CI/CD) pipeline for Java microservices on an existing Amazon Elastic Container Service (Amazon ECS) cluster by using AWS CodeBuild. When the developer commits the changes, the CI/CD pipeline is initiated and the build process starts in CodeBuild. When the build is complete, the artifact is pushed to Amazon Elastic Container Registry (Amazon ECR) and the latest build from Amazon ECR is picked up and pushed to the Amazon ECS service.

Prerequisites and limitations

Prerequisites

- An existing Java microservices application running on Amazon ECS
- Familiarity with AWS CodeBuild and AWS CodePipeline

Architecture

Source technology stack

- Java microservices running on Amazon ECS
- Code repository in Amazon ECR
- AWS Fargate

Source architecture
Target technology stack

- Amazon ECR
- Amazon ECS
- AWS Fargate
- AWS CodePipeline
- AWS CodeBuild

Target architecture
Automation and scale

CodeBuild buildspec.yml file:

```yaml
version: 0.2
phases:
  pre_build:
    commands:
      - echo Logging in to Amazon ECR...
      - aws --version
      - $(aws ecr get-login --region $AWS_DEFAULT_REGION --no-include-email)
      - REPOSITORY_URI=$AWS_ACCOUNT_ID.dkr.ecr.$AWS_DEFAULT_REGION.amazonaws.com/
      - COMMIT_HASH=$(echo $CODEBUILD_RESOLVED_SOURCE_VERSION | cut -c 1-7)
      - IMAGE_TAG=build-$(echo $CODEBUILD_BUILD_ID | awk -F":" '{print $2}')
  build:
    commands:
      - echo Build started on `date`
      - mvn clean install
      - echo Building the Docker image...
      - docker build -t $REPOSITORY_URI:$BUILD_TAG .
      - docker tag $REPOSITORY_URI:$BUILD_TAG $REPOSITORY_URI:$IMAGE_TAG
```
post_build:
  commands:
  - echo Build completed on `date`
  - echo Pushing the Docker images...
  - docker push $REPOSITORY_URI:$BUILD_TAG
  - docker push $REPOSITORY_URI:$IMAGE_TAG
  - echo Writing image definitions file...
  - printf '(["name":"%s","imageUri":"%s"])' $DOCKER_CONTAINER_NAME $REPOSITORY_URI:$IMAGE_TAG
  > imagedefinitions.json
  - cat imagedefinitions.json
artifacts:
  files:
  - imagedefinitions.json
  - target/DockerDemo.jar

Tools

AWS services

- **AWS CodeBuild** is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy. AWS CodeBuild scales continuously and processes multiple builds concurrently, so your builds are not left in the queue.

- **AWS CodePipeline** helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously. You can integrate AWS CodePipeline with third-party services like GitHub, or use an AWS services such as AWS CodeCommit or Amazon ECR.

- **Amazon Elastic Container Registry (Amazon ECR)** is a fully managed registry that makes it easy for developers to store, manage, and deploy Docker container images. Amazon ECR is integrated with Amazon ECS to simplify your development-to-production workflow. Amazon ECR hosts your images in a highly available and scalable architecture so you can deploy containers for your applications reliably. Integration with AWS Identity and Access Management (IAM) provides resource-level control of each repository.

- **Amazon Elastic Container Service (Amazon ECS)** highly scalable, high-performance container orchestration service that supports Docker containers and allows you to easily run and scale containerized applications on AWS. Amazon ECS eliminates the need for you to install and operate your own container orchestration software, manage and scale a cluster of virtual machines, or schedule containers on those virtual machines.

- **AWS Fargate** is a compute engine for Amazon ECS that allows you to run containers without having to manage servers or clusters. With AWS Fargate, you no longer have to provision, configure, and scale clusters of virtual machines to run containers. This removes the need to choose server types, decide when to scale your clusters, or optimize cluster packing.

Other tools

- **Docker** is a platform that lets you build, test, and deliver applications in packages called containers.

- **Git** is a distributed version-control system for tracking changes in source code during software development. It is designed for coordinating work among programmers, but it can be used to track changes in any set of files. Its goals include speed, data integrity, and support for distributed, non-linear workflows. You can also use AWS CodeCommit as an alternative to Git.

### Set up the build project in AWS CodeBuild

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a CodeBuild build project.</td>
<td>In the <a href="https://console.aws.amazon.com/codebuild/">AWS CodeBuild console</a>, create a build project, and specify its name.</td>
<td>App developer, AWS systems administrator</td>
</tr>
<tr>
<td>Select the source.</td>
<td>This pattern uses Git for the code repository, so choose <a href="https://github.com">GitHub</a> from the list of available options. Choose a public repository or from your GitHub account.</td>
<td>App developer, AWS systems administrator</td>
</tr>
<tr>
<td>Select a repository.</td>
<td>Select the repository from which you want to build the code.</td>
<td>App developer, AWS systems administrator</td>
</tr>
<tr>
<td>Select the environment.</td>
<td>You can select from a list of managed images or opt for a custom image using Docker. This pattern uses the following managed image:</td>
<td>App developer, AWS systems administrator</td>
</tr>
<tr>
<td></td>
<td>• Amazon Linux 2</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Runtime: Standard</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Image version 1.0</td>
<td></td>
</tr>
<tr>
<td>Choose a service role.</td>
<td>You can create a service role or select from a list of existing roles.</td>
<td>App developer, AWS systems administrator</td>
</tr>
<tr>
<td>Add environment variables.</td>
<td>In the <a href="https://docs.aws.amazon.com/codebuild/latest/userguide/environment-variables-reference.html">Additional configuration</a> section, configure the following environment variables:</td>
<td>App developer, AWS systems administrator</td>
</tr>
<tr>
<td></td>
<td>• <code>AWS_DEFAULT_REGION</code> for the default AWS Region</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>AWS_ACCOUNT_ID</code> for the user account number</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>IMAGE_REPO</code> for the Amazon ECR private repository</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>BUILD_TAG</code> for the version of the build (<a href="https://docs.aws.amazon.com/codebuild/latest/userguide/environment-variables-reference.html">latest</a> build is the value for this variable)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>DOCKER_CONTAINER_NAME</code> for the name of the container in the task</td>
<td></td>
</tr>
<tr>
<td></td>
<td>These variables are placeholders in the <code>buildspec.yml</code> file and will be replaced with their respective values.</td>
<td></td>
</tr>
</tbody>
</table>
## Create a buildspec file.

You can create a `buildspec.yml` file at the same location as `pom.xml` and add the configuration that is provided in this pattern, or use the online buildspec editor and add the configuration. Configure the environmental variables with the appropriate values by following the steps provided.

**Skills required:** App developer, AWS systems administrator

## Configure the project for artifacts.

(Optional) Configure the build project for artifacts, if required.

**Skills required:** App developer, AWS systems administrator

## Configure Amazon CloudWatch Logs.

(Optional) Configure Amazon CloudWatch Logs for the build project, if required. This step is optional but recommended.

**Skills required:** App developer, AWS systems administrator

## Configure Amazon S3 logs.

(Optional) Configure Amazon Simple Storage Service (Amazon S3) logs for the build project, if you want to store the logs.

**Skills required:** App developer, AWS systems administrator

## Configure the pipeline in AWS CodePipeline

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a pipeline.</td>
<td>On the <a href="http://aws.amazon.com/codepipeline/docs">AWS CodePipeline console</a>, create a pipeline and specify its name. For more information about creating a pipeline, see the <a href="http://aws.amazon.com/codepipeline/docs">AWS CodePipeline documentation</a>.</td>
<td>App developer, AWS systems administrator</td>
</tr>
<tr>
<td>Select a service role.</td>
<td>Create a service role or select from the list of existing service roles. If you are creating a service role, provide a name for the role and select the option for CodePipeline to create the role.</td>
<td>App developer, AWS systems administrator</td>
</tr>
<tr>
<td>Choose an artifact store.</td>
<td>In Advanced settings, if you want Amazon S3 to create a bucket and store the artifacts in it, use the default location for the artifact store. Or, select a custom location and specify an existing bucket. You can also choose to encrypt the artifact by using an encryption key.</td>
<td>App developer, AWS systems administrator</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Specify the source provider.</td>
<td>For <strong>Source provider</strong>, choose <strong>GitHub (Version 2)</strong>.</td>
<td>App developer, AWS systems administrator</td>
</tr>
<tr>
<td>Select the repository and branch of the code.</td>
<td>If you are not logged in, provide the connection details to connect to GitHub, and then select the repository name and branch name.</td>
<td>App developer, AWS systems administrator</td>
</tr>
<tr>
<td>Change detection options.</td>
<td>Choose <strong>Start the pipeline on source code change</strong> and move to the next page.</td>
<td>App developer, AWS systems administrator</td>
</tr>
</tbody>
</table>
| Select a build provider. | For **Build provider**, choose **AWS CodeBuild**, and then provide the AWS Region and project name details for the build project.  
For **Build type**, choose **Single build**. | App developer, AWS systems administrator |
| Choose a deploy provider. | For **Deploy provider**, choose Amazon ECS. Choose the cluster name, the service name, the image definitions file, if any, and a deployment timeout value, if required. Choose **Create pipeline**. | App developer, AWS systems administrator |

Use AWS CodeCommit and AWS CodePipeline to deploy a CI/CD pipeline in multiple AWS accounts

Created by Kirankumar Chandrashekar (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>DevOps</th>
<th>Workload:</th>
<th>All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>AWS CodeCommit; AWS CodePipeline</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern shows you how to deploy a continuous integration and continuous delivery (CI/CD) pipeline for your application code workloads in separate Amazon Web Services (AWS) accounts for DevOps, developer, staging, and production workflows.

You can use a multiple AWS account strategy to provide a high level of resource or security isolation, optimize costs, and separate out your production workflow.

Your application's code remains identical in all these separate AWS accounts and is maintained on a central AWS CodeCommit repository hosted by your DevOps account. Your developer, staging, and production accounts have separate Git branches in this CodeCommit repository.

For example, when code is committed to the developer Git branch in your central CodeCommit repository, Amazon EventBridge in your DevOps account notifies EventBridge in your developer account of the repository changes. In your developer account, AWS CodePipeline and the source stage go into InProgress status. The source stage is configured from the developer Git branch in the central CodeCommit repository and CodePipeline assumes a service role for the DevOps account.

The contents of the CodeCommit repository in the developer branch are uploaded to an artifact store in an Amazon Simple Storage Service (Amazon S3) bucket and encrypted with an AWS Key Management Service (AWS KMS) key. After the source stage's status changes to Succeeded in CodePipeline, the code will be transitioned to the next stage of the pipeline execution.

Prerequisites and limitations

Prerequisites

- Existing AWS accounts for each required environment (DevOps, developer, staging, and production). These accounts can be hosted by AWS Organizations.
- AWS Command Line Interface (AWS CLI), installed and configured.

Architecture
### Technology stack

- **AWS CodeBuild**
- **AWS CodeCommit**
- **AWS CodePipeline**
- **Amazon EventBridge**
- **AWS Identity and Access Management (IAM)**
- **AWS KMS**
- **AWS Organizations**
- **Amazon S3**

### Tools

- **AWS CodeBuild** – CodeBuild is a fully managed continuous integration service that compiles source code, runs tests, and produces software packages that are ready to deploy.
- **AWS CodeCommit** – CodeCommit is a fully-managed source-control service that hosts secure Git-based repositories.
- **AWS CodePipeline** – CodePipeline is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates.
- **Amazon EventBridge** – EventBridge is a serverless event bus service for connecting your applications with data from a variety of sources.
- **AWS Identity and Access Management (IAM)** – IAM helps you to manage access to AWS services and resources securely.
- **AWS KMS** – AWS Key Management Service (AWS KMS) helps you create and manage cryptographic keys and control their use across a wide range of AWS services and in your applications.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.
## Epics

### Create resources in your DevOps AWS account

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a CodeCommit repository.</td>
<td>Sign in to the AWS Management Console for your DevOps account, and open the CodeCommit console. Create a repository and set up all the required Git branches for your developer, staging, and production AWS accounts. For help with this and other stories, see the &quot;Related resources&quot; section.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Create access credentials for the CodeCommit repository.</td>
<td>On the IAM console, create access credentials to allow application developers to push and pull the application’s code base from the CodeCommit repository.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Create an IAM role for CodePipeline service roles.</td>
<td>On the IAM console, create an IAM role that can be used by all your CodePipeline service roles to access the central CodeCommit repository.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td>Set up the EventBridge rules for your other AWS accounts.</td>
<td>On the Amazon EventBridge console, set up rules to send notifications about relevant CodeCommit repository changes to EventBridge in the individual developer, staging, and production AWS accounts.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td>Create an AWS KMS key.</td>
<td>On the AWS KMS console, create a KMS key that allows CodePipeline in your individual developer, staging, and production AWS accounts to encrypt and decrypt artifacts.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>

### Create resources in your other AWS accounts

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set up EventBridge to receive events from the DevOps AWS account.</td>
<td>Sign in to the AWS Management Console for one of your individual AWS accounts (developer, staging, or production). Create the EventBridge rules and roles for your individual AWS accounts.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>
Create an S3 bucket. | On the Amazon S3 console, create an S3 bucket to store CodePipeline artifacts. | Cloud administrator

Create all required AWS resources for CodePipeline stages. | Create all the other AWS resources that will be required by the CodePipeline stages. These resources will vary depending on the role of each AWS account in your CI/CD pipeline. | Cloud administrator

Create an IAM role. | On the IAM console, create an IAM role for the CodePipeline service role. This service role must be able to assume the IAM role in the DevOps account to access the CodeCommit repository. | Cloud administrator

Create a pipeline in CodePipeline. | On the CodePipeline console, create a pipeline. Then create a source stage that points to the CodeCommit repository in the DevOps account for its individual Git branch. | Cloud administrator

Repeat the steps for all your AWS accounts. | Repeat these steps for all the AWS accounts that are required as part of your CI/CD strategy. | Cloud administrator

**Related resources**

Create resources in your DevOps AWS account

- Create a CodeCommit repository
- Set up a CodeCommit repository
- Create and share a branch in your CodeCommit repository
- Create access credentials for the CodeCommit repository
- Create an IAM role for CodePipeline service roles
- Set up rule in EventBridge
- Create an AWS KMS key
- Set up account policies and roles for CodePipeline

Create resources in your other AWS accounts
• Turn on EventBridge to receive events from your DevOps AWS account
• Create an S3 bucket for CodePipeline artifacts
• Create all other necessary AWS resources for CodePipeline stages
• Create an IAM role for CodePipeline service role
• Create a pipeline in CodePipeline
• Create a pipeline in CodePipeline that uses resources from another AWS account

Other resources

• Establish your best practice AWS environment
• Authentication and access control for CodeCommit
Deploy a firewall using AWS Network Firewall and AWS Transit Gateway

*Created by Shrikant Patil (AWS)*

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: PoC or pilot</th>
<th>Technologies: DevOps; Networking; Security, identity, compliance</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws-network-firewall-deployment-with-transit-gateway</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**AWS services:** AWS Network Firewall; AWS Transit Gateway; Amazon VPC; Amazon CloudWatch

**Summary**

This pattern shows you how to deploy a firewall by using AWS Network Firewall and AWS Transit Gateway. The Network Firewall resources are deployed by using an AWS CloudFormation template. Network Firewall automatically scales with your network traffic and can support hundreds of thousands of connections, so that you don't have to worry about building and maintaining your own network security infrastructure. A transit gateway is a network transit hub that you can use to interconnect your virtual private clouds (VPCs) and on-premises networks.

In this pattern, you also learn to include an inspection VPC in your network architecture. Finally, this pattern explains how to use Amazon CloudWatch to provide real-time activity monitoring for your firewall.

**Tip:** It's a best practice to avoid using a Network Firewall subnet to deploy other AWS services. This is because Network Firewall can't inspect traffic from sources or destinations within a firewall's subnet.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- AWS Identity and Access Management (IAM) role and policy permissions
- CloudFormation template permissions

**Limitations**

You could have issues with domain filtering and a different kind of configuration could be necessary. For more information, see [Stateful domain list rule groups in AWS Network Firewall](#) in the Network Firewall documentation.

**Architecture**

**Technology stack**

- Amazon CloudWatch Logs
AWS Prescriptive Guidance Patterns
Tools

- Amazon VPC
- AWS Network Firewall
- AWS Transit Gateway

Target architecture

The following diagram shows how to use Network Firewall and Transit Gateway to inspect your traffic:

The architecture includes the following components:

- Your application is hosted in the two spoke VPCs. The VPCs are monitored by Network Firewall.
- The egress VPC has direct access to the internet gateway but is not protected by Network Firewall.
- The inspection VPC is where Network Firewall is deployed.

Automation and scale

You can use [CloudFormation](https://aws.amazon.com/cloudformation/) to create this pattern by using [infrastructure as code](https://aws.amazon.com/infrastructure-as-code/).

Tools

AWS services

- [Amazon CloudWatch Logs](https://aws.amazon.com/cloudwatch/logs/) helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- [Amazon Virtual Private Cloud (Amazon VPC)](https://aws.amazon.com/vpc/) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- [AWS Network Firewall](https://aws.amazon.com/network-firewall/) is a stateful, managed, network firewall and intrusion detection and prevention service for VPCs in the AWS Cloud.
- [AWS Transit Gateway](https://aws.amazon.com/transit-gateway/) is a central hub that connects VPCs and on-premises networks.

Code

The code for this pattern is available in the GitHub [AWS Network Firewall deployment with Transit Gateway](https://github.com/aws-samples/aws-network-firewall-deployment-with-transit-gateway) repository. You can use the CloudFormation template from this repository to deploy a single inspection VPC that uses Network Firewall.
Epics

Create the spoke VPC and inspection VPC

<table>

<tr>
<td></td>
<td><strong>Create a transit gateway attachment</strong> for the following:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• An <strong>Inspection</strong> attachment in the inspection VPC and Transit Gateway subnet</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• A <strong>SpokeVPCA</strong> attachment in the spoke VPCA and private subnet</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• A <strong>SpokeVPCB</strong> attachment in the spoke VPCB and private subnet</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• An <strong>EgressVPC</strong> attachment in the egress VPC and private subnet</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1. <strong>Create a transit gateway route table</strong> for the spoke VPC. This route table must be associated to all the VPCs other than the inspection VPC.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. <strong>Create a transit gateway route table</strong> for the firewall. This route table must be associated to the inspection VPC only.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. Add a route to the transit gateway route table for the firewall:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• For 0.0.0/0, use the <strong>EgressVPC</strong> attachment.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• For the <strong>SpokeVPCA</strong> CIDR block, use the <strong>SpokeVPC1</strong> attachment.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• For the <strong>SpokeVPCB</strong> CIDR block, use the <strong>SpokeVPC2</strong> attachment.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4. Add a route to the transit gateway route table for the spoke VPC. For 0.0.0/0, use the <strong>Inspection</strong> VPC attachment.</td>
<td></td>
</tr>
</tbody>
</table>
## Create the firewall and routes

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a firewall in the inspection VPC.</td>
<td>1. Sign in to the AWS Management Console and open the <a href="https://aws.amazon.com/vpc/">Amazon VPC console</a>.&lt;br&gt;2. In the navigation pane, under Network Firewall, choose Firewalls.&lt;br&gt;3. Choose Create firewall.&lt;br&gt;4. For Name, enter the name that you want to use to identify this firewall. You can't change the name of a firewall after you create it.&lt;br&gt;5. For VPC, select your inspection VPC.&lt;br&gt;6. For Availability Zone and Subnet, select the zone and firewall subnet that you identified.&lt;br&gt;7. In the Associated firewall policy section, choose Associate an existing firewall policy, and then select the firewall policy that you created earlier.&lt;br&gt;8. Choose Create firewall.</td>
<td>AWS DevOps</td>
</tr>
<tr>
<td>Create a firewall policy.</td>
<td>1. Sign in to the AWS Management Console and open the <a href="https://aws.amazon.com/vpc/">Amazon VPC console</a>.&lt;br&gt;2. In the navigation pane, under Network Firewall, choose Firewall policies.&lt;br&gt;3. On the Describe firewall policy page, choose Create firewall policy.&lt;br&gt;4. For Name, enter the name that you want to use for the firewall policy. You’ll use the name to identify the policy when you associate the policy with your firewall later in this pattern. You can’t change the name of a firewall policy after you create it.&lt;br&gt;5. Choose Next.&lt;br&gt;6. On the Add rule groups page, in the Stateless rule group.</td>
<td>AWS DevOps</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td></td>
<td>section, choose <strong>Add stateless rule groups</strong>.</td>
<td></td>
</tr>
<tr>
<td>7.</td>
<td>In the <strong>Add from existing rule groups</strong> dialog box, select the check box for the stateless rule group that you created earlier. Choose <strong>Add rule groups</strong>. <strong>Note:</strong> At the bottom of the page, the firewall policy's capacity counter shows the capacity consumed by adding this rule group next to the maximum capacity allowed for a firewall policy.</td>
<td></td>
</tr>
<tr>
<td>8.</td>
<td>Set the stateless default action to <strong>Forward to stateful rules</strong>.</td>
<td></td>
</tr>
<tr>
<td>9.</td>
<td>In the <strong>Stateful rule group</strong> section, choose <strong>Add stateful rule groups</strong>, and then select the check box for the stateful rule group that you created earlier. Choose <strong>Add rule groups</strong>.</td>
<td></td>
</tr>
<tr>
<td>10.</td>
<td>Choose <strong>Next</strong> to step through the rest of the setup wizard, and then choose <strong>Create firewall policy</strong>.</td>
<td></td>
</tr>
</tbody>
</table>
## Update your VPC route tables

### Inspection VPC route tables

1. In the ANF subnet route table (Inspection-ANFRT), add 0.0.0/0 to the Transit Gateway ID.
2. In the Transit Gateway subnet route table (Inspection-TGWRT), add 0.0.0/0 to the EgressVPC.

### SpokeVPCA route table

In the private route table, add 0.0.0.0/0 to the Transit Gateway ID.

### Spoke VPCB route table

In the private route table, add 0.0.0.0/0 to the Transit Gateway ID.

### Egress VPC route tables

In the egress public route table, add the SpokeVPCA and Spoke VPCB CIDR block to the Transit Gateway ID. Repeat the same step for the private subnet.

## Set up CloudWatch to perform real-time network inspection

### Update the firewall's logging configuration.

1. Sign in to the AWS Management Console and open the Amazon VPC console.
2. In the navigation pane, under Network Firewall, choose Firewalls.
3. In the Firewalls page, choose the name of the firewall that you want to edit.
4. Choose the Firewall details tab. In the Logging section, choose Edit.
5. Adjust the Log type selections as needed. You can configure logging for alert and flow logs.
### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Alert</strong> – Sends logs for traffic that matches any stateful rule where the action is set to <strong>Alert</strong> or <strong>Drop</strong>. For more information about stateful rules and rule groups, see <a href="https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/SAW-EIP.html">Rule groups in AWS Network Firewall</a>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Flow</strong> – Sends logs for all network traffic that the stateless engine forwards to the stateful rules engine.</td>
<td></td>
</tr>
</tbody>
</table>

6. For each selected log type, choose the destination type, and then provide the information for the logging destination. For more information, see [AWS Network Firewall logging destinations](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/NetworkFirewall-LogSettings.html) in the Network Firewall documentation.

7. Choose **Save**.

### Verify the setup

<table>

Deploy an AWS Glue job with an AWS CodePipeline CI/CD pipeline

Created by Bruno Klein (AWS) and Luis Henrique Massao Yamada (AWS)

| Environment: Production | Technologies: DevOps; Big data | AWS services: AWS Glue; AWS CodeCommit; AWS CodePipeline; AWS Lambda |

Summary

This pattern demonstrates how you can integrate Amazon Web Services (AWS) CodeCommit and AWS CodePipeline with AWS Glue, and use AWS Lambda to launch jobs as soon as a developer pushes their changes to a remote AWS CodeCommit repository.

When a developer submits a change to an extract, transform, and load (ETL) repository and pushes the changes to AWS CodeCommit, a new pipeline is invoked. The pipeline initiates a Lambda function that launches an AWS Glue job with these changes. The AWS Glue job performs the ETL task.

This solution is helpful in the situation where businesses, developers, and data engineers want to launch jobs as soon as changes are committed and pushed to the target repositories. It helps achieve a higher level of automation and reproducibility, therefore avoiding errors during the job launch and lifecycle.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Git installed on the local machine
- Amazon Cloud Development Kit (Amazon CDK) installed on the local machine
- Python installed on the local machine
- The code in the Attachments section

Limitations

- The pipeline is finished as soon as the AWS Glue job is successfully launched. It does not wait for the conclusion of the job.
- The code provided in the attachment is intended for demo purposes only.

Architecture

Target technology stack

- AWS Glue
- AWS Lambda
- AWS CodePipeline
- AWS CodeCommit
Target architecture

The process consists of these steps:

1. The developer or data engineer makes a modification in the ETL code, commits, and pushes the change to AWS CodeCommit.
2. The push initiates the pipeline.
3. The pipeline initiates a Lambda function, which calls `codecommit:GetFile` on the repository and uploads the file to Amazon Simple Storage Service (Amazon S3).
4. The Lambda function launches a new AWS Glue job with the ETL code.
5. The Lambda function finishes the pipeline.

Automation and scale

The sample attachment demonstrates how you can integrate AWS Glue with AWS CodePipeline. It provides a baseline example that you can customize or extend for your own use. For details, see the Epics section.

Tools

- AWS CodePipeline – AWS CodePipeline is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates.
• **AWS CodeCommit** – AWS CodeCommit is a fully managed source control service that hosts secure, Git-based repositories.

• **AWS Lambda** – AWS Lambda is a serverless compute service that lets you run code without provisioning or managing servers.

• **AWS Glue** – AWS Glue is a serverless data integration service that makes it easy to discover, prepare, and combine data for analytics, machine learning, and application development.

• **Git client** – Git provides GUI tools, or you can use the command line or a desktop tool to check out the required artifacts from GitHub.

• **AWS CDK** – The AWS CDK is an open source software development framework that helps you define your cloud application resources by using familiar programming languages.

Deploy an Amazon EKS cluster from AWS Cloud9 using an EC2 instance profile

Created by Sagar Panigrahi (AWS)

<table>

Summary

This pattern describes how to use AWS Cloud9 and AWS CloudFormation to create an Amazon Elastic Kubernetes Service (Amazon EKS) cluster that can be operated without enabling programmatic access for users in your Amazon Web Services (AWS) account.

AWS Cloud9 is a cloud-based integrated development environment (IDE) that helps you write, run, and debug your code by using a browser. AWS Cloud9 is used as a control center that provisions an Amazon EKS cluster by using Amazon Elastic Compute Cloud (Amazon EC2) instance profiles and AWS CloudFormation templates.

You can use this pattern if you don't want to create AWS Identity and Access Management (IAM) users and want to use IAM roles instead. Role-based access control (RBAC) regulates access to resources based on the roles of individual users. This pattern demonstrates how to update RBAC within an Amazon EKS cluster to allow access to a specific IAM role.

The pattern's setup also helps your DevOps team use AWS Cloud9 features to maintain and develop infrastructure as code (IaC) resources for creating Amazon EKS infrastructure.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Permissions to create IAM roles and policies for the account. The IAM role for the user must include the AWSCloud9Administrator policy. The AWSServiceRoleForAmazonEKS and eksNodeRoles roles must also be created because they are required to create an Amazon EKS cluster.
- Knowledge of Kubernetes concepts.

Limitations

- This pattern describes how to create a basic Amazon EKS cluster. For production clusters, you must update the AWS CloudFormation template.
- The pattern doesn't deploy additional Kubernetes components (for example, Fluentd, ingress controllers, or storage controllers).
Architecture

Technology stack

- AWS Cloud9
- AWS CloudFormation
- Amazon EKS
- IAM

Automation and scale

You can expand this pattern and incorporate it into continuous integration and continuous deployment (CI/CD) pipelines to automate the complete provisioning of Amazon EKS.

Tools

- AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications.
- AWS Cloud9 – AWS Cloud9 offers a rich code-editing experience with support for several programming languages and runtime debuggers, and a built-in terminal.
- AWS CLI – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.
- Kubect – kubectl is a command line utility that you can use to interact with an Amazon EKS cluster.

| Install kubectl in the AWS Cloud9 environment.  
Install `kubectl` in your AWS Cloud9 environment by following the instructions from [Installing kubectl](https://docs.aws.amazon.com/eks/latest/userguide/install-kubectl.html) in the Amazon EKS documentation. | Cloud administrator |

Update the new Amazon EKS configuration in AWS Cloud9.  
Run the following command in the AWS Cloud9 terminal to update the kubeconfig from the Amazon EKS cluster to the AWS Cloud9 environment:  
`aws eks update-kubeconfig --name EKS-DEV2 --region <your_AWS_Region>` | Cloud administrator |
## AWS Prescriptive Guidance Patterns

### Related resources

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Important:** EKS-DEV2 is the name of the Amazon EKS cluster in the AWS CloudFormation template that you used to create the cluster. Run the `kubectl get all -A` command to view all Kubernetes resources. | **Add the administrator IAM role to the Kubernetes RBAC.** Run the following command in your AWS Cloud9 terminal to open the RBAC configuration map for Amazon EKS in edit mode:  

```bash
ekubectl edit cm/aws-auth -n kube-system
```

Append the following lines under the `mapRoles` section:

```
- groups:
  - system:masters
  roleARN: <ARN_of_IAM_role_from_second_epic>
  username: eksadmin
```

Lint the YAML-formatted file to avoid syntax errors. Save the file using `vi` commands and then exit the file.  

**Note:** By adding this section, you inform the Kubernetes RBAC that `<ARN_of_IAM_role_from_second_epic>` is to receive full administrator access on the Amazon EKS cluster. This means that the identified IAM role can carry out administrative actions on the Kubernetes cluster. AWS adds the existing section under `mapRoles` while the Amazon EKS cluster is provisioned. | Cloud administrator |

Deploy code in multiple AWS Regions using AWS CodePipeline, AWS CodeCommit, and AWS CodeBuild

Created by Rama Anand Krishna Varanasi (AWS)

<table>
<thead>
<tr>
<th>Created by: AWS</th>
<th>Environment: PoC or pilot</th>
<th>Technologies: Management &amp; governance; DevOps</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>AWS CodeCommit; AWS CodePipeline; AWS CodeBuild</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern demonstrates how to build infrastructure or architecture across multiple Amazon Web Services (AWS) Regions by using AWS CloudFormation. It includes continuous integration (CI)/continuous deployment (CD) across multiple AWS Regions for faster deployments. The steps in this pattern have been tested for the creation of an AWS CodePipeline job to deploy to three AWS Regions as an example. You can change the number of Regions based on your use case.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Two AWS Identity and Access Management (IAM) roles for AWS CodeBuild and AWS CloudFormation with proper policies for CodeBuild to perform the CI tasks of testing, bundling, packaging the artifacts, and deploying to multiple AWS Regions in parallel. Note: Cross-check the policies created by CodePipeline to verify that CodeBuild and AWS CloudFormation have proper permissions in the CI and CD phases.
- A CodeBuild role with the AmazonS3FullAccess and CloudWatchFullAccess policies. These policies give CodeBuild access to watch events of AWS CodeCommit through Amazon CloudWatch and to use Amazon Simple Storage Service (Amazon S3) as an artifact store.
- An AWS CloudFormation role with the following policies, which give AWS CloudFormation, in the final Build stage, the ability to create or update AWS Lambda functions, push or watch Amazon CloudWatch logs, and to create and update change sets.
  - AWSLambdaFullAccess
  - AWSCodeDeployFullAccess
  - CloudWatchFullAccess
  - AWSCloudFormationFullAccess
  - AWSCodePipelineFullAccess

Architecture
This pattern's multiple-Region architecture and workflow comprise the following steps.

1. You send your code to a CodeCommit repository.
2. Upon receiving any code update or commit, CodeCommit invokes a CloudWatch event, which in turn starts a CodePipeline job.
3. CodePipeline engages the CI that is handled by CodeBuild. The following tasks are performed.
   - Testing of the AWS CloudFormation templates (optional)
   - Packaging of the AWS CloudFormation templates for each Region included in the deployment. For example, this pattern deploys in parallel to three AWS Regions, so CodeBuild packages the AWS CloudFormation templates into three S3 buckets, one in each specified Region. The S3 buckets are used by CodeBuild as artifact repositories only.
4. CodeBuild packages the artifacts as input for next Deploy phase, which runs in parallel in the three AWS Regions. If you specify a different number of Regions, CodePipeline will deploy to those Regions.

Tools

- **AWS CodePipeline** – CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software changes continuously.
- **AWS CodeBuild** – CodeBuild is a fully managed build service that compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- **AWS CodeCommit** – CodeCommit is a version control service hosted by Amazon Web Services that you can use to privately store and manage assets (such as source code and binary files) in the cloud.
- **AWS CloudFormation** – AWS CloudFormation is a service that helps you model and set up your Amazon Web Services resources so that you can spend less time managing those resources and more time focusing on your applications that run in AWS.
- **AWS Identity and Access Management** – AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers.
The following sample code is for the BuildSpec.yaml file (Build phase).

```yaml
---
artifacts:
discard-paths: true
files:
- packaged-first-region.yaml
- packaged-second-region.yaml
- packaged-third-region.yaml
phases:
build:
commands:

Export AWS Backup reports from across an organization in AWS Organizations as a CSV file

Created by Aromal Raj Jayarajan (AWS) and Purushotham G K (AWS)

<table>
<thead>
<tr>
<th>Code repository:</th>

<table>
<thead>
<tr>
<th>Workload:</th>
<th>AWS services:</th>
</tr>
</thead>
<tbody>
<tr>
<td>All other workloads</td>
<td>AWS Backup; AWS Identity and Access Management; AWS Lambda; Amazon S3; Amazon EventBridge</td>
</tr>
</tbody>
</table>

Summary

This pattern shows how to export AWS Backup job reports from across an organization in AWS Organizations as a CSV file. The solution uses AWS Lambda and Amazon EventBridge to categorize AWS Backup job reports based on their status, which can help when configuring status-based automations.

AWS Backup helps organizations centrally manage and automate data protection across AWS services, in the cloud, and on premises. However, for AWS Backup jobs configured within AWS Organizations, consolidated reporting is available only in the AWS Management Console of each organization’s management account. Bringing this reporting outside of the management account can reduce the effort required for auditing and increase the scope for automations, notifications, and alerting.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An active organization in AWS Organizations that includes at least a management account and a member account
- AWS Backup configured at the organization level in AWS Organizations (for more information, see Automate centralized backup at scale across AWS services using AWS Backup on the AWS Blog)
- Git, installed and configured on your local machine

Limitations

The solution provided in this pattern identifies AWS resources that are configured for AWS Backup jobs only. The report can’t identify AWS resources that aren’t configured for backup through AWS Backup.

Architecture

Target technology stack

- AWS Backup
- AWS CloudFormation
- Amazon EventBridge
The following diagram shows an example workflow for exporting AWS Backup job reports from across an organization in AWS Organizations as a CSV file.

The diagram shows the following workflow:

1. A scheduled EventBridge event rule invokes a Lambda function in the member (reporting) AWS account.
2. The Lambda function then uses AWS STS to assume an IAM role that has the permissions required to connect to the management account.
3. The Lambda function then does the following:
   - Requests the consolidated AWS Backup jobs report from the AWS Backup service
   - Categorizes the results based on AWS Backup job status
   - Converts the response to a CSV file
   - Uploads the results to an Amazon S3 bucket in the reporting account within folders that are labeled based on their creation date

Tools

- **AWS Backup** is a fully managed service that helps you centralize and automate data protection across AWS services, in the cloud, and on premises.
• **AWS CloudFormation** helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.

• **Amazon EventBridge** is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.

• **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

• **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

• **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

**Code**

The code for this pattern is available in the GitHub [aws-backup-report-generator](https://github.com/aws-samples/aws-backup-report-generator) repository.

Export tags for a list of Amazon EC2 instances to a CSV file

Created by Sida Ju (AWS) and Pac Joonhyun (AWS)

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: Production</th>
<th>Technologies: DevOps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search and export EC2 tags</td>
<td></td>
<td></td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon EC2</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern shows how to programmatically export tags for a list of Amazon Elastic Compute Cloud (Amazon EC2) instances to a CSV file.

By using the example Python script provided, you can reduce how long it takes to review and categorize your Amazon EC2 instances by specific tags. For example, you could use the script to quickly identify and categorize a list of instances that your security team has flagged for software updates.

Prerequisites and limitations

Prerequisites

- Python 3 installed and configured
- AWS Command Line Interface (AWS CLI) installed and configured

Limitations

The example Python script provided in this pattern can search Amazon EC2 instances based on the following attributes only:

- Instance IDs
- Private IPv4 addresses
- Public IPv4 addresses

Tools

- Python is a general-purpose computer programming language.
- virtualenv helps you create isolated Python environments.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

Code repository

The example Python script for this pattern is available in the GitHub search-ec2-instances-export-tags repository.

- [Configuring the AWS CLI](AWS CLI User Guide)
Generate an AWS CloudFormation template containing AWS Config managed rules using Troposphere

*Created by Lucas Nation (AWS) and Freddie Wilson (AWS)*

**Environment:** Production  
**Technologies:** DevOps; Management & governance; Security, identity, compliance  
**Workload:** Microsoft; Open-source  

**AWS services:** AWS Config; AWS CloudFormation

---

**Summary**

Many organizations use AWS Config managed rules to evaluate the compliance of their Amazon Web Services (AWS) resources against common best practices. However, these rules can be time consuming to maintain and this pattern helps you leverage Troposphere, a Python library, to generate and manage AWS Config managed rules.

The pattern helps you to manage your AWS Config managed rules by using a Python script to convert a Microsoft Excel spreadsheet containing AWS managed rules into an AWS CloudFormation template. Troposphere acts as the infrastructure as code (IaC) and this means that you can update the Excel spreadsheet with managed rules, instead of using a JSON or YAML-formatted file. You then use the template to launch an AWS CloudFormation stack that creates and updates the managed rules in your AWS account.

The AWS CloudFormation template defines each AWS Config managed rule by using the Excel spreadsheet and helps you to avoid manually creating individual rules in the AWS Management Console. The script defaults each managed rule's parameters to an empty dictionary and the scope's ComplianceResourceTypes defaults from THE_RULE_IDENTIFIER.template file. For more information about the rule identifier, see [Creating AWS Config managed rules with AWS CloudFormation templates](https://docs.aws.amazon.com/config/latest/developerguide/config-managed-rules-cloudformation-templates.html) in the AWS Config documentation.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account.
- Familiarity with using AWS CloudFormation templates to create AWS Config managed rules. For more information about this, see [Creating AWS Config managed rules with AWS CloudFormation templates](https://docs.aws.amazon.com/config/latest/developerguide/config-managed-rules-cloudformation-templates.html) in the AWS Config documentation.
- Python 3, installed and configured. For more information about this, see [Python documentation](https://docs.python.org/3/).  
- An existing integrated development environment (IDE) such as AWS Cloud9. For more information about this, see [What is AWS Cloud9?](https://aws.amazon.com/cloud9/) in the AWS Cloud9 documentation.
- Identify your organizational units (OUs) in a column in the sample excel_config_rules.xlsx Excel spreadsheet (attached).
## Epics

**Customize and configure the AWS Config managed rules**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update the sample Excel spreadsheet.</td>
<td>Download the sample excel_config_rules.xlsx Excel spreadsheet (attached) and label as Implemented the AWS Config managed rules that you want to use. Rules marked as Implemented will be added to the AWS CloudFormation template.</td>
<td>Developer</td>
</tr>
</tbody>
</table>
| (Optional) Update the config_rules_params.json file with AWS Config rule parameters. | Some AWS Config managed rules require parameters and should be passed to the Python script as a JSON file by using the `--param-file` option. For example, the access-keys-rotated managed rule uses the following `maxAccessKeyAge` parameter:  

```json  
{
    "access-keys-rotated": {
        "InputParameters": {
            "maxAccessKeyAge": 90
        }
    }
}  
```

In this sample parameter, the `maxAccessKeyAge` is set to 90 days. The script reads the parameter file and adds any `InputParameters` that it finds. | Developer |
| (Optional) Update the config_rules_params.json file with AWS Config ComplianceResourceTypes. | By default, the Python script retrieves the ComplianceResourceTypes from AWS defined templates. If you want to override the scope of a specific AWS Config managed rule, then you need to pass it to the Python script as a JSON file using the `--param-file` option. For example, the following sample code shows how the | Developer |

Give SageMaker notebook instances temporary access to a CodeCommit repository in another AWS account

Created by Helge Aufderheide (AWS)

| Environment: Production | Technologies: DevOps; Analytics; Machine learning & AI; Management & governance | AWS services: AWS CodeCommit; AWS Identity and Access Management; Amazon SageMaker |

Summary

This pattern shows how to grant Amazon SageMaker notebook instances and users temporary access to an AWS CodeCommit repository that's in another AWS account. This pattern also shows how you can grant granular permissions for specific actions each entity can perform on each repository.

Organizations often store CodeCommit repositories in a different AWS account than the account that hosts their development environment. This multi-account setup helps control access to the repositories and reduces the risk of their accidental deletion. To grant these cross-account permissions, it's a best practice to use AWS Identity and Access Management (IAM) roles. Then, predefined IAM identities in each AWS account can temporarily assume the roles to create a controlled chain of trust across the accounts.

Note: You can apply a similar procedure to grant other IAM identities cross-account access to a CodeCommit repository. For more information, see Configure cross-account access to an AWS CodeCommit repository using roles in the AWS CodeCommit User Guide.

Prerequisites and limitations

**Prerequisites**

- An active AWS account with a CodeCommit repository *(account A)*
- A second active AWS account with a SageMaker notebook instance *(account B)*
- An AWS user with sufficient permissions to create and modify IAM roles in account A
- A second AWS user with sufficient permissions to create and modify IAM roles in account B

**Architecture**

The following diagram shows an example workflow for granting a SageMaker notebook instance and users in one AWS account cross-account access to a CodeCommit repository:
The diagram shows the following workflow:

1. The AWS user role and SageMaker notebook instance role in account B assume a named profile.
2. The named profile’s permissions policy specifies a CodeCommit access role in account A that the profile then assumes.
3. The CodeCommit access role’s trust policy in account A allows the named profile in account B to assume the CodeCommit access role.
4. The CodeCommit repository’s IAM permissions policy in account A allows the CodeCommit access role to access the CodeCommit repository.

**Technology stack**

- CodeCommit
- Git
- IAM
- pip
- SageMaker

**Tools**

- [AWS CodeCommit](https://aws.amazon.com/codecommit/) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- [AWS Identity and Access Management (IAM)](https://aws.amazon.com/iam/) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [Git](https://git-scm.com) is a distributed version-control system for tracking changes in source code during software development.
- [git-remote-codecommit](https://git-scm.com) is a utility that helps you push and pull code from CodeCommit repositories by extending Git.
• **pip** is the package installer for Python. You can use pip to install packages from the Python Package Index and other indexes.

### Best practices

When you set permissions with IAM policies, make sure that you grant only the permissions required to perform a task. For more information, see [Apply least-privilege permissions](https://docs.aws.amazon.com/iam/latest/UserGuide/apply-least-privilege-permissions.html) in the *AWS IAM User Guide*.

When implementing this pattern, make sure that you do the following:

• Confirm that IAM principles have only the permissions required to perform specific, needed actions within each repository. For example, it’s recommended to allow approved IAM principles to push and merge changes to specific repository branches, but only request merges to protected branches.

• Confirm that IAM principles are assigned different IAM roles based on their respective roles and responsibilities for each project. For example, a developer will have different access permissions than a release manager or AWS Administrator.

### Epics

**Configure the IAM roles**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure the CodeCommit access role and permissions policy.</td>
<td><strong>Note:</strong> To automate the manual setup process documented in this epic, you can use an <a href="https://console.aws.amazon.com/cloudformation/home">AWS CloudFormation template</a>. In the account that contains the CodeCommit repository <em>(account A)</em>, do the following: 1. <a href="https://docs.aws.amazon.com/iam/latest/UserGuide/create-iam-role.html">Create an IAM role</a> that can be assumed by the SageMaker notebook instance role in account B. 2. <a href="https://docs.aws.amazon.com/iam/latest/UserGuide/policies-create.html">Create an IAM policy</a> that grants access to the repository and <a href="https://docs.aws.amazon.com/iam/latest/UserGuide/policies-attach.html">attach the policy to the role</a>. For testing purposes only, choose the <a href="https://aws.amazon.com/iam/policies/">AWSCodeCommitPowerUser</a> AWS managed policy. This policy grants all CodeCommit permissions except the ability to delete resources. 3. <a href="https://docs.aws.amazon.com/iam/latest/UserGuide/modify-trust-policy.html">Modify the role’s trust policy</a> so that account B is listed as a trusted entity.</td>
<td>General AWS, AWS DevOps</td>
</tr>
</tbody>
</table>

**Important:** Before moving this setup into your production environment, it’s a best
### Task

<table>
<thead>

<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>practice to write your own IAM policy that applies <strong>least-privilege permissions</strong>. For more information, see the <strong>Additional information</strong> section of this pattern.</td>
<td>General AWS, AWS DevOps</td>
</tr>
</tbody>
</table>

#### Grant the SageMaker notebook instance's role in account B permissions to assume the CodeCommit access role in account A.

In the account that contains the SageMaker notebook instance's IAM role (*account B*), do the following:

1. Create an IAM policy that allows an IAM role or user to assume the CodeCommit access role in account A.

   **Example IAM permissions policy that allows an IAM role or user to assume a cross-account role**

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": "sts:AssumeRole",
         "Resource": "arn:aws:iam::accountA_ID:role/accountArole_ID"
       }
     ]
   }
   ```

2. Attach the policy to your SageMaker notebook instance's role in account B.
3. Have the SageMaker notebook instance's role in account B assume the CodeCommit access role in account A.

**Note:** To view your repository's Amazon Resource Name (ARN), see [View CodeCommit repository details](https://docs.aws.amazon.com/CodeCommit/latest/userguide/repository-details.html) in the AWS CodeCommit User Guide.
### Set up your SageMaker notebook instance in account B

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Set up a user profile on the AWS SageMaker notebook instance to assume the role in account A. | **Important:** Make sure that you have the latest version of the AWS Command Line Interface (AWS CLI) installed. In the account that contains the SageMaker notebook instance (account B), do the following:  
  1. Sign in to the AWS Management Console and open the SageMaker console.  
  3. Choose **New**, and then choose **Terminal**. A new terminal window opens in your Jupyter environment.  
  4. Navigate to the SageMaker notebook instance's `~/.aws/config` file. Then, add a user profile to the file by entering the following statement:  
     ```  
     [profile remoterepouser]  
     role_arn = arn:aws:iam::<ID of Account A>:role/<rolename>  
     role_session_name = remoteaccesssession  
     region = eu-west-1  
     credential_source = Ec2InstanceMetadata  
     ----------------------------------  
     ```  | General AWS, AWS DevOps                                                                                             |
| Install the git-remote-codecommit utility.                           | Follow the instructions in [Step 2: Install git-remote-codecommit](https://docs.aws.amazon.com/codecommit/latest/userguide/codecommit-code-source-git.html) in the AWS CodeCommit User Guide. | Data scientist                    |

### Access the repository

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access the CodeCommit repository by using Git commands or SageMaker.</td>
<td><strong>To use Git</strong></td>
<td>Git, bash console</td>
</tr>
</tbody>
</table>
IAM principals that assume the SageMaker notebook instance's role in account B can now run Git commands to access the CodeCommit repository in account A. For example, users can run commands such as `git clone`, `git pull`, and `git push`.

For instructions, see [Connect to an AWS CodeCommit repository](https://docs.aws.amazon.com/codecommit/latest/userguide/welcome.html) in the AWS CodeCommit User Guide.

For information about how to use Git with CodeCommit, see [Getting started with AWS CodeCommit](https://docs.aws.amazon.com/codecommit/latest/userguide/getting-started.html) in the AWS CodeCommit User Guide.

**To use SageMaker**

To use Git from the SageMaker console, you must allow Git to retrieve credentials from your CodeCommit repository. For instructions, see [Associate a CodeCommit repository in a different AWS account with a notebook instance](https://docs.aws.amazon.com/sagemaker/latest/dg/codecommit-find-code-repo.html) in the SageMaker documentation.

### Related resources

- Configure cross-account access to an AWS CodeCommit repository using roles ([AWS CodeCommit User Guide](https://docs.aws.amazon.com/codecommit/latest/userguide/welcome.html))
- IAM tutorial: Delegate access across AWS accounts using IAM roles ([AWS IAM User Guide](https://docs.aws.amazon.com/iam/latest/userguide/tutorials-use-iam-access-keys.html))

### Additional information

#### Restricting CodeCommit permissions to specific actions

To restrict the actions that an IAM principal can take in the CodeCommit repository, modify the actions that are allowed in the CodeCommit access policy.

**Note:** You can also edit the `AWSCodeCommitPowerUser` AWS managed policy to fit your use case.

#### Restricting CodeCommit permissions to specific repositories
To create a multitenant environment where more than one code repository is accessible to only specific users, do the following:

1. Create multiple CodeCommit access roles in account A. Then, configure each access role's trust policy to allow specific users in account B to assume the role.
2. Restrict what code repositories that each role can assume by adding a "Resource" condition to each CodeCommit access role's policy.

**Example “Resource” condition that restricts an IAM principal’s access to a specific CodeCommit repository**

```
"Resource" : [<REPOSITORY_ARN>,<REPOSITORY_ARN> ]
```

**Note:** To help identify and differentiate multiple code repositories in the same AWS account, you can assign different prefixes to the repositories' names. For example, you can name code repositories with prefixes that align to different developer groups, such as `myproject-subproject1-repo1` and `myproject-subproject2-repo1`. Then, you can create an IAM role for each developer group based on their assigned prefixes. For example, you could create a role named `myproject-subproject1-repoaccess` and grant it access to all of the code repositories that include the prefix `myproject-subproject1`.

**Example “Resource” condition that refers to a code repository ARN that includes a specific prefix**

```
"Resource" : arn:aws:codecommit:<region>::<account-id>:myproject-subproject1-*
```
Automatically detect changes and initiate different CodePipeline pipelines for a monorepo in CodeCommit

Created by Helton Henrique Ribeiro (AWS) and Ricardo Morais (AWS)

<table>
<thead>
<tr>
<th>Code repository:</th>

<th>Workload: Open-source</th>
<th>AWS services: AWS CodeCommit; AWS CodePipeline; AWS Lambda</th>
</tr>
</thead>
</table>

Summary

This pattern helps you automatically detect changes to the source code of a monorepo-based application in AWS CodeCommit and then initiate a pipeline in AWS CodePipeline that runs the continuous integration and continuous delivery (CI/CD) automation for each microservice.

This approach means that each microservice in your monorepo-based application can have a dedicated CI/CD pipeline, which ensures better visibility, easier sharing of code, and improved collaboration, standardization, and discoverability.

The pattern uses AWS Cloud9 as the integrated development environment (IDE) and AWS Cloud Development Kit (AWS CDK) to define an infrastructure using two AWS CloudFormation stacks: MonoRepoStack and PipelinesStack. The MonoRepoStack stack creates the monorepo in AWS CodeCommit and the AWS Lambda function that initiates the CI/CD pipelines. The PipelinesStack stack defines your pipeline infrastructure.

Important: This pattern’s workflow is a proof of concept (POC) and we recommend that you only use it in a test environment. If you want to use this pattern’s approach in a production environment, see Security best practices in IAM in the IAM documentation and make the required changes to your IAM roles and AWS services.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information about this, see Installing, updating, and uninstalling the AWS CLI in the AWS CLI documentation.
- Python 3 and pip, installed on your local machine. For more information about this, see the Python documentation.
- AWS CDK, installed and configured. For more information about this, see Getting started with the AWS CDK in the AWS CDK documentation.
- An AWS Cloud9 IDE, installed and configured. For more information about this, see Setting up AWS Cloud9 in the AWS Cloud9 documentation.
• The GitHub AWS CodeCommit monorepo multi-pipeline triggers repository, cloned to your local machine.

• An existing directory containing application code that you want to build and deploy with CodePipeline.

• Familiarity and experience with DevOps best practices on the AWS Cloud. To increase your familiarity with DevOps, you can use the pattern Build a loosely coupled architecture with microservices using DevOps practices and AWS Cloud9 on the AWS Prescriptive Guidance website.

Limitations

• This pattern's workflow is a proof of concept (POC) and we recommend that you only use it in a test environment. If you want to use this pattern's approach in a production environment, see Security best practices in IAM in the IAM documentation and make the required changes to your IAM roles and AWS services.

Architecture

The following diagram shows how to use AWS CDK to define an infrastructure with two AWS CloudFormation stacks: MonoRepoStack and PipelinesStack.
The diagram shows the following workflow:

1. The bootstrap process uses AWS CDK to create the MonoRepoStack and PipelinesStack AWS CloudFormation stacks.
2. The MonoRepoStack stack creates the CodeCommit repository for your application and the monorepo-event-handler Lambda function that is initiated after each commit.
3. The PipelinesStack stack creates the pipelines in CodePipeline that are initiated by the Lambda function. Each microservice must have a defined infrastructure pipeline.
4. The pipeline for microservice-n is initiated by the Lambda function and starts its isolated CI/CD stages that are based on the source code in CodeCommit.
5. The pipeline for microservice-1 is initiated by the Lambda function and starts its isolated CI/CD stages that are based on the source code in CodeCommit.

The following diagram shows the deployment of the MonoRepoStack and PipelinesStack AWS CloudFormation stacks in an account.
1. A user changes code in one of the application’s microservices.
2. The user pushes the changes from a local repository to a CodeCommit repository.
3. The push activity initiates the Lambda function that receives all pushes to the CodeCommit repository.
4. The Lambda function reads a parameter in AWS Systems Manager Parameter Store to retrieve the most recent commit ID. The parameter has the /MonoRepoTrigger/{repository}/{branch_name}/LastCommit naming format. If the parameter is not found, the Lambda function reads the last commit ID from the CodeCommit repository and saves the returned value in Parameter Store.
5. After identifying the commit ID and the changed files, the Lambda function identifies the pipelines for each microservice directory and initiates the required CodePipeline pipeline.

**Tools**

- **AWS CDK** – AWS Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- **Python** – Python is a programming language that lets you work quickly and integrate systems more effectively.

**Code**

The source code and templates for this pattern are available in the Github AWS CodeCommit monorepo multi-pipeline triggers repository.

Integrate a Bitbucket repository with AWS Amplify using AWS CloudFormation

Created by Alwin Abraham (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Technologies:</th>
<th>DevOps</th>
<th>AWS services:</th>
<th>AWS Amplify; AWS CloudFormation</th>
</tr>
</thead>
</table>

**Summary**

AWS Amplify helps you to quickly deploy and test static websites without having to set up the infrastructure that is typically required. You can deploy this pattern's approach if your organization wants to use Bitbucket for source control, whether to migrate existing application code or build a new application. By using AWS CloudFormation to automatically set up Amplify, you provide visibility into the configurations that you use.

This pattern describes how to create a front-end continuous integration and continuous deployment (CI/CD) pipeline and deployment environment by using AWS CloudFormation to integrate a Bitbucket repository with AWS Amplify. The pattern's approach means that you can build an Amplify front-end pipeline for repeatable deployments.

**Prerequisites and limitations**

**Prerequisites**

- An active Amazon Web Services (AWS) account
- An active Bitbucket account with administrator access
- Access to a terminal that uses `cURL` or the Postman application
- Familiarity with Amplify
- Familiarity with AWS CloudFormation
- Familiarity with YAML-formatted files

**Architecture**
Technology stack

- Amplify
- AWS CloudFormation
- Bitbucket

Tools

- **AWS Amplify** – Amplify helps developers to develop and deploy cloud-powered mobile and web apps.
- **AWS CloudFormation** – AWS CloudFormation is a service that helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications that run in AWS.
- **Bitbucket** – Bitbucket is a Git repository management solution designed for professional teams. It gives you a central place to manage Git repositories, collaborate on your source code, and guide you through the development flow.

Code

The bitbucket-amplify.yml file (attached) contains the AWS CloudFormation template for this pattern.

Epics

Configure the Bitbucket repository

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Optional) Create a Bitbucket repository.</td>
<td>1. Sign in to your Bitbucket account and create a new repository. For more information about this, see Create a Git repository in the Bitbucket documentation. 2. Record the workspace’s name.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------</td>
</tr>
</tbody>
</table>
| **Open the workspace settings.** | 1. Open the workspace and choose the **Repository** tab.  
2. Choose the repository that you want to integrate with Amplify.  
3. Choose the name of the workspace that is above the repository's name.  
4. On the sidebar, choose **Settings**.                                                                                           | DevOps engineer          |
| **Create an OAuth consumer.**  | 1. In the **Apps and Features** section, choose **OAuth consumers**, and then choose **Add consumer**.  
2. Enter a name for your consumer, for example, **Amplify Integration**.  
3. Enter a callback URL. Although this field is a required input, it’s not used to complete the integration so the value could be **http://localhost:3000**  
4. Check the box for **This is a private consumer**.  
5. Choose the following permissions:  
   - **Project** – Read  
   - **Repositories** – Admin  
   - **Pull requests** – Read  
   - **Webhooks** – Read and Write  
6. Leave the default choices for all the other fields and choose **Submit**.  
7. Record the key and secret that are generated.                                                                                      | DevOps engineer          |
### Obtain OAuth access token.

1. Open a terminal window and run the following command:
   
   ```bash
   curl -X POST -u "KEY:SECRET" https://bitbucket.org/site/oauth2/access_token -d grant_type=client_credentials
   ```
   
   **Important:** Replace `KEY` and `SECRET` with the key and secret that you recorded earlier.

2. Record the access token without using the quotation marks. The token is only valid for a limited time and the default time is two hours. You must run the AWS CloudFormation template in this timeframe.

### Create and deploy the AWS CloudFormation stack

#### Task
- **Download the AWS CloudFormation template.**

#### Description
- Download the `bitbucket-amplify.yml` AWS CloudFormation template (attached). This template creates the CI/CD pipeline in Amplify, in addition to the Amplify project and branch.

#### Skills required
- DevOps engineer

#### Task
- **Create and deploy the AWS CloudFormation stack.**

#### Description
- 1. Sign in to the AWS Management Console in the AWS Region that you want to deploy in and open the AWS CloudFormation console.

   2. Choose **Create Stack (with new resources)** and then choose **Upload a Template File**.

   3. Upload the `bitbucket-amplify.yml` file.

   4. Choose **Next**, enter a stack name, and then enter the following parameters:

   - **Access token:** Paste the OAuth access token that you created earlier.

   5. Choose **Create stack**.

   6. Wait for the stack to complete and ensure it is in a successful state.

   7. Access the Amplify CLI and run `amplify configure` with your AWS Access Key.

   8. Run `amplify push` to deploy the Amplify stack.

   9. Add the Amplify site to a domain.

   10. Once the domain is approved and the DNS is updated, you can access your Amplify website.

#### Skills required
- DevOps engineer
### Test the CI/CD pipeline

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Deploy the code to the branch in your repository. | 1. Clone your Bitbucket repository by running the following command: git clone https://bitbucket.org/<WORKSPACE_NAME>/<REPO_NAME>  
2. Check out the branch name that was used when running the AWS CloudFormation script. To create and check out a new branch, run the git checkout -b <BRANCH_NAME> command. To check out an existing branch, run the git checkout <BRANCH_NAME> command  
3. Commit the code into the branch and push it to the remote branch by running the git commit and git push commands. | App developer |
<table>

Launch a CodeBuild project across AWS accounts using Step Functions and a Lambda proxy function

Created by Richard Milner-Watts (AWS)

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: Production</th>
<th>Technologies: DevOps; Management &amp; governance; Operations; Serverless</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Cross-Account CodeBuild Proxy</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

AWs services: AWS CodeBuild; AWS Lambda; AWS Step Functions; AWS X-Ray; AWS CloudFormation

Summary

This pattern demonstrates how to asynchronously launch an AWS CodeBuild project across AWS accounts by using AWS Step Functions and an AWS Lambda proxy function. You can use the pattern's sample Step Functions state machine to test the success of your CodeBuild project.

CodeBuild helps you launch operational tasks using the AWS Command Line Interface (AWS CLI) from a fully-managed Amazon Linux 2 runtime environment. You can change the behavior of your CodeBuild project at runtime by overriding environment variables. You can also use AWS CodePipeline to launch operational tasks, but you can't override environment variables with CodePipeline. Additionally, you can use CodeBuild to manage workflows. For more information, see Service Catalog Tools on the AWS Workshop website and Schedule jobs in Amazon RDS for PostgreSQL using AWS CodeBuild and Amazon EventBridge on the AWS Database Blog.

Prerequisites and limitations

Prerequisites

• Two active AWS accounts: a source account for invoking a Lambda proxy function with Step Functions and a target account for building a remote CodeBuild sample project

Limitations

• This pattern cannot be used to copy artifacts between accounts.

Architecture

The following diagram shows the architecture that this pattern builds.
The diagram shows the following workflow:

1. The Step Functions state machine invokes the Lambda proxy function (codebuild-proxy-lambda).
2. The Lambda proxy function uses AWS Security Token Service (AWS STS) to assume an IAM proxy role (codebuild-proxy-role) and use an IAM policy (codebuild-proxy-policy) in the target account.
3. The Lambda function launches the CodeBuild project and returns the CodeBuild job ID.
4. The Step Functions state machine loops and polls the CodeBuild job until receiving a success or failure status.

**Technology stack**

- AWS CloudFormation
- CodeBuild
- IAM
- Lambda
- Step Functions
- X-Ray

**Tools**

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS CloudFormation Designer provides an integrated JSON and YAML editor that helps you view and edit CloudFormation templates.
• **AWS CodeBuild** is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.

• **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

• **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

• **AWS Step Functions** is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.

• **AWS X-Ray** helps you collect data about the requests that your application serves, and provides tools that you can use to view, filter, and gain insights into that data to identify issues and opportunities for optimization.

**Code**

The code for this pattern is available in the GitHub [Cross Account CodeBuild Proxy](https://github.com) repository. This pattern uses the AWS Lambda Powertools for Python library to provide logging and tracing functionality. For more information on this library and its utilities, see [ Powertools for AWS Lambda (Python) ](https://aws.amazon.com).

**Epics**

Create the Lambda proxy function and associated IAM role in the source account

</tr>
<tr>
<td></td>
<td>Record the AWS account ID for your source and target accounts.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For more information, see <a href="https://aws.amazon.com">Finding your AWS account ID</a> in the IAM documentation.</td>
<td></td>
</tr>
<tr>
<td>Download the AWS CloudFormation templates.</td>
<td>1. Download the <code>sample_target_codebuild_template.yaml</code> AWS CloudFormation template from the GitHub repository for this pattern.</td>
<td>AWS DevOps</td>
</tr>
<tr>
<td></td>
<td>2. Download the <code>codebuild_lambda_proxy_template.yaml</code> AWS CloudFormation template from the GitHub repository for this pattern.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> In the AWS CloudFormation templates, <code>&lt;SourceAccountId&gt;</code> is the AWS account ID for the source account, and <code>&lt;TargetAccountId&gt;</code> is the AWS account ID for the target account.</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
</tbody>
</table>
| Create and deploy the AWS CloudFormation stack. | 1. Sign in to the AWS Management Console for your source account, open the [AWS CloudFormation console](https://console.aws.amazon.com/cloudformation/home), and then choose **Stacks**.  
2. Choose **Create Stack** and then choose **With new resources (standard)**.  
3. For **Template source**, choose **Upload a template file**.  
4. For **Upload a template file**, choose **file**, and then choose your downloaded `codebuild_lambda_proxy_template.yaml` file. Choose **Next**.  
5. For **Stack name**, enter a name for the stack (for example, `codebuild-lambda-proxy`).  
6. Replace the `crossAccountTargetRoleArn` parameter with your `<TargetAccountId>` (for example, `<arn:aws:iam::123456789012:role/proxy-lambda-codebuild-role>`). **Note:** You aren’t required to update the default value for the targetCodeBuildProject parameter.  
7. Choose **Next**, accept the default stack creation options, and then choose **Next**.  
8. Choose the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** check box, and then choose **Create stack**.  

**Note:** You must create the AWS CloudFormation stack for the proxy Lambda function before creating any resources in target accounts. When you create a trust policy in a target account, the IAM role is translated from the role name to an internal identifier. This is why the IAM role must already exist. | AWS DevOps |
## Confirm the creation of the proxy function and state machine.

1. Wait for the AWS CloudFormation stack to reach `CREATE_COMPLETE` status. This should take less than one minute.
2. Open the AWS Lambda console, choose Functions, and then find the lambda-proxy-ProxyLambda-<GUID> function.
3. Open the AWS Step Functions console, choose state machines, and then find the sample-crossaccount-codebuild-state-machine state machine.

</tbody>
</table>
| Validate the environment variables | 1. Sign in to the AWS Management Console for your target account.  
2. Open the [AWS CodeBuild console](#), expand **Build**, and then choose **Build projects**.  
3. Choose the sample-codebuild-project project and then choose **View details**.  
4. On the **Build history** tab, choose the most recent build of the project and then choose **View logs**.  
5. In the log output, verify that the environment variables printed to STDOUT match the environment variables from the Step Functions sample state machine. | AWS DevOps      |
Monitor Amazon ECR repositories for wildcard permissions using AWS CloudFormation and AWS Config

Created by Vikrant Telkar (AWS), Sajid Momin (AWS), and Wassim Benhallam (AWS)

| Environment: Production | Technologies: DevOps; Containers & microservices | AWS services: AWS CloudFormation; AWS Config; Amazon ECR; Amazon SNS; AWS Lambda |

Summary

On the Amazon Web Services (AWS) Cloud, Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that supports private repositories with resource-based permissions using AWS Identity and Access Management (IAM).

IAM supports the "*" wildcard in both the resource and action attributes, which makes it easier to automatically choose multiple matching items. In your testing environment, you can allow all authenticated AWS users to access an Amazon ECR repository by using the ecr:* wildcard permission in a principal element for your repository policy statement. The ecr:* wildcard permission can be useful when developing and testing in development accounts that can’t access your production data.

However, you must make sure that the ecr:* wildcard permission is not used in your production environments because it can cause serious security vulnerabilities. This pattern’s approach helps you to identify Amazon ECR repositories that contain the ecr:* wildcard permission in repository policy statements. The pattern provides steps and an AWS CloudFormation template to create a custom rule in AWS Config. An AWS Lambda function then monitors your Amazon ECR repository policy statements for ecr:* wildcard permissions. If it finds non-compliant repository policy statements, Lambda notifies AWS Config to send an event to Amazon EventBridge and EventBridge then initiates an Amazon Simple Notification Service (Amazon SNS) topic. The SNS topic notifies you by email about the non-compliant repository policy statements.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information about this, see Installing, updating, and uninstalling the AWS CLI in the AWS CLI documentation.
- An existing Amazon ECR repository with an attached policy statement, installed and configured in your testing environment. For more information about this, see Creating a private repository and Setting a repository policy statement in the Amazon ECR documentation.
- AWS Config, configured in your preferred AWS Region. For more information about this, see Getting started with AWS Config in the AWS Config documentation.
- The aws-config-cloudformation.template file (attached), downloaded to your local machine.

Limitations
• This pattern’s solution is Regional and your resources must be created in the same Region.

Architecture

The following diagram shows how AWS Config evaluates Amazon ECR repository policy statements.

The diagram shows the following workflow:

1. AWS Config initiates a custom rule.
2. The custom rule invokes a Lambda function to evaluate the compliance of the Amazon ECR repository policy statements. The Lambda function then identifies non-compliant repository policy statements.
3. The Lambda function sends the non-compliance status to AWS Config.
4. AWS Config sends an event to EventBridge.
5. EventBridge publishes the non-compliance notifications to an SNS topic.
6. Amazon SNS sends an email alert to you or an authorized user.

Automation and scale

This pattern’s solution can monitor any number of Amazon ECR repository policy statements, but all resources that you want to evaluate must be created in the same Region.

Tools

• AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
• **AWS Config** – AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time.

• **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable. Amazon ECR supports private repositories with resource-based permissions using IAM.

• **Amazon EventBridge** – Amazon EventBridge is a serverless event bus service that you can use to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your applications, software as a service (SaaS) applications, and AWS services to targets such as AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other accounts.

• **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

• **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

**Code**

The code for this pattern is available in the `aws-config-cloudformation.template` file (attached).

Perform custom actions from AWS CodeCommit events

Summary

When you use an AWS CodeCommit repository to store code, you might want to monitor the repository and initiate a workflow of actions when specific events occur. For example, you might want to send an email notification when a user comments on a line of code in a commit, or initiate an AWS Lambda function to perform security scans on repository contents after a commit. This pattern outlines the steps for configuring a CodeCommit repository for custom actions. The pattern uses AWS CodeCommit notification rules to capture the events of interest, and then sends these events to a configured target.

Prerequisites and limitations

Prerequisites

• An active AWS account.
• Familiarity with Git commands.
• AWS CodeCommit, set up. For instructions, see Setting up for AWS CodeCommit.
• (Recommended) AWS Command Line Interface (AWS CLI), installed and configured. For instructions, see Getting started with the AWS CLI.

Architecture
Tools

AWS services

- **AWS CodeCommit** is a fully-managed source control service that hosts secure Git-based repositories. It makes it easy for teams to collaborate on code in a secure and highly scalable ecosystem. CodeCommit eliminates the need to operate your own source control system or worry about scaling its infrastructure.

- **Amazon Simple Notification Service (Amazon SNS)** is a web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud. Amazon SNS provides topics (communication channels) for high-throughput, push-based, many-to-many messaging. Using Amazon SNS topics, publishers can distribute messages to a large number of subscribers for parallel processing, including Amazon Simple Queue Service (Amazon SQS) queues, AWS Lambda functions, and HTTP/S webhooks. You can also use Amazon SNS to send notifications to end users using mobile push, SMS, and email.

Publish Amazon CloudWatch metrics to a CSV file

Created by Abdullahi Olaoye (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>DevOps</th>
<th>AWS services:</th>
<th>Amazon CloudWatch</th>
</tr>
</thead>
</table>

Summary

This pattern uses a Python script to retrieve Amazon CloudWatch metrics and to convert the metrics information into a comma-separated values (CSV) file for improved readability. The script takes the AWS service whose metrics should be retrieved as a required argument. You can specify the AWS Region and AWS credential profile as optional arguments. If you don't specify those arguments, the script uses the default Region and profile that are configured for the workstation where the script is run. After the script runs, it generates and stores a CSV file in the same directory.

See the Attachments section for the script and associated files provided with this pattern.

Prerequisites and limitations

Prerequisites

- Python 3.x
- AWS Command Line Interface (AWS CLI)

Limitations

The script currently supports the following AWS services:

- AWS Lambda
- Amazon Elastic Compute Cloud (Amazon EC2)
  - By default, the script doesn't collect Amazon Elastic Block Store (Amazon EBS) volume metrics. To collect Amazon EBS metrics, you must modify the attached metrics.yaml file.
- Amazon Relational Database Service (Amazon RDS)
  - However, the script doesn't support Amazon Aurora.
- Application Load Balancer
- Network Load Balancer
- Amazon API Gateway

Tools

- Amazon CloudWatch is a monitoring service built for DevOps engineers, developers, site reliability engineers (SREs), and IT managers. CloudWatch provides data and actionable insights to help you monitor your applications, respond to systemwide performance changes, optimize resource utilization, and get a unified view of operational health. CloudWatch collects monitoring and operational data in the form of logs, metrics, and events, and provides a unified view of AWS resources, applications, and services that run on AWS and on-premises servers.
## Epics

### Install and configure the prerequisites

- Network Load Balancer Metrics
- Amazon API Gateway Metrics

Additional information

Script usage
Example syntax

```
python3 cwreport.py <service> <--region=Optional Region> <--profile=Optional credential profile>
```

Parameters

- **service (required)** – The service you want to run the script against. The script currently supports these services: AWS Lambda, Amazon EC2, Amazon RDS, Application Load Balancer, Network Load Balancer, and API Gateway.
- **region (optional)** – The AWS Region to fetch metrics from. The default Region is ap-southeast-1.
- **profile (optional)** – The AWS CLI named profile to use. If this parameter isn't specified, the default configured credential profile is used.

Examples

- To use the default Region ap-southeast-1 and default configured credentials to fetch Amazon EC2 metrics:
  ```bash
  $ python3 cwreport.py ec2
  ```
- To specify a Region and fetch API Gateway metrics:
  ```bash
  $ python3 cwreport.py apigateway --region us-east-1
  ```
- To specify an AWS profile and fetch Amazon EC2 metrics:
  ```bash
  $ python3 cwreport.py ec2 --profile testprofile
  ```
- To specify both Region and profile to fetch Amazon EC2 metrics:
  ```bash
  $ python3 cwreport.py ec2 --region us-east-1 --profile testprofile
  ```

<table>
<thead>
<tr>
<th>AWS services:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS CloudFormation; AWS CodeBuild; AWS CodeCommit; AWS CodePipeline; AWS Glue</td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

You can run unit tests for Python extract, transform, and load (ETL) jobs for AWS Glue in a local development environment, but replicating those tests in a DevOps pipeline can be difficult and time consuming. Unit testing can be especially challenging when you're modernizing mainframe ETL process on AWS technology stacks. This pattern shows you how to simplify unit testing, while keeping existing functionality intact, avoiding disruptions to key application functionality when you release new features, and maintaining high-quality software. You can use the steps and code samples in this pattern to run unit tests for Python ETL jobs in AWS Glue by using the pytest framework in AWS CodePipeline. You can also use this pattern to test and deploy multiple AWS Glue jobs.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- An Amazon Elastic Container Registry (Amazon ECR) image URI for your AWS Glue library, downloaded from the Amazon ECR Public Gallery
- Bash terminal (on any operating system) with a profile for the target AWS account and AWS Region
- Python 3.9 or later
- Pytest

**Architecture**

**Technology stack**

- Amazon Elastic Container Registry (Amazon ECR)
- AWS CodeBuild
- AWS CodeCommit
- AWS CodePipeline
- AWS Glue
- Pytest
Tools

AWS tools
AWS Prescriptive Guidance Patterns

Best practices

- **Amazon Elastic Container Registry (Amazon ECR)** is a managed container image registry service that’s secure, scalable, and reliable.
- **AWS CodeBuild** is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- **AWS CodeCommit** is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- **AWS CodePipeline** helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- **AWS Glue** is a fully managed ETL service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.

Other tools

- **Pytest** is a framework for writing small unit tests that scale to support complex functional testing for applications and libraries.
- **Python** is a high-level, interpreted general purpose programming language.
- **Python ETL library** for AWS Glue is a repository for Python libraries that are used in the local development of PySpark batch jobs for AWS Glue.

Code

The code for this pattern is available in the GitHub [aws-glue-jobs-unit-testing](https://github.com/aws-glue-jobs-unit-testing) repository. The repository includes the following resources:

- A sample Python-based AWS Glue job in the `src` folder
- Associated unit test cases (built using the pytest framework) in the `tests` folder
- A CloudFormation template (written in YAML) in the `deploy` folder

Best practices

Security for CodePipeline resources

It’s a best practice to use encryption and authentication for the source repositories that connect to your pipelines in CodePipeline. For more information, see [Security best practices](https://docs.aws.amazon.com/codepipeline/latest/userguide/codepipeline-security.html) in the CodePipeline documentation.

Monitoring and logging for CodePipeline resources

It’s a best practice to use AWS logging features to determine what actions users take in your account and what resources they use. The log files show the following:

- Time and date of actions
- Source IP address of actions
- Which actions failed due to inadequate permissions

Logging features are available in AWS CloudTrail and Amazon CloudWatch Events. You can use CloudTrail to log AWS API calls and related events made by or on behalf of your AWS account. For more information, see [Logging CodePipeline API calls with AWS CloudTrail](https://docs.aws.amazon.com/codepipeline/latest/userguide/logging-api-calls.html) in the CodePipeline documentation.

You can use CloudWatch Events to monitor your AWS Cloud resources and applications running on AWS. You can also create alerts in CloudWatch Events. For more information, see [Monitoring CodePipeline events](https://docs.aws.amazon.com/codepipeline/latest/userguide/events-monitoring.html) in the CodePipeline documentation.
## Epics

### Deploy the source code

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Prepare the code archive for deployment. | 1. Download code.zip from the GitHub <https://github.com/aws-samples/aws-glue-jobs-unit-testing> repository, or create the .zip file yourself by using a command-line tool. For example, you can create the .zip file on Linux or Mac by running the following commands in the terminal:

```bash
git clone https://github.com/aws-samples/aws-glue-jobs-unit-testing.git
cd aws-glue-jobs-unit-testing
git checkout master
zip -r code.zip src/ tests/ deploy/
```
2. Sign in to the AWS Management Console and choose the AWS Region of your choice.  
3. Create an S3 bucket, and then upload the .zip package and code.zip file (downloaded earlier) to the S3 bucket that you created. | DevOps engineer |
| Create the CloudFormation stack. | 1. Sign in to the AWS Management Console and then open the CloudFormation console.  
2. Choose Create stack, and then choose With existing resources (import resources).  
3. In the Specify template section of the Create stack page, choose Upload a template file, and then choose the pipeline.yml template (downloaded from the GitHub repository). Then, choose Next.  
4. For Stack name, enter glue-unit-testing-pipeline, or choose a stack name of your choice. | AWS DevOps, DevOps engineer |
<table>
<thead>
<tr>

<tr>
<td>5. After the deployment stage is complete, run and monitor the deployed AWS Glue job on the AWS Glue console. For more information, see <strong>Monitoring AWS Glue</strong> in the AWS Glue documentation.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

A pipeline with an Amazon S3, Amazon ECR, or CodeCommit source no longer starts automatically

If you change any configuration settings for an action that uses event rules in Amazon EventBridge or CloudWatch Events for change detection, the AWS Management Console might not detect a change where source identifiers are similar and have identical initial characters. Because the new event rule is not created by the console, the pipeline no longer starts automatically.

For example, changing a CodeCommit branch name from `MyTestBranch-1` to `MyTestBranch-2` is a minor change. Because the change is at the end of the branch name, the event rule for the source action might not update or create a rule for the new source settings.

This applies to the following source actions that use events in CloudWatch Events for change detection:

- The S3 bucket name and S3 object key parameters or console identifiers when the source action is in Amazon S3
- The repository name and image tag parameters or console identifiers when the source action is in Amazon ECR
- The repository name and branch name parameters or console identifiers when the source action is in CodeCommit
<table>
<thead>
<tr>
<th>Issue</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>To resolve the issue, do one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Change the configuration settings in Amazon S3, Amazon ECR, or CodeCommit, so that changes are made to the starting portion of the parameter value. For example, change your branch name from <code>release-branch</code> to <code>2nd-release-branch</code>. Avoid a change at the end of the name, such as <code>release-branch-2</code>.</td>
</tr>
<tr>
<td></td>
<td>• Change the configuration settings in Amazon S3, Amazon ECR, or CodeCommit for each pipeline. For example, change your branch name from <code>myRepo/myBranch</code> to <code>myDeployRepo/myDeployBranch</code>. Avoid a change at the end of the name, such as <code>myRepo/myBranch2</code>.</td>
</tr>
<tr>
<td></td>
<td>• Instead of using the AWS Management Console, use the AWS Command Line Interface (AWS CLI) or AWS CloudFormation to create and update your change-detection event rules. For instructions on creating event rules for an Amazon S3 source action, see <a href="#">Amazon S3 source actions and CloudWatch Events</a>. For instructions on creating event rules for an Amazon ECR action, see <a href="#">Amazon ECR source actions and CloudWatch Events</a>. For instructions on creating event rules for a CodeCommit action, see <a href="#">CodeCommit source actions and CloudWatch Events</a>. After you edit your action configuration in the console, accept the updated change-detection resources created by the console.</td>

Set up a Helm v3 chart repository in Amazon S3

Creating by Abhishek Sharma (AWS)

Environment: PoC or pilot

Technologies: DevOps; Containers & microservices; Modernization

Workload: All other workloads

AWS services: Amazon S3

Summary of setting up a Helm v3 chart repository in Amazon S3

This pattern helps you to manage Helm v3 charts efficiently by integrating the Helm v3 repository into Amazon Simple Storage Service (Amazon S3) on the Amazon Web Services (AWS) Cloud. To use this pattern, you must be familiar with Kubernetes and with Helm, which is a Kubernetes package manager. Using Helm repositories to store charts and control chart versions can improve mean time to restore (MTTR) during outages.

This pattern uses AWS CodeCommit for Helm repository creation, and it uses an S3 bucket as a Helm chart repository, so that the charts can be centrally managed and accessed by developers across the organization.

Prerequisites and limitations for setting up a Helm v3 chart repository in Amazon S3

Prerequisites

- An active AWS account
- Python version 2.7.12 or later
- pip
- A virtual private cloud (VPC) with subnets and an Amazon Elastic Compute Cloud (Amazon EC2) instance
- Git installed on the EC2 instance
- AWS Identity and Access Management (IAM) access to create the S3 bucket
- IAM (programmatic or role) access to Amazon S3 from the client machine
- AWS CodeCommit repository
- AWS Command Line Interface (AWS CLI)

Product versions

- Helm v3
- Python version 2.7.12 or later
Architecture for setting up a Helm v3 chart repository in Amazon S3

Target technology stack

- Amazon S3
- AWS CodeCommit
- Helm
- Kubectl
- Python and pip
- Git
- helm-s3 plugin

Target architecture

Automation and scale

- You can incorporate Helm into your existing continuous integration/continuous delivery (CI/CD) automation tool to automate the packaging and version control of Helm charts (out of scope for this pattern).
- GitVersion or Jenkins build numbers can be used to automate version control of the charts.
Tools for setting up a Helm v3 chart repository in Amazon S3

- **Helm** – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- **helm-s3 plugin** – The helm-s3 plugin supports interaction with Amazon S3. It can be used with either Helm v2 or Helm v3.

Epics for setting up a Helm v3 chart repository in Amazon S3

Install and validate Helm v3

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Install the Helm v3 client.</td>
<td>To download and install the Helm client on your local system, run the following command: `sudo curl <a href="https://raw.githubusercontent.com/helm/helm/main/scripts/get-helm-3">https://raw.githubusercontent.com/helm/helm/main/scripts/get-helm-3</a></td>
<td>bash`</td>
</tr>
<tr>
<td>Validate the Helm installation.</td>
<td>To validate the Helm client, run the following command: <code>helm version --short</code></td>
<td>Cloud Administrator, DevOps Engineer</td>
</tr>
</tbody>
</table>

Initialize an S3 bucket as a Helm repository

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an S3 bucket for Helm charts.</td>
<td>Create a unique S3 bucket. In the bucket, create a folder called stable/myapp. The example in this pattern uses <code>s3://my-helm-charts/stable/myapp</code> as the target chart repository.</td>
<td>Cloud Administrator, DevOps Engineer</td>
</tr>
<tr>
<td>Install the helm-s3 plugin for Amazon S3.</td>
<td>To install the helm-s3 plugin on your client machine, run the following command: <code>helm plugin install https://github.com/hypnoglow/helm-s3.git</code></td>
<td>Cloud Administrator, DevOps Engineer</td>
</tr>
<tr>
<td>Initialize the Amazon S3 Helm repository.</td>
<td>To initialize the target folder as a Helm repository, use the</td>
<td>Cloud Administrator, DevOps Engineer</td>
</tr>
</tbody>
</table>
### AWS Prescriptive Guidance Patterns

#### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>following command:</strong> <code>helm s3 init s3://my-helm-charts/stable/myapp</code>&lt;br&gt;<strong>The command creates an index.yaml file in the target to track all the chart information that is stored at that location.</strong></td>
<td></td>
<td>Cloud Administrator, DevOps Engineer</td>
</tr>
<tr>
<td><strong>Verify the newly created Helm repository.</strong></td>
<td><strong>To verify that the index.yaml file was created, run the following command:</strong> <code>aws s3 ls s3://my-helm-charts/stable/myapp/</code></td>
<td></td>
</tr>
<tr>
<td><strong>Add the Amazon S3 repository to Helm on the client machine.</strong></td>
<td><strong>To add the target repository alias to the Helm client machine, use the following command:</strong> <code>helm repo add stable-myapp s3://my-helm-charts/stable/myapp/</code></td>
<td></td>
</tr>
</tbody>
</table>

### Package and publish charts in the Amazon S3 Helm repository

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Clone your Helm charts.</strong></td>
<td>If no local Helm charts are present on in your CodeCommit repository, clone them from your GitHub repo by running the following command: <code>git clone &lt;url_of_your_helm_source_code&gt;.git</code></td>
<td>Cloud Administrator, DevOps Engineer</td>
</tr>
<tr>
<td><strong>Package the local Helm chart.</strong></td>
<td>To package the chart that you created or cloned, use the following command: <code>helm package ./my-app</code>&lt;br&gt;As an example, this pattern uses the my-app chart. The command packages all the contents of the my-app chart folder into an archive file, which is named using the version number that is mentioned in the Chart.yaml file.</td>
<td>Cloud Administrator, DevOps Engineer</td>
</tr>
<tr>
<td><strong>Store the local package in the Amazon S3 Helm repository.</strong></td>
<td>To upload the local package to the Helm repository in Amazon S3, run the following command: <code>helm s3 push ./my-app-0.1.0.tgz stable-myapp</code></td>
<td>Cloud Administrator, DevOps Engineer</td>
</tr>
</tbody>
</table>
### Upgrade your Helm repository

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modify and package the chart.</td>
<td>In <code>values.yaml</code>, set the <code>replicaCount</code> value to 1, and then package the chart, this time changing the version in <code>Chart.yaml</code> to 0.1.1. Version control is ideally achieved through automation by using tools like GitVersion or Jenkins build numbers in a CI/CD pipeline. Automating the version number is out of scope for this pattern. To package the chart, run the following command: <code>helm package ./my-app/</code></td>
<td>Cloud Administrator, DevOps Engineer</td>
</tr>
<tr>
<td>Push the new version to the Helm repository in Amazon S3.</td>
<td>To push the new package, version of 0.1.1, to the <code>my-helm-charts</code> Helm repository in Amazon S3, run the following command: <code>helm s3 push ./my-app-0.1.1.tgz stable-myapp</code></td>
<td>Cloud Administrator, DevOps Engineer</td>
</tr>
<tr>
<td>Verify the updated Helm chart.</td>
<td>To confirm that the updated chart appears both locally and in the Amazon S3 Helm repository, run the following commands. <code>helm repo update</code> <code>helm search repo stable-myapp</code></td>
<td>Cloud Administrator, DevOps Engineer</td>
</tr>
</tbody>
</table>
**Search for and install a chart from the Amazon S3 Helm repository**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search for all versions of the my-app chart.</td>
<td>To view all the available versions of a chart, run the following command with the <code>--versions</code> flag: <code>helm search repo my-app --versions</code>&lt;br&gt;Without the flag, Helm by default displays the latest uploaded version of a chart.</td>
<td>DevOps Engineer</td>
</tr>
<tr>
<td>Install a chart from the Amazon S3 Helm repository.</td>
<td>Automated installation is out of scope for this pattern, but you can manually install. The search results from the previous task show the multiple versions of the my-app chart. To install the new version (0.1.1) from the Amazon S3 Helm repository, use the following command: <code>helm upgrade --install my-app-release stable-myapp/my-app --version 0.1.1 --namespace dev</code></td>
<td>DevOps Engineer</td>
</tr>
</tbody>
</table>

**Roll back to a previous version by using Helm**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Review the details for a specific revision.</td>
<td>Automated rollback is out of scope for this pattern, but you can roll back to an earlier version manually. Before you switch or roll back to a working version, and for an additional layer of validation before installing a revision, view which values were passed to each of the revisions by using the following command: <code>helm get values --revision=2 my-app-release</code></td>
<td>DevOps Engineer</td>
</tr>
<tr>
<td>Roll back to a previous version.</td>
<td>Automated rollback is out of scope for this pattern. To manually roll back to a previous revision, use the following command: <code>helm rollback my-app-release 1</code>&lt;br&gt;This example is rolling back to revision number 1.</td>
<td>DevOps Engineer</td>
</tr>
</tbody>

Home

Automating your software build and release process with continuous integration and continuous delivery (CI/CD) supports repeatable builds and rapid delivery of new features to your users. You can quickly and easily test each code change, and you can catch and fix bugs before releasing your software. By running each change through your staging and release process, you can verify the quality of your application or infrastructure code. CI/CD embodies a culture, a set of operating principles, and a collection of practices that help application development teams to deliver code changes more frequently and reliably. The implementation is also known as the CI/CD pipeline.

This pattern defines a reusable continuous integration and continuous delivery (CI/CD) pipeline on Amazon Web Services (AWS). The AWS CodePipeline pipeline is written using AWS Cloud Development Kit (AWS CDK) v2.

Using CodePipeline, you can model the different stages of your software release process through the AWS Management Console interface, the AWS Command Line Interface (AWS CLI), AWS CloudFormation, or the AWS SDKs. This pattern demonstrates the implementation of CodePipeline and its components using AWS CDK. In addition to construct libraries, AWS CDK includes a toolkit (the CLI command cdk), which is the primary tool for interacting with your AWS CDK app. Among other functions, the toolkit provides the ability to convert one or more stacks to CloudFormation templates and deploy them to an AWS account.

The pipeline includes tests to validate the security of your third-party libraries, and it helps ensure expedited, automated release in the specified environments. You can increase the overall security of your applications by putting them through a validation process.

The intent of this pattern is to accelerate your use of CI/CD pipelines to deploy your code while ensuring the resources you deploy adhere to DevOps best practices. After you implement the example code, you will have an AWS CodePipeline with linting, testing, a security check, deployment, and post-deployment processes. This pattern also includes steps for Makefile. Using a Makefile, developers can reproduce CI/CD steps locally and increase the velocity of the development process.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A basic understanding in the following:
• AWS CDK
• AWS CloudFormation
• AWS CodePipeline
• TypeScript

Limitations

This pattern uses AWS CDK for TypeScript only. It doesn’t cover other languages supported by AWS CDK.

Product versions

• AWS Command Line Interface (AWS CLI) version 2.61.0 or later
• cfn_nag version 0.8.10 or later
• git-remote-codecommit version 1.16 or later
• Node.js version 19 or later
• TypeScript version 4.9.4 or later

Architecture

Target technology stack

• AWS CDK
• AWS CloudFormation
• AWS CodeCommit
• AWS CodePipeline

Target architecture

The pipeline is triggered by a change in the AWS CodeCommit repository (SampleRepository). In the beginning, CodePipeline builds artifacts, updates itself, and starts the deployment process. The resulting pipeline deploys a solution to three independent environments:

• Dev – Three-step code check in the active development environment
• Test – Integration and regression test environment
• Prod – Production environment

The three steps included in the Dev stage are linting, security, and unit tests. These steps run in parallel to speed up the process. To ensure that the pipeline provides only working artifacts, it will be stop running whenever a step in the process fails. After a Dev stage deployment, the pipeline runs validation tests to verify the results. In the case of success, the pipeline will then deploy the artifacts to the Test environment, which contains post-deployment validation. The final step is to deploy the artifacts to the Prod environment.

The following diagram shows the workflow from the CodeCommit repository to the build and update processes performed by CodePipeline, the three Dev environment steps, and subsequent deployment and validation in each of the three environments.
AWS Prescriptive Guidance Patterns

Tools

**AWS services**

- **AWS Cloud Development Kit (AWS CDK)** is a software development framework that helps you define and provision AWS Cloud infrastructure in code.

- **AWS CloudFormation** helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions. In this pattern, CloudFormation templates can be used to create a CodeCommit repository and a CodePipeline CI/CD pipeline.

- **AWS CodeCommit** is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.

- **AWS CodePipeline** is a CI/CD service that helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.

- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

**Other tools**

- **cfn_nag** is an open-source tool that looks for patterns in CloudFormation templates to identify potential security issues.

- **git-remote-codecommit** is a utility for pushing and pulling code from CodeCommit repositories by extending Git.

- **Node.js** is an event-driven JavaScript runtime environment designed for building scalable network applications.

**Code**

The code for this pattern is available in the GitHub **AWS CodePipeline with CI/CD practices** repository.

**Best practices**

Review resources, such as AWS Identity and Access Management (IAM) policies, to confirm that they align with your organizational best practices.
## Epics

### Install tools

<table>
<thead>

### Set up the initial deployment

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Download or clone the code. | To get the code that is used by this pattern, do one of the following:  
  - Download the latest source code from `releases` in the GitHub repo, and unzip the downloaded file into a folder.  
  - Clone the project by running the following command.  
    ```
git clone --depth 1 https://github.com/aws-samples/aws-codepipeline-cicd.git
```
| DevOps engineer             | ![Image](https://via.placeholder.com/150)  
Remove the `.git` directory from the cloned repository.  
```
cd ./aws-codepipeline-cicd  
rm -rf ./git
```
| DevOps engineer             | ![Image](https://via.placeholder.com/150)  
Later, you will use a newly created AWS CodeCommit repository as a remote origin.                                                                 |                       |
| Connect to the AWS account. | You can connect by using a temporary security token or landing zone authentication. To confirm that you are using the correct account and AWS Region, run the following commands. | DevOps engineer       |
|                             | ```
AWS_REGION="eu-west-1"  
ACCOUNT_NUMBER=$(aws sts get-caller-identity --query Account --output text)  
echo "${(ACCOUNT_NUMBER)"
``` |                       |
| Bootstrap the environment.  | To bootstrap an AWS CDK environment, run the following commands.  
```
npm install  
npm run cdk bootstrap  
"aws://${(ACCOUNT_NUMBER)}/$ {AWS_REGION)"
```  
After you successfully bootstrap the environment, the following output should be displayed. | DevOps engineer       |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Synthesize a template.</td>
<td>To synthesize an AWS CDK app, use the <code>cdk synth</code> command.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td><code>npm run cdk synth</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>You should see the following output.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Successfully synthesized to <code>&lt;path-to-directory&gt;/aws-codepipeline-cicd/cdk.out</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Supply a stack id (CodePipeline, DevMainStack) to display its template.</td>
<td></td>
</tr>
</tbody>
</table>

For more information about AWS CDK bootstrapping, see the [AWS CDK documentation](https://docs.aws.amazon.com/cdk/latest/guide/index.html).
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deploy the CodePipeline stack.</td>
<td>Now that you bootstrapped and synthesized the CloudFormation template, you can deploy it. The deployment will create the CodePipeline pipeline and a CodeCommit repository, which will be the source and trigger of the pipeline.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

```bash
npm run cdk -- deploy CodePipeline --require-approval never
```

After you run the command, you should see a successful deployment of the CodePipeline stack and output information. The `CodePipeline.RepositoryName` gives you the name of the CodeCommit repository in the AWS account.

```text
CodePipeline: deploying...
CodePipeline: creating CloudFormation changeset...
# CodePipeline
Outputs:
CodePipeline.RepositoryName = SampleRepository
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set up the remote CodeCommit repository and branch.</td>
<td>After a successful deployment, CodePipeline will initiate the first run of the pipeline, which you can find in the <a href="https://aws.amazon.com">AWS CodePipeline console</a>. Because AWS CDK and CodeCommit don’t initiate a default branch, this initial pipeline run will fail and return the following error message.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td>The action failed because no branch named main was found in the selected AWS CodeCommit repository SampleRepository. Make sure you are using the correct branch name, and then try again. Error: null</td>
<td></td>
</tr>
<tr>
<td></td>
<td>To fix this error, set up a remote origin as SampleRepository, and create the required main branch.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>RepoName=$(aws cloudformation describe-stacks --stack-name CodePipeline --query &quot;Stacks[0].Outputs[? OutputKey=='RepositoryName'].OutputValue&quot; --output text) echo &quot;${RepoName}&quot; #</td>

<tr>
<td></td>
<td>git branch -m master main</td>
<td></td>
</tr>
<tr>
<td></td>
<td>git remote add origin codecommit://${RepoName}</td>
<td></td>
</tr>
<tr>
<td></td>
<td>git add .</td>
<td></td>
</tr>
<tr>
<td></td>
<td>git commit -m &quot;Initial commit&quot;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>git push -u origin main</td>
<td></td>
</tr>
</tbody>
</table>

Test the deployed CodePipeline pipeline

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Commit a change to activate the pipeline.</td>
<td>After a successful initial deployment, you should have a complete CI/CD pipeline with a main branch for SampleRepository as a source branch. As soon as you commit changes to the main branch, the</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>
### Pipeline Description

The pipeline will initiate and run the following sequence of actions:

1. Get your code from the CodeCommit repository.
2. Build your code.
3. Update the pipeline itself (UpdatePipeline).
4. Run three parallel jobs for linting, security and unit test checks.
5. In the case of success, the pipeline will deploy the Main stack from ./lib/main-stack.ts to the Dev environment.
6. Run a post-deployment check for deployed resources. You can follow all CodePipeline steps and results in the CodePipeline console.
7. In the case of success, the pipeline will repeat deployment and validation for the Test and Prod environments.

### Test locally by using a Makefile

**Task**: Run the development process by using a Makefile.

**Description**: You can run the whole pipeline locally by using the make command, or you can run an individual step (for example, make linting).

To test using make, perform the following actions:

- Implement the local pipeline: `make`
- Run only unit testing: `make unittest`
- Deploy to the current account: `make deploy`
- Clean up the environment: `make clean`

**Skills required**: App developer, DevOps engineer
Clean up resources

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete AWS CDK app resources.</td>
<td>To clean up your AWS CDK app, run the following command.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td>cdk destroy --all</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Be aware that the Amazon Simple Storage Service (Amazon S3) buckets that are created during bootstrapping aren't automatically deleted. They need a retention policy that allows deletion, or you need to delete them manually in your AWS account.</td>
<td></td>
</tr>
</tbody>
</table>

Troubleshooting

<table>
<thead>
<tr>
<th>Issue</th>

Set up end-to-end encryption for applications on Amazon EKS using cert-manager and Let's Encrypt

Summary

Implementing end-to-end encryption can be complex and you need to manage certificates for each asset in your microservices architecture. Although you can terminate the Transport Layer Security (TLS) connection at the edge of the Amazon Web Services (AWS) network with a Network Load Balancer or Amazon API Gateway, some organizations require end-to-end encryption.

This pattern uses NGINX Ingress Controller for ingress. This is because when you create a Kubernetes ingress, the ingress resource uses a Network Load Balancer. The Network Load Balancer doesn't permit uploads of client certificates. Therefore, you can't achieve mutual TLS with Kubernetes ingress.

This pattern is intended for organizations that require mutual authentication between all microservices in their applications. Mutual TLS reduces the burden of maintaining user names or passwords and can also use the turnkey security framework. This pattern's approach is compatible if your organization has a large number of connected devices or must comply with strict security guidelines.

This pattern helps increase your organization's security posture by implementing end-to-end encryption for applications running on Amazon Elastic Kubernetes Service (Amazon EKS). This pattern provides a sample application and code in the GitHub End-to-end encryption on Amazon EKS repository to show how a microservice runs with end-to-end encryption on Amazon EKS. The pattern's approach uses cert-manager, an add-on to Kubernetes, with Let's Encrypt as the certificate authority (CA). Let's Encrypt is a cost-effective solution to manage certificates and provides free certificates that are valid for 90 days. Cert-manager automates the on-demand provisioning and rotating of certificates when a new microservice is deployed on Amazon EKS.

Intended audience

This pattern is recommended for users who have experience with Kubernetes, TLS, Amazon Route 53, and Domain Name System (DNS).

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing Amazon EKS cluster.
- AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows.
AWS Prescriptive Guidance Patterns

Architecture

- The `kubectl` command line utility, installed and configured to access the Amazon EKS cluster. For more information about this, see Installing kubectl in the Amazon EKS documentation.
- An existing DNS name to test the application. For more information about this, see Registering domain names using Amazon Route 53 in the Amazon Route 53 documentation.
- The latest Helm version, installed on your local machine. For more information about this, see Using Helm with Amazon EKS in the Amazon EKS documentation and the GitHub Helm repository.
- The GitHub End-to-end encryption on Amazon EKS repository, cloned to your local machine.
- Replace the following values in the policy.json and trustpolicy.json files from the cloned GitHub End-to-end encryption on Amazon EKS repository:
  - `<account number>` – Replace with the AWS account ID for the account that you want to deploy the solution in.
  - `<zone_id>` – Replace with the domain name's Route 53 zone ID.
  - `<node_group_role>` – Replace with the name of the AWS Identity and Access Management (IAM) role associated with the Amazon EKS nodes.
  - `<namespace>` – Replace with the Kubernetes namespace in which you deploy the NGINX Ingress Controller and the sample application.
  - `<application-domain-name>` – Replace with the DNS domain name from Route 53.

Limitations

- This pattern doesn't describe how to rotate certificates and only demonstrates how to use certificates with microservices on Amazon EKS.

Architecture

The following diagram shows the workflow and architecture components for this pattern.

The diagram shows the following workflow:

1. A client sends a request to access the application to the DNS name.
2. The Route 53 record is a CNAME to the Network Load Balancer.
3. The Network Load Balancer forwards the request to the NGINX Ingress Controller that is configured with a TLS listener. Communication between the NGINX Ingress Controller and the Network Load Balancer follows HTTPS protocol.

4. The NGINX Ingress Controller carries out path-based routing based on the client's request to the application service.

5. The application service forwards the request to the application pod. The application is designed to use the same certificate by calling secrets.

6. Pods run the sample application using the cert-manager certificates. The communication between the NGINX Ingress Controller and the pods uses HTTPS.

**Note:** Cert-manager runs in its own namespace. It uses a Kubernetes cluster role to provision certificates as secrets in specific namespaces. You can attach those namespaces to application pods and NGINX Ingress Controller.

### Tools

**AWS services**

- **Amazon Elastic Kubernetes Service (Amazon EKS)** is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.

- **Elastic Load Balancing** automatically distributes your incoming traffic across multiple targets, containers, and IP addresses.

- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

- **Amazon Route 53** is a highly available and scalable DNS web service.

**Other tools**

- **cert-manager** is an add-on to Kubernetes that requests certificates, distributes them to Kubernetes containers, and automates certificate renewal.

- **NGINX Ingress Controller** is a traffic management solution for cloud-native apps in Kubernetes and containerized environments.

### Epics

**Create and configure a public hosted zone with Route 53**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a public hosted zone in Route 53.</td>
<td>Sign in to the AWS Management Console, open the Amazon Route 53 console, choose Hosted zones, and then choose Create hosted zone. Create a public hosted zone and record the zone ID. For more information about this, see Creating a public hosted</td>
<td>AWS DevOps</td>
</tr>
</tbody>
</table>
Configure an IAM role to allow cert-manager to access the public hosted zone

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the IAM policy for cert-manager.</td>
<td>An IAM policy is required to provide cert-manager with permission to validate that you own the Route 53 domain. The policy.json sample IAM policy is provided in the 1-IAMRole directory in the cloned GitHub End-to-end encryption on Amazon EKS repository. Enter the following command in AWS CLI to create the IAM policy.</td>
<td>AWS DevOps</td>
</tr>
</tbody>
</table>
| | | `aws iam create-policy \  
--policy-name PolicyForCertManager \  
--policy-document file://policy.json` | |
| Create the IAM role for cert-manager. | After you create the IAM policy, you must create an IAM role. The trustpolicy.json sample IAM role is provided in the 1-IAMRole directory. | AWS DevOps |

Note: ACME DNS01 uses the DNS provider to post a challenge for cert-manager to issue the certificate. This challenge asks you to prove that you control the DNS for your domain name by putting a specific value in a TXT record under that domain name. After Let's Encrypt gives your ACME client a token, your client creates a TXT record derived from that token and your account key, and it puts that record at _acme-challenge.<YOURDOMAIN>. Then Let's Encrypt queries the DNS for that record. If it finds a match, you can proceed to issue a certificate.
### Set up the NGINX Ingress Controller in Amazon EKS

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>

Subscribe multiple email endpoints to an SNS topic by using a custom resource

Created by Ricardo Morais (AWS)

| Environment: | Production | Technologies: | DevOps | AWS services: | Amazon SNS; AWS CloudFormation; AWS Lambda |

Summary

Note, August 2022: AWS CloudFormation now supports the subscription of multiple resources through the AWS::SNS::Topic object and its Subscription attribute.

This pattern describes how to subscribe multiple email addresses to receive notifications from an Amazon Simple Notification Service (Amazon SNS) topic. It uses an AWS Lambda function as a custom resource in an AWS CloudFormation template. The Lambda function is associated with an input parameter that specifies the email endpoints for the SNS topic.

Currently, you can use the AWS CloudFormation template objects AWS::SNS::Topic and AWS::SNS::Subscription to subscribe single endpoints to SNS topics. To subscribe multiple endpoints, you have to invoke the object multiple times. By using the Lambda function as a custom resource, you can subscribe multiple endpoints through an input parameter. You can use this Lambda function as a custom resource in any AWS CloudFormation template.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An AWS profile configured in your local environment with an access key and secret key. You can also run this code from AWS Cloud9.
- Permissions for the following:
  - AWS Identity and Access Management (IAM) role and policy
  - AWS Lambda function
  - Amazon Simple Storage Service (Amazon S3) for uploading the Lambda function
  - Amazon SNS topic and policy
  - AWS CloudFormation stacks

Limitations

- The code supports Linux and macOS workstations.

Product versions

- AWS Command Line Interface (AWS CLI) version 2 or later.
Architecture

Target technology stack

- AWS CloudFormation
- Amazon SNS
- AWS Lambda

Tools

- AWS CLI version 2

Code

The attachment includes the following files:

- Lambda function: `lambda_function.py`
- AWS CloudFormation template: `template.yaml`
- Two parameter files to handle multiple or single email endpoint subscriptions: `parameters-multiple-values.json` (used as the default) and `parameters-one-value.json`

To deploy the stack, you can use either parameter file. To specify multiple email endpoints:

```
./deploy.sh -p <YOUR_AWS_PROFILE_NAME> -r <YOUR_AWS_PROFILE_REGION>
```

To specify a single email endpoint:

```
./deploy.sh -p <YOUR_AWS_PROFILE_NAME> -r <YOUR_AWS_PROFILE_REGION> -f parameters-one-value.json
```

Epics

Option 1 - Deploy an SNS topic with one email subscription

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure the email endpoint for SNS topic subscriptions.</td>
<td>Edit the file <code>parameters-one-value.json</code> (attached), and change the value of the <code>pSNSNotificationsEmail</code> parameter to reflect the email address you want to use, such as <code>someone@example.com</code>.</td>
<td>IAM role with proper permissions</td>
</tr>
<tr>
<td>Deploy the AWS CloudFormation stack that creates the resources and subscription.</td>
<td>Run the <code>deploy.sh</code> command with your AWS profile name, AWS Region, and</td>
<td></td>
</tr>
</tbody>
</table>
## Option 2 - Deploy an SNS topic with two or more email subscriptions

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure the email endpoints for SNS topic subscriptions.</td>
<td>Edit the file <code>parameters-multiple-values.json</code> (attached), and change the value of the <code>pSNSNotificationsEmail</code> parameter to reflect the email addresses you want to use, separated by commas, as follows: <a href="mailto:someone1@example.com">someone1@example.com</a>, <a href="mailto:someone2@example.com">someone2@example.com</a>.</td>
<td>IAM role with proper permissions</td>
</tr>
<tr>
<td>Deploy the AWS CloudFormation stack that creates the resources and subscription.</td>
<td>Run the <code>deploy.sh</code> command with your AWS profile name and AWS Region. You don’t have to specify the <code>parameters-multiple-values.json</code> file because it’s used by default.</td>
<td>IAM role with proper permissions</td>
</tr>
</tbody>
</table>

```bash
./deploy.sh -p <YOUR_AWS_PROFILE_NAME> -r <YOUR_AWS_PROFILE_REGION> -f parameters-one-value.json
```

## Option 3 - Deploy an SNS topic through an AWS CloudFormation template

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an SNS topic.</td>
<td>Create an SNS topic through an AWS CloudFormation template, without specifying subscription endpoints in the <code>AWS::SNS::Topic</code> template object. You can use <code>template.yaml</code> in the attachment as a starting point.</td>
<td>IAM role with proper permissions</td>
</tr>
<tr>
<td>Create an SNS topic policy.</td>
<td>Create an SNS topic policy in the AWS CloudFormation template.</td>
<td>IAM role with proper permissions</td>
</tr>
<tr>

Use Serverspec for test-driven development of infrastructure code

Created by Sushant Jagdale (AWS)

<table>
<thead>
<tr>
<th>Environment</th>
<th>PoC or pilot</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technologies</td>
<td>DevOps; Infrastructure; Hybrid cloud</td>
</tr>
<tr>
<td>AWS services</td>
<td>Amazon EC2; AWS CodeBuild; AWS CodeDeploy</td>
</tr>
</tbody>
</table>

Summary

This pattern shows you how to use Serverspec to use test-driven development (TDD) when writing infrastructure code on the Amazon Web Services (AWS) Cloud. The pattern also covers automation with AWS CodePipeline. TDD will focus attention on what the infrastructure code must do and sets a clear definition of done. You can use Serverspec to test infrastructure created by tools such as AWS CloudFormation, Terraform by HashiCorp, and Ansible.

Serverspec helps with refactoring infrastructure code. With Serverspec, you can write RSpec tests to check installation of various packages and software, run commands, check for running processes and ports, check file permission settings, and so forth. Serverspec checks whether your servers are configured correctly. You install only Ruby on your servers. You don't need to install any agent software.

Test-driven infrastructure provides the following benefits:

- Cross-platform testing
- Validation of expectations
- Confidence in your automation
- Infrastructure consistency and stability
- Fail early

You can use this pattern to run Serverspec unit tests for Apache software and check file permission settings during Amazon Machine Image (AMI) creation. An AMI will be created only if all the test cases pass. Serverspec will perform following tests:

- Apache process is running.
- Apache port is running.
- Apache configuration files and directories exist at certain locations, and so forth.
- File permissions are correctly configured.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS CodeBuild
- AWS CodeCommit
• AWS CodePipeline
• A virtual private cloud (VPC) with a public subnet
• Installation of AWS Command Line Interface (AWS CLI) and Git

Product versions
• HashiCorp Packer version: 1.6.6
• Ruby version: 2.5.1 and later
• AWS CLI version: 1.18.185

Architecture

Target architecture

1. When you push the code to the CodeCommit repository, an Amazon CloudWatch Events event engages the CodePipeline. In the first stage of the pipeline, the code is fetched from CodeCommit.
2. The second pipeline stage runs CodeBuild, which validates and builds the Packer template.
3. As a part of the Packer build provisioner, Packer installs Apache and Ruby software. Then the provisioner calls a shell script that uses Serverspec to unit test the Apache process, port, files, and directories. The Packer post-processor writes a JavaScript Object Notation (JSON) file with a list of all the artifacts produced by Packer during a run.
4. Finally, an Amazon Elastic Compute Cloud (Amazon EC2) instance is created using the AMI ID produced by Packer.

Tools

• AWS CLI – Amazon Command Line Interface (AWS CLI) is an open source tool for interacting with AWS services using commands in your command line shell.
• Amazon CloudWatch Events – Amazon CloudWatch Events delivers a near-real-time stream of system events that describe changes in Amazon Web Services (AWS) resources.
• AWS CodeBuild – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
• AWS CodeCommit – AWS CodeCommit is a version control service hosted by Amazon Web Services. You can use CodeCommit to privately store and manage assets (such as documents, source code, and binary files) in the cloud.
• AWS CodePipeline – AWS CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software. You can quickly model and configure the different stages of a software release process.
• **HashiCorp Packer** – HashiCorp Packer is a tool for automating the creation of identical machine images from a single source configuration.

• **Serverspec** – Serverspec runs RSpec tests to check server configuration. Serverspec uses Ruby, and you don’t need to install agent software.

**Code**

The code is attached. The code uses the following structure, with three directories and eight files.

```plaintext
### amazon-linux_packer-template.json (Packer template)
### buildspec.yaml (CodeBuild .yaml file)
### pipeline.yaml (AWS CloudFormation template to automate CodePipeline)
### rspec_tests (RSpec required files and spec)
#    ### Gem-file
#    ### Rakefile
#    ### spec
#        ### apache_spec.rb
#        ### spec_helper.rb
### scripts
    ### rspec.sh (Installation of Ruby and initiation of RSpec)
```

**Epics**

**Configure AWS credentials**

<table>

<tr>
<td>Test your credentials.</td>
<td>To validate the configured credentials, run the following command.</td>
<td>Developer, Systems administrator, DevOps engineer</td>
</tr>
</tbody>
</table>

```plaintext
aws sts get-caller-identity --profile <profile>
```

**AWS CodePipeline**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a CodeCommit repository.</td>
<td>To create a CodeCommit repository, run the following command.</td>
<td>Developer, Systems administrator, DevOps engineer</td>
</tr>
</tbody>
</table>
### Task

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>aws codecommit create-repository --repository-name &quot;&lt;provide repository-name&gt;&quot;</strong> <code>--repository-description &quot;repository to unit test the infrastructure code&quot;</code></td>
<td><strong>Developer, DevOps engineer</strong></td>
</tr>
<tr>
<td><strong>Write RSpec tests.</strong> Create RSpec test cases for your infrastructure. For more information, see the Additional information section.**</td>
<td><strong>System Administrator, DevOps engineer</strong></td>
</tr>
<tr>
<td><strong>Push code to the CodeCommit repository. To push the attached code to the CodeCommit repository, run the following commands.</strong></td>
<td><strong>Developer, Systems administrator, DevOps engineer</strong></td>
</tr>
<tr>
<td><code>git clone &lt;repository url&gt;</code> <code>cp -R /tmp/&lt;code folder&gt;/ &lt;repository_folder&gt;/</code> <code>git add .</code> <code>git commit -m&quot;initial commit&quot;</code> <code>git push</code></td>
<td><strong>Developer, Systems administrator, DevOps engineer</strong></td>
</tr>
<tr>
<td><strong>Create the pipeline. To create the pipeline, run the AWS CLI command that is in the Additional information section.</strong></td>
<td><strong>Developer, Systems administrator, DevOps engineer</strong></td>
</tr>
<tr>
<td><strong>Start the pipeline. Commit code to the CodeCommit repository. Any commit to the repository will initiate the pipeline.</strong></td>
<td><strong>Developer, Systems administrator, DevOps engineer</strong></td>
</tr>
<tr>
<td><strong>Test the Apache URL. To test the AMI installation, use the following URL:</strong></td>
<td><strong>Developer, Systems administrator, DevOps engineer</strong></td>
</tr>
<tr>
<td><code>http://&lt;your instance public ip&gt;/hello.html</code></td>
<td><strong>Developer, Systems administrator, DevOps engineer</strong></td>
</tr>
</tbody>
</table>

The page will show a "Hello from Apache" message.

- HashiCorp Packer
- Serverspec
- [Introduction to ServerSpec: What is ServerSpec and how do we use it at Stelligent?](https://example.com) (external blog post)
- Test-driven development of infrastructure code (external blog post)
- Image creation and testing with HashiCorp Packer and ServerSpec (external article)
Write RSpec tests

The RSpec test for this pattern is located at `<repository folder>/rspec_tests/spec/apache_spec.rb`.

```ruby
require 'spec_helper'

describe service('httpd') do
  it { should be_enabled }
  it { should be_running }
end

describe port(80) do
  it { should be_listening }
end

describe file('/etc/httpd/conf/httpd.conf') do
  it { should exist }
  it { should be_owned_by 'root' }
  it { should contain 'ServerName www.example.com' }
end

describe file('/etc/httpd/conf/httpd.conf') do
  its(:content) { should match /ServerName www.example.com/ }
end

describe file('/var/www/html/hello.html') do
  it { should exist }
  it { should be_owned_by 'ec2-user' }
end

describe file('/var/log/httpd') do
  it { should be_directory }
end

describe file('/etc/sudoers') do
  it { should be_mode 440 }
end

describe group('root') do
  it { should have_gid 0 }
end

You can add your own tests to the /spec directory.

Create the pipeline

```bash
aws cloudformation create-stack --stack-name myteststack --template-body file://pipeline.yaml --parameters ParameterKey=RepositoryName,ParameterValue=<provide repository-name> ParameterKey=ApplicationName,ParameterValue=<provide application-name> ParameterKey=SecurityGroupId,ParameterValue=<provide SecurityGroupId> ParameterKey=VpcId,ParameterValue=<provide VpcId>
```
Parameter details

`repository-name` – The name of the AWS CodeCommit repository

`application-name` – The Amazon Resource Name (ARNs) are linked with `ApplicationName`; provide any name

`SecurityGroupId` – Any security group ID from your AWS account that has port 80 open

`VpcId` – The ID of your VPC

`SubnetId` – The ID of a public subnet in your VPC

`Region` – The AWS Region where you are running this pattern

`Keypair` – The Secure Shell (SSH) key name to log in to the EC2 instance

`AccountId` – Your AWS account ID

You can also create a CodePipeline pipeline by using the AWS Management Console and passing the same parameters that are in the previous command line.

Use third-party Git source repositories in AWS CodePipeline

Created by Kirankumar Chandrashekar (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>DevOps</th>
<th>Workload:</th>
<th>Open-source</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>AWS CodeBuild; AWS CodePipeline; AWS Lambda</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to use AWS CodePipeline with third-party Git source repositories.

AWS CodePipeline is a continuous delivery service that automates tasks for building, testing, and deploying your software. The service currently supports Git repositories managed by GitHub, AWS CodeCommit, and Atlassian Bitbucket. However, some enterprises use third-party Git repositories that are integrated with their single sign-on (SSO) service and Microsoft Active Directory for authentication. You can use these third-party Git repositories as sources for CodePipeline by creating custom actions and webhooks.

A webhook is an HTTP notification that detects events in another tool, such as a GitHub repository, and connects those external events to a pipeline. When you create a webhook in CodePipeline, the service returns a URL that you can use in your Git repository webhook. If you push code to a specific branch of the Git repository, the Git webhook initiates the CodePipeline webhook through this URL, and sets the source stage of the pipeline to In Progress. When the pipeline is in this state, a job worker polls CodePipeline for the custom job, runs the job, and sends a success or failure status to CodePipeline. In this case, because the pipeline is in the source stage, the job worker gets the contents of the Git repository, zips the contents, and uploads it to the Amazon Simple Storage Service (Amazon S3) bucket where artifacts for the pipeline are stored, using the object key provided by the polled job. You can also associate a transition for the custom action with an event in Amazon CloudWatch, and initiate the job worker based on the event. This setup enables you to use third-party Git repositories that the service doesn't natively support as sources for CodePipeline.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A Git repository that supports webhooks and can connect to a CodePipeline webhook URL through the internet
- AWS Command Line Interface (AWS CLI) installed and configured to work with the AWS account

Architecture

The pattern involves these steps:

1. The user commits code to a Git repository.
2. The Git webhook is called.
3. The CodePipeline webhook is called.
4. The pipeline is set to **In Progress**, and the source stage is set to the **In Progress** state.
5. The source stage action initiates a CloudWatch Events rule, indicating that it was started.
6. The CloudWatch event initiates a Lambda function.
7. The Lambda function gets the details of the custom action job.
8. The Lambda function initiates AWS CodeBuild and passes it all the job-related information.
9. CodeBuild gets the public SSH key or user credentials for HTTPS Git access from Secrets Manager.
10. CodeBuild clones the Git repository for a specific branch.
11. CodeBuild zips the archive and uploads it to the S3 bucket that serves as the CodePipeline artifact store.

### Tools

- **AWS CodePipeline** – AWS CodePipeline is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates. CodePipeline automates the build, test, and deployment phases of your release process for each code change, based on the release model you define. This enables you to rapidly and reliably deliver features and updates. You can integrate AWS CodePipeline with third-party services such as GitHub or with your own custom plugin.

- **AWS Lambda** – AWS Lambda lets you run code without provisioning or managing servers. With Lambda, you can run code for virtually any type of application or backend service with no administration necessary. You upload your code and Lambda takes care of everything required to run and scale your code with high availability. You can set up your code to automatically initiate from other AWS services or call it directly from any web or mobile app.

- **AWS CodeBuild** – AWS CodeBuild is a fully managed continuous integration service that compiles source code, runs tests, and produces software packages that are ready to deploy. With CodeBuild, you don't need to provision, manage, and scale your own build servers. CodeBuild scales continuously and processes multiple builds concurrently, so your builds are not left waiting in a queue. You can get started quickly by using prepackaged build environments, or you can create custom build environments that use your own build tools.

- **AWS Secrets Manager** – AWS Secrets Manager helps you protect secrets needed to access your applications, services, and IT resources. The service enables you to rotate, manage, and retrieve...
database credentials, API keys, and other secrets throughout their lifecycle. Users and applications retrieve secrets by calling Secrets Manager APIs, without having to hardcode sensitive information in plain text. Secrets Manager offers secret rotation with built-in integration for Amazon Relational Database Service (Amazon RDS), Amazon Redshift, and Amazon DocumentDB. The service can be extended to support other types of secrets, including API keys and OAuth tokens. In addition, Secrets Manager lets you control access to secrets by using fine-grained permissions, and audit secret rotation centrally for resources in the AWS Cloud, third-party services, and on-premises environments.

- **Amazon CloudWatch** – Amazon CloudWatch is a monitoring and observation service built for DevOps engineers, developers, site reliability engineers (SREs), and IT managers. CloudWatch provides you with data and actionable insights to monitor your applications, respond to systemwide performance changes, optimize resource utilization, and get a unified view of operational health. CloudWatch collects monitoring and operational data in the form of logs, metrics, and events, providing you with a unified view of AWS resources, applications, and services that run on AWS and on-premises servers. You can use CloudWatch to detect anomalous behavior in your environments, set alarms, visualize logs and metrics side by side, take automated actions, troubleshoot issues, and discover insights to keep your applications running smoothly.

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service that lets you store and protect any amount of data for a range of use cases, such as websites, mobile applications, backup and restore, archive, enterprise applications, IoT devices, and big data analytics. Amazon S3 provides easy-to-use management features to help you organize your data and configure finely tuned access controls to meet your specific business, organizational, and compliance requirements.

## Epics

### Create a custom action in CodePipeline

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a custom action using AWS CLI or AWS CloudFormation.</td>
<td>This step involves creating a custom source action that can be used in the source stage of a pipeline in your AWS account in a particular region. You must use AWS CLI or AWS CloudFormation (not the console) to create the custom source action. For more information about the commands and steps described in this and other epics, see the &quot;Related resources&quot; section at the end of this pattern. In AWS CLI, use the create-custom-action-type command. Use --configuration-properties to provide all the parameters required for the job worker to process when it polls CodePipeline for a job. Make sure to note the values provided to the --provider and --action-version options, so that you can use the same values when creating the pipeline with this custom source stage. You can</td>
<td>General AWS</td>
</tr>
</tbody>
</table>
also create the custom source action in AWS CloudFormation by using the resource type AWS::CodePipeline::CustomActionType.

### Set up authentication

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an SSH key pair.</td>
<td>Create a Secure Shell (SSH) key pair. For instructions, see the GitHub documentation.</td>
<td>Systems/DevOps engineer</td>
</tr>
<tr>
<td>Create a secret in AWS Secrets Manager.</td>
<td>Copy the contents of the private key from the SSH key pair and create a secret in AWS Secrets Manager. This secret is used for authentication when accessing the Git repository.</td>
<td>General AWS</td>
</tr>
<tr>
<td>Add the public key to the Git repository.</td>
<td>Add the public key from the SSH key pair to the Git repository account settings, for authentication against the private key.</td>

</tr>
</tbody>
</table>

### Create a pipeline and webhook

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a pipeline that includes the custom source action.</td>
<td>Create a pipeline in CodePipeline. When you configure the source stage, choose the custom source action that you created previously. You can do this in the AWS CodePipeline console or in AWS CLI. CodePipeline prompts you for the configuration properties that you set on the custom action. This information is required for the job worker to process the job for the custom action. Follow the wizard and create the next stage for the pipeline.</td>
<td>General AWS</td>
</tr>
<tr>
<td>Create a CodePipeline webhook.</td>
<td>Create a webhook for the pipeline you created with the custom source action. You must use AWS CLI or AWS CloudFormation (not supported in CodePipeline).</td>
<td>General AWS</td>
</tr>
</tbody>
</table>
### Task Description

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Create a Lambda function and CodeBuild project.</strong></td>
<td>In this step, you use Lambda and CodeBuild to create a job worker that will poll CodePipeline for job requests for the custom action, run the job, and return the status result to CodePipeline. Create a Lambda function that is initiated by an Amazon CloudWatch Events rule when the custom source action stage of the pipeline transitions to “In Progress.” When the Lambda function is initiated, it should get the custom action job details by polling for jobs. You can use the PollForJobs API to return this information. After the polled job information is obtained, the Lambda function should return an acknowledgment, and then process the information with the data it obtains from the configuration properties for the custom action. When the worker is ready to talk to the Git repository, you might initiate a CodeBuild project, because it's convenient to handle Git tasks by using the SSH client.</td>
<td>General AWS, code developer</td>

Summary

This pattern shows how to test HashiCorp Terraform configurations by using a continuous integration and continuous delivery (CI/CD) pipeline deployed by AWS CodePipeline.

Terraform is a command-line interface application that helps you use code to provision and manage cloud infrastructure and resources. The solution provided in this pattern creates a CI/CD pipeline that helps you validate the integrity of your Terraform configurations by running five CodePipeline stages:

1. “checkout” pulls the Terraform configuration that you’re testing from an AWS CodeCommit repository.
2. “validate” runs infrastructure-as-code (IaC) validation tools, including tfsec, TFLint, and checkov. The stage also runs the following Terraform IaC validation commands: terraform validate and terraform fmt.
3. “plan” shows what changes will be applied to the infrastructure if the Terraform configuration is applied.
4. “apply” uses the generated plan to provision the required infrastructure in a test environment.
5. “destroy” removes the test infrastructure that was created during the “apply” stage.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI), installed and configured
- Git, installed and configured on your local machine
- Terraform, installed and configured on your local machine

Limitations

- This pattern’s approach deploys AWS CodePipeline into one AWS account and AWS Region only. Configuration changes are required for multi-account and multi-Region deployments.
- The AWS Identity and Access Management (IAM) role that this pattern provisions (codepipeline_iam_role) follows the principle of least privilege. This IAM role's permissions must be updated based on the specific resources that your pipeline needs to create.

Product versions
- AWS CLI version 2.9.15 or later
- Terraform version 1.3.7 or later

Architecture

Target technology stack
- AWS CodePipeline
- AWS CodeBuild
- AWS CodeCommit
- AWS IAM
- Amazon Simple Storage Service (Amazon S3)
- AWS Key Management Service (AWS KMS)
- Terraform

Target architecture
The following diagram shows an example CI/CD pipeline workflow for testing Terraform configurations in CodePipeline.

The diagram shows the following workflow:
1. In CodePipeline, an AWS user initiates the actions proposed in a Terraform plan by running the `terraform apply` command in the AWS CLI.
2. AWS CodePipeline assumes an IAM service role that includes the policies required to access
   CodeCommit, CodeBuild, AWS KMS, and Amazon S3.

3. CodePipeline runs the “checkout” stage to pull the Terraform configuration from an AWS
   CodeCommit repository for testing.

4. CodePipeline runs the “validate” stage to test the Terraform configuration by running IaC
   validation tools and running Terraform IaC validation commands in a CodeBuild project.

5. CodePipeline runs the “plan” stage to create a plan in the CodeBuild project based on the Terraform
   configuration. The AWS user can review this plan before the changes are applied to the test
   environment.

6. CodePipeline runs the “apply” stage to implement the plan by using the CodeBuild project to
   provision the required infrastructure in the test environment.

7. CodePipeline runs the “destroy” stage, which uses CodeBuild to remove the test infrastructure that
   was created during the “apply” stage.

8. An Amazon S3 bucket stores pipeline artifacts, which are encrypted and decrypted by using an AWS
   KMS customer managed key.

Tools

AWS services

- **AWS CodePipeline** helps you quickly model and configure the different stages of a software release
  and automate the steps required to release software changes continuously.

- **AWS CodeBuild** is a fully managed build service that helps you compile source code, run unit tests, and
  produce artifacts that are ready to deploy.

- **AWS CodeCommit** is a version control service that helps you privately store and manage Git
  repositories, without needing to manage your own source control system.

- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources
  by controlling who is authenticated and authorized to use them.

- **AWS Key Management Service (AWS KMS)** helps you create and control cryptographic keys to help
  protect your data.

- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you
  store, protect, and retrieve any amount of data.

Other services

- **HashiCorp Terraform** is a command-line interface application that helps you use code to provision and
  manage cloud infrastructure and resources.

Code

The code for this pattern is available in the GitHub [aws-codepipeline-terraform-cicdsamples](https://github.com/aws-codepipeline-terraform-cicdsamples) repository. The repository contains the Terraform configurations required to create the target architecture outlined in this pattern.
## Epics

### Provision the solution components

<table>
<thead>

</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>2.</td>
<td>Update the Terraform provider configuration for creating the Amazon S3 replication bucket by updating the region value in the tf file. Make sure that you enter the Region that you want Amazon S3 to replicate objects to.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. <em>(Optional)</em> By default, Terraform uses local state files for state management. If you want to add Amazon S3 as the remote backend, you must update the Terraform configuration. For more information, see Backend configuration in the Terraform documentation.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Replication activates automatic, asynchronous copying of objects across Amazon S3 buckets.</td>
<td></td>
</tr>
<tr>
<td>Initialize the Terraform</td>
<td>To initialize your working directory that contains the Terraform configuration files, run the following command in the cloned repository's root folder:</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>configuration.</td>
<td><em>terraform init</em></td>
<td></td>
</tr>
<tr>
<td>Create the Terraform plan.</td>
<td>To create a Terraform plan, run the following command in the cloned repository's root folder:</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td><em>terraform plan --var-file=terraform.tfvars -out=tfplan</em></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Terraform evaluates the configuration files to determine the target state for the declared resources. It then compares the target state against the current state and creates a plan.</td>
<td></td>
</tr>
<tr>
<td>Verify the Terraform plan.</td>
<td>Review the Terraform plan and confirm that it configures the required architecture in your target AWS account.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>
**Deploy the solution.**

1. To apply the Terraform plan, run the following command in the cloned repository's root folder:

   ```
   terraform apply "tfplan"
   ```

2. Enter `yes` to confirm that you want to deploy the resources.

**Note:** Terraform creates, updates, or destroys infrastructure to achieve the target state declared in the configuration files.

**Skills required:** DevOps engineer

---

**Validate Terraform configurations by running the pipeline**

**Set up the source code repository.**

1. From the Terraform output, get the **source repository** details for the repository that contains the Terraform configurations that you want to validate.

2. Sign in to the AWS Management Console. Then, open the **CodeCommit console**.

3. Create a new branch in the source repository named `main`. For instructions, see [Create a branch in AWS CodeCommit](https://docs.aws.amazon.com/codecommit/latest/userguide/branches.html) in the CodeCommit documentation.

4. Clone the main branch of the **source repository** to your local workstation. For instructions, see [Setup steps for HTTPS connections to AWS CodeCommit repositories on Windows with the AWS CLI credential helper](https://docs.aws.amazon.com/codecommit/latest/userguide/setting-up-windows.html) in the CodeCommit documentation.

5. Copy the templates folder from the GitHub `aws-codepipeline-terraform-cicdsamples` repository

**Skills required:** DevOps engineer
### AWS Prescriptive Guidance Patterns

#### Epics

<table>

</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>by running the following command:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>cp -r templates $YOUR_CODECOMMIT_REPO_ROOT</code></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** The templates folder contains the build specification files and the validation script for the root directory of the source repository.

6. Add your required Terraform IaC configurations to the root folder of the source repository.

7. Add the details for the remote backend in your project's Terraform configuration. For more information, see S3 in the Terraform documentation.

8. **(Optional)** Update the variables in the templates folder to either activate or deactivate the preconfigured scans, tool change versions, and to specify your directory in custom script files. For more information, see the *Additional information* section of this pattern.

9. Push the changes to the main branch of the source repository.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Validate the pipeline stages. | 1. Sign in to the AWS Management Console and open the CodePipeline console.  
2. In the output generated from the terraform apply "tfplan" command in the previous Epic section, find the name of the generated CodePipeline.  
3. Open the pipeline in the CodePipeline console and choose Release change.  
4. Review each pipeline stage and confirm it's working as expected.  
   For more information, see View pipeline details and history (console) in the AWS CodePipeline User Guide.  
   **Important:** When a change is committed to the main branch of the source repository, the test pipeline is activated automatically. | DevOps engineer     |
| Verify the report output. | 1. On the CodePipeline console, in the left navigation pane, choose Build. Then, choose Report history.  
2. Review the tfsec and checkov scan reports that the pipeline generates. These reports can help you identify issues through visualizations and graphical representations.  
   **Note:** The &lt;project_name&gt;-validate CodeBuild project generates vulnerability reports for your code during the “validate” stage. | DevOps engineer     |

### Clean up your resources

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clean up the pipeline and associated resources.</td>
<td>To delete the test resources from your AWS account, run</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>
### Troubleshooting

<table>
<thead>
<tr>
<th>Issue</th>
<th>Solution</th>
</tr>
</thead>
</table>
| You receive an **AccessDenied** error during the “apply” stage. | 1. Review the execution logs of the CodeBuild project associated with the “apply” stage to identify any missing IAM permissions. For more information, see [View build details in AWS CodeBuild](https://docs.aws.amazon.com/codebuild/latest/userguide/), in the *AWS CodeBuild User Guide*.  
2. In a code editor, open the cloned repository's modules folder. Then, navigate to the *iam-*role folder and open the main.tf file that's in that folder.  
3. In the codepipeline_policy statement, add the IAM policies that are required for provisioning resources in your AWS account. |

### Related resources

- Module blocks (Terraform documentation)
- How to use CI/CD to deploy and configure AWS security services with Terraform (AWS Blog)

- Quotas for AWS CodeBuild (*AWS CodeBuild User Guide*)
- Data protection in AWS CodePipeline (*AWS CodePipeline User Guide*)

### Additional information

#### Custom Terraform modules

The following is a list of custom Terraform modules that are used in this pattern:

- `codebuild_terraform` creates the CodeBuild projects that form each stage of the pipeline.
- `codecommit_infrastructure_source_repo` captures and creates the source CodeCommit repository.
- `codepipeline_iam_role` creates the required IAM roles for the pipeline.
- `codepipeline_kms` creates the required AWS KMS key for Amazon S3 object encryption and decryption.
- codepipeline_terraform creates the test pipeline for the source CodeCommit repository.
- s3_artifacts_bucket creates an Amazon S3 bucket to manage pipeline artifacts.

**Build specification files**

The following is a list of build specification (buildspec) files that this pattern uses to run each pipeline stage:

- buildspec_validate.yml runs the “validate” stage.
- buildspec_plan.yml runs the “plan” stage.
- buildspec_apply.yml runs the “apply” stage.
- buildspec_destroy.yml runs the “destroy” stage.

**Build specification file variables**

Each buildspec file uses the following variables to activate different build-specific settings:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CODE_SRC_DIR</td>
<td><code>&quot;.&quot;</code></td>
<td>Defines the source CodeCommit directory</td>
</tr>
<tr>
<td>TF_VERSION</td>
<td>&quot;1.3.7&quot;</td>
<td>Defines the Terraform version for the build environment</td>
</tr>
</tbody>
</table>

The buildspec_validate.yml file also supports the following variables to activate different build-specific settings:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCRIPT_DIR</td>
<td><code>&quot;./templates/scripts&quot;</code></td>
<td>Defines the script directory</td>
</tr>
<tr>
<td>ENVIRONMENT</td>
<td>&quot;dev&quot;</td>
<td>Defines the environment name</td>
</tr>
<tr>
<td>SKIPVALIDATIONFAILURE</td>
<td>&quot;Y&quot;</td>
<td>Skips validation on failures</td>
</tr>
<tr>
<td>ENABLE_TFVALIDATE</td>
<td>&quot;Y&quot;</td>
<td>Activates Terraform validate</td>
</tr>
<tr>
<td>ENABLE_TFFORMAT</td>
<td>&quot;Y&quot;</td>
<td>Activates Terraform format</td>
</tr>
<tr>
<td>ENABLE_TFCHECKOV</td>
<td>&quot;Y&quot;</td>
<td>Activates checkov scan</td>
</tr>
<tr>
<td>ENABLE_TFSEC</td>
<td>&quot;Y&quot;</td>
<td>Activates tfsec scan</td>
</tr>
<tr>
<td>TFSEC_VERSION</td>
<td>&quot;v1.28.1&quot;</td>
<td>Defines the tfsec version</td>
</tr>
</tbody>
</table>

**Topics**

- Automate the creation of AppStream 2.0 resources using AWS CloudFormation (p. 1133)
- More patterns (p. 1138)
Automate the creation of AppStream 2.0 resources using AWS CloudFormation

Summary

This pattern provides code samples and steps to automate the creation of Amazon AppStream 2.0 resources in the Amazon Web Services (AWS) Cloud by using an AWS CloudFormation template. The pattern shows you how to use an AWS CloudFormation stack to automate the creation of your AppStream 2.0 application resources, including an image builder, image, fleet instance, and stack. You can stream your AppStream 2.0 application to end users on an HTML5-compliant browser by using either the desktop or application delivery mode.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An acceptance of AppStream 2.0 terms and conditions
- Basic knowledge of AppStream resources, such as stacks, fleets, and image builders

Limitations

- You can’t modify the AWS Identity and Access Management (IAM) role associated with an AppStream 2.0 instance after that instance is created.
- You can’t modify properties (such as the subnet or security group) on the AppStream 2.0 image builder instance after that image builder is created.

Architecture

The following diagram shows you how to automate the creation of AppStream 2.0 resources by using an AWS CloudFormation template.
The diagram shows the following workflow:

1. You create an AWS CloudFormation template based on the YAML code in the Additional information section of this pattern.
2. The AWS CloudFormation template creates an AWS CloudFormation test stack.
   a. (Optional) You create an image builder instance by using AppStream 2.0.
   b. (Optional) You create a Windows image by using your custom software.
3. The AWS CloudFormation stack creates an AppStream 2.0 fleet instance and stack.
4. You deploy your AppStream 2.0 resources to end users on an HTML5-compliant browser.

Technology stack

- Amazon AppStream 2.0
- AWS CloudFormation

Tools

- **Amazon AppStream 2.0** – Amazon AppStream 2.0 is a fully managed application streaming service that provides you with instant access to your desktop applications from anywhere. AppStream 2.0 manages the AWS resources required to host and run your applications, scales automatically, and provides access to your users on demand.
- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
## Epics

(Optional) Create an AppStream 2.0 image

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Install custom software and create an image. | 1. Install the AppStream 2.0 application that you plan to deploy to your users.  
2. Use the Photon create image agent or a PowerShell script to create a new Windows image for your custom software.                                                                                   | AWS DevOps, Cloud architect              |
|                                           | **Note:** Consider using the Windows AppLocker feature to further lock down the image.                                                                                                                      |                                           |

Deploy the AWS CloudFormation template

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Update the AWS CloudFormation template.   | 1. Save the code in the Additional information section of this pattern as a YAML file.  
2. Update the YAML file with the required values for the parameters in your environment.                                                                                                              | AWS systems administrator, Cloud administrator, Cloud architect, General AWS, AWS administrator |

Create an AWS CloudFormation stack using the template. | 1. Sign in to the AWS Management Console and open the AWS CloudFormation console.  
2. On the navigation pane, choose Stacks.  
3. Choose Create stack and then choose With new resources (standard).  
4. In the Prerequisite – Prepare template section, choose Template is ready.  
5. In the Specify template section, choose Upload a template file.  
6. Choose Choose file and then choose your updated AWS CloudFormation template. | App owner, AWS systems administrator, Windows Engineer |

### Additional information

The following code is an example of an AWS CloudFormation template that allows you to automatically create AppStream 2.0 resources.

```yaml
AWSTemplateFormatVersion: 2010-09-09
Parameters:
  SubnetIds:
    Type: 'List<AWS::EC2::Subnet::Id>'
  testSecurityGroup:
    Type: 'AWS::EC2::SecurityGroup::Id'
  ImageName:
    Type: String
Resources:
  AppStreamFleet:
    Type: 'AWS::AppStream::Fleet'
    Properties:
      ComputeCapacity:
        DesiredInstances: 5
      InstanceType: stream.standard.medium
      Name: appstream-test-fleet
      DisconnectTimeoutInSeconds: 1200
      FleetType: ON_DEMAND
      IdleDisconnectTimeoutInSeconds: 1200
      ImageName: !Ref ImageName
      MaxUserDurationInSeconds: 345600
      VpcConfig:
        SecurityGroupIds:
        - !Ref testSecurityGroup
        SubnetIds: !Ref SubnetIds
  AppStreamStack:
    Type: 'AWS::AppStream::Stack'
    Properties:
      Description: AppStream stack for test
      DisplayName: AppStream test Stack
      Name: appstream-test-stack
      StorageConnectors:
```
- ConnectorType: HOMEFOLDERS
  UserSettings:
  - Action: CLIPBOARD_COPY_FROM_LOCAL_DEVICE
    Permission: ENABLED
  - Action: CLIPBOARD_COPY_TO_LOCAL_DEVICE
    Permission: ENABLED
  - Action: FILE_DOWNLOAD
    Permission: ENABLED
  - Action: PRINTING_TO_LOCAL_DEVICE
    Permission: ENABLED

AppStreamFleetAssociation:
  Type: 'AWS::AppStream::StackFleetAssociation'
  Properties:
    FleetName: appstream-test-fleet
    StackName: appstream-test-stack
  DependsOn:
    - AppStreamFleet
    - AppStreamStack

AWS services: AWS CDK; AWS CloudFormation; Amazon EC2 Auto Scaling; Elastic Load Balancing (ELB)

Summary

NICE DCV is a high-performance remote display protocol that helps you stream remote desktops and applications from any cloud or data center to any device, over varying network conditions. With NICE DCV and Amazon Elastic Compute Cloud (Amazon EC2), you can run graphics-intensive applications remotely on EC2 instances and stream their user interfaces to simpler, remote client machines. This eliminates the need for expensive dedicated workstations and the need to transfer large amounts of data between the cloud and client machines.

This pattern sets up a fully functional, auto scaling Linux and Windows virtual desktop infrastructure (VDI) that is accessible through a web-based user interface. The VDI solution provides research and development (R&D) users with an accessible and performant user interface for submitting graphics-intensive analysis requests and reviewing results remotely.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Administrator permissions and a set of access keys.
- AWS Cloud Development Kit (AWS CDK) Toolkit, installed and configured. For more information, see Install the AWS CDK.
- AWS Command Line Interface (AWS CLI), installed and configured for your AWS account. For more information, see Installing or updating the latest version of the AWS CLI.
- Python, installed and configured. For more information, see Source releases (Python website).
- One or more virtual private clouds (VPCs) available.
- Two or more Elastic IP address available. For more information about the default limit, see Elastic IP address limit.
- For the Linux EC2 instances, set up a Secure Shell (SSH) key pair. For more information, see Key pairs and Linux instances.

Product versions

- AWS CDK version 2.26.0 or later
• Python version 3.8 or later

Architecture

Target architecture

The following figure shows the different components of this VDI solution. The user interacts with NICE EnginFrame to launch Amazon EC2 instances according to the Amazon EC2 Auto Scaling groups for Windows and Linux NICE DCV instances.

Automation and scale

The code included with this pattern creates a custom VPC, public and private subnets, an internet gateway, NAT gateway, Application Load Balancer, security groups, and IAM policies. AWS CloudFormation is also used to create the fleet of Linux And Windows NICE DCV servers.

Tools

AWS services

• AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
• AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
• **NICE DCV** is a high-performance remote display protocol that helps you deliver remote desktops and application streaming from any cloud or data center to any device, over varying network conditions. In this pattern, it provides a bandwidth-efficient experience that streams high performance computing (HPC) 3D graphics remotely.

• **NICE DCV Session Manager** helps you create and manage the lifecycle of NICE DCV sessions across a fleet of NICE DCV servers.

• **NICE EnginFrame** is an advanced frontend web interface for accessing technical and scientific applications in the cloud.

**Code repository**

The code for this pattern is available in the [Auto scaling VDI solution with NICE EnginFrame and NICE DCV Session Manager](https://github.com/aws-samples) repository.

**Epics**

**Deploy the virtual desktop infrastructure**

</thead>
</table>
| Deploy the fleet of Linux servers. | 1. Sign in to the AWS Management Console, and open the CloudFormation console.  
2. Choose Create stack, and then choose With new resources.  
3. In the cloudf ormation_files folder, select the dcv-linux-fleet.yaml file.  
4. On the Specify stack details page, define the following parameters:  
   • Stack name – The name of the stack.  
   • DcvFleet – The name of the NICE DCV fleet. Don't leave this value blank or use spaces.  
   • InstanceType – The instance type of the fleet.  
   • RootVolumeSize – The root volume size of the Linux EC2 instance.  
   • MinSize – The minimum number of nodes that should be available and not running any DCV session. For instance, if you enter 2, the solution starts with 2 nodes. When a user creates a session, the number of available nodes decreases to 1, and the solution creates another node to maintain the minimum.  
   • MaxSize – The maximum number of nodes in the fleet. Users cannot start new sessions if the maximum has been reached.  
   • BillingTagName – The tag name used for billing. This tag name must be different from the one used for the Windows stack.  
   • BillingTagValue – The tag value used for billing.  
5. Complete the stack creation wizard, and then choose Cloud architect |

Configure a data center extension to VMware Cloud on AWS using Hybrid Linked Mode

Created by Deepak Kumar (AWS)

Environment: Production  Technologies: Hybrid cloud; Infrastructure; Migration  Workload: All other workloads

AWS services: AWS Direct Connect

Summary

This pattern describes how you can use Hybrid Linked Mode to view and manage inventories in an on-premises data center and a VMware Cloud on AWS software-defined data center (SDDC) by using a single VMware vSphere Client interface.

By configuring Hybrid Linked Mode, you can migrate your on-premises virtual machines (VMs) and applications to the cloud SDDC. Your IT teams can then manage your cloud-based resources with familiar VMware tools and without requiring any new tools. You can also ensure consistent operations and simplified administration by using the VMware Cloud Gateway Appliance.

This pattern provides two options for configuring Hybrid Linked Mode, but you can only use one option at a time. The first option installs the Cloud Gateway Appliance and uses it to link from the on-premises vCenter Server to the cloud SDDC. The second option configures Hybrid Linked Mode from the cloud SDDC.

Prerequisites and limitations

Prerequisites (both options)

- An existing on-premises data center and a cloud SDDC.
- An existing connection between the on-premises data center and the cloud SDDC, using AWS Direct Connect, a VPN, or both.
- The on-premises data center and cloud SDDC are synchronized with network time protocol (NTP) or another authoritative time source.
- The maximum latency of a round-trip time between the on-premises data center and the cloud SDDC doesn't exceed 100ms.
- Cloud administrators with access to your on-premises environment.
- The vCenter Server’s fully qualified domain name (FQDN) must resolve to a private IP address.

Prerequisites for Option 1

- The on-premises environment should run on vSphere 6.5.0d or later.
- The Cloud Gateway Appliance and vCenter Server can communicate over AWS Direct Connect, a VPN, or both.
- The Cloud Gateway Appliance meets hardware requirements.
• Firewall ports are open.

Prerequisites for Option 2

• The on-premises vCenter Server runs on vSphere 6.0 Update 3 or later, or on vSphere 6.5.0d or later.
• Login credentials are available for the on-premises vSphere single sign-on (SSO) domain.
• Users in the on-premises environment have read-only access to the base distinguished name (Base DN).
• The on-premises Domain Name System (DNS) server is configured for VMware Management Gateway.
• Implement network connectivity tests using the VMware Connectivity Validator.
• Firewall ports are open.

Limitations

• Hybrid Linked Mode can only connect one on-premises vCenter Server Enhanced Linked Mode domain.
• Hybrid Linked Mode only supports on-premises vCenter Server running version 6.7 or later.

Architecture

The following diagram shows both options for configuring Hybrid Linked Mode.

Migrating different workload types using Hybrid Linked Mode

Hybrid Linked Mode supports migrating workloads between an on-premises data center and a cloud SDDC by using either a cold migration or a live migration with VMware vSphere vMotion. Factors that must be considered when choosing the migration method include the virtual switch type and version, the connection type to the cloud SDDC, and the virtual hardware version.

A cold migration is appropriate for VMs that experience downtime. You can shut down the VMs, migrate them, and then turn them back on. The migration time is faster because there is no need to copy active memory. We recommend using a cold migration for applications that accept downtime (for example, tier 3 applications or development and testing workloads). If your VMs cannot experience downtime, you should consider a live migration using vMotion for your mission-critical applications.
The following diagram provides an overview of the different workload migration types using Hybrid Linked Mode.

![Diagram showing different migration types and requirements](image)

**Tools**

- **VMware Cloud on AWS** is an integrated cloud offering jointly developed by AWS and VMware.
- **VMware Cloud Gateway Appliance** enables a number of hybrid cloud use cases where on-premises resources are connected to cloud resources.
- **VMware vSphere** is VMware's virtualization platform, which transforms data centers into aggregated computing infrastructures that include CPU, storage, and networking resources.

**Epics**

**Option 1 - Use Hybrid Linked Mode with the Cloud Gateway Appliance**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure the Cloud Gateway Appliance. | 1. Log in to the VMware Cloud on AWS console and download the Cloud Gateway Appliance.  
2. Install the Cloud Gateway Appliance in your on-premises environment with the following two steps:  
   - Choose Start to configure and then deploy the Cloud Gateway Appliance.  
   - Configure Hybrid Linked Mode.  

For more information and detailed steps, see Configuring Hybrid Linked Mode using the vCenter Cloud Gateway Appliance in the VMware documentation. | Cloud administrator |
Option 2 - Use Hybrid Linked Mode from the cloud SDDC

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure Hybrid Linked Mode from the cloud SDDC. | 1. Log in to the VMware Cloud on AWS console and use the Connectivity Validator to check all required network connectivity. For more information about this, see Validate network connectivity for Hybrid Linked Mode in the VMware documentation.  
2. Log in to the vSphere Client of the cloud SDDC, choose Menu, choose Administration, and then choose Domains.  
3. In the Hybrid Cloud section, choose Linked Domains and then connect to your on-premises vCenter Server.  
4. Add an identity source to the cloud SDDC Lightweight Directory Access Protocol (LDAP) domain. For more information about this, see Add an Identity Source to the SDDC LDAP Domain in the VMware documentation. | Cloud administrator |

Configure VMware vRealize Automation to provision VMs on VMware Cloud on AWS

**Summary**

**VMware vRealize Automation** is automation software that you can use to request and manage IT resources. By choosing to configure vRealize Automation with VMware Cloud on AWS, you can automate the delivery of virtual machines (VMs), applications, and IT services across multiple data centers and cloud environments.

Your IT teams can then create catalog items to configure service provisioning and operational capabilities that your users can request and use with their existing vRealize Automation tools. You can also improve your IT agility and efficiency by integrating VMware Cloud on AWS with **vRealize Automation Cloud Assembly**.

This pattern describes how to configure VMware vRealize Automation to automatically build VMs or application capabilities on VMware Cloud on AWS.

**Prerequisites and limitations**

**Prerequisites**

- An existing on-premises data center and a VMware Cloud on AWS software-defined data center (SDDC). For more information about the cloud SDCC, see [About Software-Defined Data Centers](#) in the VMware documentation.
- An existing connection between the on-premises data center and the cloud SDDC, using AWS Direct Connect, a VPN (route or policy-based), or both.
- The on-premises data center and cloud SDDC are synchronized with network time protocol (NTP) or another authoritative time source.
- The maximum latency of a round-trip time between the on-premises data center and the cloud SDDC doesn't exceed 100ms.
- The vCenter Server’s fully qualified domain name (FQDN) must resolve to a private IP address.
- Cloud SDDC users with access to your on-premises environment.
- Organization owner access in the vRealize Automation Cloud Assembly service role.
- End users with permission in vRealize Automation Service Broker to consume service.
- The on-premises data center’s Classless Inter-Domain Routing (CIDR) range must be open for the generating of API tokens from the VMware Cloud on AWS console. The following list provides the minimum roles required to generate API tokens:
  - Organization member
• Organization owner
• Service Roles - VMware Cloud on AWS
• Administrator
• NSX Cloud Administrator
• NSX Cloud Auditor

For more information about this, see Connectivity Options for VMware Cloud on AWS SDDCs from the AWS Partner Network Blog.

Limitations

• You can only configure 20 VMware Cloud accounts with public endpoints in one vRealize Automation. For more information about this, see Scalability and concurrency maximums in the VMware documentation.

Product versions

• vRealize Automation version 8.x or later
• VMware vRealize Identity Manager version 3.x or later
• VMware vRealize Suite Lifecycle Manager version 8.x or later

Architecture

The following diagram shows the vRealize Automation services that can use infrastructure from both on-premises and VMware Cloud on AWS environments.

VMware Cloud Assembly components

VMware Cloud Assembly is a core component of vRealize Automation and you can use it to deploy and provision VMs and compute resources. The following table describes VMware Cloud Assembly components that must be configured for provisioning VMs on VMware Cloud on AWS.

<table>
<thead>
<tr>
<th>Components</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Account</td>
<td>The Cloud Account provides connection details (for example, server name, user name and password, access key, and API token). VMware Cloud Assembly uses the Cloud Account to collect an inventory of your resources.</td>
</tr>
</tbody>
</table>
Cloud zones

Cloud zones identify resource boundaries in the Cloud Account (for example, AWS Regions and the cloud SDDC). Cloud zones associate compute resources with the Cloud Assembly project.

Projects

A project is a logical entity that consists of users and resources such as cloud zones. It also consists of resource quotas and VM naming policies that are used when building the VM.

Flavor mappings

Flavor mapping provides information about the VM's capacity (for example, number of CPUs and amount of memory) that are used in the Cloud Template.

Image mappings

Image mapping maps the VMware vSphere VM template and Amazon Web Services (AWS) image that are used in the Cloud Template. For more information about this, see Learn more about image mappings in vRealize Automation in the VMware documentation.

Network profile

Network profile controls the placement decision to choose a network during VM provisioning.

Storage profile

Storage profile controls the placement decision to choose storage during VM provisioning.

Cloud Templates

VMware Cloud Templates are an important component of vRealize Automation because they define cloud infrastructure provisioning and orchestration. The Cloud Templates are specifications for the resources and include the resource type, resource properties, and input to be collected from users.

Tools

- **VMware vRealize Automation** – vRealize Automation is an infrastructure automation platform with event-driven state management and compliance. It is designed to help organizations control and secure self-service clouds, multi-cloud automation with governance, and DevOps-based infrastructure delivery.
- **VMware Cloud on AWS** – VMware Cloud on AWS is an integrated cloud offering jointly developed by AWS and VMware.

Summary

This pattern describes how to create a VMware-based Software-Defined Data Center (SDDC) that’s hosted in the Amazon Web Services (AWS) Cloud. You can deploy an SDDC to migrate your VMware vSphere-based workloads to the AWS Cloud and take advantage of AWS services while you use your existing VMware tools and skills. You can use this SDDC to run your production applications across VMware vSphere-based private, public, and hybrid cloud environments, with optimized access to AWS services. For example, you can use the SDDC as a secondary site for disaster recovery or to extend your data center to different geographical locations.

VMware Cloud on AWS is a pay-as-you-go (on-demand) service that enables enterprises of all sizes to run workloads across VMware vSphere-based cloud environments by using a wide range of AWS services. You can start with a minimum of 2 hosts per SDDC cluster and scale up to 16 hosts per cluster in your production environment. For more information, see the [VMware Cloud on AWS](https://aws.amazon.com/vmware-cloud-on-aws/) website. To learn more about SDDCs, see [About Software-Defined Data Centers](https://docs.vmware.com/en/vsphere/6.7/topic/com.vmware.vsphere.datacenter.toc.html) in the VMware documentation.

Prerequisites and limitations

Prerequisites

- Sign up for a [MyVMware account](https://myvmware.com) and fill out all fields.
- Sign up for an [AWS account](https://aws.amazon.com). For instructions, see the [AWS Knowledge Center](https://aws.amazon.com/getting-started/).  
- Sign up for a [MyVMware Cloud on AWS account](https://aws.amazon.com/vmware-cloud-on-aws/). An activation link is sent to the email address you specify when you sign up.

Limitations

- See [VMware Cloud on AWS configuration limits](https://aws.amazon.com/vmware-cloud-on-aws/configuration-limits/) pages on the VMware website.

Product versions

- See [VMware Cloud on AWS Release Notes](https://aws.amazon.com/vmware-cloud-on-aws/release-notes/) in the VMware documentation.

Architecture

Target technology stack

The following diagram shows the VMware software stack, including vSphere, vCenter, vSAN, and NSX-T, running on AWS bare-metal dedicated infrastructure. You can manage your VMware-based resources and tools on AWS with seamless integration with other AWS services such as Amazon Elastic Compute Cloud.
The basic entity of VMware Cloud on AWS is an SDDC, which includes the following components:

- **Compute:** The compute component is the lowest layer of the VMware Cloud on AWS SDDC. VMware Cloud on AWS runs on Amazon EC2 bare metal instance types. These include `i3.metal`, `i3en.metal`, and `i4i.metal`, and provide direct access to physical resources such as processors and memory.

  **Important:** The `i3.metal` instance type for VMware Cloud on AWS, including on-demand and subscription options of one-year and three-year terms, is set to reach its end of life and end of support on December 31, 2026. Additionally, new customers are currently not able to request `i3.metal` instances. For more information, see the [announcement on the VMware Cloud Blog](https://vmwarecloud.com/blog).

- **Storage:** SDDC clusters support VMware vSAN with an all-flash configuration for storage using non-volatile memory express (NVMe) flash storage, which provides fast and high-performance storage. Starting with SDDC version 1.20, VMware Cloud on AWS offers support for two types of external storage: Amazon FSx for NetApp ONTAP and VMware Cloud Flex Storage.

- **Networking:** Networking capabilities and policies are managed by using VMware NSX-T in the SDDC cluster. Multi-tier virtual networks are created in the SDDC cluster to separate network resources from physical equipment. This enables VMware Cloud on AWS users to create logical, software-defined networks.

## Tools

- **VMware Cloud on AWS** is an integrated cloud offering jointly developed by AWS and VMware.

## Epics

Create a VPC and subnet in your AWS account

<table>

<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Create a new VPC.</td>
<td>In this step, you define a virtual private cloud (VPC) that links to the SDDC. If you already have a VPC you want to use for the SDDC, skip this step.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td></td>
<td>1. Choose the AWS Region to deploy your VMware Cloud on AWS SDDC.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. Open the Amazon VPC console at <a href="https://console.aws.amazon.com/vpc/">https://console.aws.amazon.com/vpc/</a>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. In the navigation pane, choose Your VPCs.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4. Choose Create VPC.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>5. Specify VPC settings such as the VPC name tag, IPv4 CIDR block, Tenancy (keep as Default), and then choose Create VPC.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>6. When the VPC has been created, choose Close.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For more information, see <a href="https://docs.aws.amazon.com/createsysdiguide/latest/sddc/create-vpc.html">Create and configure your VPC</a> in the AWS documentation.</td>
<td></td>
</tr>
</tbody>
</table>
### Create a private subnet.

You will now create a private subnet for the elastic network interface (ENI) for each Availability Zone. We recommend that you use a subnet without an internet gateway attached.

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **Subnets**.
3. Choose **Create Subnet**.
4. On the **Create Subnet** page, choose the VPC that you created earlier.
5. Complete the settings for the subnet, including a **subnet name**, **Availability Zone**, and **IPv4 CIDR block**.
6. Choose **Create Subnet**.

Repeat these steps to create subnets for each Availability Zone in the Region.

### Activate VMware Cloud on AWS

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activate the service</td>
<td>When you sign up for a MyVMware account, VMware sends you a welcome email and activation link to the email address you specified.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>

1. Open the **Activate Service** link from the welcome email in your browser.
2. Log in with MyVMware credentials.
3. Review and accept the terms and conditions for the use of services.
4. Complete the account activation process. You will be redirected to the VMware Cloud on AWS console.  
   (Note: VMware Cloud on
### AWS accounts are based on an organization, which represents a group or line of business subscribed to the account. This organization has no relationship to AWS Organizations.

5. On the **Select or Create Organization** page, create an organization that is linked to the MyVMware account.

6. Enter the **Organization Name** and **Address** for logical distinction.

7. Select **Create Organization** to complete the process.

For more information about this process, see [SDDC Deployment and Best Practices Guide on AWS](#) in the AWS documentation.

---

**Assign IAM roles.**

When the organization has been created, assign privileged access to specific users to access the Cloud Services and SDDC console, SDDC, and NSX components. For instructions, see [Assign a VMC Service Role to an Organization Member](#) in the VMware documentation.

There are two types of organization roles:

- Organization owners can add, remove, and modify users and access all cloud resources.
- Organization members can access cloud resources only.

---

### Deploy an SDDC

Migrate VMs to VMware Cloud on AWS by using HCX OS Assisted Migration

Created by Deepak Kumar (AWS)

<table>
<thead>
<tr>
<th>Environment</th>
<th>Source</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>PoC or pilot</td>
<td>Non-vSphere environment</td>
<td>VMware Cloud on AWS SDDC</td>
</tr>
</tbody>
</table>

R Type: Relocate  Workload: All other workloads  Technologies: Hybrid cloud; Migration

Summary

This pattern describes how to migrate a virtual machine (VM) from a non-vSphere environment to VMware Cloud on Amazon Web Services (AWS) by using OS Assisted Migration (OSAM).

OSAM is part of VMware Hybrid Cloud Extension (HCX), which is included with VMware Cloud on AWS. You can use OSAM to migrate a non-vSphere environment such as VMware KVM or Hyper-V to VMware Cloud on AWS. OSAM uses Sentinel software, which you install on a Windows or Linux guest VM to assist in replicating the VM from your on-premises environment to a Software-Defined Data Center (SDDC) on VMware Cloud on AWS.

This pattern explains how to enable OSAM, install Sentinel software on a Windows VM, connect and register with an HCX Sentinel Gateway (SGW) appliance at the source site, and establish a forwarding connection with an HCX Sentinel Data Receiver (SDR) appliance at the destination site to initiate migration.

For more information about OSAM, see the VMware documentation.

Prerequisites and limitations

Prerequisites

- Install HCX in your source and target environments. For HCX prerequisites, see Migrate VMware SDDC to VMware Cloud on AWS using VMware HCX in the AWS Prescriptive Guidance documentation.
- For OSAM prerequisites, see the installation checklist in the VMware documentation.
- For OSAM port information, see VMware HCX port requirements on the VMware Ports and Protocols website.

Limitations

- VMware HCX 4.2.0 Configuration Limits
- Considerations for OSAM Deployment
- Supported Guest Operating Systems
- Guest Operating System Considerations

Product versions
Architecture

The following diagram shows how HCX OSAM works with the Sentinel software to replicate non-vSphere VMs from your on-premises environment to VMware Cloud on AWS.

OSAM consists of three components:

- The Sentinel Gateway (SGW) appliance, which is used to connect and forward workloads and applications in the source VMware-based environment
- The Sentinel Data Receiver (SDR), which is used in the destination VMware Cloud on AWS environment to receive migrated workloads from the source
- Sentinel software, which must be installed on each guest VM that you want to migrate

OSAM uses the Sentinel software that is installed on Windows or Linux guest VMs to assist in replicating a VM from on premises to a VMware SDDC. The Sentinel software that you install on guest VMs collects the system configurations from the guest VM and assists with the data replication. This information is also used to create the inventory of guest VMs for migration and helps prepare the disks on the replica VM for replication and migration purposes.

Tools

- VMware HCX 4.2.0
- VMware Cloud on AWS SDDC

• VMware HCX 4.2.0
• VMware SDDC 1.12

<th>AWS services: AWS CDK; AWS CodePipeline; Amazon ECS; AWS Systems Manager; AWS CodeCommit</th>
</tr>
</thead>
</table>

Summary

Amazon ECS Anywhere is an extension of the Amazon Elastic Container Service (Amazon ECS). It provides support for registering an external instance, such as an on-premises server or virtual machine (VM), to your Amazon ECS cluster. This feature helps reduce costs and mitigate complex local container orchestration and operations. You can use ECS Anywhere to deploy and run container applications in both on-premises and cloud environments. It removes the need for your team to learn multiple domains and skill sets, or to manage complex software on their own.

This pattern describes a step-by-step approach to provision an Amazon ECS cluster with Amazon ECS Anywhere instances by using Amazon Web Services (AWS) Cloud Development Kit (AWS CDK) stacks. You then use AWS CodePipeline to set up a continuous integration and continuous deployment (CI/CD) pipeline. Then, you replicate your GitLab code repository to AWS CodeCommit and deploy your containerized application on the Amazon ECS cluster.

This pattern is designed to help those who use on-premises infrastructure to run container applications and use GitLab to manage the application code base. You can manage those workloads by using AWS Cloud services, without disturbing your existing, on-premises infrastructure.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A container application running on on-premises infrastructure.
- A GitLab repository where you manage your application code base. For more information, see Repository (GitLab).
- AWS Command Line Interface (AWS CLI), installed and configured. For more information, see Installing or updating the latest version of the AWS CLI (AWS CLI documentation).
- AWS CDK Toolkit, installed and configured globally. For more information, see Install the AWS CDK (AWS CDK documentation).
- npm, installed and configured for the AWS CDK in TypeScript. For more information, see Downloading and installing Node.js and npm (npm documentation).
Limitations

- For limitations and considerations, see External instances (Amazon ECS Anywhere) in the Amazon ECS documentation.

Product versions

- AWS CDK Toolkit version 2.27.0 or later
- npm version 7.20.3 or later
- Node.js version 16.6.1 or later

Architecture

Target technology stack

- AWS CDK
- AWS CloudFormation
- AWS CodeBuild
- AWS CodeCommit
- AWS CodePipeline
- Amazon ECS Anywhere
- Amazon Elastic Container Registry (Amazon ECR)
- AWS Identity and Access Management (IAM)
- AWS System Manager
- GitLab repository

Target architecture
This diagram represents two primary workflows described in this pattern, provisioning the Amazon ECS cluster and setting up the CI/CD pipeline that sets up and deploys the CI/CD pipeline, as follows:

1. **Provisioning the Amazon ECS cluster**
   a. When you deploy the first AWS CDK stack, it creates a CloudFormation stack on AWS.
   b. This CloudFormation stack provisions an Amazon ECS cluster and related AWS resources.
   c. To register an external instance with an Amazon ECS cluster, you must install AWS Systems Manager Agent (SSM Agent) on your VM and register the VM as an AWS Systems Manager managed instance.
   d. You must also install the Amazon ECS container agent and Docker on your VM to register it as an external instance with the Amazon ECS cluster.
   e. When the external instance is registered and configured with the Amazon ECS cluster, it can run multiple containers on your VM, which is registered as an external instance.
   f. The Amazon ECS cluster is active and can run the application workloads through containers. The Amazon ECS Anywhere container instance runs in on-premises environment but is associated with the Amazon ECS cluster in the cloud.

2. **Setting up and deploying the CI/CD pipeline**
   a. When you deploy the second AWS CDK stack, it creates another CloudFormation stack on AWS.
   b. This CloudFormation stack provisions a pipeline in CodePipeline and related AWS resources.
   c. You push and merge application code changes to an on-premises GitLab repository.
   d. The GitLab repository is automatically replicated to the CodeCommit repository.
   e. The updates to the CodeCommit repo automatically starts CodePipeline.
f. CodePipeline copies code from CodeCommit and creates the deployable application build in CodeBuild.
g. CodePipeline creates a Docker image of the CodeBuild build environment and pushes it to the Amazon ECR repo.
h. CodePipeline initiates CodeDeploy actions that pull the container image from the Amazon ECR repo.
i. CodePipeline deploys the container image on the Amazon ECS cluster.

Automation and scale
This pattern uses the AWS CDK as an infrastructure as code (IaC) tool to configure and deploy this architecture. AWS CDK helps you orchestrate the AWS resources and set up Amazon ECS Anywhere and the CI/CD pipeline.

Tools

AWS services

- **AWS Cloud Development Kit (AWS CDK)** is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- **AWS CodeCommit** is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- **AWS CodePipeline** helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- **Amazon Elastic Container Registry (Amazon ECR)** is a managed container image registry service that's secure, scalable, and reliable.
- **Amazon Elastic Container Service (Amazon ECS)** is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster. This pattern also uses Amazon ECS Anywhere, which provides support for registering an on-premises server or VM to your Amazon ECS cluster.

Other tools

- **Node.js** is an event-driven JavaScript runtime environment designed for building scalable network applications.
- **npm** is a software registry that runs in a Node.js environment and is used to share or borrow packages and manage deployment of private packages.
- **Vagrant** is an open-source utility for building and maintaining portable virtual software development environments. For demonstration purposes, this pattern uses Vagrant to create an on-premises VM.

Code repository

The code for this pattern is available in the GitHub **CI/CD pipeline for Amazon ECS Anywhere using AWS CDK** repository.

Best practices

Consider the following best practices when deploying this pattern:

- **Best practices for developing and deploying cloud infrastructure with the AWS CDK**
• **Best practices for developing cloud applications with AWS CDK** ([AWS blog post](https://aws.amazon.com/blogs/development/))

<tr>
<td><strong>Deploy the Amazon ECS Anywhere infrastructure stack.</strong></td>
<td>1. List the stacks by entering the following command.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td><code>$cdk list</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. Confirm that the output returns the EcsAnywhereInfraStack and ECSAnywherePipelineStack stacks.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. Deploy the EcsAnywhereInfraStack stack by entering the following command.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>$cdk deploy EcsAnywhereInfraStack</code></td>
<td></td>
</tr>
</tbody>
</table>

If you encounter any errors about missing packages when you enter these commands, see the **Troubleshooting** section of this pattern.
### Verify stack creation and output.

2. On the Stacks page, select the EcsAnywhereInfraStack stack.
3. Confirm that the stack status is either CREATE_IN_PROGRESS or CREATE_COMPLETE.

Setting up the Amazon ECS cluster can take some time. Do not proceed until the stack creation is complete.

<table>

</tr>
</thead>
</table>
| Verify stack creation     | 1. Sign in to the AWS Management Console and open the CloudFormation console at [https://console.aws.amazon.com/cloudformation/](https://console.aws.amazon.com/cloudformation/).  
                               2. On the Stacks page, select the EcsAnywhereInfraStack stack.  
                               3. Confirm that the stack status is either CREATE_IN_PROGRESS or CREATE_COMPLETE.  
                               Setting up the Amazon ECS cluster can take some time. Do not proceed until the stack creation is complete. | DevOps engineer          |

### Set up an on-premises VM

#### Set up your VM.

Create a Vagrant VM by entering the `vagrant up` command from the root directory where Vagrantfile is located. For more information, see the [Vagrant documentation](https://www.vagrantup.com/docs).

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set up your VM.</td>
<td>Create a Vagrant VM by entering the <code>vagrant up</code> command from the root directory where Vagrantfile is located. For more information, see the <a href="https://www.vagrantup.com/docs">Vagrant documentation</a>.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

#### Register your VM as an external instance.

1. Log in to the Vagrant VM by using the `vagrant ssh` command. For more information, see the [Vagrant documentation](https://www.vagrantup.com/docs).
2. Install AWS CLI on the VM by following [AWS CLI installation instructions](https://docs.aws.amazon.com/cli/latest/userguide/installing.html) and entering the following commands.

   ```
   $ curl "https://awsc1i.amazonaws.com/awsc1i-exe-linux-x86_64.zip" \
   > -o "awsc1iv2.zip"
   $sudo apt install unzip
   $unzip awsc1iv2.zip
   $sudo .aws/install
   $aws configure
   AWS Access Key ID [None]: <your-access-key-ID>
   ```

</table>
| Register your VM as an external instance. | 1. Log in to the Vagrant VM by using the `vagrant ssh` command. For more information, see the [Vagrant documentation](https://www.vagrantup.com/docs).  
                               2. Install AWS CLI on the VM by following [AWS CLI installation instructions](https://docs.aws.amazon.com/cli/latest/userguide/installing.html) and entering the following commands.  
                               ```
                               $ curl "https://awsc1i.amazonaws.com/awsc1i-exe-linux-x86_64.zip" \
                               > -o "awsc1iv2.zip"
                               $sudo apt install unzip
                               $unzip awsc1iv2.zip
                               $sudo .aws/install
                               $aws configure
                               AWS Access Key ID [None]: <your-access-key-ID>
                               ``` | DevOps engineer          |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Create an activation code and ID that you can use to register your VM with AWS Systems Manager and to activate your external instance. The output from this command includes the activation ID and activation code values.</td>
<td>Requires knowledge of AWS CLI and basic system management skills.</td>
</tr>
</tbody>
</table>

```bash
aws ssm create-activation
  > --iam-role EcsAnywhereInstanceRole
  > | tee ssm-activation.json
```

If you receive an error when you run this command, see the Troubleshooting (p. 1183) section.

| 2. | Export the activation ID and code values. | Requires basic shell scripting knowledge. |

```bash
export ACTIVATION_ID=<activation-ID>
export ACTIVATION_CODE=<activation-code>
```

| 3. | Download the installation script to your VM. | Requires internet access and basic shell scripting knowledge. |

```bash
curl --proto "https" -o "ecs-anywhere-install.sh"
```

| 4. | Run the installation script on your VM. | Requires basic shell scripting knowledge. |

```bash
sudo bash ecs-anywhere-install.sh
```
This sets up your VM as an Amazon ECS Anywhere external instance and registers the instance in the Amazon ECS cluster. For more information, see Registering an external instance to a cluster in the Amazon ECS documentation. If you experience any issues, see the Troubleshooting (p. 1183) section.

Verify the status of Amazon ECS Anywhere and the external VM. To verify whether your VM is connected to the Amazon ECS control plane and running, use the following commands.

```
$aws ssm describe-instance-information
$aws ecs list-container-instances --cluster $CLUSTER_NAME
```

### Deploy the CI/CD pipeline

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a branch in the CodeCommit repo.</td>
<td>Create a branch named main in the CodeCommit repo by creating the first commit for the repository. You can follow AWS documentation to Create a commit in CodeCommit. The following command is an example.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

```
aws codecommit put-file
--repository-name EcsAnywhereRepo
--branch-name main
--file-path README.md
--file-content "Test"
--name "Dev Ops"
--email "devops@example.com"
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>--commit-message &quot;Adding README.&quot;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Set up repo mirroring.</td>
<td>You can mirror a GitLab repository to and from external sources. You can select which repository serves as the source. Branches, tags, and commits are synced automatically. Set up a push mirror between the GitLab repository that hosts your application and the CodeCommit repository. For instructions, see <a href="https://docs.gitlab.com/ee/cdn/remote_sources.html">Set up a push mirror from GitLab to CodeCommit</a> (GitLab documentation). <strong>Note:</strong> By default, mirroring automatically syncs the repository. If you want to manually update the repositories, see <a href="https://docs.gitlab.com/ee/cdn/remote_sources.html">Update a mirror</a> (GitLab documentation).</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Deploy the CI/CD pipeline stack.</td>
<td>Deploy the EcsAnywherePipelineStack stack by entering the following command.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>$cdk deploy EcsAnywherePipelineStack</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------</td>
</tr>
</tbody>
</table>
| Test the CI/CD pipeline.    | 1. Make application code changes and push it to the source, on-premises GitLab repo. For more information, see [Push Options](https://gitlab.com/pages) (GitLab documentation). For example, edit the ../application/index.html file to update the application version value.  
2. When the code is replicated to the CodeCommit repo, this starts the CI/CD pipeline. Do one of the following:  
   • If you are using automatic mirroring to synchronize the GitLab repo with the CodeCommit repo, continue to the next step.  
   • If you are using manual mirroring, push the application code changes to the CodeCommit repo by following the instructions in [Update a mirror](https://gitlab.com/pages) (GitLab documentation).  
3. On your local machine, in a web browser, enter http://localhost:80. This opens the NGINX web page because port 80 is forwarded to localhost in Vagrantfile. Confirm that you can view the updated application version value. This validates the pipeline and image deployment.  
4. (Optional) If you want to verify the deployment in the AWS Management Console, do the following:  
   a. Open the Amazon ECS console at [https://console.aws.amazon.com/ecs/](https://console.aws.amazon.com/ecs/).  
   b. From the navigation bar, select the Region to use.  
   c. In the navigation pane, choose Clusters.  
   d. On the Clusters page, select the EcsAnywhereCluster cluster. | DevOps engineer       |
## AWS Prescriptive Guidance Patterns
